he can speak is implanted in the patient's mind, and directly this is achieved the disability will disappear. Or, again, this end may be attained by the use of persuasion and re-education, the procedure then being as follows: It is explained to the patient that examination has shown that all the organs of speech are perfectly healthy, that he has merely forgotten how to use those organs, and that it is proposed to teach him how to recover that use immediately. He is then told that if he fills his chest, opens his mouth, and blows out his breath, he will make the sound of "ah." This result follows, of course, inevitably. The sound of "o" is next produced by instructing him to open the lips, approximate the teeth, place the tongue against the lower teeth, and again blow out the breath. Other vowel sounds can be similarly taught, and one then passes on to consonants. The patient is told to close his lips and then to separate them smartly, blowing out the breath at the same moment, thereby producing the sound of "pah." By these methods the patient can be taught to make any required sound, but it is not, of course, necessary to go through all the sounds in the English language. It must always be remembered that our aim is merely to destroy the patient's conviction that he cannot speak. This conviction is shaken directly he makes the first articulate sound, and it is generally removed altogether by the time he has articulated a few vowels and consonants. He then realizes that his disability no longer exists, and the capacity for speech returns at the same moment. The method of treatment described tends to produce in the first place an aphonic and not a voiced speech; but this defect can be remedied by the employment of similar means, and must not on any account be allowed to persist.

The proximate cause of the disorder having been dealt with in one of these ways, the question arises as to whether, and to what extent, it is necessary to attack the more remote causes. The nature of the latter have been already explained, and unless they also can be removed, it is obvious that the destruction of the proximate causes, the breaking of the chain of causation at its penultimate link, cannot effect a complete and permanent cure. The symptoms will perhaps disappear for the time being, but the original source persists and a fresh outbreak of the same or similar symptoms is always possible. Clearly, therefore, efficient treatment requires that these underlying emotional disturbances should be adjusted. Time does not permit of any detailed description here of the methods by which this end may be attained, but it is evident that the conflict described in a former paragraph will have to be investigated and an attempt made to adjust the warring forces involved. This may be done partly by making the nature and action of these forces clear to the patient himself and instructing him how he may control them consciously and deliberately, partly by pressing into service all these emotional forces in the patient's mind—self-respect, ambition, interest, and so forth—which can be used to aid that control. In many cases of the type now under consideration we shall find that the patient's constitution is such that it cannot deal with the stresses of war, and adjustment will then only be possible by altering the environment in which he has to live—that is to say, he must cease to be a soldier.

The principles dealt with above enable us to understand the well-known clinical observation that, though it is easy to remove hysterical symptoms, it is difficult to ensure that relapses and the outbreak of fresh symptoms do not occur. They provide, moreover, a gauge by which we may measure the merits and demerits of rival methods of treatment, according as they endeavour merely to remove the patient's symptoms, or to attack the more fundamental causes of which the symptoms are only an expression.

ANXIETY NEUROSES.

We may now pass on to consider a type of case for whose treatment a more advanced knowledge of psychological processes is required, and we may select for this purpose another example of a war psychoneurosis, of a kind to which the name "anxiety neurosis" has been applied.

A soldier after some months of service at the front, including several episodes of a particularly distressing character, breaks down, and when we see him some weeks later presents the following clinical picture. As he enters the room we observe a generalized tremor, much accentuated by any emotional disturbance; he starts violently

when the door shuts behind him, and we note that the palms of his hands are wet with sweat. He tells us that his sleep is disturbed by dreams, in which he is once more fighting in the front line, and from which he wakes in terror. These dreams are a frequent feature of the war psychoneuroses, and have been generally christened by the name of "battle dreams." The patient complains, moreover, that he is unable to concentrate his thoughts, and that he becomes promptly fatigued whenever he attempts any physical or mental exercise.

When we investigate the psychological factors responsible for this condition we do not find any "conviction" comparable to that which constituted the proximate cause in the hysterical case previously considered. On questioning the patient, however, we soon discover that he displays a certain noteworthy attitude towards the experiences he has passed through in the war. If we ask him whether he ever thinks of his life in France, he promptly replies that he does everything he possibly can to avoid thinking about it. He carefully occupies his mind with other things to prevent the memories of what he has endured entering consciousness, avoids any newspapers or other literature which might recall them to him, and turns away whenever his comrades introduce the subject of the war. He points out, moreover, that, if in spite of his efforts the forbidden memories force themselves upon him, he immediately becomes agitated, tremulous, and terror-stricken. In a word, he finds that certain memories are inexpressibly painful to him, and he therefore endeavours to keep them at arm's length and so far as he can to forget them.

Now this attitude is not a mere symptom to be added to the list of those already described; it is an actual cause of the latter. In order to understand how this may be it will be necessary to devote a moment to the consideration of certain psychological principles. When the memory of an important emotional episode is thrust out of consciousness it does not thereby cease to exist. It is merely driven beneath the surface of consciousness, as it were, imprisoned in the depths of the mind, and prevented from entering consciousness by the interposition of a barrier. This barrier is not, of course, an actual entity, but is constituted by those psychological processes of repulsion, occupation of the mind with other things, and so forth, which have already been described. The barrier prevents the direct entry of the offending memories into consciousness, but it cannot prevent them from influencing consciousness indirectly, and thereby producing certain characteristic symptoms.

Applying these principles to the case under consideration the actual state of affairs may be stated as follows: The patient's war memories are subjected to the "repressive" process which has just been described, and are thereby prevented from entering consciousness directly. Nevertheless, certain elements of the offending memories influence consciousness indirectly, and are responsible for the tremors and "jumpy" which we observe in our patient. These last may be regarded, of course, as physiological manifestations of the fear which attaches to the buried memories. Again, although the barrier can be maintained during the hours of waking activity, it is inevitably relaxed so soon as the patient composes himself for sleep, the memories emerge into consciousness, and the resulting emotional agitation accounts for the patient's insomnia. When sleep does finally supervene the barrier is almost completely removed, and the released memories are thus free to provide the material of the well-known battle dreams. Lastly, the exhaustion of energy produced by the lack of harmony and conflict in the patient's mind explains, in some part at least, the rapid fatigue which arises whenever any mental or physical exercise is attempted.

So soon as the existence of this mechanism has been ascertained the main indication for treatment is at once obvious. If the repression is responsible for the symptoms the repression must be removed. In the first place, the state of affairs must be fully explained to the patient, and he must be made to understand that his attitude, although apparently dictated by common sense, is really the immediate cause of his troubles. The explanation is not difficult, and can be put into language easily comprehensible to men of mediocre intelligence and education. The next stage is to instruct the patient how this attitude may be corrected. The objects to be attained are clearly the abolition of the barrier and of the repulsion which has

produced that barrier. Translated into everyday language, this means that the patient must get used to his war memories, so that he may regard with comparative equanimity those past events whose recollection now fills him with anguish and terror. He must be persuaded to describe them fully to the physician, to face them squarely rather than to shun them, and to accustom himself to discuss them with his comrades. To begin with, the process will be extremely painful and distressing, but this aspect will steadily diminish with the continuation of the treatment. The abolition of the repulsion is aided materially by constantly impressing upon the patient that the events in question are past and are now merely memories, and by endeavouring to elicit every circumstance which will place them in a more favourable and less distressing light. That is to say, every means must be used to alter the perspective in which these memories are regarded, so that they will no longer be outlaws in the mind, as it were, but will fall into their proper place in the mental structure. When this reintegration of the repressed elements has been attained, when the patient can describe and discuss the events of his war experience with equanimity, then the symptoms due to the repression will naturally disappear.

In cases of this type it will be found that, behind the proximate causes just dealt with, there lie more remote causes of much the same nature as those elicited in the hysterical case described in a preceding section. Here also these causes must be taken into account and suitably treated if a satisfactory result is to be obtained. Finally, a process of re-education must be carried out, in order to train the mental and physical activities gradually back to normal functioning.

GENERAL PRINCIPLES.

It will be observed that two out of the three cases which have been selected for description are war cases. This circumstance is, not entirely fortuitous. Owing to the comparatively simple character of the psychogenic factors in the pure war psychoneuroses, and the corresponding simplicity of analysis and treatment in these cases, they are admirably adapted for a demonstration of the essential nature and principles of psychotherapy. A large number of the psychoneurotic cases met with in civilian practice have a far longer history, and a correspondingly more complicated etiology and structure, and their treatment therefore requires more elaborate methods and a more extensive knowledge of psychopathology. Nevertheless, the broad principles which have been described hold good here also, and so long as they are constantly kept in view the problem presented by each individual case can be satisfactorily attacked.

A careful examination of the cases considered in this lecture will disclose the fact that in each instance the patient has failed to adapt himself adequately to a particular situation, and the psychoneurosis has arisen because the psychological factors in that situation have been wrongly adjusted. This is the characteristic feature of all the psychoneuroses, both of war and peace, and once it is grasped it becomes clear that the only rational treatment for these conditions must consist in the elucidation and adjustment of the factors which are at fault. In the light of this principle, the utility of rest cures and voyages is immediately apparent, for the patient's troubles are in his mind, and he takes them with him wherever he may be sent. A rest cure may be an excellent adjuvant measure, and a voyage may be a valuable help in convalescence, but unless the factors responsible for the disorder are properly dealt with, both are worse than ineffectual. The physician who undertakes the treatment of these cases must not be satisfied until he has ascertained the situation to which the patient has failed to adapt himself, the psychological factors which have conditioned the lack of adjustment, and the mode in which these factors have acted. If I were required to sum up in a sentence the essential features of the modern treatment of functional nervous disorders, I should say that they consist in taking into account not only the physical antecedents of the patient, but also his psychological antecedents, and in the devising of methods whereby the morbid psychological processes can be rectified.

* For a fuller description of this method of treatment see W. H. R. Rivers, *Repression of War Experience*, *Proceedings of the Royal Society of Medicine*, 1918.

In conclusion, it may be pointed out that in the space of a single lecture it has naturally been impossible to attempt more than a sketch of general principles, and the cases selected for description have been dealt with in an unduly simplified manner in order to bring into relief the facts essential for our purpose. Throughout the lecture, moreover, emphasis has been laid on the psychological factors in causation and treatment, because the recognition of their importance is the keynote of modern methods of treatment.

This must not be taken to mean, however, that physical

factors are of no account in these disorders. On the contrary, they must be carefully estimated and suitably treated. Recent researches in endocrinology promise that in the future a flood of light will be thrown upon the nature of the physical factors which play a part in the psychoneuroses, and in particular upon that vague but vastly important thing we call "constitutional predisposition." In this field, moreover, it seems possible that the physiologist and the psychologist will ultimately find a meeting place in which they can join hands and adjust their claims.

APPENDICECTOMY BY A NEW ROUTE.

BY

R. H. ANGLIN WHITELOCKE, M.A., M.D., F.R.C.S.,

HONORARY SURGEON, RADCLIFFE INFIRMARY AND COUNTY HOSPITAL, OXFORD, AND LITCHFIELD LECTURER IN CLINICAL SURGERY IN THE UNIVERSITY.

THE operation here described is designed for the removal of the appendix vermiformis through the right iliac fossa in cases where no general exploration of the abdominal cavity is called for—that is, in acute cases rather than chronic. The method is a muscle-splitting one, and has proved so successful that I employ it in preference to all others. Indeed, its advantages, anatomical, surgical, and clinical, appear sufficient to justify its general adoption in suitable cases as a substitute for the procedures in general use.

I.—INCISION AND APPROACH.

The incision used for opening the abdomen may from its anatomical situation be described as the parailio-spino-inguinal (or ilio-inguinal for brevity's sake), and is made half an inch or less internal or medial to and parallel with the anterior superior spine of the ilium, or as near to it as practicable. The anterior iliac spine, a constant and definite landmark, which is easily felt or demonstrated however obese the subject, forms the centre. The cut is carried above and below this point to an equal extent and parallel with the iliac crest and spine and the attached inguinal (Poupart's) ligament. The length of the incision varies with the size of the individual, but usually need not be longer than 2½ in., although it may be extended in either or both directions if required.

The cut at once divides the skin, subcutaneous fascia, and aponeurosis of the external oblique muscle to its full length, when an assistant, armed with a pair of blunt rectangular retractors, holds the edges apart, whilst the muscular fibres of the internal oblique muscle are defined and exposed to view. At this stage a white line of varying distinctness may usually (roughly in about 58 per cent. of cases noted) be seen passing across the muscle almost horizontally, in a direction from the anterior superior spine of the ilium to the middle line of the body; this line, which is bloodless, indicates a natural division of the muscle into an upper and lower section. With this line as a guide (the same direction must be followed when no line is visible) the thick fibres of the muscle are incised and then separated with the aid of a blunt instrument such as a Kocher's director, or by the gloved index finger (Fig. 1). The subjacent transversalis muscle is then similarly treated, its fibres being separated at the same time and by the same manoeuvre to the full extent allowed by the skin incision. As soon as the fibres of these horizontal muscles

FIG. 1.—Separation of the fibres of the internal oblique muscle.

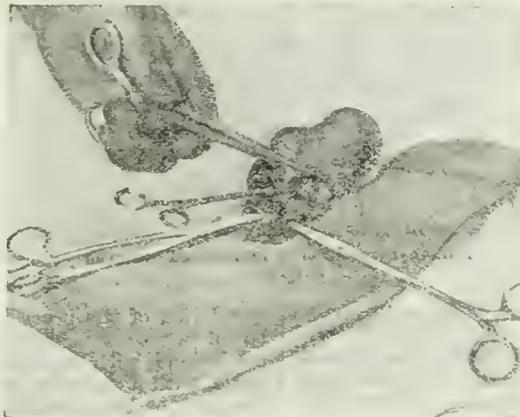

FIG. 2.—Delivery of the caecum and appendix through the wound.

have been freely separated and any bleeding stanchcd the retractors are removed and replaced at right angles to their former position so as to pull and hold the fibres apart, thus exposing the transversalis fascia. This fascia, usually thin, may at times be somewhat thickened and resistant, and through it the exploring finger ascertains the precise condition of the subjacent peritoneum. Up to this stage the procedure is identical for all forms and stages of appendicitis, whether acute or chronic, simple or "interval," with or without abscess. In uncomplicated cases, and whenever there is no evidence of suppurative, as may usually be determined by palpation of the peritoneum through the transversalis fascia, this fascia and the peritoneum are seized with blunt-pointed catch-forceps and divided in a direction parallel with the skin incision, medial or internal to the reflection of the parietal peritoneum on to the iliac fossa, deep to and parallel with the inguinal (Poupart's) ligament.

Where, however, an abscess is present or suspected, it is safer to turn the peritoneum inwards or medialwards from its seat of reflection behind Poupart's ligament and to open it posteriorly from the iliac fossa. The transversalis fascia and peritoneum are usually divided together in a line parallel with the skin incision, but they may be cut transversely as with the deep muscles, if the incision is likely to require enlargement. The peritoneal opening should be made as free as the skin and muscle divisions allow, and the edges caught and held apart securely with a pair of blunt-pointed catch-forceps. These instruments are attached near to the extremities of each edge, and serve to retain the cut edges of the peritoneum, acting as retractors during the subsequent manipulations. The forceps should be blunt, lest they wound the bowel; moreover, unless the peritoneal opening is ample there may be difficulty in replacing the viscus at a later stage. When the abdomen is opened, the viscus first seen is generally (86 per cent. of cases noted) large intestine, either the first part of the ascending colon or, less frequently, the caecum. Except in children and in abscess cases the omentum or transverse colon are rarely seen, still less often is the small gut observed, except in cases of excessive intestinal paralysis and distension due to a generalized septic peritonitis.

II.—TREATMENT OF THE APPENDIX.

The large intestine is now seized, and drawn gently upwards through the wound, its anterior muscular band serving as a guide, until the caecum with its appendix is delivered through the wound (Fig. 2). When the appendix happens to be retrocaecal—a condition more frequently found than is reported—and is therefore sessile, or is otherwise adherent so that it cannot be delivered completely through the opening without risk or injury, it is wisest to detach the caecum at once, to deliver it through

the wound, and to leave the appendix *in situ* to be dealt with afterwards.

In a simple or "interval" case the appendix is removed outside the abdomen by clamping and dividing its mesentery up to its root. The mesentery is then ligatured, the appendix crushed at its base with a clamp, ligatured with catgut, and divided with a sharp knife at a point distal to the ligature, but proximal to a pair of forceps so placed as to prevent any escape of contents (Fig. 3, A, B, C). The stump is now carefully disinfected with pure phenol and buried between the peritoneal folds of the caecum and small intestine, or invaginated and stitched into the caecum by means of two superimposed layers of Lembert's sutures. The caecum is then cleansed with hot saline swabs, and rapidly returned to the abdomen.

Some difficulty is at times experienced at this stage in returning the bowel through the small opening, especially in prolonged operations and in cases with a large movable caecum, although the difficulty may be readily prevented or overcome if the following details are attended to:

1. The opening through the peritoneum should be always as free as or more free than that through the muscles.
2. The exposed and delivered bowel must be kept warm by gauze or lint wrappings soaked in hot saline lotion whenever the manipulations are likely to be prolonged.
3. The edges of the wound must be held firmly apart by an assistant whilst the operator is engaged in returning the caecum.

The wound is closed in layers with catgut sutures (fine for the peritoneum, stout for the muscles), the skin being brought together with silkworm ligatures interrupted so as to allow of the escape of serum (Fig. 4). Only a few sutures are required, since there is but little strain on the edges, and the muscles tend to fall together of their own accord.

When the appendix is so adherent that it cannot be delivered readily with the caecum through the wound—as, for instance, in cases of chronic abscess—the safest and easiest plan is to deal with it as a foreign body by detaching the caecum from its root, and completing the operation by burying the stump as already described. The adherent and detached appendix is then seized at its divided end with a pair of forceps and gently pulled upon until it comes away.

In many cases, when the inflamed viscus lies in retrocaecal or retroperitoneal situations, the muscular and mucous portions of the organ may be pulled out with ease from its inflamed and thickened peritoneal sheath, a firm rubber tube of sufficient calibre then being inserted into the track. When the appendix is approached by this route and its base sought for at the junction of the large and small intestines, it can always be found and removed. Only twice out of a series of over 800 consecutive operations was there any insuperable difficulty in discovering the appendix; in one case, after the ingestion of a barium meal, the Roentgen rays showed a complete transposition of the viscera; in the other, owing to displacement, probably congenital, of the right kidney downwards into the paracolic fossa, the caecum, with its appendix, was pushed across to the left side of the body.

Drainage is now seldom used except in case of abscess. The practice of removing the appendix as a routine, and with it the focus of sepsis and infection, is a sound one, for not only does it minimize the immediate risks and any tendency to relapse, but it shortens the period of drainage, and indeed usually enables drainage to be dispensed with altogether.

III.—ADVANTAGES AND DISADVANTAGES OF THE NEW METHOD.

Since the technique described differs but little from that in general use in muscle-splitting operations, the question may be asked, What are the special advantages of this route of approach? The answer is that it presents definite anatomical, surgical, and clinical advantages.

Anatomical Advantages.

The anterior superior spine

of the ilium is an unfailing landmark which can readily be felt in all circumstances of life. An incision or scar running through the external oblique muscle within an inch of, and parallel with, its bony origin is practically free from strain, since it lies in a natural groove or fold of the body. The deep muscles—internal, oblique, and transversalis—are divided where their fibres are thickest and strongest, and more capable of bearing strain—that is, along the line which indicates their natural division into an upper and lower section. As a rule, no blood vessels are present to require ligature nor is any muscle nerve liable to be divided. Moreover, the parietal peritoneum is here thick and taut, and well supported by extraperitoneal fat at its line of reflection to the iliac fossa hence it is less likely to approach the skin wound and so predispose to hernia, even after prolonged drainage. Such approximation of the peritoneum towards the skin through the muscles is perhaps the most important predisposing cause of ventral or other form of hernia. A further advantage is that the ascending colon or caecum is situated in the direct route, so that the surgeon may rely on discovering the appendix at its origin from the viscus, no matter where its body lies (except in the rare event of visceral transposition). There is probably no viscus which varies more than the appendix in its position and movements under the ever-changing circumstances of life. Hence an assurance that the appendix will be found in almost all conditions is a great recom-

mendation of the procedure here advocated. If the large bowel is traced downwards or drawn upwards through the wound, with the anterior muscular band as a visible guide, until its junction with the small intestine is reached, the root of the appendix may be found, while, if it is covered by peritoneum, it may be felt and readily dealt with.

Surgical Advantages.

The ilio-spinal approach to a great extent prevents the risk of ventral hernia, since the two main factors concerned in the process—pouching of the parietal peritoneum and musculo strain—are almost wholly eliminated or rendered improbable by the anatomical facts already described. In the oblique incision of McBurney, on the other hand, the scar from its position is exposed to considerable intra-abdominal strain, and as a result the peritoneum often pouches; in fact, in cases of prolonged drainage the peritoneum often approaches the skin

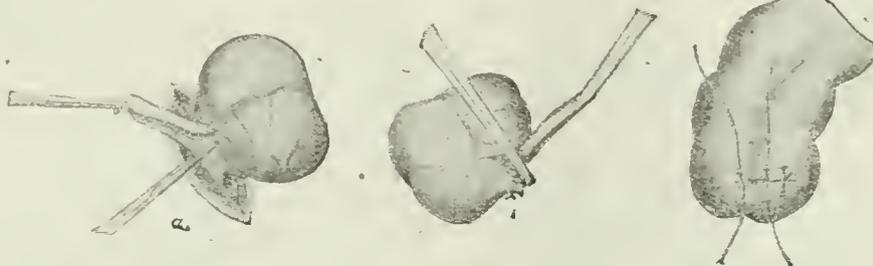

FIG. 3.—Treatment of appendix in a simple or "interval" case. A, Division of mesentery; B, use of forceps before division of appendix; C, preparations to bury stump. (After Kelly.)

FIG. 4.—Disposition of interrupted silkworm sutures.

through the weakened muscles, and may even become adherent to it. Both these circumstances predispose to ventral hernia. Further, the not infrequent division of or injury to the twelfth dorsal nerve, supplying the region of the internal inguinal ring, and the ligation of the deep epigastric vessels predispose to inguinal hernia.

General Peritoneal Cavity.—Even more important than the prevention of hernia is the fact that the ilio-inguinal route avoids the necessity of involving the general peritoneal cavity while dealing with the appendix. Such violation defeats Nature's efforts at self-preservation or cure, efforts which are revealed by the tendency of inflammatory processes within the abdomen to become limited and shut off by protective lymph. Any procedure, therefore, which counteracts this natural and conservative tendency should be condemned as non surgical. This criticism is applicable to most of the operations practised to-day in which the appendix is approached through the general peritoneal cavity, whether the organ is at the time healthy, inflamed, or even gangrenous; especially is this true of the straight or para-median incision, to a less extent the oblique. By the ilio-inguinal route, on the other hand, the peritoneum may be opened and the abscess easily reached and evacuated through the iliac fossa without the difficulties and dangers of soiling or infecting the general peritoneal cavity. For this reason the new route is unquestionably safer and in harmony with the principles of surgery. As a further advantage the appendix may invariably be removed at the time. The necessity for a subsequent operation is thus obviated, with its concurrent risks, waste of time, increased expenditure, and worry, apart from the possibility of hernia.

Drainage, when established through the iliac fossa to the stump of the appendix, or even into the pelvis itself, is simpler and safer than when an abscess is drained through the general peritoneal cavity; an extruded faecal concretion may also be more readily found and safely extracted. Again, the procedure as a whole is simpler and takes less time; in uncomplicated cases the saving of time is remarkable. The appendix is so quickly found, and the wound requires so few sutures, that on more than one occasion four such operations have been performed at the Radcliffe Infirmary within sixty minutes, all the details, including dressings and bandages, being carried out by the operator. Indeed, few abdominal operations will be found so simple. No doubt speed may matter little in an ordinary operation. On the other hand, it may be of the first importance when the patient is *in extremis*, cyanosed or ashy-white in colour, with an irregular or flickering pulse, severe meteorism, and where even the anaesthetic adds appreciably to the danger. Simplicity of method and rapidity in execution are of priceless value when life hangs by a thread.

Diagnosis of Gravity.—Further, the ilio-inguinal route of approach, whether for exploration or removal, enables the surgeon to make a fair estimate of the gravity of the case before the peritoneum is opened. When the transversalis fascia is reached, digital palpation makes it possible to determine not only the presence but the precise situation of an abscess. The extraperitoneal fat in cases of abscess is often considerably thickened and oedematous, and offers distinct resistance even in the early stages; hence if the fingers are pressed gently through the fat against the peritoneum the resistance encountered enables the surgeon to form some idea as to whether the abscess is immediately subjacent or has passed upwards behind, or to the outer side of the colon, or downwards and forwards into the pelvis. When the resistance is slight, the peritonitis is almost certainly localized and the peritoneum may be incised anterior and internal or medial to its anatomical line of reflection, so that the general cavity can be opened with but little risk. On the other hand, if the resistance is such as to justify the suspicion of abscess it is safer to turn the peritoneal fold inwards and forwards, to open the abscess from behind through the iliac fossa, and then to deal with the appendix or its concretion, and to establish drainage through the opening.

Clinical Advantages.

The principal gain lies in the lessening of the period of convalescence. Prolonged drainage is seldom needed, since the actual source of disease is removed at the time, and consequently recovery is usually rapid. When no drainage

is necessary, the patient may be allowed out of bed as soon as the wound is quite healed (usually from the tenth to twelfth day), and is able to walk soon after.

DISADVANTAGES OF THE NEW METHOD.

What are the drawbacks?

In the first place, one possible objection is that by this route no satisfactory exploration of the contents of the abdominal cavity can be made. This objection, however, is scarcely to the point, since, as stated before, the operation is recommended for the removal of the appendix, and not for general exploration. Laparotomy and exploration of the abdomen may be superadded by means of another incision, and without detriment.

Secondly, it may be urged that, when the mischief in the appendix is insufficient to account for the symptoms entirely, the return of the caecum after removal of the appendix may be difficult through the small peritoneal opening. This objection is valid; but if care is taken to make a free opening through the peritoneum to begin with, if the edges are well retracted, and if the exposed bowel is kept warm, the difficulty will rarely be formidable, and never insuperable.

Thirdly, the provision of adequate drainage is felt to be a difficulty by those surgeons who believe that gravity plays an important rôle in abdominal drainage. Experience, however, proves that an appendix abscess, even in Douglas's pouch, may be quite as efficiently drained through the iliac fossa as through the central abdomen, provided that a sufficiently rigid though pliable rubber tube is used. It is not suggested, however, that every case need be drained in this way, since treatment must always be adapted to existing circumstances; and it is quite possible that in a few cases it may be advantageous to supplement it by another incision.

IV.—CONCLUSIONS.

The value of the operation is attested by a wide experience, having been practised by the writer for over twelve years; during the last eight years it has been used almost exclusively. The procedure was at first reserved for simple, quiescent, or "interval" cases, the oblique muscle-splitting incision of McBurney being substituted whenever an abscess was suspected or evident. With increasing experience, however, the special method was found to be suited for almost every condition and adaptable to almost every emergency. Out of 843* consecutive operations performed at all stages of the disease, whether simple or complicated, and all ages ranging from 3 to 79 in both sexes, there have been in all 18 fatal cases, yielding a mortality of approximately 2.25 per cent. In a recent sequence of 117 cases there was no death, whilst the 118th and 119th were unsuccessful. The immediate mortality would appear, therefore, to be no higher than that pertaining to any of the other modes of procedure, while as regards remote sequelae not a single case of hernia or abnormally weak scar has occurred. These results amply justify an appeal that the suggested operation should receive at least a trial. In fact, now that it is becoming the rule to operate in almost every acute case as soon as the diagnosis is established and the necessary arrangements can be made, there is every reason to anticipate a fall in the immediate mortality, whilst the necessity for prolonged drainage and convalescence will be so lessened that any permanent abdominal weakness will be rarely met with.

The results, immediate as well as remote, obtained from any particular method of operation must, however, depend upon clinical details, as well as on operative technique. Did space allow, a full account of post-operative treatment and clinical methods would have been added. It is thought advisable, however, to record these later in a special article.

* Since this paper was written 51 additional operations have been performed, with one death.

THE *Boston Medical and Surgical Journal* states that there were 1,367 deaths from tuberculosis in Boston last year. The local association for the relief and control of the disease has after careful investigation come to the conclusion that for each death from tuberculosis there are twenty persons ill with the disease, of whom nine are in the advanced or contagious stage.

THE RESULTS OF PROTECTIVE INOCULATION AGAINST INFLUENZA IN THE ARMY AT HOME, 1918-1919.

BY MAJOR-GENERAL SIR WILLIAM B. LEISHMAN, K.C.M.G., C.B., K.H.P., M.B., F.R.C.P., F.R.S., DIRECTOR OF PATHOLOGY, WAR OFFICE.

THE BRITISH MEDICAL JOURNAL was good enough to publish, on October 26th, 1918, the proceedings of a conference of bacteriologists, summoned by the D.G.A.M.S. to consider the advisability of employing in the army a preventive vaccine against influenza. This conference, of which I had the honour to be chairman, agreed that such a vaccine might be expected to be of service, and made recommendations as to its constitution and use.

The vaccine recommended was accordingly prepared at the Royal Army Medical College, and, in certain commands, used on a considerable scale.

In view of the opinion, widely expressed in both medical and lay journals, that we are threatened with another epidemic wave of influenza, it is felt that the results obtained in the army commands at home last winter with the vaccine in question should be made known; not only

because it is proposed to advocate its employment again in the army, if we should be so unfortunate as to find ourselves in the presence of a serious recrudescence of the disease, but also because the modified vaccine now in army use has, I understand, been adopted by the Ministry of Health for employment in the civil community.

The vaccine formula recommended by the conference mentioned above was as follows:

<i>B. influenzae</i>	Millions.
Streptococci	60 in 1 c.cm.
Pneumococci	80 "
	200 "

Several strains and types of each organism were used, all comparatively freshly isolated from cases of the disease. Two doses were recommended, the first 0.5 c.cm., and the second, given after ten days' interval, 1 c.cm. The statistical results recorded below apply solely to the vaccine prepared in accordance with the above formula.

As was naturally to be expected, in view of the divergent views held as to the bacteriology of the epidemic, the proposed constitution of the vaccine was subjected to a certain amount of criticism in subsequent issues of the medical press, and the points made in these communications, many of them most valuable and helpful were duly noted. One of the principal criticisms was concerned with the dosage which had been agreed on as appropriate for

* One dose only.

Summary of Table.

	Inoculated.	Non-inoculated.
Strength	15,624	43,520
Incidence of attack, per 1,000	14.1	47.3
Incidence of pulmonary complications, per 1,000	1.6	13.3
Deaths, per 1,000	0.12	2.25

the *B. influenzae* moiety of the vaccine, it being urged that a considerably larger dose of this might be given with safety and with the prospect of an enhanced degree of immunity. In view of this, and also of the fact that, as the bacteriological experience of the epidemic extended, the etiological rôle of Pfeiffer's bacillus came more and more into prominence, I consulted my colleagues of the original conference afresh upon this point and found them all in agreement with an increased dose of Pfeiffer's bacillus, which I proposed should be raised from 60 millions to 400 millions in 1 c.cm., it being understood that the strains employed should not have been so cultivated or so recently derived from cases as to be unduly toxic in their action.

The formula of the vaccine as thus revised, and as now employed in the army, is therefore:

	Millions:
<i>B. influenzae</i>	400 in 1 c.cm.
Streptococci	80 "
Pneumococci	200 "

From the first it was desired that every attempt should be made to secure clear statistical evidence of the results of the inoculations with the vaccine, and the necessary instructions to this effect were circulated by the War Office; returns, in accordance with a simple *pro forma* being called for at regular intervals. In theory, such clear evidence should have been easy to collect through the workings of official machinery; in practice, it has been very difficult. Only those familiar with the strain thrown on the medical personnel by the addition of a severe and widespread epidemic to the already sufficiently arduous labours of those days of urgent and wholesale demobilization can appreciate the difficulties of collecting and recording, in accurate detail, the information required for the returns. In spite of these difficulties, which unfortunately vitiated some of the returns, a considerable number of inoculations were carried out and the records were received and analysed at the War Office.

Although it is very far from my intention to make any claim that the figures here presented are conclusive and free from all or even, in some cases, from possibly large fallacies, they serve, I think, to show at least the general trend of the inoculation results, and they have encouraged the hope that, with the larger dose of Pfeiffer's organism now employed, the vaccine, should it be needed, may prove a powerful reinforcement to other measures of protection.

A few words are called for in explanation of the table. The individual returns are shown under the name of the unit or the principal station in or near which the soldiers in question were located. The period covered by each return is shown in a separate column. The "strength" is the "average strength" of the unit or station; no other method was possible in view of the fluctuations of the population. The "inoculated" include those inoculated before the period in question, as well as those done during it, while the "uninoculated" are arrived at by deducting the inoculated from the average strength. The number of cases, complications, and deaths are, of course, not averages but actual figures derived from the hospital records. The recording of pulmonary complications is probably lacking in uniformity, since different medical officers may have taken different views as to the degree of bronchial or pulmonary involvement which should be taken as a complication.

The returns, all of which lie within the period between November, 1918, and April, 1919, comprise all those relating to this period which conformed to the following requirements:

1. That the vaccine used was that prepared at the Royal Army Medical College, according to the original formula.

2. That influenza should have been present in the unit during the period under review. In many stations where inoculation had been largely carried out there was a rapid cessation of the epidemic. Such returns would have swelled the total of the inoculations without throwing any light on their protective effects.

3. That only such returns are included as showed that at least one-tenth of the average strength had been inoculated, whether with one dose or two.

Periodic returns have continued to be received since the period dealt with in the table, but these have been either negative altogether as regards incidence of the disease, or show so few cases of influenza in either group as to be valueless from a statistical standpoint.

Information was asked for as to the interval occurring between inoculation and a subsequent attack of influenza, but the figures in response to this are too few to be worth analysing; it need only be said that they furnish little or no evidence of any increased susceptibility in the days immediately following inoculation, and that they throw no light of any value on the duration of the immunity conferred by the inoculations. The figures bearing on the latter point would, in any case, have been exposed to the fallacy that the epidemic was rapidly declining throughout the forces, and that the inoculated population was drifting, with increasing rapidity, out of our control into civil life.

No bad effects were reported from the inoculations, and the reactions, in the overwhelming majority, were trivial or non-existent.

It will be noted from the table that nearly one-half of the inoculated had received only the first dose of the vaccine—that is, one-third of the amount which we considered essential to effective protection. It is reasonable to assume that, had all received the full dosage, the protective results would have been still more evident. No statistical evidence bearing upon this point is, however, available.

The table had best be left to speak for itself, but it will, I think, be admitted that in general the results are encouraging, and that they tend to confirm and even strengthen our original anticipations, which were, briefly, that at least a moderate degree of protection against infection might be expected, while more decidedly beneficial effects might be hoped for in a diminution of both the frequency and the gravity of the pulmonary complications.

OBSERVATIONS ON THE X-RAY TREATMENT OF NEOPLASMS.

By G. E. VILVANDRÉ, M.R.C.S., L.R.C.P.,

CHIEF ASSISTANT X-RAY DEPARTMENT, LATE HOUSE PHYSICIAN SKIN AND LIGHT DEPARTMENT, LONDON HOSPITAL.

WHEN we are able in all cases to diagnose malignant disease early the use of x-ray therapy will be limited to those cases only in which mechanical and physiological considerations prevent operation. Until this be attained we have to deal with a large number of tumours which, because of their size and position, forbid the use of the knife.

This paper is not a criticism; it gives the result of observations of facts and deductions, I believe logical, which have been forced upon me during the past three years. Thanks to the kindness of my former chief, Dr. J. H. Sequeira, many cases came partly under my care and observation.

My object in investigating them was not only to obtain successes, but also to inquire why we succeeded in some and failed in others, for upon this knowledge depends future success and the alleviation of much suffering.

R. G. was sent by Dr. Lack as being beyond operative treatment with sarcoma of the tonsil. The right side presented a large growing tumour, obviously quite vascular. Before November 22nd, 1915, attempts at removal when small had been made, but the tumour recurred, and on that date she was, under Dr. Sequeira's direction, submitted to x-ray treatment, the dose being a weekly one of Sab. B₄ pr. 1½ mm. to outside of tumour and Sab. B₂ pr. 1 mm. of aluminium to the nasopharynx. In January, 1916, she was very much better, and the glands were going down. She had more x-rays on February 7th, 1916. On February 23th Dr. Lack saw her and reported, "Much better—

no glands." The same doses were given until May 29th, 1916, and then once monthly to September 18th, 1916.

On September 28th, 1916, Dr. Lack wrote: "Firm fibrous thickening above right tonsil, neck smaller." In January, 1917, more treatment (three doses). On February 23rd, 1917, "Much thickening" was noted, and afterwards treatment was followed by gradual improvement; except for a small radiotherapeutic burn she had continuously done well.

To-day she is still well, and though the growth may not be completely eliminated, she looks fit, and is living an efficient life; the neoplasm has remained stationary since March, 1917; the pain—once a prominent symptom—has gone, and a hopeless prognosis in 1915 has been converted into a possible cure and three years of efficient and comfortable life.

The following case is more striking still:

B. C. was admitted in April, 1911, with a tonsillar affection of some duration for which he attended several hospitals. The right tonsil was swollen and red and protruded forward into the mouth; its lower limit could not be seen. He was very thin, pale, and had lost much weight. A diagnosis of sarcoma was made. A week after he was much worse, the swelling protruding more into the mouth, and his condition was looked upon as hopeless; Dr. Sequeira did not think the boy should attend the hospital again. In May the glands were irradiated through filters and improvement occurred, but on May 23rd there was a setback in his general condition. Treatment by radiation was persevered with, and July saw improvement and the "swelling much less."

In November, 1911, "the palate moves easily and the growth has almost gone," but glands were still palpable on the left side, and more treatment was given twice a month until May 4th, 1912, when he was pronounced quite well. A month later the same note was made. In September, 1912, he was still well and passed a medical examination for the Railway Clearing House. When seen again in January, 1913, and May of the same year, he was still well. He joined the army in 1914, and was still well in June, 1916.

This was an undoubted success.

Early in 1914 I saw a case which had been diagnosed by a surgeon of repute as sarcoma of the chest wall. When treated with x rays the whole disappeared. The surgeon, on seeing the case again, suggested that the diagnosis could not have been accurate; but he himself had made the diagnosis. The tumour had been there and was gone, and x rays alone had been used. The patient, a girl, died some two years after of pneumonia.

E. O., aged 17, had a swelling of the right upper maxilla, which was hard and definitely enlarged to the touch and sight; the patient was sent for treatment with the diagnosis of sarcoma. The tumour had been present for six months; the Wassermann reaction was negative. I thought the prognosis bad. Heavy doses of x rays were given during September every four days, and when seen on November 21st, 1918, the swelling was much smaller. The patient's general health was good and more treatment was carried out. In February, 1919, the condition was quite good and the swelling negligible. When I saw her on October 26th, 1919, she was quite fit, and there was no indication for treatment.

I might quote other cases, but only wish to establish a fact which is known to some—namely, that some sarcomata may be inhibited by x -ray treatment.

To quote cases of inoperable carcinoma of breast in which benefit, such as prolongation of life, complete disappearance of pain, retrogression of the growth, improvement in general health, are well-marked features would weary the reader. Some of us know by experience of many cases so benefited, and the number runs into hundreds. I may, however, be excused for mentioning the case of a school teacher who had carcinoma mammae; x -ray treatment was delayed and, as often happens, recurrence followed. The combination of x -ray treatment and radium has, however, enabled her to carry on for nine years since the appearance of the first recurrence. Each new growth is tracked by the application of a radium plate; she illustrates vividly the spread of carcinoma by lymphatic vessels in so far that the radium reaction has left telangiectasies wherever the plate has been applied. Although taken late for treatment, this patient has had nine years of life and the capability to earn her daily bread. I saw her last a few months ago.

Of the value of radiation of the site of glands after removal there can be no doubt, and I would plead for the routine radiation of scars after removal of squamous-cell carcinoma of the lip and other such tumours, just as surgeons send their cases of breast cancer after operation.

Looking back upon cases of new growths treated by x rays, I have seen the greatest benefit or inhibition in sarcomatous neoplasms, and in my experience in the slow-growing varieties.

Leaving rodent ulcers on one side—in which radium treatment shows at its best, and of which many cures have been published by others, such as Dr. Sequeira as far back as 1903 at the International Congress of Surgery, Brussels—it may be said of carcinomas that the results of radiation are not so striking. A patient with carcinoma is more likely to have secondary glandular involvement than one diagnosed early as suffering from fibro-sarcoma; but, putting this probability on one side, the results are not so good in squamous-cell carcinoma, for instance.

I was inclined to think that the vascularity of the growth was a determining factor, looking upon a fibro-sarcoma, for instance, as one less vascular than the fungating tumour received from the surgical side of a hospital for x -ray treatment as a last resort; but experience with enlarged spleens tends to modify that hypothesis, for it is difficult to imagine a more vascular organ, and yet the diminution under x rays of an enormous spleen, such as is seen in cases of leukaemia, is most striking.

Breaking down malignant glands such as follow an "epithelioma" of the lip, or squamous-cell carcinoma springing upon an ulcerated lupus lesion, do not do well under x -ray treatment.

A case in point was that of B. N., who had had lupus vulgaris of the face for years. Squamous-cell carcinoma made its appearance. Thorough treatment was carried out by diathermy and not without success; the lower two-thirds of the lesion did well and healed, but there remained a focus in the lax tissues of the lower eyelid which, when again attacked by diathermy and x rays, grew apace.

Neoplasms of the lung react to hard rays, and though I have not seen one disappear, diminution of pain, cyanosis, and cough, and even retrogression of the neoplasm, do follow radiation; but heavy filtered doses are necessary.

Bulk is no hindrance; it is the nature of the growth that counts. As I mentioned before, the vascularity of the growth is not the important factor, but the more fibrous tissue present in the stroma, as a rule, the slower the growth and the better the result of radiation. Natural means of checking invasion are helped readily by the physical. X rays tend to cause or help the formation of fibrous tissue, but only x rays of a certain type.

Much good histological work has been done on the effect of radiation on cells, as anyone who reads the excellent work of Sidney Russ and Colwell on radium, x rays, and the living cell can see. But we are only on the threshold of knowledge of these phenomena. The removal at fortnightly or monthly intervals of irradiated glands whenever possible, their section-cutting and examination by a competent pathologist would prove of value. The radio-therapeutical department of a hospital should work hand in hand with the pathological.

In many of these cases submitted to x radiation it is useful to ascertain whether the Wassermann reaction is present, especially where the position of the growth or other condition forbid the removal of specimens for histological examination.

The x rays can be divided into at least two great classes, according to their effect—namely, those that give rise to stimulation of growth, and those that cause inhibition and, further, necrosis. The first effect seems certainly to be associated with the treatment of superficial lesions, such as lupus vulgaris and its frequently accompanying ulceration. In this connexion two points are of importance: first, the rather frequent occurrence of "epithelioma" on lupus, especially in cases that have received frequent x -ray treatment by small doses of unfiltered rays. It is a point among others showing the necessity of the skilled control of a therapist over the too-often haphazard methods of x -ray treatment. X -ray burns are a sad evidence of injudicious dosing, but they at least call attention to over-treatment. The formation of epithelioma on lupus works silently, only revealing itself, as a rule, too late for cure. Needless to say, the constant granulation that goes on, the repeated attempt at healing, the frequent division of cells, are factors in the production of cancer in these cases, but there remains a large number where the presence of squamous cell carcinoma coincides with repeated application of rays in small doses. These are often the legacy of earlier days in radiotherapy.

X Rays and Arsenic.

I was inclined to look upon this appearance of squamous-cell carcinoma on lupus and also in *x* ray workers from repeated small exposures of $\frac{1}{2}$ to $\frac{1}{4}$ Sab. B, as being due to an irritative effect of the "soft" rays, the formation of the skin cancer being regarded as similar to that of lip cancer in clay pipe smokers, epithelioma of the tongue following dental irritation, and so on. The parallel between the effects of *x* rays and arsenic is not without significance. Both may cause erythema, both give rise to pigmentation and hyperkeratosis. Arsenic certainly causes a neuritis, and *x* rays have been described as doing the same. After the prolonged effects of each we may observe carcinoma. To have looked upon this common action as an over-stimulation was, I think, natural. But, in the words of Dixon:

Arsenic under certain conditions gives rise to a peripheral neuritis which closely resembles that of alcohol. The action is essentially one on the interstitial tissues, the connective tissue sheaths of the nerve being affected in the same way as connective tissue elsewhere in the body. It becomes hyperaemic, shows multiplication of new tissue elements and migration of leucocytes. These changes lead to pressure on nerve fibres, and so to later degeneration.

The end results of prolonged exposures to "soft" *x* rays are the same on the skin as those of the prolonged use of arsenic. Hyperkeratosis, usually affecting the soles and palms, is peculiar to arsenic among drugs. Hyperidrosis is then often prevalent in these places, appearing as small elevations like millet seeds or small corns. Epitheliomas may develop on these small corns. The hands of the radiographic assistant of early days may be compared with this.

Is it, then, too much to deduce that in the latter case nerve fibres also become degenerated, and that some forms of carcinoma are due to lack of nerve control of the cells? I have heard this theory before, and only suggest that the similarity of action of *x* rays and arsenic is another fact in favour of the theory.

Mrs. M. was at one time a skin patient. She had also exophthalmos, some cyanosis, dyspnoea, clubbing of fingers, dullness in the sternal region, and other signs, and was sent to the physician for thoracic disease; a diagnosis of mediastinal neoplasm was made. The patient ultimately died of bronchopneumonia, and *post mortem* a growth around the arch of the aorta, of the size of a small apple, was found.

This patient had some *x*-ray treatment, and though certainly the case was advanced, her death was not without a lesson, which I now wish to point out with due humility. Such a tumour should be radiographed, and I will even suggest localized. To hand over such a case as "tumour of the thorax" to a lay assistant for radiation is a mistake. His knowledge of anatomy is negligible, of disease still less; and unless careful focussing of penetrating rays in heavy and repeated doses are carefully and accurately applied to the growth, it may be from several angles by a cross-fire method, the chances of hitting the tumour are nil. It is therefore essential in such cases to transfer upon the thoracic wall with indelible pencil the findings of clinical and radiographic and localization methods. Accuracy of focus is, I am certain, a primary essential factor in *x*-ray treatment. The chances of missing with a pencil of rays a tumour the size of a small apple in such a large cavity as the thorax are, of course, very great. Careful localization and markings are of primary importance.

It is easily realized that neoplasms, be they sarcomas or carcinomas, especially if large, will require prolonged treatment. The care of the skin is therefore paramount, for unless great precautions be taken erythema and, too often, burns will follow, preventing further treatment, and consequently destroying all chances of alleviation or cure. A shield on the patient will protect all organs except those in the direct paths of the rays passing through an aperture in the shield. Only the diseased tissues will therefore be irradiated. It may be argued with reason that many foci of infection are possibly present, and that wide radiations are beneficial. If such be the case the prognosis is bad whatever treatment be given. The presence or absence of secondary deposits will sometimes be revealed by radiographic examination.

That the localization of the growth is essential will be easily understood when it is remembered that the power of the rays is inversely proportional to the distance of the

object from the anticathode. For success, therefore, it is essential that the depth of the object be known, for on that, I think, the dosage should also be based. Far less radiation will reach an object 8 in. than one 2 in. deep.

Time will show that the doses we have given are inadequate. Heavier doses of "harder" rays through thicker filters are those that will cause inhibition of neoplasms. We have done well in some cases, failed in others. Where two years ago I gave 4 Sab. B through 2 mm., I now give 8 or 12 B's through thicker filters and the results are better.

My thanks for opportunity and advice are due to Dr. Sequeira; for practical help and I also indebted to Mr. Blackall of the London Hospital. The mistakes are mine.

CHRONIC INFECTION OF THE FAUCIAL AND POST-NASAL LYMPHOID TISSUE IN CHILDREN.

BY

PERCIVAL W. LEATHART, M.B., B.Ch. CANTAB.,
ASSISTANT SURGEON, LIVERPOOL EYE AND EAR INFIRMARY.

A CHILD with enlarged tonsils and adenoids is not ill because of the increased size, but because of a chronic infection of its faucial and post-nasal lymphoid tissue, which serves not only as a nidus for the manufacture of toxins but also as a port of entry for many other systemic diseases. This condition of chronic infection is extremely common, and diagnosis is easy if the three cardinal physical signs—enlarged tonsils, rhinitis, and enlarged cervical glands—are kept in mind. Additional physical signs are often to be noticed, such as running ears, bronchitis, mastoiditis, etc., but are more correctly described as complications, and are found as a rule only in neglected cases. That the disease is highly infectious is shown by the following facts:

1. That it is far more frequent among school children than among children who do not go to school.
2. That when one child in a family is attacked the disease subsequently spreads to his brothers and sisters who were previously healthy.
3. Micro-organisms can always be grown from the nasal and post-nasal secretions, which are normally sterile.

For these reasons the disease may be considered as infectious in exactly the same way as measles and scarlet fever are infectious.

Unfortunately in this disease there does not appear to be as great a tendency to spontaneous cure as in some of the other specific infections of childhood; it is a very much more chronic condition, and in consequence of this once a child is attacked he may, and often does, continue in a more or less normal manner for years; but on examination will be found to present the three cardinal signs of the disease, and micro-organisms will be detected in the nasal and post-nasal secretion.

Such a child is, in fact, a "carrier," and is for that reason a source of danger to all healthy children with whom he may come into contact. Because of the chronicity of the disease it follows that nearly all untreated cases are carriers for a longer or shorter period, and this would appear to be a good reason for its frequency.

A sufficient number of bacteriological examinations of secretions from the nasal and post-nasal spaces have not hitherto been made to enable us to be dogmatic with regard to the nature of the specific causal organism. But in a very large proportion of such examinations some form of pneumococcus has been the predominant organism, and in some cases it has been the only one grown. This, coupled with the fact that some form of pneumonia is a frequent complication, renders it possible that the pneumococcus is to blame. But whatever the organism may prove to be it is one which attacks the faucial and post-nasal lymphoid tissue, producing a form of inflammation which is not acute, so that pain is seldom complained of; it is typically a chronic inflammation in the course of

which the lymphoid tissue becomes softer and larger. The infection spreads to the lymphatic glands, draining the inflamed area, causing them to enlarge.

In an uncomplicated case there is no tendency to suppuration either in the lymphoid tissue itself or in the lymphatic glands. Suppuration when it occurs is probably always due to the implantation of one or more of the common pyogenic organisms on a tissue the normal resistance of which has been impaired by disease.

If so much be accepted we may fairly claim that the disease is highly infectious, and that children suffering from it are "carriers," and therefore a source of danger to others.

The treatment required is that of the individual, and preventive treatment.

1. Treatment of the Individual.

The ideal is to render the post-nasal space sterile and the diseased tissue normal; it is doubtful whether this ideal can ever be attained, for the tonsils and adenoids, once they are infected, never appear to regain their normal structure. As in other chronic infections elsewhere, the process whereby infection is eliminated is one in which the diseased tissue is replaced by fibrous tissue, and not until the fibrosis is complete can the disease be said to have been arrested. In this condition, as in other chronic infections, the "natural" cure postulates the disappearance of function in the affected structures.

In these circumstances it is unlikely that any medication will ever be satisfactory; and it is certain that at the present time there is no local application capable either of rendering the post-nasal space sterile or the infected lymphoid tissue normal in structure and function.

In view of the failure of this method of achieving our object we must resort to surgery, and anticipate Nature by removing as much of the diseased tissue as possible. The great advance made in recent years in the treatment of the individual is by the introduction of the operation of enucleation of the tonsils and thorough removal of the adenoid mass.

After this operation, efficiently performed, the majority of children show improvement at once, in that the rhinitis disappears, the cervical glands cease to be palpable, the beds of the tonsils and pillars of the fauces become healthy in appearance, and in some cases the post-nasal space becomes sterile; a sufficient number of bacteriological examinations have not, however, yet been made for us to be sure that this happens in the majority of cases.

There is a definite relation between the thoroughness of the operation and the number of "cures" effected. Partial removal is followed by disappointing results; children are frequently seen of whom it is stated that they have undergone removal of tonsils and adenoids two or even three times, yet the three cardinal physical signs are found still to be present, and, in addition, some complication, such as running ears, which was not present at the primary partial removal.

Apart from such cases as these, there are a few in which even after thorough removal the disease continues unchecked. Perhaps in some of these the lingual tonsil and lateral bands which cannot be removed are sufficient to keep the infection active. In others the inferior turbinates, which sometimes remain enlarged, would appear to be the cause. In the remainder possibly the causal organism is of a different nature, and is able to thrive in the nose and post-nasal space even after the diseased lymphoid tissue has been removed.

2. Prevention.

The reason why no steps have hitherto been taken with regard to the prevention of this disease is possibly to be found in the fact that its infectious nature has not received the attention it deserves.

Preventive measures have been taken with regard to other diseases spread by carriers, such as diphtheria and cerebro-spinal meningitis, which are not nearly so common or far-reaching in their complications, though they are more immediately serious to the individual in that they are more acute; yet in the aggregate the amount of harm done to the community as a whole is insignificant compared to that done by the disease in question.

The harm done by chronic infection of the lymphoid tissue of the fauces and post-nasal space is very great.

Its direct complications are far-reaching, spreading beyond the sphere of the throat and ear surgeon, the ophthalmic surgeon, and the laryngologist, into the domain of the physician, in the shape of bronchial affections and lobar and broncho-pneumonia.

Its indirect complications are even more serious, for the lymphoid tissue, having lost its natural resistance, is rendered more liable to become a port of entry for other specific infections such as tubercle, rheumatic fever, measles, scarlet fever, diphtheria, and influenza. If preventive measures which resulted in lessening the incidence of this disease were adopted, the incidence of all its complications, both direct and indirect, would be lessened also. Further, recognizing that in the above list of complications are included the diseases from which a large proportion of the death and disability of the community results, the importance of stamping out the origin to which they can all be traced is evident.

A discussion of the details of prevention would unduly prolong this article; the difficulties are numerous, but by organization on sound lines much could be accomplished. Encouraging results may be confidently expected from the adoption of open-air schools and vaccination, but before the latter method can be used the specific organism must be definitely isolated.

It is to be hoped that the Ministry of Health will consider the subject of prevention of this "carrier" disease, for until adequate measures are adopted the disease and its complications, both direct and indirect, will continue to be rampant.

Summary.

1. The disease is highly infectious.
2. It is spread by carriers.
3. Its complications cause widespread death and disability.
4. The treatment of the individual is satisfactory if complete removal be carried out.
5. The necessity for preventive measures is urgent.

RUPTURED GASTRIC ULCER IN AN OLD MAN: LAPAROTOMY: RECOVERY.

BY

ANDREW FULLERTON, C.B., C.M.G., F.R.C.S.IREL.,
SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST;

AND

T. S. S. HOLMES, F.R.C.S.ENG.,
SURGICAL REGISTRAR, ROYAL VICTORIA HOSPITAL, BELFAST.

A SUCCESSFUL case of laparotomy for ruptured gastric ulcer at an advanced age is sufficiently rare to justify the publication of the following:

Mr. W. G., retired civil engineer, aged 78½ years, had enjoyed good health all his life and was never known to suffer from dyspeptic symptoms till within a week or so of his present sudden illness. He had always been very regular in his habits and most abstemious in diet. Lately he had confined himself to two substantial meals a day, breakfast and lunch. The latter meal was generally taken at 2 p.m. A cup of tea without solid food at 6.30 p.m. completed his diet for the day, and nothing more was taken until next morning.

History.

In April, 1909, he was operated upon by one of us (A. F.) for stone in the bladder, and in May, 1911, for enlarged prostate. Except for a small ventral hernia in the neighbourhood of the suprapubic scar, he had remained well until a week previous to the present illness. During this week he had suffered from rather vague dyspeptic symptoms with some tenderness in the right epigastric region. On the day of perforation, December 16th, 1919, he had a meal of haddock and rice pudding at 2 p.m. At 6 p.m. he was sipping his usual evening cup of tea when a sudden severe pain in the epigastric region doubled him up. When seen at 7.30, he was in great agony, cold, clammy, and blue, with rigid abdomen and dilated pupils. The pulse was 50, weak and irregular, and his general condition so serious that death appeared imminent. He was given morphine gr. ½ in three doses at short intervals, with very little if any relief of pain. At 9 p.m. he was again thoroughly examined. The abdomen was like a board, the liver dullness was diminished but not lost, and there was no evidence of fluid in the flanks; he was cyanosed, the pulse was 65, and the heart's apex was outside the nipple line. His arteries were hard, tortuous, and ringed. There was no vomiting. The pain was now more general, but the maximum intensity was in the epigastrium. The bowels had acted as usual that morning.

Operation.

It was decided, on consultation with his friends, to give him the slight chance that operation alone afforded, and he was removed to a neighbouring nursing home. The operation was begun five hours after the onset of pain. Ether, with a small quantity of alcohol and chloroform, was administered by Dr. Robert Marshall, and anaesthesia was quiet and satisfactory. In addition, conduction anaesthesia was produced by blocking the intercostals with novocain, and good relaxation was obtained. The abdomen was opened in the middle line above the umbilicus. On incising the peritoneum a quantity of thin, slightly turbid fluid, with some gas, escaped. A punched-out, circular aperture about the diameter of a lead pencil was found in the stomach. From this exuded a small quantity of dark-coloured mucoid fluid. Surrounding the opening for at least an inch the stomach wall was indurated, inelastic, and friable. There were some omental adhesions to the upper part of the indurated area. The ulcer was situated on the anterior surface, three or four inches from the pylorus, and near the lesser curvature. The edges of the ruptured ulcer were infolded with difficulty, owing to their rigidity and friability, by two rows of linen thread sutures. A piece of omentum was sewn over the repair for greater security. The fluid lying in the neighbourhood was mopped up and the abdomen was closed in three layers without drainage, the whole procedure, including the induction of anaesthesia, having lasted twenty-six minutes.

After-History.

Recovery was uneventful, and the patient left the nursing home within three weeks, apparently quite well.

He was examined on January 22nd, 1920, about five weeks after the operation, and was then free from pain, in his ordinary health, and able to get about as usual.

A METHOD OF TREATING TINEA.

BY

C. J. GLASSON, M.D., M.R.C.S.ENG., L.R.C.P.LOND.,

LATE CAPTAIN R.A.M.C., AND OFFICER IN CHARGE
X-RAY DEPARTMENT, NETLEY.

As a result of so many men having to serve in many districts of the East (India, Mesopotamia, and Egypt) and East Africa, a form of tinea, known in the East as dhubie or washerman's itch, has become prevalent in England.

This variety invariably attacks the crutch and upper and inner surfaces of the thighs, sometimes extending upwards around the root of the penis and posterior part of the scrotum; the intense irritation causes a desire to scratch, accentuated at night and leading to insomnia. It is very contagious, and may easily be conveyed to others by laundries unless means are used to disinfect the clothing and sheets effectually before they are sent to be washed. Patients should be isolated completely until a cure is obtained.

I have treated many cases, both at home and abroad, with success by a combination of x rays and chrysophanic acid ointment (gr. xxx to $\bar{3}$ j of lanoline).

An ordinary x -ray tube of medium hardness may be used, or, better, one of the later "gas" tubes which can be regulated, or, best of all, the Coolidge tube, as by its use the hardness required can be got and the exact dosage wished given. If a "gas" tube is used it should be tested to give a penetration of 8 by Wehnelt's radiometer. With a Coolidge tube the battery should be 4 ampères, and the primary current should give a reading of 8 to 10 milli-ampères.

When the tube selected is ready the patient undresses and lies upon a couch, so that the part to be treated can easily be got at. Every part in this region, except that to be treated, must be adequately protected; this can best be done by a sheet of the prepared lead-lined rubber the same as used in protective aprons. Over the part to be treated is placed a thin sheet of lead $\frac{1}{16}$ in. thick, with a hole a little larger than the exposed part. A thin layer of the chrysophanic ointment is spread all over the part and a little beyond the outer borders of the tinea. The tube is then brought into position so that the target is directly over the centre of the part to be treated, and from 8 to 10 in. away from the surface of the skin; an exposure of five minutes exactly is given. Having finished one area, the application is made with the same precautions to another patch.

The dose is large, but I cannot give the exact amount, none of the methods at present in use being reliable. I measure by time guided by experience.

After the treatment is finished the ointment should be wiped off the skin in order to prevent staining of the linen or clothes by the chrysophanic acid.

In 90 per cent. of the cases treated in this way one application was sufficient to cure; in a few a second was given to make doubly sure.

For the first two days the skin shows a brown pigmentation due to the chrysophanic acid; this gradually disappears with slight desquamation, and by the end of a week the skin is clear and normal, the tinea having disappeared. Several cases, even those of long standing, cleared in two or three days.

In brunettes or dark-haired people no filter is necessary, but in persons who are fair or with a tinge of red in the hair a filter should be used, $\frac{1}{8}$ in. aluminium being sufficient; in red or coppery-red-haired people $\frac{1}{4}$ to $\frac{3}{16}$ in. will be necessary. Fair-haired and very red-haired people are much more susceptible to x rays, and in them I have found it necessary to reduce the time of exposure to three minutes, otherwise a radio-dermatitis with deep pigmentation due to the chrysophanic acid will result; this is, however, easily got rid of by zinc ointment.

The same treatment can be carried out with tinea on any other part, but before applying the ointment the tinea should be washed with other soap. By the same method psoriasis also can be got rid of, but it does not cure, as patches always return either in the spring or fall of the next year.

X rays alone will not cure this very irritating complaint; the chrysophanic acid ointment will in time, but it stains the clothing. The two combined will cure, and, curiously enough, all irritation ceases after the application, so that patients are not worried and get at once a good night's rest.

There should not be the slightest risk to any patient of sterilization if proper precautions are used to protect the generative organs.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HERPES ZOSTER AND GREYNESS OF HAIR.

This is a case in which grey patches appeared in the hair of the right side of the face during an attack of herpes zoster which affected the region of the right forehead.

The attack of herpes zoster and the appearance of the grey patches occurred in 1887. The patches of greyness were permanent; they are now becoming merged in the general greyness of advancing years.

It can be seen in the figure that the patches of greyness appeared on the fronto-nasal (inner extremity of right eyebrow), naso-labial, and mental maximum points described by Dr. Henry Head in *Brain*, Part III, 1894, "On disturbances of sensation with especial reference to the pain of visceral disease."

I venture to publish this case for two reasons: the first is that it supports the observations I have published in many articles in this JOURNAL on the relation between certain forms of the hair's greyness and the nervous system; the second reason is that it is so difficult—at least I find it difficult—to discover any additional changes of nutrition accompanying lesions of herpes zoster. The grey patches of hair observed in this case appear to me to exhibit an additional change of that kind. The figure here produced is made from photographs taken years ago. The subject is a doctor, who has kindly given them to me with the history of his case.

London, W.

G. LENTHAL CHEATLE.

ATROPINE IN ACUTE SUFFOCATIVE CATARRH.

As acute suffocative catarrh is, in my experience, very rare, I wish to mention one case I treated some years ago.

A gentleman, aged 70, went to bed one night quite well,

but in an hour awakened suffocating, with blood-stained froth coming in such quantities from his mouth that it half filled a large basin. I saw him about twenty minutes after the onset of the attack. Crepitant râles were heard all over his chest, there was great distress in breathing, and the pulse was irregular; there was no fever.

I injected at once $\frac{1}{32}$ grain atropine sulphate and $\frac{1}{16}$ grain strychnine nitrate, and administered oxygen by inhalation. I also gave three separate drachm doses of sal-volatile at intervals during the night. I left him next morning at 9 o'clock, practically as well as ever. I considered the atropine to be the chief factor in producing his recovery.

Dublin. W. M. VERNER FURLONG, M.D.

TWO CASES OF HEMIPLEGIA.

THE two following cases of hemiplegia present certain points of interest; both occurred in a ward under my charge in a war hospital.

CASE I.—A soldier, aged 26, was much upset by Zeppelin raids. During a raid he was found late one evening lying underneath his bed; next morning he had right-side hemiplegia and partial aphasia, which gradually became more complete. Fluid obtained by lumbar puncture and blood gave negative results to Wassermann's test. He lived for about five months. *Post-mortem* examination showed an old altered blood clot in a cyst-like cavity in the usual area (internal capsule).

CASE II.—This case had generalized and rapidly increasing signs in the lungs diagnosed as probably a military tuberculosis. The sputum was very scanty, and tubercle bacilli were not observed in it. About the sixth day after admission he complained of diplopia, and there was evidence of involvement of the third nerve on the left side. This was quickly followed by right hemiplegia and rapidly increasing coma. At the *post-mortem* examination extensive military nodules were found throughout both lungs, and four very small yellow nodules in the meninges at the base of the brain, accompanied by encephalitis spreading into the left crus cerebri. A smear from lung, and also one of the nodules in the meninges squeezed out on a slide, both showed many tubercle bacilli.

KENNETH ROGERS, O.B.E., M.D. Lond.

RIFLE BULLET IN BLADDER.

ON the night of September 2nd, 1919, Pte. J. B., aged 20, was troubled with an "itchy sensation" in the urethra and tried to relieve this by passing a rifle bullet into the meatus. This he accomplished without pain or discomfort, and "suddenly the bullet slipped right down and disappeared." He at once reported to his medical officer, who passed a catheter into the bladder, meeting no resistance. He was sent to hospital on September 4th and came under my care on September 8th.

During these six days after his "accident" the only symptoms complained of were occasional slight delay in commencing micturition and a sensation of something inside the bladder. He stated that he could feel the bullet change its position when he rolled over suddenly in bed or if he stooped forwards quickly. X rays showed the bullet lying transversely in the pelvis. Chemical examination of the urine showed no abnormality, but a catheter specimen taken just before operation and examined microscopically revealed ample evidence of infection—the bacteriologist reporting "numerous organisms present; pus cells; oxalate crystals and epithelial (bladder) cells."

The bullet was removed by suprapubic cystotomy (extra-peritoneally) on September 10th, the bladder wall sutured in two layers and the wound closed without drainage.

Apart from a mild degree of cystitis which rapidly responded to treatment the patient made an uneventful recovery and was evacuated on October 2nd, 1919.

F. R. BROWN,

Major R.A.M.C. (T.C.); Surgical Specialist,
—Casualty Clearing Station, Batumi.

A "FROGHOPPER" AS A BLOOD-SUCKING INSECT.

To add to the list of the several blood-sucking insects already known I now send in the name of a member belonging to the order Homoptera or Hemiptera-Homoptera. So far as I am aware this order has not supplied any

instance of a species with such propensities. In Madras, especially after the north-east monsoon—that is, in the months of November and December—large numbers of small whitish-green "froghoppers" come to light at night, and some of these bite, or rather sting, by means of their sharp proboscides. Several people used to complain to me of being stung by these insects, but, not being cognizant at the time of such habits among the Homoptera, I discounted these tales of the presumed aggressors. It was only when I was myself a victim of the insects' action that I was disillusioned.

These insects stung both at night and on cloudy days. I procured four of these "froghoppers," two caught actually in the act of sucking blood and two others hopping about at the same time and place. These I took to Dr. Gahan, of the South Kensington Museum, and they were identified by Mr. Distant. The two blood-suckers were *Phrynomorphus indicus*, Distant, and the other two included one of the same species and another Jassid, named *Nephotettix bipunctatus*, Fabr., which I cannot accuse of any malpractice. Dr. Gahan tells me that Dr. Guy Marshall informs him that he has from time to time received Jassidae sent to him from Africa as blood sucking insects, but he does not know of any records of the kind published.

In adding this member to the list of blood-sucking insects I wish to demonstrate that we have reached no finality in our knowledge of sanguivorous flies.

C. DONOVAN, Lieut.-Colonel, I.M.S.

CAESAREAN SECTION FOR PLACENTA PRAEVIA WITH CONCEALED HAEMORRHAGE.

THE case reported by Mr. Arthur Cressy in the BRITISH MEDICAL JOURNAL of November 29th, 1919, p. 706, is similar to one with which I had to deal recently.

A woman, aged 39, pregnant for the fourteenth time, was admitted to the Nightingale Maternity Home, Derby, on May 14th, 1919, in a state of profound collapse. Her daughter said she had been bleeding for a week. When I saw her she was cold, blanched, and almost pulseless and had an irritating cough. Haemorrhage from the vagina continued. The cervix admitted one finger and a soft mass presented. The abdomen was distended, rigid and excessively tender. The uterus was hard. There was marked dullness in both flanks. Her whole appearance reminded me strongly of cases of bullet wound of the abdomen, and I decided to treat her on the lines we adopted at a casualty clearing station for such cases.

First Operation.

A hypodermic injection of morphine and scopolamine was given at once. Half an hour later she was anaesthetized with ether and oxygen. An intravenous transfusion of alkaline hypertonic saline was set going and during the operation 2½ pints were administered. On opening the abdomen blood escaped and about 2 pints were removed from the peritoneal cavity. The uterus was very distended and blood oozed steadily from several tears in the perimetrium, which, however, did not extend deeply into the muscular layer of the uterus, but explained the presence of blood in the abdomen. On incising the uterus a large clot was found separating the placenta and membranes from the lower hemisphere of the uterus. The membranes containing the fetus were shelled out intact. On account of the perimetrial tears I performed subtotal hysterectomy. The peritoneal toilet was completed and the incision closed layer by layer. The patient was in the theatre about half an hour.

After-History.

Shortly after her return to bed her condition was distinctly better than on admission, but the pulse was poor. During the night she was much disturbed by the cough, which was partly relieved by a hypodermic injection of heroin $\frac{1}{4}$ grain.

Next day she still suffered from blood shortage, and I transfused 1½ pints of blood from her daughter. The improvement was striking. Listlessness, pallor, and subnormal temperature gave place to restlessness, flushed face, a temperature of 103°, free action of the skin, and improvement in the volume of the pulse. The following day her condition was very satisfactory, and the temperature 99.2°. The severe cough only distressed her. The temperature settled down to normal on the fourth day, and remained so till the ninth, when the stitches were removed. Early the following morning, during a very severe fit of coughing, the wound burst open and the intestines escaped beneath the abdominal dressing. They were skillfully replaced by the night nurse, who retained them in position by packing with abdominal swabs. I removed these two days later and found the wound clean and adhesions formed. The temperature, which had risen to 102° after the packing, settled to normal in two days, and the wound healed rapidly, with no suppuration. On the fifteenth day her condition was satisfactory, and I went away for ten days' holiday.

Second Operation.

On my return I was surprised to find that there had been a running temperature, and that she had the appearance of septicæmia. On vaginal examination I found a soft fluctuating mass in the pelvis. Under an anaesthetic I opened through the posterior fornix and evacuated large quantities of pus and an abdominal swab. I accepted the responsibility of leaving this in the abdomen at the time of operation, until I found that it did not correspond with the swabs then used, being of different size and having no tape attached to it. It was, however, recognized as one used by the nurse when she replaced the intestines on the ninth night, and it must have been introduced deeply into the abdomen with a coil of bowel. The temperature fell to normal five days later, and for the next three weeks rose only twice to 99° F.

Death.

As she showed no sign of regaining strength, she was removed to a sanatorium where she could have open air, but she died a fortnight later, about two months after the Caesarean section.

On inquiring into her previous history I found she was a confirmed alcoholic. There was also evidence that the hæmorrhage was preceded by a sharp attack of influenza, for which she had stayed in bed ten days but had not seen a doctor.

Two conclusions can, I think, be drawn from this case: (1) That Caesarean section is the right method for delivering this class of case, and (2) that adequate methods for counteracting hæmorrhage and collapse will give results as satisfactory in civil practice as in war surgery.

R. DOUGLAS LAURIE, M.B.,

Derby. Hon. Assistant Surgeon, Derbyshire Royal Infirmary.

VOLVULUS OF THE WHOLE JEJUNO-ILEUM.

A LABOURER, about 45 years of age, was admitted to the J. J. Hospital one afternoon as an emergency case, with a history of abdominal pain, vomiting, and constipation of four days' duration. He was a well developed and well nourished man, and gave no history of any previous abdominal trouble. He did not look acutely ill. The pain was generally distributed all over the abdomen, which, though distended, was not tense. No particular spot of maximum tenderness was made out. He vomited only after food. The constipation was absolute. An enema was given without result. He was immediately prepared for operation.

On incising the peritoneum, greatly distended coils of small intestine protruded through the wound, rendering further exploration impossible. Enterotomy was performed in two places, and about three pints of faecal fluid removed. This permitted the necessary manipulations. The whole of the small intestine was found to be distended. The colon was empty and contracted. On tracing the ileum from the caecum upwards it was found that about six inches from the ileo-caecal junction it was tightly compressed by and kinked over the mesentery, the whole of which was twisted completely round once, from right to left (reverse clock-wise). The volvulus was relieved by giving the mesentery one turn in the opposite direction. At the seat of compression the peritoneal coat of the ileum was damaged. This was repaired by Lembert sutures, and the wound was closed without drainage.

Healing took place by first intention and convalescence was uneventful, except for an attack of abdominal pain and distension during the second week, which was relieved by an enema. He left hospital quite well at the end of the third week.

Leichtenstern's description, quoted in Treves's *Intestinal Obstruction*, fits this case exactly. Although the obstruction had lasted four days, the patient's general condition was not bad on admission. The placid expression, the absence of severe pain and vomiting were remarkable. A possible explanation may be that the onset of the volvulus was gradual, and that the compression of the ileum took place late in the course of the illness.

I have to thank Lieut.-Colonel A. Street, I.M.S., S.M.O. J. J. Hospital, for permission to publish this case.

B. P. SABAWALA, F.R.C.S.Ed.,

Captain I.M.S. (Hon. T.C.),
Honorary Surgeon J. J. Hospital, and
Marine Lines War Hospital, Bombay.

DR. LÉON BERNARD, Professor of Hygiene in the Faculty of Medicine, Paris, and a well known writer on tuberculosis, has been elected a member of the Académie de Médecine. Dr. Lesbire of Lyons and Dr. Lignières of Buenos Aires have been elected correspondents.

Reports of Societies.**GAS POISONING**

At a meeting of the War Section of the Royal Society of Medicine, held on February 9th, a discussion was held on the subject of gas poisoning in warfare.

Drift Gas.

SIR WILMET HERRINGHAM said that in April, 1915, in a Canadian field ambulance in France, he came across three French (Algerian) soldiers who said that while they were in their trenches they had seen the Germans opposite come out bearing certain tubes from which they poured some stuff out on the ground and set light to it, whereupon clouds of choking smoke had drifted towards the French line. The story was subsequently found to be inaccurate in certain particulars. Chlorine had been used in this first attack, and its change from colourlessness to white and green had deceived the Algerians into thinking that it had been ignited. That was the speaker's first introduction to the effects of stifling or asphyxiating gas used in warfare in the form of clouds or drifts. At about the same time he also saw the effects of lacrymatory gas, for there was brought into the dressing-room a man whose clothes smelt strangely, and in a few minutes no one could remain in that room because of the severe watering of the eyes which was occasioned, yet this man had been lying out in the open for four hours on a windy day. Three days after the first gas attack another attack was made, and as a result of this he found six or seven hundred men in the two hospitals at one centre all suffering from its effects. They were gasping for breath, coughing, and bringing up thin yellow, frothy fluid, which often ran out of their mouths when they lay on their sides. Various measures of treatment were tried at that time, but nothing seemed to be of very much use. He had never before seen a cyanosis which did not yield to the ordinary administration of oxygen. The methods of employing oxygen were those that had been customary in dealing with pneumonia and the like, and they were not of the slightest use. He was inclined to think at first that the cyanosis must be due not to reduced hæmoglobin, but to a morbid change in the hæmoglobin; that supposition, however, was proved to be wrong. In *post-mortem* examination the effects found were mainly three—laryngitis, extreme oedema of the lungs, and emphysema. Experiments were immediately made in England with the object of elucidating the pathology, and it was soon shown that the chief symptoms, if not all of them, might be explained by the impossibility of getting oxygen into the blood through the great wall of oedema. He could not help thinking that, to explain the rapid collapse, there must have been some further action on the heart. Presently it became possible to divide these cases into three groups. The first were the "grey" cases, which collapsed almost at once; in these cases, as a rule, nothing could be done. Then came an intermediate group of cases, which required very close supervision; here neglect was dangerous, but otherwise there was good hope of recovery. The third group were cases only slightly affected, which recovered even though more or less left alone. The mainstay of treatment was oxygen, and the speaker showed the makeshift apparatus, such as improvised petrol tins, which were used until Dr. Haldane's apparatus became available.

Mustard Gas.

Attacks with chlorine gas went on all through the summer of 1915; in the course of the winter phosgene was substituted. Later, gas shells took the place of drift. The British forces were the first to employ gas in projectors. In July, 1917, came mustard gas attacks. He saw the first *post-mortem* examinations of these cases, and when the attack was repeated a fortnight later near Nienport he saw the first gassed men brought in. The principal action of chlorine and phosgene was to produce an enormous oedema; that of mustard gas was first of all to inflame the eyes, though little permanent injury resulted to the eye; secondly, to scorch the air passages; and thirdly, to scorch the skin. The main danger was septic bronchopneumonia,

produced by sloughing of the membrane of the trachea. Sir WILMOT HERRINGHAM mentioned that a research chemist in this country who was accustomed to pay periodical visits to Germany before the war was there in 1909, when, walking in the country, he detected a strange odour, and, following it up, came to a small hill on which were a number of soldiers and also some sheep; several of the animals appeared to be dead. He was not allowed to trespass further, but it was evident that he had come upon some poison gas practice for German military purposes.

Colonel C. G. DOUGLAS said that gas warfare could be conveniently divided into three phases: first, the cloud gas on a limited front; then the lethal gas shells; and, finally, the mustard gas poisoning. Mustard gas caused 80 per cent. of the total gas casualties during the period for which it was employed. The problem that confronted the medical officer in treating gas casualties in modern warfare differed according to the character and mode of action of the gas. In the case of lung-irritant gases the most difficult task was to tide the patient over the first forty-eight hours. In the case of mustard gas the mortality was comparatively low; where death occurred it was caused by bacterial infection of the bronchial tubes, and the medical officer's concern in dealing with mustard-gas cases was to cope with the large number in which eyes and skin were affected, and to get the cases cured as quickly as possible. In chlorine and phosgene poisoning late deaths were infrequent; death, when it occurred, was almost immediate. In mustard gas poisoning, on the other hand, the deaths did not reach their maximum until the fourth day after exposure, and their incidence fell slowly, so that there were deaths on the tenth or twelfth day or even later.

Pathology of Poison Gas.

Major J. W. McNEE said that with chlorine gas the pathological lesions were comparatively simple; the lesions were entirely those brought about by a pulmonary irritant. The only subsequent condition of any importance was that during the period of convalescence a certain amount of bronchitis was commonly found. With regard to phosgene the conditions were somewhat different. Phosgene gave rise to lesions which were distal from the lungs. In the lungs the lesions were similar to those caused by chlorine, with great oedema and disruptive emphysema. It was on the distal effects of phosgene that he wished to lay stress. Clinically, phosgene had in some way a definite effect on the heart not seen in the case of chlorine poisoning. In phosgene a larger proportion of cases were pallid and suffered from circulatory failure. In addition to the emphysema and oedema, a considerable capillary thrombosis in the lung was frequently found. Hyaline thrombi were also to be found in the capillaries of the brain. The pathology of mustard-gas poisoning was entirely different. After a latent period, generally of about a day, an intense inflammatory reaction took place, resulting in the bronchial membrane becoming entirely necrosed. In dealing with war pensioners he had noticed that men who had been gassed showed a tendency to develop bronchitis during foggy weather. He also found among these pensioners a number of cases of what the French called pseudo-tuberculosis, with cough and expectoration, some alteration of the x-ray picture, but no tubercle bacilli. This was believed to be due to fibrosis around the lumen of the bronchi.

Anti-gas Measures.

Colonel S. L. CUMMINS addressed himself to the defensive rather than the clinical measures. The first gas attack found them entirely unprepared, but within a few weeks defensive measures were well in operation, thanks to Professors Haldane, Baker, and Watson, and also the help of Colonel Horrocks and others at home. At first the anti-gas defence was run as part of the medical service, but a stage was soon reached when it became evident that this question was not wholly a medical one. Commanding officers of regiments in the line had to detail somebody to make wind observations; gas discipline, also, was a regimental responsibility. Therefore he came to see, as did others, that defence, like offence, should be made an administrative service. But working with the fighting services, maintaining the closest possible touch, and aware of every secret development, must be the

medical service, whose officers were responsible to the Director-General for work on the physiological and medical side.

Professor J. S. HALDANE said that the clinical evidence was very clear that in certain cases bleeding did relieve symptoms. Resort to bleeding was familiar to him before the war in cases of poisoning from nitrous fumes. The reason people thought of bleeding was because the sufferer's veins were distended. The only cases which were benefited by bleeding were the "blue" cases; in the "grey" cases it was of no use. With regard to anoxaemia, a serious anoxaemia was, to his mind, a very dangerous thing. Anoxaemia in the "grey" cases was far worse than in the "blue," for the reason that in the "blue" there was probably an excess of CO₂ in the blood as well as a deficiency of oxygen.

Late After-effects.

Dr. J. A. RYLE said that he was inclined to divide the late effects of gas poisoning into four groups: (1) A small proportion of cases showed gross damage. These were cases of chronic bronchitis, awakened tuberculosis, and cases not specifically described but to which he would apply the term bronchiectasis, the result of mustard-gas poisoning. (2) Cases of structural damage which could be demonstrated, but was not superficially obvious. In most of these cases a history of pneumonia following "gassing" would be found. (3) Cases of "D.A.H.," or Lewis's effort syndrome group. (4) Functional cases, in which there was often vomiting, giving rise to a diagnosis of chronic gastritis. These cases of vomiting, however, were, he thought, functional, and many of them had been cured by methods of re-education and persuasion.

Dr. T. J. BENNETT asked for experience as to gastrointestinal symptoms in "blue-cross" gas shell (arsenic) cases.

Sir WILMOT HERRINGHAM, replying to the last speaker, said that he did not remember any blue cross gas shell cases with intestinal symptoms. The most interesting thing about these cases was certain nervous developments, chiefly of the nature of paralyses and anaesthetics, but so far as he knew the effects quickly passed off, save for some loss of reflexes.

TYPHUS AND RELAPSING FEVER IN THE EAST.

At a meeting of the Section of Medicine of the Royal Society of Medicine, held on January 27th, the President, Dr. A. F. VOELCKER, being in the chair, Dr. W. H. WILLCOX, in the course of a paper on typhus and relapsing fever in Mesopotamia and Northern Persia, dealt fully with the history of the two diseases and gave accounts of outbreaks during 1916, 1917, and 1918 in those countries.

The Louse Factor.

The etiological factors were all in accordance with the view now generally held that the body louse is the main channel of infection of both diseases. The factors associated with prevalence of the diseases were likewise favourable to the life and multiplication of the body louse. It was pointed out that these diseases were endemic in Northern Persia. In Persia, owing to the lower degrees of maximum temperature, occurrence was all the year round, while in Mesopotamia the great heat of the summer would effectively stamp out the diseases. In Lower Mesopotamia the diseases were uncommon amongst the natives, the temperature conditions being adverse to their spread. In the Baghdad area, however, the diseases occurred practically always in the early part of each year; they were, no doubt, brought along the caravan routes from Persia and the upper regions of the Euphrates and Tigris by pilgrims and others. The Turkish troops in Mesopotamia during the whole war suffered terribly from typhus and relapsing fever, and an interesting account of their prevalence, written by a doctor who had served with the Turkish army during this period, was related. Another source of the diseases in 1918 was the influx of the great number of refugees, some 50,000 in number, from the lower Caspian region. These brought with them a heavy louse infestation accompanied by cases of both diseases. In 1916 and 1917, since communication with the local Arabs in the infected areas had not been

established, the main source of infection of the few cases that occurred was from Turkish prisoners. Those of our troops who came into contact with them—such as medical personnel, motor transport, drivers, military guards—ran serious risks of infection. After the occupation of Baghdad and the occupation of the large areas of Northern Mesopotamia the troops came more into contact with the local population, so that in 1918 the main source of infection was the local population (Arabs, Kurds, and Persians). Many of these had been enrolled into native labour corps, and in them both diseases occurred, so that those of our troops who were brought closely into contact with these men ran grave risks of infection; thus the medical personnel, ambulance and transport drivers, military police, and those in charge of the native labour corps were specially exposed.

Other Channels of Infection.

With regard to other channels of infection than the louse, it was pointed out that since the excreta probably contained the virus of the disease, general precautions to limit infection were necessary in the nursing of patients. With typhus no case was observed where the disease had spread from patient to patient in hospital, and no case was known of the spread of this disease where the agency of lice could be excluded. With relapsing fever the risk of infection appeared decidedly greater. Several instances occurred where the disease had spread from a patient to another person where every precaution had been taken to prevent access of lice. Two cases were quoted in which a bacteriologist contracted the disease after taking blood from a patient for examination; in each case the usual incubation period intervened, and it seemed likely that the blood of an infected person might convey the infection, also possibly the excreta in cases of a relapsing fever might serve as carriers of the disease. An unusual type of relapsing fever occurring in Northern Persia at Mianeh was described; this appeared to be conveyed by a tick known as the Miaeh bug, and the symptoms resembled those of ordinary relapsing fever such as occurred in Mesopotamia, the attacks being perhaps more severe. No opportunity of blood examination in these cases occurred. The close association of typhus fever and relapsing fever was alluded to, and also the interesting fact that a patient suffering from one of these diseases might carry on him lice which were capable of producing both diseases. The native population (Arabs, Kurds, Persians) appeared to have considerable immunity to typhus fever, and often had the disease in a very mild form. The occurrence of outbreaks of typhus and relapsing fever amongst the troops was described, and the source of the different outbreaks traced. The interesting feature of the Mesopotamian campaign was that, owing to the difficulties of communication through the long distances between the posts where troops were stationed, the origin of each outbreak of disease could usually be traced, and the spread of infection effectively guarded against. At no period did these diseases get out of control, and outbreaks were quickly localized and stamped out.

Symptoms and Treatment.

Special attention was drawn to the marked severity of the mental symptoms in typhus and to the profound effect on the brain, lasting many months after the fever had subsided. Lack of concentration and inability for mental effort, associated with a condition of slight deafness, commonly lasted for at least six months. An important diagnostic symptom in the acute stage of illness was the loss of the knee-jerk which usually disappeared about the fifth day and remained lost during the febrile stage and for a varying period after this had subsided. In severe cases a condition of coma with incontinence sometimes lasted for a week or more after the temperature had become normal. The character of the rash and its distinctions from the rash of enteric and paratyphoid and other rashes which occurred in Mesopotamia were fully described. In the treatment of typhus attention was called to the great value of administration of normal saline. In severe cases this was given rectally every four hours, commencing about the eighth day, and in the later stages subcutaneous and intravenous saline were given. Where symptoms of venous thrombosis threatened, an intravenous injection of normal saline containing $\frac{1}{2}$ per cent. and 1 per cent. of sodium citrate was of value.

The symptoms also of relapsing fever were fully described, and attention was called to the cerebral type of the disease in which marked mental symptoms occurred. The value of kharsivan or salvarsan in the treatment of this disease was emphasized, and a dosage of 0.3 gram was recommended (or 0.45 gram of neo-salvarsan). Almost invariably the temperature would fall to normal within eighteen hours, and usually no relapse occurred. In a series of 241 cases treated by kharsivan, in only 5 per cent. did relapses occur. Doses smaller than 0.3 gram were found to be inefficient, while doses greater were inadvisable owing to the risk of hyperpyrexia. When a relapse occurred after the dose of kharsivan recommended it was usually of a very mild nature, and generally the apyrexial period was much prolonged.

APPENDICECTOMY INCISION.

At the meeting of the Section of Surgery of the Royal Society of Medicine held on February 4th, with Sir JOHN BLAND-SUTTON in the chair, a paper was read by Mr. R. H. A. WHITELOCKE of Oxford on appendicectomy by a new route. The paper appears at p. 211. In the discussion which followed—

Mr. G. A. R. NITCH questioned whether the particular incision advocated gave sufficient room for dealing with acute perforating appendicitis when there was a large collection of fluid in the pelvis. It was very necessary to sponge that fluid out, and he thought it must be difficult to get the sponge down into the bottom of the pelvis without using a considerable amount of force.

Mr. H. J. PATERSON said that this small incision had the grave disadvantage that with its use it was impossible to get an adequate exposure of the abdominal contents. He took it that the chief reason for adopting the method was to avoid the risk of subsequent hernia. That risk, however, could be obviated almost entirely by making the incision in the middle line of the abdomen. He held very strongly that the right place to operate was through the middle line, which made it possible to ensure that no secondary foci were left undrained.

Professor RAYMOND JOHNSON said that he did not feel inclined to change his usual habit of operating after hearing the information given them that evening. He was not quite clear what particular advantage was claimed for the new route. He disagreed entirely, however, with Mr. Paterson as to taking the middle line. His feeling was that that was absolutely the worst position to take. The advantage which the middle line offered of dealing with small pockets of pus was a very small one to put in the balance against its obvious disadvantages.

Mr. McADAM ECCLES said that the incision was likely to be very useful in certain cases, but it would be a most disastrous incision in cases of general peritonitis, because these could not be drained properly.

Mr. R. P. ROWLANDS said he believed in the muscle-splitting operation for acute appendicitis; it was more suitable, he thought, for acute cases than for chronic. Out of about 1,000 cases of acute appendicitis treated in this way he had only found two in which hernia had developed, and in both these cases there were other circumstances which favoured the development of hernia. He had kept a keen eye on his patients with a view to this occurrence. Statistics showed that the risk of pulmonary embolism was greatest between the ninth and the seventeenth day or thereabouts. To prevent pulmonary embolism he had adopted the plan of getting his patients up on the fifth day. They (or the nurses) did not like it, but he had found it answer, and whereas he used to get about one pulmonary embolism in his cases of appendicitis in a year, he had now not seen one for seven years.

Sir JOHN BLAND-SUTTON said that for every operation in surgery there seemed to be as many methods as there were men to use them. Each man had his own accustomed method, and had good results from it. With regard to the avoidance of hernia, he had come to the conclusion that the only way of avoiding hernia was to refuse to open the abdomen at all. Some years ago an enthusiastic student who wanted to become an abdominal surgeon asked him to suggest a theme for his thesis, and, as the student had means, he advised him to go to the Continent for a year and study the work of the best operators, and

then decide what would serve best for the purpose. He returned with his thesis already written; it was "On the different methods of closing abdominal wounds with a view to the avoidance of hernia." He found an extraordinary variety of methods, and the material used for sutures was as remarkable as the methods; it included catgut, silk, silkworm gut, horsehair, and iron, aluminium, silver, gold, and platinum wire. The speaker had still to find a man with a way of sewing up a wound so as to be quite certain that he would not get hernia. Probably the surgeon who had done the abdominal operation did not see the patient when the hernia had occurred; other men would see his failures, and he would see theirs. But if a man thought he had succeeded by any device in getting over the possibility of hernia he was living in a fool's paradise.

Dr. WHITELOCKE said that he had tried to see as many of his patients afterwards as he could, and he had not yet seen a hernia. He had not the slightest doubt that the frequency of hernia was appalling after operations for appendicitis, especially by the para-median incision. In all his abdominal operations he never swabbed out the pelvis; he put in a rubber tube of sufficient calibre, and left the respiratory movements to swab out; he inserted the tube right down to where the abscess was. Mr. Paterson's idea of opening the appendix abscess through the middle line of the abdomen appeared to him absolutely unsurgical. In reply to other questions, he said that it was only in well developed people that one got muscle fibres; he welcomed muscle fibres, such cases gave the best scar. He did not divide them with his scalpel, but separated them with his fingers. He was quite ready to try the fifth day for getting the patient up, but he could not recall a single case of his which had died from embolism.

GYNAECOLOGICAL CASES AND SPECIMENS.

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Manchester on January 16th, with the President, Mr. MILES H. PHILLIPS (Sheffield), in the chair. Mr. BLAIR BELL (Liverpool) exhibited a specimen of diverticulum of the bladder showing cystitis. The diverticulum was adherent to the right ovary, and was undoubtedly congenital. Mr. CARLTON OLDFIELD (Leeds) said he had often observed cases of diverticula of the bladder, but in no case had infection occurred. He asked if it were not possible in the present case that a portion of bladder wall had been pulled out by inflammatory tissue in the neighbourhood of the right uterine appendage. Mr. BLAIR BELL, in reply, did not think that the diverticulum had originated in the way suggested by Mr. Oldfield.

The PRESIDENT demonstrated a specimen of adenomyoma of the recto-vaginal septum which had caused a constant coffee-coloured vaginal discharge for several months in a multipara aged 45 years. A very tender nodular cystic growth occupied the posterior fornix and presented a small area of papillary growth; no connexion with the cervical mucosa could be demonstrated. He had operated on more than twenty of these cases, and in the majority had found inflammatory disease of the uterine appendages; he expressed the opinion that these growths were of inflammatory origin. Dr. LEITH MURRAY (Liverpool) recalled a case of adenomyoma presenting unusual features, related to the Society by the late Dr. Wallace in 1914.

A hysterectomy with removal of one ovary was carried out in 1908, but a complete removal of the infiltrating growth was not possible. Nine months later a regular monthly haemorrhage occurred, similar in all respects to her previous menstrual periods, and persisted for some years. By 1914 the growth was filling the pelvis and causing chronic intestinal obstruction. Dr. Leith Murray performed a colostomy with marked benefit, and at the same time a search was made for the remaining ovary with the intention of removing it, and of inducing the menopause, in the hope that the periodic haemorrhage indicated a Müllerian origin of the tumour mass, and that the growth might react favourably to such a step. Unfortunately, as the result of excessive infiltration of the broad ligaments, the ovary could not be localized. The patient lived till the latter end of 1918, and was in fairly good health and able to walk about until two or three months before her death.

Dr. D. DOUGAL (Manchester) described two cases in which he had performed Caesarean section for dystocia, due to (1) uterus bicornis unicollis, and (2) ventrifixation, or adherent myomectomy scar.

In the first case the non-pregnant horn of the double uterus lay within the pelvic brim, and caused obstruction, much in the same way as a fibroid situated in the lower part of the uterus.

The second patient had a myomectomy performed four years previously. The anterior uterine wall was firmly adherent to the parietes, but whether this was accidental or due to a fixation operation could not be ascertained. The posterior uterine wall had become enormously hypertrophied, and had pulled the cervix upwards and backwards to the level of the sacral promontory. Owing to the fixation the Caesarean incision had to be made through the posterior uterine wall, and a few days after operation a coil of small intestine lying in the pouch of Douglas became adherent to it, and caused acute intestinal obstruction. This was remedied at a second operation, and the patient then made a good recovery.

Dr. W. W. KING (Sheffield) showed microscopic sections of a spindle-celled sarcoma which appeared at the lower end of a colporrhaphy wound within one month of operation. The first nodule, the size of a bean, was removed, but in ten days' time the growth had recurred, and was then the size of a large pea. After treatment with Coley's fluid the growth disappeared to the naked eye, and a piece removed two months after the first appearance of the tumour showed no sign of sarcoma. The PRESIDENT thought the appearance of the section very suggestive of granulation tissue. Dr. DONALD thought that diagnosis by microscopic examination in cases of sarcoma was very difficult, and apt to be misleading. The clinical picture in this case did not seem to be altogether in favour of sarcoma. Dr. KING, in reply, thought the rate of growth too rapid for granulation tissue. He would keep the case under observation and report further in six months' time.

Mr. CARLTON OLDFIELD (Leeds) described a case of hydatid mole with bilateral ovarian cysts and toxæmia.

The patient, a multipara aged 36, was three and a half months pregnant when she first came under observation. Her husband had contracted syphilis a year previously, and she herself had a positive Wassermann reaction. Severe toxæmia with albuminuria developed suddenly at this time. The uterus was retroflexed and the size of a three and a half months' pregnancy. Seven days later the uterus was much larger and reached the costal margin. Abdominal pain and tenderness and marked tachycardia were present, and her general condition was grave. There was no external haemorrhage, and the cervix was closed. Under an anaesthetic the uterus was emptied and the contents found to be a hydatid mole. There was practically no haemorrhage during the operation. During the pelvic examination at the time of operation bilateral ovarian cysts were discovered, the left being apparently the size of two fists. In three days' time the patient was very much better, and within three weeks was practically well. Three months after the commencement of the illness her general health was normal, and the ovarian cysts, which had been noticeably decreasing in size since the operation, had entirely disappeared.

Dr. FOTHERGILL had met with a case of hydatid mole in which severe symptoms of toxæmia were present. He had found it necessary to remove the uterus in this case, but toxæmic symptoms persisted, and caused her death two months later.

The PRESIDENT related a case where a large cervical fibroid caused severe haemorrhage ten years after the climacteric.

The patient was a spinster aged 57 years, and had a sudden profuse haemorrhage which came on without warning, and was only controlled by packing the vagina. A pelvic tumour had been known to exist for years, but had recently caused no discomfort. Hysterectomy was performed; the uterus was atrophied, but the cervix was lengthened to over six inches, and extremely thinned by a large cervical fibroid. Under the cervical mucous membrane covering the lower pole of the tumour were many large veins, and it was considered that rupture of one of these had led to the profuse bleeding.

Mr. MICHAÏLO GAVRILOVITCH, Envoy of the Kingdom of Serbs, Croats, and Slovenes, has become the President of the Serbian Red Cross Society in Great Britain.

A CASE was reported to a recent meeting of the Society of Medical Sciences of Lyons in which M. Patel had treated right facial paralysis, due to mastoiditis and caries, by operation. The patient was inconvenienced by the inability to close the eye, its prominence, and constant watering. The operation consisted in section of the right sympathetic and excision of the superior cervical ganglion. It was successful; the palpebral fissure was diminished and the globe retreated into the orbit. At the same time contraction of the pupil on the right side was observed, but the reactions to light and accommodation were retained.

Rebicus.

THE GROUNDWORK OF SURGERY.

In his *Groundwork of Surgery*¹ Mr. ARTHUR COOKE, Surgeon to Addenbrooke's Hospital, Cambridge, and University Teacher in Surgery, describes surgical diseases, their pathology and treatment, in the simplest way. A general wide idea of the subject is obtained, to which detailed work and experience in the wards can soon be added. The book is systematically arranged; in seven chapters it deals with infections; these are followed by others on injuries and shock, on deformities, on new growths, and later by an excellent chapter on prophylaxis and preventive treatment. Finally there is a chapter on the time factor in surgical treatment, in which the causes that render early operation so necessary in certain classes of cases are set out, and it is judiciously observed that the medical man can only insist upon early operation if he can arrive at his diagnosis with confidence.

Mr. Cooke says that his book is designed to give the student on beginning clinical work an elementary groundwork of knowledge as to common lesions and their causes; and it is, we think, one of the best books that has yet been written for the third-year student. It will save him from the bewilderment which many a student experiences when he begins to attend in the wards of his hospital, and will provide him with the main general facts of his subject.

FOOD POISONING AND FOOD INFECTIONS.

DISEASES due to food, though their existence is well recognized, are probably more frequent than is generally known and are often wrongly interpreted: it is indeed, not uncommon to find references to "ptomaine poisoning" in textbooks and in the evidence of medical men at inquests, although there is no longer any justification for the continued use of this popular phrase. It is therefore highly appropriate that an authoritative monograph on *Food Poisoning and Food Infections*² should have been contributed to the Cambridge Public Health Series by Dr. W. G. SAVAGE, who has devoted much time to this subject during the last fifteen years, and is the author of valuable reports and papers dealing with this aspect of public health administration.

Food poisoning is often classified according to the kind of food; but as the majority of cases are due to bacteria, and usually to bacteria of the Gaertner group, a division based on the vehicle of the infection, such as those due to ordinary meat, shellfish, sausages, milk, cheese, and ice-cream, is unsatisfactory, and the only scientific classification is one which depends on the infective agent. The three groups of bacterial food poisonings are those due to the Gaertner bacilli, to *B. botulinus*, and to other bacteria, of which putrefactive bacteria, *B. coli* and *B. proteus*, are usually considered to be the most important. Dr. Savage deals with these in detail, and shows that all, or almost all, the large and widespread outbreaks of bacterial food poisoning investigated by modern methods are due to the Gaertner group, that mass infection by bacteria not necessarily specific in nature is very doubtful as a factor in food poisoning, and that the poisonous effect of food rendered putrid by bacilli such as *B. coli* and *B. proteus*, though often assumed, still requires more rigid proof before it can be finally accepted. The description of the general clinical picture and other features of food poisoning of bacterial origin is derived from an analysis of about 112 outbreaks in this country investigated by the author, and, though mainly based on outbreaks due to the Gaertner group, may be taken as applicable to all outbreaks of bacterial origin except botulism. As the author has not been able to find any definite cases of botulism in this country, and it will be remembered that the recent outbreak of encephalitis

lethargica was at first erroneously thought to be of this nature, he depends for his description mainly on the work of Van Ermengen and E. C. Dickson; the latter has within the last few weeks published investigations on the resistance of the spores of *B. botulinus* to the sterilizing agencies commonly employed in canning foods.

Chapters are devoted to food poisoning due to chemical poisons introduced unintentionally and as preservatives; to foods inherently poisonous, such as certain fish, mainly in the tropics, and ergot; to food idiosyncrasies, in which anaphylaxis is sketched; to the prevention of outbreaks of food poisoning, and to the methods of investigating the outbreaks. The work can be most cordially recommended as a clear and standard guide in this important subject.

UROLOGICAL PRACTICE.

DR. V. C. PEDERSEN, in his *Textbook of Urology in Men, Women, and Children*,³ has accumulated a vast amount of information. He states in his preface that this volume represents the experience of many years in urological departments in New York City, in private practice, and at St. Mark's Hospital, and that the actual writing of the text and the preparation of the illustrations represent four years of steady concentrated work. The result is a book which no one can read without being impressed with the industry, thoroughness, and knowledge of the author. That he has utilized his intimate knowledge of the subject to the best advantage is, however, not so certain. The language of the earlier chapters is often difficult to follow, and clearness of expression is too often lacking. It is only when he has left questions of theory and deals with matters of practice that the author appears to write with ease and with corresponding lucidity. The paragraphs and chapters on diagnosis and treatment are therefore the best. Here it is that the author's great store of clinical experience is given to the reader in a style that is simple and vastly more readable than that employed elsewhere. Fortunately diagnosis and treatment have been allotted a liberal allowance of the book.

Physical treatment—comprising electrotherapy, heliotherapy, and hydrotherapy—has been dealt with in far greater detail than is customary in textbooks of urology. The author, while admitting the limitations of electrotherapeutics in the treatment of genito-urinary diseases, considers that many of the failures reported are due to the use of second-rate apparatus in a semi-skilled manner. For this reason he supplies the reader with the information necessary for forming a clear judgement of the scope of electrotherapy in urinary diseases. Instruction is given as to the best form of machine, the type of application, its strength, duration, and frequency, and what class of case is most likely to benefit from its use. Hydrotherapy, though dealt with at less length, is given its due place amongst the therapeutic weapons available. It is, however, curious that in a work that is so comprehensive and that lays so much stress on physical remedies no mention should be made of the treatment of inflammatory conditions of the genito-urinary apparatus by passive congestion. We can find no mention of such an apparatus for the urethral canal, or of Bier's cups, or of the *rationale* of treatment by venous congestion.

While dealing with the bacteriology of the urethral canal, Dr. Pedersen emphasizes—unduly perhaps—the impertance of distinguishing between infections due to the gonococcus and those caused by *Micrococcus catarrhalis*. In support of his statement that the latter organism is occasionally to be found in the human urethra, the author quotes the work of W. Ayres. Whether he will find much support for this statement on this side of the Atlantic is extremely doubtful. So competent an authority on the *Micrococcus catarrhalis* as Dr. Mervyn Gordon has categorically denied that it is ever found in the urethra. Still, whatever be the truth with regard to this difference of opinion, we cannot believe that the question of urethral discharge due to *Micrococcus catarrhalis* need seriously disturb the clinician.

¹*Groundwork of Surgery*. For First-year Students. By Arthur Cooke, M.A., M.B., B.Ch. Oxon., M.A. Cantab., F.R.C.S. Cambridge: W. Heffer and Sons, Limited. 1919. (Cr. 8vo, pp. viii + 183. 7s. 6d. net.)

²*Food Poisoning and Food Infections*. By William G. Savage, B.Sc., M.D., D.P.H. Cambridge Public Health Series. Edited by G. S. Graham-Smith, M.D., and J. E. Purvis, M.A. Cambridge: At the University Press. 1920. (Demy 8vo, pp. viii + 247. 15s. net.)

³*A Textbook of Urology in Men, Women, and Children, including Urinary and Sexual Infections, Urethroscopy, and Cystoscopy*. By V. C. Pedersen, A.M., M.D., F.A.C.S., Major Medical Corps, United States Army. London: H. Kimpton. 1919. (Med. 8vo, pp. 991; 262 figures, 13 coloured plates. 36s. net.)

MEDICAL HISTORY.

Owing to the exigencies of the war the first volume of the *Annals of Medical History*,⁴ begun in 1917, was not completed till 1919, and the first number of vol. II is now before us. It begins with Dr. G. W. Corner's article on "The Anatomists in Search of the Soul": in the third century before Christ Erasistratus regarded the meninges and subsequently the cerebellum as the site of this intellectual faculty; Herophilus discovered the cerebral ventricles and gave them this function, and Strato of Lampsacus decided that the frontal sinuses were *pars princeps animae*. René Descartes's famous assumption at a much later date, that the pineal body is the seat of the soul, was promptly opposed by Bartholin and Wharton, two of the best contemporary anatomists; then followed Henry More's advocacy of the fourth ventricle. Dr. W. A. Jayue of Deuver writes on "The Medical Gods of Ancient Iran," and Dr. J. Collins Warren of Boston contributes an illustrated account of "The Pulmotor of the Eighteenth Century," an apparatus designed for the purpose of inflation of the intestinal canal as a means of resuscitation of the apparently drowned. The history of laryngology and rhinology is traced by Dr. J. J. Walsh, and Dr. Jonathan Wright supplies the first of two "Modern Commentaries on Hippocrates." The descriptive list of the incunabula in the library of the College of Physicians of Philadelphia occupies 34 pages. Sir William Osler has provided an attractive note on James Currie's *Manuscript Journal*, sold at Sotheby's on July 24th, 1918, and his review of Dr. Parkes Weber's *Aspects of Death*, a book dedicated to him, has a melancholy interest. Sir Norman Moore's *History of St. Bartholomew's Hospital* is pleasantly praised by Dr. C. Singer, and there are several short articles by the editor, who must be congratulated on this successful number.

SUSSEX SEVENTY YEARS AGO.

Sussex in Bygone Days,⁵ first published in 1906 for private circulation only under the title of "The Reminiscences of Nathaniel Paine Blaker," has now been much expanded, and is a charming record of one who loves both the country and his profession. The author, who was born in 1835 on a Sussex farm, gives a vivid account of the rural life and customs which have largely gone beyond recall, such as the patus, the ox teams, and the smugglers. The picture of the remote days and villages is tantalizingly peaceful; the amount of traffic was not more than two or three carts a day, and even a stranger on the road was so rare that people turned and stared after he had passed. There was little illness, and doctors were seldom seen in the village; when they were summoned for a grave case they always came on horseback, and dressed, as a rule, in summer, in dark swallow-tailed coats and brass buttons, light waistcoat and breeches, top boots and spurs, and large white tie and white frill.

In 1852 Mr. BLAKER was apprenticed as a resident pupil at the Sussex County Hospital, which had been opened in 1828; he gives a graphic if rather grim description of the surgery of those days when anaesthetics were little used and "laudible pus" was thought to prevent erysipelas. Three years later he went to Guy's, where he attended Addison's last course of lectures, and was fascinated by his manner and eloquence.

An empyema which he spat up cut short his London and nearly his earthly life. He, however, became house-surgeon and eventually senior consulting surgeon, to the Royal Sussex County Hospital, and his modest but wise meditations, especially those on the altered type of disease in relation to social customs, are the fruit of ripe experience. He suggests that it is the people rather than the diseases that have changed, and mentions the dictum of his old uncle: "Men are very much changed since I was a boy; they swear less and lie more." It is difficult not to quote more of the good things in a book which the reader is unlikely to put down until he is disappointed to find it is finished.

⁴ *Annals of Medical History*, 1919, vol. II, No. 1, Spring Number. Edited by Francis R. Packard, M.D. New York: Paul B. Hoeber. Yearly subscription, 6 dols.; single copy, 2 dols.

⁵ *Sussex in Bygone Days*. Reminiscences of Nathaniel Paine Blaker, M.R.C.S. With a foreword by Habberton Latham and an introductory letter by Sir Arthur Newsholme, K.C.B. Hove, Sussex: Combridges, 1919. (Fcap. 8vo, pp. xvi + 197; 4 illustrations. 5s. net.)

NOTES ON BOOKS.

THE *Year Book of Pharmacy*⁶ for 1919 contains some 300 pages of abstracts of papers dealing with pharmacy, materia medica, chemistry, new remedies and formulae, therapeutics, and kindred subjects; these are of great interest to pharmacologists and dispensers. The volume also contains a full report of the proceedings of the fifty-sixth annual meeting of the British Pharmaceutical Conference, held in London last summer, together with lists of members and indexes.

Mr. KINGZETT'S *Popular Chemical Dictionary*⁷ is a brave attempt to solve a wellnigh impossible problem—namely, that of producing a dictionary explaining the nature and actions of important chemical substances or terms and physico-chemical processes in phrases intelligible to the layman. His endeavour has been to produce a popular educational work and general book of reference not only for chemists but also for the larger body of the public who take interest in chemical matters. The *Dictionary* covers a great deal of ground, and is full of facts, definitions, and explanations that should be of service to the general inquirer. Perhaps it would be possible in a later edition to insert a few such terms as "Benzine," "Benzole," "Margarine," "Erlenmeyer flask," that do not appear to be mentioned in the book. The text contains a number of serviceable illustrations, and certainly supplies a want that must often have been felt.

MINOR SURGERY.

Some sixty years ago the first edition of Christopher Heath's *Minor Surgery and Bandaging*⁸ saw the light. Since that time it has gone through no fewer than seventeen editions, the last recipient of the mantle of the prophet being Mr. GWYNNE WILLIAMS. The book has naturally undergone many changes, the latest being the omission of the chapter on war injuries—a happy sign of the times. Such advances in surgery as the war has occasioned have been incorporated in the text. A notable omission in this respect, however, is that the method of blood transfusion is not described. No one would look for a full and wide account of this life-saving measure in so small a work, but the citrate method might have been included, for it is the easiest and most generally applicable. There are minor faults in the book: the reader is given to understand that a rectal tube can be passed high into the bowel, whilst the general experience is that in reality it coils up in the rectal ampulla. Torsion of the spermatic cord—a much commoner incident than is generally supposed—is omitted from the section on acute scrotal swellings. Rupture of a hydrocele is also not mentioned. In spite of the painstaking work of Kanavel and others in America on the principles of the treatment of infections of the hand, the new doctrines are slow in making their way in this country. In few situations can such irreparable damage be done by the common faulty placing of the incisions. The section on the sterilization of the hands and patient's skin might be made fuller. Not enough stress is laid on the truism that it is possible to render skin sterile for the moment, but that it is impossible to keep it so. The book is, in spite of these things, very serviceable, its great defect is lack of personality. In that attribute the original work was rich and often, to our eyes, picturesque. "Some visiting surgeons," says Heath, "wish to do everything for themselves, and are very wroth if a house-surgeon has opened an abscess or tightened a bandage," and proceeds to warn his readers against the attempt to bring the practice of two or three individual surgeons to one uniform level, by which all possibility of comparison would be lost. As to the chaplain, he must not be interfered with, "the only difficulty at all likely to arise in this question is the tendency of some chaplains to prolong their visits to the wards to the inconvenience of the dressers and others." These times have gone and newer and better ones taken their place. The new edition will be found to reflect that change.

SATURDAY, FEBRUARY 14TH, 1920.

MINERS' NYSTAGMUS.

THE fact that a Home Office committee is now sitting for the revision of the tests for miners' safety lamps presents a convenient opportunity for reviewing the known facts of a disease which takes so heavy a toll of the vision of the coal-mining population. The chief feature of the disease is the rapid oscillation of the eyeballs. The symptom is to be seen in other conditions; it is, for instance, common in some defects of the eyes arising from congenital malformation or acquired disease, and occurs in certain diseases of the central nervous system and of the ears. The symptom is familiar to every practitioner of medicine, and the layman can gain for himself some knowledge of the phenomenon by noting the eyes of a fellow traveller on the railway who is engaged in watching the objects that fly past the carriage window, and if he himself indulges in the same practice he will appreciate some of the fatigue associated with the movement.

The recognition of miners' nystagmus is of comparatively recent date. Decondé, an ophthalmic surgeon of Liège, first drew attention to the disease in 1861. "Almost always," he said, "vision is seriously affected, and generally I have found it impaired. If the oscillation is very frequent sight is disturbed by it and the patient cannot continue at work." Since then much work has been given to elucidating the cause of the disease and the possibility of its prevention. During these investigations attention has revolved about certain aspects of the work of the coal miners. The cramping of his body and the movements of his eyes caused by the narrowness of his position and his attitude at work, the feebleness of the light in which he has to work, the badness and sometimes the poisonous badness of the atmosphere under ground, and the intensity of the physical work done; with these there are to be brought into relation all those other ills to which flesh is liable—defective eyes, ill health of mind or body, and intemperance.

At first attention centred upon the first two of the conditions and mainly on the first, so that the disease was held to be due to the strain on the muscles of the eyes caused by the effort to see in a constrained position and in a poor light. Bell Taylor of Nottingham considered the affection a pure myopathy and likened it to writers' cramp. For a time attention became almost wholly centred on this vice of posture, largely because of the energetic work of Simeon Snell of Sheffield. He concluded "that the disease only attacks men who are compelled through the nature of their work to direct the gaze upwards—that is, hewers and deputies," and further, "the position of the miner at his work is, therefore, the prime and essential cause of miner's nystagmus."

To Josiah Court of Staveley is due the credit of showing by a series of shrewd observations that posture was not the prime cause or even a leading cause of the disease; the prime cause, he maintained, was bad light. For once the great saying, "a prophet is not without honour save in his own country," has been honoured in the breach thereof, for we recorded recently that the King had bestowed on Dr. Court the

honour of knighthood, and, further, his many writings address, and evidence have been gathered into a small volume recently published.¹ Sir Josiah Court observed in 1891 that nystagmus was common in the fiery mines where the safety lamps must be carried, but rare in safe mines where naked lights were used. "Out of 573 miners using naked lights, only 3 were affected with nystagmus who had *always used candles*. . . . But we find, in strong contrast to this, that out of 524 men using safety lamps, 164 miners were affected, or nearly one-third of them." And again, "There was not a single case of nystagmus in the torch-lamp pits amongst those men who had always used torch lamps." Finally, "The coal is got in the same manner, and holing and undercutting is done in the naked light mines just in the same way as in the collieries worked with safety lamps." Court's observations were confirmed next year by Romée in Belgium, who recorded that there was an increase in the number of cases of nystagmus following the prescription of safety lamps, and later a very large reduction when a powerful electric lamp was used. Since that period there have been some oscillations of opinion, but through all a steady trend in favour of the dominant influence of bad light. Detailed work has been done on the actual conditions of the lighting in the mines, and particularly on the defects of the safety lamp, which gives a dim, diminishing, and remote light, in an unrelieved blackness broken with points of high reflecting power, in a small area bounded by the densest shadows. Attention has also been given to adjunct factors, the greater liability of miners with defective vision as compared with emmetropes, the conducive influences of ill health and of intemperance, and the possibility of a form of chronic poisoning due to the absorption of coal gases. But that the dominant factor is the light, as pointed out by Court, has been convincingly established, so that after a discussion on "miners' nystagmus (neurosis)" at the Oxford Ophthalmological Congress in 1912 a resolution was passed unanimously declaring "that the chief factor in the disease was the deficient light present in the mine," and asking the Government to appoint a Departmental Committee to deal with the question. In the same year an admirable work of research and review was published by Dr. T. Lister Llewellyn, the first Tyndall Research student, whose work was done under the control of the Royal Society through a fund established by Mrs. Tyndall in accordance with the wish of Professor Tyndall, for the purpose of furthering scientific research in "improvements in mining and in the lot of the miners." Dr. Llewellyn's book,² and a later work by Dr. M. Stassen³ of Liège will well repay study.

The solution of the riddle of causation does not conclude the matter. The disease may be prevented by more light, but how to get that light is a problem still unsettled. The orders published under the Coal Mines Act of 1911 show how much ingenuity has been expended in recent years in attempts to secure improved lamps, both flame and electric. The difficulty of the problem may perhaps be realized when we cite some of the tests to which a flame lamp is subjected before it can receive the official approval, without which it cannot be used in the mines. The first test is to drop the lamp from a height of 6 ft. on to a wooden floor five times in succession. In the second a weight of 5 lb. is dropped from a height of

² *Miners' Nystagmus.* By T. Lister Llewellyn. London: The Colliery Guardian Company, 1912.

³ *La fatigue de l'appareil visuel chez les ouvriers mineurs.* Par le Dr. M. Stassen. Liège: Vaillant-Carmanne, 1914-1919.

6 ft. on to the top of the lamp. In the third test the lamp is hung up and a weight of 10 lb. is attached to its lower part by a cord 6 ft. long; the weight is then dropped. This is done thrice; the least sign of yielding to the strain condemns the lamp.

Electric safety lamps give a much better light than the commoner oil lamps. They are more costly and heavier, but it is said that they are slightly more economical in maintenance. But the character of the source of illumination introduces a new complication; the specific intensity of the light is very high, and it emanates from a few millimetres of glowing wire a very small luminous spot compared with the large flame of a candle. The specific intensities of lights of equal candle power are inversely proportional to the area of the source of light, and the comfort to the eyes varies in the same sense. Every town dweller will have appreciated this since the introduction of the "half-watt" glow lamps. To diffuse the glow of the wire by frosted or opalescent glass is not practicable in miners' lamps, for these devices reduce the light from 30 to 60 per cent. Something can be done by placing the lamp between the points of two conical reflectors, as advocated by Llewellyn, for the illumination of the reflectors reduces the relative intensity of the source of light. The desideratum is a true glow lamp, a lamp the whole of whose bulb is glowing with light because the whole of its contents is luminous, like the mercury vapour lamp, only without its ghastly hue. There is room for research here, and we may hope that necessity may mother an invention, and that speedily.

NON-SPECIFIC IMMUNITY.

THE work done by Petersen, Jobling, Cecil, and others in America, and by A. G. Auld and quite recently by A. E. Gow¹ in this country, on protein shock therapy, or the intravenous injection of foreign protein, either as such or in the form of a bacterial emulsion, has shown that the beneficial effect of vaccines is not specific only; thus injection of typhoid vaccine has been found to exert a curative influence on gonococcal arthritis. This rather revolutionary doctrine raises some further questions of interest: Can a vaccine exert a non-specific prophylactic effect and protect against infection by micro-organisms other than those from which it is made? How far does one infective disease protect against another?

The acquired immunity that comes with the advance of years is usually assumed to be mainly due, if not to some previous attack, to gradual immunization from repeated exposures to infection, which have not given rise to clinical manifestations sufficiently definite to attract notice. But whether abortive attacks or repeated autovaccination completely explains the gradual acquirement of immunity may be questioned, and in this connexion attention may be drawn to a suggestive paper by Victor C. Vaughan and G. T. Palmer² on non-specific immunity. Experience of epidemics in military camps in America clearly showed that when men were crowded together those from rural districts were much more susceptible to infections than those from crowded cities. Especially is this true of those infections transferred through the respiratory organs; seasoned soldiers were much more resistant to an infection new to the whole command than recently recruited men. The question therefore arose as to the existence of any scientific evidence in favour of the possibility of the

development of a non-specific bacterial immunity or increased resistance to infection.

Years ago Vaughan and Wheeler found that all true proteins—bacterial, vegetable, and animal—can be split by chemical agents into poisonous and non-poisonous fractions, the poisonous being specific for each protein, whereas the non-poisonous is common to all proteins. Experimentally the late V. C. Vaughan, junior, demonstrated that the poisonous fraction, or "protein poison," establishes a non-specific tolerance for other proteins, and that no antibodies are formed, and further, that repeated introduction of the protein poison into the body produces a non-specific bacterial immunity which is of low grade and is not comparable with that attainable in toxic immunity. Vaughan and Palmer believe that men long resident in crowded cities and frequently inhaling particulate proteins (bacteria), whether pathogenic or non-pathogenic, acquire a non-specific immunity which helps them to withstand infection. This form of immunity, though it does not prevent infection with a newly imported virus, mitigates the effect—sometimes to so great an extent that no symptoms are obvious. In this manner a non-specific immunity may, it is suggested, enable a specific immunity to be developed against a virulent infection. Thus it makes a great deal of difference whether a susceptible recruit is at once exposed to the risk of infection of, say, measles, or whether contact is delayed until he has been for months in a crowded camp, inhaling daily more or less foreign protein from which, after absorption, protein poison is liberated and causes a non-specific immunity. The new recruit is thus transformed into a seasoned soldier, but in this transformation he does not acquire a specific immunity to measles, and if exposed becomes infected as readily as the recruit, though the effects are mitigated by his increased tolerance. A similar explanation is given for the well-known fact that seasoned soldiers bear influenza and pneumonia better than recruits.

It is interesting to note the report by Walter Reed, E. O. Shakespeare, and V. C. Vaughan on enteric fever among the American troops during the Spanish-American war (1898) showed that, contrary to general belief, temporary gastro-intestinal disturbance, far from disposing to the onset of enteric fever, conferred a certain degree of immunity against subsequent infection with this disease. We may recall also that during the recent pandemic of influenza in this country some observers spoke of the existence of a "protective catarrh."

CLINICAL TEACHING "ELEMENTS" AT WORK.

THE reconstruction of the teaching organization at St. Bartholomew's Hospital is making steady progress. The Medical Element is now complete; the director is Sir Archibald Garrod, K.C.M.G., the assistant director is Dr. F. R. Fraser, and the chief assistants are Dr. A. E. Gow and Dr. George Graham. Dr. Francis Fraser, who was recently consulting physician, at Cologne, to the Army of Occupation, took up his new duties at St. Bartholomew's on February 1st. He is a son of the late Sir Thomas Fraser, was educated at the Universities of Cambridge and Edinburgh, and has held the posts of assistant physician to the Presbyterian Hospital, New York, instructor in clinical medicine at the Columbia University, and assistant resident physician to the Rockefeller Institute for Medical Research. The organization of the Surgical Element has not proceeded quite so far. The director, Mr. G. E. Gask, C.M.G., D.S.O., is only now recovering from a recent illness, and the post of assistant director has just been

¹ A. E. Gow: *Quart. Journ. Med.*, Oxford, 1919-20, xiii, 82-104.

² V. C. Vaughan and G. T. Palmer: *The Military Surgeon*. Washington, D.C., 1920, xlv, 1-8.

filled by the appointment of Mr. T. P. Dunhill, M.D., B.S.Melb., Surgeon to St. Vincent's Hospital, Melbourne, who will take up his duties at St. Bartholomew's in May next; during the war he acted as Consulting Surgeon to the British Forces in France. The chief assistants are Mr. R. Ogier Ward, D.S.O., M.C., and Mr. G. L. Keynes. Each of the two elements takes its share in the ordinary duties of the hospital, working as a single "firm," but provided with special facilities for observation and research. Each has clinical laboratories of its own for pathological investigation and routine work. The two teaching elements already formed are thus not isolated from the medical and surgical work of the hospital in general, but being so to speak "opposite numbers" there is specially free daily communication between them. We have announced certain appointments in connexion with the reconstruction of the pathological department, of which Professor F. W. Andrewes, F.R.S., remains the head. Dr. M. H. Gordon, C.M.G., is now bacteriologist and lecturer on bacteriology; Dr. B. H. Spilsbury is lecturer on morbid anatomy and histology, superintending all *post-mortem* examinations; and Dr. R. L. Mackenzie Wallis is chemical pathologist and lecturer on chemical pathology. Three senior demonstrators have been appointed as whole-time pathologists; there are in addition three demonstrators who are not whole-time pathologists, but will be eligible for posts as chief assistants in one or other of the clinical elements. It is proposed that all the chief assistants in future shall come through the pathological department, since one of their functions within the Elements will be to superintend the pathological work of the students. The object of these various changes is to make pathology more essentially a part of the clinical teaching.

PROPOSED SANATORIUM FOR MERCHANT SEAMEN.

LORD INCHEAPE, immediately before his departure for India at the end of January, issued an appeal for funds with which to equip and endow a much needed sanatorium which is to be conducted by the Seamen's Hospital Society. The existing sanatoriums are of insufficient capacity to meet the general public demands made, and presently to be made, upon their resources; and, although the percentage of cases among seamen is not abnormal, the circumstances of the sailor's calling render it difficult for him to await his turn on the long list of those seeking admission. Thus, the temptation of the tuberculous sailor is to put to sea again with the disease still active; but the conditions of his life afloat tend to aggravate his own condition and to make him, at the same time, a special source of danger to his shipmates. It is felt, therefore, that in no way can the merchant seamen's courage and devotion to duty, so manifest during the war, be more usefully recognized than by providing for the immediate treatment of such as may be attacked by tuberculosis. An initial grant has been allocated by King George's Fund towards the purchase, for such uses, of Bramshott Place, Hampshire. The chosen site has been approved by the Ministry of Health and provides the essentials of good air, suitable soil, sufficient immediate accommodation and ample space for extension. For the establishment of the sanatorium a sum of £70,000 is needed; £1,000 will suffice to endow a bed. The P. and O. Company and its associates have promised £10,000 and Messrs. Furness, Withy and Company, £2,500. The Seamen's Hospital Society is a very great institution of which the country may be proud, and support of its many activities affords the most practical way of proving our gratitude to the sailors whose courage, skill, and endurance make the life of these islands possible. The Society was founded in 1821, and was incorporated by Act of Parliament passed in the third year of the sailor King, William IV. It at first had the *Dreadnought* hulk in the river, but a hospital was established ashore in 1870. It now possesses the *Dreadnought* Hospital at Greenwich, which

has 345 beds, the Albert Dock Hospital, with 50 beds (at which until the recent move the London School of Tropical School Medicine was established), and the London Schools of Tropical Medicine and Tropical Hospital now opened at Endsleigh Gardens, where there are both beds for patients and well equipped laboratories for research and instruction. It also possesses the Angus Convalescent Home at Cudham, with 30 beds, and maintains dispensaries at the East and West India Docks and at Gravesend. A sanatorium will add one more necessary appliance to its equipment, and with no more competent body could its administration be placed. In Lord Incheape's absence, communications on the subject may be addressed to Commander Hodgkinson, R.N., at 122, Leadenhall Street, London, E.C.3.

FEDERATIONS OF BRAIN WORKERS.

IN the discussions on the better adjustment of the relations between employers and employed which have occupied so much space in the public press during the last year or so attention has been almost exclusively directed to the relations of industrial employers and manual workers. The interests of other classes of persons whose work is essential to industry have been almost ignored, although the Labour Party has declared its willingness to accept recruits from among brain workers. At the industrial conference summoned by the Prime Minister last April employers' associations and trade unions considered a proposal for a joint industrial council, and the Society of Technical Engineers at this conference moved an instruction to the council, when it should come into existence, to consider the position of unions composed exclusively of members of technical, management, and administrative grades, and to determine how such unions should be represented on the council. The industrial council has not yet come into existence, but meanwhile the Labour Research Department has been making inquiries into the position of professional classes in relation to the Labour movement, and at a meeting in London on February 7th a National Federation of Professional, Technical, Administrative, and Supervisory Workers was formed. The bodies represented at this conference included the Civil Servants Union, the Association of Local Government Board Officers, the National Union of Clerks, the National Federation of Law Clerks, the National Union of Journalists, representatives of scientific, technical, engineering, and chemical workers, together with the Actors' Association and the National Orchestral Association. A representative of the Labour Research Department said that it was not proposed that the Federation should affiliate with the Labour Party or the Trade Union Congress. Among the professions invited to join the new Federation medicine and the law are not included. It appears, however, that for some months past certain technical and scientific professional workers have been taking steps to form themselves into a confederation, and that representatives of these bodies and several others, after full discussion, have prepared a memorandum proposing that the various societies concerned should be formed into an industrial group, a financial group, a group for the public services, and a group for the other professions. Each group would form a federation, and the four would be combined into a confederation for which draft rules are being prepared. The General Secretary of the Society of Technical Engineers last week published a long letter on the subject in *The Times*, in the course of which he observed that the assumption that a salaried official must ally himself either with the employers or with the work-people ought not to be accepted without further investigation. The position of medicine and the law are similar to each other and differ fundamentally from that of the intellectual workers represented by such bodies as the Society of Technical Engineers. The medical profession will be disposed to watch with sympathetic interest the

movement for a federation of scientific and technical workers; but until their plans are more fully known it will be premature to say that medicine should have any direct concern.

THE AEROPLANE IN MEDICAL INVESTIGATION.

The enterprise of *The Times* and Lord Northcliffe in sending an aerial expedition to make the journey from Cairo to the Cape will serve a useful purpose by calling public attention to the possibilities of the aeroplane as a means of scientific investigation. Dr. Chalmers Mitchell, F.R.S., secretary of the Zoological Society, who is the scientific member of the party, will be chiefly concerned with the geological, geographical, and zoological observations, and it may be anticipated that this and future expeditions will make important contributions to these sciences. While fully recognizing this, we are disposed to think that the new method will be of particular value in medical investigation and administration. Probably medical investigation will be most efficiently advanced not by organizing flying laboratories, but by using flying machines to carry investigators to the spot. In the investigation of tropical diseases a stage always comes when laboratory inquiries in this country reach their limit, and it becomes necessary to test hypotheses by inquiry in the tropics. At the present time the organization of a scientific expedition is costly in time and money. It may take the investigator three or four months to get to the place, and as much to return. The actual investigation may only take a few weeks, but the investigator is absent for perhaps five or six months, during the greater part of which he is travelling and doing no scientific work. This involves a great waste of energy. The working life of a student of tropical medicine might be greatly lengthened if he could be transported to, say, the centre of Africa in three or four days instead of three or four months. The result of the expedition now in progress will, we trust, be to show that this hope can be realized. Several correspondents of our contemporary have called attention to the use of the aeroplane for the rapid transport of the doctor to give early treatment to a sick or injured man who could be brought by a relatively short journey to an aerodrome. A short time ago, with the aid of Professor Tuffier of Paris, we were able to publish an account of the work of this kind already being done by the French Army Medical Service in the hinterland of Algiers and Tangier and further into the Sahara itself. The arrangements are still in their infancy, but enough has been done to prove that a very valuable system can be established. Another use which it has been suggested might be made of an aeroplane service to the tropics is to bring home, or to a convenient port, colonial officers who are going on sick leave, or, indeed, ordinary leave. As it is they must spend months in slow travel before reaching a port or railhead, and the total cost in money and time to the colonial services must be very great. The matter is one which seems to deserve the attention of the Colonial Office.

OPTICAL INSTRUMENTS.

We have received a letter from Lieut.-Colonel W. D. Sutherland, M.D., I.M.S., stating that he has recently had an unsatisfactory experience with a hand spectroscope sent to him in Calcutta from this country. Many years ago he obtained from the firm of Carl Zeiss some hand spectroscopes on the Browning model, furnished with a wave-length scale which was most admirably adjusted and enabled the absorption bands seen in the spectrum of the object examined to be read off at once. These instruments having been stolen he obtained some of British manufacture, to which, he states, the old and unscientific, because purely arbitrary, scale was fixed. By dint of great pains he has managed to construct a wave-length curve to coincide with the old scale; but even so reference

must be made to the curve at each observation, which causes loss of time. He asks whether it is not possible for British manufacturers of spectroscopes to take a leaf out of the book of Zeiss and make modern instruments. Colonel Sutherland seems to have been unfortunate as regards a certain wave-length scale, but in his condemnation of British makers of spectroscopes generally, on the strength of this, he goes too far. If any defect of principle is found in spectroscopes, or indeed in any other scientific instrument, complaint should be addressed to the British Scientific Research Association, 26, Russell Square, London, W.C.1, which exists to promote the development of scientific instrument manufacture, and is already doing good work. It is, of course, difficult to make substantial advances quickly or to change old ideas as regards the superiority of German goods over British; but as a matter of fact we believe the finest spectroscope work is produced by a London firm. It is no doubt true that in many directions British instrument makers have much leeway to make up, but they have taken the right course in establishing the association of which we have given the address. We may take this opportunity of adding that new facilities have recently been provided at the National Physical Laboratory, Teddington, in the Metrology Department, for the testing of volumetric scientific glassware. In a circular issued by the laboratory it is stated that the manufacture of such ware was an industry practically non-existent in this country before the war. It was largely developed during the war, but in order that its position may be consolidated it is supremely important that the accuracy of graduated apparatus made in this country should be thoroughly reliable. The National Physical Laboratory began the work of graduating volumetric glassware fifteen years ago. Its scope has now been widened; a new building, especially equipped for dealing with this class of work on a large scale, has just been completed at the laboratory. In its apparatus is tested; when the tests are required to ensure the highest accuracy for scientific purposes a Class A certificate is granted; a Class B certificate is issued for vessels adapted to ordinary commercial purposes. Full particulars are given in a pamphlet which can be obtained free on application to the Director, the National Physical Laboratory, Teddington, Middlesex. The laboratory has a special mark for Class A and Class B tests of volumetric apparatus, and the combination of this laboratory monogram and the date of the test are etched on all vessels which comply with the regulations. In special cases in which minute accuracy is necessary, corrections to be applied to the apparatus are supplied. The work long done by the laboratory in testing thermometers is well known, and we have no doubt that it will be ready to extend its operations in other directions in order to control the graduation of optical and other glass apparatus as the demand arises. The scientific control of the institution is exercised by the President and Council of the Royal Society, and its property is vested in the Imperial Trust for the Encouragement of Industry under the Privy Council.

SALARIES OF MEDICAL OFFICERS OF LOCAL AUTHORITIES.

In consequence of the increased cost of living and other abnormal conditions due to the war, many temporary increases in the salaries of medical officers to local authorities have been made in various parts of the country, and, as might be expected, the standard of increase has varied a great deal locally. As a rule, medical men have benefited under a claim put forward by one of the general associations of local government employees, or by an association representing the whole staff—preponderantly a lay staff—of an individual authority. In a circular dated January 12th, 1920, the Ministry of Health authorizes the payment by local authorities of salaries increased according to the scale

of Award No. 101 of the Civil Service Arbitration Board; the authorities are empowered also to adopt any further increase which the Arbitration Board may grant. The effect of Award No. 101, so far as it applies to medical men, is to increase the original salary by 30 per cent., with a further addition of £60, irrespective of the amount of salary; thus, in round numbers, salaries of £400 and £500 become respectively £580 and £710. The total bonus must not exceed £500 per annum. In the case of part-time medical officers the award has usually been on a *pro rata* basis. The position of resident officers, as defined in the circular, will be of interest to many medical men; recent arbitrations, it is said, have decided that in such cases the rate of increase should be one-half that payable in the case of non-resident appointments, but the actual amount of remuneration upon which the increase is thus made is to be calculated by adding to the figure representing the salary paid in cash the estimated value of all the emoluments.

ACUTE LEUKAEMIA.

In an article on acute leukaemia,¹ extending over 250 large pages, Dr. O. Lindbom states that about 300 cases of the disease have been published, and adds 20 more observed by himself. He considers that all the white cells of the blood may be derived from the fetal mesenchymatous cell called lymphoidocyte by Pappenheim, myeloblast by Naegeli; as is notorious, the terminology employed in describing the embryological development of the blood and the various forms of blood cells is very complicated, and is rendered more difficult by the fact that different writers use the same term in different senses. It may be said that acute leukaemia is not in fact a rare disease; it may occur at any age, from birth to over 70; over two-thirds of the patients are males. The blood-picture is very variable; two main types are described—the lymphatic and the myeloid, but some cases show leucopenia throughout, others are frankly cases also described as chloroma, and it must be added that the blood-picture varies widely from week to week in many of the patients. Instances transitional between the above four main groups are often found; Dr. Lindbom concludes that the name "leukaemia" should be dropped owing to the heterogeneity of the cases included under it. The number of the blood-platelets is strikingly low in most cases of leukaemia; the white cells often show inclusions of various sorts—short rods and larger or smaller rounded masses, with different staining reactions, sometimes described as intracellular parasites; Dr. Lindbom interprets the rods as plasmatic structure, the masses as toxic-degenerative products identical with some of Doehle's cell-inclusions. Pathologically the cases often show haemorrhages into the skin and mucous membranes and into the various organs; indeed, many cases recorded as instances of the haemorrhagic diathesis have probably been cases of acute leukaemia; the bone marrow is red and diffuent, the spleen and often the lymphatic glands are much enlarged, and the thoracic and abdominal viscera exhibit leukaemic infiltration—particularly with tissue mast-cells that appear to differ from the mast-cells of the blood by giving no oxidase reaction by Schultze's original method. Histologically it is not possible always to classify cases of acute leukaemia as either myeloid or lymphatic, as transitional cases are not rare. Dr. Lindbom is unable to regard acute leukaemia as a malignant tumour of the blood, and considers Sternberg's lymphosarcomatosis merely one form of acute leukaemia—that is, he regards it much as he does chloroma. In many ways it resembles an acute infection, or septicaemia; but no specific virus has been found, and the disease is not transmissible experimentally. Yet, again, bacteria have sometimes been found in the blood, mostly secondary infections, and Dr. Lindbom finds it hard to believe that an infection of the blood is not the primary

cause of acute leukaemia. Finally, no hard and fast line can be drawn between acute leukaemia and some cases of chronic leukaemia or some cases of septicaemia with leucopenia. Other examples of acute leukaemia that often escape correct diagnosis are instances of ulceration and necrosis in the mouth and tonsils with subcutaneous haemorrhages; the diagnosis of purpura often made would be corrected by examination of the blood. Dr. Lindbom confirms the view that the prognosis is absolutely bad in acute leukaemia; the duration was from nine days to three months in eighteen of his cases, averaging six weeks, and in the other two an acute leukaemia was the terminal event of a chronic myeloid leukaemia. The treatment is, at present, purely symptomatic. Numerous references to the literature are given, and there is a coloured plate showing various forms of cell-inclusions in leucocytes.

A HYPOTHESIS AS TO THE ORGANIC BASIS OF FUNCTIONAL NERVOUS DISEASE.

In 1917 Dr. D. W. Carmalt Jones,¹ recently appointed Professor of Medicine in the University of Otago, New Zealand, wrote, while in charge of the medical division of No. 4 Stationary Hospital in France and unable to see current or standard medical literature, a paper based on the analysis of 1,300 acute or chronic cases of war neurasthenia, which is attractive both for its independence and its personal touches. In this "plain clinical study made by a general physician, with sufficient experience in disease of the nervous system to be able to make an accurate diagnosis between organic and functional conditions" of the nervous system, war neurasthenia is described as a physical disorder with symptoms affecting most of the chief systems, and the opinion is expressed that the emphasis usually laid on the psychical side of war neurasthenia sometimes entails neglect of the physical. We do not propose to follow Professor Carmalt Jones's analysis of the cases, but it may be of interest, in connexion with the experimental work of W. B. Cannon, Crile and others, and Laignel-Lavastine's recent monograph on "The Internal Secretions and the Nervous System," to refer to the hypothesis as to the organic basis of functional disorder which he very modestly puts forward. In considering the difference between a man's nervous system before and after he has developed neurasthenia, and assuming the absence of any gross change, such as punctate cerebral haemorrhages, the only physiological fact bearing on the subject that struck him was the presence in the blood of an animal under the influence of fear of an excess of sugar destined to supply the muscles with energy, and ascribed to increased secretion of adrenalin under the stimulation of the sympathetic. The same number of *Brain*, it may be pointed out, contains an elaborate paper by Kooy on "Hyperglycaemia in Mental Disorders," and embodies the same thesis. Inspired by a conversation with Major Crile, though he does not wish to father him with responsibility, Professor Carmalt Jones argues that a soldier when exposed to danger has to suppress his instincts, though his ductless glands are stimulated to over-activity, and to act in accordance with discipline and reason; and that in war neurasthenia, the exhaustion, fatigue, loss of control, and visceral disturbance are due either to exhaustion of, or intoxication with, the products of the ductless glands which have been constantly stimulated but whose products have not been properly metabolized by the actions they were intended to facilitate. In support of the thesis that the symptoms of war neurasthenia which are described in his paper, such as dilated pupils, sweating and salivation, tachycardia, the frequency of both constipation and diarrhoea, and the remarkable variations between polyuria and suppression, are referable to either over-stimulation or exhaustion of the ductless glands, especially the adrenals, appeal is made to Starling's statement that the injection of adrenalin arouses every activity normally excited by stimulation of the

¹ *Svenska Läkarsällskapets Handlingar*, Stockholm, 1919, xiv, 83.

² *Brain*, London, 1919, xlii, 171-213.

sympathetic, namely, vaso-constriction, dilatation of the pupils, increased secretion of sweat and saliva, rapid pulse, vaso-constriction of the kidneys and intestine, vaso-dilatation of the same, inhibition of the intestines, contraction of the ileo-colic sphincter, and inhibition of the bladder.

THE FIRST SUPERINTENDENT OF THE JOHNS HOPKINS HOSPITAL.

FROM August, 1889, when the Johns Hopkins Hospital opened with that brilliant quartette of teachers—Sir William Osler, Dr. W. H. Welch, Dr. W. S. Halstead, and Dr. Howard A. Kelly—none of whom were more than forty years of age, until May, 1911, Dr. H. M. Hurd was responsible for the organization and smooth running of this model institution. He was born in 1843, and when called to Johns Hopkins had for eleven years been engaged in organizing and superintending the Eastern Michigan Asylum, which had become one of the most progressive in the country. While busy with the initial organization of the Johns Hopkins Hospital, he helped to found the *Hospital Reports* and the *Monthly Bulletin*. He edited both of these periodicals, which became extremely well known among all English-speaking physicians and surgeons. It is therefore most appropriate that the December issue of the *Bulletin*¹ should be entirely devoted to an account of his numerous activities and striking characteristics, from the kindly pen of Dr. T. S. Cullen, who so recently contributed an appreciation of his former chief, Professor Howard A. Kelly.² Like other biographers in the past, he finds his admiration is much increased by the necessary investigations for his tribute; Dr. Hurd always appeared to be an indefatigable worker, but it is only now that the tremendous amount he had accomplished and his share in the phenomenal success of the hospital have been clear. In addition to being the best known hospital superintendent in the United States, he was and still is an active writer, mainly on psychiatry, hospital management, medical education, the education of nurses, and on medical history. When, at the age of 68, he resigned the superintendency he became Secretary of the Board of Trustees of the hospital, and is now engaged in writing the history of the hospital. The tribute contains a series of photographs from the age of 6 years, which were obtained surreptitiously, and therefore will surprise no one more than Dr. Hurd himself, and a bibliography of his 131 publications. The Henry M. Hurd Library, built by his friend George K. McGaw, will keep the memory of the hospital's first superintendent for ever green.

BLIND MASSEURS.

AN Association of Certificated Blind Masseurs was registered last summer, and licensed under the Board of Trade. Its objects are to promote the welfare and protect and advance the interests of all certificated and qualified masseurs and masseuses who are too blind to perform work for which eyesight is essential; to assist and secure the recognition and status of such blind masseurs in their work; to provide for them any assistance or advantage calculated to help them to work on terms of equality with sighted masseurs; to promote co-operation in all matters relating to massage and physical culture between the blind and sighted persons; and to advocate and extend the general employment of massage and other physical methods or exercises. To be eligible for membership of the association, a blind masseur must hold the certificate of the Incorporated Society of Trained Masseuses, or a certificate as may be prescribed by the Executive Council. The President is Sir Arthur Pearson, Bt., G.B.E., and amongst the Vice-Presidents are Sir Alfred Fripp, K.C.V.O., Sir Robert Jones, K.B.E., Sir Alfred Pearce Gould, K.C.V.O., Sir B. Bruce Porter, K.B.E., Dr. Risien Russell, and Major

W. H. Broad. The office of the association is at 224-6-8 Great Portland Street, London, W., where application for masseurs may be made to the Secretary.

INFLUENZA.

THE number of deaths from influenza last week in the ninety-six great towns of England and Wales was 98; of these 20 occurred in London. The London figure is lower than that several times recorded during the past four months, but the figure for the great towns as a whole is rather larger than any so far recorded this winter. The numbers of deaths from influenza, given in the weekly returns of the Registrar-General for the ninety-six great towns from October 18th, 1919, to February 7th, 1920, are as follows: 57, 71, 71, 56, 74, 79, 63, 77, 81, 64, 43, 52, 73, 62, 85, 66, 98. Influenza of a relatively mild type with low mortality seems to be spreading through the United States of America. We learn from the *Journal of the American Medical Association* that in Chicago, for example, a thousand new cases a day were being reported about a fortnight ago. Up to January 20th, 4,059 cases had occurred in that city, with 33 deaths; and 891 cases of pneumonia, with 159 deaths. The hospitals were so overcrowded that all operations save those of emergency had to be put off. The Health Commissioner of Illinois has appointed a commission of pathologists to act with the Department of Health in this emergency. The members are Drs. Hektoen, Zeit, Wilson, Kendall, Davis, Jordan, Evans, and Drake.

DINNER TO SIR GEORGE MAKINS.

IT is proposed to give a complimentary dinner to Sir G. H. Makins, G.C.M.G., P.R.C.S., some time in May of this year. Sir Cuthbert Wallace will be in the chair. St. Thomas's men, or any medical officers associated with Sir George Makins in the British Expeditionary Force, who would like to be present are asked to communicate with Mr. C. Max Page, 134, Harley Street, W.1. Final arrangements can then be made, of which due notice will be given.

WE regret to learn of the death, at Ottawa, of Sir James Alexander Grant, K.C.M.G., M.D., F.R.C.P.Lond., formerly President of the Medical Council of Ontario, and one of the small number of honorary members of the British Medical Association.

Medical Notes in Parliament.

King's Speech.

IN the early part of the speech delivered from the throne when the King opened Parliament in state on February 10th it was stated that in order to secure the full blessings of peace and prosperity to Europe it was essential that not only peace but normal conditions of economic life should be restored in Eastern Europe and in Russia. So long as these vast regions withhold their full contribution to the stock of commodities available for general consumption, the cost of living can hardly be reduced nor general prosperity restored to the world. The belief was expressed that this country and the empire were making rapid strides towards stability and prosperity; though the price of foodstuffs and other necessary commodities was causing anxiety to all the peoples, the prices in these islands were appreciably lower than they were elsewhere. The legislation foreshadowed in the speech in addition to finance includes measures for Ireland, for the coal industry, and for agriculture. It was also stated that bills would be introduced for peace time regulation of the sale and supply of alcoholic liquor, for the after-war organization of the regular and territorial armies and the navigation of the air, for the extension of insurance against unemployment hitherto confined to a few, for the regulation of hours of employment and the establishment of a minimum rate of wage, and for the necessary amendment of the Insurance Acts.

New South Wales.

ROLL OF HONOUR, UNIVERSITY OF SYDNEY.

APPROXIMATELY SOME 1,800 graduates and undergraduates of the University of Sydney enlisted in the Great War. Of this number some 204 made the supreme sacrifice, and their names have been inscribed on an honour roll which was recently unveiled by the Chancellor. The memorial has been placed in the corridor of the Fisher Library, but the main part of the ceremony of unveiling took place in the Great Hall of the University. The Chancellor, Vice-Chancellor, and members of the Senate occupied the dais. After the Registrar and Warden had read out the names of the fallen the organist played Chopin's Funeral March, the audience remaining standing. In the course of an eloquent address the Chancellor said:

To all those gallant men we do homage. To the sons of this University who fell we specially dedicate this ceremony. Those whom we would have gladly welcomed back to their places have reached a loftier place in our associations. The fallen have given all that men can give. The lustre of their renown would never be dimmed. They would remain glorious for ever.

Professor J. T. Wilson, F.R.S., Chairman of the Professorial Board, in the course of his address, said:

It is to you, young men, to whom the duty of developing that heritage rests. Do not delude yourselves with the idea that danger does not threaten us. What has been won by almost superhuman sacrifice can only be retained by the exercise of the spirit which won it.

Mr. Schofield, President of the Undergraduates' Association and himself a returned soldier, added:

The undergraduates of the University are determined that the memorial to those who have fallen shall be in the shape of a magnificent university—one of the greatest in the world. This Sydney University of ours is worth fighting for. We realize what these gallant men have done for us when they laid down their lives for us.

The National Anthem concluded the proceedings in the Great Hall, and afterwards Sir William Cullen, the Chancellor, performed the ceremony of unveiling the tablet in the Fisher Library.

On a subsequent afternoon the Chancellor and Senate of the University gave a garden party in honour of the returned university soldiers, of whom about 100 were present. The guests were allowed to inspect the various departments of the university, and special interest was taken in the roll of honour. An organ recital was given in the Great Hall, a one-act play called *The Wheel Heaver* was produced by the University Dramatic Society, and Professor David, F.R.S., Professor of Geology, gave a short lecture on the Western front and military geology, which was illustrated by lantern slides. Refreshments were served in the Cloisters and in the Great Hall.

The Senate of the University has announced that a prize of the value of £10 open to graduates and undergraduates and to returned officers and non-commissioned officers who have had experience of flying, will be given for the best essay or thesis on some phase of aeronautics. The special subject is "The commercial possibilities of aviation in Australia." Competitive papers must be sent to the Registrar by March 8th, 1920. The prize, which is to be known as the Geoffrey Sulman Memorial Prize for Aeronautics, represents the interest on the balance of pay due to Second Lieutenant Sulman at the time of his death while serving in the R.F.C.

ALIEN ENEMY PRACTITIONERS.

At an extraordinary meeting of the New South Wales Branch of the British Medical Association, held recently, the following resolutions were proposed by Dr. Scot Skirving and seconded by Dr. F. Guy Griffiths:

1. That the New South Wales Branch of the British Medical Association protests against those medical practitioners who were interned during the war, as alien enemy subjects or otherwise dangerous to the community, being allowed to resume practice.
2. That the New South Wales Medical Board be asked to take steps for the removal from the *Medical Register* of (a) persons registered in virtue of German or Austrian qualifications not resident or practising in New South Wales, and (b) persons registered who have been interned as alien enemy subjects or otherwise.

3. That the Federal Government be asked to deport those medical practitioners who were interned during the war as being alien subjects or otherwise dangerous to the community.

4. That the Federal Government be advised that claims understood to have been made on behalf of one or more of the medical practitioners who were interned during the war that they possessed certain special knowledge essential to the wellbeing of the community which would be lost by their deportation are not based on any known facts, and that any special knowledge or alertness that they may have had is possessed, perhaps in greater degree, by many practitioners in different parts of the Commonwealth.

After a considerable amount of discussion in which the spirit of these resolutions was strongly supported, the motion was put and carried unanimously.

England and Wales.

NURSING ORGANIZATION IN WALES.

THE scheme drafted by the "Priority for Wales of the Order of St. John" to co-ordinate nursing organizations in Wales and Monmouthshire and to improve facilities for training in nursing seems for the present at least to have come to nothing. It was proposed to establish a Welsh National Committee for Nursing, containing representatives of various nursing associations in Wales, of the Welsh National Memorial Association, and other bodies, as well as of the medical profession and medical officers of health. The committee, it was proposed, should discuss and recommend general lines of policy, establish training hostels or other institutions, and take steps to provide an adequate midwifery service, which is considered to be a matter of urgency. A conference which was held last October was not well attended and appears to have arrived at no definite conclusions. Another conference was held in Cardiff on February 6th, and again the attendance was poor. It would appear that the nursing associations are hanging back and an explanation may, perhaps, be found in the resolution adopted at the conference last week, to the effect that consideration of the scheme should be deferred until the British Red Cross Society and the Order of St. John had been amalgamated and until the intention of the Ministry of Health as to the training of nurses is made known. It was announced some time ago that the British Red Cross Society and the Order of St. John in England had appointed a joint peace council, and had arranged that neither should make an independent appeal for funds, but act in this respect through the joint council. It was hoped that the formation of the joint council would mean in practice so close a combination in action as almost to amount to amalgamation.

MANCHESTER ROYAL INFIRMARY.

The annual report of the Manchester Royal Infirmary states that early in October, 1914, it provided 250 beds for wounded soldiers. They were immediately occupied, and the accommodation was extended as necessity arose, until 520 out of a total of 884 were reserved for military cases. The reception of soldiers continued until the early summer of 1919, and the last of these patients were transferred to various military dispersal hospitals on August 21st, 1919. During this period 10,077 soldiers were admitted, 8,197 of whom were surgical cases, and 1,880 medical. The number of operations performed was 3,958. The personnel of the Manchester Royal Infirmary was largely drawn upon for war service. With very few exceptions its medical and surgical officers took commissions in the army or navy; the nursing staff provided senior officers for various hospitals as well as many individual nurses, whilst the lay staff joined up almost without exception. The board place on record their appreciation of the fact that notwithstanding the depleted staff, and the pressure caused by the influx of military patients, the work in connexion with the civilian patients was carried on with the same regularity as in times of peace. Special thanks are given to Mr. F. A. Southam, F.R.C.S., senior honorary consultant surgeon, who returned to duty at the request of the Board in 1914, and continued to serve the hospital until the present time, when the return of the honorary staff has made it no longer necessary to trespass on

his good-nature. Reference is made to the honours (K.B.E., C.B., C.M.G.) conferred on Colonel Sir William Thorburn, senior honorary surgeon. The infirmary, the report affirms, owes him a debt of gratitude for his invaluable services in connexion with the planning and erection of the institution on its present site. Note is also made of the honour of C.B.E. conferred on Miss M. E. Sparslott, who acted as principal matron, Territorial Force Nursing Service, East Lancashire, and organized and administered the nursing service of the 2nd Western General Hospital, comprising thirty-two branch hospitals, with a complement of 703 nurses. A gift of £4,000 by Sir James E. Jones of Rochdale to endow demonstrations to medical practitioners on diseases of the ear, in memory of his son, is noted with gratitude: as we have already announced, the first course of demonstrations began early this year. Under an arrangement with the Ministry of Pensions the Board will continue to receive pensioners; the number of beds set aside for this purpose is now 122. Altogether the board is responsible for 1,244 beds for various purposes, of which 623 are in the Royal Infirmary, 55 in the Central Branch, 136 in the Barnes Convalescent Home, and 430 in the Royal Lunatic Hospital and its branches.

MANCHESTER MEDICAL SOCIETY.

Professor R. B. Wild, on February 4th, gave the presidential address to the Manchester Medical Society on "Some racial problems, social evils and modern crusades." The racial problems as to the falling birth rate and its accentuation by the war, eugenics, and the care of the feeble-minded, were briefly discussed. The effects of tuberculous, cancer, gonorrhoea and venereal diseases upon the race as opposed to their effects upon the individual, were considered. Finally, the prevalence of certain drug addictions (including alcohol, caffeine and nicotine), their causes and results as regards both the race and the individual, were compared and reviewed.

Ireland.

NATIONAL UNIVERSITY OF IRELAND ROLL OF HONOUR.

We have received from the Registrar of the National University of Ireland a bound copy of the war list and roll of honour, giving the names of the past and present students and members of the staff who served during the war, arranged under the three constituent colleges of the university. Of the members of University College, Dublin, forty-three were killed in action or died on active service, and many received military distinctions; the war list includes students of the Medical School, Cecilia Street. Of the old students of University College, Cork, who served, twenty-five lost their lives. From University College, Galway, twelve lost their lives, and one more is entered as "wounded and missing." The university roll of honour contains a considerable number of names of distinguished naval and military officers.

MEDICAL ATTENDANCE ON THE ROYAL IRISH CONSTABULARY.

Arising out of correspondence, which has extended over a considerable time, between the Irish Committee of the British Medical Association and the police authorities, in regard to remuneration for medical attendance on members of the force, the Deputy Inspector-General has informed the Irish Medical Secretary: "That His Majesty's Treasury have approved, from a date to be fixed shortly, of a recommendation made by the Irish Police Pay Committee relieving medical attendants from the duty of attending on the wives and children of the force, the present remuneration, however, being continued." The capitation fee allowed for medical attendance (including the supply of drugs and appliances) on members of the Royal Irish Constabulary is £1 4s. per annum.

POSTAL ARRANGEMENTS IN DUBLIN.

Much objection is taken by business and professional men to the new rules of the Post Office with regard to the posting and delivery of letters in the city of Dublin. Morning letters are held over three or four hours before

delivery, and the outgoing mail is collected four hours before sailing from Kingstown. The midnight collection of letters has been abolished, with the result that Dublin doctors when settling urgent appointments with their patients, even in parts of the county in the neighbourhood of Dublin, must now use the telegraph in making arrangements which were hitherto as expeditiously and more satisfactorily carried on through the ordinary post. Sir L. W. Ormsby, M.D., in a letter to the press states that last week the morning deliveries were apparently not made until 9 a.m., and the English post was not delivered until the afternoon, whereas formerly the Irish letters were delivered at 8 a.m. and the English letters at 9 a.m.

POOR LAW MEDICAL OFFICERS' SALARIES.

The following improved scales of salaries have been made recently by boards of guardians:

Cashel (co. Tipperary). An initial salary of £300, reaching a maximal salary of £400 by triennial increments of £10.

Birr (King's County). An initial salary of £250, reaching a maximal salary of £350 by annual increments of £7 10s.

Ennis (co. Clare). An initial salary of £250, with annual increments until a maximal salary of £350 is attained. The scales in Birr and Ennis are retrospectively applied.

The old scales varied from £150 to £200 per annum. Dr. Hennessy, Irish Medical Secretary, attended the meetings of these three boards and stated the case of the Poor Law medical officers.

Scotland.

CLINICAL MEETING OF THE EDINBURGH BRANCH.

The winter clinical meeting of the Edinburgh Branch of the British Medical Association will be held in the Royal Infirmary, on Friday, February 27th. The Museum will be open from 11 a.m. Arrangements will be made for holding special clinics during the forenoon. The clinical meeting will be held at 3.15 p.m. At 5 p.m. Dr. Alexander Blackhall-Morison, London, will deliver a lecture on "The Passive Mechanical Factor in Heart Disease: Its Influence and Management." All members of the profession are cordially invited. Those who have patients or specimens to show are requested to communicate at once with Dr. John Eason. A dinner will take place at 6.30 p.m. in the hall of the Royal College of Physicians (morning dress; dinner ticket, 10s. 6d.). Members intending to be present are requested to give notice before February 23rd to one of the honorary secretaries, Dr. John Stevens, 78, Polwarth Terrace, or Dr. John Eason, 35, Melville Street.

EDINBURGH ROYAL INFIRMARY.

The report of the managers of the Royal Infirmary, Edinburgh, for the year ending September 30th, 1919, shows that the total number of patients treated was 12,550, a slight increase on the previous year. The average daily number of patients was 888. A monthly return for eight months showed that there were during that time an average of 606 persons awaiting admission to the wards. The ordinary expenditure had increased in nearly every direction. The cost of each occupied bed was £115 9s. 8d., as against £95 8s. 8d. in 1918, and the total ordinary expenditure was £102,549, an increase of no less than £15,418 over that in 1918. Consequently, the financial position of the infirmary was unsatisfactory and an appeal was made for increased contributions. The daily average number of nurses on duty was 306; 81 nurses and 21 probationers had left and 4 probationers had died. The number of applicants for admission to the training schools for nurses was 612. The daily average number of patients in the Convalescent House, Murrayfield, was 63. The managers expressed their satisfaction in being able to report that all the members of the honorary staff had now returned to duty, with the deeply regretted exception of Dr. Denis Cottorill, who had died in France. The Royal Infirmary could justly claim to have provided its full share of medical officers for all the areas in which the British armies operated, and although this involved a heavy strain on the older members of the staff who remained, they most cheerfully and successfully met the

extra responsibilities and duties thrown upon them. At the annual meeting on February 5th the necessity for providing a new nurses' home was insisted upon, and it was admitted that the infirmary was not in this respect abreast of the times, the number of nurses being inadequate for modern requirements and the hours they worked far too long. If the infirmary came into line with other great hospitals in the country and reduced the hours of each nurse to fifty four a week one hundred more nurses would be needed. The annual report was referred to a special committee, which will give particular attention to the financial position.

Correspondence.

INFLUENZA AND EPIDEMIOLOGY.

SIR,—The late Mr. C. B. Lockwood, a sound if an incisive teacher, was wont to ask the student who spoke to him of a "gouty d'athesis," or of any other ill-defined etiological factor, "Can you show it to me on a plate?" The question may not have been at all times logically justified, but it was extraordinarily helpful as an educational corrective. In your interesting editorial upon the epidemiology of influenza you say, "The great factors governing what we may term a *pandemic respiratory constitution* (the italics are mine) may be similar even when the bacteriological *verae causae* are different." Now Dr. Crookshank, whose plea for a proper consideration of first principles you support, pleads also for clearness of thought when formulating any concept to which disease prevalences may be referred. With both of these considerations few, if any, of your readers are likely to disagree; but it will come as a disappointment to many to find that "a pandemic respiratory constitution" is an accredited concept upon the basis so carefully laid down. You administer a gentle rebuke to the great Sydenham—living before the era of microbiology—for his reference to "skiey influences" in the causation of epidemics; but a "respiratory constitution," so it seems to me, leaves us still very much in the clouds.

If epidemiologists wish to justify and to establish their science, will they not reward our patience, just once, by showing us something "on a plate"?—I am, etc.,

London, W., Feb. 8th.

THOMAS HORDER.

TREATMENT OF MALARIA.

SIR,—There are one or two points in Dr. Robertson's letter in your issue of February 7th upon which I should like to make a few remarks.

1. He recommends a dose of aspirin as a routine measure. This is, I think, quite unnecessary in by far the great majority of cases, and I am not sure that some, at least, of the cases of disordered action of the heart which we frequently see in connexion with malaria are not in part caused by the use of antipyretics of this nature. I do not want to labour the point, but it is worth investigation.

2. He apparently considers that the arsenical compounds, such as galyol, are likely to succeed when quinine has failed. This is quite contrary to our experience at the malaria department of the 4th London General Hospital, where, under the guidance of Sir Ronald Ross, a large number of trials were made, and it was shown that the arsenical compounds had nothing to recommend them as substitutes for quinine.

3. I hope he is wrong when he states that "very few medical men who themselves have malaria take quinine for more than a few days after an attack." If that is so we are in the position of the preacher who told his congregation to "do as I say, not as I do." From a prolonged experience in Africa and India before the war, and in charge of malaria wards during the war, I am convinced that regular administration of quinine to the extent of about 10 grains daily, prolonged for a period of four to six months, is the only way to eradicate the infection, and I am one of Dr. Robertson's "few" medical men who have carried out the treatment on themselves, with, in my case, quite a satisfactory result.—I am, etc.,

W. A. MURRAY, O.B.E.,

M.B., D.T.M. and H.,

Late M.O. i/c Malaria Wards, 4th London
General Hospital.

February 7th.

TICKS AND RELAPSING FEVER.

SIR,—Dr. Nicholson's paper on the above subject in the *JOURNAL* of December 20th, 1919, has led to interesting communications from Captain Dunlop and Colonel Mackenzie. These appeared respectively in the numbers of the *JOURNAL* for January 24th and February 7th, 1920.

Captain Dunlop deals with the disease in Northern Persia and states that he has definitely proved that *Argas persicus* is the vector of its specific spirochaete. Although his observations are interesting and highly suggestive I fear they do not absolutely establish his claim, and further proof is required. Even if the ticks were harbouring spirochaetes derived from the men in the billet he describes, it remains to be proved that they infected healthy men. Again, there is always the possibility that the spirochaetes found in the ticks were fowl spirochaetes, *Sp. gallinarum*, which *Argas persicus* is known to transmit. The evidence furnished is merely of a circumstantial nature and experimental work is required before the role of the tick is definitely established.

It is well to recall that Dschunkowsky¹ in 1913 stated that, as a result of certain experiments, he believed that the Persian relapsing fever was transmitted by a species of *Ornithodoros*, either *O. tholozani* or *O. canestrinii*. Here also, however, the evidence was incomplete, though less so than that advanced by Dunlop. Colonel Mackenzie's note on the clinical differences between the Egyptian and Persian relapsing fevers is interesting, and it agrees with the observations of Boyd.² He believes that ticks are the transmitting agents in Palestine, but again absolute proof is wanting.

I may say that I think it is not impossible that *Argas persicus* is the carrier of the spirochaete of relapsing fever in Palestine, but I maintain that definite scientific proof that such is the case is still lacking, and I hope that the question may soon be decided, as the matter is one of very considerable importance.—I am, etc.,

ANDREW BALFOUR.

Wellcome Bureau of Scientific Research,
London, W., Feb. 9th.

SIR,—Though unable to express any opinion on the question of the transmission of relapsing fever in Palestine by ticks, I cannot agree that the characteristics observed by Lieut.-Colonel J. W. Mackenzie are sufficient to distinguish a type of relapsing fever carried by ticks from that carried by lice.

For three years from April, 1916, I was associated with the Egyptian Hospitals E.E.F.; for the first half of that period I was in charge of No. 3 Egyptian Stationary Hospital. In those hospitals thousands of cases of relapsing fever from among the Egyptian personnel attached to the E.E.F. were treated, and all the sick Turkish prisoners of war were passed through them on their way to Egypt.

The following facts seem to me to invalidate Lieut.-Colonel Mackenzie's proposition:

1. The occurrence of relapses so transient as to be represented on the temperature chart by a "spike" was quite common during the eighteen months before the advance into Palestine—that is, during a period in which it was certain that "bugs" were not the source of infection.
2. The number of cases showing that type of relapse did not increase after the advance into Palestine.
3. During all periods it was difficult to find spirochaetes in many blood films.

4. In all types of cases the relapses were very irregular.

At different periods of epidemics some clinical features—for example, the amount of rash, jaundice, etc.—seemed to vary, and it is possible that the character of the relapses varies in a similar manner, though such a phenomenon was not observed.

All the medical officers attached to the Turkish army whom I questioned on the subject stated that only a few cases of relapsing fever had occurred among the Turkish troops, and as also practically no cases were detected among the large numbers of prisoners taken, unless it was possible to trace very definitely the source of infection in

FORGETTING: PSYCHOLOGICAL REPRESSION.

SIR,—In my first letter to the *BRITISH MEDICAL JOURNAL* of January 17th, I ventured to comment upon the interesting communication by Dr. Alfred Carver on the above-named subject in the previous number.

In that article he stated that forgetfulness was "nothing other than repression, and psychological analysis" (psycho-analysis) "invariably revealed the fact that the patient's anxiety condition was directly attributable to it. This is due to dissociation and displacement of the affect"; also, "the more successful he is in repressing the memory of his unbearable experiences the more severe become his symptoms," and Dr. Carver advised that the necessary first step was the making conscious of the forgotten memory, a method of treatment that has frequently failed in the forms of psychosis met with in my experience, and I have been disappointed with it. The object of this special form of treatment is reasonable, and comes well within the scope of psycho-therapy, namely, that the patient may himself recognize the cause of his own failure and then readjust himself. I believe therefore that Dr. Carver overstates the value of his method, unwittingly of course, and I think that a compromise of opinion would be more correct—namely, that in the early stages rest and diversion are more effective, and in the later stages the revival may succeed, just as the cure of the "tics" in children is first to ignore—which is Sir William Hale-White's advice—and then to emphasize and persuade, which is Dr. Carver's. "Take no notice of his jerks and spasms at first, but have him in the looking-glass and demonstrate to him later."

It must be remembered that in Dr. Carver's treatment the proximate cause of the patient's failure is apparently in the unconscious mind and is "forgotten," and therefore *ex hypothesi* he is not aware of it, except in so far as it may be interpreted to him by his physician—a conclusion he may not accept, but for which he pays the penalty, and does not get rid of his "converted" illness; but the psycho-analyst scores in either instance. If the interpretation of the cause of the patient's illness is accepted, the psycho-analyst is right; if it is not accepted, he is equally right, for the patient is then informed that the thoughts revealed were in the unconscious mind and were "forgotten" by repression, and he could have no awareness of events in this region, and must therefore accept the conclusions offered to him. It is not surprising, therefore, that these conclusions or explanations are either often strange, uncertain, and fantastic, or that the patient often resents the irritating probing of his early life, and in consequence becomes irascible, which may be interpreted to be his "abreaction"! [I was informed by a leading psycho-analyst that the printer's error in connexion with the publication of a recent honours list was a wish-fulfilment on the printer's part that the recipients *should have received higher promotion*!]

Although the doctrines of Freud have been known to medical psychologists for a quarter of a century, there are still some who, like myself, are unable to assimilate its crude vocabulary, and who continue to feel a "resistance" to the Freudian theories. The statement commonly made that much of the mental and a good proportion of the physical disorders from which humanity suffers are due to a struggle and repression between conventional morality and the natural instincts and impulses needs more facts in its support to be convincing, and personally I believe that the psycho-neuroses are as frequently the result of some sudden failure or the fatigue of an overstrained nervous tissue as that they are psycho-genetic, and in regard to the latter much of the value of psychological analysis arises through "suggestion," which is able to overcome the native inhibition, here dignified into the endo-psychic censor. We all realize that suggestion plays a very considerable part in the relief of the milder neuro-psychoses; many patients are beguiled into recovery by the use of the faradic current; most cases of functional aphonia and dumbness, deafness, blindness, and hysterical monoplegias get quite well either

with faradism or upon being reassured that there is a complete absence of organic disease—a psycho-therapy which imposes the stronger will upon the weaker through suggestion and persuasion.

In his second letter Dr. Carver does not add to the statements made in his first, but he limits himself practically to the treatment of hysteria, a group only of the more comprehensive class of the so-called war neuroses, which necessarily includes the psychoses, neuroses, and the group under review—the psycho-neuroses—and these must come under the Pensions Minister in their later or confirmed stages.

The correspondence on the subject has been valuable and deserves attention. Dr. Robert M. Riggall has apparently fallen into line with the modern treatment which tends to avoid suggestion and hypnotism in the later stages and to rely upon psychological analysis. As to the letters of Dr. Thomas Lumsden, I certainly endorse his treatment by psycho-therapy, and I am content to be bracketed with him (if he will permit this by Dr. Arthur F. Hurst), for he is noted for his great services and patriotism. I am further fortified in my belief that "suggestion" is the chief cause of the "lightning cures" which Dr. Carver regards with suspicion. One has only to journey to Holywell in North Wales to see sticks, crutches, splints and perambulators all discarded upon emerging from the intensely cold holy well, and one will there hear also of relapses. Dr. R. G. M. Laddell calls attention to what I venture to believe is the chief advantage of the method of psycho-analysis—namely, the great length of time devoted to each patient, which alone can afford a full and complete investigation into tendencies and temperaments. Dr. Cecil A. P. Osburn, with his special experience of psychiatry feels as I do, that we should be in a position to give our patients the most effective help. Dr. Major Greenwood with much point suggests by means of an allegory that we desire to allay the consciences (why financial?) of our patients in so far as this bears upon bodily disorders, and that we should be permitted to do this without acrimony and personal reflections, but, as in other financial conundrums, the point arises as to how the ordinary civilian can best afford the cure, which is both expensive and tedious, and only applicable to the educated and the young.

The communication from Drs. C. H. L. Rixon and D. Matthews is a personal record of preparing the soldier to discuss his past experience by reviving repressed memories, and for this reason it deserves to be considered authoritatively. The employment by them of suggestion and re-education indicates the value of moral suasion of the most direct type, and although psychological analysis is not mentioned, it is clear that its practice is employed, though possibly not on Freudian lines. I have known one young girl certified as insane who repeatedly denied allegations of improper thoughts relating to her father, these having been put into her mind by psycho-analysis. In my first letter I pointed out that the "cathartic" method of first reviving and then "discussing" forgotten memories may be suitable in some cases, but the effect was the opposite with others, the latter constituting the class of confirmed psychosis, where an insight into their own condition was most difficult or impossible.

My protest is against being too pontifical and over-enthusiastic; to exalt the value of reviving forgotten memories by psychological analysis as the first and the only method of cure in the psycho-neuroses is to discard the experience of others, and to be misleading to those who are being helped. I believe there are two classes of these, one taken in the early stages, which will prove amenable to the valuable advice given by Sir William Hale-White, and the other the later which may yield best to Dr. Carver.

I believe that some of the mental unrest and the anxiety exhibited by the revival of spiritualism and the reappearance of the dead are due to the continuous probing of the mind for memories which were forgotten or were in the process of fading gradually away—Natura's method of restoration, which tends to save the sufferer from becoming the victim of permanent mental disorder, and so confirms the statement of Bergson that the human brain is first and chiefly the organ of forgetfulness, that is, of inhibition.—I am, etc.,

London, W., Feb. 11th.

ROBERT ARMSTRONG-JONES.

SIR,—I should like to criticize the letter by Sir Robert Armstrong-Jones. It appears to me that his statements succeed in minimizing or nullifying the beneficial effects of recovering the repressed memory of the "neurasthenic" only by missing the main point in the technique of psychotherapy, namely, "re-association." I do not think it would serve any useful purpose to discuss the first portion of the letter, and will confine myself to the question of the utility of the methods employed in dealing with cases of "forgetting" by modern methods.

In passing, however, I observe that the writer appears to confuse the part for the whole when he implies that the unconscious mind and the "en-do-psy-ic censor" are one. Freud uses the latter term to define what he claims to be a definite psychological influence at work in the unconscious mind. It is not the unconscious mind itself, indeed it is not even the *élan vital*, etc., but merely a product resulting upon the acceptance of the existence of a primary driving force in the mind of man. It is to be hoped that the novice of the "younger school of psychoneurologists" will avoid such confusion of terms in discussion or controversy relating to a new subject where accuracy of definition and observation are of paramount importance.

It is not the object of the psycho-therapist to cure merely by resuscitating painful memories which the patient by constant effort has at last succeeded, or partially succeeded, in driving into the unconscious. By so doing he would achieve nothing more than to bring the patient back to the very starting point from which the symptoms sprang. That is not enough—no cure can be fairly considered to have been brought about until a process of "re-association" has taken place in the mind of the sufferer. True this process may result spontaneously after analysis in the waking or hypnotic state (and in my opinion this state of affairs accounts for the type of case which clears up as the result of simple abreaction alone). But often it is essential for patient and physician to examine the newly broken ground and to pick out, as it were, the gold from the dross; this is the process of "re-association," and by it the patient is brought to realize the fact that, however painful his memories may be, the maximum portion of the pain has been caused through not knowing how to reconcile the pain-causing "conflict" with the rest of his mentality.

The aim of the psycho-therapist is as honest as that of the surgeon. His object is not to smother the malodorous wound with sweet-smelling medicaments, but radically to treat to a cure. It is not sufficient to provide the patient with a brand-new supply of "pleasant memories" to superimpose upon the old painful ones (how ineffectual such a method would be is recognized by most workers, I hope). Nor is it any better to provide a "complete rest" wherein introspection (the progenitor of morbid rationalization) is allowed to exercise a truly baneful influence. Such methods only make for the "fixation" of the symptoms, and render subsequent work along rational lines doubly difficult.

It is my experience that the patient does not leave the physician happy because his troubles have been "re-camouflaged" (hysterical symptoms, at any rate, are mere "camouflage" to begin with), but because he is now conscious with equanimity of the cause of his trouble, and is provided with practical means wherewith to combat the same, should the occasioning factor ever enter into his life again. The jilted lady need no longer waste much useful energy in expressing her emotions in symbolic hysteria. Realizing why her unhappy lot is what it is, she can now direct these introverted energies into channels leading to mere altruistic results, namely, the benefit of humanity. Thus by "re-associating" is she enabled to "sublimate" her baser tendencies and achieve that peace of mind which is the heritage of all who understand themselves within the true meaning of the phrase.—I am, etc.,

CHARLES DAVIES-JONES, M.B., Ch.B.

Ashhurst War Hospital, Littlemore,
* near Oxford, Jan. 19th.

SIR,—Some of Sir Robert Armstrong-Jones's remarks on the methods of "the younger school of psychoneurologists" are very misleading and not in accordance with either their practice or their theories. He speaks as if merely bringing to the surface forgotten memories or reminding the patient of the horrors he has seen is the essential part of the treatment by so-called "abreaction."

As a matter of fact, the mere bringing to memory or reminding the patient of his unpleasant experiences is not the essential part of the treatment. The essential part consists in "working off the emotion" attached to these memories, and in reducing them, if one may put it so, to the "commonplace."

The apparent cause of the majority of the anxiety conditions known as "shell shock" seems to be an accumulation of such emotions as fear, disgust, etc. (Into the psychological analysis of these I need not enter here.) In ordinary life one does not repress such emotions. In war, however, from day to day intolerable experiences take place, and the emotion appertaining thereto is not allowed any outlet. The man may then be likened to a steam boiler whose safety valve is closed, and in which the steam pressure continues to rise until it leaks at all the joints. By getting the patient to talk daily about his experiences and to undergo the emotions belonging to them we relieve him of this high pressure.

The matter is not a question of suggestion at all, for by far the greater number of patients whom we have to treat at the present time have already spent any period up to two years in hospitals, and have in a large proportion of cases had treatment by either suggestion or hypnotism. Yet in the vast majority of cases the patients suffering from these anxiety conditions (excluding phobias and obsessions) improve wonderfully in a very short period after "abreaction" of their repressed emotions. One is often informed at the end of the first week of the relief the patient feels, and this corresponds very much to the relief some people feel after a good fit of weeping if they are in trouble.

I am not referring to a few isolated instances. These statements are made as the result of studying the *individual* psychology of from six to ten patients almost daily for the last two years. Of course a certain percentage of cases show a different etiology, and for these psycho-analysis or other methods of treatment are necessary.

As regards the point, raised in the same letter, as to whether it is possible to repress what is intolerable, I can only state that in a very large percentage of the above-mentioned cases the most horrible isolated events in the patients' memories have been repressed, and are not recalled until some of the emotions connected with lesser horrors have been worked off, and this applies (with a rather different mechanism, which space will not permit me to go into) even in several cases of complete amnesia which I have treated recently.

The point is really beyond dispute now, and a study if only of hypnotic phenomena of this kind should convince anyone of its possibility.—I am, etc.,

PAUL BOUSFIELD,

Physician to the Lancaster Gate Clinic of Psycho-Therapy
(Ministry of Pensions).

London, W., Jan. 26th.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—Though differing profoundly from him, I think Dr. Baskett is to be congratulated on his courage in attacking the whole trend of recent social legislation. His article in the *JOURNAL* of January 10th is worthy of careful consideration, and nothing would be more instructive to the general practitioner than the holding of the inquiry he advocates.

Meanwhile I venture to offer a few criticisms on Dr. Baskett's argument.

Destitution is undoubtedly a great cause of tuberculosis, and the height of real wages affects the amount of destitution. But they do not necessarily rise and fall together. As a fact, destitution as measured by Poor Law outdoor relief has diminished almost persistently since 1870, and the fall from 1910 to 1915 was greater than in any quinquennium since 1875. It is now only one-third what it was in 1880. (See Local Government Board chart published in *The Times* of December 27th.)

We must therefore conclude that destitution has not recently been the chief cause of tuberculosis, though I believe with Dr. Baskett that it was during the last century. We must also conclude (on the *post hoc* principle) that "State paternalism" has diminished destitution, even if it has reduced real wages.

Probably the rise in wages above the destitution line does help to decrease tuberculosis, but nothing like to the

same extent as removal of destitution. I believe that the temporary rise in wages, together with the intemperance that marked the South African war, largely explains the rise in tuberculosis during the years 1901-3, shown in Dr. Baskett's chart.

Dr. Baskett says nothing about alcoholism, housing, and other great causes of phthisis. Wages affect them, but only to a very limited extent. The conditions of industry have necessitated, and will for many years necessitate, that the workers should live in unhealthy houses, even though their wages rise.

But it is a great mistake to think that what chiefly caused a disease in the nineteenth century has continued to be its principal source in the twentieth. The great causes now are alcoholism, bad housing, unhealthy conditions of employment, and other urban and industrial conditions. State paternalism has dealt with them by Education, Housing, Factory, and Buildings Acts; and the continued fall in tuberculosis up to 1912 may be attributed to these measures as much as to the continued decrease of destitution.

Dr. Baskett considers there was an arrest of the fall of the tuberculosis death rate after 1900. But he is wrong in expecting the decline to follow an arithmetical progression. A decline from 1,000 to 500 per million is as much proportionally as a decline from 2,000 to 1,000. The decline, therefore, in 1912 was quite satisfactory. But Dr. Baskett is very sanguine if he thinks that a disease so widespread, both geographically and zoologically, as tubercle can be quickly exterminated.

Paternal legislation and administration concentrated after 1900 specially on infant welfare, and the infantile death rate, which had not previously shared in the general fall of death rates, came down with a slump. With it fell the death rate from tuberculous peritonitis and tabes mesenterica, and the fall in these continued up till 1916, which had the lowest death rate, with two exceptions. How does Dr. Baskett explain this?

I submit that Dr. Baskett is mistaken when he says that the effect of any unfavourable cause on the tuberculosis death rate is not observed for two years. He forgets that these causes act as much, if not more, on those already affected as on the well, and that there are always a vast number of tuberculous persons whose deaths will be precipitated by failure of requisites.

I maintain, then, that Dr. Baskett's main thesis—the connexion of *laissez faire* with the fall of the death rate—has but a very feeble leg to stand on.

It must be admitted that it is curious and unsatisfactory that the phthisis death rate has risen since the Insurance Act. But influenza, respiratory diseases, cancer, heart and other diseases have increased even more. (Cancer, at any rate, is not a disease of poverty, and its increase is the most marked of all.) Is the increase of all these due to State interference? *Post hoc non ergo propter hoc*, Dr. Baskett truly says. Let us by all means have the committee of inquiry, and I venture to prophesy that before its report is made—say in five years' time—it will be able to report that the phthisis death rate has fallen lower than ever.

To sum up: Destitution—not the low level of real wages—was the chief cause of tuberculosis for many years during the nineteenth century. The fall of destitution did not cease with the arrest in the rise of real wages at the end of the century, but continued to fall, faster than ever, up till the present time. The rate of decline in the tuberculosis death rate was not appreciably arrested till 1913. The decline in the past twenty five years cannot reasonably be attributed so much to lessened destitution as to social legislation. The increase of deaths from pulmonary tuberculosis since 1913 is accompanied by increase of influenza, bronchitis and other diseases having little connexion with real wages. This increase will probably soon give way to a marked decrease, assisted by an amended Insurance Act and other wise social legislation and administration.—I am, etc.,

SIDNEY DAVIES,

London, S.E., Feb. 9th.

Esq. M.O.H. Woolwich.

TREATMENT OF ADENOIDS.

SIR,—In his note to Dr. Gertrude Hickling's article on "Nasal drill" in the treatment of adenoids (January 31st, p. 148), and with reference also to Mrs. Hancock's results

recorded in the *Lancet* of August 24th, 1918, and later. Dr. C. P. Lapage, while approving generally of the nasal drill, is not hopeful as to the cure of hypertrophied tonsils and adenoids except by operation.

May I be permitted to say that while in hearty agreement as to the value of such breathing drills, my experience teaches me to be much more optimistic? During the two years before the war I succeeded in curing by medical means every case I was called upon to treat. Cases certified as requiring operation, with enlarged tonsils touching the uvula, adenoids blocking the nasal passage and with earache, deafness, and mouth-breathing were found to have no trace of any disability two or three months later. I am confident that the vast majority of operations now undertaken are really unnecessary, and if unnecessary unjustifiable.

I should be happy to demonstrate the value of the treatment to any medical man who cares to communicate with me.—I am, etc.,

JOHN KYNASTON,

26, Welbeck Street,
London, W., Feb. 6th.

Lieut.-Colonel R.A.M.C. (Retd. List).

CHRONIC PANCREATITIS.

SIR,—The point I wanted to make is that workers on the pancreas have tended to sluit, in cases of diabetes, the nine tenths associated with uric acid diathesis, which have been accepted, to nine-tenths, say, associated with pancreatitis. It is here we want, for diagnosis and therapy, some authoritative teachings—or clear notions.—I am, etc.,

Herne Hill, S.E., Feb. 6th.

J. BARKER SMITH.

TERRITORIAL GENERAL HOSPITAL STAFFS.

SIR,—The flood of decorations and honours that has recently fallen on our profession has missed as usual the men who did the hard work at home. The Territorial medical officers who served the great general hospitals are excluded from any recognition. Civilian doctors who looked after school hospitals are now, it would seem, nearly all O.B.E.'s. But the men who were in uniform for nearly five years, who gave up most of their time and energy to military work have received, in the main, neither recognition nor thanks. True, they received their pay; sufficient in many cases to defray the expense of their motor cars which took them to and from their work. But our civilian brethren also received pay. Now they are decorated in hundreds. Yet where was the real hard and responsible work done? Nowhere else than in the Territorial general hospitals.

Those of us who were not allowed to go abroad—and practically all volunteered to go abroad—are still permitted to wear our uniform on great occasions. But not a ribbon decorates that uniform, which was worn for five years in the service of the army.

I was a captain in 1908. I am a captain still. Except the printed form sent on demobilization I have received neither promotion nor thanks. The sisters and nurses have been lavishly recognized, and well they have deserved it.

Now comes along a new Territorial Army scheme. Is there any inducement for us to enter it? I confess I can see none.—I am, etc.,

February 3rd.

CAPTAIN R.A.M.C. (T.F.).

SURGICAL WAR HONOURS.

SIR,—Is it much to ask the Royal College of Surgeons of England to make a careful survey of the work performed as surgical specialists by members of the college?

During the war I have done the entire surgical work of nearly 700 beds. The military authorities have on three occasions recognized my services, but no recognition would equal that of my own college by conferring the higher diploma or some written appreciation.

My case is only one of many probably more worthy of recognition. Exceptional services in an exceptional war demands exceptional consideration and professional acknowledgement apart from the State.

Naturally I am unable to subscribe my name.—I am, etc.,

February 5th.

M.R.C.S. AND SURGICAL SPECIALIST.

SCOTTISH COLLIERY SURGEONS AND MINERS' UNION.

SIR,—Dr. Drever does not seem to have been correctly informed—at least, in some particulars. When the Miners' Union refused to consider our demand for 6d. inclusive or 5d. exclusive of medicine, we were certainly asked to sign forms agreeing to break off negotiations and to attend miners' dependants after a certain specified date as private patients. I know that in my own county these forms were signed and returned to our county representative by all, or practically all, the men who did any colliery work whatever.

Nothing came of this, however. Subsequently the miners' representatives offered 4½d. or 3½d. One man tried to induce them to accept 5d. or 4d., and circulars were again sent round asking which we would prefer, and if, in the event of the miners not accepting the higher rate, we should again agree to revert to private practice. Nothing resulted, and we found ourselves committed to the offers of the miners' representatives.

Dr. Drever's third "line" reads: "That no area should accept any settlement unless all the areas received the terms agreed on by the committee." I understand that certain areas arranged their own terms independently of the committee, and that even some localities have a higher rate than their immediate neighbours.—I am, etc.,

January 31st.

SCOTTISH COLLIERY SURGEON.

* * Dr. James R. Drever, Scottish Medical Secretary, British Medical Association writes: If I have not been correctly informed, the Committee is in the same position. I stated its policy and procedure in my last letter; in the carrying out of that policy each area was autonomous, but it was understood that resignations were not to be sent in until the Committee directed that they should be. If the policy of the Committee was not correctly explained to those in colliery surgeons' areas, or if the opinions of the latter were not correctly reported to the Committee, the fault, if any, must lie with the local committee or the delegate, and your correspondent has surely a more direct remedy than that of an anonymous letter. I am glad to hear that some areas have obtained higher rates. That does not vitiate the fact that all the areas have received "terms agreed on by the Committee."

Obituary.

LAURENCE HUMPHRY, M.D., F.R.C.P.,

Physician, Addenbrooke's Hospital, Cambridge.

WE are indebted to a correspondent in Cambridge for the following estimate of the life and work of Dr. Laurence Humphry, who died on February 5th:

By the death of Dr. Laurence Humphry the Cambridge Medical School has suffered a great loss, one that for the present, at any rate, is irreparable. Dr. Humphry was mobilized at the 1st Eastern Hospital at the beginning of the war, and gave himself to his heavy and exacting duties with unselfish devotion. By no means a strong man his periods of rest were brief and infrequent; thus, as the war wore on, especially in the last year or two, his friends noticed that the strain was telling upon him. He looked thin and worn, yet still loyally worked on. In this susceptible state Humphry became affected by some obscure septic virus which, beginning in the tonsils, gradually spread to other parts in a long and painful illness, during which the hope of recovery faded away. He died at the age of 63.

Dr. Humphry was a nephew of Sir George Humphry and inherited much of the family ability. His father was a barrister-at-law, who lived in London, where Laurence Humphry was born. His mother was a daughter of Dr. McNab of Epping, a physician of some eminence in his day. In 1889 he married Isabel, daughter of the late Professor Sir George Stokes. They had no children.

Humphry was a graduate of Cambridge (Trinity College), and by his uncle's advice settled there, and soon began to build up a consulting practice in medicine. And in later years, as his senior colleagues died or withdrew from the harder work, Humphry became the leading consultant in the district. He was physician to the Addenbrooke's Hospital, and had filled the offices of assessor to the Regius Professor of Physic, Examiner in Medicine to Cambridge and other universities, and served on the Council of the

Royal College of Physicians of London. He also took an active part in the medical school, in which he was keenly interested. For fifteen years—years of much change and revision—he was secretary to the Special Board of Medicine, a post to which he was admirably adapted. He was orderly and accurate in business, thoroughly familiar with the somewhat complex affairs and procedures of the university, and thus, and by his personal qualities, carried out a few difficult and thorny measures through the Special Board and the Senate.

Unfortunately, as we have said, Humphry was not physically robust. He had considerable talent for research, and at one time took charge of the Pathological Museum, and, following on his uncle's lines, did much good work. He was especially interested in malformations of the heart, on which subject he wrote the article in Allbutt's *System of Medicine*. He made some researches also on the functions of the pancreas, on the parathyroid glands, and on embolic aneurysms of the pulmonary artery. He often regretted that he could not do more research work, but he was liable to frequent and intense attacks of migraine which made sad inroads upon his time and energy. As a clinical physician he was excellent; sympathetic, gentle, learned, and sagacious; moreover, he was well equipped on the scientific side of pathology.

Humphry was a man of rare charm of character; modest a most to self-effacement, high minded, gentle, and with a keen sense of humour; but none the less decisive and wise in judgement. He was a chivalrous colleague and an affectionate friend. He had much taste and skill in the fine arts, in which he and Mrs. Humphry also had no little accomplishment. He was skilful in modelling in wax, especially in medallion work of low relief, very delicate and refined. During the earlier part of his illness he found in this work much relief from ailment and ennui. He was also an enthusiastic and skilful fisherman. He passes away deeply regretted.

By the untimely death of Dr. C. R. WATSON on December 23rd, 1919, Tunbridge Wells sustained a great loss. He was taken seriously ill in May, but recovered so well that his friends and patients looked forward to his taking up active work again. The end was unexpected, and he died in his sleep. He was educated at Tonbridge School, and afterwards at St. George's Hospital, where he was both house-surgeon and house physician. He took the diplomas of M.R.C.S. and L.R.C.P. in 1895, and the M.D. of Brussels with honours in the following year. After acting as physician to out-patients and resident medical officer at the York Road Lying-in Hospital, Lambeth, he settled in Tunbridge Wells, where for nearly twenty years he occupied the post of surgeon to the General Hospital. He was also surgeon to the Church of England Waifs and Strays Home and the Hawkenbury Convalescent Home. He undertook an enormous amount of additional work during the war, being surgeon to the St. Mark's V.A.D. Hospital and carrying on his brother's practice when the latter joined the R.A.M.C. There is no doubt that all this extra work caused his breakdown in health. He was a member and past chairman of the local Division of the British Medical Association, and took a keen interest in the work of the Association. The great esteem in which he was held by his professional brethren was evidenced by the very large numbers attending the funeral service. His geniality, kindness, and sweet temper will long be remembered. In the words of Hilaire Belloc,

He does not die that can bequeath
Some influence to the land he knows.

He leaves a widow and daughter and son, to whom sincerest sympathy will be extended.

WE deeply regret to record the death from septic pneumonia of Dr. WILFRID LEECH MYLES, of Pontliffraith. In him the members of the medical profession of Monmouthshire have lost a genial and loyal colleague, and the quite unexpected news of his death came as a shock to the people of the district, by whom he was warmly esteemed and affectionately regarded. On January 26th, while attending to his duties, he contracted a chill, and, though he improved at first, he had a relapse on January 30th, and passed away on February 1st from septic pneumonia. The sympathy of the community goes out

to his widow and to his sister and brother-in-law, Dr. and Mrs. T. A. Gregg, of Newbridge. Dr. Myles, who was 42 years of age, was the eldest son of the late Dr. James P. Myles, of Birr, King's County, Ireland, and a brother of the late Major C. W. Chester Myles, M.C., a Territorial officer who served with the R.A.M.C. at Gallipoli and in Egypt, and died while on active service, in October, 1918. He was a near relative of Sir Thomas Myles, the distinguished Dublin surgeon. He was educated at the Academical Institute, Coleraine, and the Medical School of Trinity College, Dublin. He qualified in 1905 and in the following year became assistant to the late Dr. Thomas at Newbridge. In 1910 he entered into partnership with Dr. Gregg, and went to reside at Pentlanfraith with his mother, who passed away seven months ago. Dr. Myles married only last October, and a very distressing feature of the sad circumstances was that Mrs. Myles had a few days previously undergone an operation for acute appendicitis. Dr. Myles was a good and conscientious worker in his profession. During the war he was the military representative on the local tribunal and wholeheartedly supported every movement in the interest of the wives, children, and dependants of the men. He was a staunch Churchman and a gentleman of high honour and noble ideals. He made many efforts to be allowed to go on active service during the war, but an ankylosis of the knee following an injury received many years ago led to his rejection. Dr. Myles was president and secretary of the local cricket club, whose members offered to carry the coffin to the graveside at Abercromby Cemetery.

THE *Journal of the American Medical Association* announces the death, after a surgical operation, of Dr. EMERY MARVEL of Atlantic City, New Jersey. The news will be received with much regret in this country, and especially by those of our profession who attended the Convention of the American Medical Association in America last June. Dr. Marvel was Vice President of the Convention and Chairman of the Committee of Arrangements. Sir Shirley Murphy writes: Dr. Emery Marvel was deservedly held in high esteem for his professional knowledge and had a personal charm which contributed in great degree to the success of the meetings of the Convention. Possessed of a mind well stored with knowledge, a kind, genial, and courteous personality, he made a charming host. He will always be remembered by those who were privileged to meet him as representative of the best type which our profession produces. He belonged to the family of which Andrew Marvell, the seventeenth century poet and satirist, was a member.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

PROPOSALS put forward by the Special Board of Medical Studies for alterations in the first and second M.B. examinations were discussed in detail by the Senate on February 5th. Sir G. Sims Woodhead, Professor of Pathology, undertook that the proposals should be considered further by the Special Board.

War List.

The *Cambridge University War List*, which will be published by the Syndics of the University Press, is now undergoing final revision. We are asked to invite any reader who (being a member of the University before the war) served in the Army, Navy, or Air Force, and has not already supplied his college with an up-to-date record of his services, to send the particulars to Mr. G. V. Carey, M.A., Editor of the *War List*, the University Press, Cambridge. The particulars required are: College and year of matriculation, unit (or units, if transferred), rank on the date of the armistice or highest substantive rank attained prior to it, casualties and distinctions.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the College was held on February 3rd, with the President, Sir Robert Philip, in the chair.

L. F. Bianchi, L.R.C.P. Ed., and W. Hughes, M.B., were elected Fellows of the College.

D. H. D. Cran, M.D., P. C. Davie, M.B., H. C. Elder, M.B., D. Cook, M.B., and E. W. Frecker, M.B., were admitted to the membership of the College.

Licences to practise were granted (in conjunction with the associated bodies) to eleven candidates who had fulfilled the conditions and passed the final examination.

Sir Robert Philip was appointed a trustee of the College.

Election of Honorary Fellows.—M. Eleutherios Venizeles, Prime Minister of Greece, was elected an Honorary Fellow of the College.

Supplementary Royal Charter.—The President announced that the Supplementary Royal Charter dated December 3rd, 1919, had now been delivered and was placed on the table of the College. The Supplementary Charter empowered the College to admit women to the membership and fellowship of the College on the same conditions and with the same privileges as men.

At an extraordinary meeting, immediately following the quarterly meeting, William Herbert Fawcett was suspended *sine die*, and deprived until the said suspension is removed or remitted of all his rights and privileges as a member and a licentiate.

The Services.

HONOURS.

THE following awards and promotions are announced in recognition of distinguished and valuable services rendered in connexion with the war in the fields of operations indicated. The officers belong to the R.A.M.C. unless otherwise specified:

ARCHANGEL (NORTH RUSSIA).

C.M.G.—Captain (acting Lieut.-Colonel) Duncan Campbell Lloyd Fitz Williams (T.F.).

C.B.E.—Colonel George St. Clair Thom, C.B., C.M.G. Temporary Captain (acting Major Eric Stewart Marshall, M.C.).

O.B.E.—Majors (acting Lieut.-Colonels) Alfred William Adamson Irwin, John Maurice, B. Rahilly, Captain (acting Lieut.-Colonel) Thomas H. Richmond (T.F.).

D.S.O.—Major Archer Irvine-Fortescue.

M.C.—Captain Jeremiah John Magner (156th Field Ambulance).

MORMANSE (NORTH RUSSIA).

O.B.E.—Captains (acting Lieut.-Colonels) John Forbes W. Sandison, M.C. (S.R.), (acting Major) Charles George G. Keane. Temporary Captains (acting Majors) Alexander Hepburn Macklin, M.C., Thomas Victor Somerville, M.C.

SOUTH RUSSIA.

O.B.E.—Captain Trevor Aveling Buncher (S.R.).

To be *Brevet Major*.—Captain C. S. P. Hamilton, D.S.O.

BUSHIRE.

C.B.E.—Lieut.-Colonel (Temporary Colonel) Charles Harford Bowle-Evans, C.M.G., I.M.S.

O.B.E.—Majors Thomas Scarborough Dadding, (acting Lieut.-Colonel) William Lapsley, I.M.S.

PERSIA (BUSHIRE FORCE).

To be *Brevet Major*.—Captain (acting Lieut.-Colonel) H. R. B. Gibson, I.M.S.

MENTIONED FOR SERVICES.

The following are among the names brought to the notice of the Secretary of State for War for valuable and distinguished services in connexion with military operations. The officers belong to the R.A.M.C. unless otherwise indicated:

North Russia (from March 25th to September 26th, 1919).

Colonel G. St. C. Thom, C.B., C.M.G.

Majors (acting Lieut.-Colonels) A. W. A. Irwin, J. M. B. Rahilly, Major A. Irvine Fortescue.

Captains (acting Lieut.-Colonels) D. C. L. Fitzwilliams (T.F.), T. H. Richards (T.F.), J. B. A. Wigmore, Captain (acting Major) L. E. Hughes, M.C. (T.F.). Temporary Captains (acting Lieut.-Colonels) E. R. Hunt, R. Gordon, Temporary Captains (acting Majors) R. T. Grant, E. S. Marshall, M.C., J. D. Watson, M.C. Temporary Captain R. L. Sinclair.

Lieutenant (temporary Captain) G. E. Spicer, M.C. Temporary Lieutenant F. C. S. Bradbury.

Murmansk.

Major (acting Colonel) E. L. Moss, C.M.G., M.C.

Captains (acting Lieut.-Colonels): J. J. D. Roche, J. F. W. Sandison, M.C. (S.R.), Captains (acting Majors): H. R. Friedlander, C. G. G. Keane, Captain J. Home L., J. Scawia tz (S.R.), M. D. Vint (S.R.), Temporary Captains (acting Majors): T. E. Coulson, A. H. Macklin, M.C., T. V. Somerville, M.C.

With the Bushire Force in Persia.

Lieut.-Colonel (temporary Colonel) C. H. Bowle-Evans, C.M.G., I.M.S.

Majors (acting Lieut.-Colonels): H. Halliday, I.M.S., G. A. Jolly, I.M.S., W. Lapsley, I.M.S. Majors: A. Cameron, I.M.S., T. S. Du ding.

Captain (acting Lieut.-Colonel) H. R. B. Gibson, I.M.S. Captains: A. L. Badoock (T.F.), B. F. Beaton, I.M.S., C. M. Finny (T.F.), W. E. Hodgkin (T.F.), T. Kenney (T.F.). Temporary Captains: N. Joshi, I.M.S., R. N. Khosla, I.M.S., P. N. Mitra, I.M.S., J. H. Onnawa, I.M.S., B. S. Rao, I.M.S., M. A. Singh, I.M.S.

Honorary Lieutenant A. J. Hardaker, I.M.D.

The names of the following have been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war. This list will not be gazetted:

Lieutenant E. J. Bader, S.A.M.C., Mr. G. W. Badgerow, C.M.G., F.R.C.S., Captain A. Barnes, R.A.M.C. (T.F.), temporary Captain E. B. Barton, R.A.M.C., Dr. W. H. Beaumont, Captain E. C. Bradford, R.A.M.C. (T.F.), Major W. Bruce, O.B.E., N.Z.M.C., temporary Major Archibald Campbell, R.A.M.C., Dr. E. H. Colbeck, O.B.E., F.R.C.P., Mr. W. H. Cooke, F.R.C.S., Dr. C. Curd, Dr. M. B. Ferguson, Captain E. E. W. Fisk, S.A.M.C., Dr. R. F. Flood, Captain C. R. Girdlestone, R.A.M.C. (T.F.), temporary Captain J. Graham, R.A.M.C., Dr. A. S. Griffith, Dr. J. M. Harper, Dr. H. Henderson, Dr. A. Hodgson, Dr. L. Kidd, Dr. P. King, Major (acting Lieut.-Colonel) W. Kirkpatrick, R.A.M.C. (T.F.), Mr. F.

Lace, F.R.C.S., temporary Captain A. W. Macgregor, R.A.M.C., Dr. G. J. K. Martyn, Dr. J. M. H. Murray, Dr. J. M. H. Murray, Major (acting Lieut.-Colonel) W. Murray, R.F.A.(T.F.) (temporary Major, R.A.M.C.), Major-General Sir W. W. Pike, K.C.M.G., D.S.O., A.M.S., temporary Captain A. H. Priestley, R.A.M.C., Major A. G. Reid (West Riding Vol. R.A.M.C.), Dr. C. W. C. Robinson, Dr. G. J. Scale, Captain A. L. Sinker, N.Z.M.C., Dr. C. Sturm, temporary Captain J. H. K. Sykes, R.A.M.C., Dr. E. C. Thompson, temporary Captain A. H. Ward, R.A.M.C., Dr. A. M. Watson, Captain R. W. F. Wood, N.Z.M.C., temporary Captain A. E. Wynne, R.A.M.C.

Medical News.

THE Prince of Wales, who has become President of Guy's Hospital, presided at a Court of Governors last week, at which he gave his approval to a special appeal for funds which the hospital is about to make.

AT a meeting of the Royal Society on Thursday next at 4 p.m. Professor W. M. Bayliss will read a further paper on the properties of colloidal systems, dealing with reversible gelation in living protoplasm.

SIR ARTHUR MAYO-ROBSON has been elected an honorary member of the Royal Medical Society of Ghent. The society was founded in 1834; for the record of its proceedings it issues *Annales* and a *Bulletin*.

MR. H. NORMAN BARNETT, F.R.C.S., who was for more than five years on active service, and held the rank of lieutenant-colonel, has returned to private practice at Bath, where he is surgeon to the Ear, Nose, and Throat Hospital.

DR. F. F. SIMPSON has come from America to discuss the possibility of forming a world congress of physicians and surgeons composed of the various international congresses and associations already existing.

As in 1918 the Caroline Institute at Stockholm has decided not to award the Nobel Medical Prize for 1919.

THE zoological station at Naples is well known for the facilities it affords for zoological research. We are asked to say that it also affords advantages as a fully equipped centre for physiological research.

MR. ALFRED SMETHAM, chemist to the Royal Lancashire Agricultural Society, has been elected president of the Society of Public Analysts in succession to Dr. Samuel Rideal.

DR. T. LISTER LLEWELLYN will open a discussion on the illumination of mines, with special reference to the eye-sight of miners, at a meeting of the Illuminating Engineering Society at the Royal Society of Arts, John Street, Adelphi, on Tuesday, February 24th, at 8 p.m.

WE are informed by the Automobile Association and Motor Union that an inquiry is being made into the justification alleged for the recent advance in the price of petrol to 3s. 8½d. a gallon. It is pointed out that imports of petrol amounted last year to something like 200,000,000 gallons, and that the consumption will probably be nearer 250,000,000 gallons this year. A very small increase in the price per gallon therefore means a large increase in the public's total expenditure.

AN institute for biology and serumtherapy under the direction of Professor Pittaluga has recently been opened at Madrid.

THE centenary of the firm of Reynolds and Branson of Leeds was celebrated a few weeks ago by a dinner at which the staff and the wives of the married workers were entertained at the Queen's Hotel, Leeds. The firm was, in fact, established by Mr. William West, F.R.S., in 1816, but the celebration was postponed owing to the war. In 1841 Mr. West was joined in partnership by Mr. Harvey, one of the founders of the Pharmaceutical Society. The firm assumed the present name in 1883 and became a limited company in 1898.

IN the annual report for the year ending June 30th, 1918, by the medical officer for Capetown, Dr. A. Jasper Anderson, the rates are calculated on the basis of a census taken for electoral purposes in May, 1918. The European population is estimated to have been 89,700, and the non-European 82,350, the total being 172,050. The birth rate was 27.4 for Europeans and 44.06 for non-Europeans. The death rate, corrected for visitors, was 11.41 for Europeans and 26.57 for non-Europeans, a decrease in both cases. The infant mortality for Europeans was 79.33, and for non-Europeans 201.16. The number of cases of enteric fever and diphtheria showed a decrease. Four cases of leprosy were notified, all among non-Europeans, and three members of the labour contingent were repatriated on this account. Dr. Anderson complains that the accommodation for infectious diseases and for tuberculosis is insufficient.

DR. J. TUBB-THOMAS, on the occasion of his retirement from the office of M.O.H. for the county of Wilts after twenty-two years' service, has been presented by the medical staff of his department with a chased silver cigar box, cedar lined, and a silver cigar case inscribed with his initials, as a mark of their esteem. Dr. Tubb-Thomas's services are being retained as consulting medical officer for the county.

MR. H. L. EASON, C.B., C.M.G., M.D., M.S., ophthalmic surgeon to the hospital, has been appointed to the post of superintendent of Guy's Hospital, in succession to Sir Cooper Perry, M.D. During the war Mr. Eason served as consulting ophthalmologist to the forces in the Mediterranean, and later to the Egyptian Expeditionary Force. On January 29th a presentation was made to Sir Cooper Perry in the Court room of the hospital.

WE mentioned last week an observation by M. Achard to the effect that the existence of lymphocytosis in the fluid obtained by lumbar puncture in a suspected case of lethargic encephalitis should not be considered to negative that diagnosis. At a subsequent meeting of the Académie de Médecine M. Widal confirmed this observation and reported the existence of lymphocytosis in the cerebrospinal fluid in three out of four cases in hospital under his care. In one the number of leucocytes was fourteen to the cubic millimetre, and in another eleven. In the latter case the first examination was made six days after the patient took to his bed and the proportion of different types of cell was mononuclear 84, polynuclear neutrophile 16; there were also a few red corpuscles. Two days later the numerical lymphocytosis was the same, but all the cells were mononuclear.

APPLICATIONS are invited for the Mary Louisa Prentice Montgomery lectureship in ophthalmology in the gift of the Royal College of Surgeons in Ireland. The lecturer is appointed for one year, but is eligible for reappointment year by year for a period not exceeding five years. The salary is approximately £150 a year, and applications must be received by the Registrar of the College on or before March 4th.

A MEETING, called by the Society for the Prevention of Venereal Disease, was held at the Mansion House, London, on February 5th, the Lord Mayor presiding. The speakers included Lord Willoughby de Broke, Sir James Crichton-Browne, Sir Arthur Sloggett (late D.G.A.M.S.), Sir Archdall Reid, Sir E. Ray Lankester, and Dr. Mearns Fraser (M.O.H. Portsmouth). Among those on the platform were Sir Humphry Rolleston, Sir Frederick Mott, Sir Bryan Donkin, Sir D'Arcy Power, Sir John MacAlister, Dr. R. A. Lyster, and Dr. A. J. Harries. The following resolution was carried unanimously: "It is obvious that the best way of avoiding venereal disease is to abstain from promiscuous sexual intercourse. It is, however, certain that a large number of persons continue, in spite of moral teaching, to expose themselves to risk and so to incur and spread disease amongst the community, the chief sufferers being women and children. Venereal disease has become a menace to national health and prosperity, and in view of the proved fact that infection can be prevented by means of self-disinfection, if properly applied, immediately after exposure to risk, it is necessary to instruct the public as to (a) the vital importance of self-disinfection at the time of exposure to risk as a preventive of venereal disease, and (b) the methods of application.

IN an Order dated January 23rd, 1920, under Section 13 (1) of the Education Act, 1918, the Board of Education, makes it compulsory, as from April 1st, 1920, that local authorities should provide for medical inspection in their secondary schools, continuation schools, pupil teacher centres, and recognized preparatory classes, as well as in junior technical schools and certain full-time technical classes. Inspections of children and young persons in such schools and classes are to be made on the occasion of their admission and thereafter once a year during their period of attendance.

THE Executive Committee of the Tuberculosis Society, to whom the subject was referred at a general meeting, have unanimously decided against affiliation with the British Federation of Medical and Allied Societies. They consider that the Federation, owing to its constitution, cannot in any circumstances represent the majority of general practitioners, and that its aims and programme have been, or should be better undertaken by the British Medical Association, which by right of numbers is best qualified to represent the profession. If it be desirable to take the opinion of medical societies, as distinct from individual members of the profession, on vital matters, the committee suggest that a subcommittee of the British Medical Association could do this at a fraction of the

expenditure required of necessity by the Federation. In conformity with this decision of the Tuberculosis Society, Dr. Halliday Sutherland has resigned from the Executive Committee of the Federation.

WE announced recently that under the terms of an agreement between St. Mary's Hospital and the Paddington Board of Guardians the clinical material in the wards of the Paddington Infirmary (which during the war was used as a military hospital) will be made available for teaching the students of St. Mary's Hospital. The current number of *St. Mary's Hospital Gazette* states that a scheme of affiliation for teaching purposes has been concluded at the same time with the Paddington Green Children's Hospital and with the Hospital for Epilepsy and Paralysis and Other Diseases of the Nervous System, Maida Vale. Henceforward the out-patient departments and the wards of these special hospitals will be open to all students of St. Mary's. The lecturer on children's diseases will be permitted to make use of all the clinical material in the wards of Paddington Green for teaching purposes, and the lecturer on neurology will have similar privileges at Maida Vale. Further, the physicians and surgeons to these two hospitals will give clinical demonstrations to St. Mary's students in the wards and out-patient departments.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephoons, 2531, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephoons, 2530, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2534, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin.

QUERIES AND ANSWERS.

"PENSIONER" wants to hear of a dry, warm, climate within a week's sail of England, where he might conduct a small unopposed medical practice.

ERYSIPELAS.

"X. Y. Z." asks the following questions: (1) Is local or general treatment the more important in cases of erysipelas? (2) Is ichthyol superior to other local applications, and will it so employed cure all cases? (3) Has death resulted in cases in which ichthyol has been employed?

TREATMENT OF PROFUSE SWEATING IN THE AXILLÆ.

DR. W. CAMERON DAVIDSON (London) writes: I would suggest that "W. K. L." should try the effect of general treatment in the case of profuse axillary sweating as local treatment has proved ineffectual. The patient should be instructed to rub the skin of the body briskly all over with a rough towel night and morning, and to take two or three hot baths weekly at a temperature of 110° F. at least. An ordinary mild diuretic mixture can be given as well, but attention must be particularly directed to the hygiene of the patient's surroundings. I have treated a similar case recently in a young lady who was living in a house with central heating. The atmosphere was very unsuitable for this climate, and although she improved a little under treatment it was only when she moved to a different house—without central heating—that she became quite free from the sweating.

DR. D. M. MACDONALD (Arnside, Westmorland) writes to suggest the use of the constant current. He has used it for the axilla and also for the more common and distressful condition of hyperidrosis of the palms. It may occur in one hand only—generally the right one. A few applications suffice as a rule.

DUPUYTREN'S CONTRACTION.

"B. W."—Dupuytren's contraction is not one of the diseases scheduled under the Workmen's Compensation Act. Beathan is scheduled, but it is not to be confounded with Dupuytren's contraction. The Report of the Departmental Committee on Industrial Diseases, 1913, which gives full

particulars of the Committee's finding on this subject, and the Act itself, can be obtained from H.M. Stationery Office, Imperial House, Kingsway, London, W.C.2, or through any bookseller, price 1½d. and 3d. respectively (without postage).

INCOME TAX.

J. A." inquires as to expenses incurred in connexion with his appointment as M.O.H.

. The emoluments are assessable under Schedule E, and the expenses deductible must therefore have been incurred "wholly, exclusively, and necessarily in the performance of the duties of the office." In so far as it is a condition of his appointment that he should keep his professional knowledge abreast of modern research, it seems to us that the expense of purchasing the necessary books and periodicals should be allowed, though admittedly the word "exclusively" raises some difficulty. The cost of removal of our correspondent's household to his new residence is not admissible; that expense is not incurred "in the performance" of his duties, but is external and preliminary thereto (*see Cook v. Knott*).

LETTERS, NOTES, ETC.

THE editors of the *Medical Directory* ask us to state that by a clerical error the name of Dr. E. Hyla Greves, of Redney House, Bournemouth, was accidentally omitted from the current issue of that directory.

ABORTIFACIENTS AND PREVENTIVES.

DR. BARBARA G. R. CRAWFORD, M.B.E. (Mancol, Chester), writes: It is to be regretted that in your editorial in last week's issue on "The Sale and Advertisement of Abortifacients" you record without recantation the error committed in 1939 by the Association in supporting Lord Bray's bill (fortunately dropped), which endeavoured to make illegal the advertisement of drugs or articles designed for the prevention of conception, classifying them with abortifacients. As is well known, these are entirely different classes of articles; abortifacients are highly dangerous and their use is criminal, but preventives of conception are quite otherwise, and are used without harm by prudent and self-respecting persons. To anyone who, like myself, has seen the moral, physical, and economic degradation caused by excessive maternity among the poor, and how the lack of knowledge of preventive methods leads many a woman to the use of abortifacients, endangering her health and perhaps her life, the classification of preventives with abortifacients is not only regrettable, but gives weight to the allegation that in some matters the policy of the Association is out of touch with the hard realities of life.

A PIN IN THE ALIMENTARY CANAL.

DR. H. B. POPE (Leeds) writes: The case mentioned by Dr. Heywood Smith (January 1/11, p. 81) reminds me that whilst acting as medical officer at the Leeds Public Dispensary, probably early in 1914, a boy of about 5 years of age was brought to the casualty room as the state that he had swallowed a pin a short time previously. About four days later he complained of a sudden intermittent pain referred to the anus. A pin-like body could be felt in the rectum on examination, and was easily withdrawn by dressing forceps under nitrous oxide anaesthesia. It proved to be an ordinary pin, rather a long one, and blackened by its transit through the alimentary canal.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 45, 46, 47, 48 and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 43, 44, and 45.

THE following appointments of certifying factory surgeons are vacant: Broughton Astley (Leicester), Long Melford (Suffolk), Maidenhead (Berks), Sleaford (Yorks, West Riding), Shrewsbury (Salop), South Molton (Devon), Uphall (Linthgow).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under 0 6 0
Each additional line 0 0 9
Whole single column 4 0 0
Whole page 12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

An Address ON ATONY AND PROLAPSE OF THE LARGE INTESTINE.

DELIVERED TO THE MANCHESTER MEDICAL SOCIETY,
DECEMBER 3RD, 1919.

BY

J. W. SMITH, F.R.C.S., M.Ch.,

PROFESSOR OF SYSTEMATIC SURGERY, UNIVERSITY OF MANCHESTER;
PRESIDENT OF THE SOCIETY.

SEVEN years ago I described some experiences of this subject,¹ and in the sudden week of mobilization in August, 1914, I had arranged to see patients, operated on in 1912 and 1913, for the purpose of this paper. Military work shelved it until six months ago, but I am dealing here mainly with those cases. They group themselves into three chief types.

CLASSIFICATION.

1. Affecting caecum and ascending colon only, the "cesspool caecum." This may be the mobile caecum alone, or combined with an appendix lying behind the caecum, colon, or terminal ileum, adherent to the posterior abdominal wall, either in iliac fossa, or internal to it, behind the end of the mesentery, and constituting Sir Arbuthnot Lane's "controlling appendix."

2. Affecting proximal colon—that is, as far as the centre of the transverse colon.

3. Where the whole colon has slipped down, sometimes alone, sometimes accompanied to some extent by stomach, small bowel, and liver—the visceroptosis described first by Glenard in 1885, and known by his name.

4. A fourth rarer type consists of prolapse of the omega loop of the pelvic colon, with lengthening of its mesocolon, and occasionally an approximation of the bowel at the two ends of the loop by thickened bands of peritoneum across the mouth of the loop. I attribute prolapse of this loop to the weight of long-retained solid contents, though a slight kink of the bowel, originated by Lane's "last kink" may start or expedite it.

In considering these changes in the large intestine, it may be argued that their results are merely due to intestinal stasis or alimentary toxæmia, and should be considered under that heading, a subject discussed so fully at the societies and written about so freely during the years 1913 to 1915.² This is to some extent true, but Lane, I think, lays most stress on delay in the small intestine—stasis of the ileal effluent—as the essential factor in the causation of the clinical picture he has so graphically portrayed, with all the widespread and far-reaching results he attributes to it. The state of the patient, as I see it, in cases of delay in the large bowel, varies considerably from this picture. My experience agrees with that of Mr. C. H. Fagge,³ who in 1913 said:

We may divide cases of stasis into those which involve the lower ileum and often simulate and probably produce gastric and duodenal diseases, and those which affect the flexures of the colon; the latter, though peculiarly amenable to surgical treatment by short-circuiting, in many cases get along by the aid of medical treatment.

ANATOMICAL AND DEVELOPMENTAL CONDITIONS.

The original source of the prolapse, the distortion and angulation of the bowel, and the presence of the accessory bands, membranes, and adhesions so commonly found in these cases is, in my opinion, primarily developmental, and due to one of two main causes: either failure of union of certain peritoneal surfaces, which normally become indissolubly fused, leaving no sign afterwards that this has taken place; or persistence of certain peritoneal bands present during intrauterine life which usually disappear just before or after birth.

By reason of the migratory changes of position of the developing proximal colon, by the rotation of the U-loop of the hind-gut at the second month of fetal life and the anchorage of its anterior limb in front of the right kidney, by the subsequent descent of the caecum from that position about and after birth, it will be apparent that the right side of the peritoneal cavity must be especially liable to such developmental changes. Thus if the caecum and ascending colon fail to unite with the parietal peritoneum

of the posterior wall, the mobile caecum results; if previously, after the rotation of the U-loop of the bowel, the caecum fails to become securely anchored in front of the right kidney, there is afterwards no fixed point at the hepatic flexure, and thus the proximal colon will almost certainly be prolapsed during life; and if, finally, the attachment of the posterior limb of the U-loop to form the splenic flexure fails to be attained, the whole large intestine is proptosed, constituting the three types here classified. The last is, however, rare. I think the splenic flexure is the most generally fixed part of the intestine except the duodenal junction. During the last month I met with by far the most unusual duodenum I have ever seen. From the subhepatic pouch it passed down the right lumbar region, curved across the middle line between the third and fourth lumbar vertebrae, ascended vertically five inches to a ligamentous attachment to the root of the mesocolon, and then passed downwards rather acutely, though the jejunum distally for nearly three feet was as equally dilated and atonic as the duodenum, and gradually passed into a state of hypertonic contraction.

Jackson's membrane, a frequent accessory structure found in the right peritoneum, first described by J. N. Jackson of Kansas City in 1909,⁴ as caused by lymph stasis in pericolic tissue due to chronic infection from the lumen, is in close association with the ascending colon. After great diversity of opinion as to its origin, it is now, I think, pretty well accepted as a developmental structure, derived from a fold of the right edge of the great omentum, included in the adhesions which the ileo-caecal loop forms when rotated to the front of the right kidney, associated with persistence of the ascending mesocolon, and probably, in view of this, acting as a support to the ascending colon. This is the view of my colleague, John Morley, as the result of comprehensive investigations reported in 1913.⁵ He found this parieto-colic fold in 4 out of 36 fetuses at birth.

A month ago, operating on a case of general enteroptosis of the great bowel, I found a typical membrane, not confined to the right abdomen, but crossing the peritoneal cavity like a veil, and extending up to the attachment of the slipped splenic flexure and over the descending colon. I have never had this before, and have never seen it described.

Appendix.—I estimate that in 20 per cent. of all cases, but most commonly in Classes 1 and 2—prolapse of caecum or of proximal colon—the appendix is situated posteriorly, either retro-caecal or retro-colic, bound closely by adhesion, and frequently acutely kinked. This may be due to its being caught behind the caecum during the descent of the latter, or by its fixation under the end of the ileum by deficit in its mesentery, or by its inclusion in the bands so frequently formed in this region during intrauterine life—for example, the genito-mesenteric fold described by Douglas Reid,⁶ who says "that this fold is the commonest cause of the retro-colic position of the appendix. Its pressure on the adhesions it produces to the left of the caecum may arrest the completion of caecal torsion." An appendix so anchored would naturally undergo devitalizing changes, become kinked, and develop the signs of a chronic inflammation. But in addition I have always thought that an appendix originally free might, by reason of subacute infective inflammation, become thus fixed behind the caecum, and then, by distorting the axis of the caeco-colic junction forwards, initiate a bulge in the anterior wall of the ascending colon, developing into a localized proptosis, the typical "cesspool caecum" of Type I.

Lane's Band, determining the Typical Ileal Kink.—The congenital origin of this is upheld strongly in the excellent articles of Seton Pringle⁷ and Sir Henry Gray,⁸ published in 1914, where it is stated to be due either to the persistence of the genito-mesenteric fold or to excessive peritoneal fusion. More than once I have found this fold present in an abdomen opened for some reason quite independent of stasis.

Arthur Keith⁹ finds that accessory bands, once regarded as pathological, are present in at least 30 per cent. of newly-born children; but in colons removed by operation for stasis or colitis he has now no doubt that "adhesions are largely increased in number and extent by pathological states. Still, the chief adhesions, or the bands which have been regarded as the cause of obstruction or stasis are invariably found at the site of the embryological adhesions. In other words, pathological varieties are exaggerations of normal adhesions or bands."

Keith's work on the morphology, the anatomy and the functions of the normal colon, as well as the pathology of colonic stasis derived from minute investigation of specimens removed on that account, has shed new light upon the one, and given new conceptions of the origin and meaning of the other; for, as always, by sufficiency of knowledge of the normal will efficiency of treatment of the abnormal be evolved.

Causation.

In spite of the adhesions, accessory bands, the angulation and prolapse of the colon, my experience agrees with Keith's when he states that he has never yet obtained a single specimen which showed the usual signs of chronic obstruction—namely, marked constriction at the site of the adhesion with hypertrophy of the muscular coat of the intestine, which had to force its contents through the constriction. All the evidence points to stasis being due, not to mechanical obstruction, but to defect in the motor mechanism of the large intestine.

Excluding cases of long-continued colitis, I think all operators will agree that the bowel in stasis is not hypertrophied. It is dilated, with increased sacculcation and more or less kinking or distortion. Its wall looks thin and atonic. It is quite a familiar sight to see the proximal colon thus affected as far as about the centre of the transverse colon; and the change in the appearance of the gut in the distal colon from that point onwards gives strong support to the belief in the divided function of the colon, the proximal half for bacterial digestion, the distal for evacuation. It also tends to support Keith's conviction that—

In the great majority of cases which are classified under the somewhat elastic term of intestinal stasis the symptoms do not result from any atony of the musculature of the bowel, but from a hypertonicity of those parts which are normally in a state of chronic contraction, such tracts as the terminal part of the ileum, and all that part of the colon which lies between the mid-point of the transverse colon and the junction of the iliac with the pelvic colon. The x-ray and anatomical evidence is altogether against the theory which regards peritoneal bands and kinks as a cause of chronic obstruction of the bowel, and altogether in favour of a disordered action of the intestinal musculature.

Keith attributes the control of rhythmic action in the gastro-intestinal canal to nodal tissue, situated in the myenteric or Auerbach's plexus, containing certain cells muscular in origin, with processes directly united with nerve cells on one hand and muscular cells on the other, having a higher degree of excitability than ordinary muscle and providing centres at which contracting waves take origin. It resembles, he says, the traffic along a railroad track, divided into sections, each placed under a pacemaker. The traffic of one centre has to be regulated in relation to adjoining sections, and there must be signal-systems which can control and act as pacemakers or regulators of neighbouring centres. The gastro-intestinal tract has six sections, each with its chief centre of excitability at the beginning or proximal end—namely, gastric, including first part of duodenum, duodenal, jejuno-ileal, proximal-colic, distal-colic, and rectal.

A potent reflex action, inhibitory as well as acceleratory, between portions of the gastro-intestinal tract, particularly between ileo-caecal junction and stomach and duodenum, as noted by Moynihan, Lane, and others, is well established. It appears equally reasonable that hypertonycity of the distal colon should, by inhibiting the proximal colon, result in its atony, dilatation, and prolapse. It appears to me also that a frequent clinical sign, the causation of which has never been explained, is attributable to the same influence—namely, ballooning of the rectum, as an indication of an obstructive lesion in the distal colon, its adjacent section.

From the point of view of treatment of enteroptosis, one more point in the dynamics of the abdomen must be mentioned—namely, the present view that viscera are merely slung from, and not supported by, the mesenteries, but are controlled by support of the abdominal wall by automatic reflex action, as in standing, and that their ptosis is due, not to congenital or acquired bands, but to defective action of the abdominal musculature.

CLINICAL FEATURES.

Whilst it is thus undetermined whether stasis is the result of the different bands or adhesions, or the disturbance

of the neuro-muscular action of the alimentary tract; whilst our knowledge of the anatomy and physiology of that tract is so incomplete, and needs establishing by the working out of many complex problems; whilst the question of what constitutes intestinal stasis has never yet been accurately defined, or its exact relation to toxic absorption determined; whilst it appears to comprise so many affections of widely separated portions of the alimentary system, it is manifest that the symptoms displayed must also vary widely in different types of case. Confining our attention chiefly to the large intestine cases, some indications may, by the light of experience, be noted:

1. The majority of cases have the history of a distinct starting point. Quite often it has been a continued and severe attack of abdominal pain, usually right iliac or lumbar, with confinement to bed for two or three weeks. After subsidence the pain continues, more marked at intervals, which tend to become shorter. When the pain is right iliac the symptoms strongly suggest a subacute appendicular attack, without pyrexia, and doubtless this has actually been present in many cases. Sometimes the pain is right lumbar, in the subhepatic area. In such cases one suspects kinking at the hepatic flexure.

2. Much rarer is left iliac pain in cases of pelvic colon trouble. When such cases are sent for surgical advice there is usually a tender spot at the original site of pain. In the cecum splash is usual in the right semilunar line, above and outside McBurney's point, but below the level of the umbilicus. This may also be found on the left side in pelvic colon cases.

3. Constipation, though frequent, is not constant. In some cases it is lifelong, but more marked since the commencing or determining attack. Where there is a regular action of the bowels it may be suspected that the sacculi of the proximal colon are not efficiently emptied thereby; but constipation, as the patient understands it, must not be taken as a synonym for intestinal stasis.

4. Dull, aching abdominal pain and feeling of weight is very constant, either in the lower abdomen more marked to the right, or in the epigastrium. Its occurrence may or may not be associated with the taking of food, but it is often associated with the erect posture, and is then relieved by lying down, and often by manual support of the abdominal wall.

5. Gastric or duodenal trouble, sometimes with frequent vomiting, sometimes with epigastric pain after food; x ray indicates the actual condition. Whether it is due entirely to reflex action, or whether there is not also a mechanical factor by direct drag on the stomach and second part of the duodenum by the prolapsed and laden colon, is not yet determined.

6. Abdominal crises, such as accompany floating kidney, are associated with enteroptosis also, in my opinion.

7. Very marked pulsation of the epigastric aorta, sometimes visible pulsation, is frequent, as would be expected when the stomach is proptosed.

After some experience, paying attention to these points a diagnosis can generally be made. And yet I am confident that an individual with slipped bowel often passes through life without the troubles and signs of intestinal stasis. As such she may have minor troubles and be classed as a "neurotic abdomen"—a diagnosis now, with the advance of knowledge, becoming much rarer. Some determining factor appears to be necessary to constitute the signs of stasis. A distinct kink or partial torsion of the loosened bowel lasting some time, the effects of a pregnancy, some illness, or even a neurasthenic attack, supervening from general or nerve debility, may be sufficient to originate the disturbances in the bowel wall, from which it never recovers, but lapses into chronic stasis.

TREATMENT.

It will be apparent that practically all cases, when they come to my notice, are, by reason of some determining attack, with subsequent failure of compensation, or by long continuance of gradually advancing symptoms, likely to be benefited only by surgical interference. But it is essential that it should be widely recognized that in the great majority of cases, especially in their early stages, medical treatment alone is needed, and that very frequently, if carried out carefully and continuously, it effects either a cure or such amelioration as to render life comfortable and useful. This lies in the province of the family

medical man; hence the necessity of his keeping stasis always in his mental vision. In view of the reflex action of the muscles of the abdominal wall in supporting the abdominal viscera, the advisability of abdominal exercises to improve their strength and tone will be grasped. In cases where the lax abdominal wall and the prominence of the lower abdominal region show that enteroptosis is already present, whether progressive or due to constitutional growth, as shown by the typical thin, sallow-complexioned, long, narrow-chested condition, the "habitus enteropticus," support from a proper abdominal belt must be sought, and the compression of the lower chest wall by corsets forbidden.

To promote passage in the large intestine, paraffin is a sheet-anchor as a lubricant and to prevent the formation of faecal masses in the sacculi, which weigh down the bowel and drag on the stomach and duodenum. But paraffin, whilst a lubricant, is not a laxative. For this, in cases after resective operations on the bowel, I mostly employ small nightly doses of castor-oil, 1 drachm more or less, as found necessary, the essential being its exhibition regularly every twenty-four hours. Cascara will also serve, and I think Parke, Davis's "cascara evacuant" is the best form available.

Surgical Treatment.

In 1912-13 I operated on 32 cases, 2 of which were fatal. To ascertain "end-results" I have communicated with the remainder, and have reports from about 26.

Class 1.—An appendix, posterior, kinked and adherent, should be removed. If accompanied by the typical ileal kink, this should be freed by division of the underlying sickle band and peritonization of the surface thus divided. If the caeco-colon is markedly "cesspool," it must be dealt with by caecoplication, narrowing the lumen by invagination of the wall between the anterior and outer taeniae.¹⁰ Alternative methods are Coffey's colopexy,¹¹ anchoring the bowel to the parietal peritoneum, or Wilm's caecopexy, fixation of the caecum to the iliac fossa. I report 5 cases of this type, 4 completely successful. One was well, and working at munitions for four years. Symptoms then recurred, and six months ago I performed a successful hemicolectomy. In cases where a greater extent of colon is involved, or where, by long duration, the condition of the patient is worse, the choice of operation lies between short-circuiting by ileo-colostomy, hemicolectomy, and colectomy.

Class 2, Prolapse of Proximal Colon.—I favour hemicolectomy, and it was done in 12 cases now reported. One died on the sixth day of leakage from the suture, 3 have returned to good health, 8 are improved, 3 of which have only to be careful of diet because of gastric trouble, and one complicated by chest trouble is only slightly improved. During the last six months, since I was set free from military duty, I have been uniting the bowel by end-to-end anastomosis instead of lateral, as in the cases here noticed done before 1914, and I think future results will be notably better, as displayed in three patients shown at the clinical meeting a fortnight ago.

Hemicolectomy appears to me a sound procedure, having regard to the evacuatory function of the distal colon, and because in this type of prolapse the terminal ileum and the centre of the transverse colon will always be found on operation lying parallel and adjacent to one another, as though Nature were indicating the site for resection of the gut. If, by prolapse of the proximal half of the transverse colon, its course has become nearly vertical in the abdomen, with a sharp angle at the splenic flexure, or if the pelvic mesocolon is short and shows signs of a mesosigmoid band, I should do an ileo-colostomy or a complete colectomy instead. The choice between these two must be decided in each case and is not always easy to make. Some weeks ago, in a case of completely slipped proximal colon, where the whole distal colon was closely bound down to the parietes and the iliac fossa, and where the lower pelvic colon appeared too adherent to afford a satisfactory ileo-colostomy junction except when freed by dissection, I decided against this and performed the colectomy. Sir Arbuthnot Lane says "the ease of this depends on the operator's familiarity with the development and arrangement of acquired bands, particularly these controlling the splenic flexure." I think I have a fair knowledge of these, and did my best to apply it in

this case; but the separation of the distal colon proved most trying and took considerable time, and though no great amount of blood was lost, death from shock took place in three hours. There were no acquired bands, except at the splenic flexure and the pelvic mesocolon, and yet the freeing of the descending and iliac colon was difficult. Should I meet with another case like this I shall trust to short-circuiting, especially as in the contracted state of the distal colon any reflux of bowel contents into it from the anastomosis would be most unlikely. This reflux militates most strongly against ileo-colostomy in the opinion of some surgeons. The crux of the operation seems to me to consist in the making the site of the anastomosis in the pelvic colon as low down as possible. Of the cases here noted, 7 were ileo-colostomy; 4 have completely recovered, 2 are much better, and one is no better.

Colectomy.—In the present imperfect state of our knowledge of the functions of the large intestine and the mechanism of stasis in it, there is no doubt that in advanced cases where its whole course is proptosed or shows kinking at various scattered points, colectomy is the ideal remedy. In most cases it is a surprisingly easy operation, and is followed by no dangerous shock. In its technique I follow the course detailed by Lane, evolved by his long and extensive experience. Three colectomies are included in the present list.

1. Female, aged 56, admitted for intestinal obstruction, with extreme prolapse, died on the third day from cardiac failure.
2. E. B., female, aged 23; duration eight years; prominent symptoms vomiting and constipation. For two years before operation was too weak to stand or walk. Operation June 10th, 1912. The stomach was dilated and dragged down by distended and prolapsed colon; appendix bound down and showing the V-shaped kink. The ileum 6 in. from its termination was united to the pelvic colon by lateral anastomosis, and all the intervening bowel excised. The patient writes last week: "I am pleased to say the operation you performed has been very successful. I keep well in health, not exactly robust, but have been working as a glove-machinist for the last three years."
3. Mrs. E. W., aged 42, duration twenty years, following birth of her only child; uterine prolapse, haemorrhoids, severe constipation and constant vomiting. During the two previous years she had had, in hospital elsewhere, four operations—namely, removal of piles; double oöphorectomy; ventrofixation of uterus; nephrorrhaphy of left kidney. Pain and constipation were even worse afterwards. Vomits several times a day, frequent blood in vomit. She had been confined to bed, had attempted her life, and on arrival in hospital was very weak, worn, and depressed. An operation was performed on November 2nd, 1912. The stomach could be pulled outside the skin level below the umbilicus, and the large intestine was much prolapsed. Lateral anastomosis between the ileum and the pelvic colon just above the rectum was performed, and then, as the patient's general condition warranted it, the colon was excised. She left hospital on the twenty-third day afterwards. She attended the clinical meeting of a fortnight ago, saying she is better now than ever before in her life, can eat anything, and has never taken a laxative since her operation. She started work six months afterwards, has worked in a cotton-mill, and is now dividing the day between cleaning offices and her own housework.

Cases like these prove the present value and status of colectomy. Whether, with the advance of knowledge—from the proposed research schools of applied anatomy and physiology—it will retain this position, is a question of the future.

THE Ministry of Social Welfare, Belgrade, has invited the Committee of the Serbian Relief Fund, London, to organize and operate the bulk of their institutions for disabled and invalid Serbian soldiers, of whom there are between 175,000 and 200,000 in Yugo-Slavia. The English staff will work in close co-operation with the Serbian Government, and orthopaedic hospitals, tuberculosis sanatoriums, workshops, and agricultural schools will be established. A formal acceptance of the offer of the Ministry of Social Welfare to undertake this responsibility is being conveyed by Major Hardwicke, Director of the Serbian Relief Fund in Serbia.

The Lettsomian Lectures

ON

TUMOURS COMPLICATING PREGNANCY,
LABOUR, AND THE PUERPERIUM.

DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON,

BY

HERBERT R. SPENCER, M.D., B.S., F.R.C.P.,
OBSTETRIC PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

(Abstract.)

LECTURE II.—OVARIAN TUMOUR COMPLICATING
PREGNANCY, LABOUR, AND PUERPERIUM.

THE lecturer presented an elaborate table, which we are unable to reproduce, giving particulars of 55 ovariectomies for ovarian tumour complicating pregnancy, labour, and the puerperium; it comprised all the cases he had seen with two exceptions. One of these was that of a woman, referred to below, who died on the third day of the puerperium owing to rupture of a very large cyst; the other was that of a lady with an ovarian tumour as big as a lemon, who had been delivered in 1918 of a living child, and who, as the tumour caused no inconvenience, did not wish to be operated upon. The ages of the 55 patients varied from 20 to 43, the average age being 30. Nine patients were nulliparæ at the time the ovarian tumour was present, nine had had five or more children, one had had nine, and three ten. Altogether the 55 patients had had 150 children, an average of nearly three, before the tumours were removed.

ABORTION.

Information as to occurrence of abortion was not noted in 7 cases; the remaining 48 women had had 125 children and 33 abortions. The proportion of abortions to pregnancies was therefore 26.5 per cent.

Of the 55 cases, 40 were not operated on during pregnancy and 15 were. In only 5 of those not operated on during pregnancy, or 12.5 per cent., did abortion occur in the pregnancy preceding the ovariectomy. The rate may have been lower, as the notes leave a doubt about the date of the abortion in one case. In 5 out of 6 cases in which both ovaries were affected abortion did not occur; in the sixth case the notes leave the matter in doubt.

Of the 15 cases operated on during pregnancy 4 aborted (26.6 per cent.).

One had bilateral dermoids removed at the twelfth week; one had bilateral fibroids removed at the fifth week of pregnancy; another had hæmorrhage before the operation at the thirteenth week, when a large multilocular cyst was removed; the patient passed a mole twenty-seven days afterwards. The fourth had an acute twist of the pedicle of a parovarian cyst with hæmorrhage into the broad ligament; the tumour was removed at the thirteenth week of pregnancy two hours after the twist occurred.

In 10 of the 15 cases operated on (66.6 per cent.) the pregnancy continued and living children were born, but one died shortly after. As 3 of the patients were operated on at term, when the question of abortion does not arise, the true abortion rate for patients operated on before the child is viable is in this series 4 out of 12 cases (33.3 per cent.).

NATURE OF TUMOUR.

The tumour was cystadenomatous in 33 cases (60 per cent.), dermoid in 15 (27.2 per cent.), ovarian fibroid in 3 (5.4 per cent.), and "parovarian" in 6 (10.9 per cent.). Torsion of the pedicle was found 12 times in cystadenomatous tumours, 5 times in dermoid tumours, and once among the "parovarian" tumours, a total of 18 (32.7 per cent.).

Cystadenomatous Tumours.

Of the 33 cystadenomatous tumours 22 were multilocular (in 2 cases papillomatous); 11 of the unilocular tumours may originally have been multilocular. The cystadenomatous tumours were mostly of large size; 3 had ruptured, as noted below. A few were small. The two papillomatous tumours were also multilocular. One case was complicated with hydrosalpinx and another with pyosalpinx and ovarian abscess.

Dermoid Tumours.

Most of the dermoid tumours were small, not more than 10 to 12 cm. in their greatest diameter; the exceptions were a

tumour which contained three pints of pus, another which was as big as an adult head, a third which measured 16 cm. in its longest diameter, and a fourth which was as big as the pregnant uterus at the sixth month, and contained pill-like balls of fat. In 2 of the cases tumours were removed on both sides, and in another a dermoid had been removed from the opposite side thirteen years previously. Thus 20 per cent. of the dermoids were bilateral.

Ovarian Fibroids.

In one case the tumour was small and contained pus; in another it was calcified, weighed 1 lb. 8 oz., blocked the pelvis, and was mistaken for a uterine fibroid before the operation; in the third case the tumours were bilateral—the right tumour weighed 3 lb. 8 oz. and was removed with the rest of the ovary; the left, 1 in. in diameter, was excised and the remains of the ovary stitched up. The patient had a living child in the following year.

"Parovarian" Tumours.

All the parovarian tumours except one, which contained ten pints, were of small size. In one case a subfimbrial cyst on the left side was associated with an ovarian cyst on the right. In only one case (the only case in which the pedicle was twisted) was the corresponding ovary removed.

Rupture of the Cyst.

Rupture of the tumour occurred in 3 cases (5.4 per cent.).

In one of these cases the rupture probably occurred at labour; the tumour was removed a month later. Another had been tapped at a lying-in hospital to relieve pressure; the tumour was removed during labour. The other case was admitted during labour with much free fluid in the abdomen. The cyst was removed twelve hours after labour, and was found, as expected, to be ruptured, but holding 2 gallons of bloody fluid, some of which had escaped into the peritoneum. All these tumours were very large multilocular cysts. The largest ruptured ovarian tumour met with by the lecturer contained 31 pints of fluid. It burst on the third day after an easy labour. The patient had been advised, both before and during pregnancy, to have the tumour removed, but refused. She had been progressing favourably, but when the cyst ruptured became collapsed and was removed in an ambulance to hospital, but died of syncope immediately after her admission. The wall of the cyst was very thin, and looked as if it had been stretched.

Suppuration of the Cyst.

The tumour suppurred in 8 cases; in all the suppuration occurred after delivery.

In one case the tumour contained 2 gallons of fetid pus, and the patient was very emaciated and feverish; in another there were 15 pints of pus. In another case the patient had been delivered with forceps (the child dying on the third day), and the tumour had been tapped twice, 10 pints of pus being evacuated. In another case the child was delivered (dead) with forceps, and the tumour contained 26 oz. of pus. In one case the tumour was small and did not become evident till the uterus had involuted; in another it was complicated with an ovarian abscess and pyosalpinx on the other side. The pedicle was twisted in one case.

Six of the suppurating tumours were cystadenomatous, one was a dermoid; the infection in this case probably was caused by the tapping. The supposed proneness of dermoids to suppurate is due to an error of observation; the liquid fat at the temperature of the body looks very like pus to the naked eye. Examination with the microscope shows its nature. Dermoids very rarely suppurate. They are no doubt more prone to it as a result of labour, owing to the risk of injury when they are in the pelvis. Out of 59 dermoid tumours removed Dr. Spencer only met with suppuration in two cases besides the case mentioned above, and in one of them the tumour communicated with the sigmoid flexure of the colon.

Seat and Position of the Tumour.

The tumour was situated in the right ovary in 23 cases, in the left ovary in 18 cases, in both ovaries in 8 cases, in the right parovarium in 4 cases, in the left parovarium in 1 case, in the left parovarium and in the right ovary in 1 case.

The tumour was incarcerated in the pelvis in 5 cases. In 1 case the tumour was mistaken for a uterine fibroid, Caesarean section was performed, with a successful result to the mother and child. In the other 4, which were all dermoids, the value of treating the obstructing tumour either by pushing it up out of the pelvis or removing it by operation was illustrated. The danger of delivering the child while an ovarian tumour is in the pelvis is illustrated by a specimen exhibited before the Obstetrical Society in 1898, which showed rupture during version after an attempt at delivery by forceps, with a fatal result to the mother.

During the course of labour, the reposition of the tumour is facilitated by putting the patient in the Trendelenburg position under chloroform anaesthesia, a procedure which should always be tried before resorting to abdominal

* Delivered February 16th. The valuable table to which reference is made will be published, with the full text of the lectures, in the *Transactions of the Medical Society of London*.

section. If it is found to be impossible to push up the tumour, the uterus should be withdrawn from the abdomen through a 6-inch incision, which is quite long enough if the uterus be brought out cornerwise. If the child be in good condition the tumours may be removed, and the child delivered by forceps; but if the child's heart sounds are slowed or weak, the child should be delivered as soon as the tumour has been pulled out of the pelvis, and before it is removed; thus the child will be spared some minutes of anaesthesia. It is of great importance that the cervical canal should be dilated before operation for the removal of the tumour, otherwise it may be necessary, after removing the tumour, to close the abdomen, which is done with difficulty, owing to the tension of the abdominal wall. In delivering the child at the end of the first stage it is not necessary to replace the uterus in the abdomen; the forceps may be applied (if possible by a second operator) while the uterus lies on the abdominal wall. If the cervical canal is not dilated, the tumour should be pushed up with the patient in the Trendelenburg position, and removed at a later stage of labour or after delivery.

Adhesions.

Adhesions were found in 26 cases (47.2 per cent.). All the suppurating cases were adherent. Dermoid tumours in which the pedicle was not twisted were free from adhesions except in two instances.

GROWTH OF THE TUMOUR DURING PREGNANCY OR PUERPERIUM.

There does not appear to be any evidence in the cases observed of specially rapid growth of the tumour during pregnancy. Fifteen (27.2 per cent.) of the tumours were dermoids, which usually grow slowly, and do not attain a size which enables the growth to be easily observed, at least by the patient. In one case the left-side dermoid grew in three months from the (estimated) size of a hen's egg to a size of 8.5×7.5×6 cm.; in another the dermoid tumour, at the third month of pregnancy of the size of a hen's egg, measured 16×10×8.7 cm. nine months later. It must be remembered that the growth of ovarian tumours, apart from pregnancy, is often rapid. In one case the growth was sudden and rapid, and the cyst ruptured during labour; it contained 2 gallons of bloody fluid, and was removed twelve hours after delivery. In another case the tumour grew so fast that it had been tapped in a lying-in hospital to relieve pressure. These cases of rapid growth are, however, exceptional, and on the whole it appears that pregnancy exercises no special influence in increasing the rate of growth, the evidence pointing usually in the opposite direction. In the puerperium there seems to be a greater tendency to a rapid growth.

In one instance, however, the tumour diminished greatly during ten weeks' observation in the hospital; the patient was also suffering from pleural effusion, of tuberculous origin. A large suppurating ovarian cyst, extending high up into the abdomen, gradually got smaller, until, at the time of its removal, it was of the size of a fist. At the operation adhesions to the omentum, abdominal wall, and intestines were found to encapsulate the tumour, and no doubt the vessels in these adhesions had absorbed some of the fluid in the cyst, thus leading to the remarkable reduction in size. The patient recovered well from the operation, and slowly recovered from the pulmonary phthisis, and was examined by me and found to be in fairly good health twenty-seven years later.

THE RESULTS OF OVIARTOMY.

Of the 55 patients submitted to ovariectomy, one died.

In this fatal case the tumour was a dermoid. The patient had been delivered eight months before the operation. She had noticed abdominal pain five months after the confinement. There were no adhesions. The pedicle was not twisted at the time of the operation, but the Fallopian tube was almost divided, possibly as the result of a twist which had become undone. After the operation intestinal obstruction was caused by the adhesion of a coil of small intestine to the stump of the ovariectomy pedicle. The abdomen was opened and the coil separated, but the patient succumbed.

Ovariectomy during Pregnancy.

Of the fifteen ovariectomies during pregnancy twelve were performed during the first half, two were operated upon during labour, and one immediately after Caesarean section at term. In two labour was induced on account of contracted pelvis. All the mothers recovered.

The children (in one case twins) were born alive in 11 cases, but one of the children died soon after birth;

4 patients aborted; thus, in 5 out of 15 cases the child was lost; thus the mortality rate for the children was 33.3 per cent.; the abortion rate was 26.6 per cent., or, more correctly, 33.3 per cent. (see *ante*). In four other cases seen by the lecturer during pregnancy, and operated on, the mothers recovered and the children survived.

Thus, of the 19 cases seen during pregnancy, all the mothers recovered; and in 15 the children were born alive and in 14 survived, the mortality rate of the children being 26.3 per cent., the abortion rate 21.5 per cent.

The Operation.

The ovariectomy incision was made in or near the middle line, usually through the inner edge of the left rectus muscle. In two cases the transverse Pfannenstiel incision was made: it lessens the exposure of the intestine and the risk of hernia subsequently, but may entail more manipulation; it is only exceptionally suitable for cases operated on during pregnancy. Silk was used exclusively for ligatures and buried sutures. Drainage was employed in three cases. The pedicle was tied with interlocking silk ligatures and stitched over with fine silk. In the later cases isolated ligatures were also placed on the ovarian artery, as first practised by Burd in 1846. The advisability of this practice is shown by Laroyenne's case¹:

The patient died in the second month of pregnancy from haemorrhage from slipping of the ordinary ligature applied at an ovariectomy three months previously; at the autopsy the two ends of the artery were found gaping, the growing uterus having displaced the ligature by stretching the broad ligament.

Fehling² also lost a patient from the same cause; the labour pains, which began on the day following an abdominal ovariectomy near term, after two hours caused the ligature to slip and led to intraperitoneal haemorrhage, for which the abdomen was opened and the pedicle again tied, but too late to save the patient.

Cases of Ovarian Tumour not Operated on.

In the 40 cases not operated on during pregnancy all the mothers recovered from the labour or abortion. In 29 cases (out of 37 in which the fate of the child is given) the child was born alive; in 4 cases the child died as a result of difficult delivery by forceps or version. In 4 (possibly in 5) out of the 40 cases abortion occurred. The mortality rate for the children is 8 out of 37 = 21.6 per cent. The abortion rate is 10 per cent., or possibly 12.5 per cent. (see *ante*).

Etiology of Malignant Change.

The question of the influence of pregnancy in causing malignant changes in ovarian tumours was discussed by Sir John Williams in his Cavendish Lecture. He showed that there was no evidence of such influence. In support of this opinion is the fact that malignant ovarian tumours are rarely found in pregnancy; in my 55 cases there was not an instance, whereas, apart from pregnancy, malignancy is met with in more than 20 per cent. of ovarian tumours. It is noteworthy that in advanced age, in women over 70 years of age, malignant ovarian tumours are also rare. What the cause of this rarity is cannot at present be stated.

After full consideration of the view expressed by Sir John Williams that sterility favoured the production of ovarian tumour, the lecturer expressed the opinion that the evidence was inconclusive, and that the question could not be settled until the frequency of ovarian tumours in large numbers of virgins was known.

SYMPTOMS.

Many patients with an ovarian tumour go through pregnancy without any symptoms arising from its presence, if it is small and does not block the pelvis or become twisted or inflamed. The only way in which such tumours can be diagnosed is by routine examination of the abdomen and pelvis during pregnancy, which ought to be carried out in every case. In advanced pregnancy it is important to examine the lumbar regions, as small tumours may easily escape notice or may be mistaken for renal tumours. Large tumours give rise to feelings of weight and pressure.

If the tumour becomes inflamed or strangulated by twisting of its pedicle, the symptoms are acute and may closely simulate strangulation or necrobiosis of a fibroid, acute appendicitis, or pyonephrosis. The symptoms of rupture will depend upon the nature of the contents; in some cases the accident scarcely gives rise to any other effect than alteration in the shape of the abdomen from

the peritoneal effusion; in others shock, pain, and vomiting ensue. Malignant tumours are fortunately rare; they may cause emaciation and cachexia, and are usually painful, though in some cases there are no symptoms which suggest malignant disease.

DIAGNOSIS.

The diagnosis of pregnancy complicated with ovarian tumour is usually not difficult. In some cases of early pregnancy, where the ovarian tumour is large or adherent, it may be difficult to make out the shape and consistence of the uterus. But in all cases where menstruation is delayed pregnancy should be suspected, and the colour of the vagina, the consistence of the uterus, and the appearance of the breasts should be investigated; the presence of morning vomiting may help in the diagnosis. In the early months the increased width of the uterus may be made out by examining the patient bimanually in the dorsal position with the fore and middle fingers of the right hand on each side of the cervix. In conducting this examination the greatest gentleness should be used; any forcible pressure may easily separate the ovum, an objection which applies to the so-called "Hegar's sign." In the second half of pregnancy the "certain signs" (heart sounds, parts or movements of the child, and ballottement), the contraction of the uterus and the breast changes, usually render the diagnosis of pregnancy easy if care is employed; but hydramnios may render the detection of the fetus difficult even when the patient is placed in the kneeling position, which, causing the fetus to fall to the most dependent part of the abdomen, renders its detection by ballottement easier. It is important to bear in mind the softness of the supravaginal cervix—the physical condition which enables Hegar's sign to be obtained—which may cause the body to be apparently separate from the cervix, and may therefore be mistaken for an ovarian tumour. Occasionally a lop-sided pregnant uterus is met with, which I have known taken for an extrauterine tumour. If the uterus is very thin-walled—and sometimes it feels as thin as an ovarian cyst—the body, or a bulging portion of it, may be mistaken for an ovarian cyst if careless examination is made. Error is avoided by careful bimanual examination in the dorsal position, when under gentle manipulation the uterus will be felt to contract, to become one with the cervix and regular in shape.

In some cases of ectopic pregnancy a doubt may exist as to whether the enlarged uterus is pregnant or not and the tubal swelling is a mole, a haematocoele, or an ovarian cyst; but the haemorrhage which usually occurs in these cases will lead to an exploration of the uterus, which is found to be unimpregnated. The rare coexistence of intrauterine and extrauterine pregnancy must be borne in mind.

The recognition of the ovarian tumour is usually easy, as it ordinarily forms a cystic tumour movable apart from the uterus, on a pedicle which can sometimes be detected under anaesthesia. If the tumour is small it may easily escape notice in the lumbar region or may be mistaken for a tumour of the kidney or gall bladder. Examination under anaesthesia facilitates the diagnosis in these cases. If the tumour is twisted and inflamed it sometimes closely simulates a necrotic or strangulated uterine fibroid. Under an anaesthetic its cystic character can usually be made out. Tumours of small size impacted in the pelvis often feel as hard as uterine fibroids, for which they may be mistaken. Rectal examination is of great value in these cases. It must be remembered that uterine fibroids may be as cystic as ovarian tumours, and, on the other hand, ovarian tumours may be solid and are often associated with hydroperitoneum, which is rarely found with uterine fibroids. In some cases the diagnosis cannot be made between these two conditions with certainty, though in a patient under 25 a uterine tumour is very unlikely to occur.

If the tumour be ruptured the symptoms will depend upon the nature of its contents. In some cases the accident is followed by few symptoms; in others, shock, pain, vomiting, and peritonitis rapidly ensue. If the tumour be multilocular the unruptured portion of the cyst can be felt, and there are signs of free fluid in the abdomen. If the cyst be unilocular the only sign is the presence of free fluid in the peritoneum, which should always be suspected to be due to a ruptured cyst if there are no renal, hepatic, or cardiac causes present.

Suppuration of ovarian cysts is indicated by high fever, wasting, tenderness, and occasionally tympanites; a history of tapping or injury during labour is often obtained. Twisted tumours usually give rise to local peritonitis, and to fever, which usually subsides after a few days; a considerable rise of temperature, lasting some days after the acute peritonitis has subsided, will usually indicate that suppuration has taken place.

Malignant ovarian tumours are fortunately rare during pregnancy. They are usually solid, bilateral, and associated with hydroperitoneum and wasting; secondary nodules may be felt in the abdomen and in Douglas's pouch.

TREATMENT.

The treatment of ovarian tumours apart from pregnancy is generally acknowledged to be removal as soon as practicable. When pregnancy exists the matter is not so simple; the interests of the child and the desirability of maintaining the fertility of the mother may justify a postponement of the operation. In the introductory remarks a case was mentioned where this was done. In another patient, from whom a dermoid was removed before the occurrence of pregnancy, the other ovary was found to be cystic, but was not removed, as the patient was childless, with the result that in this case also the patient has since had a living child.

On the other hand, in another case the patient, pregnant for the first time, was operated on for bilateral dermoids at the twelfth week, aborted, and has, of course, remained childless. The tumours were causing no trouble, and were discovered during an examination on account of sterility a few months previously. Had the operation been postponed, in all probability she would have had a child; as it was, she aborted as a result of the operation.

I should like again to direct attention to the results to the child in this series, according as the operation was performed during pregnancy or after delivery. In cases operated on the infantile mortality was 33.3 per cent., the abortion rate 26.6 (or 35.3 per cent. of the cases operated on in "early pregnancy"). In those not operated upon during pregnancy (although sometimes unskillfully treated during labour) the infantile mortality was only 21.6 per cent., and might have been reduced to 10.8 by more skilful treatment during labour; the abortion rate was 10 to 12.5 per cent. Five at least (possibly all) of the six cases of bilateral ovarian tumours unoperated on during pregnancy did not abort; both the cases of bilateral ovariectomy during pregnancy aborted. From these figures it appears that operation during pregnancy involves an increased risk to the child.

The statistics, based on published cases, in McKerron's classical work show that the risk of abortion is least in the early months of pregnancy.

Although the risk to the child of operation during pregnancy should be taken in most cases to prevent the grave consequences which may result to the mother from leaving the tumour till the end of pregnancy, yet in uncomplicated cases of small tumours giving rise to no symptoms in patients who are childless, and particularly when bilateral tumours are present, the operation should be postponed, at least until the child is viable.

The treatment of ovarian tumours complicating pregnancy, labour, and the puerperium has been by some writers considered too much from a surgical standpoint; the obstetrical aspect is not less important and in some cases is the dominant factor. Amongst the nineteen cases which I have personally treated during pregnancy there were three cases of contracted pelvis which necessitated induction of premature labour in two of the cases, and would have done so in the third had the patient not aborted. It is clear that a contracted pelvis may profoundly modify our treatment, and that an obstetric examination of the pelvis should be carefully made in every case. Then the existence of bilateral tumours in patients who have not had children may justify the postponement of the operation in the hope of obtaining a living child, and should lead us whenever possible to conserve some part of the ovary.

SCHEME OF TREATMENT.

The following scheme of treatment was published in 1909 in the *Transactions of the American Gynecological Society*. As I have not seen any reason for modifying it,

A. *During the First Half of Pregnancy.*

Ovarian tumours should be removed wherever their situation and whatever their size.

Exceptions.—The following tumours should not usually be removed:

1. Lutein cysts complicating hydatidiform mole; these often subside spontaneously.
2. Bilateral tumours causing no symptoms, if the patient is childless; or, if operated on, part of an ovary should be left behind.
3. Primary adherent malignant cysts.
4. Secondary malignant cysts.

B. *During the Second Half of Pregnancy.*

(a) All large ovarian tumours and ruptured, inflamed, and strangulated tumours should be immediately removed.

(b) Small tumours which are in the abdomen or which can be easily pushed up out of the pelvis in the knee-chest or Trendelenburg position should be watched, and if no untoward symptoms arise should be removed either at the end of pregnancy, or towards the end of the first stage of labour, or after delivery.

(c) Small tumours which are incarcerated in the pelvis and cannot easily be replaced in the abdomen may be watched and removed at the end of pregnancy, or, if circumstances will allow, towards the end of the first stage of labour. If the tumours are adherent or solid Caesarean section should be performed.

In all ovariectomies during pregnancy the vessels of the pedicle should be separately tied; the pedicle should be ligatured as far as possible from the uterus, and morphine should be given for the first two or three days after operation.

C. *During Labour.*

The best treatment is abdominal ovariectomy, immediate in the case of large tumours, at the end of the first stage or after delivery in the case of small tumours. When the operation is performed at the end of the first stage a second operator may deliver the child by forceps while the tumour is being removed. If the tumour be incarcerated in the pelvis and cannot be pushed up in the Trendelenburg position, the uterus should be withdrawn from the abdomen in order that the tumour may be dealt with.

For solid and adherent tumours occupying the pelvis Caesarean section may be necessary. It should not be performed for cystic non-adherent tumours. When labour is advanced and a cystic tumour is impacted in the pelvis, the circumstances may render it advisable to deliver the patient by the natural passages after evacuating the contents of the tumour by incision and packing the cyst with gauze, but the tumour should, if practicable, be removed within twenty-four hours, preferably through an abdominal incision.

Vaginal ovariectomy may be performed in non-adherent cases; but, though simpler in technique, avoiding an abdominal scar, and requiring fewer instruments, it is inferior to the abdominal operation in that there is greater danger from haemorrhage, difficulty in safely tying the pedicle, the necessity of cutting up the tumour, the impossibility of examining the other ovary, and from the presence of the vaginal wound.

Induction of premature labour, forceps, version, and simple tapping of a cyst, as means of overcoming the dystocia produced by ovarian tumour, are absolutely contraindicated.

D. *In the Puerperium.*

Ovarian tumours should be removed as soon as practicable, when possible within twenty-four hours of delivery. If there is doubt as to the aseptic condition of the uterus, a delay of a week or two may be advisable, unless indications of strangulation or infection of the tumour arise, when the tumour should be immediately removed.

Part of the money will be used to build in Washington a home for the two organizations, and the remainder will be placed in the hands of the academy for the permanent endowment of the National Research Council.

THE EFFECTS OF DEFICIENT DIETARIES
ON MONKEYS.

BY

ROBERT McCARRISON, M.D., D.Sc., F.R.C.P., LL.D.,

BREVET LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.
(Pasteur Institute of S. India, Coonoor.)

(Abstract.*)

I.—EFFECTS ON GASTRO-INTESTINAL TRACT.

The experiments recorded were made on monkeys (*Macacus sinicus*) captured from the local jungles. Ten were fed on autoclaved rice, and four on autoclaved rice plus butter. Twelve monkeys, fed on rice, bananas, monkey-nuts, milk, onions, and bread, served as controls. The rice (milled) was autoclaved at a temperature of 130° C. for an hour and a half.

An exclusive diet of rice so autoclaved may be considered to be wholly deprived of accessory food factors of all three classes; it is excessively rich in starch and deficient in proteins, fats, and salts. A dietary of autoclaved rice plus butter is lacking in accessory food factors of the "B" and "C" classes, while it is ill balanced with respect to proteins, carbohydrates, and salts. The results of these experiments on monkeys confirm those previously recorded in the case of pigeons¹ fed on similar food. They may be considered as applicable in kind, if not in degree, to human beings subsisting, as frequently happens, on food similar in composition to that on which the monkeys were fed.

Loss of Body Weight.

Monkeys fed exclusively on autoclaved rice lost weight at the average rate of 18 grams a day. Those fed on autoclaved rice plus butter lost weight twice as rapidly—37.5 grams a day. As the animals were not weighed daily but only at the commencement and at the end of the experiment the averages given are approximate. It is probable that the loss of weight was much more rapid towards the close of the experiment than during its earlier days. The monkeys which received butter died much more rapidly than those which received no butter—the former in an average of fifteen days, the latter in an average of 23.4 days. The sex of the animal appears to have influenced the results to some extent, but the figures are too small to justify definite conclusions on this point.

No observations were made with regard to body temperature and respirations, as the monkeys were too wild to handle. In addition to loss of body weight, the main clinical evidences of disease exhibited by the animals were: progressive anaemia, gastro-intestinal disorders, and progressive asthenia ending in death. No clinical evidences of polyneuritis or of oedema were observed in any.

CLINICAL EVIDENCES OF GASTRO-INTESTINAL DISORDER.

Loss of appetite was mainly due to loathing for the food, accentuated by the gastro-intestinal derangements resulting from the deficient diet. The symptom is an important effect of "vitaminic" deficiency.

Vomiting was observed in four cases. The symptom did not persist for more than two days; the animals so affected refused all food and died rapidly.

Diarrhoea was the most constant symptom. It was present in ten out of fourteen animals. It made its appearance between the fourteenth and the twenty-fifth day of the experiment and persisted. In six cases the diarrhoea continued down to the time of death, in four it merged into true dysentery. The diarrhoeic motions were small, numerous, and pale, resembling pea-soup. Microscopical examination showed the stool to consist mainly of (1) epithelial cells in various stages of disintegration, (2) enormous numbers of bacteria, and (3)—in iodine-stained specimens—a small amount of undigested starch. Amoebae, but without ingested red blood corpuscles, were present in one case. In animals receiving butter in addition to the autoclaved rice large amounts of fatty acid crystals were seen on microscopical examination, and the stools were paler; in two instances they were distinctly frothy, resembling those of spruce.

Dysentery.—In 4 cases out of 10 in which diarrhoea occurred this symptom was preliminary to the onset of

* The full paper will appear in the *Indian Journal of Medical Research*.

dysentery. After the lapse of a day or two, during which diarrhoeal stools were passed, the motions became mucoid and streaked with bright red blood; later they consisted of pledgets of tough blood-stained mucus, sometimes intermingled with traces of pale yellow-white faecal matter, but more often consisting solely of mucus mixed with blood. In two cases dysentery occurred without any preliminary diarrhoea. The familiar characters of dysenteric stools were obscured to some extent in these cases by the nature of the animal's food and by the small faecal output induced by the state of semi-starvation. Nevertheless, they were such as in the human subject would have suggested "amoebic" dysentery. Animals rarely survived the onset of dysentery for more than a few days. In two cases dysenteric stools were passed only for two days prior to death; in four others the animals survived the onset of dysenteric symptoms for four, five, six, and seven days respectively.

In the diagnosis of these cases I have had to limit myself to investigation of the microscopical characters of the stool. Bacteriological studies could not, unfortunately, be undertaken. I am therefore unaware of the extent to which bacilli may have been responsible for, or participated in, the production of the dysenteric symptoms. In the stools enormous numbers of cellular elements of the most diverse form and size were present; they included, in addition to amoebae in some cases: (1) Desquamated epithelial cells in various stages of disintegration, appearing singly or in connected groups of a dozen or more; (2) red blood corpuscles, always in considerable numbers; (3) leucocytes and pus cells in large numbers; (4) single, double, and, more rarely, four-nucleated round cells; and (5) large mononuclear cells ranging in size up to 25μ or even more. The majority of these cells showed degenerative changes.

In arriving at a diagnosis in any particular case I have followed the rule laid down by Wenyon and O'Connor,² and called no case "amoebic" unless I found "at least some amoebae with included red blood corpuscles present, or definite *E. histolytica* cysts associated with the amoebae in the stool." On this basis, four cases were classed as "amoebic" dysentery. Amoeboid organisms of varying sizes up to 25μ were present in a fifth case, but as these did not contain ingested blood corpuscles and were not associated with *E. histolytica* cysts, this case was not classed as "amoebic." In the sixth case no amoebae were present. The histological characters of the stool in this, as in the previous case, were such as to render the diagnosis of bacillary dysentery legitimate.

In order to determine whether the monkeys were amoebae carriers the faeces of eight healthy control animals were examined (one examination only). *E. histolytica* cysts were found after prolonged search in one case, blastocysts (considered by Flu⁴ to be degenerative forms of *E. histolytica*) were found in moderate numbers in a second and in very large numbers in a third; *E. coli* were present in three others. No amoebae were found in the faeces of the two remaining control animals.

Throughout the greater part of the experiment the twelve control monkeys remained free from gastro-intestinal disturbances of any kind. Towards its close, however, seven developed jaundice, thought to be due to a too generous provision of monkey-nuts with lack of exercise. Under a meagre diet of bread and milk, to which was added a pinch of Epsom salts, for a few days, the jaundice cleared up. In no case did diarrhoea or dysentery occur.

It is possible that flies may have conveyed *E. histolytica* cysts or dysenteric bacilli from infected to non-infected animals in the same room. Since, however, the control monkeys did not suffer from dysentery—although equally exposed to possible infection—it is obvious that the provision of a well balanced dietary secured their immunity.

This observation indicates (1) that monkeys in the wild state in South India may be carriers of *E. histolytica*, and (2) that states of malnutrition favour the multiplication of pathogenic agents of dysentery present in the intestinal tract, whereas a satisfactorily balanced dietary has the reverse effect.

Workers in the tropics have long been familiar with the facts that cysts of *E. histolytica* may be present in the stools of perfectly healthy individuals, and absent from the stools in a proportion of cases possessing the clinical

characters of the type of dysentery called "amoebic" (Manson⁵). I know of no work, however, designed to determine the percentage of *E. histolytica* carriers amongst natives of India, but recently Flu⁴ has estimated that at least 10 per cent. of natives of the Dutch Indies are *E. histolytica* carriers, and has concluded that this estimate is probably much too low. Amongst 946 British soldiers, invalided to India from Mesopotamia, who gave no history of dysentery MacAdam and Keelan⁶ found 15.7 per cent. to be harbouring the cysts of *E. histolytica*. Wenyon and O'Connor² also found 4.5 per cent. of *E. histolytica* carriers amongst healthy British troops in Egypt who gave no history of dysentery. They record also that 13.5 per cent. of healthy natives of Egypt were *E. histolytica* carriers. It appears, therefore, that *E. histolytica* may exist in the healthy intestine as a pathogenic saprophyte without giving rise to dysentery until the conditions requisite for its growth upon and in the intestinal mucosa are provided by certain favouring circumstances. Amongst these circumstances, malnutrition—including deficiency of accessory food factors^{*}—is one. It appears probable that bacillary dysentery also is favoured by like circumstances.

These observations have a practical bearing on the prevalence, prevention, and cure of dysentery. The occurrence of "famine dysentery" is well recognized in India, and it is submitted that the specific agents of dysentery, whether recently ingested or existing as pathogenic saprophytes, find in the malnourished state of the intestinal mucosa of famine-stricken individuals the conditions necessary for their unhampered growth. It is not necessary to assume a fresh amoebic infection in every case of amoebic dysentery.

Dysentery has frequently occurred amongst the starving inhabitants of certain occupied territories⁷ during the late war. No doubt both war and famine often provide greater facilities for the entry of the specific micro-organisms of dysentery into the human intestine than do the more sanitary conditions of peace and plenty; but while recognizing this the present experiment brings into special prominence the importance of suitable dietaries in preventing this malady. It suggests also that disturbance of gastro-intestinal function from any cause, such as a malarial attack, for example, may lead to the recrudescence of acute symptoms of dysentery in carriers of the specific agents of this malady, or determine a first attack in persons recently infected.

In the prevention of dysentery two precautions are necessary: (1) The maintenance of the healthy and protective activity of the gastro-intestinal mucosa, and (2) the prevention of infection. I venture to think that the conditions necessary for infection of the intestinal mucosa differ little from those necessary for infection of the skin, that these conditions are provided by ill-nourished, poisoned, or necrosing tissues, and that an improper food supply is the most ready means of inducing them.

The cessation of this experiment afforded me an opportunity to observe, on the substitution of a normal dietary, the rapid disappearance of diarrhoea (and of dysentery in one case) in monkeys reduced to a grave state of asthenia by the deficient dietary. In the treatment of dysentery it is necessary to take care that the milk and rice-water dietaries employed are not lacking in "vitamines." If they are, not only will recovery from the dysenteric process be greatly impeded, but symptoms of beri-beri will be prone to manifest themselves. Many examples of the association of dysentery with beri-beri are on record.

PATHOLOGICAL EVIDENCES OF GASTRO-INTESTINAL DISEASE.

I shall confine myself here to an enumeration of the morbid anatomical and histo-pathological evidences of disease; details and *post-mortem* records are given in my full paper.

1. Naked Eye Appearances.

Fat disappeared from the omentum. The normal omentum in monkeys weighs from 50 to 56 grams; in

* Since this report was written dysentery has developed in two monkeys fed on autoclaved food (rice, bread, monkey-nuts, and milk)—that is to say, on food containing the requisite attributes of proteins, calories, and salts, but in which accessory food factors have been destroyed by autoclaving at 130° C. for an hour and a half.—R. McC.

monkeys dying in consequence of the deficient diet it weighed only 3 to 4 grams. Congestion of the mesenteric vessels was frequently but not constantly observed. The mesenteric glands were always enlarged and frequently discoloured (grey to dark slate-grey), most markedly in the vicinity of the caecum and in the colonic mesentery. There was very pronounced dilatation of the stomach, with thinning of its walls; thinning of the walls of the small intestine, amounting in places to actual transparency, and ballooning in certain areas were constant phenomena. Descending intussusceptions, the majority being agonal in origin, were frequent. A number of the larger intussusceptions presented evidences of congestion and constriction of the invaginated bowel which suggested their occurrence some hours at least before death. No inflammatory change was present in any.

Congestion of the small intestine and subserous ecchymoses, usually most marked in the duodenum and lower ileum, sometimes limited to these areas, were seen, as also congestion of the large bowel, and subserous ecchymoses sometimes throughout its entire length, but often confined to its lower six inches. In circumscribed areas the colon was greatly ballooned and its walls thinned, so that sometimes they were transparent (Fig. 1 and 2). The ballooning was due, not to the accumulation of faecal matter, but to distension with gas and to loss of muscular tone; on cutting into them they collapsed like a burst balloon. Owing to great atrophy and thinning of the longitudinal bands of muscle the normal puckerings of the colon disappeared. In butter-fed pigeons the same appearances were noted, but the whole gastro-intestinal tract was usually more ballooned and of a pale yellow-white colour.

Necrotic changes in the mucous membrane of the stomach were seen, and ecchymoses were frequently present at its pyloric end. In one case an ulcer was found at the pylorus. There was intense congestion of the duodenal mucous membrane, sometimes limited to the upper part, but often extending throughout. Sometimes in the jejunum and ileum there was congestion of the mucous membrane, with ecchymotic areas, the congestion being usually more marked in the lower ileum or confined to it. Above the larger intussusceptions, and sometimes also in the ballooned areas of small intestine, a thin glue-like mucoid material was found. There was great congestion of the invaginated bowel in the majority of the larger intussusceptions; no notable congestion occurred in those which were obviously agonal. Intense colitis was present in the great majority of cases, sometimes throughout the entire length of the large bowel, usually limited to the lower six inches; in rare cases the colitis was confined to limited areas of the transverse colon. In the areas of pronounced ballooning the walls of the colon were transparent. Occasionally great enlargement and discoloration of lymphoid follicles of the colon were seen.

2. *Histo-pathological Evidences of Gastro-intestinal Disease.*

Microscopic examination showed congestion and haemorrhage, usually limited to the serous, submucous, and mucous coats, rarely affecting the myenteron. This condition was most marked in the duodenum, the lower colon, the pyloric end of stomach, and the lower ileum, and its degree was in the order in which the organs are named. There was great atrophy of the myenteron throughout the entire tract; it was most notable in the longitudinal muscular bands of the colon. Pronounced degenerative changes were seen in many ganglia of the myenteric plexus of Auerbach.

The mucous membrane of the entire tract was the seat of atrophic, necrotic and inflammatory changes—most marked in the duodenum, the colon, the pyloric end of the stomach, and the lower ileum. There was atrophy and necrosis of all secretory elements of the entire tract: of the pyloric glands, the glands of Brunner, the glands of Lieberkühn, the mucous glands of the large bowel, and atrophy also of the lymphoid elements of the intestinal mucosa. I have not yet studied the histological changes in the pancreas, but judging by the diminution of weight the atrophic change must be pronounced. The average weight of the pancreas per kilo of body weight in two control monkeys was 1.66 grams; in ten fed exclusively on autoclaved rice the average weight of the pancreas per kilo of original body weight was 1.135 grams; in four fed on autoclaved rice plus butter, the average weight of the organ per kilo of original body weight was 0.95 gram.

EFFECTS OF THE PATHOLOGICAL CHANGES.

It is evident that the changes above detailed will lead to impairment of the functions of the gastro-intestinal tract. There will be impaired production of digestive ferments and other secretions of the entire gastro-intestinal tract, leading to imperfect digestion, excessive carbohydrate fermentation, and distension of the stomach and intestines with gas. Depressed functional activity of the pancreas will result from the impaired production of hydrochloric acid by the pyloric glands, and of prosecretion by the duodenal glands. Impairment of the neuro-muscular control of the entire tract will lead to delayed transit of the intestinal contents, especially in the colon, and weakening of its walls and "ballooning." The deranged neuro-muscular control of the bowel may favour production of intussusceptions. The conditions enumerated will lead to intense toxic absorption from the intestinal tract, and impairment of

the protective resources of the entire gastro-intestinal mucosa against infecting agents, leading to infection of the mucous membrane by pathogenic saprophytes and by ingested pathogenic organisms. These infections give rise to gastro-intestinal catarrh, to gastritis, duodenitis, enteritis, and colitis, and frequently to haemic

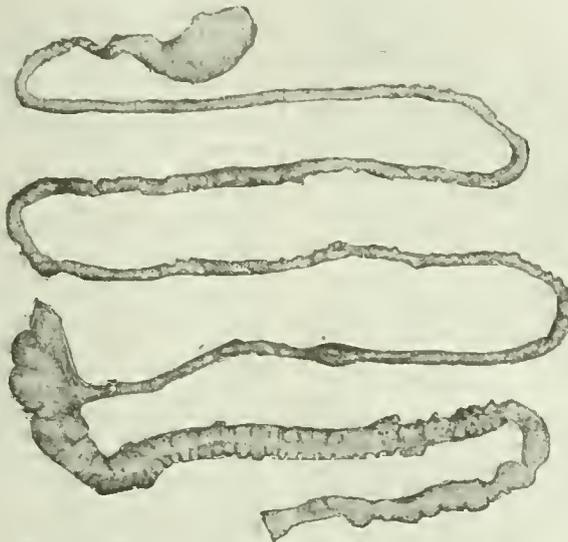

FIG. 1.—Gastro-intestinal tract of healthy monkey. Killed fifteen hours after last meal. Period under observation, 104 days. Compare with Fig. 2. Same scale in both figures.

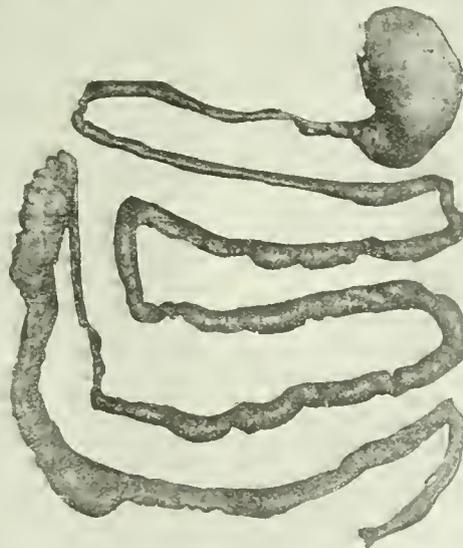

FIG. 2.—Gastro-intestinal tract of monkey fed on autoclaved rice for twenty-eight days, and thereafter on autoclaved food. Note dilatation of empty stomach, ballooning of small bowel (ballooned areas contained air only), inert appearance of large bowel, with great atrophy and thinning of its walls; severe colitis was present throughout colon. Period under experiment, eighty-two days.

infections. The occurrence of dysentery in these circumstances is significant.

COMMENTARY.

Such degrees of malnutrition as those produced in this experiment are rarely encountered in man during peace, but the late war afforded many examples of gastro-intestinal disorder amongst refugees, prisoners of war in Germany and Turkey, and the starved inhabitants of certain countries.⁷ The facts here recorded afford a pathological explanation. They present an extreme picture: the end-results of malnutrition. But between this extreme on the one hand and perfect nutrition on the other there are intervening degrees of malnutrition which must determine the departure from health of the gastro-intestinal tract. It is with the "mean" rather than with the "extreme" that the physician is mainly concerned; with the long-continued use of imperfectly balanced and deficient food rather than with the lack of vitamins; with the beginnings of disease rather than with the end-results.

The gastro-intestinal lesions here described were initiated by dietaries too rich in carbohydrates and too poor in other essential attributes of a perfectly balanced ration. It may be expected, then, that gastro-intestinal lesions of like kind, if not of like degree, will result in man from the continued use of such dietaries.

To maintain the gastro-intestinal tract in health, and to enable it to protect itself and the body generally against invasion by ingested pathogenic organisms, it is necessary to provide from birth onwards a satisfactorily balanced dietary containing a sufficiency not only of proteins, calories, and salts, but also of accessory food factors of all three classes.

II.—THE GENERAL EFFECTS.

Attention is directed to the composition of the dietaries given in these experiments. Their balance, or lack of balance, with respect to proteins, carbohydrates, and fats requires consideration as much as their deficiency in vitamins.

Experimental Diets.

A. An exclusive diet of autoclaved rice—that is to say, one deficient in suitable protein, in fat, in accessory food factors of all three classes, and excessively rich in starch. Ten monkeys were fed to the point of death on this diet.

B. A diet of autoclaved rice and butter—that is to say, one deficient in suitable protein, in accessory food factors of the "B" and "C" classes, and excessively rich in starch as well as in fat. Four monkeys were fed to the point of death on this diet.

C. A diet of autoclaved food—rice, wheaten bread, milk, and ground-nuts—to which a small ration of fresh onion was added; that is to say, a diet deficient in accessory food factors of the "A" and "B" classes. Six monkeys were fed to the point of death chiefly on this diet.

D. A diet of autoclaved food—rice, wheaten bread, milk, and ground-nuts—to which fresh onion and fresh butter were added; that is to say, a diet deficient only in accessory food factors of the "B" class and excessively rich in fats. Five monkeys were fed to the point of death chiefly on this diet.

Controls.—Nine monkeys, fed on wheaten bread, plantains, milk, fresh onions, and ground-nuts, acted as controls.

The experiments emphasize the importance of studying the "dietetic history" in every case of gastro-intestinal disorder or of vague ill health in man. Deficiency of vitamins of the "B" class often runs parallel with the excessive richness of a dietary in starch, especially so when the source of the starch is polished rice, white flour, white bread, sago, tapioca, and many proprietary foods. A dietary excessively rich in starch thus often implies a deficiency of "B-vitamins." The results recorded show what the effects of deficiency of this vitamin are in monkeys, and from these we are justified in assuming in similar circumstances like results in man. In man, however, it is not with complete but with incomplete vitaminic deficiency that we have most often to deal in practice. The former causes rapid dissolution and death, the latter protracted dissolution and disease. It will be noted, moreover, that "neuritic" lesions are by no means the most important of the effects of deficiency of "B-vitamins." Unfortunately the adjective "antineuritic" has been attached to accessory food factors of the "B" class, so that a deficiency of this factor suggests the onset of "polyneuritis" or of "beri-beri" as its sole results. These, however, are the grosser and later manifestations of such deficiency. The

changes in the nervous system to which want of this vitamin gives rise are not its most important effects with respect to time of onset, to frequency of occurrence, and to need for recognition. It is true that lack of "B-vitamins," associated as it usually is with an insufficient supply of protein and an excess of starch, may ultimately lead to degenerative changes in nerve cells, but it is of greater practical importance to recognize that this combination of defects in human dietaries may be expected to lead more early and more often to degenerative changes in, and to depression and failure of function of, those cells upon which the processes of digestion and assimilation are dependent. It is possible that the depression of function so induced may account for a number of the commoner gastro-intestinal disorders, to which no bacterial or parasitic label has so far been attached.

It will surprise those who investigate the "dietetic history" of cases of chronic gastro-intestinal disorder to find how many persons habitually subsist on "bread-and-butter" and "milk puddings." Such a dietary is poor in "B-vitamins" and in protein, as well as excessively rich in starch and fats. It is my experience in India that the "dietetic history" of European sufferers from chronic colitis, and of those suffering from chronic gastro-intestinal disorder, commonly reveals the fact that their food does not contain the requisite proteins or the due proportion of starch, fats, salts, water, and vitamins. This one cannot "digest" vegetables, fruit, or meat, or "never touches them in India"; that one can "carry on only on farinaceous food." Thus the form of diet they commonly adopt is often that most calculated to promote the very disorder from which they seek relief. These experiments show that the cardinal effects of deficient and ill-balanced dietaries in monkeys are gastro-intestinal disorder, dilatation of the stomach, gastritis, and colitis. They are likely to be the same in man. It did not surprise me, therefore, to find that a patient who consulted me recently, and who for ten years had subsisted mainly on milk puddings, had a dilated stomach, air locks in the small bowel which caused her great discomfort, delay in the passage of the intestinal contents, colitis, tenderness in the caecal region, and an inefficient pancreas with glycosuria. The results of these experiments have helped me to visualize the changes which are likely to be occurring in the gastro-intestinal tract in such a chronic invalid. I desire, therefore, to emphasize the importance in practice of a study of the dietetic history in such cases, believing as I now do that bacterial agencies are often but weeds which flourish in soil made ready for them by dietetic defects, and believing also that in the fuller comprehension of the science of dietetics we shall understand more perfectly the beginning of disease and its therapy.

The following is a summary of the results of the experiments, full details of which are given in the original paper.

Monkeys fed exclusively on rice, autoclaved at a temperature of 130° C. for one and a half hours, died in an average period of 23.4 days. Monkeys fed on rice, similarly autoclaved, to which fresh butter was added, died in an average period of fifteen days. The addition of butter to the dietary (excessively rich in starch and deficient in vitamins and proteins) hastened the death of animals. A similar result has previously been recorded in the case of pigeons.

Monkeys the basis of whose dietary was autoclaved food (wheaten bread, ground-nuts, milk, rice) survived much longer than those the basis of whose dietary was autoclaved rice—an average of seventy days as compared with an average of twenty days. The more liberal provision of proteins and the more perfect balance of the food with respect to proteins and carbohydrates prolonged the life of the animals in these categories. Monkeys (*Macacus sinicus*) cannot sustain life for periods much longer than one hundred days on a dietary which is devoid of accessory food factors of the "B" class. Lack of this factor is a fundamental cause of the animals' dissolution; deficiency of proteins, excess of starch, and excess of fat in the absence of "B-vitamins" contribute to this dissolution.

The total loss of weight in monkeys of all four categories was from 25 to 32 per cent. of the original weight; the greatest loss occurred in those fed on autoclaved food and onion—that is, in those which survived the longest time. Those to whose dietary of autoclaved rice butter was added lost weight more rapidly than those receiving no butter.

The chief clinical evidences of disease due to the deficient dietaries were progressive anaemia and asthenia, loss of appetite, diarrhoea, dysentery, diminished sensibility, weakness of the limbs, headache, impaired nutrition of the skin, subnormal temperature, and enfeebled heart's action. Symptoms referable to the nervous system were less prominent and appeared later than those referable to the digestive system; they were for the most part obscured by the profound asthenia. The symptoms were similar in all four categories, but manifested themselves later in monkeys whose food was more perfectly balanced with respect to proteins and carbohydrates. Symptoms referable to the digestive system were on the whole less common in monkeys whose food was more perfectly balanced with respect to proteins and carbohydrates. Nevertheless gastritis and colitis were frequent clinical features in them.

Haemic infections, as determined by aerobic culture of the heart's blood at necropsy, were commonly present in monkeys whose food was excessively rich in starch and deficient in proteins and vitamins. Dropsy was not present in any of the monkeys fed on the deficient dietaries. All caused an increase in weight of the adrenal glands. It was more marked in those fed exclusively on autoclaved rice and was associated with an increase in the adrenalin content of the glands, provided no haemic infection was present. No increase in the adrenalin content of the suprarenal glands occurred in monkeys to whose dietary of autoclaved rice butter was added. Similar results have previously been recorded in pigeons. No increase in the adrenalin content of the suprarenal glands was found in monkeys whose deficient dietaries were more perfectly balanced with respect to proteins and carbohydrates. The adrenalin content of the suprarenal glands was below the average of health in monkeys presenting haemic infections.

The deficient dietaries gave rise in all categories to an increase in weight of the brain. When similarity in the age of the monkeys rendered the findings in the different categories comparable it was noted that the increase in weight of the brain was more marked in those whose food was excessively rich in butter and starch and at the same time deficient in proteins and vitamins. A similar observation in pigeons has previously been recorded. The increase in weight of the brain in these circumstances amounts in monkeys to approximately one-seventh part of its normal average weight per kilo of original body weight, and in pigeons the same proportionate increase is observed. This may account for the headache and other symptoms observed in certain cases of mental disorder in the human subject.

Three classes of deficient dietaries—namely, (a) autoclaved rice, (b) autoclaved rice and butter, (c) autoclaved food and onion—caused in monkeys an increase in the weight of the pituitary body. Its weight was decreased in monkeys fed on autoclaved food, butter, and onion. Similar results have been recorded in the case of pigeons fed on the first two of these classes of deficient dietaries. The pituitary gland was heavier per kilo of body weight in female than in male control monkeys. The pituitary gland increased in weight in male but not in female monkeys in consequence of an exclusive diet of autoclaved rice. Similar results have been recorded in both respects in pigeons.

Atrophy of all other organs—the thyroid, the reproductive organs, the thymus, the submaxillary gland, the pancreas, the spleen, the liver, the heart, and the lungs—occurred in consequence of the deficient dietaries. The weight of the kidneys diminished only in those animals the basis of whose dietary was autoclaved food. The atrophy of the testicle was slight in monkeys fed on autoclaved food, fresh butter, and onion. The atrophy of the pancreas, the thyroid, the spleen, and the heart was more marked in monkeys to whose deficient dietary of autoclaved rice fresh butter was added. The same is true of pigeons. The atrophy of the submaxillary gland was likewise more marked in monkeys whose deficient dietaries were excessively rich in butter. The decrease in weight of the liver was not so marked in monkeys to whose dietary of autoclaved rice or of autoclaved food fresh butter was added. A similar observation has been recorded in pigeons fed on autoclaved rice, butter, and onion.

In addition to the enlargement or atrophy of the organs mentioned, the main pathological states observed in monkeys at autopsy were dilatation of the stomach,

gastritis, duodenitis, enteritis, ballooning of the small intestine, intussusception, colitis, atrophy of the muscular coats of the bowel, complete loss of fat from the omentum, and enlargement of the abdominal lymphatic glands. Excess of starch, in the absence of protein and vitamins, appeared to be largely responsible for the great dilatation of the stomach, the ballooning of the bowel, and the "air locks" in the intestine. The stomach and the small bowel were less affected in monkeys whose food was more perfectly balanced with respect to proteins and carbohydrates. In general the gastro-intestinal tract was not so frequently or extensively diseased in animals fed on autoclaved food, butter, and onion, although both gastritis and colitis were present in 40 per cent. In all categories atrophy of the heart occurred; it was less marked in animals fed on autoclaved food, butter, and onion. In no case was hypertrophy of the heart encountered. Slight hydropericardium occurred in a small percentage of cases. *Post-mortem* evidences of oedema were very scanty in all four categories.

The reproductive organs atrophied to a considerable extent in both sexes, but the atrophy was much less marked than that previously found in pigeons in like circumstances. The atrophy of the spleen was less marked in monkeys than in pigeons similarly fed. The weight of the lungs decreased in monkeys in all categories, thus contrasting markedly with pigeons, in which an increase in weight of these organs was noted to result from a dietary of autoclaved rice, butter, and onion. Degenerative changes were present in the femoral nerves as follows: Controls, nil; autoclaved rice, two; autoclaved rice and fresh butter, one; autoclaved food and onion, four; autoclaved food, fresh butter and onion, two.

CONCLUSIONS.

1. Dietaries which are deficient in vitamins and in protein, and at the same time excessively rich in starch or in fat, or in both, are potent sources of disease, and especially of gastro-intestinal disease.

2. An excess of fat, in association with deficiency of "B-vitamine" and protein and superabundance of starch, is peculiarly harmful to the organism.

3. Certain dietetic deficiencies greatly favour the invasion of the blood and tissues by bacteria; especially is this the case when deficiency of vitamins and protein is associated with an excessive intake of starch.

4. Since life cannot be sustained in the monkey, *Macacus sinicus*, for much longer than 100 days on a dietary almost wholly devoid of "B-vitamine," it would appear that complete absence of this vitamine from the food is of less practical importance from the point of view of the production of disease in human beings than its subminimal supply. Complete deprivation of "B-vitamine," especially if there be also imperfect balance in other essential requisites of the food, will lead to rapid dissolution and death; subminimal supply of this vitamine will lead, in like circumstances, to slow dissolution and disease.

5. The results recorded in this paper may afford some explanation of the genesis of that great mass of ill defined gastro-intestinal disorder and vague ill health which forms so high a proportion of human ailments at the present day.

THE publication of the *Revue Générale d'Ophthalmologie* was discontinued during the war, as the three editors, Dor, Rollet, and Truc, were on active service. We are glad to know that this invaluable French bibliography of current ophthalmology is not to be allowed to die after thirty-three years of vigorous life. Two final parts of the thirty-third volume (October-December, 1914) are now to hand, and from January, 1920, the *Revue* will reappear as of old, under the capable editorship of Jourdain of Geneva. Eperon of Lausanne, and Vogt of Basel.

PROTECTIVE INOCULATION AGAINST INFLUENZA.

BY

W. H. WYNN, M.D., M.Sc., M.R.C.P.,

HONORARY PHYSICIAN TO THE GENERAL HOSPITAL, BIRMINGHAM;
LECTURER IN CLINICAL MEDICINE, UNIVERSITY OF BIRMINGHAM.

THE possibility of a recrudescence of influenza and the distribution of vaccine by the Ministry of Health has caused much questioning, both by medical men and the general public, as to the advisability of prophylactic inoculation. Although the true value of vaccines for prophylaxis against epidemic influenza cannot be established until the morbidity of a large sample of the population, inoculated before an outbreak, as compared with that in uninoculated controls, is submitted to expert statistical treatment, yet we possess much useful information gained during the last epidemics.

Until we know the true cause of influenza, the use of a vaccine must necessarily be empirical, but whatever the cause, there is little doubt that Pfeiffer's bacillus, and various strains of pneumococci and streptococci, are important secondary or coincident infecting agents, and are responsible for the severe and fatal complications. There is evidence that a vaccine composed of these three organisms will not only diminish the mortality and reduce the complications of the disease, but will also lessen the incidence of uncomplicated influenza. If this latter fact can be proved, it must be taken seriously into account in any discussion upon the true virus of influenza. Most authorities agree that a vaccine should contain several strains of Pfeiffer's bacillus, pneumococci and streptococci, but there is much difference of opinion as regards the proportions and number of these organisms to be used. Confronted with so many vaccines of varying strength and composition, the practitioner may well hesitate as to which he should choose.

The amount of immunity produced by a vaccine depends within certain limits upon the size of the dose inoculated, the limits probably being set not so much by the actual quantity of vaccine used as by the amount of antigen which the tissues can set free from it. Experience with other infections has taught us that when protection lasting for a considerable period is required large doses of vaccine are necessary. Thus with typhoid fever doses of 1,000 and 2,000 million are used, and with pneumonia three injections at seven days' interval of 6,000 million pneumococci have been given. But in these two instances the vaccine is used upon selected individuals or communities and inoculation of the general public is not undertaken. When, as with influenza, it is desirable to inoculate as many of the general public as possible, and sufficient immunity to protect during an epidemic period of a few months only is aimed at, such large doses may not be necessary. It is also important to choose such a dose as will not produce unpleasant reactions and so interfere with work and deter large numbers from being inoculated.

My own preference is for a vaccine containing equal numbers of Pfeiffer's bacilli and various strains of pneumococci and streptococci recently isolated. With pneumococci only first cultures are used, with streptococci either primary or first subcultures. I am convinced that the activity of a vaccine depends upon its being made from primary, or, at the most, first or second subcultures. Unfortunately it is difficult to make such vaccines on a large scale for widespread use, and the antigenic value of many commercial vaccines is greatly impaired. During the epidemic period of 1918-19 I gave a first dose of 100 million of each organism, and after one week 200 million at first, but later increased to 200 and 400 million. These doses I am using at the present time. They seem sufficient to give adequate protection without causing more than a trifling reaction. In several cases these doses have been followed by a third of 800 million and even a fourth of 1,200 million. In my opinion when the increased protection of these larger doses is aimed at it is best to begin with a dose of 200 million, and give three or four increasing doses at weekly intervals, rather than to give two doses of 500 and 1,000 million.

Over 1,000 persons were injected with two doses, about half having a maximum dose of 200 million and the remainder of 400 million. Of these there is a record of

the result in 680. Of these only 14 developed influenza, but 4 of these were attacked three months after the last injection. In all cases the disease was mild, and there was no case of pneumonia. In one village in which influenza was very prevalent there were two large preparatory schools. In one no vaccine was used and nearly every boy, besides masters and servants, suffered from influenza. In the other school 75 boys and 38 adults were injected. One adult was injected after infection had occurred and developed pneumonia. All the others escaped influenza. In the village 31 adults and 16 children were injected, and all escaped. One boy injected during the vacation returned to a boarding school, and 19 out of 23 boys suffered from influenza soon after the beginning of term; the inoculated boy was among the four who escaped. In another doctor's practice there were 35 cases of influenza, 7 with pneumonia; 40 immediate contacts with these patients were injected, and of these 3 had mild influenza, in 2 fever only lasting one day. At one institution 117 nurses and maids out of a staff of 170 were inoculated during the autumn of 1918. Of the 53 uninoculated 25 had mild attacks in June, 1918, and escaped in the epidemics of November and February. Of the 28 presumably unprotected, 14 suffered from influenza, 2 with severe bronchopneumonia, of whom one died. Of 5 who only received one inoculation one had mild influenza and one a severe attack. It is not pretended that these results have any statistical value or are free from fallacies, but they support the favourable results obtained elsewhere.

In America protective inoculation was practised on a much larger scale, and much larger doses of vaccine were given than in this country.

Rosenow¹ used a vaccine with the formula: Pneumococci, 3,000 million (Type 1, 500 million; Type 2, 750 million; Type 3, 500 million; Type 4, 1,250 million); *Streptococcus haemolyticus*, 1,000 million; *B. influenzae*, 500 million; staphylococci, 500 million, in 1 c.cm.; $\frac{1}{2}$ c.cm. was given as a first dose, and then 1 c.cm. and 1.5 c.cm. at intervals of seven days. The final doses, therefore, consisted of 7,500 million organisms. A vaccine of this formula is obtainable in this country. In my experience it is apt to cause rather unpleasant reactions, and Rosenow remarks that the number of severe reactions is sufficiently large to prevent general vaccination, except at the time of an acute emergency. It might be thought that the injection of such large doses might have a prejudicial effect upon chronic infections, especially of the respiratory tract. But the reports show that 931 persons with chronic bronchitis were benefited, and 38 made worse; 127 persons with chronic sinusitis were benefited, and 4 made worse; 121 with chronic myositis and 129 with chronic arthritis were benefited, and in one of the former and 22 of the latter the symptoms were aggravated; 997 pregnant women were inoculated, with excellent results.

In institutions where the conditions among the vaccinated and unvaccinated were comparable, 8,306 were injected three times and 9,388 were unvaccinated. Among the vaccinated the incidence of influenza per 1,000 was 31 and among the unvaccinated 200, the incidence of pneumonia 1.0 and 12.0 per 1,000 respectively. Among the general population 93,476 persons received three injections; the incidence of influenza was 87.9 per 1,000, and of pneumonia 4.4 per 1,000, as compared with 281.8 and 21.0 per 1,000 among the unvaccinated. Taking all the results, the average mortality rate in the inoculated was one-fifth of that in the uninoculated.

Minaker and Irvine² in San Francisco used a vaccine containing 5,000 million *B. influenzae*, 7,000 million pneumococci (3,000 million each of Type 1 and Type 2, 1,000 million of Type 4), and 100 million *Streptococcus haemolyticus* per cubic centimetre; 0.5, 0.8, and 1.0 c.cm. were given at three-day intervals. The final dose was therefore 12,100 million organisms. This, so far as I am aware, is the largest dose given for influenza. Of the civil population 1,080 were inoculated; their morbidity was 1.4 per cent. and mortality nil. These persons mixed with an uninoculated population whose morbidity was 5.3 per cent. and mortality 9.2 per cent.; 1,950 marines were inoculated and 8,232 not inoculated. The respective morbidity and mortality rates in the former were 1.8 and 2.8 per cent., as compared with 15.7 and 5.0 in the latter. For uninoculated nurses and attendants in hospitals the morbidity was 33.8 per cent., among the inoculated 3.5 per cent.

Cadman³ in Winnipeg used a vaccine of 300 million streptococci, 200 million influenza bacilli, and 150 million pneumococci. Out of 7,600 soldiers, 4,842 were inoculated, but only about half received two doses. Of cases admitted to hospital, 6.05 per cent. of those previously inoculated developed pneumonia, against 17.1 in the uninoculated. The deaths in the uninoculated were 7.1 per cent., in the inoculated 1.7 per cent., but all these had only received one dose of vaccine; there were no deaths among those who had two injections. In the civil population 24,184 received two injections; the incidence of influenza was 9.8 per cent., pneumonia 0.57 per cent., and deaths 0.16 per cent., as compared with 21,285 uninoculated, among whom the incidence of influenza was 24.8 per cent., pneumonia 2.2 per cent., and deaths 0.66 per cent.

In England there has been an unnecessary timidity in the use of large doses for prophylaxis, and the original formula recommended by the War Office Conference—namely, 60 million *B. influenzae*, 80 million streptococci, and 200 million pneumococci in 1 c.cm.—of which it was recommended that 0.5 c.cm. should be given as a first dose and 1 c.cm. after ten days, met with considerable criticism. Nevertheless the results, just published by Sir William Leishman,⁴ obtained in the Home Commands showed that this vaccine gave some measure of protection. Of 15,624 inoculated the incidence of influenza was 14.1 per 1,000, of pulmonary complications 1.6 per 1,000, and deaths 0.12 per 1,000, as compared with 43,520 uninoculated giving an incidence of 47.3, 13.3, and 2.25 respectively. About half the inoculated received only one dose of the vaccine.

The vaccine now recommended and adopted by the Ministry of Health contains 400 million *B. influenzae*, 80 million streptococci, and 200 million pneumococci. Thus, whilst the dose of pneumococci and streptococci remains the same, the dose of influenza bacilli has been increased from 60 to 400 million. It would be interesting to have the reasons why this formula was adopted. The streptococcus is probably the most dangerous of the three organisms, and in view of Rosenow's experience with doses of 1,000 million of haemolytic streptococci, it seems advisable that as large a dose of this organism should be given as of the others. The experience of Lister, Cole, and others with pneumococcal vaccine shows that large doses can be given without undue reactions. With the increase of the dose of influenza bacilli to 400 million the point is made "that the strains employed should not have been so cultivated or so recently derived from cases as to be unduly toxic in their action." Some of the advantage of the larger dose is therefore lost by using less active cultures. The dose contrasts with that used in San Francisco, namely, 5,000 million influenza bacilli, with such excellent results.

The St. Mary's Hospital formula—*B. influenzae* 500 million, pneumococcus (mixed types) 1,000 million, and streptococcus 100 million, $\frac{1}{2}$ c.cm. to be followed by 1 c.cm. in a week—gives a larger dose and has been used on a large scale, but no results of its use have been published.

Of other vaccines that have been advocated Rosenow's vaccine suspended in oil instead of normal saline may, in the light of Fennel and Cecil and Vaughan's studies of the pneumococcal lipo-vaccine, give a greater degree of protection. Detoxicated vaccines are being strongly advertised. The evidence in their favour is not convincing. My own experience of them leads me to regard them as comparatively inert, and I doubt if any reliance should be placed upon them for purposes of prophylaxis.

There is evidence of a considerable degree of cross-protection from vaccines. In connexion with the severe outbreaks of camp septicæmia and bronchopneumonia in America,⁵ it was found that inoculation with a pneumococcal vaccine gave some protection against the streptococci responsible for the outbreaks, the incidence of streptococcus pneumonia being nearly ten times as great among the unvaccinated as in those injected with the pneumococcal vaccine. It must also be within the experience of many that during the epidemics of last winter, patients who were undergoing vaccine treatment for other complaints were comparatively immune to influenza. Also injection of the triple influenza vaccine often has a beneficial effect in patients suffering from chronic infections.

In the circular accompanying the vaccine issued by the Ministry of Health the inoculation of children under

3 years of age is not advised. It is difficult to understand the reason of this. Young children show no special resistance to influenza, and their chance of recovery is less than in older patients. Children respond to vaccines very well, and I have had no hesitation in giving suitably reduced prophylactic doses to children under 3 years of age.

The records here given show that no medical man need hesitate to advise prophylactic injections to his patients. In most instances the vaccine of the Ministry of Health will doubtless be used, but there is evidence that much larger doses can be safely used. Indeed, it seems advisable that persons particularly exposed to infection should reach larger doses, and 0.75 c.cm. and 1.5 c.cm. of the Ministry's vaccine or a vaccine of a stronger formula could be chosen. It is to be hoped that in every case careful statistics will be kept, and that where the dose varies from that of the standard vaccine a note of this will be made.

SOME UNUSUAL FORMS OF DYSENTERY.

BY

GEORGE C. LOW, M.A., M.D., C.M., M.R.C.P.,

PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, ENDSLEIGH GARDENS,
 N.W., AND SEAMEN'S HOSPITAL, ROYAL ALBERT DOCKS; LECTURER
 AND CONSULTING PATHOLOGIST TO THE LONDON SCHOOL
 OF TROPICAL MEDICINE.

THE term dysentery is more or less indiscriminately applied to any condition producing blood and mucus in the stools, or even to diarrhoea alone.

For a proper classification the cause of the condition must be determined, and at the present day we talk of protozoal dysenteries, helminthic dysenteries, bacterial dysenteries, pseudo-dysenteries, and so on. As a general rule, when the term dysentery is used, unless some qualifying adjective is attached to it, either a case of amoebic or bacillary dysentery is indicated—namely, dysentery due to the *Entamoeba histolytica* or to the bacillus of Shiga or Flexner. We are apt to rest at this and consider the matter settled, but so many other conditions, many of them very common, may produce an almost similar clinical picture to these real dysenteries that a careful examination must always be made to exclude them before definitely settling our diagnosis.

A few specific instances culled from a large experience of the treatment of dysentery in London during the war will explain what I mean.

1. SYPHILIS RESEMBLING DYSENTERY (SYPHILITIC DYSENTERY).

Syphilitic ulceration of the rectum is not uncommon; ultimately it leads to stricture of the bowel and other troubles. The patient passes bloody stools with mucus, and is at once branded as "dysentery" and probably dosed with emetine or given antidyenteric serum. I have the records of such a case by me now:

The patient started his trouble in France, in 1916, with diarrhoea. Though the result of the examination of the stools was negative as to protozoa, the diagnosis of dysentery was made and he was given emetine. He was no better, but returned to his work. He soon broke down again and spent the next years going in and out of various hospitals and having more emetine, though again no protozoa were found in his stools. At one of these hospitals a shadow was seen in the rectum on x-ray examination. Finally he came under my care in 1919. A sigmoidoscopic examination made by Sir James Cantlie then revealed ulceration with a stricture just below the sigmoid flexure; the opinion was that this was not malignant but syphilitic. There was an old history of syphilis. The Wassermann reaction was negative. A course of novarsenobillon injections was then given and everything cleared up satisfactorily, the blood and mucus disappearing and the stools becoming normal in consistence and appearance. After some time he relapsed and a second series of injections was given. The condition again improved, but not so much as the first time. He is now on mercury and iodide. During his stay in hospital no protozoa were ever found in his stools.

2. MALIGNANT DISEASE.

Mr. Dobell has told me of a case, very similar to the one described above, in which the patient was treated for dysentery and dosed heavily with emetine for quite a long

time. Finally it was discovered that he had a large fungating malignant growth in the rectum. The moral of such a case is that the rectum should always be examined in cases of dysentery and also if the patient has piles, a source of mistake with the uninitiated. Three times recently cases have been sent to me as dysentery because they had blood in the stools; in each instance I found that they had not got dysentery, the blood being derived from obvious piles.

3. TUBERCLE.

An Indian patient was sent into hospital with the diagnosis of dysentery. He was extremely emaciated and was passing diarrhoeic stools with sloughs, blood, and mucus. No protozoa were found nor dysentery bacilli isolated. An examination of the lungs revealed evidence of consolidation at the right apex and below. A specimen of the stool was then examined for tubercle bacilli and a positive result was at once obtained. The patient died and the autopsy revealed advanced tuberculosis of the lungs, with extensive tuberculous ulceration in the small and large bowel. The value of proper stool examinations is well seen in this case.

4. SCHISTOSOMIASIS DYSENTERY.

This common helminthic dysentery should be easily diagnosed by the finding of the characteristic ova during the routine examination of the stools. Nevertheless cases have been sent to me which had been diagnosed as dysentery and treated by emetine injections, but after all turned out to be schistosomiasis infection only. This is a bad mistake, because emetine can do such cases no good, whereas intravenous injections of tartar emetic will cure them.

5. PARAGONIMUS DYSENTERY.

The *Paragonimus westermani*, as regards its habitat in man, is not necessarily limited to the lungs. It has been recorded also in the abdomen and the brain. When found in the walls of the intestine the mucosa may become ulcerated, and then there will be diarrhoea with blood and mucus in the stools. I recently had a case of this nature. The man—a Japanese—had some obscure abdominal trouble with a tendency to looseness of the bowels, but no blood and mucus. Nothing could be found to account for this with the exception of scanty numbers of paragonimus ova in the faeces. Thymol was tried, but no adult worms appeared and the eggs persisted.

6. HETEROPHYTES DYSENTERY.

The presence of large numbers of the *Heterophyes heterophyes*, a minute fluke, in the small intestine may give rise to signs and symptoms of enteritis. The following are the notes of such a case:

A Japanese was admitted into the Albert Dock Hospital under my care supposed to be suffering from dysentery. The stools resembled the pea-soup evacuations of typhoid, but the patient looked quite well and the temperature was not raised. There was mucus in the stools, and on one occasion some traces of blood. On examination of the faeces no amoebae or cysts were found, but quite a large number of ova of *Heterophyes heterophyes*. The question whether the flukes were causing the symptoms then arose. To settle this I administered an anthelmintic (eucalyptus, castor oil, and chloroform mixture), after the usual starvation. The result was excellent, over 500 adult flukes coming away. The symptoms after this all subsided and the stools became quite normal. In a week the patient left hospital cured.

7. ANKYLOSTOMIASIS.

Occasionally diarrhoea with blood is seen in ankylostomiasis. Last year a patient was admitted with the diagnosis of dysentery, because there was blood in the stools. He passed a liquid stool with blood in it; microscopic examination gave the diagnosis, many ankylostoma ova being present. Under suitable treatment, leading to expulsion of the worms, all the symptoms disappeared. In this case there was also considerable epigastric pain, which had puzzled several people, before the true nature of the disease was discovered.

8. BALANTIDIAL DYSENTERY.

Balantidium coli is also a cause of dysentery; the symptoms, indeed, resemble very closely those seen in amoebic dysentery. The diagnosis is made by finding the characteristic ciliates in the faeces. No instance of this

disease was seen in my series of cases, but I have heard of it from other observers. It is not uncommon in the Philippine Islands.

9. PSEUDO-DYSENTERIES.

This name has been applied to cases which do not fall under any of the headings described above. Foreign bodies impacted in the rectum above the anus may cause ulceration and discharge and be diagnosed as dysentery, especially if the patient has been abroad.

I once saw a patient with a rectal discharge of a purulent nature, and on making a digital examination found what appeared to be a growth just inside the sphincter. Next day he passed the tumour, a large piece of bone, and all symptoms and discharge disappeared. He did not remember swallowing it.

Such examples show that it is most necessary to exercise care in diagnosing cases presenting symptoms of dysentery. Careful and accurate examination of the stools comes first, of course, and after that local rectal examination, either with the finger or the sigmoidoscope.

ANKYLOSIS OF THE MANDIBLE AND ITS OPERATIVE TREATMENT.*

BY

GILBERT CHUBB, D.Sc., M.B., F.R.C.S.ENG.,

ASSISTANT SURGEON, THROAT HOSPITAL, GOLDEN SQUARE, AND PLASTIC SURGEON, QUEEN'S HOSPITAL FOR FACIAL INJURIES, SIDCUP.

THE operations hitherto described for this condition fall broadly into two groups, according as the bone resected is from the region of the condyle or from the horizontal ramus. Operations in the first group fail to give relief when the cause of fixation is wholly or in part anterior to the condyle. Those in the second group, in bilateral cases, leave the jaw so weak as to be practically useless for mastication. In the recent third edition of Brown's *Surgery of Oral Diseases and Malformations* it is recommended that, save in rare cases of urgent necessity, such cases should be left undisturbed, rather than that a bilateral Esmarch operation should be performed.

The present paper deals with the operative treatment of five consecutive cases of ankylosed mandible. In each case, irrespective of the original cause, it was found that a factor in the fixation was the formation of fibrous or bony adhesions between the anterior border of the coronoid and the pterygoid aspect of the maxilla. The operation described permits of the complete resection of the whole of the coronoid. In one case this structure was removed on both sides, together with the condylar neck region of either side also. In no case was there any involvement of the facial nerve, and in each case the patient was left with a gape of at least 2½ cm. and a very satisfactory power of mastication.

Four of the cases were traumatic, all in the malar region and accompanied by fracture of the zygoma. One was infective in origin, and followed a bilateral suppurative arthritis of the temporo-mandibular joints in infancy.

In each case the whole of the coronoid was removed, so that the anterior aspect of the condyle passed in a clean sweep down to the commencement of the alveolar border of the horizontal ramus.

The incision for this operation starts in the pre-auricular fold at the lower level of the external auditory meatus, and passing vertically upwards to the level of the tip of the pinna, curves forwards below the superior temporal crest to terminate anteriorly within the hair area of the temporal region. The incision is carried down to the bone, and the skin, temporal fascia and muscle are separately defined and turned forwards. The deeper of the two layers into which the temporal fascia splits as it approaches the zygoma is divided, and the latter bone, still working from the deep aspect of the temporal fascia, is removed piecemeal with gouge forceps. The tip of the coronoid is defined, and both its surfaces cleared of muscular attachments with the raspator. By means of suitably shaped gouge forceps the whole of the coronoid process can now be removed. During this process the surgeon is working

* Abstract of a paper read before the Odontological Section of the Royal Society of Medicine, October 27th, 1919.

between the temporal muscle and belly of the external pterygoid on the one hand, and the under surface of the masseter as this passes to its insertion into the outer face of the coronoid and angle on the other. Throughout the operation the surgeon stands at the head of the patient, and the approach to the pterygoid region is by way of the temporal fossa.

In the four traumatic cases the temporo-mandibular joint was not involved, and in three of these cases the fracture of the zygoma directly involved the coronoid process in the resulting adhesions to the surrounding structures. Nevertheless in each case the formation of fibrous or bony adhesions between the lower part of the anterior border of the coronoid and the maxilla could be determined. In each case also free movement of the mandible was not obtained until the coronoid process had been completely removed down to its base.

In the fifth case, Mr. X., the fixation, which was of fifteen years' standing, was bilateral, and followed suppurative arthritis of both temporo-mandibular joints accompanying measles in infancy. The condition before operation is seen in Fig. 1. The molar teeth were firmly clenched and imperfectly erupted. A faint "spring" could be obtained on the right side, from which the condyle had been resected ten years previously, but no movement at all could be obtained on the left. The mandible shows the lack of development characteristic of such cases, and which is due to the involvement of the two epiphyses in the original lesion.

As a result the lower incisors, which in point of level actually overlapped the upper, were situated at some distance behind the latter. A gap was thus left through which the patient had managed to feed himself.

The operation in this case was performed in two stages. At the first stage the condylar neck region and coronoid of the left side were resected. At the second stage a similar operation was performed on the right side. On the left the condylar region was found to be represented by a mass of bone of ivory hardness, causing the ascending ramus to blend smoothly with the skull. The area of bone immediately below this, and representing the neck of the condyle, was removed. On the right side the firm fibrous union occupying the place of the previously resected condyle was likewise resected. Both these resections were carried out by means of curved gouge forceps, and the anterior aspect of the neck was approached by the route described above for the resection of the coronoid. On account of the extent and density of bone on the left side,

FIG. 1.

FIG. 2.

and in order to minimize the risk of injury to the internal maxillary artery, both these resections were completed from behind. For this purpose the angle of the jaw was exposed by a horizontal incision placed below it, and the neck reached by freeing the posterior border of the ascending ramus from the adjacent soft parts. On both sides movement of the mandible was not free until the coronoids had been completely resected. As in the traumatic cases, dense fibrous adhesions were found between the anterior border of this process and the maxilla. The operation on each side was completed by a flap of temporal fascia and muscle being brought down through the gap made by the resection of the neck region and secured in the deeper layers of the lower wound. In closing the temporal wound the temporal muscles and fascia were stitched back into place, a small drainage tube being left in this and the angle wound for forty-eight hours.

The precarious nature of the patient's teeth precluded gagging at the time of the operation. A gape was, however, obtained sufficient to permit of the teeth being capped a week later. The mouth was then wrenched open under gas and fitted with a detachable elastic gag. The patient's present condition, four months after the operation, is seen in Fig. 2. The unassisted gape is $2\frac{1}{2}$ cm. Mastication is quite painless, and the bite is of sufficient strength to make it exceedingly unpleasant to leave the finger between his teeth.

The case demonstrates the possibility of surgical relief for the condition of bilateral ankylosis in which the cause of fixation is in part anterior to the condyle, while still leaving the patient with a satisfactory control over the mandible.

The post-operative treatment in these cases was carried out by my colleague, Mr. Mendleson, and the results obtained owe not a little to his care.

In the bilateral case the fact that a second long operation followed within a fortnight of the first in a patient whose general condition was naturally far from satisfactory made the choice of the anaesthetic one of some importance. The operation was performed under gas and oxygen, administered by Mr. Wade through a preliminary tracheotomy by means of the apparatus used with so much success by Mr. Geoffrey Marshall while in France. The method proved so successful, and the condition of the patient both during and after the operation was so satisfactory, that I have since adopted it in other cases of prolonged jaw operations.

MEDICAL, SURGICAL, AND OBSTETRICAL.

CARDIAC MASSAGE IN ASPHYXIA NEONATORUM.

WHEN in general practice some years ago I found cardiac massage of considerable value as an aid to artificial respiration in asphyxia neonatorum. The method was especially useful in white asphyxia, in which there is probably cardiac as well as respiratory failure. It does not do away with the necessity of artificial respiration by the usual and only really efficacious method—traction on the arms; but it renders this successful in a large number of cases where it would otherwise fail.

If smacking and clearing the pharynx does not make the child breathe, artificial respiration is resorted to for a minute or so. If this fails the child's body is placed flexed and supine. The head and shoulders rest against the upper portion of the operator's forearm, and his left hand grasps the infant's left thigh. The fingers of the right hand are now pressed into the upper part of the flaccid abdominal wall beneath the diaphragm, and the right thumb is placed over the cardiac area externally. Massage can now be performed much more effectively than in an

adult with the abdomen opened, and is sometimes strikingly successful. Every now and again the operator pauses for a moment to resume artificial respiration, and then begins the massage again if needful.

Asphyxia neonatorum should be regarded as a surgical emergency exactly similar to cessation of respiration on the operating table, and should be dealt with on similar lines. The many methods of resuscitating infants described in textbooks may be of historical interest, but are calculated in some ways to confuse the student. If smacking, artificial respiration by traction on the arms, and cardiac massage will not restore the infant, it is most improbable that any other methods will succeed.

Tuberculosis Officer, South Devon.

ACUTE SUFFOCATIVE CATARRH.

A FEW days ago I was summoned to a patient in this institution who was said to have had "a heart attack." He is an old gentleman of about 75, who, though failing, is still

able to be up and about and to walk considerable distances. He has a little emphysema and a considerable degree of arterio-sclerosis. He suffers from systematized delusional insanity and no change has been observed in his mental condition for several years.

I learnt that this attack had come on without warning just as he was returning to the ward after a substantial tea—a meal of which he always partakes heartily, though not excessively as a rule. When I saw him his condition was identical in every way with that of the second patient described by Dr. Gale in the *JOURNAL* of December 13th, 1919, p. 775. His colour was leaden and skin covered with perspiration. Dyspnoea was intense and was accompanied by much wheezing and coughing. He spoke with difficulty between gasps, and was sitting forward on a chair bending over a vessel into which he was expectorating large quantities of what I can only describe in Dr. Gale's own words as "frothy watery fluid of a mucous character, faintly tinged pink." His pulse was strong and quick.

I was in great doubt as to the real nature of the condition and the appropriate treatment, when the recollection of Dr. Gale's note came to my mind, and I realized the identical nature of the symptoms in this case and in his. I accordingly prescribed a hypodermic injection of one-sixth of a grain of morphine. In a very few minutes the patient became more comfortable, his colour became normal, the dyspnoea lessened and expectoration diminished. He was taken downstairs to bed, and as I now had no doubt as to the correctness of the treatment, I gave him a second injection of one-sixth of a grain of morphine. Within fifteen minutes he was to all appearance in his usual health, though somewhat weak and shaky. He slept well, and was only with great difficulty persuaded to remain in bed on the following morning.

The condition was quite new to me, save for Dr. Gale's note, but I have no doubt from the symptoms and response to treatment that the case was of the same nature as those he describes. I should, of course, have had the full courage of this conviction, and not given the morphine in two separate doses. I am indebted to Professor G. M. Robertson, the physician-superintendent, for permission to send this note.

HENRY YELLOWLEES, M.D., F.R.F.P.S.Glasg.
Craig House, Edinburgh.

RUPTURE OF MEMBRANES NOT FOLLOWED BY NATURAL EVACUATION OF THE UTERUS.

Mrs. A. B., aged 21, was delivered of a full-term male child on January 23rd, 1919. She became pregnant again on June 2nd, 1919.

On September 9th, 1919, she complained of losing a large quantity of blood, and was advised to stay in bed. On the following day she travelled about fifty miles over a rough road in a motor car and about a hundred miles by train, much against her medical attendant's advice.

She was seen by me on September 14th, when she complained of feeling a dead weight in the lower part of the abdomen and also of a bearing-down pain in the lower abdomen. The fundus of the uterus reached about two fingerbreadths below the umbilicus; it was flabby, there was tenderness over the right cornu, and a hard mass was felt inside the uterus. On auscultation no uterine souffle could be heard. On vaginal examination the external os admitted the tip of the second finger; she was advised to stay in bed and have complete rest. On September 16th she still complained of a dull pain in the lower part of the abdomen and of a bearing-down pain. The pains, she said, were more severe than on September 14th, and she was still losing blood. A dead fetus was diagnosed. She was given a mixture of iron and ergot and advised to stay in bed. No improvement took place, and the pains over the cornu at times became acute. It was then decided to evacuate the uterus. On September 21st, during that operation, a quantity of fetal membranes were withdrawn, and on account of the bleeding it was decided not to interfere any further. The internal os resisted dilatation beyond 11 Hegar. Afterwards there was no pain and only a slight amount of bleeding, which ceased on September 23rd. The temperature remained normal except on the evening of September 2nd, when it rose to 99° F. On the evening of September 25th she complained of a slight pain over the

right cornu of the uterus and a slight amount of brownish discharge.

On the evening of September 26th she complained of severe pain over the right cornu, and there was marked tenderness on pressure. Captain Mahoney, I.M.S., was asked to see the patient in consultation, and it was decided to evacuate the uterus under an anaesthetic. This was done on September 28th. It was found practically impossible to dilate the internal os so much as to admit two fingers without lacerating the cervix. A central placenta praevia was found, and this explained the severe haemorrhage which occurred during the first operation. With great difficulty the uterus was completely emptied after embryotomy had been performed. The patient lost a great amount of blood. The temperature ranged between 100° and 102° F. until October 3rd, yet the lochia remained perfectly sweet and normal, and gave no indication that septic trouble was going to follow.

Apart from the temperature the patient made an uninterrupted recovery, being up on the fourteenth day after the second operation.

I have to thank Captain Mahoney, I.M.S., who very kindly assisted at the second operation, and also Captain A. C. Jebb, R.A.M.C., who gave the anaesthetic for both operations.

W. F. MASON, Captain R.A.M.C.(S.R.),
Attached British General Hospital,
Nowshera, N.W.F.P., India.

IDIOSYNCRASY TO QUININE.

THE following case is of interest, as it would appear from it that the local application of quinine may cause untoward symptoms in cases of severe idiosyncrasy. The patient, a healthy, active woman, with no neurotic tendencies, good kidney elimination, and regular action of the bowels, has on three occasions suffered from taking quinine. In 1912 she took a small dose, "about 2 or 3 grains, for a cold in the head." Shortly afterwards she became very tremulous, giddy, and sick, and had to lie down for several hours. Some years later she took a tablet of quinine just before going to bed. She woke some hours later shaking all over so severely that the bed shook under her. On the third occasion, in 1918, a few hours after taking "a small dose" of ammoniated quinine, she became sick and vomited, and was prostrate for about six hours. This attack was more severe than either of the two former. Since that time she had been very careful to avoid anything containing quinine, and to warn anyone treating her of her idiosyncrasy.

In November, 1919, her dentist, knowing nothing of her idiosyncrasy, sprayed her gums with a solution containing quinine. Two hours after the application she felt very ill, became tremulous, giddy, and sick, and vomited. She had to lie down for four hours, after which she was able to do a little work, though the tremulousness persisted for some time longer. About five to six hours from the time of the application her lips and chin began to swell, and there was a serous exudation under the cuticle of the lips. When seen by me there was considerable swelling of the lips and surrounding parts, and also over and extending a little underneath the chin. The appearance of the lips was similar to that seen in severe herpes, when the vesicles have been so crowded together that they have coalesced. There was no pain, tenderness, burning, or itching felt. After some days the condition cleared up. With the drying up of the exudation a crust like that seen in herpes formed which covered the entire surface of both upper and lower lips.

London, W.

GRACE MACKINNON.

THE CONTROL OF INFLUENZA.

IN view of the possible return of a wave of epidemic influenza, may I impress upon all resident medical officers in charge of institutions the importance of immediate isolation where possible? In hospitals a small ward may be set aside for this purpose. I have on more than one occasion proved the efficacy of this measure in preventing the spread of the disease. The same plan should, of course, be adopted in private, and the spread of the disease would be materially affected.

Reports of Societies.

MEASUREMENT OF EMOTION.

At a meeting of the Royal Society of Medicine, on February 11th, Professor A. D. WALLER, F.R.S., gave a lecture on the measurement of human emotion and its control. Emotion, he said, as was well known, produced appreciable changes in the skin, such as vasomotor effects and sweating. He believed that, in addition to these phenomena, there existed others that were under the control of the central nervous system. Cell metabolism was probably influenced directly by impulses arising in the central nervous system, the influence being exerted on the porous envelope surrounding every cell, so that under certain conditions these cell membranes became more porous and cell metabolism increased; under other conditions they became less permeable, and metabolism diminished. These changes were capable of being appreciated through the alterations produced in the resistance to an electric current. For this purpose the hand of the subject under examination was placed in the arm of a Wheatstone bridge and the resistance measured. If the subject of the experiment was then subjected to any painful stimulus, either physical or psychical, a deflection of the mirror galvanometer took place, and its extent could be measured by the movement of a spot of light on a screen. The alteration of the subject's resistance must, he thought, be attributed to the effect of nervous impulses passing down the peripheral nerves, and acting on the cells through their surrounding membranes. Resistance in the passive state varied in different individuals, and at different times of the day. It was necessary therefore before making an observation to adjust the apparatus to the subject's resistance whilst in a passive state. A definite daily cycle in the resistance of an individual had been observed, the resistance being at its highest during the early hours of the morning, and at its lowest during the corresponding hours of the afternoon. These periods coincided with the periods of minimum and maximum metabolism. When making these observations it was always necessary to employ the palms of the hands or the soles of the feet; the reactions obtained when other surfaces of the body were utilized were less marked and open to some doubt. The reason for this was obscure, but it seemed likely that something more was entailed than a mere action on the sweat glands. Charts showing the deflection of the galvanometer that occurred when a subject was submitted to a variety of shocks were exhibited. One extremely good record exhibited the changes during an air raid. A practical demonstration of the phenomenon was then made both on his assistant and on a volunteer from the audience. The striking of a match with the threat of burning caused an immediate deflection of the galvanometer, indicating diminution of resistance. The actual burning caused a greater diminution, but the difference was not so large as might have been expected. A deflection was shown to occur also when the subject coughed; this was due not to any emotion associated with the cough, but to the passage of a nervous impulse down the nerves of the arm. An appreciable interval occurred between the cough and the deflection of the galvanometer. This latent period was probably caused by changes in the periphery rather than in the higher centres. Dr. Waller concluded by stating that he left to others the task of deciding how this method could be most usefully employed in practical medicine. He had found, however, that, contrary to what might be expected, hysterical subjects were less likely to show deflection than normal individuals.

After the President, Sir HUMPHRY ROLLESTON, had thanked Dr. Waller in the name of those present, Dr. J. A. OMBROD recalled the fact that Charcot had shown that an alteration in resistance to the passage of an electrical current occurred in Graves's disease. Dr. Waller's statement that hysterical patients showed less rather than more deflection than normal beings was of particular interest, for no less an authority than Janet had stated that hysteria was not, as generally supposed, associated with a condition of increased emotion.

Sir KENNETH GOADBY related some of the results observed when he himself was the subject. He agreed that

the observations were very striking, but felt that there existed a considerable danger of the method falling into the hands of unskilled and unscrupulous persons. When employed by a skilled practitioner the method was likely to yield interesting and valuable data.

Dr. DAWSON WILLIAMS said that personal experience would leave no doubt in the subject's mind of the existence of the phenomena described. To himself the effect produced on the galvanometer by the sudden intrusion into his consciousness of a disagreeable memory, ingeniously revived by Dr. Waller, had seemed to him even more remarkable than the response elicited by physical pain.

Dr. PARKES WEBER suggested that some interesting results might be obtained by making observations on patients suffering from myxoedema.

NAKED-EYE DIAGNOSIS OF THROAT INFECTIONS.

At a meeting of the Medical Society of London held on February 9th, with the President, Mr. V. WARREN LOW, in the chair, Dr. H. DRINKWATER read a paper on the clinical diagnosis of diphtheria and other diseases of the throat by means of the naked-eye appearances. Dr. Drinkwater's paper followed the main lines of the lantern demonstration given by him at the Clinical and Scientific Meeting of the British Medical Association in April last.¹ During three years' experience of a large number of cases of diphtheria and other infectious diseases in the East Denbighshire Fever Hospital the bacteriological examination had in every case confirmed the naked-eye diagnosis, thus upholding the correctness of the opinion reached by him twenty-five years ago. As on the occasion of the April meeting, Dr. Drinkwater dealt in turn with the diagnosis of diphtheria, Vincent's angina, follicular tonsillitis, and influenza, illustrating his remarks with coloured diagrams, and explaining his diagnostic division of the fauces into certain well-defined areas, three on each side of the middle line.

Sir JOHN BROADBENT said that the illustrations depicted very accurately the appearances of the throat in diphtheria, Vincent's angina, and follicular tonsillitis. The membrane in diphtheria was ashen-grey or whitish in colour, and not like the wash-leather of the textbooks. There was little difficulty in diagnosis in such definite cases as were portrayed, but in many others the appearance was less characteristic, or only suspicious, and bacteriological examination could alone supply the diagnosis. The same was true of cases seen first in a later stage. Some cases of scarlet fever, with ulceration of the throat, presented great difficulty, for they might be almost exactly like diphtheria, and the two were certainly combined occasionally. In these cases throat culture was important, for if undiagnosed they might become carriers.

Dr. F. PARKES WEBER referred to the herpetic condition of the throat which had been illustrated. Herpes in the mouth, in his opinion, was nearly always bilateral and of the catarrhal form, not herpes zoster. It was rare on the soft palate. He compared it with the herpes met with on the nose and face, remote from the lips, in mild pneumonia.

Dr. W. HILL said that there were occasional cases in which reliance must be placed on the bacteriological findings. Mistakes were likely to be made in diphtheria when the lesions were multiple, the throat clearing up. In several instances he had met with combined lesions. It might be impossible to distinguish between Vincent's angina and diphtheria from the naked-eye appearances. The "coccal" patches depicted as influenzal might certainly occur in influenza, but they were an epiphenomenon, and might also occur apart from that disease. In difficult cases the illustrations would not help.

Dr. MONTAGUE SMITH narrated a case of what appeared to be typical follicular tonsillitis from which the Klebs-Loeffer bacillus had been recovered.

Dr. DRINKWATER pointed out, in reply, that bacteriological examination had been done in every case. If the appearances which he had demonstrated were better known by the general practitioner who saw the cases in their early stage there would not be so many inexcusable mistakes, nor would diagnosis be delayed for the time necessary to receive a bacteriological report.

Rebielus.

THE LIFE OF SIR VICTOR HORSLEY.

(With Portrait Plate.)

SIR VICTOR HORSLEY died on July 16th, 1916, at Amara on the Tigris while consulting surgeon to the British forces in Mesopotamia. In the *BRITISH MEDICAL JOURNAL* of July 29th, 1916, was published a sketch of his life, in which an endeavour was made to indicate briefly the main facts of his brilliant career. It was not possible to do more, for Horsley's interests extended in many directions and in every field he entered, his virile intellect, his energy, and his powers as a leader of men quickly won for him a commanding position. His industry in collecting facts and his skill in marshalling them were only less remarkable than his grasp of principles and clear view of the result to be attained. With the help of the Medical Secretary of the British Medical Association (Dr. Alfred Cox) we were then able to give a fairly full account of his services to the profession through the British Medical Association, which, directly or indirectly, include most of his medico-political work. But it was not possible at that time to attempt any adequate estimate of his achievement as a neurologist and pioneer in the surgery of the central nervous system: the subject was too large. Nor were we able to give an account of his military services during the war owing to the lack of sufficient information inevitable in the circumstances of the time. Mr. STEPHEN PAGET has now written a biography¹ in which all the aspects of Horsley's strenuous life are depicted with the writer's accustomed sympathy and skill. It has been read no doubt ere this by many members of the profession, and we can only regret that the publishers have considered it necessary to put so high a price on the volume, for it is one that should be read by all of us for the interest of the story and the stimulating lessons to be found in it. It has been thought that a further tribute to Horsley's eminent qualities and achievements could here best be rendered by asking two colleagues intimately associated with him, the one in his work as a surgeon in civil life and the other during the war, to give our readers their estimate of the manner in which Mr. Paget has accomplished his task.

The obituary notice published in 1916 was illustrated by a portrait which some of his friends preferred; but others have since expressed a wish to have a remembrance of him in less stern mood, and this opportunity has been taken to present another portrait which we feel sure many will be glad to possess.

NEUROLOGY AND SURGERY.

We are indebted to Mr. PERCY SARGENT, C.M.G., D.S.O., surgeon to the National Hospital for the Paralysed and Epileptic, Queen Square, where Horsley did much of his work on the surgery of the brain and spinal cord, for the following observations on the earlier part of Mr. Paget's volume:

It is difficult at the present time to form a just estimate of Sir Victor Horsley, or to define the exact position which future generations will assign to him upon the roll of honour of British Medicine. We are too near to the controversies in which he played a leading part in the years immediately preceding the war to see him in true perspective, for the dust of conflict still obscures our vision. Mr. Stephen Paget has given us a study of his life and work which is of absorbing interest. It goes far to satisfy those whose admiration comes near to hero-worship, and it rebukes those who allow political views to warp their appreciation of his greatness in the world of science. Mr. Paget has no hesitation in placing Horsley amongst the greatest of surgeons of all time: "He is with Ambroise Paré, Lister, and Hunter: with them, not below them."

To those who never came into personal contact with Horsley, or who are only vaguely aware of what he did for physiology and for surgery, the record of energy expended and work accomplished may well appear almost incredible. It is one of the features of Mr. Paget's book that we are never allowed to lose sight of the restless

energy and indomitable courage which characterized all that Horsley undertook.

Gifted men are often lazy; workers of less ability may surpass them by industry and perseverance, but the combination of intellectual brilliance with tireless industry is rarely found. When it is, once in a generation or two, we get a Victor Horsley. Men of his gifts have often been born at an unpropitious time, into an age which knew them not nor cared to know them; their gospel has fallen upon deaf ears, and it has been for some future generation to appreciate their worth. It was not so with Horsley. The scientific age was ready for him, and he came into his kingdom in princely fashion. The genius of Lister had not only thrown open to his successors the doors of a new surgery, but it had also shaken the complacency of an older generation of surgeons. Not only in these ways was Horsley favoured, but he came at once into contact with men of broad views and wide sympathies, men whose own names are household words, and by whom the brilliant young scientist was stimulated and encouraged. One illustration alone is sufficient. The Commission appointed by the Local Government Board to inquire into Pasteur's treatment of rabies consisted of Sir James Paget, Sir Lauder Brunton, Dr. George Fleming, Lord Lister, Sir Richard Quain, Sir Henry Roscoe, and Sir John Burdon-Sanderson, and Horsley as its Secretary. To the casual observer at that time he must have seemed but a pigmy amongst the giants, yet he was destined to outgrow them all, and to leave behind a name second to none, save perhaps that of Lister.

So many and so varied were Horsley's contributions to medical science, that Mr. Paget has had a difficult task to review them in so comparatively small a volume. He has achieved it with admirable clearness. The research work is described under three main headings: (1) The localization of function in the brain; (2) the thyroid gland; and (3) the protective treatment against rabies. The chapters on myxoedema and rabies furnish a concise epitome, in the first case of the progress of knowledge regarding the functions of the thyroid gland from 1873 to 1893; and in the second, of the history of the stamping out of a preventable disease in the face of the incredibly stupid opposition of the antivivisectionists. In both these directions the dominant share taken by Horsley is clearly indicated. The greatest of the three divisions of Horsley's research work concerns the central nervous system. Of this Paget says: "It was natural that Horsley should take the brain as his chief subject of study. All that was intellectual in him urged him to care more for the seat of intellect than for any other organ in the body; it offered him problems and opportunities and rewards that nothing else could offer." What interested him most of all was the central representation of function, for he held that improvement in the results of cerebral surgery was to be sought for in earlier operations, and that to this end earlier diagnosis, which could only come about from extended knowledge of cerebral function, was essential.

The experimental work, done between 1884 and 1891, in conjunction with Schafer, Beevor, Semon, Spencer, and Goteh, is tabulated and analysed in such a manner as to present the salient results of each research, and their interdependence, in a readily assimilable form. It is astonishing to learn that all this was going on concurrently with the work on rabies and the thyroid gland, as well as with active professional practice. Mr. Paget calls the period from 1884 to 1900 "the wonderful years." Wonderful indeed they were, for in them was well and truly laid, upon the solid basis of experimental physiology, the foundation of the surgery of the nervous system. This all too brief, but nevertheless clear, summary of the research work leads up to the record of what he accomplished for practical surgery. When Horsley was appointed surgeon to the National Hospital for the Paralysed and Epileptic, Queen Square, the surgery of the brain and spinal cord, as distinguished from that of the skull and vertebral column, was in its infancy. Sir William Macewen and Arthur Barker had operated for cerebral abscess, and Godlee for tumour of the brain, but "we can count on our fingers the cases of modern brain surgery recorded in our surgical literature up to the time of Horsley's appointment at Queen Square." His first operation at Queen Square, in 1886, was for epilepsy resulting from an old injury; Hughlings Jackson and Ferrier were present. "Horsley removed the scar in the brain, and the

¹ *Sir Victor Horsley. A Study of His Life and Work.* By Stephen Paget, F.R.C.S. London: Constable and Co., Ltd. 1919. (Demy 8vo, pp. xi + 558, illustrated. 21s. net.)

Richard Horsely

Photograph by Mr. G. C. Beresford.

surrounding brain substance, to a depth of 2 cm. The wound healed well; the mental condition was improved, and the fits ceased."

From that time onwards he rapidly enlarged the field of neurological surgery. The operation of laminectomy as now usually practised is Horsley's; his was the first deliberate operation for the removal of a tumour compressing the spinal cord; the operation of ligaturing the internal jugular vein for septic thrombosis of the lateral sinus was planned by him. A year before William Rose's bold pioneer attempt to remove the Gasserian ganglion Horsley had "in one case divided the trigeminal nerve close to the brain, between the base of the brain and the Gasserian ganglion." He afterwards practised what is usually known as the Hartley-Krause operation for removal of the ganglion, and no one who was privileged to see him perform one of these operations is likely to forget his astonishing dexterity. Paget says, "No surgeon will ever surpass him in skill and judgement over this very difficult operation, and in the earlier years none was equal to him." He was the first to venture to attack the pituitary body, which he approached by the temporal route; the palliative operation for relief of pressure in cases of irremovable cerebral tumour, now known as decompression, was worked out by him. These pioneer operations, any one of which might be thought enough for fame by most surgeons, by no means exhaust the account of what practical surgery owes to Horsley.

He was endowed with all the gifts which make a good operator; skill in the use of tools, quickness devoid of haste, resource in difficulty, and that attitude of mind which allowed no detail of technique to be considered beneath his notice. All this contributed to his many undoubted successes in a field where success is, from the nature of the cases, harder to win than in many another special branch of surgery. One of the many secrets of his success is to be found in the fact that "he never let hold, in special surgery, of general surgery."

Of his published works, the Address in Surgery at the Toronto Meeting of the British Medical Association in 1906 is considered by Mr. Paget to be amongst the most important. In it Horsley reviewed the whole field of brain surgery in the light of his own experience, extending over twenty years. He emphasized the fact that the principles of cerebral surgery which he had advanced twenty years earlier were based upon experiments on animals, and that since then further experimental research on animals had confirmed and extended these principles. He discussed the appropriate time for surgical intervention in intracranial disease; the significance of "optic neuritis" in conditions of increased intracranial pressure, and the certainty with which blindness from that cause could be averted by the "simple proceeding of opening the dura mater," and his own views as to the localizing value of the incidence of the neuritis. The technique of cerebral operations was also fully entered into, and explicit reasons were advanced for each detail concerned, including the method of inducing anaesthesia and the means of avoiding shock, besides many lesser, though still important, matters.

For the most part Mr. Paget writes with judicial fairness, but the reader cannot help feeling sometimes that he adopts the tone of counsel for the defence rather than of judge, and in so doing occasionally seems to bring weak points into undue prominence. To certain calumnies he gives the lie direct, as when he justly denounces as "brutal nonsense" the "gossip that Horsley was in a hurry to operate, and would even operate for the sake of operating." Throughout the book we get a good impression of Horsley's personal charm, his generosity, his care for his patients, and his love of animals. "The young men who worked with him in hospital wards and physiological laboratories . . . found him keen to help them, lavish of his gifts, enjoying to advise and guide them in their work so that it should tell to the best advantage, not for him, but for them." He "spent himself with superb extravagance"; he "played his life for all it was worth; there is nothing that he kept back from us, there is nothing that he feared."

THE WAR.

Dr. W. H. WILLCOX, C.B., C.M.G., who served with Horsley in Egypt and Gallipoli, and was consulting physician with the British Forces in Mesopotamia when

Horsley was consulting surgeon, has written the following review of the later chapters, in which Sir Victor Horsley's services during the war are related:

A very interesting account is given of his war service, and the letters published contain many local touches portraying his love of nature and his human interest in the everyday life of these around him. Horsley possessed in a remarkable degree the qualities of fearlessness, disregard of self and personal comfort, tireless industry and personal charm, to which perhaps might be added the sporting instinct or love of adventure. All these qualities were exemplified by his services during the war.

In a recent letter the distinguished American surgeon, Dr. W. W. Keen, speaks of "The sad loss to Science and to Medicine specially, and in fact to the World, by the death of Victor Horsley. I had known him ever since the Congress of 1881, so that my intimate knowledge covered almost forty years. I know of no one who has advanced Surgery more than he. It was a great mistake, it seems to me, ever to have allowed him to go into the Field anywhere, but especially into the climate of Mesopotamia. In his Laboratory he would have been worth ten men at the Front." But Horsley could not remain at home without, as he wrote in one of his letters, "eating his heart out in enforced idleness." He felt that there was pressing need of expert surgeons near the fighting line where the necessary operative treatment could be carried out before septic complications had set in. It was only later in the war that the army authorities, as the result of experience, realized the importance of this.

Horsley was on the staff of the 3rd London General Hospital; it was mobilized early in August, 1914, and he worked hard for its organization and equipment. There was, however, little surgical work to be done there during the first few weeks of the war, and a plethora of surgical specialists on its staff. He chafed for more active work, and as early as August 12th, 1914, applied for transfer to the active service list. On March 28th, 1915, he left for France, being in charge of the Surgical Division of No. 21 British General Hospital as Major R.A.M.C., and after a short period of service there was transferred with his hospital to Egypt in May, 1915.

In July, 1915, he was given a wider sphere for his activities, being made consulting surgeon with the rank of Colonel A.M.S. His tireless energy and wide outlook on things extended their influence over the whole sphere of operations, and he fearlessly called attention to the needs not only of the Medical Department but of the troops in general. October, 1915, was spent in visiting Mudros and Gallipoli, during which period he was exposed to much personal privation and danger. His expert advice and help were of incalculable value, and his fine example of disregard of danger and hardships acted as a great stimulus and encouragement to the medical officers who were doing their utmost under most trying and difficult conditions.

After the evacuation of Gallipoli there was less pressing need of his services in Egypt, and he wished for a more active sphere. At that time the needs of Mesopotamia were becoming manifest, and the testimony of the wounded who were being evacuated home through Egypt made Horsley realize that he might do much to rectify the great defects in the medical arrangements in that field of war. We accordingly find him volunteering for service in Mesopotamia, though he knew full well the obvious hardships and dangers to which he would most certainly be exposed. On March 25th, 1916, he arrived in Bombay. While in India he did much to stimulate the authorities with regard to the medical needs of Mesopotamia, and his advice was fully appreciated and acted upon. He reached Basrah on April 16th, 1916, and it is characteristic of him that within a few days he was at the front making a personal investigation of the actual surgical needs in the fighting line.

His letters from Amara in May and June, 1916, graphically describe the climatic discomforts and hardships of the campaign. He told a colleague, however, that he did not feel personal discomfort from the intense heat, but thought that it did him good. His letters show also how much he felt the pressing needs of the force in Mesopotamia and the steps he took in endeavouring to improve the trying conditions. He spoke in the highest praise of the self-denying and splendid work done by all the medical officers in Mesopotamia, and made it known to the world

that they did all that could possibly have been done with the means at their disposal.

His indisposition of July 14th, 1916, culminating in a fatal attack of heatstroke on the evening of July 16th, are related. It was a tragic misfortune that this calamity should thus have occurred, for it was known that he had intended to leave Amara for India early in July in order to use his influence at head quarters there to improve the conditions in Mesopotamia. He delayed his departure in order to meet the Army Commander who was coming up river.

It has been said that Horsley needlessly exposed himself to the fierce climatic conditions of Mesopotamia, relying on his abstinence from alcohol as a safeguard. This is untrue. It was closely associated with him as a colleague in Mesopotamia, and can state that during this period there was a very great deal of pressing consulting work which demanded attention. There was a deficiency of transport in the shape of motor cars and launches, and these were not available for consultants at that time, so that the choice had to be made between "inaction or doing one's duty with risk of heatstroke." It need not be said which course Horsley adopted. During the mornings he visited the hospitals at Amara, of necessity walking several miles in the intense heat in order to do the work which demanded his attention, and there is not the least doubt that this exposure caused the fatal attack of heat hyperpyrexia.

Horsley nobly did his duty, and thereby gave up his life for his country.

OBITER SCRIPTA MEDICI MILITARIS.

THOSE who have often turned with relief from some technical article to Sir R. FIRTH's thoughtful writings in the *Journal of the Royal Army Medical Corps* will give a hearty welcome to the seventy-five essays now collected in a book with the title *The Musings of an Idle Man*.² It is dedicated to his old comrades and to the memory of the 568 officers and 4,634 other ranks of the Royal Army Medical Corps who gave their lives for King and country in the great war of 1914-1918. These pleasantly written meditations were begun to while away the tedium of long railway journeys in India, were continued in France and at home, and cover a period of some eight years. The subject matter is varied and touches on ethics, evolution, idiosyncrasies, manners, morals, philosophy, mysticism, sociology, and other topics. The tone is subdued and reflects the calm and kindness that should come with the experience of the fleeting years, and is well illustrated in Sir Robert Firth's modest thoughts "on being superannuated," and by his remarks "on death." Though written by a distinguished medical officer, these essays are not professional any more than P. G. Hamerton's writings on *Human Intercourse* and *The Intellectual Life*, which they somehow recall, deal with art and etching; their soothing tone will serve to correct the worries of the hard pressed practitioner.

NOTES ON BOOKS.

THE issue of *Medical Science*³ for February contains reviews of recent literature on diseases of the respiratory system, cardio-vascular diseases, extradural subcranial dermoid cysts, the surgical measures for empyema of the thorax, diverticula of the bladder, and the representation of the bladder in the cerebral cortex, together with abstracts of papers in various departments.

Psychologies,⁴ by Sir RONALD ROSS, is a collection of five poems in the dramatic form, and their tragic effect is derived less from the concourse of external events than from the reaction of human characters in moments of emotional intensity. In our judgement the best poem is "Evil"; it is truly dramatic: there is a definite unveiling of character and a crescendo of emotions, but told with restraint, irony, and pathos. The whole series is distinguished, and the verse, although not rising to any great heights of poetic imagery, is always admirably suited to the subject, and its quality is, in places, faintly reminiscent of the old ballad literature. There is vigorous underlying

force, which often rises to the surface and gives great beauty to the words, and although it is the chords of pity and terror that are heard, and not those of sweetness and joy, they are always struck with firm touch. Sir Ronald Ross in his brief preface promises more, and the hope may be expressed that he will keep his word.

The fifth edition of FRIEDENWALD and RUHRÄH'S *Diet in Health and Disease*⁵ provides the reader with a large and comprehensive book on the subject, full of facts, figures, tables, and percentages that should enable him to devise diets of great variety to suit persons and patients of all classes. The first 360 pages deal with the principles of dieting, the nature of various foods and beverages, and special methods of feeding. The rest of the book deals with diet in diseases of all sorts, with special chapters on army and navy rations, diets in public institutions, recipes, food values, and the like. The authors discuss impartially the many diets they set out in their pages, and appear to be commendably free from dietetic fads and fancies, leaving the reader to draw his own conclusions unprejudiced.

Evening Play Centres for Children,⁶ by JANET PENROSE TREVELYAN, sketches the origin and development of the play-centre movement. In a well written and concise form it gives details that should be valuable to the many local authorities and other agencies which are about to start new centres. Descriptions are given of nearly a hundred suitable hall and playground games.

² *Diet in Health and Disease*. By Julius Friedenwald, M.D., Professor of Gastro-enterology in the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, and John Ruhräh, M.D., Professor of Diseases of Children in the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore. Fifth edition, reset. Philadelphia and London: W. B. Saunders Co., Ltd. 1919. (Med. 8vo, pp. 919. 25s. net.)

³ *Evening Play Centres for Children*. By Janet Penrose Trevelyan. Preface by Mrs. Humphry Ward. London: Methuen and Co. 1920. (Cr. 8vo, pp. xvii + 177; 12 illustrations. 5s. net.)

ROYAL MEDICAL BENEVOLENT FUND.

AT the meeting of the committee held on February 10th seventeen cases were considered and £183 2s. voted to fourteen of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 38, of M.D. Dubl. Applicant is a trained nurse, but is unable to work at present on account of ill health of self and child. Pays 5s. a week rent for one room. Relieved four times, £29. Voted £10.

Widow, aged 38, of L.R.C.P. Edin. who died in 1917. Has been living on her capital, which is now entirely exhausted. Has three children, aged 12, 10, and 4, and is without means. Relieved once, £10. Rent 17s. for two rooms. Voted £5 and a special grant of £2 2s.

Daughter, aged 58, of F.R.C.S. Eng. who died in 1890. Has no income. She receives £13 from the Guild. Rent 4s. a week. Relieved fourteen times, £156. Voted £18 in four instalments.

Daughter, aged 57, of M.R.C.S. Eng. who died in 1877. Applicant receives £18 from dividends and £21 from another charity. Does a little needlework occasionally. Rent 10s. 6d. for two rooms. Relieved four times, £38. Voted £18 in twelve instalments.

Daughter, aged 61, of M.D. Lond. who died in 1868. Acts as housekeeper, or does a little nursing when her health permits. Receives £26 from another charity, and £12 from friends. Rent 10s. a week for one room. Relieved six times, £56. Voted £12 in twelve instalments, and a special grant of £2.

Widow, aged 70, of M.R.C.S. Eng. who died in 1906. Was left unprovided for with six children; four of them are now married, and are unable to help. Eldest daughter is a teacher, and pays the rates and taxes, £22; the other daughter helps at home. Applicant takes in boarders. Rent £38. Relieved by the Fund many years ago, and again in 1913, when she was granted £12. Voted £10.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W. 1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessaries, with applications for coats and skirts for ladies and girls holding secretarial posts and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who, in happier times, would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W. 1.

¹ *Musings of an Idle Man*. By Colonel R. H. Firth, K.B.E., C.B. London: John Bale, Son, and Danielsson, Ltd. 1919. (Cr. 8vo, pp. xii + 60. 7s. 6d. net.)

² Annual publication, 1; a little number, 2s.

³ *Psychologies*. By Sir Ronald Ross. London: John Murray, 1919. (Cr. 8vo, pp. 111. 2s. 6d. net.)

ST. CHAD'S HOSPITAL, BIRMINGHAM :

A HOSPITAL FOR PAYING PATIENTS.

BY

WILLIAM BILLINGTON, M.S., F.R.C.S.

SEVEN years ago a small group of Birmingham consultants formulated a scheme for the provision of special medical and surgical treatment at moderate inclusive cost. There was then no provision for the large number of patients unable to afford the heavy expense of a private operation and who were not yet of the class for whom the voluntary hospitals are primarily intended. It was felt that a frankly non-charitable self-supporting institution where such patients could be treated would be a great boon.

To make the scheme a success it was necessary—

1. That the hospital or nursing home should contain a sufficient number of beds to allow of the fixed and administrative expenses being spread over as many patients as possible.

2. That the medical staff should make their fees proportionate to the institution charges in order to bring the inclusive cost within the means of the patient.

The need for such an institution in the Midlands was real and urgent, as indeed it is in every large centre of population in the country. To meet it new ground had to be broken and many difficulties, ethical and financial, to be faced and overcome without the help of a precedent. After careful deliberation it was decided that the most satisfactory solution of the problem would be :

1. To eliminate charity in any form and to found the institution on strictly business lines.

2. While incorporating all that experience has proved of value in the administration and working of the large voluntary hospitals, to keep free from any actual association with them.

3. While obtaining all possible assistance from the outside public, to retain the real control in the hands of the medical staff.

Proceeding in accordance with the above principles, a public company was formed. The articles of association provide that—

1. The affairs of the company shall be administered by a board of directors, three of whom shall be elected by the shareholders and two by the Medical Committee. The chairman shall be one of the three members elected by the shareholders.

2. The directors shall control and generally carry on and manage the work of the institution, subject nevertheless to the restrictions arising out of the powers conferred upon the Medical Committee.

3. The directors shall not (a) publicly advertise the institution in any way whatsoever; (b) admit patients except on the recommendation of a member of the medical staff and on the conditions laid down by the Medical Committee.

4. There shall be a medical staff consisting of such a number of medical practitioners as the Medical Committee shall from time to time determine.

5. Every member of the medical staff must be the holder in his own right of shares to the nominal value of £200.

6. The medical staff shall constitute a Medical Committee, on which each member shall have equal voting powers.

7. The Medical Committee shall retain the sole right of appointment to and removal from the medical staff. Resolutions to be effective must be supported by three-quarters of the members present.

8. The Medical Committee shall control all matters relating to the medical work of the institution, but all resolutions involving the expenditure of money shall be in the form of recommendations to the board of directors.

Finance.

A large house standing on 3 acres of freehold land in the suburb of Edgbaston was purchased, together with the site. The entire cost of this and the new building amounted to about £22,000. This was obtained by the issue of £10,000 6 per cent. preference shares and £2,000 ordinary shares, the balance of £10,000 being raised in the form of a mortgage. All the shares have been issued and fully paid up. There are nearly 100 shareholders, most of them large firms in the city and prominent men interested in the scheme. Except for the first year after the opening of the hospital, when only 4 per cent. was paid on the preference shares, these shares have received the full 6 per cent. interest, while for the past two years a dividend of 6 per cent., free of tax, has been paid on the ordinary shares.

The Patients.

No patient can be admitted except on the recommendation of a member of the medical staff, under whose care he is placed. Subject to a minimum charge of £5 5s. a week, the amount of the inclusive fee is arranged between the patient and the member of the medical staff concerned. The arranged fee is notified to the house governor, whose business it is to collect it and apportion it according to a scale agreed upon between the Medical Committee and the board of directors. Each member of the staff receives every month a statement showing the fees collected from his patients, together with a cheque for the proportion due to him.

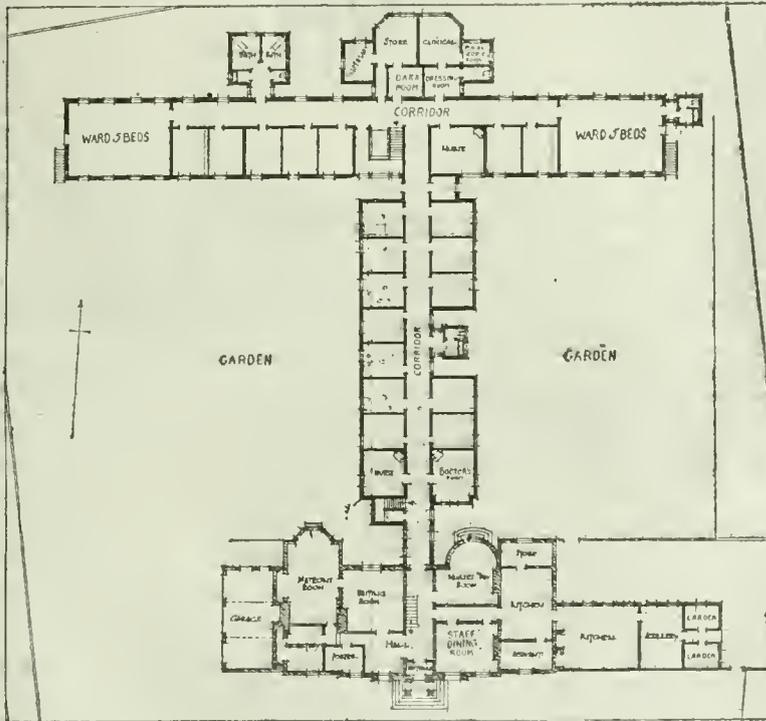

Patients are divided into two classes:

1. "Composition" patients, who pay an inclusive fee not exceeding £10 10s. a week for nursing home accommodation and all professional attendance. Composition patients form 90 per cent. of the total admissions.
2. Ordinary "Private" patients who pay the usual fee to the physician or surgeon in attendance quite independently of the nursing home charges.

A rebate from the usual nursing home charges is made in the case of composition patients, provided that the whole amount of the inclusive fee is notified to and collected by the house governor.

Example of the Working of the "Composition" Scheme.

1. A. B. is admitted for haemorrhoids or hernia. A charge of £14 14s. covers the operation, the anaesthetic, and a fortnight's stay in the hospital.

Plan of Ground Floor. Showing a series of rooms for single cases, and two wards of five beds each.

2. C. D., suffering from chronic appendicitis, is accepted for an inclusive charge of £21. This covers the cost of the operation, the anaesthetic, and three weeks' stay in the hospital. The anaesthetist receives a direct payment of one guinea from the inclusive fee.

3. E. F. is admitted for cretting or for a repair of ruptured perineum; £15 15s. covers operation, anaesthetic, and a fortnight's stay in the hospital.

4. G. H. is admitted with obscure gastric symptoms, and stays in the hospital four weeks for a composition charge of £31 10s. His case requires full investigation and may call for a consultation between a physician and surgeon, an x-ray examination, and subsequent operation. The cost is covered by the single inclusive payment.

5. I. J. is admitted for investigation of haematuria of unknown origin. He remains in the hospital for a fortnight for an inclusive charge of £14 14s. The case has necessitated a cystoscopic examination, a radiograph, and a bacteriological examination of the urine.

6. K. L., suffering from adenoids, stays one night and is charged a fee of £3 3s., covering the cost of operation, anaesthetic, and nursing expenses.

7. M. N. has symptoms suggesting that he may be suffering from phthisis. He is admitted under the care of a physician for a fortnight's observation at an inclusive charge of £15 15s. The case is watched in an open-air ward, and may require bacteriological and radiographic investigation.

The hospital building is entirely new. It contains sixty small private wards, four large wards with accommodation for six patients each, and two large open-air balconies facing due south; it is capable of accommodating one hundred patients. It is provided with two complete operating theatres, a small dispensary, a pathological laboratory, and x-ray rooms. Every room has an outlook on to a large open garden, and receives direct sunlight part of the day. There are three floors, each forming a separate entity from the point of view of the nursing, which is carried out on the lines of a large ward in a voluntary hospital. The equipment and general arrangements conform to the requirements of a modern hospital. The whole building is warmed by radiators (hot-water circulation). The hospital is conducted on the same lines as the large voluntary hospitals. The staff consists of a whole-time house governor and his clerk, a resident medical officer, a matron, assistant matron, six sisters (one of whom is home sister and house-keeper), twelve staff nurses, and nineteen probationers. The College of Nursing, after an official visit and inspection by two matrons of large general hospitals, have recognized St. Chad's Hospital as a training school for nurses, and its certificate of training constitutes eligibility for membership of the college.

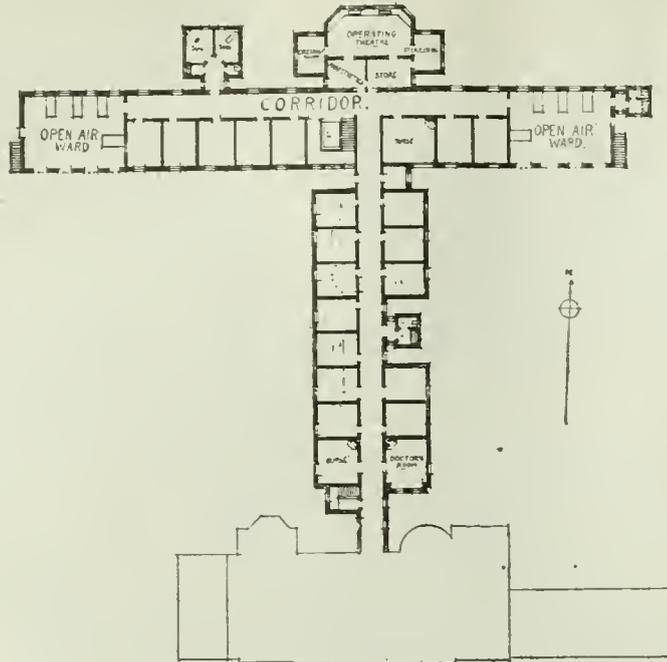

The medical staff of the hospital consists of twenty-three members, each of whom is a consultant and a member of the staff of one of the Birmingham hospitals. Every speciality is represented by at least two members, no one being allowed a monopoly. On application to the house governor a printed list containing the names and addresses of the medical staff, arranged in alphabetical order, can be obtained. Admission to the hospital is only possible through a member of the staff, but the ordinary relationship between consultant and practitioner is maintained, and the latter has free access to his patient while in the hospital,

and where practicable is invited to assist in the treatment. This holds good especially with regard to the administration of anaesthetics and assistance at operations (for which a fee is paid out of the inclusive charge).

A point of great practical value is the right that each member of the staff possesses to call upon any other member for assistance in the treatment of a "composition" patient without fee.

The first patient was admitted into St. Chad's Hospital on September 5th, 1914. Since then, in spite of the many serious difficulties arising out of the war, its history has been one of successful progress. The particulars given in the following table, taken from the last Annual Report, afford evidence of the wide scope and progressive character of the hospital's activities. It is worthy of note that last year more than 900 patients were of the "composition" class. All

these were unable to afford the cost of treatment in an ordinary nursing home, and would have been compelled to apply for admission into a charitable hospital had St. Chad's not been available.

Plan of First and Second Floors. Showing a series of rooms for single cases, and open-air wards.

In-patients Admitted.	1914-15.	1915-16.	1916-17.	1917-18.	1918-19.
Total admitted	133	523	767	898	1,011

Revenue received	£1,287*	£3,417	£5,605	£7,714	£9,719

* Seven months.

Five years' practical experience of the working of the scheme of which St. Chad's Hospital is the outward and visible sign has demonstrated that with proper organization "paying" hospitals can be made a success and satisfy the consultant, the practitioner, and the patient.

THE remuneration of the medical superintendents of London mental hospitals is at present, in the case of hospitals with 2,000 or more beds, £1,025 a year, with emoluments of unfurnished house, rates, taxes, and water. The new scale in the case of hospitals of more than 2,000 beds is to be £1,200 a year, and, in the case of the one smaller hospital, £1,000, the emoluments attaching to the offices remaining the same as at present. With the percentage addition of war bonus the annual remuneration in these two cases will amount to £1,400 and £1,180 respectively. At Bexley Mental Hospital, where there are certain special circumstances, the remuneration will amount to £1,510 so long as the present superintendent holds office.

THE town of Southampton has increased its donation to the Village Centres Council for the erection of a Southampton hut at the Enham Village Centre to £1,000, and the city of Winchester has contributed £500 for a Winchester hut.

SATURDAY, FEBRUARY 21st, 1920.

"THE PITIES OF OLD SURGEONS."

SURGICAL ANAESTHESIA is a subject of perennial interest, indeed of general interest, for who can say when he may not have need to experience its benefits in his own person? It is common to assume that it was a blessing given to the world by the nineteenth century, and the assumption is true of complete anaesthesia as now scientifically produced. But it would be a mistake to suppose that before ether and chloroform were used to produce general anaesthesia our forefathers took no means to dull the senses of him who had to submit to the surgeon's knife. A correspondent in Singapore, Mrs. Ferguson Davie, M.D., has sent us a quotation from the *De Trinitate* of St. Hilary, in which, speaking of the relations of the body with a sentient soul, he says: "When through some grave necessity part of the body must be cut away, the soul can be lulled to sleep by drugs which overcome the pain and produce in the mind a death-like forgetfulness of its power of sense. Then limbs can be cut off without pain; the flesh is dead to all feeling, and does not heed the deep thrust of the knife, because the soul within is asleep." This our correspondent finds the more interesting since Celsus, "writing a century or more earlier," confidently assumes that all surgical operations must be painless. Celsus lived in the reigns of Caesar Augustus and Tiberius, more than three centuries before the Athanasius of the West. The passage of Celsus referred to is the well known description of the qualities that fit a man to be a surgeon; among them is "a mind undaunted, so that he is not moved by the patient's shrieks to unnecessary haste or to do less than is absolutely expedient."

Hilary was not the first Father of the Church who spoke of surgical anaesthesia. From a casual reference by Origen (*circa* A.D. 185-254) to a draught which casts patients about to undergo an operation into a deep sleep the practice of anaesthesia would seem to have been fairly common in the third century. The effects of mandragora, henbane, *Datura stramonium*, hemlock and lettuce were known in the East in remote antiquity. The Egyptians are believed to have used Indian hemp and poppy juice as surgical anaesthetics. The anodyne properties of mandragora were praised by the ancient Egyptians, Babylonians, and Hebrews. Rachel begged Leah for this drug, probably to soothe the pains of childbirth. A preparation of Indian hemp is probably referred to by the prophet Amos (ii, 8) seven centuries before Christ. Richard Burton, in his notes to the *Arabian Nights*, says that drugging with henbane was common among the ancient Hindus and Arabs: "These have been used in surgery throughout the East for centuries before ether or chloroform became the fashion in the Civil War." S. J. Mozans¹ says the ancient Peruvian Incas probably utilized the anaesthetic properties of the active principle of *Erythroxylon Coca* in trephining. A Chinese surgeon named Hoa-tho, who flourished A.D. 220-230, is recorded to have administered Ma-Yo before operating; this seems to have been Indian hemp. In a few moments it made the patient

insensible as if drunk or deprived of life; after a few days he recovered having felt no pain during the operation.

The ancient Greeks used drugs to deaden sensibility, and it is probably from these that Celsus learnt of mandragora, which he mentions (*De Medicina*, xxv, 2), but only as a soporific. The younger Pliny (A.D. 32-79), in his *Natural History*, says that the "herbe mandragoras" is useful before "the cutting or cauterizing, pricking or lancing to take away the sense and feeling of such extreme cures. And sufficient it is in some bodies to cast them into a sleep with the smell of mandrage against the time of such chirurgery." The drug is also mentioned by Paul of Aegina, Seneca, and Dioscorides (*circa* A.D. 50), who gives a prescription for its use as a surgical anaesthetic. Benjamin Ward Richardson tried this and found that "the phenomena repeated themselves with all faithfulness."

A mixture of mandragora, henbane, and other substances (*confectio soporifica*) was used in the thirteenth and fourteenth centuries by Hugo of Lucca, and his son Theodoric (A.D. 1205-1296), Bishop of Cervia near Ravenna, and confessor of Pope Innocent IV, in his *Chirurgiae* (Lib. IV, cap. viii), describes a *spongia somnifera*. The mode of preparation is given by Guy de Chauliac in his *Chirurgia Magna* (1363): "Some, like Theodoric, prescribe medicaments which put to sleep so that the pain of the incision shall not be felt, such as opium, nightshade juice, hyoseyamus, mandragora, tree ivy, hemlock, lettuce, and with these juices soak a new sponge and allow it to dry in the sun. And when the need arises, they place this sponge in hot water and give it to be smelt till sleep comes to the patient. And when he is asleep they do the operation." Formulas for mixtures of opium, mandragora, and henbane are given by Arnold of Villanova (1235-1315) in his *Breviarium* and Nicolas of Salerno in his *Antidotarium*, which was printed in 1471. One of the stories in Boccaccio's *Decameron* (1461) proves that the use of anaesthetics was familiar in Italy in the fifteenth century even for purposes outside the province of surgery. A little later Jean Canappe, in *Le Guidon pour les Barbiers et les Chirurgiens* (1538), gives a list of *médicines obdormifères* employed in surgery. Shakespeare's reference to poppy, mandragora, and the other "drowsy syrups" is too familiar to need quotation. But the following passage from a somewhat later Elizabethan is interesting. Middleton in his play *Women, Beware Women*, says:

I'll imitate the pities of old surgeons
To this lost limb, who, ere they show their art,
Cast one asleep, then cut the diseased part.

Du Bartas, in the middle of the sixteenth century, wrote, as Englished by Silvester:

Even as a surgeon, minding off to cut
Some cureless limb, before in use he put
His violent engines on the vicious member,
Bringeth his patient in a senseless slumber,
And griefless then (guided by use and art)
To save the whole cuts off th' infected part.

Till the sixteenth century mandragora (the *Atropa mandragora*, allied to the *Atropa belladonna* of modern pharmacy) was in common use as an anaesthetic. Then it fell into disrepute, and we find Ambroise Paré writing that the *spongia somnifera* was "formerly" used by operators.

Considering what the horrors of the surgical knife were without some means of deadening sensibility, there must have been some powerful reason for the abandonment of such anaesthetics as were available. Possibly the mixtures of mandragora, Indian hemp, henbane, and opium in the quantities required to produce any real effect were found to be too dangerous.

¹ *Along the Andes and Down the Amazon*. New York, 1911.

Nothing more was heard about anaesthesia till the end of the eighteenth century, and it was not till 1846 that the triumph over pain in operative surgery was achieved.¹

TOXINS AND ANTITOXINS.

Toxins and antitoxins are familiar in our mouths as household words. The theoretical interest of the problems raised is only equalled by the practical importance of the application of theory to practice. Much remains to be ascertained, and the student who seeks to become acquainted with the subject in all its aspects is confronted with an enormous mass of literature—good, bad, and indifferent. We may therefore be grateful to Drs. Nicolle, Césari, and Jouan, of the Pasteur Institute in Paris, for giving² a connected account of their experimental work, including an exposition of their methods, observations, and results, with a minimum of explanatory hypothesis, all most lucidly set forth. In their summing up of the essential experimental data that they have accumulated, they review and compare in succession toxins, immunity, hypersensitiveness, sensitization, antibodies, and antitoxins. Finally, they present the reader with a general conception of the nature and modes of action of toxins and antibodies. No special mention is made of the endotoxins or bacterial poisons that remain in the bodies of bacteria without to any extent escaping from their cells, although "soluble toxins" are distinguished from what the authors call "solid toxins," or virulent bacteria employed experimentally, living or dead. The actions of "soluble" and "solid" toxins for any given microbe are, according to their observations, identical.

It is concluded that a toxin contains two elements; one active, common to the several poisons of one group, and incapable of producing antibodies; the other inactive, but producing an antibody almost always specific for each toxin. Toxins and enzymes may be regarded as forming a continuous series, the two ends united by substances such as papain that act as both; enzymes may be regarded as acting on inanimate matter, toxins as enzymes acting on living matter. The active element of a toxin is a relatively simple chemical substance, the antigen element a colloidal substratum thereto. The direct action of a toxin may be to coagulate proteins, to hydrolyze the lipoids of red blood corpuscles or the nervous system; great natural variations exist in the amount of toxin produced by animals, bacteria or plants under different conditions or at different periods of growth. As for the composition of antibodies, it is even less definite than that ascribed above to toxins; it may well be of the same general character. The action of antibodies as such is to coagulate or decoagulate—if one may transliterate a serviceable French word—the antigens corresponding to them; an antitoxin neutralizes a toxin by coagulating its separate particles, an anti-enzyme destroys an enzyme in the same manner. Cytolysis may be taken as an instance of both coagulation and decoagulation; it consists of two stages—first, fixation of the amboceptor, producing coagulation; secondly, solution of the coagulum by the complement. The process is analogous to the cytotoxicity by normal guinea-pig serum of the guinea-pig's normal red cells, after they have been treated (coagulated)

with mercuric chloride—the cells dissolve in the excess of protein offered to them in the serum.

The genesis of antihodies is shrouded in the deepest mystery; it can only be said that experimental animals react in the most variable manner to the exhibition of antigens—sometimes they produce no antibody, sometimes one, sometimes many. Indeed, the study of autolysis has led Nicolle to conclude that all living cells normally produce antibodies just as they produce enzymes or toxins; no picture of their method of production can even be outlined. Of recent years there has been a tendency among physiologists to express metabolic processes in terms of physical chemistry, with use of the physico-chemical conceptions furnished by the study of surface tension, adsorption, ionization, and colloid chemistry generally. Nicolle, Césari, and Jouan have avoided anything like a mathematical or physical treatment of the subject. They confine themselves to the well-ordered recording of experiments and their results. It would be of no little interest to see how far their observations could be utilized by a mathematically-minded chemical physiologist as a basis for a more physical exposition of the singularly difficult series of problems outlined above.

INTERNATIONAL ORGANIZATION OF MEDICAL SOCIETIES.

An informal meeting was held on February 13th, at the house of the Royal Society of Medicine, to hear a statement by Dr. F. F. Simpson, who is on a mission to Europe from the United States of America to explain to the medical profession of the allied countries of Europe a scheme for the organization of simultaneous meetings of international associations in the various departments of medicine. The general conception of the scheme Dr. Simpson presented was that in each country and in each department of medical science and practice there should be a national association—as, for instance, for medicine, surgery, gynaecology, physiology, anatomy, and ophthalmology and other specialties—and that these national associations should be in organic connexion, so as to form international associations. The scheme included the establishment of an international council to keep the various international associations in relation to each other and to arrange for simultaneous meetings in selected cities of Europe and America. He proposed the immediate constitution of a provisional committee, consisting of two representatives each of Belgium, France, Great Britain, Italy, and the United States of America, which, it was hoped, might meet in March in order to draw up suggestions for submission to certain congresses which are to be held in Paris this year during June and July. The meeting had the advantage of hearing the views of Sir Wilmot Herringham, who was the general secretary of the last International Medical Congress, which, it will be remembered, was held in London in 1913. He states his view of the matter fully in a letter published elsewhere in this issue, and it will suffice here to note his opinion, with which we believe most of those who have taken part in International Medical Congresses will agree, that such assemblies were a waste of time and energy. It would appear that Dr. Simpson's proposal does not contemplate the revival of these congresses, although it would not necessarily prevent their being held. It has been the custom in the past for an International Medical Congress to select the country at which the next Congress should be held and to leave the general arrangements to a national committee. The Congress in London in 1913 accepted an invitation to Germany, but there are obvious reasons against an International Medical Congress being held in Germany for many years to come. Dr. Simpson's plan, as we understand it, would be an alternative to the revival of International Medical Congresses, and is designed to produce

¹ A history of anaesthesia will be found in the BRITISH MEDICAL JOURNAL of October 17th, 1896, issued on the occasion of the jubilee of Morton's discovery. Reference may also be made to Sir James Simpson's chapter on ancient history in *Collected Essays on Some of the Great Therapeutic Subjects* (1871).

² *Étude des Antitoxines*. By M. Nicolle, E. Césari, C. Jouan, du Institut Pasteur, Paris, Masson et Cie. Paris 3vo, pp. viii + 125. Fr. 5.00.

more business-like assemblies. The informal meeting on February 13th eventually decided to ask the council of each of the sections of the Royal Society of Medicine, and of any other suitable body, to state whether it wishes international organization for its speciality.

EXPERIMENTAL PRODUCTION OF INFLUENZA.

THE doubts that have been cast on Pfeiffer's bacillus as being the cause of influenza, and the failures hitherto experienced by trustworthy workers in attempting to reproduce the disease by filtered or unfiltered secretions or by cultures of the bacillus, make one chary of accepting straightway any claims to have solved the problem. Yet the recent experiments of Blake and Cecil,¹ of the Bacteriological Laboratories of the Army Medical School at Washington, demand attention. These workers have succeeded in producing experimentally in monkeys an acute respiratory disease, closely resembling influenza in the human subject, by nasal instillation or intratracheal injection of cultures of *B. influenzae*. It is well known that the Pfeiffer bacillus soon loses its pathogenic power in cultures. The authors, using a strain originally isolated from a case of influenzal bronchopneumonia in a child, exalted its virulence by successive animal passages through a series of eleven white mice, and then through a series of thirteen monkeys, injecting the cultures intraperitoneally, and withdrawing the peritoneal exudate eight to ten hours afterwards. By these means the virulence of the strain was so exalted that 0.01 c.cm. of a sixteen hours broth culture was fatal to mice. Since monkeys that have been for any length of time in captivity are particularly delicate, the authors used two species of monkeys freshly imported from the Philippines and Central America, and made no preliminary attempts to lower their resistance. For some days before the experiments morning and evening temperatures were recorded, and daily total and differential leucocyte counts were made. Twelve monkeys were inoculated in the nose, or in the nose and mouth, with the cultures taken up and applied by a cotton swab. In every instance an acute respiratory disease was set up in from three to six hours after inoculation, characterized by sudden onset, with profound prostration, a variable febrile reaction lasting for three to five days, the development of rhinitis and tracheo-bronchitis, with sneezing, cough, and the outpouring of a scanty mucoid or muco-purulent exudate. There was either a leucopenia or no noteworthy change in the leucocyte count. In five cases this disease was complicated by purulent sinusitis, and in two by fairly extensive haemorrhagic pneumonia, with areas of peribronchial consolidation. The Pfeiffer bacillus was recovered at necropsy from the lesions either in pure culture or in association with organisms normal to the air passages of monkeys. The disease produced bears a close resemblance in its symptoms, complications, and pathology to influenza in man. Of ten monkeys injected intratracheally with the cultures, seven developed pneumonia, two developed tracheo-bronchitis without pneumonia, and one resisted infection. The general symptoms produced were the same as in the preceding group—sudden onset, prostration, a variable febrile reaction, and leucopenia or no significant leucocytic change. The disease was accompanied by severe cough and accelerated respirations, and in two cases infection of the upper respiratory tract ensued. *B. influenzae* was recovered in pure culture from the lungs, bronchi, or trachea in those animals killed during the active stage of the disease. The pneumonia produced presented the same pathological picture as that found in the two animals developing influenzal pneumonia following inoculation into the nose, and appeared to be essentially identical with that ascribed to pure influenza bacillus infection of the lungs in man. In view of these facts and the constant association of *B. influenzae* with

early uncomplicated cases of influenza, the authors feel justified in inferring that Pfeiffer's bacillus is the specific cause of influenza.

HEALTH SURVEYS.

THE Ministry of Health has recently issued a memorandum as to the contents and arrangement of the annual reports for 1919 of medical officers of health, together with a covering letter. The details of the memorandum are not of special interest to others than medical officers of health, but points touched upon in the covering letter deserve wide recognition. The Ministry remarks that the conditions of war-time have hindered scrutiny of the prevailing conditions, and that at present it is extremely important to take stock of the position. Such an inquisition has "become doubly requisite in order, first, to bring to light any local consequences of war conditions that may need special attention; and secondly, to form the basis for that careful and comprehensive scheme of health developments generally which it is hoped may shortly follow, in every locality, upon the recent unification in the Ministry of Health of the various central functions in respect of all matters affecting the health of the people; since this unification of the central administration implies, and, indeed, cannot be effective without, a corresponding co-ordination of local health activities." It is further pointed out that local authorities should endeavour to secure wider publicity for their reports, bringing them more directly to the notice of the inhabitants so as to engender popular interest in the subject. The following paragraph is of special importance: "It will also be found advantageous for local authorities to establish a regular system of exchange of the annual reports of the medical officers of neighbouring authorities and also of areas in other parts of the kingdom whose conditions are more or less comparable. In the past there has been a tendency for authorities to work too much in isolation, and it is important to realize that some of the opportunities for progress and improvement are lost unless all who are now studying public health problems can arrange to pool their experience for the common good. It should be remembered that an apparent failure may be as illuminating and as important in its ultimate results as an immediate success; and for this reason it is to be noted that the reports of different areas will be all the more useful generally if they deal fully with difficulties and failures, a frank examination of which may prove to be of vital importance." The moral of this passage is of wide application. Not only must there be co-operation between various local authorities, a pooling of experience, but all medical men must participate in the scheme. Sir George Newman in his recent memorandum dwelt upon the need of a solidarity, or, as he termed it, an integration. The danger of specialism is that persons tend to peg out individual claims and to regard visitors as trespassers. There is an old and probably apocryphal story of an eminent pre-Victorian surgeon who, attended by his dressers, entered a ward as his medical colleague left it. "Thank God, gentlemen," he said, "thank God I know nothing of medicine!" Co-operation upon an inquisition into the national health, the preparation of a medical Domesday Book, would go far to exorcise this spirit.

LEAGUE OF RED CROSS SOCIETIES.

PREPARATIONS are now in progress for the first meeting of the General Council of the League of Red Cross Societies, which will assemble in Geneva on March 2nd. The thirty Red Cross Societies now comprising the League have been invited to attend the conference. Two main topics are put down for discussion. The first relates to the improvement of public health and prevention of disease according to the programme outlined by the Cannes conference in April, 1919. The scope of this discussion is indicated by naming the departments already established or in process

¹ Journ. Amer. Med. Assoc., January 17th, 1920.

of organization in the general medical office of the League at Geneva: (1) Medical information and publication; (2) child welfare; (3) nursing; (4) miscellaneous communicable diseases; (5) laboratory; (6) library; (7) museum; (8) sanitary engineering; (9) malaria; (10) vital statistics; (11) tuberculosis; (12) industrial hygiene; (13) venereal diseases. The second general topic for discussion will be the programme of service in peace time of each national Red Cross Society, and the best means of extending its membership and resources. In addition to these general topics, the various societies, members of the League, have been invited to propose specific subjects for discussion and study. The conference will last eight days. Among recent appointments announced by the *Bulletin* of the League is that of Mr. C. R. Hewitt, as librarian of the League; he was at one time at the Royal College of Surgeons of England, and until lately assistant librarian of the Royal Society of Medicine. With a view to fighting the epidemics of typhus and relapsing fever in Eastern Europe the Swedish Red Cross has organized and equipped a mobile hospital of a hundred beds; this unit was due to leave on February 1st. The current number of the *Bulletin* contains also an appreciation of the late Sir William Osler, written by Dr. Thomas R. Brown, director of the Department of Medical Information of the League, who, together with Colonel Strong, the general medical director of the League, were members of Dr. Osler's first class in Johns Hopkins University Medical School. In the course of this article Dr. Brown says of Sir William Osler: "While always frankly sceptical about the treatment of disease in its narrower sense, he was the arch apostle of a vigorous sanitation, a broad prophylaxis, a wide preventive medicine, a general utilization of all the forces of Nature in the prevention and cure of disease, and this made him, from its beginning, a real friend of the League of Red Cross Societies, with its many potentialities in the field of hygiene and preventive medicine."

BRONZE MEDICO-CHIRURGICAL INSTRUMENTS.

In an archaeological account of some bronze instruments recently bought from the collection made by the Russian Baron Ustinov in Palestine and Syria between 1872 and 1890, Dr. S. Holth¹ of Christiania makes some interesting comments on their probable use in surgery. The twenty-two instruments were apparently obtained from Palestine, and especially from the old port of Ascalon. As European museums do not contain any Arabian surgical instruments, peculiar interest centres round what is believed to be an Arabian ophthalmic instrument for depressing a cataractous lens, the only operation known until extraction of the lens was adopted in 1752; one part of the handle of this instrument bears a knob 2 mm. in diameter, probably designed to produce a preliminary depression on the surface of the eye, where the incision was to be made. Among the Graeco-Roman instruments there was a sound with a terminal sharp spoon 12 mm. wide by 6 mm. deep, probably used, among other purposes, for the removal of granulation tissue; the stem of the sound showed a very fine measure scale with transversely filed lines so arranged as to lead to the conclusion that what is practically a millimetre scale was employed 1,500 years before the invention of the metric system during the French revolution. Some of the other sounds might well have been suitable for dilating post-gonorrhoeal strictures, which, however, have only been recognized anatomically since Morgagni's time; attention is therefore drawn to the forgotten record of Heliodorus, a surgeon in Rome during the reign of Trajan; he is mentioned in Juvenal's Sixth Satire, and is said to have removed fleshy growths from the urethra and then to have introduced bronze tubes in order to prevent union of the surfaces, though he did not

recognize the underlying cause. Many of the sounds may have been used to bring on abortion, a common practice among the Greeks and Romans, and not regarded in the light of a crime, as the life of the fetus was not supposed to begin until birth. Holth also points out that the Roman netting needle with forks in two planes at right angles to each other, though not made with that intent, was employed for surgical suturing.

PHYSIOLOGICAL STUDY AT THE NAPLES ZOOLOGICAL STATION.

OWING to the war the zoological station at Naples has suffered in many ways, and it is highly necessary that this very important international scientific institution should receive the support necessary to enable it to carry on its work without restriction. But, although its importance for zoological and morphological research has always been recognized, its advantages for physiological and bio-chemical studies are by no means as widely known as they ought to be. The station is fully equipped with all necessary apparatus and materials, and the section for Physiology and Bio-chemistry, being under the very capable direction of Professor Bettazzi, the professor of physiology in the University of Naples, students are assured not only of the opportunities of carrying out independent and untrammelled research, but of the best advice and direction from the staff. There is an admirable library, with very complete sets of periodical publications. The rent of a table is 2,500 francs a year (payable in gold), and the director of the station will furnish all details to students who propose to carry out any research there. The study of comparative physiology has bearings upon immunology, upon the question of functional activities, upon bio-chemistry and physiology in general, the importance of which in their relation to medicine needs no emphasis. The effect on international relations of a free use of these scientific facilities being made by British students and of their intercourse with Italian men of science is but little less important.

COURSES IN PSYCHIATRY.

COURSES of lectures and practical instruction in psychiatry have been arranged by Sir Frederick Mott at the Maudsley Hospital, Denmark Hill, S.E., in order to provide teaching for graduates whose work is chiefly concerned with the institutional treatment of mental diseases. Hitherto there has been no special instruction in mental pathology and allied subjects, and as a consequence institutional medical officers have been handicapped by lack of knowledge of the scientific methods that might be employed with advantage. The course of teaching is based on the requirements for the Cambridge diploma in psychological medicine. It is probable that in the near future a degree or diploma in this subject will be regarded as essential for all applying for medical posts in psychiatric institutions. The Maudsley Hospital has already a library and chemical and histological laboratories; to these are being added laboratories for neuro-physiology and experimental psychology. The first part of the course consists of twelve lectures on the anatomy of the nervous system by Sir Frederick Mott, with eight two-hourly sessions of practical instruction and demonstrations. Dr. F. L. Golla will give twelve lectures on the physiology of the nervous system, and a course in practical physiology designed to put students in possession of such methods as might be employed in minor research work in mental diseases. Dr. J. V. Lowson will give ten lectures on psychology and eight demonstrations in practical psychology. The second part of the course consists of twelve lectures by Dr. C. Hubert Bond on the diagnosis, prognosis, and treatment of mental diseases; two lectures on crime and responsibility, by Sir Bryan Donkin; two lectures, with demonstrations of cases, on the practical aspect of mental deficiency, by Dr. F. C. Shrubsall; six lectures on

¹ S. Holth, *Videnskapselskabet's Skrifter. I. Mat.-Naturv.* Klasse 1919, No. 1, Kristiania.

the pathology of mental diseases, including brain syphilis, with demonstrations, by Sir Frederick Mott; eight lectures on the psychology of conduct, by Dr. William MacDougall; twelve clinical demonstrations in neurology, by Dr. Golla and Sir Frederick Mott; and six lectures on the psychoneuroses, by Dr. Bernard Hart. The lectures and demonstrations will be given in the afternoons between 2 and 5 o'clock; the days and times of the several courses of instruction will be arranged to suit the convenience of the majority of those attending. The course will begin in the first week of March. The fee for the whole course is fifteen guineas, or ten guineas for either part taken separately. Further details and a syllabus of lectures will be issued shortly.

PENSIONS OF SENIOR SURGEON COMMANDERS, R.N.

THE negotiations with the Admiralty concerning the position of senior Surgeon Commanders, R.N., as affected by the new regulations for retirement and retired pay have now reached a stage in which the Admiralty has written declining to deal with the case of medical officers apart from the rest of their comrades of the Executive, Engineering and other branches of the service. The Naval and Military Committee of the British Medical Association, after consideration of the Admiralty's letter, referred it to the Naval Subcommittee with certain suggestions. The opinion of the subcommittee is that the matter should not be left where it is, but that further representations ought to be made to the Admiralty. The Naval and Military Committee is ready to give further consideration to the subject at an early date with a view to taking any steps which may be deemed advisable in bringing it again to notice. The Committee, however, has so far not found it easy to obtain definite information as to how widely senior surgeon commanders are affected by the new regulations, and it would be a great help if any officer who considers that he is seriously affected would at once send particulars of his case to the Medical Secretary. So far, the number of letters received has not been sufficiently great to make it certain that the new provisions affect a large number of officers. The Association is earnestly desirous of taking any opportunity that offers to champion the just claim of the medical officers of the Royal Navy, but it must be clear that this is difficult to do unless the officers concerned bestir themselves to assist to the utmost of their power by furnishing the Medical Secretary with reliable data.

SIR BERTRAND DAWSON has taken the title of Baron Dawson of Penn, in the county of Buckingham. On February 18th he took the oath and subscribed the Roll of the House of Lords.

Medical Notes in Parliament.

Dogs' Protection Bill.—A bill "to prohibit the vivisection of dogs" was introduced on February 16th by Sir Frederick Bantury, supported by Sir John Butcher and Mr. Frederick Green. It was put down for second reading on Friday, March 19th.

Military Service Civil Liabilities Claims: Time Extended.—Sir Robert Horne announced, on February 12th, that he had been able to arrange with the Treasury for an extension of time for applications by disabled men for grants from the Military Service Civil Liabilities Department. The new terms were:

1. In the case of disabled men who have had to undergo medical treatment since demobilization, the time limit for application has been as follows:

(a) To six months after the termination of treatment, with a further extension to March 31st, 1920, where the treatment ceased during the September quarter, 1919.

(b) Or, alternatively, up to November 30th, 1919, where applicants were discharged prior to the armistice.

(c) Up to March 31st, 1920, in cases where the local War Pensions Committee certify that the disabled man was deterred from making application by the committee's advice, but had he applied would have been eligible under this extended scheme.

2. In all cases arising under paragraph 1 (a) and (b) applications must be accompanied by a certificate from the local war pensions committee concerned stating:

(a) That the applicant had been under treatment since discharge.

(b) The date on which such treatment ceased.

3. The time limit in regard to applications made by disabled men who have not had to undergo medical treatment since discharge will remain as at present that is—

(a) Men discharged previous to the armistice—on or before September 30th, 1919.

(b) Men discharged since armistice—one year from date of demobilization or discharge.

Army Estimates.—A White Paper estimating the expenditure on the army in 1920-21 was issued on February 17th. It is for an establishment of 525,000; the number is expected to fall in the course of the financial year to about 280,000, including colonial and native Indian troops serving outside India. The estimate of expenditure is £125,000,000. This sum includes terminal charges of the war and extraordinary provisions for garrisons in occupied territories, amounting altogether to £70,000,000. Vote A, issued at the same time, gives the number of men on the establishment of the army, exclusive of India. This shows that the number of officers of the R.A.M.C. is 1,723, as compared with 663 in 1914-15, and the number of other ranks as 10,602, as compared with 3,797. It is stated that the establishment of British regiments in India is still under discussion with the Government of India; the officers of the R.A.M.C. in 1914-15 numbered 321, the number of other ranks is not given.

Pensions Medical Referees.—Mr. Doyle asked, on February 12th, whether, in regard to War Pensions Committees, medical men could be paid for services rendered in connexion with field cases. Sir L. Worthington-Evans replied: Under the new procedure detailed in Circular 201, which was addressed to local War Pensions Committees on December 23rd, the services of medical referees are no longer required in connexion with the forwarding of appeals to the Pensions Appeal Tribunals. The question of payment, therefore, did not now arise.

Regional Directors for the Pensions Ministry.—Sir J. Craig, on February 16th, informed Major Hills that eleven regional directors had been appointed for the Ministry of Pensions. The districts are: Ulster, Ireland South, Scotland, Wales, South-Eastern England, East Midland, North-Western, Northern, South-Western, Yorkshire, West Midland. The salary in each case is £800 a year.

Pensions Administration.—In reply to questions on February 12th, the Pensions Minister said that he hoped soon to announce a revised scale of payment to members of local War Pensions Committees for loss of remunerative time. The second report of the Select Committee on Pensions contained about fifty recommendations, and he was not yet able to say to what extent they could be adopted. The arrears in the widows and dependants branch had been greatly diminished, and the delays in the award and payment of parents' pensions that now occurred were due to the fact that in the majority of cases they could be settled only after local inquiries and the collection of evidence of dependence and means. On February 17th Mr. Bonar Law declined to give a day for the discussion of the report mentioned above.

Defective Children in Industrial Schools.—Mr. Shortt replied, on February 16th, to a question by Mr. Pemberton Billing as to the transfer of defective children from industrial schools to certified institutions for defectives under Section 9 of the Mental Deficiency Act, 1913. In such cases a certificate must be given by two duly qualified medical practitioners to the effect that the child is a defective, and before an Order of Transfer is made, each case is considered by the Board of Control and the Home Office, and full inquiry is made as to the home circumstances in each case. Further, under the provisions of the Mental Deficiency Act, 1913, each case comes up periodically for reconsideration by the visitors of the certified institution.

Medical Grants under the Insurance Act.—Mr. T. Griffiths asked, on February 16th, why the extra grant made to medical men and chemists to meet the increased price of drugs and cost of living had not been paid out to medical men engaged by workmen's medical associations. Dr. Addison replied: If the hon. member is referring to institutions recognized under Section 15 of the Insurance Act, I must refer him to the answer I gave on October 29th. The Friendly Societies Medical Alliance has still failed to send in the requisite information as regards institutions in England. Information has recently come in from certain institutions in Wales, and this is under consideration with a view to determining such grants as may be due.

Milk and Dairies Legislation.—Dr. Addison stated, in answer to Mr. Dawes, on February 16th, that it is intended before bringing into force the Milk and Dairies Act of 1915, to introduce proposals for legislation to provide for the licensing of milk producers and dealers, for the definition and grading of milk, and to empower local authorities to undertake the supply and distribution of milk in their areas. A bill was being prepared to give powers to control the price and distribution of milk and its use for manufacturing purposes in an emergency.

Army Nurses.—In reply to Brigadier-General Croft, on February 11th, the Secretary of State for War said that all untrained nurses who served under the War Office as nursing sisters on active service had, on being demobilized, received an official letter conveying thanks for their services. Recommendations for the award of the Royal Red Cross, whether at home or abroad, were in all cases made by the general officer commanding under whom the person recommended had served, and so far as he (Mr. Churchill) was aware, there had been no case in which nurses serving abroad who had been so recommended had not been given the decoration.

Scotland.

THE NEONATAL DEATH RATE IN EDINBURGH.

ALMOST exactly a year ago it was stated in this column (*BRITISH MEDICAL JOURNAL*, February 22nd, 1919, p. 229) that the health authorities of Edinburgh intended to publish in the newspapers a monthly statement regarding the neonatal mortality in the city. The intention has been carried out and importance has thus been given to what may be called the third of the three mortality rates, the other two being the general death rate and the infantile death rate. The neonatal rate, it will be remembered, is the number of deaths in the first month of life per 1,000 live births, and it must always be borne in mind that it does not include the stillbirths. The rate in the past twelve months has been as follows, the numbers for the corresponding months in 1918 being added for comparison:

	1918.	1919.		1918.	1919.
January ...	37.2	67.4	July ...	25.2	34.2
February ...	41.6	62.3	August ...	42.7	52.2
March ...	35.3	38.9	September ...	29.7	45.1
April ...	31.5	28.1	October ...	44.8	42.7
May ...	44.8	10.5	November ...	66.9	38.8
June ...	27.7	42.0	December ...	43.6	37.2

For the whole year the neonatal rate in 1918 was 39.4 and in 1919 41.4, no great difference; but it will be noticed at once that the variations from month to month have been sharply marked, and the sharpness has been intensified in 1919. The three months which top the list as regards neonatal mortality were November, 1918, and January and February, 1919, in all of which the rate rose above 60 per 1,000. This high rate is probably to be accounted for by the incidence of influenza waves in these three months. Close scrutiny of the infantile and general mortality rates for the same two years will be required before much can be said about the significance of the neonatal rate, but its seriousness need not be again emphasized. In the past month (January, 1920) the rate was 22.2, as against 67.4 last year.

CRAIGLEITH MILITARY HOSPITAL.

The 2nd Scottish General Hospital at Craigleith, which was opened on August 11th, 1914, was closed on February 15th, 1920. On August 5th, 1914, the Edinburgh Territorial Force Association obtained the use of the Craigleith poor-house from the Parish Councils, and within a week the house had been converted to its new use, operating theatres and x-ray rooms being provided, together with a special railway platform behind the buildings. The arrangements were made by Lieut.-Colonel Sir Joseph Fayer, Bt., C.B.E., and Miss A. M. Milligan, with a staff of trained nurses. The first convoy was admitted on September 28th, 1914, and soon it became necessary to provide extra accommodation; the Royal Victoria Hospital was converted to the purpose, and a ward in the Royal Infirmary was assigned for the reception of wounded men. Later a school was obtained for the medical section of the hospital, but this was handed back to the education authority last year. After the armistice the pressure was not relieved for some time, and was increased in December, 1918, by the arrival of repatriated men, who, though they did not stay long, kept the staff busy. Then followed the influenza epidemic, which resulted in many patients being sent in from the troops in the neighbourhood. About the middle of last year a number of heavy convoys arrived from Russia, but after that the work rapidly decreased. The principal matron during the war was Miss A. W. McGill, R.R.C. The hospital started with thirteen nurses, but altogether 222 members of the Territorial Force Nursing Association—the majority recruited from the Edinburgh Royal Infirmary—served in it. The first batch of V.A.D. nurses arrived in May, 1915; before the end 281 served. During the war the following decorations were received by members of the nursing staff: Bar to R.R.C., 2; R.R.C. (1st class), 8; R.R.C. (2nd class), 33; Military Medal, 3; Serbian Cross of St. Sava, 1; and Médaille des Epidémies, 1. The medical and surgical staff was drawn from the Edinburgh hospitals, and its members, while doing duty at Craigleith, continued their work in the civil hospitals. The services they rendered have been beyond all praise,

and, as has been said, were in keeping with the name Edinburgh enjoys as a world-famous centre of medicine.

MORISON LECTURES.

The Morison Lectures of the Royal College of Physicians of Edinburgh will be delivered by Dr. Richard Gundry Rows, C.B.E., on Monday, Wednesday, and Friday, March 1st, 3rd, and 5th, at 5 p.m. on each day. The subject of the lectures is mental illnesses, but in dealing with it the lecturer will discuss the importance of a knowledge of collateral sciences and describe recent researches. He will set out Pavlov's theory of conditioned reflexes, and describe the possibility of its application to the study of mental illnesses. The later part of the course will deal with the emotions, the pathogenesis of "anxiety states," and the primary and secondary stages of mental illnesses.

GLASGOW ROYAL INFIRMARY.

The annual report of the managers of Glasgow Royal Infirmary for 1919 states that the daily average number of patients resident was 665, and that altogether 10,389 civilians and 30 sailors and soldiers were treated as in-patients. The number of patients treated in the wards of the ophthalmic department was 906, an increase of 94 as compared with the previous year, and 13,039 patients attended the ophthalmic dispensary for the first time. Eight beds and 1 cot were endowed during the year, raising the total to 67 beds and 3 cots, but the burden of this report, as in the case of those of so many other hospitals, is the critical financial position. The ordinary income (£52,802) showed an increase of less than £1,000, and the ordinary expenditure (£98,676) showed an increase of nearly £9,000. The deficiency of the ordinary income was £45,874.

England and Wales.

GENERAL HEALTH COUNCIL, MINISTRY OF HEALTH.

THE Consultative Council on General Health questions established under the Ministry of Health Act has been appointed, and held its first meeting on February 12th, when the Minister of Health, who was accompanied by Lord Astor, Parliamentary Secretary to the Ministry, presided. Dr. Addison asked the Council to put before him a statement of the main defects in existing provisions for safeguarding the health of the people, and to suggest remedies from the standpoint of persons who, as members of the general public, will be affected by the health services supervised by the Ministry.

The members of the Council, of whom a majority are women, are as follows:

Lady Rhondda (*Chairman*), Mr. Arthur Greenwood (*Vice-Chairman*), Mrs. Aspinall (United Textile Factory Workers' Association), Councillor C. Aveling (Past President of the National Chamber of Trade), Mrs. F. Harrison Bell (Labour Party), Mrs. Burke (Women's Co-operative Guild), Mr. George Goodenough (Parliamentary Committee of the Co-operative Congress), Mrs. Ogilvie Gordon, D.Sc. (President of the National Council of Women of Great Britain and Ireland), Mr. W. L. Hichens (Chairman of Messrs. Cammell, Laird and Co., Ltd.), Mrs. Hood (Women's Co-operative Guild), Mr. W. Littler (Civil Service Alliance), Mr. Samuel Lord, F.S.S. (National Association of Local Government Officers), Miss Margaret Macmillan (Labour Party), Mrs. Maye (a member of the Dorsetshire County Council, with a wide knowledge of rural conditions), Mr. F. H. Norman (Professional Workers' Federation), Miss E. M. Phelps (National Association of Domestic Workers), Mrs. Fember Reeves, Lady Edmund Talbot, and Miss Gertrude M. Tuckwell, J.P.

DR. F. H. HAYNES OF LEAMINGTON.

Dr. F. H. Haynes has now completed fifty years as a member of the staff of the Warneford Hospital, Leamington, first as house-surgeon, then for thirty-three years as honorary physician, and subsequently as honorary consulting physician. During the war he gave his services once more as honorary physician, resuming his consultant rank last summer. At a recent meeting of the Warneford Hospital Committee an illuminated address was presented to Dr. Haynes, whose long and valuable work for the institution was praised by Mr. Frederick Shaw, chairman of the general committee, and by Dr. T. W. Thursfield. It was resolved to invite Dr. Haynes to sit for his portrait in oils.

Ireland.

IRISH GENERAL NURSING COUNCIL.

The Chief Secretary, in pursuance of the powers conferred on him by the Nurses' Registration (Ireland) Act, 1919, has constituted the first General Nursing Council for Ireland as follows:

E. Coey Rigger, M.D., D.P.H., Chairman Irish Public Health Council.

The Countess of Kenmare, Vice-President of the Queen Victoria Jubilee Nursing Institution, and Member of the Irish Public Health Council.

Colonel Sir Arthur G. Chance, F.R.C.S.I., Mater Misericordiae Hospital, Dublin; President Irish Board College of Nursing.

Colonel W. Taylor, C.B., F.R.C.S.I., Meath Hospital, Dublin; ex-President Royal College of Surgeons, Ireland.

R. J. Johnston, F.R.C.S., Royal Victoria Hospital, Belfast; Chairman Irish Medical Committee.

P. T. O'Sullivan, M.D., F.R.C.P., South Charitable Infirmary, Cork. Miss Matheson, Secretary Irish Board College of Nursing.

Miss Reeves, Matron Dr Stevens's Hospital. Miss Michie, Superintendent Queen Victoria Jubilee Nurses, Dublin.

Miss Huxley, Matron Elpis Private Hospital, Dublin. Miss O'Flynn, Lady Superintendent Children's Hospital, Temple Street, Dublin.

Miss Bostock, Irish Board College of Nursing, Matron Royal Victoria Hospital, Belfast.

Miss Walsh, Lady Superintendent Nurses' Training School, Waterford Union Infirmary.

Mrs. Blunden, Superintendent Mosaphir Private Nursing Home, Cork.

Miss Curtin, Lady Superintendent Mater Infirmorum Nurses' Training School, Belfast; Irish Board College of Nursing.

INFLUENZA VACCINE.

The Local Government Board for Ireland has made arrangements for the supply of influenza vaccine gratuitously to medical practitioners and to dispensary medical officers in Ireland who may wish to use it. The supply is made under conditions similar to those applicable to England and Wales (BRITISH MEDICAL JOURNAL, January 3rd, 1920, p. 19), that is to say, no charge is to be made for the vaccine used, but a professional fee for the administration in private practice is in a different position. The expectation is also expressed that medical practitioners will co-operate in investigating the value of the vaccine by keeping accurate notes of the name, address, age, and sex of each person so treated. The vaccine will be issued to the local medical officers concerned in bottles containing a quantity sufficient for six, nine, or twelve persons.

New South Wales.

TUBERCULOUS SOLDIERS.

As in most other countries, there are in this State a large number of returned soldiers who are the subjects of tuberculous disease of the lungs in various stages. To provide accommodation for the advanced cases a site at Randwick, a suburb of Sydney in which the principal military hospital of the State is situated, was selected by the Department of Defence, but was strongly objected to by the residents of that suburb as well as by others on various grounds. A special committee was accordingly appointed by the Minister for Defence, consisting of two members of the New South Wales Branch of the British Medical Association and one member of the Victorian Branch, to inspect and report on the proposed site. This committee reported that the question hinges largely on the meaning of the term "advanced" in reference to cases of pulmonary tuberculosis. Many persons who show signs of advanced disease are able to move freely among their fellows, while, on the other hand, there are others in whom, in addition to signs of advanced disease, have their general health so much impaired that they are practically bedridden. Under adequate supervision in suitable premises this latter class of sufferers can be well cared for in a populous centre without any danger to the community; but it is otherwise with the former class if they are permitted at times to mix indiscriminately with the rest of the general public. The committee therefore concluded:

1. That it is desirable that advanced cases of pulmonary tuberculosis should be segregated and that particular attention should be directed more to provide for their care and comfort and their easy accessibility to friends and relations than to considerations of climate.

2. That the site inspected by them at Randwick is well suited for the purpose for which it has been selected.

3. That there is no danger of infection to the population of the district, provided that the patients be confined in the hostel. The committee is of opinion that this is so essential that such patients as are sufficiently recovered to press for leave should be transferred to another institution.

ROYAL PRINCE ALFRED HOSPITAL.

Miss Susan B. McCauley, formerly matron of the Royal Prince Alfred Hospital, died on November 16th, 1919. She was trained at the London Hospital and was selected by the late Sir Alfred Roberts as matron of the Carrington Convalescent Hospital at Camden. She was subsequently appointed to the Royal Prince Alfred Hospital, where she developed the Nurses' Training School to a very high standard of efficiency. She retired from this hospital some fifteen years ago and subsequently conducted a high class private hospital for some years. As her health failed, she retired from this position and lived at Carlingford until her death.

Dr. H. J. Clayton, who has occupied the position of medical superintendent of the Royal Prince Alfred Hospital for a period of six years, during one of which he was absent in Egypt and Gallipoli, has resigned owing to the strain of the work. The Board of Directors have received his resignation with regret, and have decided to appoint as his successor Dr. A. J. Collins, who was formerly acting medical superintendent, and has for the past four years been on active service. He attained the rank of lieutenant-colonel, and was awarded the Military Cross and the Distinguished Service Order.

Dr. Joseph Foreman has notified the Senate of the University of his resignation of the lectureship in gynaecology which he has held since 1897. His resignation has been accepted with regret, and a letter of appreciation of his services as lecturer has been sent to him. This resignation involves also his resignation from the staff of the Royal Prince Alfred Hospital as senior gynaecologist.

Correspondence.

PROPOSAL FOR A MEMORIAL TO SIR VICTOR HORSLEY.

SIR,—I have for some time been watching the columns of the BRITISH MEDICAL JOURNAL to see if any proposal was put forward to raise any form of memorial in connexion with Sir Victor Horsley's work for the Association. I have spoken to several members on the subject and have hoped that the initiative would have been taken by some more prominent and important person than myself. But, as no one else has made a move, I have accepted the suggestion made to me by others, and ask permission to ventilate the question.

There is no doubt that Horsley, by his outspoken, and sometimes even vehement, advocacy of unpopular movements in the social world, and by his biting sarcasm in controversy, made many enemies, both in the Association and outside it, but we members ought never to forget his services to the Association when in the throes of transformation nor his persistent and persevering work as Chairman of Representative Meeting, in Council, and in Committees. I need not touch on his work and research as a pioneer in brain surgery, in the treatment of myxoedema, etc., which carried the reputation of British surgery all over the world and gained for Horsley academic honours in nearly every European State. I suggest that we ask permission to hold a meeting of those who are in favour of some Memorial at the Head Office.

If a Memorial be decided upon, the meeting can consider whether it take the form of a portrait (either an oil painting or a bust), or whether it should take the form of a Research Scholarship in Neurology or other subject associated with Horsley's name.

I should be very glad to receive the names of any who could attend such a meeting, or who, if unable to attend, are yet in sympathy with its object, and hand the names to whoever may be chosen to carry out a scheme.—I am, etc.,

EDWARD J. DOMVILLE.

Shutes, Synonbury, Bridport.
January 27th.

INTERNATIONAL ORGANIZATION OF MEDICAL SOCIETIES.

SIR,—Before a small meeting held on Friday last a proposal was brought forward for the creation of a new international body to deal with medicine. It will be easier to explain it if I contrast it with the international congresses of medicine to which we are accustomed.

International congresses have been open to all comers, and have, in consequence, become immense pleasure parties rather than, or at least as much as, centres of serious work. The new organization proposed rests upon permanent international associations such as exist now in surgery, gynaecology, ophthalmology, and some other branches, which are composed of those specially interested in the subject, have already the habit of holding international conferences, and meet for work rather than for play.

It was expressly stated that the new organization was not intended to supersede international congresses. I hope, however, that the latter, which were a great public nuisance, will die a natural death. Meetings held on the lines of special international associations are greatly to be preferred.

The staff of the new organization will be more permanent than that of the old. It is proposed that in any country the special international associations shall elect a *National Executive Council*, and that each such *National Executive Council* shall send one or two representatives to form an *International Executive Council* which shall be a permanent body meeting periodically in Paris or some other convenient capital. This *International Executive Council* is to "determine principles and policies," and call a world congress if it likes. The *National Executive Council* is to apply these principles and policies in its own country, to nominate new members of the special associations, and to stimulate the profession in various ways.

There is nothing to criticize in this scheme except that it is obvious to anyone who knows what international staff work means that there is not enough business to keep either the *National Executive Council* or the *International Executive Council* alive. Men will take trouble for important affairs, but they will not take trouble for business that is formal. The importance laid by some speakers on the future influence of such an *International Executive Council* is wholly chimerical. Who would pay the slightest attention to a body of ten or twelve medical men laying down principles and policies—on what? On the treatment of fractures, or on the method of dealing with subject races?

But, though I think that the proposal has some decided advantages, it contains one feature which is of a serious nature, and requires the gravest consideration.

It is not proposed to admit to the proposed organization the special international associations of any but Allied countries. It is definitely intended to create a ring of these countries which shall be more or less exclusive of the rest of the world.

That is, in my opinion, a mistake, and I would not take part in any movement conceived with that purpose. It is not yet possible to meet enemy nations in a friendly spirit, and it will be a long time before that comes about. It would be quite impossible to hold an international medical congress now, or for several years to come. Yet some time or other the present animosities will be softened, and no one will deny that they should be. But an organization expressly confined to the Allies, yet calling itself "international" and considering a "world congress" as one of its functions, is a sure way to perpetuate the feud which it is the interest of the world to compose.

I am quite ready to support an "Interallied" Association of Medicine to carry on until such time as the world is ready to resume international relations, though I think its functions would be confined to holding professional meetings, and do not anticipate that any great effect would be exercised by an *International Executive Council* either upon the medical profession or the world at large. But I am not prepared to set up a fresh barrier to the resumption of friendly relations with the enemy or to keep open in science a wound which politics and commerce are even now trying to heal.—I am, etc.,

Witley, Surrey, Feb. 14th.

W. P. HERRINGHAM.

THE TREATMENT OF MALARIA.

SIR,—The correspondence which has arisen out of the discussion at the Medical Society of London has shown such differences of opinion that it seems necessary for

those who, like myself, have had long experience of the disease in the tropics to try to help with their experience.

In a most excellent paper by Dr. Taylor, entitled "Routine treatment of malaria in Uganda," published in the *BRITISH MEDICAL JOURNAL* of January 24th, he gives clearly and definitely the line of treatment followed in that colony, and I may say at once that the routine followed by me and most others in British Guiana was almost exactly the same.

My regular treatment was to give at once gr. iij to gr. v calomel, followed in about four hours by a saline—preferably sodium sulphate—and then gr. v of quinine hydrochloride every three or four hours. This was the regular treatment for all ordinarily severe to mild cases. Having continued the administration of quinine in gr. v doses every three to four hours till the temperature remained normal for forty-eight hours, the dose was reduced to gr. v three times a day for ten days, then to gr. v twice daily for another ten days, and thereafter, if possible, gr. v were given every morning for three to four months; tonics such as arsenic (but never iron) were given regularly during the last stage of treatment.

My experience of cases which did not yield to this treatment was small. Such cases did occur occasionally, and examination would usually show a very heavily furred tongue, pointing to some gastric condition which hindered absorption of the quinine, and in these it was found advisable to give one or two intramuscular injections. Cases of the severe cerebral type I need hardly say were treated at once with injections. They admit of no delay. The type of malaria met with in British Guiana was mostly the subtertian variety, with occasional cases of benign tertian; the quartan was practically unknown. I notice that in all the correspondence there has been no mention of the initial treatment by calomel and salines except for Dr. Robertson's somewhat casual mention of a "mercurial purge" in his letter of February 7th. Yet this calomel and saline I look on as the key to success; it is absolutely all important. I have occasionally omitted it, thinking the case in hand was a very mild one, but I have invariably had cause to regret the omission. I have no scientific reason to give of how or why this calomel and saline exerts such an influence, but I do know that without it all the quinine one can give will have no effect. Dr. Taylor emphasizes this point as strongly as I do, and I think it is due to his sound methods in this direction that he is able to say that "intramuscular injections were required in less than 1 per cent." My own percentage was certainly not more than this, and I cannot but think that if the preliminary treatment which he and I emphasize so strongly were more regularly adopted there would be much less need for the syringe than apparently there has been.

Another important point is the preparation of quinine used, and the dose. During my last ten years in British Guiana, for oral administration I used quinine hydrochloride only. This I found much more satisfactory than the sulphate. It dissolves easily in water, requiring no addition of acid and is more readily tolerated by the stomach, whilst it contains nearly 10 per cent. more of the alkaloid. I have never seen any advantage in giving more than gr. v at a time, and gr. xxx in twenty-four hours should not be exceeded. The larger doses advocated so freely by many writers appear to me to be quite unnecessary and probably harmful. Whilst, however, I hold that by far the greater number of cases will yield to treatment on the lines I have indicated, yet it is clearly agreed by all that there is a certain percentage in which a more rapidly acting method is necessary. These are chiefly the cerebral type which so rapidly prove fatal, and in them quinine must be given either intramuscularly or intravenously. Personally I have no experience of the latter, which theoretically would seem to be the best in very urgent cases, but which, as Dr. A. Balfour states, should be chiefly confined to hospitals. The intramuscular method is easily and rapidly carried out, and if done with all necessary precautions is perfectly safe and reliable. I have seen no ill effects following its use, and it certainly acts rapidly; gr. x of the bihydrochloride is as a rule sufficient, though in exceptional cases I have given up to gr. xv. Whilst administering the quinine in this way the purgative treatment I have indicated should not be neglected.

Dr. Willcox in his letters of December 8th and 29th lays

stress on the fact that many of his cases were complicated with influenza. I also have had this experience, but it made no fundamental difference in treatment, and the ratio of cases requiring intramuscular injections of quinine was little, if at all, increased by the complication.

As to subcutaneous and rectal injections of quinine nothing need be said—neither method has anything to recommend it.—I am, etc.,

W. F. LAW, M.D., F.R.C.S.I., Major,
Late Medical Inspector, British Guiana.

Dublin, Feb. 10th.

SIR,—The necessity, to the general practitioners of this country, for some knowledge of the nature and treatment of malaria is growing, since there is little doubt that the infection exists and is increasing in certain districts. The fairly large number of infected individuals who have sojourned in Macedonia and Mesopotamia (and other such places), and who are now, since peace, scattered throughout the country, renders it advisable that useful methods of treatment should become more generally known.

A choice between the oral and the intramuscular or intravenous administration of quinine depends, I believe, upon the consideration of each individual case. The intensity of illness in each individual—which, in turn, depends upon the variety and dose of the intoxication, and the state of the patient's health at the time of the attack—are factors which cannot be lost sight of when deciding the mode of quinine administration. The experience of a quarter of a century in British Central America and on the West Coast of Africa has taught me that the large majority of cases—even subtertian malaria—is amenable to treatment by the mouth.

The initial dose of calomel is always useful and necessary to remove bile, with which quinine forms, in the stomach, an insoluble salt as inert as sand. Phenacetin or aspirin if indicated, blankets and copious drinks, and quinine, constitute the routine treatment. The choice of the quinine salt is of importance. The sulphates are somewhat irritating to the stomach, and, excepting in robust people, should not be pressed beyond moderate, though frequent, doses. The salts of hydrochloric acid and the hydrobromide are much more grateful preparations, and euclinin is not without merit. For people who have lived in malaria-stricken countries, and who have suffered from several infections of the disease, 15 grains of a quinine salt, especially the sulphate, three times a day, should be given with great caution. There is no doubt of the existence of a "quinine haemoglobinuria," although this is not so severe, as a rule, as true "blackwater fever," whatever the cause of this disease may be. Heroic doses of quinine are a thing of the past, and indeed experience points to the fact that very satisfactory results in cutting short an attack of malaria are obtained by prescribing the drug in smaller doses (3 to 5 grains), and giving it at more frequent intervals.

Where continued residence in an infected country is not a factor for consideration, a moderate infection of benign type may be eradicated by treatment of the attack only; but where new infections are likely to take place, or should an infection have been untreated for some time, the use of the drug only during the period of the acute symptoms of fever, or for one or two days after, is insufficient to effect a cure. Quinine must be taken on some system for from a fortnight to some three months after an infection, especially if this be subtertian. As a prophylactic measure the administration of quinine on some recognized plan (5 grains daily, or in larger doses at regular intervals) has made a remarkable difference in the incidence of malaria in the tropics.

Quinine must be administered by intramuscular injections when, from the type of the fever (the so-called bilious remittent), or from the associated disordered condition of the liver and stomach, the drug cannot be retained when administered by the mouth. Absorption is naturally much slower by this method, but it is said that the effects on the parasite are more lasting. Untoward consequences, beyond tenderness for some time in the puncture area, are rare in my experience, if reasonable care be taken to secure asepsis.

The intravenous exhibition of the drug is by far the quickest and most reliable method of obtaining the best results, but is not indicated except in "explosive" cases of malignant malaria and in malaria of the brain, where

I have seen some remarkable recoveries in what at first appeared to be hopeless cases.

Treatment of the general health on generous lines, between the attacks of pyrexia, with quinine, iron, arsenic, food, etc., will appeal to the general practitioner everywhere when he remembers that a single bout of fever may reduce the red blood cells from normal to as low a number as 1,182,760 and 2,800,000 per cubic millimetre in severe cases.—I am, etc.,

Guernsey, Feb. 10th.

J. WALLACE COLLETT, M.D.

TICKS AND RELAPSING FEVER.

SIR,—The paper by Dr. Nicholson, followed by the observations of Captain Dunlop, Colonel Mackenzie, and Dr. Andrew Balfour, on the tick responsible for the transmission of relapsing fever in Palestine and Persia, reminds me of an epidemic of this disease in the Somali country a few years ago.

In British Somaliland the tick responsible for relapsing fever is *Ornithodoros savignyi*. Both *O. savignyi* and *Argas persicus* are common there, but whereas the former is found more commonly in the interior and also in the coast towns, the latter is only found at the coast, where practically every fowl is infested with them.

The Somalis were certain that *A. persicus* never attacked human beings, and personally I never had any reason to believe that it did. The epidemics that occurred while I was in British Somaliland were all traced to *O. savignyi*.

While this is no proof that, in the absence of *O. savignyi*, *A. persicus* might not transmit the spirochaete of relapsing fever, I am inclined to agree with Dr. Balfour that further proof is required before we can definitely accuse *A. persicus* as the vector.—I am, etc.,

R. E. DRAKE-BROCKMAN, M.R.C.S., L.R.C.P.

London, Feb. 15th.

PREVENTION OF VENEREAL DISEASE.

SIR,—None of the protagonists of the rival societies advocate what is the most sure and natural preventive of venereal disease, and that is "early and congenial marriage."

Let me also point out that the school which preaches continence is really advocating sexual total abstinence, and not merely continence, which expression actually signifies sexual temperance. There is some incongruity in middle-aged people who have been married once, twice, or perhaps three times, and are the parents of three, six, twelve, or more children, advocating sexual total abstinence to young people. They would be on firmer ground logically in urging early and congenial marriage for those of ardent temperament.

The statement that sexual total abstinence is not injurious to health is a half-truth. There are certainly recorded cases where the health has been affected by repression. The natural normal sexual life of married persons is the healthier life for most people of both sexes. It is a question of temperament. Young people should be encouraged to marry. Girls should be provided with dowries instead of useless expensive educations. "Celibate" appointments should be made illegal. I refer especially to the hospital and asylum appointments which are closed to young married members of our profession.—I am, etc.,

JOHN ROBINSON, M.B.Lond., D.P.H.

Weymouth, Jan. 24th.

SIR,—May I give my experience as specialist sanitary officer to a district comprising 20,000 soldiers?

1. We had, amongst the British troops, "early treatment" centres. The American troops in the same area had a "packet" system. The incidence of disease was five times as great amongst the American troops. Their medical officers quite disapproved of the system.

2. The Australian troops also had a "packet" system. The incidence of venereal disease in those troops has always been much greater than amongst the British in the same areas.

What happens is this: The seeming security of the packet induces a far greater proportion of men to indulge, and far oftener, and then far more indiscriminately amongst the female population. Next, it became almost a point of honour not to use the preventive appliance, as conveying a doubt as to the ladies' chastity or at least immaculateness. Then—and this governs the whole question—it

was found by both parties that the pleasure was infinitely greater when coverings were not used. Finally, one found that those who did use the appliances supplied by the packet system consistently gradually acquired a taste for unnatural vice.—I am, etc.,

J. C. McWALTER, M.D., F.R.F.P. and S.

Dublin, Jan. 24th.

SIR,—I have refrained from joining in the controversy on this subject now appearing, but it seems to me rather ludicrous to read the arguments for and against its use.

Two eminent ladies have been reviled for disagreeing with the statistical branch of the Society for the Prevention of Venereal Disease, although in my opinion clinical experience bears out amply the contention of Drs. Sturge and Molloy. Statistics, we know, can be manipulated so as to make a fallacy appear as the truth (some of your readers will remember how 4d. was made to appear equivalent to 9d.), but what we require are clinical facts, and in my experience (which has been nurtured from nearly all parts of the civilized world) prophylaxis as recommended by the society is utterly valueless and dangerous.

To issue "packets" to a hundred men and compare the results with another hundred who have had no "packets" is clinically fallacious and useless, for so many factors must enter into consideration before a conclusion can be arrived at. No two urethrae are alike with regard to gonorrhoeal infections; one may be virgin soil, another may have its epithelial cells altered through previous attacks. No two persons are alike as regards resistance or immunity. Every venereologist is aware that ten men may have intercourse with the same woman, yet nine may escape infection and the tenth succumb, and I presume if those that escaped had "packets" in their pockets they would be used as evidence of the value of prophylaxis.

There has not been produced one tittle of evidence by the Society for the Prevention of Venereal Disease that prophylaxis, as recommended by them, is other than dangerous and valueless—dangerous in that it gives the unwary a position of false security.

Early skilled irrigations given by a skilled person before the gonococcus has had time to penetrate the mucosa would be beneficial, but that is not prophylaxis as advised. Simply urinating, after connexion, and ballooning the urethra by holding the meatus, is more satisfactory and safer than the application of chemicals by a layman. Washing with soap and water is simpler and just as efficacious as the smearing of calomel ointment for the prevention of syphilis.

The glaring posters publishing the dire results and exaggerated calamities in store for those who have had venereal disease are, in my opinion, doing more harm than good. I can readily predict a race of venereal neuroasthenics. The clarion cry of any society for the prevention of venereal disease should be early and immediate skilled treatment, and the society should see that the means of obtaining such treatment is easy.—I am, etc.,

M. W. BROWDY, M.B.

Manchester, Jan. 11th.

FORGETTING: PSYCHOLOGICAL REPRESSION.

SIR,—The late Dr. C. Mercier stated that the ability to forget is the attribute of sanity; and another well known mental authority remarked to his students, "We are all insane, some more so than others."

In my opinion the human mind remembers everything except trivialities which escape through the sieves of thought. But the important events of life, such as the experiences of this great war, do they not become permanently pictured on the memory?

The prospective suicide who has failed, or recovered from the attempt—does he not balance his stupidity with more enlightened common-sense views? The morbid mental condition passes off as time and improved ideas cross his path. Let us remember, too, that "minds" may be compared to the pebbles on the beach—of different patterns when we regard them alongside each other. Much has to be considered in respect to their heredity, environment, and education.

May I be privileged to add a few lines in support of the very useful discussion on Forgetting and Psychological Repression. The simple and practical way of treating the many nervous cases of soldiers and sailors who come before our boards by means of the skill and ingenuity of psycho-

therapeutics is as old as Adam. Yet, nevertheless, we are indebted to a number of professional men who, during this great war, have brought it so thoroughly up to date.—I am, etc.,

Boscombe, Bournemouth, Feb. 8th.

J. F. BRISCOE.

SIR,—Drs. Rixon and Matthew have struck quite a new note in the discussion which arose from Dr. Carver's article and Sir Robert Armstrong-Jones's letter. Their letter is written by men who have not only read and pondered but have evidently theorized upon the actual experiences of practice of psycho-analysis for a considerable time. With all due deference to Sir Robert Armstrong-Jones, and with full acknowledgement of his eminence in the world of psychiatrics, I maintain that Drs. Rixon and Matthew are correct when they write that he has not yet grasped the full meaning and scope of psycho-analysis.

It has never been claimed that psycho-analysis will cure every case of psycho-neurosis; but, if it is intelligently and patiently carried out, it will indicate the underlying and often deeply buried origin of the disease. Cure is only to be hoped for when the patient understands what has happened to him and has sufficient backbone to support him while he rearranges his life. The crux of the process of the cure by psycho analysis does not lie in the recalling of painful memories, nor even in analysis pure and simple; it lies in the interpretation of the symbolism employed by the unconscious. It is not easy to illustrate this by a definite example, but perhaps the following case (who has had only one session with me so far) may help.

A., aged 28, single, sergeant in the R.G.A., served from 1915 to July, 1919. Moderate "anxiety state," which developed after his demobilization. His recent dreams and much of his conversation with me centred round his repeated disappointments in not being demobilized as soon as the war was over. The dreams were but superficially analysed, and then A. was asked to apply the dreams symbolically to his present life. Without hesitation he said that it seemed as if he had demobilized all his faculties, and instead of these being under the control of a commanding officer they were acting independently and thus causing confusion—a priceless word picture and the beginning of the cure, for as this patient attains the understanding of his mental *bouleversement* so will he get better.

The application of symbolism and its interpretation and explanation to the patient is a point that, so far as I am aware, has not yet been plainly and definitely described in psycho-analytic literature, though Jung describes it rather vaguely. Drs. Rixon and Matthew, however, seem to understand the value of this.

Ferenczi says:

Still the unconscious is only able to control the mental and bodily being of man until the analysis reveals the content of the thought processes behind it.

Note that phrase "the content of the thought processes," for in the extent of his appreciation of its meaning lies the measure of success or non-success of the psycho-analyst.—I am, etc.,

A. G. MIDDLETON,

Medical Superintendent, John Leigh Memorial Hospital (for Shell Shock), Brooklands, Cheshire.

February 10th.

STERILITY.

SIR,—Accustomed as we are to the ravages wrought by the sequelae of gonorrhoea among the patients in women's hospitals, and to the reproach of sterility so often causelessly brought against women, we have read with appreciation the able article by Mr. Kenneth Walker, M.B., F.R.C.S., appearing in your issue of January 3rd, 1920. We were the more surprised at his insertion of the following paragraph (the italics are ours):

... Alcoholism, sexual excesses, debilitating diseases, and X rays produce an azoospermia or oligospermia which is temporary in nature. *Prolonged and absolute continence has been said to have a similar result (Barney).*

On looking up this reference to the observation made by an American writer (*Boston Medical and Surgical Journal*, June 18th, 1914) we find that this theory rests upon one case only, which has been recorded without reference to any collateral circumstances, and on second-hand evidence; the author candidly admitting that he has been able to find no allusion to the theory elsewhere. Surely a writer of Mr. Kenneth Walker's experience in research ought to be more guarded in the apparent propagation of opinions

based on evidence so unreliable. So able an investigator as Sir William Gowers has stated in reference to this very question that in the whole range of his experience he had never known any one to be the worse for continence. Equally strong testimony is borne by Sir James Paget, and by many other high medical authorities. A clean life, according to Sir Wilmot Herringham, so far from detracting from virility, promotes both vigour and fertility. A recent communication by Dr. Amand Routh to the BRITISH MEDICAL JOURNAL of January 17th, 1920, brings further reinforcement in the same direction.

A theory of the above description could only be brought forward by a writer unacquainted with the acknowledged trend of recent medical opinion, and is worthy of a place among the exploded fallacies of fifty years ago. If men are to be encouraged in incontinence by the dissemination of theories so ill founded, women will inevitably reap the calamitous results which are vividly depicted in Mr. Kenneth Walker's article.

It might be added that the advocates of male prophylaxis against venereal disease who have recently written in your columns ought to bear in mind that, in so far as their recommendations tend to induce vice by unintentionally encouraging a sense of security in the practice of unchastity, just in so far will they wrong women by rendering them more liable to injury, no method having been discovered by which women can be kept safe from risk of infection. When the public arrives at a comprehension of the crudely selfish character of this procedure, it may result in an outcry which will render the advocacy of such methods difficult if not impracticable.—We are, etc.

E. KNIGHT, M.B.
S. E. WHITE, M.B., B.Sc.

January 27th.

The Services.

HONOURS.

O.B.F.—Major (acting Lieut.-Colonel) Alfred Spitteler and Captain Hugh Michael Collins, I.M.S., in recognition of valuable services rendered in connexion with military operations in Southern and Central Kurdistan.

MENTIONED FOR SERVICES.

The names of the following officers have been brought to the notice of the Secretary of State for War for valuable services rendered during the military operations:

Central Kurdistan.—Major J. F. Grant and Captain (acting Major) J. M. Weddell, R.A.M.C.; Major (acting Lieut.-Colonel) A. Spitteler and Captain (acting Major) C. J. Stocker, M.C., I.M.S.; Assistant Surgeon J. Luxa and Subassistant Surgeon G. B. Yemkanmudi, I.M.D.

Southern Kurdistan.—Lientenant (acting Captain) L. G. Blackmore, R.A.M.C.; Lieut.-Colonel (temporary Colonel) J. A. Hamilton, C.M.G.; Captain (acting Major) M. Purvis, Captain H. M. Collins, and temporary Captain W. G. Miller, I.M.S.

Captain H. Colwell Rook, R.A.M.C.(S.R.), has been promoted Brevet Major for distinguished services in connexion with military operations in Archangel, North Russia.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on February 14th the degree of Doctor of Medicine was conferred upon F. E. Chavasse.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on February 14th the following medical degrees were conferred:

M.B., B.Ch.—H. G. Taylor. M.B.—C. E. Bond.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on January 28th.

The title of professor of physiology has been conferred upon the following teachers of the University: Dr. Marcus Seymour Pembrey (Guy's Hospital Medical School), Dr. Winifred Clara Cullis (London School of Medicine for Women); the title of assistant professor of psychology at University College has been conferred upon Dr. Aveling, and that of reader in bio-chemistry on Mr. J. H. Ryfel (Guy's Hospital Medical School).

The Senate adopted a resolution in appreciation of the generosity of Messrs. S. B. and J. B. Joel, of £20,000 for the endowment of the University chair of physics tenable at Middlesex Hospital Medical School.

The External Council reported that the Vice-Chancellor had authorized the admission to the first examination for medical

degrees in March, 1920, of external students who had matriculated as from September, 1919.

Applications are invited for a university studentship in physiology of £50 for one year. It is awarded to a student qualified to undertake research in physiology, and is tenable in a physiological laboratory of the University or of a school of the University. Applications must be received by the Principal Officer not later than May 31st.

Remuneration of Professors and Readers.—The second section of the regulations with regard to the conferment of the titles of University Professor and University Reader was amended to read as follows:

The guaranteed minimum salary for a university professor giving his whole time to the work of his post shall be £800 per annum, and the guaranteed minimum salary for a reader giving his whole time to the post shall be £450 per annum, provided that the title of "University Professor" and "University Reader" may be conferred in exceptional cases on the occupants of posts of which the duties do not take up the whole time of the occupant, and of which the guaranteed salaries are not less than £400 and £200 respectively, and provided in each case that the personal qualifications of the occupant are such as to justify the conferment of the title in question. Provided that the senate shall not withdraw any title of University Professor or University Reader, conferred in respect of a post of which the salary was in accordance with the regulations previously in force on the ground that the salary of such post does not comply with the existing regulations.

The Senate may also in exceptional cases confer the title of University Professor or University Reader on the occupant of a post who acts without remuneration for his services or receives a nominal honorarium in respect thereof, provided that his personal qualifications are such as to justify the conferment of the title in question.

UNIVERSITY OF BRISTOL.

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*Part II (Completing Examination):* B. A. Astley-Weston, Hilda M. Brown, D. G. Cossbam, Sukha-agar Datta, F. V. Jacques. *Part I only:* Khai Way Chan, Marjorie Wadsworth.
D.P.H.—W. H. Scott. *Part I only:* S. H. Kingston, A. D. Symons, G. C. Williams

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on February 12th, when Sir George Makins, President, was in the chair.

Issue of Diplomas.—Diplomas of Membership were granted to sixty-five candidates and Diplomas in Public Health were granted, jointly with the Royal College of Physicians, to fifteen candidates found qualified at the recent examinations.

Court of Examiners.—Mr. John Murray was re-elected a member of the Court.

Honorary Fellows.—The following were elected Honorary Fellows: A. Depage, Surgeon to H.M. the King of the Belgians; Pierre Duval, Professor in the Faculty of Medicine, Paris; John Miller Turpin Finney, Professor of Surgery, Johns Hopkins University; A. Gosset, Professor in the Faculty of Medicine, Paris; Charles H. Mayo, Professor of Surgery, Mayo Foundation for Medical Education and Research, University of Minnesota. The presentation of diplomas to the newly-elected Honorary Fellows will take place on Thursday, July 8th, 1920.

Appointment of Representatives.—Dr. W. S. A. Griffith was reappointed Representative on the Central, Midwives Board, and Mr. William F. Haslam on the Medical Board of the University of Wales.

Bradshaw Lecturer.—The President reported that he had appointed Sir Berkeley Moynihan to be Bradshaw Lecturer for the ensuing year.

The Diploma in Tropical Medicine.—The alterations in the regulations for the Diploma in Tropical Medicine and Hygiene, approved by the Royal College of Physicians on January 29th (see page 204), were adopted.

Election of Council.—A meeting of the Fellows will be held at the College on Thursday, July 1st, for the election of three Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir Anthony A. Bowlby, Mr. W. Harrison Cripps, and Sir D'Arcy Power. The date of the election will be announced to the Fellows by advertisement and by circular on March 5th, and March 15th will be the last day for the nomination of candidates. A voting paper will be sent to every Fellow of the College whose address is registered at the College.

CONJOINT BOARD IN ENGLAND.

At a meeting of Comitia of the Royal College of Physicians on January 29th and of the Council of the Royal College of Surgeons on February 12th diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following candidates who have passed the requisite examinations and have complied with the by-laws of the Colleges:

M. K. Abdel-Khalik, H. E. Archer, H. A. M. Bosman, Doris I. Bosworth, P. J. Briggs, E. F. Brown, J. H. Bulcock, H. G. Burford, G. F. Burrell, F. W. Chamberlain, G. L. Clements, M. Coburn, J. J. Cogblao, B. H. Cole, Alison Margaret Collie, A. C. M. Coxon, G. W. Dando, A. N. M. Davidson, C. O. Davies, D. J. Davies, T. Draper, W. Edge, I. Frost, L. P. Garrod, Mary L. A. Grimmer, E. A. H. Grylls, *G. C. Hartley, F. S. Horrocks, C. A. Hutchinson, Evelyn H. Johnson, O. E. Kennedy, J. V. Landau, F. F. Langridge, G. P. Lindsay, P. T. McDroy, S. F. Mahmood, Ida C. Mann, G. Massie, T. Mensa-Anon, O. G. Misquith, A. W. Moore, C. Nicory, F. A. O'Reilly, S. T. Parker, E. F. J. Peregrine, *G. Perkins, H. H. Perry, N. A. M. Petersen, G. J. Preston, L. I. Roberts, R. E. R.

Sanderson, H. N. Shapiro, F. P. Schofield, C. Shaw, G. M. J. Slot, S. S. H. Sof, S. Somasundram, S. D. Sturton, W. A. Turner, Kathleen S. Vine, N. V. Wadsworth, A. D. Weeden, C. J. L. Wells, J. S. White, Kathleen M. Wilkinson, D. W. Winnicott, Jane E. Wood.

* L.R.C.P. diploma not yet conferred.

† M.R.C.S. diploma granted on November 11th, 1919.

An examination in Public Health, Parts I and II, will be held in April next, commencing on the 19th and 26th respectively.

Obituary.

DR. HELEN MOORE, who was in charge of the Church of England Zenana Mission Hospital at Sukkur, Sindh, has died of septic influenza. She entered the London (Royal Free Hospital) School of Medicine for Women in the spring of 1897, and graduated M.B.Lond. in 1902. She first went to India at the end of 1905, taking temporary work in the Church of England Zenana Mission Hospital in Bangalore for over two years. After a time in England she returned to India and worked in the Church of England Zenana Mission hospitals in Bangalore, Quetta, and in Khammatt in the Nizam's Dominions; of this last hospital she was in charge during the furlough of another doctor. In 1912 she was appointed to the Church of England Zenana Mission hospital in Sukkur as the first qualified medical woman there, and, except during a furlough of some months in 1914-15, she remained there till her death. In her work in India she was much beloved by fellow workers and patients. Her mental power was great, and her charm of manner endeared her to all who were privileged to know her. Her death is a great loss both to Sukkur, where there is no medical woman to take charge of the Mission Hospital, and to her many friends.

MR. A. REGINALD F. EVERSHED, M.R.C.S., L.R.C.P., died on January 25th at Parkstone, aged 55, from bronchopneumonia following an attack of influenza. He was the eldest son of the late Dr. Arthur Evershed. He studied medicine at Guy's Hospital, and joined his father at Hampstead for a short time before starting practice in Penzance. After establishing a large connexion the work proved too great for his health, and he went to London, where he was able to fulfil his ambition to specialize as an oculist. After six years in the City he removed to Harley Street, where his practice so greatly increased that it was a bitter disappointment to be forced to withdraw from his work by a breakdown in health in November, 1919. Among a number of appointments he held were honorary oculist to the Cripples' Home, Winchmore Hill, oculist to the Stock Exchange Benevolent Fund, honorary oculist to the Brixton Dispensary, and for many years clinical assistant at the Royal Westminster Ophthalmic Hospital. His work was well known to amateur photographers, especially among members of the Camera Club (in the resuscitation of which he was instrumental) and the South London Photographic Society. As a member of an old Sussex family he helped in the institution of the "Men of Sussex" Society.

CAPTAIN WILBERFORCE VAUGHAN EAVES, M.B.E., R.A.M.C., died on February 10th in a nursing home, after an operation, aged 52. He was born in Australia in 1867, but came to England in early life, and took the M.R.C.S. and L.R.C.P.Lond. in 1889, subsequently the M.R.C.P. and M.D. He served in the South African war, and took a temporary commission in the R.A.M.C. in the first week of the late war, on August 10th, 1914, being promoted to captain after a year's service. For most of his service he was employed at Woolwich Arsenal. He was well known as a lawn-tennis player. He was in the very first rank for over twenty years, and retained his skill to a much later age than most men. Though he never succeeded in winning the championship, he came within one point of doing so, against Mr. W. Baddeley, in 1895. In his time he had gained the championships of Scotland, Ireland, Wales, New South Wales, and Victoria; he won the covered courts championship in 1897-98-99, represented England against Ireland in 1895 and 1896, was a member of an English team which played against America in 1897, and of the All England team which toured in South Africa in 1908-09, and represented the British Isles in the Davis Cup matches of 1907.

Medical News.

A CONFERENCE of the medical superintendents of sanatoriums, training colonies, and other residential institutions for cases of tuberculosis will be held on Monday, February 23rd, at 4 p.m., at 122, Harley Street, to discuss the problems which specially concern such institutions, and to consider by what machinery similar periodical conferences may be arranged.

AN Order in Council, dated February 9th, 1920, and made under the provisions of the Anthrax Prevention Act, 1919, prohibits the importation into the United Kingdom of shaving brushes manufactured in, or exported from, the Empire of Japan, whether such shaving brushes are exported direct to the United Kingdom or otherwise. This Order may be cited as the Anthrax Prevention (Shaving Brushes) Order, 1920.

THE Ministry of Health has set up a Joint Committee representing the departmental Advisory Committee on the Welfare of the Blind and the National Institute for the Blind, of which Sir Arthur Pearson is president, in order to co-ordinate effort and to advise on the grants the Ministry now makes in aid of the blind. It is hoped that ways of diminishing overlapping and preventing waste of effort in the collection of voluntary contributions will be devised.

THE Automobile Association is organizing a petition to the Prime Minister protesting against the present high price of motor spirit, which is as much a national necessity as gas or electricity, and praying that legislation may be at once introduced to ensure the immediate production of benzol and power alcohol in large quantities. Copies of the petition can be obtained from the Secretary at Fanau House, Whitcomb Street, London, W.C.2.

THE President of the French Republic has conferred the Cross of Officer of the Legion of Honour on Dr. James H. Nicoll, consulting Surgeon to the Western Infirmary, and Rector's Assessor in the University Court from 1914 to 1919. The Royal permission to accept and wear the decoration has been granted to Dr. Nicoll.

THE anniversary dinner of the Medical Society of London will be held at the Wharfedale Rooms, Hotel Great Central, Marylebone, on Wednesday, March 17th, at 7.30 o'clock.

TWO Emeritus lectures will be delivered at the Middlesex Hospital Medical School, the first, by Sir Alfred Pearce Gould, K.C.V.O., F.R.C.S., on February 26th, and the second, by Sir Richard Douglas Powell, Bt., K.C.V.O., M.D., F.R.C.P., on March 5th. The lectures will be delivered at 3 p.m. on each day.

OFFICERS who were attached to No. 20 General Hospital, B.E.F., during the war, will dine together in London on Saturday, March 13th. The chair will be taken by Major-General Guise Moores, C.B., C.M.G., A.M.S., now Commandant of the Royal Army Medical College. Those who wish to attend are asked to write to Dr. H. Drinkwater at 7, Cavendish Place, London, W.1.

THE Federation of Medical and Allied Societies will give a dinner at the Café Royal, Regent Street, on Wednesday, February 25th, when Lord Dawson of Penn (Sir Bertrand Dawson), G.C.V.O., K.C.M.G., C.B., M.D., will be the guest of honour. Dr. Addison, Lord Astor, and Sir Robert Morant are among those intending to be present.

THE Silvanus Thompson Memorial Lecture of the Röntgen Society will be delivered on March 2nd by Professor W. H. Bragg, C.B.E., F.R.S. The subject is "Analysis by x rays." A discussion on electric apparatus in relation to x rays will take place at a joint meeting of the Röntgen Society, the Institution of Electrical Engineers, and the Therapeutic Section of the Royal Society of Medicine on Thursday, February 26th. The meeting will be held at the Royal Society of Medicine at 5 p.m., when Dr. Reginald Morton will open the discussion.

AT the meeting of the Zoological Society of London on February 10th, Mr. F. Martin Duncan, F.Z.S., demonstrated a series of photomicrographs of acari from the lungs of *Macacus rhesus*, illustrating the larval, nymph, and adult stage of the acarid. Both young and adult monkeys appeared to be infected, but so far as his observations had gone, the presence of the mites in the lungs had in no case been the cause of death. Eggs had not been observed in the vesicles formed by the presence of the mites, though serial sections of adult acarids had shown the egg in an advanced state of development, pointing to the probability of this stage being completed within the body of the female.

THE Society of Apothecaries has awarded the Gillson scholarship for original research in pathology, of the annual value of £105, to A. L. Urquhart, of St. Thomas's Hospital.

THE No. 19 Casualty Clearing Station dinner will be held in London on Saturday, February 28th, at the Trocadero Restaurant, Piccadilly Circus, at 7.30 p.m. It is hoped that all officers of the unit will be able to be present. Members of other casualty clearing stations, and all who were associated with No. 19 C.C.S., are cordially invited. Applications for tickets should be made as soon as possible to the Rev. E. C. Doddrell, 6, Alexandra House, Regent's Park Road, Finchley, N.3. Dress, dinner jackets. Tickets 50s., to include wines, etc.

THE annual dinner of past and present students of the Royal London Ophthalmic Hospital will be held at the Criterion Restaurant, Piccadilly, on Thursday, March 11th, when Mr. William Lang, consulting surgeon to the hospital, will take the chair at 7.30 p.m. Tickets, 12s. 6d. (excluding wine), can be obtained from Mr. Charles Goulden, 42, Welbeck Street, W.1.

LORD ASHTON has forwarded a cheque for £5,000 towards the extension and improvements of the Preston and County of Lancashire Royal Infirmary. Just over a year ago he paid off a debt of £2,000 in the maintenance account.

IN the appointment of professors to German universities precedence is at present being given to university teachers who have left towns which have passed out of Germany's possession. The anatomist, Professor Ingo Fuchs, who had recently been appointed to Königsberg, has thus been transferred to Göttingen as Merkel's successor.

A DINNER will be held on Monday, March 1st, at the Wharnclyffe Rooms, Hotel Great Central, at 7.30 o'clock, to give an opportunity for social reunion for those who worked abroad during the war on behalf of Serbia. Most of the medical missions will be represented, and the committee includes a number of medical men and women. The honorary secretary is Miss Marx, 24, Melcombe Court, Dorset Square, N.W.1, from whom tickets (price 15s., exclusive of wine) may be obtained. Evening dress or uniform will be worn, with decorations.

THE customary course of lectures arranged by the Child-Study Society has begun at the Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1. The lectures on March 11th and 25th will deal with adolescence, and on April 29th Dr. A. E. Shipley, F.R.S., will give a lantern lecture on biting insects and children. The lectures begin at 6 p.m.

As already announced, the Royal Society of Medicine will entertain Sir John Y. W. MacAlister at dinner at the Connaught Rooms, Great Queen Street, W.C., on Thursday, March 18th, at 7.30 p.m. It has been decided to admit guests, both ladies and gentlemen. Applications for tickets, price 15s. each, must be received by the Honorary Secretaries of the Dinner Committee, 1, Wimpole Street, London, W.1, before March 16th.

A MEETING of the Pathological Society of Manchester will be held in the Medical School, Manchester University, on Tuesday, February 24th, at 5 p.m., when Sir Walter Fletcher, K.B.E., M.D., F.R.S., Secretary of the Medical Research Committee, will deliver an address on Medical Research after the War. All medical practitioners and medical students are cordially invited.

THE Minister of Health has issued amended regulations designed to reduce the expenses connected with the preliminary proceedings for obtaining land compulsorily for housing in rural districts when the extent of the land does not exceed five acres.

THE D.D.M.S. of the London District has lately appointed a special board for the purpose of advising the authorities as to the disposal of long standing cases in military hospitals and as to the treatment of chronic cases. The president of the board is Brevet-Colonel H. J. Waring, R.A.M.C.(T.F.), surgeon to St. Bartholomew's Hospital; the other members are Brevet-Colonel F. MacLennan, D.S.O., R.A.M.C., Major W. Essex Wynter, R.A.M.C.(T.F.), physician to the Middlesex Hospital, and Captain C. M. Hinds Howell, R.A.M.C.(T.F.), physician to the Great Northern Hospital. Colonel T. H. Openshaw, A.M.S., surgeon to the London Hospital, joins the board when orthopaedic cases are under consideration. The board has already done a considerable amount of work in visiting military hospitals in the London District and examining patients.

THE date fixed for the health week, organized by the Royal Sanitary Institute, is May 2nd to 8th.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

QUERIES AND ANSWERS.

PARAESTHESIA.

"A. R. J." describes a case of numbness and tingling of both lower limbs, with a transverse band across the abdomen and another across the limbs in a man aged 46, and asks for advice.

* * It is presumed that there is no question in this case of any organic disease. Fornication is so frequently a very early symptom of disseminated sclerosis that it is a recurrence in a marked degree must often be regarded with some anxiety. When the fornication is limited to the extremities and there are no other signs of involvement of the central nervous system, it most frequently occurs as a form of disturbance of the autonomic system in patients past middle age, and most frequently in women. Small doses of thyroid extract are occasionally of benefit, but belladonna and tincture of hyoscyamus, together with small doses of potassium iodide, usually give the best results. The diet should be plain and restricted as to meat, and alcohol should be avoided.

INCOME TAX.

"V. V." inquires (1) whether he can deduct as a business expense one-half the annual value of his residence as a professional expense, and (2) what deduction can be made in respect of the cost of servants' keep, wages, etc.

* * (1) Yes. "V. V." is assessed to income tax under Schedule A as being in receipt of the rent of the house, and is entitled to charge *qua* practitioner one-half of the rent assessed on him *qua* owner of the house. (2) A reasonable proportion can be charged both of wages and of the cost of food, laundry, etc. A practice which is fairly frequent is to regard one maid as employed solely for professional purposes, and to charge for one servant accordingly—for example, if three servants are kept, to charge one-third of the total expense against the practice. Of course, a great deal depends on the actual circumstances of each case.

LOCAL RATING.

"J. M. P." has been asked by the local borough council to make a declaration for the purpose of rating his residence, and in doing so to divide the rental between the private and professional portions of the total. He has also a surgery half a mile away.

* * As the surgery is not situated on the premises, we suggest that not more than £30 should be allotted to the professional portion. Where the surgery is included in the total rent, a common practice in rural and suburban localities is to regard the rent as equally attributable to private and professional use, so far as income tax is concerned. In any case, the exact apportionment can only be conjectured and is a matter of opinion, and the income-tax practice, modified as suggested in this particular case, seems to provide a reasonable basis of division.

ERYSIPELAS.

DR. F. S. ARNOLD (Berkhamssted) writes: If "X. Y. Z." will try buttermilk as a local application in erysipelas he will, I think, be led to the conclusion that it is far superior to any other treatment. I do not know any other local treatment which can be regarded as certain, though many give

quite good results on occasion. I have used buttermilk in erysipelas for the past twenty-four years, and have so far never seen it fail to give immediate relief to pain and rapidly to abort the whole morbid process. I have just had under treatment a case of eczema of the face and scalp in a man aged 77, and another of the leg in a woman aged 60, and in both the buttermilk treatment has been brilliantly successful. The buttermilk should be applied on soft rags or butter-muslin, renewed often enough to keep the part constantly wet. The buttermilk must, of course, be free from salt. The action is so uniform that one cannot help regarding it as specific, and the question arises to what element in the buttermilk it is due. I am myself inclined to regard it as microbic.

DR. J. W. DUNCAN (Hockley, Birmingham) writes: In reply to "X. Y. Z.," but not exactly to the point, I think the general treatment as useful as the local. I have not tried either alone. In two cases lately notified by me (February 1st and 2nd), one had only a local dusting powder (zinc iodide) and medicine; the other had ichthyol ointment and the dusting powder as well as medicine. In my experience no cases of erysipelas have died, even although in one case the disease ran over face and neck and body to the legs. In it ichthyol, dusting, and medicine were employed, while a disinfecting lotion was also used, if memory is true. The medicine is a preparation of liquor ferri perchloridi, with or without liquor strychninae hydrochloridi.

DR. F. S. JACKSON (Aberdovey) writes in answer to "X. Y. Z.": In a fairly extensive experience at a base hospital in France I found that: (1) General treatment was of very little service; 5 grains of quinine, if the temperature rose to 104° or over, seemed to be of benefit, but as the temperature is apt to be erratic it was difficult to say for certain. In a few cases I gave antistreptococcal serum with marked benefit, but as the supply of serum was called in I was not able to treat many cases. (2) Ichthyol ointment seemed to answer all requirements, so that I did not experiment with anything else, but it is not possible to say that it will cure all cases. (3) There were three or four deaths among my patients—all cases of severe facial erysipelas and all treated with ichthyol. They died from general septic poisoning, and there was no *post-mortem* evidence of meningitis or other complications. It is necessary to apply the ointment until every trace of inflammation has subsided, otherwise there is apt to be recrudescence and further spread of the disease.

LETTERS, NOTES, ETC.

"NEW LAMPS FOR OLD" IN OBSTETRICS.

DR. W. M. MACLEATH (Bradford) in the course of a letter on this subject remarks: I quite agree with "G. P." in your issue of January 17th, 1920, that forceps have often to be used by a general practitioner, and that when used with discretion and proper precautions no ill results. Let consultant surgeons say what they will, they only get worst cases, not the general run. The general practitioner's work is practically unknown land for a "surgeon"; let each criticize his own field.

ADJUSTING THE MATTER.

AT Tower Bridge police court this week a kitchen porter was charged with biting a piece out of the ear of his brother during a family quarrel. The prosecutor said he felt some pain in his left ear and afterwards found that a piece had been bitten out. According to *The Times* report the magistrate said that "there was no excuse for such a cannibal act, but the parties concerned all being relatives, he should remand the prisoner for a week on one surety in £25, to see if the matter could not be adjusted." A week seems rather long to wait for restoration of the missing piece of ear by a plastic operation, if that is what the magistrate meant by his dark hint about "adjusting" the matter. Sir J. O. Skevington recorded in our issue of September 27th, 1919, the successful suturing of the end of a man's nose cut off an hour before by a falling skylight; and a fortnight later Dr. W. E. Hadden cured this by relating how his father successfully stitched the tip of a man's nose bitten off a few minutes before in a street row.

COELUM NON ANIMUM.

MR. THOS. FREDK. I. BLAKER, M.R.C.S. (Brighton), writes: There is a passage in Dr. Bernard Hart's lecture on anxiety neuroses in the current number of the BRITISH MEDICAL JOURNAL in which he says: "The futility of rest cures and voyages is immediately apparent, for the patient's troubles are in his mind, and he takes them with him wherever he may be sent." This reminds me of a clever rhyme in two languages, which appeared in *The Isis*, an Oxford publication, some thirty years ago. I quote from memory. Life has rubbed them well into me:

Who can fly from himself? Bitter cares when we feel 'em,
Are not cured by travel. As Horace says, "Coelum
Non animum mutant, qui currant trans mare."
'Tis climate, not mind, that, by roaming, new vary.

A PLEA FOR THE NOTIFICATION OF MEASLES.

DR. A. G. NEWILL (Harringay) writes: At present in some areas the notification of measles is being continued whilst in others it has ceased. Such differentiation of action can be of no general benefit to the public, though of local utility. The days of the argument that notification of this disease is useless because you could not isolate them or because the infection had already spread I trust are gone. The notification of measles since the war has had an educative value. It has shown the ignorant that measles cannot be trifled with as it kills from complication. Further, in these days with existing staffs of health visitors, sanitary inspectors, nurses, it gives an opportunity to lessen the spread of the disease by permitting them to follow up the cases and prevent their early entrance to schools, etc. If our national asset remains in every succeeding generation it behoves us in public health affairs to utilize all means in safeguarding the infant and child welfare. I would therefore seek the co-operation of all those interested, especially medical officers of health, in getting their local authority to maintain the notification of measles as a permanent measure. The public so far has been educated by notification, and it would be a pity to revert to pre-war measures or arguments. I shall be pleased to hear what medical officers of health think.

PREGNANCY DURING AMENORRHOEA.

DRS. WILLIAM F. GRANT AND GEORGE Y. OLIVER (Sydenham, S.E.) write: Mrs. S., aged 41, and married twenty years, had four children and no miscarriage. The fourth child, born in August, 1915, was suckled until May, 1916. The first and only menstrual period after the birth of this child occurred in October, 1916, so that since that date there had been complete amenorrhoea. The husband, who had served during the war, was demobilized in January, 1919. The patient was delivered of her fifth child on January 20th, 1920, and as prior to this menstruation had been in abeyance since October, 1916, it is assumed that impregnation occurred about the middle of April, 1919, and that the ovum which was then fertilized was that belonging to an oncoming menstruation which was held in abeyance because fertilization had taken place.

EXCRETION OF QUININE IN THE FAECES.

MR. M. NIENENSTEIN, Ph.D. (The University, Bristol) writes: In my report entitled "Excretion of quinine in the urine," recently published by the War Office in *Observations on Malaria* (pp. 4-79), edited by Sir Ronald Ross, I have limited myself to observations on the excretion of quinine in the urine. It has, however, been pointed out to me by Major F. P. Mackie, I.M.S., that the fact that I only found traces or no quinine in the faeces will be of interest to those engaged in the treatment of malaria, and I therefore mention that of sixteen stools examined by me eleven contained only traces of quinine, whereas in the remaining five stools I entirely failed to detect quinine. All stools came from patients who had taken 30 grains of quinine sulphate daily, and who were found to excrete daily 35 to 50 per cent. of quinine in the urine. The quinine was recovered from the faeces by Giemsa and Schaumann's method for identification (*Arch. f. Schiffs- und Tropen-Hyg.*, 1907, vol. xi, p. 44), and tested qualitatively by Herepath's method as modified by Ramsden and Lipkin (*Ann. Trop. Med. and Parasit.*, 1918, vol. xi, p. 444). As will be seen from my report (p. 13), this test gave on reinvestigation most satisfactory results, and was found never to fail. My results are therefore in full agreement with those of Giemsa and Schaumann (*loc. cit.*), Ramsden, Lipkin, and Whitley (*Ann. Trop. Med. and Parasit.*, 1918, vol. xii, p. 248), and others, that the amount which is excreted with the faeces is so small as to be negligible.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 46, 47, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 43, 44, and 45.

THE following appointments of certifying factory surgeons are vacant: Hungerford (Berks), North Walsham (Norfolk).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

As average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea restante* letters addressed either in initials or numbers.

A Lecture

ON

THE DIAGNOSIS OF GLAUCOMA.

GIVEN AT THE NORTH EAST LONDON POST-GRADUATE COLLEGE,
TOTTENHAM, JANUARY 20TH, 1920.

BY

LIEUT.-COLONEL R. H. ELLIOT, I.M.S.(RET.).

THE teaching of post-graduates differs from that of students in one very important particular—namely, that of the angle from which we approach the subject. The teaching of the student is synthetic. An idea is presented to his mind under the cover of the name of a disease—for example, glaucoma. Round that idea we build up a number of items of knowledge having reference to the symptoms, the diagnosis, the pathology, the prognosis, the treatment, etc., of the disease we are studying. Such a line of study is made easy for the student by the fact that when he enters the wards he finds the cases allotted to him already marked with the diagnoses which have been made by his teachers.

The post-graduate practitioner is in a very different position. His patient comes to him with a complaint of one or more signs or symptoms, any or all of which may be, and indeed usually are, common to many diseases. Starting from one or more of the clues thus offered, the medical man has to work his laborious way in a search for the cause of the trouble. Very often he has to do so through a tangle which time and study alone will enable him to unravel.

One of the tragedies of ophthalmic practice lies in the frequency with which we meet men and women blinded by glaucoma, simply owing to the failure of the medical men in charge to make an early diagnosis of the condition and to take unflinching action thereon. It is not that there is any real difficulty in recognizing what is wrong, but rather that the possibility of the existence of the disease is too often forgotten, with the result that the symptoms are ascribed to some more commonly met with condition. It is therefore from this angle that we shall approach our subject to-day. First, we shall take the outstanding signs of glaucoma which first impress themselves on the attention of the patient and of his doctor; then we shall show what steps the practitioner can and should take in order either to make a firm diagnosis of glaucoma, or to exclude the presence of that disease. On another occasion we shall study the means at the disposal of the expert for the assistance of the practitioner who consults him.

HEADACHE.

This may be of various kinds.

(A) *A Passing Morning Headache.*

The patient complains that he awakes in the morning with a dull headache, which passes away after he has been up and about for a while; sometimes he will volunteer the information that it is gone by the time he has finished shaving, or that he has forgotten it after reading the paper on his way down to office. On questioning him he will admit that the sight of that eye is dim whilst the headache is on. Rarely he will have noticed dilatation of the pupil and still more rarely haloes round lights. I am far from wishing to suggest that all morning headaches, or even the majority of those headaches which undoubtedly emanate from eye trouble, are due to glaucoma; for, strange as it may seem, headaches due to an error in refraction are sometimes most complained of in the morning, though, as a rule, they are worse at night and relieved by sleep. We have also to take account of the large numbers of other causes of morning headache which are in no way connected with the eyes.

The points of diagnosis have already been indicated. The patient should be warned to look out for the association of headache, misty vision, dilatation of the pupil, slight circumcorneal congestion and haloes round lights; and an ophthalmoscopic examination should be made to ascertain whether there is cupping of the disc, or abnormal pulsation of the retinal vessels.

The explanation of this early morning glaucoma is of interest. Throughout life the clear fluid which fills the chambers of the eye (both the aqueous and vitreous

chambers) is being continually derived from the blood circulating through the ciliary body. With equal regularity it is steadily oozing away at the angle of the chamber through the pectinate ligament into the canal of Schlemm, and thence into the vessels which lead the blood out from the eye. If the rates of inflow and outflow correspond, the amount of fluid retained within the eye remains constant, and the intraocular pressure continues at the same level; but if there is any obstruction to the outflow of the fluid, whilst the rate of inflow remains the same, the tunic of the eye will become overstretched by this increase in the mass of the fluid it contains, and the intraocular pressure will rise correspondingly. If I may be permitted to use a simile: We take a rubber globe like a football, and to it we attach two pipes; one of these leads fluid into it from a tap, which is kept constantly running at an even rate, the other allows fluid to escape at exactly the same rate. The pressure of the fluid within the ball remains the same, and the tension of the coat of that ball does not alter. If now, we slightly pinch the exit tube, more fluid accumulates within the globe than before; the walls are distended in consequence; the pressure of the fluid within the ball rises; and the coat, as felt from outside, becomes harder. If we increase the rate of outflow, the previous condition of affairs is restored.

Professor Arthur Thomson has shown strong reason to believe that during our waking hours there is constantly at work a mechanism whereby the intraocular fluid is pumped out of the eye. The motive force of this pump is supplied by the movements of the iris, and by the contraction of the ciliary muscle. Every time that the pupil contracts and expands under varying conditions of light, and every time that we bring our ciliary muscle into play, as we adjust the eye for sight at varying distances, fluid is being sucked from within the globe into the canal of Schlemm and is again being driven out of the canal of Schlemm into the efferent vessels. During the hours of sleep this pump action ceases, but a normal eye is capable of providing sufficient outflow even without the aid of this mechanism. It is when the excretory channels are, for one reason or another, becoming less efficient, that danger arises. The cessation of the pump action during the hours of sleep may then determine the onset of a condition in which excretion is insufficient for the needs of the eye. A slight addition to the fluid accumulated within the globe will then give rise to moderate attacks of increased tension during the hours of sleep. The consequence is that the patient awakes with a slight attack of glaucoma, as evinced by the headache, the dimness of vision, etc. When he gets up, and begins to use his eyes, the pump action is restored, excretion is hastened, and the symptoms pass away for the time, only to return with increasing frequency and severity as time goes on. Here we have (1) a ready explanation of these morning headaches, and (2) an obvious direction as to the timing of our miotic drops when we use them.

Diagnosis.

It is only when the headaches are accompanied by the other signs and symptoms of glaucoma that we are justified in making a diagnosis of that disease. In any and every case of the kind one of the first things to do is to have the patient's refraction carefully estimated and any errors corrected. It must never be forgotten that an error in refraction may be a cause of congestion of the eye, and so may be a predisposing factor in the onset of glaucoma.

You will ask me why it is that medical men consider it an axiom that sleep is good for glaucomatous patients, and how I reconcile this with the statements I have just made. The answer is simple. Glaucomatous attacks usually depend on the onset of a state of congestion of the eye; sleep quiets the whole nervous system, inclusive of its vasomotor mechanism, and so gives the eye a chance of recovering its normal condition of vascular equilibrium. On the other hand, if the channels of excretion are gradually becoming too constricted for their work, and if, in consequence, instead of being free enough to allow of the ready escape of the necessary amount of intraocular fluid they are so far constricted that they need the assistance of the pump action above outlined, the patient has reached a condition in which sleep brings a constant and steadily increasing danger. I say steadily increasing because (1) it increases more and more as the constriction

of the channels becomes aggravated with the advance of life, and (2) in any one night it increases in proportion to the length of sleep the patient indulges in. The order of events is here as follows: Cessation of the pump action; overfilling of the eye with fluid; consequent obstacle to the outflow of blood through the overstretched coat of the globe; and thus increase of intraocular pressure produced in a double manner and with the establishment of a vicious circle.

(B) *Headaches after Near Work.*

As a man advances in life small errors in refraction, which have not troubled him hitherto, give rise to symptoms, prominent among which are headache, pains in the eyes, a feeling of ocular fatigue, and increased lachrymation. The onset of presbyopia, too, takes its toll of his energy. If his refraction is carefully corrected, and suitable glasses are prescribed, and if any error in muscle balance is likewise attended to, the symptoms should pass away completely, leaving the patient once again forgetful that he even possesses eyes. If, however, the symptoms do not completely subside, and especially if the presbyopia increases more rapidly than we should normally expect it to do, we must look further afield for the cause of the trouble, and one of the many possibilities we should bear in mind should always be the occurrence of high tension in the eye. Such a suspicion should lead us to examine the fundi with great care. The presence of a glaucomatous cup would at once put us on our guard, but, even apart from this, an increase in the pulsation of the retinal vessels, especially if arterial in character, would have a marked significance for the careful observer. Increased pulsation—especially when arterial—is probably invariably the earliest sign of glaucoma, though it cannot always be elicited, owing to the fact that the increase in tension is often intermittent in character. The moral of all this is: Be suspicious of headaches in elderly patients when these persist in spite of careful correction in errors of refraction and muscle-balance.

(C) *Severe Headaches often attended by Vomiting.*

These are often taken to be due to some form of gastrointestinal disturbance, and are then spoken of as "bilious headaches." At other times they are caused by a tumour of the brain, or by some other form of cerebral disturbance. There are many other possibilities, into which we have no time to enter. The one lesson I desire to drive home to-day is that whenever you see an elderly patient suffering from severe headache, whether accompanied by vomiting or otherwise, you should at once rank glaucoma as one of the possibilities to be considered and to be excluded if possible. Other causes of severe headache come and go, leaving the patient little the worse, except for the memory of his experience. It is far otherwise with glaucoma. The headache and the sickness are more passing events in comparison with the appalling possibilities that loom before your patient if you leave one of these severe bouts of increased tension untreated.

You must obtain a good view of your patient's eyes and, if necessary, you must instil a 4 per cent. solution of cocaine to enable him to face the light for the purpose.

If the eye is congested, and especially if the circumcorneal zone stands out pink, as contrasted with the rest of the eye, two ideas should flash into your mind, namely, acute iritis and glaucoma. Is the pupil widely and evenly dilated? If so, the probability is that you are dealing with a case of glaucoma. But remember the possibility that a mydriatic may have been used very early for iritis. Search the anterior capsule for evidences of adherent iris pigment; and look also for any characteristic irregularity in the outline of the pupil.

Take the tension of the eye with your hand, especially in comparison with its fellow. The acute glaucomatous eye is stony hard. There are many cases of glaucoma in which the rise in tension is so small that two or more medical men may well argue whether it is present or not. No such doubt exists in these cases. The student can recognize the hard eyeball without fail.

Then look at the cornea! In the glaucomatous eye it is steamy; most unmistakably so, indeed. Its polished lustre is gone; the beautiful mirror of the eye looks as if it had been breathed upon; the details of the iris pattern are lost. At the same time we observe that the anterior chamber is abnormally shallow.

In less severe cases, where the media are still transparent, an ophthalmoscopic examination will probably show cupping of the disc. It will not necessarily do so, for, though rarely, glaucoma may make its first appearance as an acute attack, and then the disc has not had time to be depressed, but arterial pulsation will be well seen if the media are clear enough to permit examination.

It is not that there is the least difficulty in making a diagnosis. Certainly not. The trouble is that the busy practitioner may for a moment allow himself to forget that whenever he meets with severe headache of this type, glaucoma is one of the possibilities that should at once flash through his mind. Forewarned will be forearmed.

Just a word or two more on the differential diagnosis between glaucoma and acute iritis. In the latter the pupil, unless it has been artificially dilated, tends to be severely contracted; at an early stage it fills up with plastic exudate. If a mydriatic has been used evidences of irregularity of outline of the pupil, or at least of pigmentary deposit on the anterior capsule, will rarely be lacking. The cornea will be clear, while the pattern of the iris will be muddy; engorged vessels will be seen to stand out on the surface of the iris; the anterior chamber will be of normal depth and not shallow, as it is in acute glaucoma.

There remain the cases in which glaucoma is secondary to iridocyclitis. The wise practitioner will hasten to share the responsibility of such with his specialist colleague at the earliest possible moment.

Loss of Sight.

This, like the headaches, may vary greatly in different patients. We shall consider the typical varieties in turn.

(A) *Gradual Loss of Sight without any Apparent Cause.*

Let me pause here to explain that when a patient comes to you complaining that his "sight is not so good as it used to be," you should not be content merely to set a Snellen type up before him and to ask him to read it down to the 6 m. line. Many a surgeon, under these conditions, will endeavour to reassure his patient, and will then send him away. Those who do so are taking grave risks, for the patient may be right and the surgeon may be wrong, despite the test that has been applied. Let me elaborate the subject. Sight does not merely consist of central visual acuity as measured by a standard card. On the contrary, there are a number of elements to be considered:

(i) *The rapid increase in presbyopia met with in glaucoma* we have already referred to; this is doubtless due to the numbing pressure exerted on the third nerve endings in the ciliary muscle, which gradually robs that structure of its contractile power.

(ii) *The visual field may gradually shrink in area*, thus robbing the patient of one of the safeguards of his daily life, whenever he is on the move amongst other people or even amongst inanimate objects. He does not realize what his trouble is, so naturally he cannot explain it to you, but he is conscious that he is more apt to run into people or things than he used to be. Using even a rough test you may learn that one or both of his fields is contracted. No apparatus is needed. You bid him stand opposite to you, and fix your right eye with his left or vice versa; at the same time you both shut the other eye, then, moving each hand in turn midway between him and you, you roughly map out his field, making your own the standard of comparison; any great contraction of the visual area will be thus easily revealed.

(iii) *The light sense may be greatly reduced.* This is a characteristic of glaucoma, though but little attention is usually paid to it. From the patient's point of view it is a matter of great importance. Print or writing no longer stands out vividly like it used to do, even in a good light, and he finds great difficulty in reading when the illumination is of poor quality. When he passes from bright light into darkness, or comparative darkness, he has great difficulty in seeing until his eyes have become dark adapted. On the other hand, when he passes from a poor light into a bright one, he is dazzled, and must wait until he can get accustomed to the glare.

(iv) *Reading test.* In spite of the fact that the patient can make out all the letters on the 6 m. line of a test

card, he may be conscious, perhaps only dimly so, that he does it more slowly, and with more difficulty, than he used to do formerly; or perhaps he may in past time have had vision well above the normal, and be dimly conscious of the change in his visual power, though he would find it difficult to express the change to a sceptical surgeon.

To sum the matter up: When a patient, who you have reason to believe is honest, thinks that his sight is failing, it is unwise to dismiss him as a *malade imaginaire*. Remember that simple glaucoma may be far advanced, with nothing to indicate its presence but what I have ventured to call "the triad of glaucoma signs"—(a) contraction of the visual field; (b) cupping of the disc, and (c) failure of central visual acuity. Even then the last named defect may be but poorly marked.

Differential Diagnosis.

We shall now shift our ground and assume that the gradual loss of sight has not only been complained of by the patient, but has also been recognized as a clinical fact by the doctor. What dangers still attend us? In other words, with what other conditions are we likely to confuse a chronic glaucoma? I speak from frequently repeated practical experience, when I answer: (1) Cataract, (2) refraction errors, (3) brain trouble, and (4) optic atrophy. We shall consider these in turn.

1. Cataract.

Not a great while ago I saw a patient who had been sent to see a specialist by her doctor. She was told she had cataract, and must wait until she was worse before she could be made better. Six months later the patient made the striking and alarming observation that her "sight was at some times much worse than at others"; her doctor found she had cupped discs; the specialist confirmed it, and I had no difficulty in agreeing. Such a mistake should not occur. A cataract can always be seen, and that quite easily, by a method which I do not think you will find in the textbooks. Put a +10 lens behind the eyehole of your ophthalmoscope, and examine the eye (preferably with the pupil dilated) at a distance of five or six inches, moving backwards and forwards until sharp focus is obtained; every detail of the lens opacity will stand out clear to your view against the bright fundus reflex. Your diagnosis is a positive one, and is very easily made. As time goes on you will be able to follow the increase in the strokes or dots that make up the opacity. On the other hand, the cupping of the disc and, what is often more marked still, its pallor will put you on your guard against glaucoma.

2. Refraction Errors.

When a man finds that his sight is steadily failing, and that the careful correction of any errors present does not help him to see again, you may assume that something is wrong either with his media, or with his retina and optic nerve. Once again the diagnosis is not difficult in most cases; what is important is that the possibility of the presence of glaucoma should be borne in mind, and that the examination of the patient should be careful and on routine lines. There is a great deal of rubbish being sold the public to-day—probably more than ever in history—and medical advice must sometimes be included in the category. It is not that men—specialists as well as practitioners—cannot do good work if they choose: what is wrong is that the hurry and bustle of an aeroplane age lead many to give too little time to their cases, with the result that they do bad work. To put it on the lowest of all grounds: it does not pay. Make up your mind that you will not do it! I know a chemist who advertised, "I cork my reputation in every bottle of medicine I send out." Try that in your practice.

3 and 4. Brain Tumours and Optic Neuritis.

What has just been said applies here again. Any man can use an electric ophthalmoscope; it requires no learning; only intelligent man can see an optic neuritis and distinguish it from a glaucoma.

5. Optic Atrophy.

Now, here we come to the one real difficulty—namely, the differential diagnosis between the various forms of optic atrophy, inclusive of that due to chronic glaucoma. The discs are pale and the cupping is not pronounced, do

not hesitate to call in expert aid. You will be wise in your own interests and kind to your patients if you do so as early as possible.

A word may be said about "tobacco amblyopia," because it is so very susceptible to satisfactory treatment. A rough test will suffice in most cases. Take a clean sheet of white paper; on it make a number of dots with black ink, and then a number of similar dots with red ink; give your patient a pencil, and bid him rapidly tick off the red dots; if he can do so without hesitation, it is most unlikely that he has tobacco trouble. If he cannot do so, and if he is an excessive smoker and has been gradually losing his sight without a recognizable cause, except possibly pallor of the outer quadrant of his disc, you may win much kudos by treating him firmly and promptly for tobacco poisoning.

(B) Gradual Loss of Sight, with Intermittent Headaches.

In all such cases be on the look-out for glaucoma as a possible causative factor. Do not be content to treat your patient for biliousness, or for a nerve breakdown—that blessed modern refuge of the diagnostically destitute—until you have at least thought of glaucoma and cerebral tumour. With regard to the former, as it is our subject for to-day, make a point of seeing your patient in an attack, and look for the dilated pupil, the rise in tension, the shallow chamber, and the evidences of ocular congestion that attend rises in intraocular pressure. In the intervals examine his discs and his visual fields. If you are still in doubt, get an expert opinion.

(C) Marked Losses of Sight, clearly following Severe Attacks of Headache.

We have already discussed this subject under the heading of "headaches," and need only now mention the possibility of the eye condition being altogether missed. If the surgeon bears the possibility of its occurrence in mind, he will not go wrong.

ENTOPTIC PHENOMENA.

Photopsiac, or subjective sensations of light, are a common and early symptom of congestive glaucoma. They may take many forms, one or more of which may be described by the same patient. Thus we may hear of flashes of light, compared to summer lightning, or in the tropics to dancing fireflies; of a ball of fire that rolls across the field of vision from side to side, of sudden flash-like spots of light, or of a continuous luminous glow, which may last for seconds, minutes, or even longer. The patient may volunteer the information that he sees these phenomena most when he is tired, and that they are especially common when he is getting into bed, or has just turned out the light, or soon after he has lain down to sleep. It is to be remembered that photopsiae are seen under many conditions other than glaucoma; in fact, they are likely to appear whenever the retina is irritated, dragged upon, or in any way interfered with. Nor must we forget that similar phenomena, but of central origin, are met with in neurasthenic patients under many conditions. The moral is that such phenomena always indicate the necessity for a careful ophthalmoscopic examination, as well as for a thorough investigation of the patient's refraction, and of the state of his general health.

RAINBOWS ROUND LIGHTS.

These are seen when anything occurs to interfere with the natural transparency of the cornea. They are best observed when the patient looks from a little distance at a bright light in the dark. At least two colours are discernible—an inner blue or violet and an outer red; a yellowish band is generally seen between them. The diameter of the halo is from 7 to 8 degrees. Sometimes the patient has to be warned to look for them before he can observe them; in other cases they are so brilliant that every tiny flickering flame in the firelight is iridescent with colours. Some patients speak of them with amused interest, whilst others are inspired by them with deep alarm. Any one of you can observe the phenomenon for yourselves by breathing on your glasses and holding them up to a bright flame or electric light. Anything which interferes with the transparency of the cornea may be productive of haloes, and these may therefore be seen in other conditions beside glaucoma. They are invariably

to be found after treating the iris with silver nitrate. They are also, though not commonly, seen in the early stages of cataract. It must not be forgotten that there are apparently healthy eyes which habitually see haloes round lights in the dark; this phenomenon is probably connected with a faulty state of the patient's refraction. Transient haloes round lights are often complained of by those who suffer from conjunctivitis associated with mucous discharge. Wiping or washing away the offending flake of mucus from in front of the cornea will abolish the symptom.

CONCLUSION.

It is not pretended that this lecture is exhaustive; it merely touches the fringe of a large subject, but it is an effort to help you, by drawing your attention to matters which may too easily be relegated to the background of your mind, with harmful results to your patient's sight and with damage to your own reputation.

NEUROLOGICAL JOTTINGS.*

BY

JAMES TAYLOR, M.A., M.D., F.R.C.P.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE; CONSULTING PHYSICIAN TO MOORFIELDS EYE HOSPITAL, AND TO THE QUEEN'S HOSPITAL FOR CHILDREN.

I wish in these notes to direct attention to some points of interest that have come under my notice in the course of neurological work.

Complications of Epilepsy.

When I was seeing, through a long course of years, many epileptics every week at Queen Square, I was not infrequently surprised by curious developments. I remember, for example, one man, treated for many years before I saw him as a chronic epileptic. He had been attending the hospital for seventeen years, and there was nothing in his history to suggest that his case was anything more than one of chronic epilepsy. But one day he appeared at the out-patient room complaining of severe headache, and ophthalmoscopic examination revealed the presence of marked optic neuritis. He was admitted to the hospital, and died in a few weeks of a large tumour of the right hemisphere. Another case which surprised and interested me was that of a healthy looking young man, a railway signalman, who came as an out-patient one afternoon with the history that he had had an attack characterized by loss of consciousness, convulsions, and tongue biting. There was no family history of any such illness, and his personal history was uneventful. He had never had syphilis, and he had no optic neuritis. There was no doubt that the attack was of the nature of epilepsy, and naturally he could not remain at his work as a signalman. He became a barrier ticket collector, and for over four years attended the hospital regularly, and was treated with bromide. At first the attacks occurred about once a month, but they gradually disappeared under treatment. He continued to attend, and one day complained of severe headache which he said he had had for two or three weeks. He had not been subject to headaches before. I examined his eyes then (they had been carefully examined from time to time before, but nothing abnormal discovered) and I found a flaring optic neuritis in each eye. He was admitted, and a decompression operation done to relieve his headaches. He had a large growth in the left hemisphere, from which he died in a few weeks.

I could record a good many similar cases, and I feel sure my colleagues at Queen Square have had similar experiences. I suspect they are cases characteristic of a large group, and the existence of such cases shows how necessary it is not to be content with the diagnosis of "ordinary epilepsy." I remember Dr. Hughlings Jackson remarking on one occasion that there is no such thing as a case of "ordinary epilepsy," and that every case of convulsion or so-called fainting ought to be investigated most fully and carefully, and kept under observation. These cases would seem to "point the moral," but it is obvious that diagnosis of the true cause of the convulsion is in the first instance impossible.

* Part of this paper constituted the Presidential address to the Harveian Society.

Variability in Response to Treatment in Epilepsy.

I have frequently been struck with the variability in response to treatment of some cases of recurrent loss of consciousness with or without convulsion. One case will not be influenced by bromide until he is getting up to something like 30 grains thrice daily. It may then be found that such a patient not only remains free from attacks with such treatment, but improves greatly in general health. I have a patient I see now about twice a year who for the last seven years has taken 35 grains twice a day, and has remained well, and able to carry out responsible duties in a City office. I have another patient, a lady, who for five years has remained well although taking 30 grains thrice daily.

On the other hand, one has seen patients who, with large doses of bromide, become progressively worse, but who improved on different treatment. One little girl was brought to me at the hospital some years ago who suffered from frequent attacks, several a day, of loss of consciousness without convulsion. She was only 6, and I put her on 10 grains of bromide thrice daily. In a month I saw her again. The attacks had become more frequent. I stopped the bromide for a month and saw her again. The attacks were not so frequent as while she was taking the bromide, but as frequent as when I saw her first. I then put her on 5 minims of tincture of belladonna thrice daily and saw her again in a month. There had been no attacks during that time and she remained well. Of course, I cannot explain this. I only state the facts. I understand that a similar result not infrequently follows the administration of *Adonis vernalis*.

Another interesting point I have observed about so-called "nocturnal" epilepsy. I may say, in passing, that this is an unfortunate term and really incorrect. It would seem to indicate that in these cases the fits occur only at night, but this is not the case. It is really sleep which determines the onset of an attack, for in many of these cases of so-called nocturnal epilepsy inquiry will elicit the fact that a fit occasionally occurs during the day, but only if the patient has happened to go to sleep during the day. The point, however, which I wished to emphasize is that while bromide alone is very useful in these cases, its effect seems to be reinforced by the addition of tincture of digitalis, and 30 grains of bromide with 5 minims of tincture of digitalis taken nightly are, as a rule, effective in controlling the attacks.

Dislocation in Epilepsy.

There is one point about epilepsy which is worth remembering. As is well known, after a Jacksonian fit affecting one side and starting in the arm there is frequently temporary weakness of the affected side, usually more marked in the limb in which the convulsions started—that is to say, in the arm in such a case as I refer to. But it must also be remembered that dislocation at the shoulder-joint not infrequently occurs in the course of a convulsion. I remember one case in which one of these conditions was remembered by the observer but the other forgotten. A junior colleague of mine, in my absence on one occasion, saw my out-patients. One of them was a young man subject to occasional fits. He came up on this occasion saying that he had had a fit the previous week and found that after it he could not use his arm. There was a note made to the effect that weakness of the right arm was present, and that although the right leg was not complained of there seemed to be an exaggerated knee-jerk on that side. Obviously my colleague, who had not seen the patient before, thought he was dealing with a Jacksonian fit with weakness of the affected side following the fits. But when the patient came up the following week it was found that he had only a dislocation at the shoulder-joint, and when this was reduced the weakness cleared up.

Recurrent Attacks of Herpes.

I have been considerably interested in herpes, and one or two jottings on this disease are, I think, of interest. I rather think we were all taught that a second attack of herpes is practically unknown. I think I am right in saying that that great observer, Jonathan Hutchinson, was in the habit of telling us that second attacks of herpes did not occur. I have seen three cases which certainly controvert this. One is the case of a man whom I saw at the Moorfields Eye Hospital for some eye condition unrelated

to herpes, who came up one day complaining of an eruption on his neck. I told him it was an attack of "shingles"—cervical herpes—and he told me that he had had an attack on his chest some years before. On stripping him it was obvious from the marked scarring that he had had a severe attack of herpes zoster. The second case was that of a friend of mine—a medical man—whom I saw about twenty years ago with herpes frontalis. About two years ago he had another attack of herpes frontalis on the other side, and he told me that in the intervening years he had had two other attacks of herpes, one in the deltoid region and one of herpes zoster. So that this patient had had in all four separate distinct attacks of herpes, two of which I saw myself.

In a patient whom I saw with Dr. Melvill Green a few years ago—an old lady of 80—a condition was present which I have never seen before—namely, herpes of three different distributions. She had had, about two years before I saw her, not only herpes frontalis but also herpes in the deltoid region and herpes zoster. It was on account of the very severe post-herpetic pain that I was asked to see her, and the scarring in all three regions was extremely severe. The eruption in all three distributions in this case occurred at the same time. She died soon after I saw her, exhausted by the severe and intractable pain. I have also recently seen, with Dr. Robertson-Fullarton, a lady with facial herpes and severe post-herpetic pain who a year ago had an attack of herpes zoster.

This leads me to remark on another point—namely, the curious variability in the occurrence of post-herpetic pain. Such pain in children is, in my experience, practically unknown; in the majority of adults it is severe, but sometimes of comparatively short duration. In a certain number it is not only severe but persistent, and not infrequently leads to a great impairment of health. In old people especially post-herpetic pain is always fraught with a certain amount of anxiety because of the exhaustion to which the pain and consequent loss of sleep give rise. On the other hand one has met some adults, by no means young, who have experienced no pain at all after an attack of herpes.

Herpes and Chicken-pox.

A very interesting point about shingles is its relationship to chicken-pox. Of this relationship the evidence seems convincing, but its explanation is still very difficult. In the *British Journal of Dermatology and Syphilis*, October to December, 1917, there is a most interesting paper by Dr. W. P. Le Feuvre, in which he actually urges that "shingles should be recognized as an infectious disease, and one under certain unknown conditions likely to become a starting point for a chicken-pox epidemic." Reference to the possible connexion of these diseases has been made, especially in the correspondence columns of the *BRITISH MEDICAL JOURNAL*, and evidence in favour of it adduced. The points common to all the cases brought forward were three in number—

1. Chicken-pox in one individual followed shingles in another within the ordinary incubation period of chicken-pox—namely, twenty-one days.
2. No other source of infection was discovered; and
3. Chicken-pox in a child followed an attack of shingles in an adult.

In Dr. Le Feuvre's paper fifty cases in all are referred to. Before seeing this I myself had been struck by the curious coincident occurrence of these diseases, and I had notes of four instances. One of these—a lady with a very severe attack of herpes of the fifth nerve affecting all its branches—I saw in consultation with Dr. Woollerton. A fortnight later I was asked to see the same lady again, and the doctor asked me also to see her daughter, a young lady of 28, who had such a severe attack of chicken-pox that he had been afraid it might be small-pox. I also saw, in consultation with Dr. Haward, a patient suffering with severe neuralgia after herpes zoster. Being interested in the matter, I asked Dr. Haward if there had been any cases of chicken-pox in the house at or about the same time. He was surprised at the question, but on my explaining the reason for it, he said that three children in the house certainly had had chicken-pox, but he could not remember whether it was about the same time. He promised to look into the matter of dates, and was kind enough to write me to the effect that chicken-pox in two children in the house

had appeared about a fortnight after the shingles eruption in the father. Another patient I saw in consultation with Dr. Hewetson on account of pain and actual muscular wasting following a severe attack of herpes in the deltoid region. He also was surprised at my question, but was able to tell me that two children in the house had suffered from chicken-pox within a week or two of the attack of herpes in the adult. Of course I cannot explain this curiosity. The vesicles of herpes are almost, if not quite, indistinguishable from those of chicken-pox except that in the former disease they are so often confluent. Yet one frequently sees in cases of herpes isolated vesicles in parts of the body even remote from the herpetic area—a fact which was brought to my notice some years ago by Dr. Pernet. Dr. Pernet saw with me the medical man to whose case I have already referred, who had four attacks of herpes, and this doctor's only daughter within three weeks of her father's fourth attack of herpes had an attack of chicken-pox. It is stated in the paper I have referred to that shingles may occur in an individual in the house in which chicken-pox is present, and that shingles and chicken-pox may occur coincidentally in the same individual. I have not myself seen either of those occurrences, unless the isolated vesicles in remote parts of the body in cases of shingles are really vesicles of chicken-pox.

Lethargic Encephalitis.

Those of us who are working amongst neurological cases are unfortunately only too familiar in these days with cases of lethargic encephalitis. In some of them the condition is fatal, and the changes in the central nervous system now regarded as characteristic are found. In another class of cases recovery takes place, but the patients are gravely altered, and this alteration remains permanent. In most of them the condition established by the disease is practically indistinguishable from paralysis agitans, although when tremor is present it is not of the regular rhythmical type usually met with in paralysis agitans. In many, however, tremor is absent, but the stiff gait, the mask-like immobile face, the low monotonous voice, and often the everted, dribbling lip, make the resemblance to paralysis agitans very striking.

I wish, however, to call attention to what I believe are examples of this illness of a very mild type which apparently make a good recovery. I had recently under my care at Queen Square a young woman admitted on account of diplopia who on examination presented no abnormality except the presence of nystagmus and some general weakness. All the reflexes were normal, and this, of course, excluded the diagnosis first thought of—namely, disseminated sclerosis. And the history was significant; it was to the effect that a few weeks before admission she had become ill—very drowsy, but could be roused to take her food. After partaking of it she at once went to sleep again. This sleepiness had passed off before she came to the hospital. The diplopia gradually ceased to trouble her, but a little nystagmoid jerking still remained when she left the hospital. I cannot but think that this was a mild case of encephalitis lethargica.

Another case I saw in private, a young healthy man of 35 who had been working very hard for a long time. Diplopia in his case was the first trouble, and when I saw him he had obvious weakness of one sixth nerve. He had been sleeping badly. I advised his going to bed. At first his sleep was not good, then it became unusually good, and there was rise of temperature and slight delirium. When I last saw him, however, he was improving in the most satisfactory way. His father was a medical man, and I think I should have heard had there been any relapse. This also I am inclined to think was probably of the same nature, although not so definitely as the other cases I have related.

A SERIES of congresses will be held at Monaco on April 15th and following days. They include congresses of hygiene and climatology, mineral spas, and seaside resorts.

THE Council of l'Assistance Publique has drafted a scheme for the improvement and extension of the hospitals of Paris. Extensive alterations in existing hospitals are proposed in order to bring their various departments up to date, both for the treatment of patients and for clinical instruction; it is intended also to provide several new hospitals, built and equipped in the best manner.

INTRAVENOUS PROTEIN THERAPY.*

BY

A. E. GOW, M.D., F.R.C.P.,

FIRST ASSISTANT IN MEDICAL CLINIC, ST. BARTHOLOMEW'S
HOSPITAL, LONDON.

By "intravenous protein therapy" is implied the intravenous injection of a "foreign" protein in the treatment of disease. A "foreign" protein is one not normally present in the tissues of man. Intravenous injection of certain proteins in certain doses gives rise to a chain of symptoms and signs to which the expressive but misleading term "protein shock" has been applied by American workers.

Various proteins have been employed, mainly in the form of bacterial emulsions, though peptone is of value in several conditions. Of bacterial emulsions, the protein complex of the coli-typhoid group of micro-organisms is more efficacious in inducing this "shock" reaction than is that of other species; and when such a reaction is desired, it is a vaccine of typhoid or colon bacilli that is most frequently employed, and the remarks immediately following apply solely to the reaction induced by that type of antigen which may be given either plain or sensitized.

Dosage.

Within fairly wide limits the size of the dose has but little effect on the severity of the reaction. Thus a higher temperature response has been experienced after an initial dose of 50 million killed *B. coli* vaccine in one patient than after 200 million of the same vaccine in another, though it must be admitted the general constitutional disturbance was greater in the latter. The initial dose for an average adult may with perfect safety lie between 50 and 100 million, though Gay,¹ in the treatment of typhoid fever, advocates 150 million sensitized typhoid vaccine as a first dose. Cecil² mentions that by an error in technique 400 or 500 million killed typhoid bacilli were given as a first dose to three of his patients with arthritis, yet the reaction was little, if any, more severe than that caused by smaller doses, and the therapeutic effect was no better.

In order to effect the desired result it is necessary to produce a moderate reaction. The dosage in successive injections must be progressively slightly increased so that a like train of symptoms may follow each inoculation.

Technique of the Injection.

The patient is confined to bed for twenty-four hours at least. In order to lessen as far as possible the nausea and liability to vomiting commonly met with, especially after a first injection, a mild aperient is given the evening before. A light breakfast is advisable, and the injection should be made, if possible, before midday, so that the transitory unpleasantness of the reaction may be over before night.

The requirements are: (1) Ether and wool to clean the skin. (2) A sterilized needle and syringe of 10 c.c.m. capacity. (3) The vaccine containing, say, 100 million coli or typhoid bacilli per cubic centimetre. (4) Ten c.c.m. of sterile warm normal saline solution. This is for diluting the vaccine, as it is more convenient if the volume of the injection measures 10 c.c.m. rather than $\frac{1}{2}$ or 1 c.c.m., as the larger quantity is easier to handle, and the dose of protein can be given more slowly. (5) Adrenalin solution 1 in 1,000, or $\frac{1}{100}$ grain tablets of atropin sulphate. (6) An assistant to help in filling the syringe and to constrict the patient's arm, and thus render prominent the veins in the antecubital fossa, is also desirable. Dr. R. G. Cantl has designed a very simple tourniquet, easy to release, which is admirably suited for the latter purpose.

Method.—The skin over the selected vein is cleansed, and the desired dose of vaccine, whether $\frac{1}{2}$, 1, or 1 c.c.m., is drawn into the syringe, and the volume made up to 10 c.c.m. with normal saline. The assistant now applies the tourniquet, or constricts the upper arm, which is lying flat on the bed fully extended, and the patient is told to open and clench the fist several times until the vein on the front of the elbow becomes prominent; in some individuals the veins are more easily felt than seen. The needle of the syringe is inserted into the vein in the usual manner of vein puncture; a successful puncture is indicated by a flow of blood into the syringe. The assistant now relaxes the tourniquet (or his hold on the arm), and the injection is made very slowly; that the fluid is entering the vein and not the perivascular tissues is shown by complete absence of swelling in the region of the needle point. When the contents of the

syringe have been pushed into the vein the needle is withdrawn and the arm held vertically upwards for a few minutes to prevent extravasation of blood; no dressing is required.

The Reaction.

General.—In the afebrile human subject the intravenous injection of from 50 to 100 million killed coli vaccine is followed by a very definite train of symptoms which comprise the so-called "protein shock reaction." For a period varying from three-quarters of an hour to five hours the patient will experience no abnormal sensations, but after that symptoms will appear somewhat suddenly. The earliest symptom is commonly an involuntary twitching of the muscles of the legs. This may spread to the trunk and become general without the patient at first feeling cold, and last, perhaps intermittently, for from fifteen to forty-five minutes; the onset of the rigor is occasionally preceded by a dull ache in the back or shins.

Before the shivering is finished the patient commonly has abdominal discomfort with nausea and, not infrequently, vomiting; he has headache, which is usually frontal and sometimes pronounced. In a reaction of unusual severity the patient may be restless with dyspnoea and cyanosis. Such symptoms are speedily relieved by a hypodermic injection of 0.75 c.c.m. of 1 in 1,000 adrenalin or $\frac{1}{100}$ grain atropin sulphate.

As the reaction passes off, especially if it be after a second or third injection, general pains in the limbs, with cutaneous hyperaesthesia, may be complained of for a short time; yawning is frequently seen. As a rule the patient is quite free from headache and other discomfort after the seventh hour, though exceptionally facial herpes may develop two or three days later, with or without tender areas in the skin.

Just prior to the onset of the shivering the temperature begins to rise, and continues to do so until about the sixth hour. It commonly reaches 103° or 104° before returning to normal at the end of twenty-four hours; deferescence may be interrupted by a short secondary rise of a degree or so. With succeeding injections of increased dose the fever, though reaching an equal height, is apt to be of shorter duration, and the whole reaction is more quickly completed.

The pulse frequency also is increased during the reaction, and extra-systoles may occur during the rigor, and for a short time afterwards. The increase of the pulse frequency is generally of somewhat longer duration than is the raised temperature.

*Blood Pressure Changes.*³—The systolic blood pressure usually shows a fall of a few millimetres before any symptoms are evident. During the rigor I have met with a small rise on two occasions only, and that either to the preinjection figure or a few millimetres above it; more generally the fall continues for twelve hours or so, the reading then being about 20 mm. below the initial figure. The systolic blood pressure is commonly normal again after twenty-four hours. The diastolic pressure generally rises appreciably within the first half-hour. The rise may continue until the end of the rigor, but more frequently this pressure drops rapidly after the first half-hour, and may be at its lowest by the end of the second hour—perhaps a drop of 30 mm. in an hour and a half. It tends to remain at this level for twelve hours or so, but is normal again in twenty-four hours.

*Cytological Changes in the Blood.*³—The intravenous injection of *B. coli* vaccine causes an almost immediate fall in the white blood cells. Following a first injection the retreat of the polymorphonuclears from the peripheral circulation is hurried, and by the end of the first hour they may be outnumbered by the lymphocytes. A rapid increase follows the rigor, and the maximum of 20,000 to 30,000 per cubic millimetre is reached in twenty-four hours; during the leucocytosis neutrophil myelocytes frequently appear, and normoblasts have also been met with. The rise in the number of the circulating leucocytes is succeeded by a steady fall, the preinjection figure being reached in approximately seventy-two hours. Though the fall in the lymphocytes is less abrupt, it is a very striking feature of the blood picture, and of far longer duration than is the polymuclear leucopenia. It is not followed, however, by a lymphocytosis.

The intravenous injection of peptone must be made very slowly, or somewhat alarming symptoms may arise rapidly. When giving peptone as a 10 per cent. solution I use a very fine needle, a No. 28 or 30, and, as recommended by Nolf,⁵ a nurse keeps constant observation on the pulse frequency, calling out the number of beats in each quarter of a

* An abridgement of a paper read before the Hunterian Society on January 28th, 1920.

minute. If this exceeds 35 per quarter the injection is temporarily stopped.

On one occasion when giving the fourth of a series of peptone injections to a patient with streptococcus infective endocarditis, when 10 c.cm. had been given the pulse frequency suddenly increased. In successive quarter minutes the figures were 26, 26, 28, 34—injection stopped—38, 43, 36, 34, 34, 28, 26—injection restarted—28, 26, 26, and, shortly after, 22. The patient, not highly intelligent, said that during this time he felt giddy and "as though his head were going to blow open." He experienced a tickling in the throat, a stomach-ache, and he began to cough, the face became suffused and he sweated a little. The subjective disturbance lasted not more than three minutes.

These symptoms accompany, and are doubtless the outward and visible sign of, a considerable drop in blood pressure and a very rapid fall in the circulating leucocytes induced by the peptone, or primary proteose present with it in solution.

Just as the populace fled from the streets for cover in the tubes on the warning of an air raid, so on the approach of peptone do the leucocytes decamp from the peripheral circulation for the shelter of the pulmonary capillaries, and it is not until an "all clear" is sounded that they emerge from their retreat, accompanied by others, to mark the result of the invasion. With certain doses of peptone these changes take place with extreme rapidity—so much so that it is difficult to obtain accurate records of them—in a moment, in the twinkling of an eye, they are passed. And it is very surprising that in most instances they are unaccompanied by any symptoms whatever appreciable to the patient, who remains in all respects oblivious to the ferment within him. The injection of peptone may likewise be followed by a rigor an hour or so later, but I have never found peptouria.

It is obvious from the foregoing description of the clinical symptoms and signs that are wont to follow upon the intravenous injection of certain proteins in certain doses that the reaction is in no sense a "shock" in the usually accepted surgical application of the term. Following immediately on a surgical operation, if the patient survive, three phases are commonly seen, termed respectively, "Shock," "Reaction," and "Traumatic Fever." The stage of "Shock" is characterized in the main by subnormal temperature, high pulse frequency, and lowered blood pressure. This is succeeded by "Reaction," in which there is a return of the temperature to normal and a fall in the pulse frequency. Nor does the reaction come under the heading of the so-called "Anaphylactic Shock," which is brought about in the animal body by the reinjection of a foreign protein after the lapse of a certain period of time. Following the initial or sensitizing injection the animal may become "hypersensitive" to the specific protein, so that it reacts in a peculiar fashion to a second or intoxicating dose. Such a reaction may on occasion resemble that of "protein shock" in certain important features, but it differs from it in other essentials. To avoid confusion Auld⁴ has suggested "pyrogenic" as a distinguishing term for the reaction under consideration, but this also is not without objection. Fever may follow the intravenous injection of a number of substances containing no protein, and further, the clinical improvement consequent on the injection cannot be ascribed to the short bout of fever produced thereby. A cumbersome but expressive and non-committal title would be the "Intravenous Protein Reaction," and its practical application, "Intravenous Protein Therapy."

Types of Cases Benefited.

The diseases in which benefit by this form of treatment has been reported fall into four main groups:

1. Infective disease in which the causal organism is known and in which the vaccine is given intravenously both for its specific and possible "shock" effect; for example, typhoid fever, coliform infections of the urinary tract, and the septicaemias.
2. Infective disease in which the causal organism is unknown or not certainly determined. Here the protein is given solely as a non-specific factor in the treatment of the affection. This group includes rheumatic fever and multiple infective and rheumatoid arthritis.
3. Infective disease in which the causal organism is known but in which specific vaccine therapy is of little value. Here also a protein is given entirely for its shock effect; for example, pneumonia, gonorrhoeal arthritis.
4. Chronic disorders of doubtful or unknown etiology: psoriasis, pemphigus, lupus erythematosus, bronchial asthma.

In typhoid fever both sensitized and unsensitized typhoid vaccine has been used by several workers; Gay¹ summarizes their results, and adds 98 cases of his own, which show a mortality of 6.6 per cent. and 13 complications.

Gay states that the milder cases of the disease react better to the treatment than the more severe, but even the most severe will, in some instances at least, be benefited and even aborted. The usual dose of the initial injection was 150 million, and the dosage in successive inoculations was slightly increased in order to produce a similar reaction. He states that in typhoid fever the injection is followed in from fifteen minutes to an hour by a chill, which may last for a quarter of an hour, and is accompanied by a rise in temperature of one to three degrees, reaching its maximum within three hours and then falling, reaching normal or subnormal in about twelve hours, with sweating and usually improvement of such symptoms as headache, delirium, etc. If the temperature again rises over a period of two or three days, a slightly increased dose is given; if no striking result follows three or four injections at two or three days' interval, very little improvement from further treatment on the same lines is to be expected. The disease in one-third of the cases in his series was aborted, benefited in another third, while in the remainder it was unaffected; the liability to complications appeared to be diminished, but as a means of preventing relapses the injections are of little value.

Nolf⁶ speaks highly of the value of peptone in the treatment of the typhoid fevers. He found morning injections more efficacious than those made in the afternoon, possibly because the patient was fasting, and acting on this hypothesis he is accustomed to allow his subjects nothing but water from the night before.

The reaction induced by peptone is proportional to the dose; in an adult 5 to 6 c.cm. of a 10 per cent. solution produce a rise in temperature in one to two hours lasting for several hours; 7 to 10 c.cm. have the same immediate effect, but possibly in addition a rigor followed by sweating and a rapid fall of temperature to normal. Other things being equal it seems that a complete reaction—that is, one accompanied by a marked and persistent fall in temperature—is more difficult to produce in the first ten days of typhoid than later.

Thus it would seem that in the early stages of the disease the best effects may be expected from sensitized vaccine and in the later from peptone; perhaps peptone and vaccine should be given together after the second week of the fever.

I have employed an autogenous coli vaccine intravenously in the treatment of *pyelonephritis* with good result on several occasions. One case of two months' duration in a man showed a tender swelling in the right renal region, pyrexia, and 10 per cent. of pus in the urine. After four injections the urine became free from cells and bacilli and was still sterile when last examined six months later.

A female, aged 38, was admitted to the medical clinic of St. Bartholomew's under Sir Archibald Garrod, with the history of a sudden onset of pain during, and frequency of, micturition five weeks previously, associated with haematuria and a temperature stated to have been 105°. Her right kidney was palpable and a little tender; she had red blood cells and an abundance of pus and coliform bacilli in the urine. As her condition did not clear up on alkalis and urinary antiseptics, she was given an autogenous plain vaccine intravenously. The first dose of 100 million gave rise to no abnormal sensations for five hours, but then mild shivering began, which lasted an hour, associated with slight headache and nausea; there was no abdominal pain, but some increase in frequency on micturition during the night—she was not quite comfortable again for forty-eight hours.

This reaction is mentioned in some detail as it shows that when an autogenous coliform vaccine is employed the onset of the reaction is apt to be considerably delayed in point of time. Two further injections were given to this patient at seven and five days' interval, and she was discharged free from pyuria and bacilluria.

In pyogenic infections, both local and general, vaccine may be administered by the intravenous route. In cases of septicaemia, using a plain or sensitized vaccine alone, it is difficult to produce a rigor; I am convinced on clinical grounds that the ultimate results are better, in really desperate streptococcal cases, when such a reaction occurs. As to the nature of a rigor I am in ignorance, but one is more likely to ensue if, in addition to the sensitized vaccine intravenously, anti-streptococcus pyogenes serum is given subcutaneously at the same time, possibly owing to the more rapid liberation of endotoxin. The improvement of the patient on such treatment may not be entirely recorded on the chart, for the general condition is bettered before the temperature falls—the dusky look is lost, the tongue moistens, the patient sleeps

and eats much better than before; indeed, in those cases which are going to respond a striking improvement in the general condition takes place in a couple of hours or so.

Local streptococcal infections are also often abated by intravenous vaccine.

A patient who had miscarried at the sixth week was admitted five days later to hospital, under Mr. Rawling, with a rapidly spreading cellulitis of both arms and the right calf and severe constitutional disturbance. Blood culture was negative. Twenty-four hours after an intravenous injection of 500×10^6 sensitized streptococcus vaccine her general condition was much improved; she had lost her pain and the redness and swelling had greatly diminished. A second dose, of 1,000 million, was given, and the inflammation in the left arm entirely disappeared, and in the right arm and leg it became localized with pus formation, which subsequently required draining.

In the febrile subject it is exceptional for the intravenous injection of streptococcus vaccine to produce a sharp rise in temperature, but in the afebrile a brisk thermal reaction may result.

A traumatic ulcer of the foot, consequent on a wound sustained in the Zeebrugge raid, which resisted subcutaneous vaccine and antiseptic treatment for five and a half months, healed rapidly after one intravenous injection of antigenous sensitized streptococcus vaccine. The dose of 100×10^6 produced a sharp reaction—shivering at the nineteenth hour and a rise of temperature which lasted for eighty hours, reaching its maximum of 104.2° at the twentieth hour.

I have given peptone intravenously in conjunction with sensitized vaccine subcutaneously in streptococcal septicæmia, and am convinced of its value in such cases. Nolf⁷ maintains that intravenous injections of peptone not only check the course of streptococcal and staphylococcal septicæmias, but are also useful in severe local infections as a stimulant to the forces of defence.

In certain forms of arthritis great benefit may be derived from intravenous protein therapy. Here the vaccine is given entirely for a shock effect. The type of joint disease which responds best, in my experience, is the multiple infective arthritis for which no active source of primary infection or septic absorption is demonstrable. The patients are free from pyorrhœa, tonsillitis, sinusitis, chronic skin or urogenital infections, and present no other suggestion of intestinal toxæmia.

The disease syndrome comprises muscular wasting around, pain in, and deformity of, both smaller and larger joints, the main lesion being in the soft periarticular tissues rather than in the bones or cartilage, and osteophyte formation with erosion of cartilage characteristic of senile osteo arthritis is not seen. These changes are prone to begin symmetrically in the proximal interphalangeal or other small distal joints before the larger articulations are involved. A low fever, increased pulse frequency, and slight enlargement of superficial lymphatic glands may accompany the joint changes. Albuminuria is a late development.

In such cases, provided treatment is instituted sufficiently early, I believe one is justified in saying that there is a good chance that the course of the disease may be arrested and the pain and fever abolished. In a certain proportion the periarticular swelling will be considerably reduced and the range of movement correspondingly increased, but it is obvious that when marked structural alteration has already occurred, leading to subluxation, deflection, etc., one cannot hope for complete anatomical restoration. The following are examples of those so treated by me:

A. P., male, aged 13, under the care of Dr. James Calvert. Eight months' duration; steadily progressive, involving both hands, wrists, ankles and knees, and the cervical spine. Was just able to walk with the aid of two sticks. Much pain. Evening temperature rarely above 100° , though occasionally 101° F. No albuminuria. After the fourth injection the note says, "he has lost pain in and stiffness of joints, and has abandoned his sticks when walking. Left knee can be straightened completely and the right nearly. Neck is improved. Both wrists less swollen, especially the left. Interphalangeal joints still much swollen, but swelling quite gone from ankles and very nearly from knees. No fever." Eleven injections were given altogether. He is now well, able to play football and the violin.

A. A., female, aged 29. (Dr. Morley Fletcher.) Twelve months' duration. Both hands, knees, elbows and shoulders. No albuminuria. Low irregular fever, not above 100° F. Much pain, especially at night. Given seven injections; the first of 100×10^6 T.A.B. was followed by a temperature of 104.2° F. and herpes of the lower lip. Fever and pain quickly stopped,

swelling slowly disappeared, and she was able to sew and walk without pain or difficulty on her discharge.

E. J., female, aged 40. (Sir Archibald Garrod.) Seven years' duration. Both wrists, metacarpal- and inter-phalangeal joints and both knees. No fever. Four injections given. Joints stiff in morning, but not painful; much less periarticular swelling, and is able to sew. Middle finger of left hand, which was flexed, is now straight.

The next is a case in which an immediate improvement was not maintained.

Mrs. N., aged 60. Six years' duration. All joints of extremities involved. Walked with difficulty; unable to dress herself; much pain. Trace of albumin in urine. She was considerably improved for a couple of months, being quite free from pain and able to walk and dress herself without difficulty. But the latest report says the pain and swelling in the knees has returned.

In the following case the pain was relieved and the fever abated, but there was no obvious change in the swelling or deformity, and the patient remained bedridden.

A. B., female, aged 22. (Dr. Morley Fletcher.) Fourteen months' duration. All joints of extremities involved, with much flexion of knees and elbows. Low irregular fever and albuminuria. Twelve injections of T.A.B.; also given rheumatism "phylacogen" both subcutaneously and intravenously.

These cases may be supplemented by a brief summary of some of the records published by others.

Cecil² reports on 40 cases of rheumatic fever, acute toxic arthritis, and gonorrhœal arthritis treated by intravenous injection of typhoid vaccine. In rheumatic fever and "non-specific" arthritis about 40 per cent. are stated to have recovered completely in two to ten days without salicylate, and most of the others were much improved. In rheumatic fever the average number of injections required was two, the dose varying from 30 to 100 million; salicylate was given if one or two doses of vaccine proved incapable of producing recovery. His seven patients with gonorrhœal arthritis were benefited but little if at all. In one case of chronic gonorrhœal arthritis and fibrositis marked improvement in the pain and stiffness followed the intravenous injection of a diphtheroid bacillus which I isolated from the urine after prostatic massage.

Peterson⁸ records a case of "acute multiple arthritis" which received at intervals doses of typhoid vaccine intravenously on three occasions and was thereby much improved. The precise nature of the arthritis is not revealed.

Miller and Lusk⁹ also report favourable results in the treatment of acute and chronic arthritis by the injection of foreign protein.

Nolf⁵ considers that the addition of peptone intravenously to salicylate treatment renders the latter more efficacious in certain obstinate cases of articular rheumatism, and that peptone in association with salicylate enlarges the group of acute arthritides amenable to salicylate treatment.

Certain other acute infections have been treated, in some instances with success, by the intravenous injection of typhoid vaccine.

Squier¹⁰ mentions two cases of influenza pneumonia in which two transfusions with immune blood caused no reaction or change in the patients' temperature, pulse, respiration rate, or general condition, yet the injection of typhoid vaccine was followed immediately by a dramatic improvement.

Cowie and Bevan,¹¹ using typhoid vaccine in influenza pneumonia, obtained no improvement in cases injected after the third day of the pneumonia, while all recovered who were so treated before the third day.

The skin lesions of psoriasis and lupus erythematosus may be relieved temporarily by injections of coli-typhoid vaccine. The condition apparently always relapses during the course of a few weeks or months.

Auld¹² has reported good results in the treatment of bronchial asthma by the intravenous injection of small doses of peptone. He states:

The cases best suited are those characterized by favourable intervals, with freedom from bronchitis and much attendant emphysema. The more recent the disease and the more regularly spaced the intervals the better the result. . . . Peptone stops the attacks over a period roughly proportionate to their former frequency. Generally speaking, the initial dose is 0.3 c.cm. of a 2 per cent. solution of Witte's peptone, increased by 0.2 c.cm. every fifth day until six injections have been given. Three or four more injections are to be given, employing in each the same dose as that given in the sixth injection. No reaction appreciable to the patient occurs. No injection is to be given during attacks, and when the latter occur at long intervals begin the treatment about three weeks before one is expected.

While I believe intravenous protein therapy to be of great value in certain carefully selected cases—more particularly of arthritis, the septicæmias, and coliform infections—I do most emphatically say that it is not a panacea for all ills; and even in those diseases in which it is of

use it is to be regarded solely as an accessory weapon in our armament for employment in conjunction with, not to the displacement of, other remedies.

I wish to express my thanks to those members of the staff of St. Bartholomew's who have allowed me to refer to patients who have been in their charge.

THE POISON OF THE SPINY DOG-FISH.

A CASE OF ACUTE OEDEMA THE RESULT OF A PRICK BY A DOG-FISH, AND A PRELIMINARY NOTE ON THE POISON GLAND OF THE SPINY DOG-FISH.

BY

H. MUIR EVANS, M.D.LOND.

TOWARDS the end of October, 1919, a fisherman came up to the Lowestoft Hospital complaining of a poisoned hand. There was a punctured wound at the base of the thumb

FIG. 1.—Section of gland showing ducts and vacuoles. A, Duct cut obliquely. B, Duct cut transversely. C, Vacuoles. D, Vacuoles bursting into inner end of duct. E, Duct. (From a micro-photograph by Dr. D. Hutcheson of a section by the author.)

Six hours previously he had been pricked by a dog-fish. The injury was followed by acute stabbing pain in the part which lasted four or five hours; the hand then began to swell, and when he arrived at the hospital there was great swelling and oedema of the back of the hand, and the front of the wrist and forearm were painful, tender, red, and oedematous.

This acute inflammatory oedema lasted for four days and for a time it seemed that suppuration would occur. On the fifth day the oedema at the back of the hand had subsided, but it was not until seven days had elapsed that the tenderness and swelling over the wrist had disappeared and the patient was convalescent.

The treatment adopted was to paint the hand and the front of the wrist and forearm with liniment and solution of iodine in equal parts and to apply hot fomentations.

Owing to the length of time that had elapsed since the injury no special treatment was applied to the wound; if the case had been seen earlier a weak solution of potassium permanganate would have been injected into the site of the puncture, as this is known to have an immediate effect on the pain and symptoms of poisoning in cases of the sting from the envenomed spines of the greater and lesser weaver.

As this was the first case of injury by a dog-fish that had occurred in my experience, I was anxious to investigate

the nature of the poison if any existed, and for this purpose I obtained a number of fresh spines, which at that time could be easily obtained from the steam trawlers which were landing large catches of dog fish.

The Spines and Poison Gland of the Spiny Dog-fish or Spur-dog, Acanthias vulgaris (Gray, Cat. British Museum).

This, the commonest dog-fish, also known as the pickled dog-fish, under which name it is described and pictured by Couch,² has a sharp, strong spine in front of each of the two dorsal fins. The usual length of the fish is from 18 in. to 2 ft.

Spiny dog-fish. After Cunningham.

The accompanying sketch is taken from Cunningham's *Marketable Marine Fishes*,¹ and shows diagrammatically the position of the two dorsal spines.

The anterior spine is the longer, is slightly curved, and measures an inch or more in length, while the posterior is nearly straight, and is shorter—from half an inch to three-eighths of an inch in length. The posterior aspect of each spine is grooved, the groove becoming more shallow towards the point.

When examined with the naked eye, each groove is seen

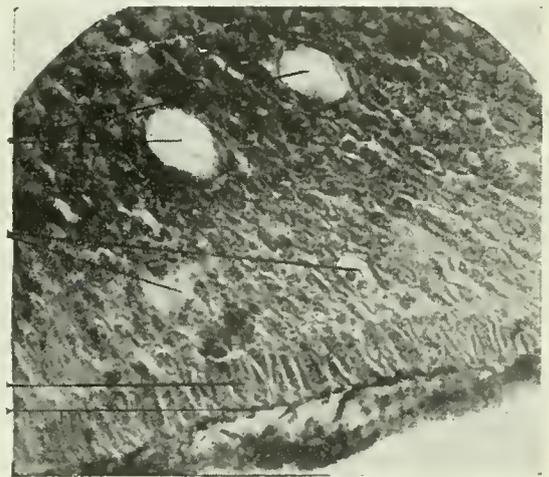

FIG. 2.—Section of gland showing basement membrane and columnar cells. A, Vacuoles. B, Commencing formation of vacuoles. C, Columnar cells. D, Basement membrane. (From a photograph by Dr. D. Hutcheson of a section by the author.)

to be occupied by a glistening, pearly-white substance, and towards the base there may be seen in its centre a small linear depression about one-sixteenth of an inch long, which is often discoloured, possibly by the presence of a secretion poured out by the glandular structure in the centre of which it lies.

This pearly-white structure was removed from the groove and teased on a slide; the teased gland showed follicles in which layers of epithelial cells could be demonstrated surrounding a central mass of cells and granular matter staining by the van Gieson method, just as does the secretion of the weaver's poison gland. Small detached portions showed columnar cells against a basement membrane, and upon them layers upon layers of round and cubical cells, some vacuolated, and some distended with granular matter in which the nuclei alone were distinguishable.

I have cut a series of sections of the hardened gland, the details of which I hope to publish elsewhere. The gland consists of a number of follicles which discharge their contents into the groove. It commences at the junction of fin and groove, and here it is partially enclosed in a chitinous framework; it gradually becomes smaller and finer as the tip of the spine is approached, to the apex of which it does not reach for a variable distance, usually about one-eighth of an inch or more

I have at present no experiments to publish on the nature of the secretion, but it seems a justifiable conclusion to attribute the acute pain and inflammatory oedema, the result of the prick by the spine, to some venom produced by this remarkable glandular structure lying in the groove.

As far as I am aware there is no previous description, in the literature of fish with poison organs, of a poison gland in Acanthias. Dr. Tate Regan, of the British Museum of

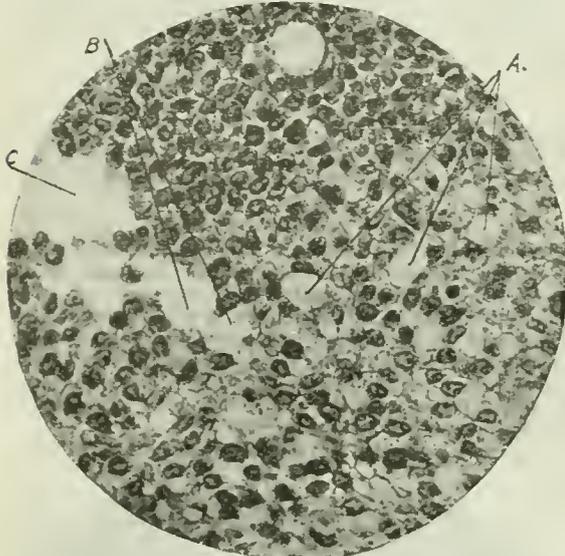

FIG. 3.—Section of gland stained with haemalum and counterstained by van Gieson method. A, Vacuoles. B, Vacuoles bursting into commencement of duct. C, Duct.

Natural History, kindly referred to such sources of reference as were unavailable to me, and to him my thanks are due for always extending ready help and advice to those engaged in research.

Description of the Gland.

The histological appearances of the gland lying in the grooved spine of the spur-dog are as follows: The two low-power microphotographs show the general structure, and the high-power changes in the cells which take place during secretion. That portion of the gland lying deepest in the groove consists of cylindrical cells on a basement membrane. Superficial to these cells are several layers of round cells the nuclei of which stain

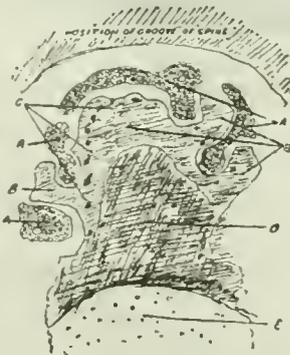

FIG. 4.—Section showing root of fin where it joins the base of spine (semi-diagrammatic). A, Gland dipping into recesses formed by (B) chitinous processes at base of fin. (The spine is not shown as the base of the fin is cut off where it joins the groove.) C, Large pigment cells. D, Connective tissue joining chitinous processes to (E) cartilage of the fin.

readily with haemalum, and in some areas the nuclei show marked evidence of activity, as exemplified by the presence of mitotic figures. Well-marked ducts dip into the substance of the gland, around which the cells become definitely flattened. These three types of cell are obviously transition forms of the same cell. In the neighbourhood of the duct areas are seen in which the cells are breaking down or disintegrating so as to give rise to a sponge-like appearance, and in these areas are also seen round lacunae in which phantoms of pale cells may be distinguished, and in one section one can see one of these lacunae bursting into the apex of a duct into which it is apparently discharging its contents.

If my observations are confirmed, the dog-fish adds one more to the examples of fish with poison organs, in the ranks of which the sting-ray has so recently found a place after centuries of scientific doubt.³

METASTATIC STAPHYLOCOCCAL INFECTION OF THE KIDNEY.

BY

H. R. SOUPER, M.A., M.B., CH.B. ABERD.,

TEMPORARY CAPTAIN R.A.M.C.,

SPECIAL MILITARY SURGICAL HOSPITAL, NEWCASTLE-UPON-TYNE.

AN account of the following case may be of interest as illustrating infection of the kidney following upon operative interference with an infected wound of the forearm, the difficulty of making an early and accurate diagnosis of the condition, and the success of treatment by an autogenous vaccine.

A pensioner, aged 32, had undergone amputation through the lower third of the right thigh, and had an old gunshot wound of the left forearm, with an ununited fracture of the ulna in its upper third. He was wounded in both these situations on November 10th, 1917, in France, and the leg had been amputated at the casualty clearing station within a day or two of his wound; the forearm was cleaned and splinted. The subsequent history of the thigh is that it was recamputated and sutured at a general hospital in France on December 8th, 1917, and an abscess of the stump drained in January, 1918. An artificial limb was supplied in May, 1918, and the stump had not given any further trouble.

The fractured left forearm was put in good position, and the wound sutured in January, 1918, at a hospital in England; though the wound apparently healed at this time, the ulna remained ununited, and for this disability he was admitted as a pensioner to the Special Military Surgical Section of the 1st Northern General Hospital on December 19th, 1918.

On February 5th, 1919, the ends of the ulna were freshened and the bone plate¹; the wound subsequently became septic. In the beginning of May the patient came under my care, and, as a sinus was still present in the forearm leading down to the site of operation, and x-ray examination showed that union of the bone was apparently proceeding satisfactorily, I operated on May 6th, excised the sinus completely, removed the screws and plate, applied bipp to the wound, and closed it completely without drainage.

The wound healed by first intention, and has given no trouble since; but on the evening of May 19th the temperature, which had been normal since the third day after operation, rose to 1.0° and continued to rise in "step-ladder" fashion till, on the evening of May 23rd, it reached 104.4°. This pyrexia was accompanied by malaise, slight vomiting, vague pain in the bladder region, frequency of micturition, and stranguary; the patient stated that on May 19th he had "passed a few drops of blood with the urine," but, as this specimen was not saved, the statement could not be confirmed. Though he felt "shivery" there was never any actual rigor. No abnormal physical signs could be detected in any system, and he was put on light diet and a simple diaphoretic mixture.

Naked-eye and chemical examination of the urine revealed no abnormality; but on May 23rd a trace of albumin and some pus were present, and on the following day a specimen was taken for bacteriological examination. Hexamine, gr. x thrice a day, with large quantities of fluid, was then prescribed. No abnormal physical sign was detected till, on May 26th, he complained of pain in the left loin and bilateral palpation of the left kidney region elicited marked tenderness, though no tumour could be made out. The laboratory report received on May 27th stated: "Few red corpuscles and a fair number of pus-cells present; no tubercle bacilli or *B. coli* detected; *Staphylococcus pyogenes aureus* present."

The diagnosis of acute metastatic pyelonephritis could now be made. A second specimen of urine was sent to the bacteriologist for the preparation of an autogenous vaccine.

Meantime the temperature had been gradually falling since May 26th, reaching 99° or 100° in the morning, but rising to 102° to 103° in the evening; and on May 29th the daily range settled down to between 99° and 100°. The second laboratory report was identical with the first, except that pus was present in greater quantity; and, pending the preparation of the autogenous vaccine, I gave 125 million of a stock staphylococcal vaccine on June 3rd; this produced a slight general reaction; no reaction followed 250 million given on June 7th and 500 million on June 11th.

The patient's general condition meantime was still unsatisfactory; he was anaemic and very weak, suffered from profuse sweats, loss of appetite, and vomiting after practically every meal. The hexamine was discontinued on June 11th, as it was thought that it might be the cause of the vomiting. Kidney tenderness was still present, but no tumour or enlargement of the organ could be made out.

The sickness improved, but recurred on June 16th, when a mixture containing bismuth and soda with nux vomica was ordered. On this day also the administration of the autogenous vaccine was started, 250 million being given; only a slight general reaction followed (evening rise of temperature to 100°). The pyrexia had altogether subsided by June 20th, but culture of the urine still revealed the presence of staphylococci; the general condition showed signs of slow improvement. The autogenous vaccine was continued at weekly intervals, in gradually increasing doses, till a dose of 1,000 million was reached on July 28th, and repeated on August 2nd; the vaccine treatment was then discontinued.

As on June 28th patient still complained of left lumbar pain, and the sickness had disappeared, he was again ordered hexamine gr. x, with acid sodium phosphate gr. xv. This was continued till the end of July, when the patient had completely recovered, and was able on August 6th to begin work in the curative workshops of the hospital.

Since that date the renal symptoms have not recurred; the urine has remained free from pus. The left ulna has firmly united and the patient has full use of the forearm.

Although the diagnosis of this condition was for some days very difficult, I think there can be no doubt, in view of the laboratory findings and the few physical signs which eventually developed, that the diagnosis finally reached was correct. During the later period of the patient's illness it was of interest to note the correspondence which started in the *Lancet* of June 7th, 1919, and continued for the three following weeks, on "Epidemic perinephric suppuration"; and in some ways this case resembled cases instanced in that correspondence. But, as in the cases of perinephric abscess, it was stated that it is rare to find pus in the urine, and as in my case there was no evidence of any abscess in the loin, that diagnosis could almost certainly be ruled out; and the symptoms and signs of my case were practically identical with those of acute haematogenous pyelonephritis described by Thomson Walker in Choyce's *System of Surgery*. The primary focus of infection was undoubtedly the sepsis in the forearm, and the metastasis followed operation on this site. But it is remarkable that the pyelonephritis should have followed only after the second operation, and that, by the time the pyelonephritis developed, the primary focus, never clinically of great intensity, had cleared up. Horder, in the correspondence referred to, states that "the point of primary infection may be easily overlooked" (apparently owing to its slight character) in cases of perinephric abscess, so that staphylococcal metastasis in or around the kidney is known to arise from a primary focus so slight that its discovery may require careful investigation. Pasteur, in the same correspondence, states that "staphylococcal infection of this type (*S. aureus*) never seems to give rise to staphylococcal septicaemia." Though there was no evidence of septicaemia in my case, it is unfortunate that cultural examination of the blood was not made when the pyelonephritis developed, nor of the pus from the forearm at the time of operation. A blood count might also have been of assistance in the diagnosis.

Finally, it is interesting to note how well the condition cleared up on treatment with an autogenous vaccine. Thomson Walker (*loc. cit.*) states that such treatment is suitable only for chronic cases, but in this acute case it answered remarkably well. Herringham (*Kidney Diseases*, p. 302) describes a case of acute pyelonephritis due to a coliform bacillus (which, he states, is the commonest causal organism of such conditions) treated by an autogenous vaccine which produced gradual improvement; but three months after the onset there was still a slight amount of pus in the urine, and a considerable number of bacilli; so that the patient could not be considered cured. The cases, however, are scarcely analogous, and there is no doubt that in this staphylococcal case the vaccine treatment produced a complete cure.

I have to thank my Commanding Officer, Lieut.-Colonel D. Wells Patterson, O.B.E., R.A.M.C.(T.), for permission to publish this case; and Dr. P. C. W. Laws, bacteriologist to this hospital, for the bacteriological investigations, and the preparation of the vaccine.

PROFESSOR AUGUST BIER has addressed a memorandum to the Prussian authorities pointing out that as the abolition of compulsory military service robs the growing generation of beneficial physical training, compulsory physical training for all young men should be enforced, beginning, if possible, in early boyhood. He advocates the inclusion of physical exercises by the University of Berlin as a compulsory subject.

VOLVULUS OF THE CAECUM: DOUBLE OBSTRUCTION.

BY

R. ECCLES SMITH, O.B.E., M.B., F.R.C.S.,
SURGEON TO THE BARRY HOSPITAL.

IN view of the recent article by Sir Arbutnot Lane¹ on the evolution of disease, I think the following case worthy of note by reason of its rarity, the unusual way in which it was produced (only fully recognized at autopsy), the surprising condition of obstruction of the small and large bowel at two distinct sites, and the associated atypical gastric symptoms over a period of years.

Lieutenant R. N. R., aged 33, gave a history which was a little meagre owing to his general condition. For a period of some years he had had attacks of "indigestion," never sufficient to cause him to report sick. Associated with this was a marked intestinal atasia and obstinacy of the bowels; pain and discomfort after meals, with occasional vomiting, were quite common features. One night he was suddenly seized with acute abdominal pain, at first spasmodic and later continuous, with vomiting of everything taken. He was transferred to me twenty hours after the onset of the attack.

Condition on Admission.

He was in extreme pain, with all the symptoms and signs of an acute abdominal catastrophe. The abdomen was full, rigid, distended, and tender. Fluid in the flanks and the complete absence of liver dullness suggested, in view of the prior gastric symptoms, perforation of a viscus. The bowels had been relaxed prior to the sudden onset of the acute pain.

The vomit on arrival was not faecal, but consisted of stagnant stomach contents. The temperature was 100°, the pulse 120 to 130, feeble and thready.

Operation.

A right paramedian incision was made in the epigastrium. The stomach and duodenum were found to be normal. The incision was enlarged downwards, and a large black balloon emerged from the abdomen. This consisted of the much distended caecum and ascending colon, which were turned over towards the middle line as on a hinge at the inner border, forming a definite volvulus. The transverse colon was empty, the small gut was moderately distended. The hepatic flexure, being obviously the seat of obstruction, was explored. There was an acute "kink," and on the inner side of the "kink" a mass, first thought to be malignant, but on section found to be a calcareous gland outside the lumen of the gut. Further exploration and interference being impossible, a Paul's tube was tied into the caecum, the contents of the colon drained, and the abdomen closed.

After-Treatment and Result.

The colon drained freely, and the patient's general condition improved for the first twenty-four hours. The liver dullness returned immediately. Then symptoms of further obstruction came on, the abdomen became distended, vomiting returned and became faecal. In spite of all treatment the patient died forty-eight hours after operation.

Post-mortem Examination.

The caecum and ascending colon were completely deflated. The caecum was very mobile, and had a definite mesentery. The small gut was distended in its entirety, a condition not present at the operation.

The hepatic flexure was a potential tube by virtue of the pull from outside at the site of the gland noted, rather than by any organic obstruction. From the calcareous gland there stretched a thick, organized adhesion passing across and adherent to the anterior leaf of the mesentery, and fixed firmly to the ileum about two inches from the ileo-caecal valve. At this point the small gut was acutely kinked in a similar manner to that at the hepatic flexure. All other organs were apparently normal.

There is no doubt that the original lesion in this case was a tuberculous affection of the mesenteric glands leading to a strong adhesion between the hepatic flexure and the last two inches of the ileum. The early stages of this were noted in the atypical gastric symptoms due to an ileal "kink" and obstruction to the ileal efflux, so often mentioned in the literature. Some indiscretion of diet, followed by decomposition of the contents of the caecum produced a "balloon" of this viscus, which, being mobile, rose up, turned on a hinge and became a volvulus, producing further obstruction at the already kinked hepatic flexure.

Relief of this obstruction and the replacing of the caecum away from the ileum brought into force the second kink—that in the ileum from which ensued the intestinal obstruction. I think that this was not a paralytic distension of gut, but originated from the ileal obstruction.

¹ *Lancet*, December, 1919.

THE USE OF IMMUNIZED BLOOD DONORS IN THE TREATMENT OF PYOGENIC INFECTIONS BY WHOLE BLOOD TRANSFUSION.

BY
H. J. B. FRY, M.D. OXON.,
CAPTAIN R.A.M.C.(T.F.).

SEVERE septicaemia, generally of streptococcal origin, was a wound complication which was only too frequent and fatal during the war.

The usually desperate condition of such cases and their high mortality made an urgent appeal for attempts at a cure, and almost any method which promised success worthy of trial. The marked benefit attendant upon whole blood transfusions which were being performed in large numbers in No. 8 General Hospital in the summer of 1918, suggested the use of immunized blood donors for transfusion in cases of septicaemia and chronic wound infections.

The large number of transfusions and the wide field for selection of blood donors afforded by numerous light duty patients gave an unusually favourable opportunity for a trial of the method. This so-called "vaccination" transfusion had been tried by Ransom Hooker¹ in five cases of staphylococcal septicaemia, three of which recovered. A successful result had been reported by Heyd² in a case of endocarditis with a positive *Streptococcus viridans* blood culture, and McClure and Dunn³ had experienced satisfactory results with cases of typhoid fever.

The hypothetical advantages envisaged in the present series by the use of this method were:

1. The antibacterial mass action obtained by the use of a large volume of immune serum—for example, 900 c.cm. as against the 20 to 40 c.cm. of antistreptococcal serum usually employed.
2. A "protein shock therapy" on a considerable scale, and the use of a homologous serum.
3. The possible "sensitizing" of the patient towards a vaccine by means of the immune serum, the same vaccine being used for the patient as was employed for the production of immunity in the blood donor.
4. The replacement of red blood cells in the circulation of the patient instead of those broken down by the haemolytic activity of streptococci, thus directly combating the anaemia caused by the infection.

Methods Employed.

1. *Blood donors* were light duty patients. All those selected were volunteers, who fully understood what was necessary and performed their part with enthusiasm. Their age varied from 20 to 36. Their medical history was investigated, and only those free from malaria and trench fever or any recent infectious disease were taken. Wassermann reactions were done in all cases and were negative in all the donors selected.

2. *Blood matching* was performed by the method of Lee.⁴ For donors only men of Class IV (universal donors) were taken. The blood of the recipients was similarly tested before transfusion to determine their class.

3. The vaccine employed for the immunization of the donors was a polyvalent one prepared as follows:

Purity of culture of the various strains having been determined by broth and agar cultures, the strains were inoculated into 5 c.cm. broth containing 1 c.cm. fresh sterile human serum. They were incubated at 37° C. for twenty-four hours, in which time sufficient growth was usually obtained. The tubes were centrifuged at high speed and the supernatant fluid was pipetted off and 5 c.cm. sterile saline added. The emulsion was well shaken and allowed to stand a quarter of an hour to permit large particles to sediment. Upper layers of fluid were taken for the vaccine, which was sterilized by cold in the ice chest, with the addition of 0.1 c.cm. of 1 in 20 carbolic acid for each 1 c.cm. of vaccine. The vaccine was then incubated twenty-four hours, tested for sterility, and diluted to required strength. The vaccine was estimated by Wright's method or in the counting chamber.

Strains of streptococci from the following series were employed for vaccines, together with one strain of staphylococcus:

Series 1:

1. Fatal streptococcal infection in a case of cerebro-spinal fever.
2. Wound of knee-joint. Pure culture from fluid from joint.
3. Wound of knee-joint. Pure culture from pus from joint.
4. Fatal septicaemia following gunshot wounds. Blood culture.
5. *Staphylococcus aureus* from case of furunculosis.

Series 2:

1. Streptococcal septicaemia following gunshot wounds. Blood culture.
2. Gunshot wound of knee. Pure culture from pus from joint.
3. Fatal streptococcal septicaemia. Blood culture.
4. Gunshot wound of chest. Isolated from haemothorax.
5. Gunshot wound of leg and fatal septicaemia. Isolated from thrombus in femoral vein and by blood culture.
6. Gunshot wound of chest. Isolated from haemothorax.

TABLE I.—Bacteriology of Strains Employed.

Strength of Vaccine.—Series 1: 60 million streptococci and 105 million *Staphylococcus aureus* per 1 c.cm. Series 2: 120 million streptococci per 1 c.cm.

Dosage.

The total number of injections given to each donor was on the average 6, the greatest number being 9 and the least 3, the injections being given at intervals of five days. The amount of the final dose was on the average 120-150 million streptococci and 400 million staphylococci where a mixed vaccine was used. The period of immunization was about one month or more. None of the donors were the worse for the administration of the vaccines and some appeared to be benefited. The lapse of time between the last dose of vaccine and the giving of blood was on an average five days, but varied from one to thirty-one days, according to the exigency of circumstances.

Determination of Immunity.

The necessity was felt of an accurate method for rapidly determining the changes in the immunity reaction, both in the donors in response to the vaccine, and in the patient before and after the transfusions and during the course of the treatment. Complement fixation tests were not practicable. Various other methods were tried, such as estimates of the haemophagocytic index and increase in the agglutinins in the serum. No sufficiently accurate results were however obtained, and the attempt was abandoned. In this respect the investigation is lacking in accurate data. Ransom Hooker (loc. cit.) states the want of a method for determining the immunity response under these conditions.

Transfusion was in all cases performed by means of the Kimpton paraffined tube with the usual technique. The amount of blood transfused was generally 900 c.cm., but varied from 450 c.cm. upwards.

The total number of cases treated by transfusion with the blood of immunized donors was nine, of which six were acute septicaemia and three severe suppurative wounds of the thigh.

Following is an account of the cases mentioned in Table II.

A. ACUTE INFECTIONS.

CASE 1.—Septicaemia: *Haemolytic Streptococcus*: Complete Recovery.

Lieut. W., aged 22; gunshot wound of chest and right arm, July 23rd, 1918.

Admitted July 25th. Condition: Wounds very foul; temperature high. Wounds opened up and damaged muscle cut away. Fractured right humerus above surgical neck. Large foreign body removed from under right pectoralis major. Axillary and brachial vessels and nerves exposed for about three

TABLE II.—Analysis of Cases.

Class of Case.	Bacteriology (Blood Culture).	Result.
A. Acute Infections.		
1. Septicaemia	Haemolytic streptococcus	Complete recovery.
2. Septicaemia	Ditto	Died.
3. Septicaemia	Ditto	Died.
4. Septicaemia	Ditto	Died.
5. Septicaemia	Ditto	Died.
6. Septicaemia	Staphylococcus	Died.
B. Chronic Infections.		
7. Acute suppurative arthritis of right knee-joint; gunshot wounds of leg	Pus from joint; streptococcus—pure culture	Rapid recovery.
8. Chronic suppurative wounds of left thigh; fractured femur	Pus from wounds; mixed streptococci and staphylococci	Rapid recovery.
9. Wound of right buttock; fractured neck of femur	—	Rapid recovery.

Mortality of streptococcal cases (Cases 1-5) = 80 per cent.; of all cases of septicaemia (Cases 1-6) = 83.5 per cent.

inches. Wounds packed with Dakin's gauze. July 25th to August 8th: Temperature 100° to 102°. Thrombosis left femoral artery. On August 9th there was secondary haemorrhage from third part of right axillary artery; rapidly controlled and vessel tied.

Transfused; ordinary donor, Class IV, amount 600 c.cm. August 11th: Temperature 105° F. and remaining high. August 15th: Conscious but drowsy; pale and anaemic, tremulous and twitching, occasional delirium. Left thigh very swollen. Blood culture positive—haemolytic streptococcus, medium length of chains. Blood group, Class IV.

August 18th: Apparently moribund, delirious, twitching, Hippocratic facies, sordes on lips. The following day transfused, immunized donor, Class IV, 600 c.cm. The donor had received five injections—highest dose 90 million streptococci, 150 million staphylococci; blood donation eleven days after last injection. August 20th: Slept quietly after transfusion, conscious on waking, tremor and twitching absent, colour improved, appetite improved. August 22nd: Condition again becoming unsatisfactory; marked tremor, drowsy, semi-conscious, incontinence of urine and faeces.

August 23rd: Transfused; immunized donor, Class IV, 800 c.cm. The donor received five injections—highest dose 90 million streptococci, 150 million staphylococci; blood donation fifteen days after last injection.

August 24th: Result of transfusion again very good; slept well, delirium and tremor absent, appetite returned. Satisfactory condition maintained on August 26th, but on the following day his condition was again grave; temperature high, unconscious and delirious; marked oedema of left ankle and leg from thrombosis of vessels.

August 28th: Transfused; immunized donor, Class IV, 900 c.cm. The donor had received six injections—highest dose 120 million streptococci; blood donation two days after last injection. Result again excellent; slept well, consciousness recovered, free from twitching, good appetite. His condition still good on August 31st, when an autogenous vaccine was given.

September 3rd: Thrombosis of left femoral vein extending; veins prominent on abdomen, great oedema of left thigh and leg. September 5th: General condition improved; drowsy, but quite conscious; autogenous vaccine. On the 9th he had a rigor, but general condition was satisfactory. On the 13th he was better, temperature remaining on lower level; autogenous vaccine.

September 16th: Autogenous vaccine. Condition improved; thigh softer and less swollen. September 21st: Condition unchanged; autogenous vaccine.

September 27th: Thrombosis of right femoral vein and swelling of right leg and groin; abscess in right arm evacuated and drained. Autogenous vaccine was injected on this date and again on October 3rd. On the 4th a large abscess of the left thigh was evacuated and drained; the right leg and foot were swollen from thrombosis of the right femoral vein.

Autogenous vaccine was injected on October 7th and 12th, when the patient's condition was much improved. A blood culture taken four days later proved sterile. October 17th: Autogenous vaccine; condition still improving. The temperature was normal on the 19th, and on the 22nd the last dose of vaccine was given. On November 1st the drainage tubes were removed from the right arm, and two days later he was evacuated to the United Kingdom, the temperature having been normal since October 19th; pulse about 100.

Subsequent history, 1919: Alive and well and walking with the aid of a stick.

CASE 2.—*Streptococcal Septicaemia: Death.*

Pte. T.; gunshot wound of thigh, compound fracture of left femur, October 18th, 1918. Injured portion of left femoral artery ligatured and excised at casualty clearing station.

Admitted October 28th with gangrene of left foot, suppurating fracture of left femur, and acute bilateral bronchitis. Amputation; bipp; sutured. The same day secondary haemorrhage occurred, and the left common femoral was tied. Transfusion 900 c.cm. from ordinary donor. A blood culture on November 1st resulted in the growth of a haemolytic streptococcus. Blood group, Class IV.

November 2nd: Temperature 104-105°, rapid respiration, tremor, muttering delirium. Transused 900 c.cm. from immunized donor, Class IV. The donor had received eight injections—highest 150 million streptococci, 160 million staphylococci; blood donation three days after last injection. On the following day the patient died in coma.

Autopsy.—Thin blood-stained oedema below subcutaneous tissue near wound of thigh. Left ilio-psoas muscle soft and oedematous. Spleen enlarged (17 oz.) and contained recent infarcts. Parenchyma necrotic. Liver large; with pin-point multiple abscesses. Lungs: Subserous petechiae, nodular abscesses along posterior borders from which *B. welchii* was isolated. The pleural and pericardial cavities contained blood-stained fluid.

CASE 3.—*Streptococcal Septicaemia: Death.*

Pte. B.; gunshot wound of thigh, October 13th, 1918; fractured left femur.

Admitted October 16th. Temperature 99° to 101°. Wounds apparently clean; bipp and suture above knee. On October 28th the wounds were broken down; temperature 102° to 104°. Three days later metastatic abscess of hand opened; urine contained albumin, blood, and granular casts. A blood culture, on November 2nd, produced a growth of a haemolytic streptococcus. Blood group, Class IV.

November 3rd: Drowsy, semi-delirious, twitching; urine scanty, casts numerous. Transused (800 c.cm.) from immunized donor, Class IV. The donor had received seven injections—highest 150 million streptococci, 160 million staphylococci; blood donation four days after last injection. The following day the patient's condition very bad—tremulous, respiration rapid.

On November 5th he was again transfused (900 c.cm.); immunized donor, Class IV. The donor had received seven injections—highest 150 million streptococci, 360 million staphylococci; blood donation one day after last dose. The patient died two days later.

Autopsy.—The left pleural cavity contained 20 oz. of turbid fluid. Left lung collapsed; bronchitis both lungs. The heart showed an old fibrous nodular vegetation on the mitral valve. Kidneys showed a chronic mixed nephritis with cysts and a calcareous patch in the left kidney. The spleen showed interstitial haemorrhages.

CASE 4.—*Streptococcal Septicaemia: Death.*

Pte. P.; gunshot wound of right knee, fractured left femur, September 3th, 1918.

Admitted October 10th with single suppurating anterior wound of left thigh; oblique fracture of middle third of left femur in fair position. Wound of right knee partly sutured, partly packed with flavine gauze; bipp. Left leg, Carrel's tubes and bent Thomas's splint.

On October 26th posterior drainage to left thigh. On the 28th the temperature rose rapidly to 104° and remained high; pulse rate 160. On November 6th blood culture resulted in the growth of a haemolytic streptococcus. Blood group, Class IV. Condition very grave—pallid, semi-conscious, sordes on lips, dry furred tongue; very tremulous and unable to speak; wounds clean. The following day he was bled 500 c.cm. and then transfused (immunized donor, Class IV), receiving 900 c.cm. The donor had received seven injections—highest dose 150 million streptococci, 360 million staphylococci; blood donation three days after last dose. The next day the temperature was a little lower, but his condition still very bad; semi-conscious and unable to speak.

On November 10th the temperature rose to 106°; pulse 160. The patient died on the 11th.

Autopsy.—Turbid fluid in right pleural cavity, blood-stained fluid in left. Lungs showed tuberculous, caseous and cicatricial foci at apices; recent small infarct at base of left lower lobe. Spleen soft and friable.

CASE 5.—*Streptococcal Septicaemia: Death.*

Capt. L., aged 22; gunshot wound of right leg, November 1st, 1918. Vessels tied; supracondylar amputation right thigh.

Admitted November 5th; temperature 101°, pulse 86. The next day the stump was cleaned with spirit and flavine; delayed primary suture. On the 7th the temperature rose to 104°, pulse 120; stump clean. Blood culture showed growth of a haemolytic streptococcus. Blood group, Class IV.

On November 13th his condition was fair: conscious, not tremulous, no marked pallor. Temperature 103°, pulse 120; stump clean. The following day he was bled 200 c.cm. and then transfused; immunized donor Class IV. The donor had received eight injections—highest dose 150 million streptococci, 400 million staphylococci; blood donation four days after last injection. Patient slept well after the transfusion, but there was no marked improvement.

November 16th: Pleural effusion at base of right lung; fluid from right pleural cavity gave pure culture of a streptococcus with same fermentation reactions as were given by the organism obtained by blood culture. On the 17th he was given a polyvalent vaccine—the same as was used for immunizing donor. The next day there was a marked fall of temperature, and his condition showed great improvement. On the 19th the tempera-

ture was normal, respiration more rapid but easy; slept well. On the 20th, temperature rising, respiration rapid; left-sided parotitis. Vaccine given. The next day he was delirious and very restless; respiration increased. On the 22nd he was better—conscious, parotitis diminishing, no cough or pain in chest. On the 24th the respiration was rapid and rather laboured; 300 c.cm. purulent fluid removed from right side of chest. The patient died the next day.

Autopsy.—Left pleural cavity contained 60 oz. of purulent fluid; right 30 oz. Lungs collapsed; some small abscesses with bronchopneumonia at base of right lung; three small infarcts at base of left lung. Spleen large, soft and friable.

CASE 6.—*Staphylococcal Septicaemia: Death.*

Lieut.-Cpl. F., aged 21; gunshot penetrating wound of right chest, August 1st, 1918.

Admitted August 5th with basal pleurisy of left side of chest. X rays showed foreign body on left side under left dome of diaphragm; no haemothorax. Entry wound right side of chest. Temperature 102° to 104.2°.

On August 28th abscess of liver drained along track of foreign body; about 4 oz. of purulent fluid in cavity. On September 2nd patient was semi-delirious, emaciated and pale; temperature 102° to 104°, pulse 130. Blood culture gave a growth of *Staphylococcus pyogenes* in pure culture. On September 5th he was transfused (900 c.cm.) from immunized donor, Class IV. The donor had received seven injections—highest dose 155 million staphylococci, 150 million streptococci; blood donation five days after last injection. The next day patient's condition was still bad; semi-conscious. He died on September 7th.

Autopsy.—Fragment of metal (weight 9 grams) lying in gastro-splenic omentum; partly closed suppurating track through liver. Spleen much enlarged through pressure on splenic vessels. Pylephlebitis. Semi-purulent fluid in right ventricle; recent vegetations on auricular surface of cusps of tricuspid valve; *Staphylococcus pyogenes* isolated from heart blood of left ventricle.

B. CHRONIC INFECTIONS.

CASE 7.—*Suppurative Arthritis (Streptococcal): Rapid Recovery.*

Pte. K., aged 20; gunshot wound of right knee and multiple wounds, July 7th, 1918. Foreign body removed from external condyle of right femur; joint not involved; bipp.

Admitted July 7th with suppurative arthritis of right knee-joint. Joint laid open and drained; leg oedematous below right knee. Temperature 104°; drowsy. Pus from joint gave pure culture of streptococcus. Blood group, Class IV.

On July 12th he was transfused (450 c.cm.) from immunized donor, Class IV. The donor had received five injections—highest dose 90 million streptococci, 150 staphylococci; blood donation five days after last injection. Two days later patient's condition satisfactory; autogenous vaccine given. On July 18th the temperature was normal; condition improved; wounds very clean and healthy. On the 19th autogenous vaccine again given. Two days later abscess in calf opened. On July 31st the wounds were healing rapidly; general condition good, temperature normal; vaccine discontinued.

CASE 8.—*Chronic Suppuration (Wound Sinus): Mixed Infection: Rapid Recovery.*

Pte. P., aged 20; gunshot wound of left thigh, August 23rd, 1918. Perforating shell wound above left knee-joint; compound fracture of femur. Wounds freely excised; Carrel's tubes and gauze packs.

Admitted August 25th. Wounds appeared clean; completely closed by delayed primary suture. On September 17th one large loose fragment of bone was removed; backward, displaced lower fragment of femur suspended by silver wire loop.

October 28th: Sutured wounds broken down ten days after suture. Large open sinuses discharging profuse thick greenish pus. Patient very pale, anaemic, and rather emaciated. Blood culture sterile. Pus from wound yielded streptococci, medium length chains, and staphylococci. The following day he was transfused (900 c.cm.) from immunized donor, Class IV. The donor had received nine injections—highest dose 150 million streptococci, 250 million staphylococci; blood donation twenty-six days after last injection. The transfusion was followed by a sharp rise of temperature, which immediately returned to normal. Patient looked and felt better.

On November 2nd a polyvalent mixed vaccine was given, similar to that used for immunizing donors; no marked reaction. On the 5th, sinus in thigh opened up. On the 7th polyvalent mixed vaccine again given; temperature down to normal. On the 10th the discharge from sinuses was much less. Polyvalent mixed vaccine was again given on the 12th and 17th, when the condition was much improved. The last dose of vaccine was given on the 22nd, when the wounds were very clean and discharge slight; temperature normal.

CASE 9.—*Chronic Suppuration (Wound Sinus): Mixed Infection: Rapid Recovery.*

Lieut. L., aged 29; gunshot wound of right buttock, November 1st, 1918.

Admitted November 7th with penetrating wound of right buttock and right inguinal region; bulging of right buttock.

On the 13th the posterior wound was discharging thick greenish pus. X rays showed fracture of right acetabulum. Posterior wound incised; cavity granulating; fragments of bone removed and bare bone felt. Two days later wound enlarged obliquely down and inwards; fairly large infected cavity; posterior half of wound sewn up; bipp and gauze packs.

On December 14th x rays showed necrosis of head of right femur. Temperature swinging. Head of right femur excised; thorough drainage established. On December 24th the patient looked anaemic and thin; temperature 102°. Blood culture sterile. Transfused (900 c.cm.) from immunized donor, Class IV. The donor had received five injections—highest dose 120 million streptococci, 480 million staphylococci; blood donation twenty-four days after last injection. The next day the temperature was lower and patient's condition satisfactory. He continued to improve. On December 31st he was again transfused (900 c.cm.) from a donor of the same class as before who had received five injections—highest dose 120 million streptococci, 960 million staphylococci; blood donation thirty-one days after last injection. The patient was evacuated to England on January 8th, 1919; colour good and general condition much improved; temperature 98° to 100° F.

DISCUSSION.

A superficial examination of the above results obtained by the use of immunized donors in septicaemia suggests that the method is not of any value. If, however, the case and *post-mortem* reports are analysed it will be noted that in all except two cases the conditions of the patients were absolutely hopeless before the transfusions, and that they were, indeed, practically moribund. In the first case, which appeared equally desperate, a completely successful result was, however, achieved, a result which alone was worth the trouble of immunization, and justified the trial of the method. Without personal knowledge of the case a just estimate of the result obtained in this instance can hardly be conveyed. In the previous experience of none of the observers of the case has a patient in such a condition recovered.

It is true that cases of septicaemia due to infection by haemolytic streptococci may recover by their own powers, as in one case investigated by the writer which had no special treatment; but the patient in this instance never presented very grave symptoms. In all except two instances the method was adopted as a last resort, too late for any hope of success.

Some details of technique suggest themselves as a result of the trial of this method. The treatment should be commenced as early as possible. Donors of the same group as the patient are probably to be preferred.

The transfusion should be done very slowly to prevent a sudden overfilling of the venous system with a consequent transudation into the serous cavities. Such transudations might be rapidly converted into purulent fluids owing to the presence of circulating pyogenic organisms. For this reason, prior to the transfusion, bleeding the patient is, perhaps, advisable if his condition permits.

Care should be taken to guard against the formation of small clots during the transfusion in order to prevent the formation of septic emboli.

The cases of chronic suppurative infections of wounds which were treated by this method all made a rapid and satisfactory recovery.

Precise evidence as to the value of the treatment in these conditions is lacking, but the fact remains that the patients were in a stationary and chronic condition before the adoption of the method, and that the wound surfaces appeared to become rapidly more healthy, to heal quickly, and the discharge to diminish after the treatment had been instituted.

The use of the method in civil practice may be rather limited by the difficulty in obtaining suitable donors. It seems worthy of further trial and may prove of value in the treatment of malignant endocarditis, acute and chronic suppurative bone or joint infections, or purpuric septicaemia.

I am indebted to Lieut.-Colonel S. G. Butler, D.S.O., R.A.M.C., for permission to use the notes of these cases, and desire to emphasize my acknowledgements to Major Taylor, R.A.M.C., Officer in Charge Surgical Division, and to the surgeons to whose skill and care the success in the treatment of certain of these cases was largely due.

THE FUNCTIONAL CONNEXION BETWEEN THE REPRODUCTIVE ORGANS AND OTHER GLANDS OF INTERNAL SECRETION.

BY

EVELYN E. HEWER, M.Sc.,

LECTURER IN HISTOLOGY AT THE LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

It has been shown previously that there is some definite connexion in white rats between the thymus gland and the gonads, more particularly in the male. In animals where a condition of hyperthymism had been established, there was found to be marked degeneration of gonads in the male, and sterility in the female; or—if the animal were young—delayed sexual development.¹ Further experiments, with x rays, failed to show that any very marked influence is exerted by the thymus directly on the gonads, but irradiation of the testes or ovaries determined hypertrophy of the thymus.² At the same time changes in the pancreas and suprarenal glands were usually observed, and it was to follow up the connexion between the suprarenal glands, pancreas, thymus, and gonads, that the present series of experiments was begun.

In the series previously reported it was thought that some of the changes observed in the female might have been due to the influence of pregnancy rather than to an indirect action of x rays through the ovaries. Consequently material has been collected from a large series of pregnant rats at various stages of pregnancy, and the results, it is hoped, will shortly be published.

At the same time a series of experiments was begun to investigate directly the functional connexion said to exist between the suprarenal cortex and the gonads. Owing to the difficulty of obtaining fresh material for feeding experiments, inoculation with various preparations of suprarenal cortex was tried. Full details of the preparations, method of experiment, and findings will be published later, but it was thought that the following preliminary note might be of interest. White rats only have been used up to the present.

Results.

1. In nearly every case the hair began to come out, although the coat was usually very fine and glossy. In a few cases, however, with young animals, the hair came out so much that the whole coat looked quite ragged.

2. The animals appeared to be perfectly healthy. There have been a very few exceptions, where the inoculations were pushed.

3. *Thymus*.—Macroscopically, no constant variation has yet been found. Microscopically, the whole gland appears unusually vascular, but otherwise normal.

4. *Pancreas*.—Hypertrophy of the islets of Langerhans has been observed, but is inconstant. Since the distribution and size of the islets varies so much in normal animals, further investigation of this point must be carried out before it will be possible to arrive at any conclusion.

5. *Suprarenals*.—The gland does not appear to be altered in size. Histologically the medulla is normal. The cortex, particularly the zona reticularis, is unusually vascular. Large spaces have been seen in the zona glomerulosa between the cells, the spaces containing blood and debris. Signs of disintegration are present in the two outer layers of the cortex.

6. *Testes*.—Very marked degeneration has been obtained. The degree of disintegration appears to depend on the duration of treatment, and the stages so far observed are exactly similar to the degenerative changes previously obtained under the action of x rays in graduated doses.

7. *Spleen and Liver*.—Normal.

The material from the female rats has not yet been examined microscopically.

In another series of experiments feeding the animals with desiccated suprarenal cortex brought about some change in the rate of growth.

If the feeding was begun at the age of about 4½ weeks, the rate of increase of weight was less, both in males and females, than in the controls. On the other hand, if the feeding was begun either earlier (at 3 to 3½ weeks) or later (at 5½ weeks), the rate of increase of weight was markedly greater in both males and females than in the controls.

The possibility of breeding from these treated animals and the microscopic examination of the glands is still under investigation.

The expenses of this research are being defrayed by a grant from the Royal Society.

APPENDICECTOMY.

THE ileo-inguinal incision described by Mr. Whitelocke,¹ like the oblique inguinal incision of McBurney, may prove quite successful in uncomplicated cases of appendicitis, but very few surgeons nowadays would, I am sure, like to pin their faith to a definite diagnosis of an uncomplicated appendicitis. In fact, the mimicry of appendicitis by many different pathological conditions is so great that it is sound surgery to adopt an incision which will enable the surgeon to deal not only with a diseased appendix, but also with any accompanying pathological lesion which may be present.

Mr. Whitelocke seems to emphasize the fact that the ileo-inguinal incision will prevent the occurrence of hernia, but surely the well-tried incision of Battle—where the rectus muscle is left intact—is much to be preferred, seeing that the occurrence of hernia after Battle's incision is relatively very uncommon, even after appendicectomy for suppurative appendicitis. Through the same incision also any complication can be dealt with at the same operation, and thus prevent the surgeon from performing an incomplete operation.

I recently had under my care at the Victoria Hospital, Keighley, three patients who well showed the advantages of Battle's incision. In each case the doctor sent the patient to hospital with a diagnosis of acute suppurative appendicitis, but in the first case there was a well marked gangrenous appendix firmly adherent to an ovarian dermoid cyst with torsion of its pedicle. The second was a gangrenous appendix adherent to a pyosalpinx, and the third a gangrenous appendix adherent to the bladder. In each case I am convinced that the complete surgical treatment required would have been quite unsatisfactorily performed by the ileo-inguinal incision.

Another patient, a young lady aged 22 years, was operated upon by me at a nursing home for what was clinically an ordinary recurrent appendicitis. My diagnosis in this case was confirmed before operation by a very eminent surgeon. At the time of operation the appendix showed the ordinary signs of chronic inflammation with two faecal concretions in its lumen. Having used Battle's incision, I examined the other abdominal organs, and found a shrunken gall bladder full of stones. By extending the original incision upwards I also performed cholecystectomy. In this way the patient was in all probability saved the necessity for a further operation at a later date.

Similar experiences are common to every surgeon, so that, unless we have more certain evidence for the diagnosis of a definite uncomplicated appendicitis, surgeons will, I have no doubt, prefer to use an incision with a much wider application than that afforded by the ileo-inguinal one suggested by Mr. Whitelocke.

H. STEWART BRANDER, M.A., M.D., Ch.B.,
Honorary Surgeon, Victoria Hospital, Keighley.

ACUTE OEDEMA OF THE LUNGS.

THE cases described in recent issues under the title "Acute suffocative catarrh," especially those of Dr. Anderson and Dr. Gale, appear to me to be identical with the disease called "acute oedema of the lungs," of which a description is to be found in the latest edition of Osler's *Practice of Medicine*.

Some years ago I had the opportunity of observing the following case: A man, aged 57, previously strong and healthy, was awakened about midnight by a feeling of suffocation. Almost immediately after large quantities of

¹ BRITISH MEDICAL JOURNAL, February 14th, 1920, p. 211.

frothy watery fluid poured from his mouth and nostrils; there was no evidence of bleed in the fluid. The complexion was extremely pallid and the skin was cold and clammy; dyspnoea was intense. In spite of all assistance the patient died in about a quarter of an hour.

About four years ago I read for the first time Dr. Langden Brown's *Physiological Principles in Treatment*. In the notes upon the condition termed "acute oedema of the lungs" I at once recognized the diagnosis of my case.

The condition has been explained upon a theory that the left side of the heart, for some reason or other, fails, whilst the right side continues to work as usual. In this way it is presumed that the lungs become engorged, so that the fluid contents of the blood are forced into the air spaces, thus accounting for the great amount of frothy watery expectoration which is so noticeable a feature in these cases.

I must confess that, to me at any rate, this theory is not satisfactory. In the entire absence of past evidence, why should the heart be constantly the first organ called upon to afford an explanation for so many cases of death which may be difficult otherwise to account for?

In urticaria following food poisoning, and in so-called angioneurotic oedema no person would call immediately upon the heart for an explanation of the oedema. I fail to see why the lungs should not be the site of the oedema in some of the cases. Such an occurrence would account fully for the rapidity of onset and the usual early fatal termination which seems to be so frequent in the cases recorded.

One point which the correspondence on the subject has brought out is, that the disease is probably more common than it is usually thought to be.

The very nature of the cases necessitates their falling into the care of general practitioners much more frequently than hospitals. Upon this point of view, however, Sir James Mackenzie, in his address on "Clinical Research," dwells much more eloquently than I can. "I saw," he states, "that I must look for assistance to those who had undergone experiences similar to my own, and it is for this reason that I seek the help of the general practitioner."

STEWART McNAUGHTON, M.D. Edin., D.P.H. Camb.,
Honorary Physician, Monkwearmouth Hospital, Sunderland.

TREATMENT OF THE RUNNING EAR.

I HAVE just received the *JOURNAL* of August 23rd, 1919, and read "Efficient treatment of the chronic running ear," by Mr. A. J. Wright, F.R.C.S., of Bristol, and I feel bound to ask certain questions and state my own experiences:

1. When does Mr. Wright consider a discharge from an ear chronic? On reading his letter I am not clear whether he has not mixed up chronic cases with long-lasting acute cases.

2. Does Mr. Wright seriously wish us to believe that syringing ears is modern treatment, and that syringing will "prevent stagnation of discharge in the middle ear"? How does the lotion get into the recesses of the middle ear?

3. Does Mr. Wright deny that the antrum is, in a great number of cases, the cause of the persistence of the discharge? If he do not, how can syringing affect the antrum?

I agree most heartily that greater care should be given to the treatment and the treatment carried out at least twice daily, and that by a specialist who knows every move in the game. I disagree most strongly with the use of hydrogen peroxide and syringing. Both, in my opinion, do harm. If the doctor have patience, he should sit down and carefully sponge out the discharge, using Pelitzer's bag to expel gently what is in the middle ear, and leave the meatus and membrana dry. Painting with ether—despite its stinging, which I warn my patients about—or alcohol will harden the skin and prevent or cure external otitis, which is so common, and obviate softening and proliferation of the epithelium of the membranes.

What I complain about is that the acute discharges are not attended to properly. I agree with many otologists that if the acute discharges last more than ten days without showing signs of clearing up, or if the temperature remains elevated and accompanied with middle-ear or mastoid pain, the mastoid should be opened up. This has been my practice, and I can truthfully say that the results have been excellent, the perforation closing and excellent hearing resulting.

But I cannot understand the bringing about of cessation of chronic discharges in two to three weeks. I have secured that with prolonged acute discharges. In my opinion

chronic discharges are due to three things chiefly: first, to infections of the Eustachian tubes and nasopharynx; secondly, to infection of one or more of the mucous spaces in the attic, with bone trouble among the ossicles; and thirdly, infections of the antrum, including the lining and bone. In the case of Eustachian trouble cure may be looked for, but the nose and throat must receive attention—a point not mentioned in Mr. Wright's letter. In the other two instances I agree with Mr. Adair Dighton that nothing short of a mastoid operation will cure most of these cases, as I believe that the majority have bone infection at bottom.

If Mr. Wright can persuade specialists to give more personal attention to these cases, and not to leave them to house men or inexperienced persons, he will benefit humanity.

I am sorry I cannot agree with his statements. My simple mastoid operations, numbering about 200, show easily 75 per cent. of cessation of discharge and healing of the perforation with excellent hearing.

Christchurch, N.Z.

Reports of Societies.

ALCOHOL AS A THERAPEUTIC AGENT.

At a meeting of the Therapeutical Section of the Royal Society of Medicine on February 17th, Dr. H. H. DALE presiding, a discussion took place on the value of alcohol as a therapeutic agent.

Dr. DALE said that many such discussions had been complicated by the intrusion of views on the common use of alcohol. It ought to be possible to hold strong opinions as to the value or the danger of alcohol in daily life without committing oneself to the admission or rejection of it in therapeutics. The known actions of alcohol might be divided into those of a food and those of a drug. Beyond dispute alcohol could be used by the body as a source of energy. There were limitations to the power of the body to use alcohol in this way, but there was no longer any room for doubt that the body could oxidize considerable amounts. As a source of energy alcohol had certain peculiarities. Like dextrose alone among ordinary constituents of diet, it required no digestion; it could be rapidly and completely absorbed, and it was not susceptible to fermentation by yeasts and bacteria. The mere value of alcohol as an emergency food, therefore, should give it a place in rational therapeutics. One very specialized type of treatment in which alcohol was used purely for the supply of energy was during the preliminary period of starvation which introduced the modern treatment of diabetes. As for the use of alcohol in convalescent diet, when they had once dismissed as quite unsupported by evidence the traditional notion crediting alcohol with a specific effect on metabolism or a special body-building power, they were left to individual opinions that would be coloured by the relative importance attached to the immediate comfort of the patient on the one hand, and the danger of habit-formation on the other. It was still a debatable question how alcohol influenced respiration. The good effects might be attributed not to direct action on the respiratory centre, but to such indirect actions as the lessening of an excessive reflex excitability; in so far as alcohol could restore a quiet, deep breathing, it ought to be of value. Among the several conditions which were probably confused under the vague expression "shock" it might be expected that these in which inhibitions were predominant would get some benefit from alcohol; in others, in which a toxæmia causing peripheral stagnation in the blood was the predominant factor, there seemed no likelihood of alcohol doing good. It would not be without value if the Section registered a protest against what he held to be the superstitious view that alcohol was a sort of specific against infection, influenza in particular. There was no evidence for a specific prophylactic action of any kind. Alcohol was a mild sedative and narcotic, and a superficial vaso-dilator. On the lines of these demonstrated actions he believed that such therapeutic value as it possessed could be explained, and its inclusion in the pharmacopœia could be defended. The value of alcohol in therapeutics had, however, been discounted by its indiscriminate and unreasonable use.

Clinical Experience.

Sir WILLIAM HALE-WHITE said that therapeutically it seemed to him alcohol was of great value as a food, for example, in the anorexia and vomiting met with in phthisis or cancer. It must not be given, of course, in functional anorexia or vomiting, because such patients were just those who would form an alcohol habit; but in an acute fever when anorexia and vomiting or indigestion were present, and therefore limited the food which the patient could take in, alcohol was an admirable food, requiring no digestion. Being easily absorbed it had the inestimable advantage of making the patient feel comfortable and sending him to sleep. The disadvantage was that occasionally headache followed, and in some cases sleep was not obtained. On the whole, however, in acute fevers, where the patient could not take food well, alcohol was beneficial, and had no deleterious effects. In convalescence it often did much good. The patient just recovering from a severe illness or an attack of influenza or diarrhoea often felt better for a glass of wine with his meals. His digestion was left weak, and he described himself as "all on edge," which, translated into physiological language, meant that all sorts of peripheral stimuli were worrying him as they would not were he in health. A glass of wine would lull these peripheral stimuli without doing any appreciable harm; the patient would feel better and more comfortable. Personally he had never known the alcohol habit contracted through taking alcohol during convalescence in the way he had described. Its therapeutic action on the circulation was difficult to estimate, save in the simple case of strongly concentrated alcohol given during fainting, when the alcohol seemed to act reflexly. When he entered the profession large amounts of alcohol were given in pneumonia. To-day most cases received no alcohol, but he was unaware that the outlook in pneumonia was better. He was not convinced, from watching many patients, that it did any grievous harm, but he was convinced that most patients suffering from pneumonia could do very well without it. The effect of alcohol on the respiratory centre did not appear to him to be of very much clinical significance. The chief effect of alcohol therapeutically was as a pleasant depressant, particularly efficacious in inhibiting peripheral impulses, such as a pain here and a discomfort there, and diminishing the trifling worries that bothered the sick. In small doses it was useful for the convalescent; in larger doses it was useful for the patient acutely ill; in larger doses still it had the advantage of making the patient sleep. But in all these discussions they were faced with two difficulties—the one that it by no means followed that the effect of a drug in health was the same as in disease, while its effect in disease was often very difficult to estimate; the other, that no person, whether acutely ill or convalescent, was ever given pure alcohol and water. Perhaps the other bodies present in wines and spirits had their actions; certainly there was a widespread belief that brandy was the best form of alcohol in diarrhoea, just as the glass of wine was acceptable to those with tired digestions, and there was a firm belief among the laity, and among some doctors, that old brandy was more efficacious than new.

Alcohol a Food?

Dr. E. MELLANBY, after relating some observations on dogs, said it was proved that alcohol could supply up to 40 per cent. of the total energy of the human body lost in the course of the day; but it differed from other food-stuffs in that its rate of combustion was independent of the amount of alcohol in the body (in order to get the maximum food value out of alcohol it was only necessary to give small quantities). It had no specific dynamic action, no stimulating effect on metabolism, it did not increase the amount of energy available at any particular moment (if only alcohol were given to a starving man there would be no increased production of heat in his body); its rate of oxidation was independent of all other metabolizing processes; and, finally, if it was desired to use alcohol as a source of muscular energy, this could only be done with relatively small amounts. He did not think it was clear that any substance which was only a source of energy was of any value at all to the body, and he doubted whether it could justifiably be called a foodstuff.

Dr. R. HUTCHINSON claimed that therapeutically alcohol should be considered as a food; if it was a sparer of protein and fat, that was just the kind of action which

was wanted in acute fevers. It was agreed that alcohol was a digestive stimulant; many people took food better with a certain amount of alcohol than without. With a tired stomach a glass of wine was a direct aid to digestion, and this was valuable in convalescence. Alcohol was also of clinical use in dilating the superficial blood vessels. With people who had been exposed to cold and ran the risk of congestion of their internal organs, alcohol undoubtedly did good, and the same was true in rigor and during an acute attack of angina pectoris. The main difference of opinion would come in with the question whether alcohol could be regarded clinically as a heart stimulant in acute illness. If alcohol had no direct stimulating effect, might not the heart benefit from the indirect effect upon the patient as a whole, whereby mental calm and sleep were promoted?

Dr. W. H. WILLCOX dealt simply with the use of alcohol as a therapeutic remedy in the form of vapour when combined with oxygen. He was convinced that the value of this combination was considerable in cases where there was cardiac failure. The desirable percentage of alcohol in vapour was from 3 to 5. The use of brandy or whisky was of little value because it gave such low percentages. He did not suggest that this mixture of alcohol vapour and oxygen had any physiological action on the normal person, but there was no question of its markedly beneficial effect in profound cardiac failure associated with various severe diseases.

Dr. LANGDON BROWN said that the four definite points on which alcohol might be regarded as having real therapeutic action were (1) in the fasting treatment of diabetes; (2) in convalescence, in promoting a flow of gastric juice; (3) in the occasional removal of temporary inhibitions of a troublesome kind; (4) in pneumonia, in which alcohol was combined in administration with oxygen.

Dr. ESTHER HARDING said that in the treatment of children alcohol was useful in certain definite respects. Small doses were useful in bronchopneumonia in infants and young children. In the form of brandy alcohol was an efficient sedative drug in the case of young children. Alcohol was also of use in some cases of marasmus, when a child could not take milk; its digestion could be started and got back through whey and other foods to milk again. Great care, of course, had to be exercised because of the effect of alcohol on the liver in small children.

Dr. O. LEYTON described a case of diabetes mellitus in which he gave alcohol with useful results during the period of alimentary rest. Professor W. E. DIXON, in a brief comment on the discussion, said that two points of disagreement had made an impression on him—the one, as to the possible stimulating action of alcohol on the heart; the other, as to the definition of a food. He thought it was quibbling with the question to say, as Dr. Mellanby had said, that alcohol was not a food, though it could be a sparer of other foods. Dr. C. F. HARFORD thought that the discussion had shown that the profession was only on the threshold in its study of the subject. He laid stress upon the fact which had been brought out that alcohol was naturally a narcotic and not a stimulant.

Dr. DALE, in closing, confessed himself still unconverted as to the directly stimulating action of alcohol on the heart. With regard to Dr. Harford's emphasis on the newly elucidated fact that alcohol was purely a narcotic, he reminded him that from the point of view of therapeutics—he was not talking of common life—there was no inherent desirability in a stimulant action and no inherent drawback in a narcotic action.

ANAESTHESIA IN THROAT OPERATIONS.

A MEETING of the Section of Anaesthetics of the Royal Society of Medicine was held on February 6th, with Dr. LLEWELYN POWELL, the President, in the chair.

Mr. A. L. FLEMMING showed a regulating dropper for the supply of ether, consisting of a container, a side dripper, a small tap to control dropping, and a nozzle; the whole could be connected with a stand attached to the anaesthetic or operating table.

Dr. FELIX ROOD read a paper on "Anaesthesia in throat and nose operations," in which he argued that ether was the proper anaesthetic. It could be used to produce a light or a very deep anaesthesia; the latter being the form to be employed for the modern operation for removal of tonsils and adenoids. He described a modified "open

ether" technique for securing the requisite depth of narcosis, in which with a fresh colour there were dilated pupils, quiet automatic breathing, and widely abducted vocal cords. The correct position of the patient was a necessary adjunct of this deep anaesthesia; the head should be extended over a firm pillow so as to rest on the vertex. The surgeon should have all the leisure and facility ordinarily supplied to him in such operations as that for cure of cleft palate.

Mr. HERBERT TILLEY said that primarily the safety of the patient, and secondly the convenience of the surgeon, must be considered. Ether was indisputably safer than chloroform or any mixture containing it. He had seen eleven deaths with chloroform, and one could never tell when one of these tragedies might occur. Ether caused a little more oozing of blood at the time of operation, but this was preferable to the greater risk of haemorrhage after chloroform. In five years he had only had to return to two patients on account of bleeding. To prevent blood entering the air passages the position described in the paper was essential.

Dr. WILLIAM HILL criticized the length of time necessary for induction by Dr. Rood's method; it would render out-patient operating impossible on its present scale. Rapid operations could be done very satisfactorily under ethyl chloride.

Dr. G. H. A. BARTON warmly supported the method, but preferred to start induction with small doses of ethyl chloride. For intralaryngeal operations he approved of rectal anaesthesia.

Sir STCLAIR THOMSON said that operations on the nose, where the blood could be cut off from the air passages by post-nasal sponges, differed little from any other surgical operation. Similarly, when laryngotomy or laryngo-fissure was done, and packing put on top of the tracheotomy tube, the anaesthesia was one of the smoothest and least risky possible. Anxiety came with operations on the pharynx. He had been associated with three fatalities, all in private practice; in no case was death due to blood entering the larynx, nor to traction, nor could he say the patient was too profoundly under; in all three cases an independent pathologist found status lymphaticus after death. In America, where ether was so universally used, one of the most skilful operators on the tonsils had gone back to chloroform. Chevalier Jackson carried out his endoscopic operations without any anaesthetic either general or local.

Dr. F. W. SILK was convinced of the truth of Dr. Rood's advocacy of ether. He held that the upright sitting position was good for many cases. Ethyl chloride was to be objected to only if given from a bag. He advocated the addition of a minute quantity of chloroform to ether, and urged the advantage that often arose from using Kuhn's intubation tube.

Mr. W. STUART-LOW believed in the importance of atropine beforehand, of warmth and quiet in the room, and of an early morning hour for operating. He upheld the merits of chloroform.

Dr. P. WATSON-WILLIAMS referred to blocking the nerves by injection of branches of the fifth nerve, and to injection of adrenalin. He felt strongly that ether was the best anaesthetic for operation on the respiratory tract.

Sir WILLIAM MILLIGAN said that no operation, however slight, should be regarded as trivial; it never was so from the patient's point of view. He had a leaning towards chloroform, but thought that ether and chloroform were used about equally often by the anaesthetists with whom he worked. He used Kuhn's tube on all possible occasions; it enabled one to obviate all risk of blood entering the air passages. A considerable amount of gauze must be packed into the pharynx; when this was taken out there was always a clot of blood, which must be removed lest it be sucked in. Adrenalin was extremely dangerous if injected during anaesthesia; placed on the mucous membrane it was innocuous. Before ether he insisted on preliminary injection of morphine and atropine.

Mr. H. E. G. BOYLE described a combination of anaesthetics which he had used for the last two years in nose and throat operations. A hypodermic was given beforehand and anaesthesia induced with gas and oxygen, and maintained by gas and oxygen in conjunction with ether or C.E. mixture or chloroform, according to the case. He used chloroform whenever the diathermic cautery was to be employed. Anaesthesia was maintained by endobuccal

or endopharyngeal methods. The anaesthesia was light and the patient was kept pink all the time.

Mr. HAROLD BARWELL considered that ether given by modern methods and preceded by atropine was on the whole the best anaesthetic in nose and throat cases. For such operations as resection of the septum the intra-tracheal method was inconvenient; the post-nasal plug was embarrassing and unnecessary if proper ischaemia were secured. He used cocaine a quarter of an hour before operation and injected adrenalin (1 to 15,000) beneath the mucous membrane before anaesthesia was started. This was perfectly safe; it was injection during anaesthesia that had been shown to be dangerous. He did not agree that the position demonstrated was the only proper one for dissection of tonsils. Hyperextension of the head caused discomfort and congestion and made the removal of adenoids difficult. The side position was perfectly safe and more comfortable for the patient if slightly less so for the surgeon.

Dr. BROWN KELLY recommended ethyl bromide for operations on children requiring only brief anaesthesia. He had used this drug for twenty-five years in large numbers of cases. A child of 6 required about one drachm and a child of 12 about two. Induction took about a minute and recovery was extremely rapid.

Dr. Z. MENNELL preferred to start with gas and oxygen, continuing with ether. He considered the position with head over-extended essential. Wide abduction of the cords took place only in very deep anaesthesia, and the pink colour came only when pupils were widely dilated and inactive to light. He knew of two deaths this year under ethyl chloride in one hospital. In operating theatres of the Royal Infirmary, Edinburgh, a notice was put up forbidding the use of chloroform without special permission.

Dr. CECIL HUGHES said that when anaesthesia had been induced with ether, or gas and ether, a moderate anaesthesia could be safely maintained with chloroform.

PUERPERAL SEPSIS.

At a meeting of the Edinburgh Obstetrical Society, held on February 11th, with Dr. WILLIAM FORDYCE, president, in the chair, Dr. BERRY HART read a paper on suggestions as to the causes of the persistence of puerperal septicaemia since the end of the pre-antiseptic period. The question of antiseptics and a sepsis was considered. These only give a relative not an absolute asepsis. In this connexion the importance of using gloves, a sterilized gown, aseptic sheets, instruments, and the minimization of internal examination were all emphasized. In connexion with the mechanism of labour it was important to remember that the study of casts and frozen sections showed that Naegele's flexion did not occur during labour. "Our management must be altered accordingly. Deflection begins even in the first stage (Braune, Chiari, and many others). It is marked at crowning." Dr. Berry Hart claimed that the placenta was always normally separated during the intervals between the pains. For this reason the Credé method should be abandoned as a means of separating the placenta. It was pointed out that this method was associated with great danger when applied early in the third stage. It tended to cause retention of membranes and subsequent infection. The statement that retention of pieces of membranes did no harm, that antiseptic management would prevent mischief, was dangerously fallacious. For these reasons a return to the old waiting policy must be made. A maximum of three-quarters of an hour to an hour must be given for the third stage of labour.

In the subsequent discussion Drs. BARBOUR, LOWRY (Belfast), RITCHIE, HAIG FERUSON, LACKIE, PATERSON, ROBERTSON, NICHOLSON, JOHNSTONE, YOUNG, DAVIDSON, and ARMOUR spoke. It was held by some speakers that the indiscriminate use of gloves by those who had not a special training in aseptic methods might be fraught with great dangers. Dr. Berry Hart's explanation of the separation of the placenta was criticized by some speakers, and it was pointed out that the placenta might be separated in the course of one pain, for example, after pituitary extract.

THE congress of French-speaking members of the medical profession which was to have been held in Brussels on September 30th, 1914, will take place in that city at Whitsuntide.

Rebuelus.

PSYCHIATRY AND PSYCHO-ANALYSIS.

THE third edition of Dr. STODDART'S manual of *Mind and its Disorders*¹ will disappoint many who would have been prepared to welcome a revision and possible amplification of what was an excellent textbook, written by an author of great experience as a psychiatrist and at the same time a sound neurologist. It would seem, however, that since the appearance of the last edition Dr. Stoddart has become a convert to the sexual theory of Freud and that he finds it to be of general application in the study of neuroses and psycho-neuroses.

This is no place to discuss the validity of the Freudian view, but it is not without interest to note its effects on the mind of an acute and scientifically trained observer. It would be a thankless task to set out at length the opinions to which the whole-hearted adoption of Freud's doctrines may lead; they have been made sufficiently familiar by the utterances of the Freudian extremists. In the book before us we read that "ten per cent. of females" are "homosexual" (p. 187); that "psychoanalysis reveals that neurasthenia is always due to partially or completely repressed auto-eroticism" (p. 212); that "anxiety neurosis is begotten of sexual excitations which are unable or not allowed to follow their natural course" (p. 219); that "the most superficial analysis of such patients [cases of anxiety neurosis] reveals the phallic significance or symbolism (in their minds) of Zeppelins, aeroplanes, and bombs" (p. 220); that, in children, "psychoanalysis reveals this instinct to retain the faeces to be the first attempt at economy, for such persons invariably grow up thrifty and methodical, and it is remarkable how frequently it is found during a psychoanalysis that faeces symbolizes money" (p. 74). The views expressed may or may not be the logical outcome of the Freudian theory, but they will seem to many to verge on the ludicrous. However this may be, we had supposed that experience gained during the war had proved beyond peradventure that Freud and his disciples had made a rather serious mistake in asserting that the sexual content is always discovered. We believe we are right in saying that in some of his writings before the war Freud himself admitted that the content was not always sexual, but any admission of this nature seems to have produced very little effect on many of his disciples, who appear to have treated it as qualifying the theory to so small an extent that it might be ignored.

The key to the problem lies in the recognition of the essentially mechanical basis of the Freudian hypothesis. The attempt to translate the mind in terms of mechanical causation has resulted in a *reductio ad absurdum*. It is a true product of German scientific materialism. The French as it is the British understanding of the issues of the great war has been summed up by Bergson as a struggle of spirit against matter, but the incubus of mechanism still weighs heavily on psychology as studied by the psychiatrist. The brilliant work of our great English psychologist, James Ward, seems to be unknown to the average writer on psychotherapy, for otherwise the dull monstrosities conjured up by Teutonic mechanism would hardly obtain the credit they do. So long as it is recognized that psychoanalysis like any other scientific method is purely an intellectual shorthand for expressing certain aspects of phenomena in terms of mechanical causation no one would care to dispute its value to psychology; it is when we forget this truism and mistake the mechanical aspect for the whole that we are landed in a morass of paradoxes. Freudians have, in defending their theories, sometimes accused those who disagree with them of being inspired by repressed sexual complexes, and it may clear the atmosphere if the writer of this review admits that there is no argument without emotional tone, and that in his case the complex is a belief in the ultimate rationality of humanity.

It seems a rather serious omission from a textbook written for senior students and junior practitioners, in which psycho-analysis is recommended as a standard method of treatment, that mention is not made of the

pitfalls that surround the analyst. Given a suggestible subject and an inexperienced investigator, it is probably an even chance whether the data of the psycho-analysis may not be furnished by the examiner himself. It is not, however, with the ultimate truth of the Freudian theory that we are at present concerned, but with the fashion in which the medical public is advised to use a two-edged weapon such as sexual psycho-analysis. There is a risk of unmerited public discredit falling on psychotherapy generally. It is time to say plainly that where neurologists gather together tales are heard of young minds soiled and perverted by the reckless use of gross sexual suggestions by inexperienced or ill-balanced followers of Freud. It is no answer to say that in the hands of men of the character and attainments of Dr. Stoddart no harm can come. There are many men mindful of their patients' welfare who yet cannot safely be exposed to the strain involved in the elucidation of sexual complexes. Dr. Stoddart would be ready to admit the incalculable influence that preoccupation with the sexual instinct may exercise on otherwise well-balanced minds. We must regard the present position in respect to the Freudian doctrines as most unsatisfactory and even dangerous. It is unsatisfactory because the lack of discrimination with which a considerable number of physicians have adopted the most extreme views of Freud as to the sexual content must tend to divert the attention of others from the merits of psycho-analysis, whatever those merits may be; and it is dangerous because in injudicious hands treatment founded on the theory of the sexual origin of all neuroses may lead to much mischief.

In the meantime we can only counsel the younger members of our profession who may read Dr. Stoddart's book, and quite properly wish to study the analytic method in psycho-pathology, to remember that the Freudian view is by no means generally accepted, and that by acting upon it they may accept a responsibility which they might be better advised not to incur.

THE TRANSMUTATION OF BACTERIA.

THE phenomena of bacterial variation offer a field of study of constantly increasing interest, and present problems of the greatest practical importance.

In his recently published monograph on *The Transmutation of Bacteria*² Dr. S. GURNEY-DIXON discusses systematically the evidences of bacterial variation which he has collected from the literature in relation to their bearing on the possibility of transmutation of species among bacteria. He also records some experiments of his own tending to illustrate the difficulties met with in interpreting the results of animal experimentation, bearing on the supposed occurrence of transmutation in the living body. It may be said at once that his book is a valuable contribution to the study of the meaning of variation in bacteria and the importance to be attached to it. It is remarkable as much for lucidity of expression and arrangement, and for acumen of criticism, as for the moderation of the general conclusions. A large amount of very useful information has been brought together and summarized in its pages, which cannot fail to be of great assistance to other workers.

Dr. Gurney-Dixon originally undertook his investigation in the hope of finding an answer to the question whether actual transmutation—meaning by that term the changing of members of one recognized species into those of another—may not occur among bacteria. In prosecuting this inquiry an endeavour was first made to collect the published records of experiments in which transmutation was alleged to have occurred. They proved to be few in number. In the second place, a series of experiments was carried out with the object of disproving the contention put forward in one of these cases. Thirdly, with a view to criticizing the claim made in the remaining cases, and in the hope that it might throw some light on the problem of transmutation as a whole, a general study of the subject of variation amongst bacteria was undertaken.

In the book itself the author presents his material in the reverse of the order just named, beginning, as was most natural and logical, with an account of the conditions which have been found to modify the characters of

² *The Transmutation of Bacteria*. By S. Gurney-Dixon, M.A., M.D. Camb. Univ. Press, 1919. (Demy 8vo. pp. xviii + 180. 10s. net.)

oacteria, followed by a discussion of the numerous instances of variation in morphology, chemical activity, virulence and pathogenicity which have been recorded by observers. Then he proceeds to the critical examination of supposed instances of transmutation, and the detailed consideration of the possibilities regarding its occurrence in the living body. The concluding chapters are devoted to a general review of the whole subject, to a discussion of the enzyme theory of disease and its bearing on the problem of transmutation, and to a statement of the author's own conclusions.

The chapter on the enzyme theory of disease is largely speculative, and forms much the weakest and least satisfying part of Dr. Gurney-Dixon's essay. In it he puts forward a remarkable hypothesis. Starting from a consideration of the diversity of "symptoms" which one and the same micro-organism may produce in different individuals, or in different epidemics, he suggests that each separate symptom of disease may be attributable to a separate and distinct bacterial enzyme. He discusses the question whether these enzymes may not be dissociable from the specific organism of the disease, and if completely dissociable, whether they may not be able to produce the disease—symptoms and lesion—in the entire absence of the specific organism. He believes that the considerations he puts forward "lend some measure, if not of certainty at least of probability, to the supposition that the organisms associated with certain diseases are not themselves the causal agents of these diseases, but merely act as carriers of ultra-microscopic bodies, possibly parasitic in character, which have hitherto eluded detection, but which are the real causal agents of the lesions and symptoms produced." It will follow from this that "obviously if it is possible for the enzyme or enzymes which produce a certain disease to become dissociated from the organism to which that disease is commonly attributed, and to become attached to some other organism, the effect, though not the actual process of transmutation, would be brought about." Dr. Gurney-Dixon adds, "A transference of this kind would present certain difficulties"; and we may add that it is difficult to see what is gained by propounding purely speculatively the hypothesis that bacterial enzymes are ultra-microscopic parasites of the bacteria—smaller microbes within the microbes we already know. It may be that:

The bigger fleas have little fleas
Upon their backs to bite 'em,
The little fleas have lesser fleas,
And so ad infinitum.

But however much that idea might commend itself to our ultimate sense of justice in relation to those ravenous insects, we do not put it forward as a scientific proposition in the absence of the necessary evidence.

In his discussion of supposed instances of transmutation the author is on surer ground. In particular his analysis and criticism of certain experiments of Horrocks, which were put forward as evidence of the transmutation of *B. typhosus* at one time into an organism intermediate between *B. typhosus* and *B. coli*, and at other times into *B. faecalis alkaligenes* or a Gram-positive coccus, is clear, concise, and destructive. It is shown that in the experiments on animals the only evidence of transmutation afforded was that on some occasions, after the intraperitoneal injection of living *B. typhosus*, a different organism was subsequently recovered from the infected peritoneal cavity. Dr. Gurney-Dixon characterizes Horrocks's statements as startling, and the criticism is fully justified.

But the main part (nearly two-thirds) of the book is occupied with the author's study of the conditions, instances, and principles of bacterial variation, and these chapters constitute, as already stated, the most generally useful portion of the work. They form a valuable and often suggestive contribution to the study of general bacteriology, which we can confidently commend to the attention of other workers in the same field of study.

PHYSIOLOGICAL EFFECTS OF HIGH ALTITUDES. *Altitude and Health*¹ is the title of an interesting work by M. F. F. ROGET of Geneva, founded on the Chadwick lectures he gave in 1914. Sir William Collins, in a pre-

factory note, cites the opinion of Farr, who was a contemporary of Chadwick, and established the correlation between crowding and high mortality, to the effect that "the vigour of their own lives is the best security men have against the invasion of their organization by low corpuseular forms of life; quarantine, vaccination, and other preventives are subordinate as means of subduing mortality."

M. Roget has much of interest to say on the immunity of natives of high tablelands from consumption and lung diseases and on the climate of the Alps and its stimulating effect. In winter there are occasional snowstorms, lasting, perhaps, two or three days, but usually followed by calm sunny weather day after day for weeks at a time. In the upper Alps in winter pure cold dry air surrounds the body; sunlight warms the body by day, and at night the air is dry and cold; usually the air is calm, and wind can be avoided in sheltered sunny nooks. The snow on the ground reflects and intensifies the sunlight and catches dust. The air is so dry and germ-free that meat can be dried in strips in the sun, and joints of meat will not go bad if kept out of the sun. The peasants show cheeses 100 years old. There are no flies or mosquitos. The cold dry air and the sun dry up catarrhs, sores, moist eczema, etc.; the skin thickens and hardens and the hair grows in exposed parts. The evaporative and cooling power of the air has a most beneficial effect on the respiratory passages, promoting the flow of blood and secretion, as has been pointed out by Leon: rd Hill.

The value of M. Roget's book depends on the account he gives of the climate and health of high Alpine villages and at the St. Bernard's Hospice. He is, however, not sufficiently acquainted with recent physiological research. For example, he writes: "Press the blood out of your ear, the rays (of the sun) will all pass through it—the ultra-violet rays are retained by the blood." The experimental evidence adduced by J. E. Barnard and others shows, however, that the ultra-violet rays do not penetrate the outer surface of the skin. In speaking of sunburn M. Roget says: "The composition of pigment has not been accurately gauged so far. Is it a carbon deposit in the cells ensuing upon oxidation of the blood?" It is known that the pigment is melanin, probably derived from tyrosin and so of protein origin. The carbon idea has long been exploded.

M. Roget mentions Barcroft's work on respiration and the blood at high altitudes, and draws attention to the evidence of "acidosis" in connexion with mountain sickness. "Acidosis" of the blood is now recognized to be a diminution of its sodium bicarbonate content produced by increased pulmonary ventilation and consequent "washing out" of CO₂. The resulting sodium carbonate is removed from the blood by the tissues. CO₂ is washed out in order to get in more oxygen by raising the alveolar partial pressure of oxygen. The result is increased alkalosis, not acidosis of the body, as has been pointed out by B. Moore and Haldane. A moderate altitude regenerates the blood, like the old-fashioned habit of blood-letting, by stimulating the formation of new blood cells.

EPIDEMIC DISEASES IN MAURITIUS.

The Epidemics of Mauritius,⁴ by Dr. D. E. ANDERSON, will be found interesting. Islands are specially suitable sites for studying epidemics, and Mauritius is no exception to the rule, the introduction of surra and malaria into it forming one of the most interesting epidemiological studies in tropical medicine. In the preface the author states that he has purposely written in a popular style in order that the book may be interesting to readers who do not belong to the medical profession. It is as well, however, to be accurate even when addressing the laity. We cannot accept as accurate statements such as "the seven days Phlebotomic Mediterranean fever resembling dengue" (p. 217), and "the consensus of opinion as to the carrier or transmitter" (of dengue) "is that it is a *Phlebotomus*, probably the *Papatasi*," which is also believed to carry the micro-organism of the so-called "seven days Mediterranean fever," and possibly of the *Micrococcus melitensis* (p. 221). Phlebotomus fever is "three-day" fever, not

⁴ *The Epidemics of Mauritius*. With a descriptive and historical account of the island. By Daniel E. Anderson, M.D., B.A., B.Sc., F.R.C.S., F.R.C.S. London: H. K. Lewis and Co., Ltd., 1918. (Demy 8vo, pp. xvi + 312; maps and other illustrations. 16s. net.)

¹ *Altitude and Health*. By M. F. F. Roget. London: Constable and Co., Ltd., 1919. (Demy 8vo, pp. xii + 186. 12s. net.)

seven-day fever, and we know of no evidence that the *P. papatasi*, the carrier of three-day fever, also carries dengue or undulant fever. The recent work by Clelland and his fellow workers in Australia clearly shows that *S. fasciata* is the carrier of dengue. Throughout the book specific names are rendered with capitals: *Plasmodium Malariae* (p. 185), *Myzorhynchus Mauritianus* (p. 191), *Micrococcus Melitensis* (p. 221), etc. All these second or species names should be written in small letters. Apart from some minor defects, such as those pointed out, the book contains a mass of interesting detail both as regards epidemics and other points. In an appendix will be found the fauna, flora, and conchology of the island, and a bibliography; not only so, but a photograph of the author adorns the frontispiece of the work.

NOTES ON BOOKS.

In an appendix to *Nursery Schools*⁵ the Board of Education's Regulations of 1918, including the important prefatory Memorandum, are reprinted. The bulk of the volume consists of seven papers (based on articles appearing originally in *Maternity and Child Welfare*) in which various writers discuss the ways in which the provisions of the Act may be made to bridge the gap which exists in child welfare work between the age of 1 or 2—when infant consultation centres cease to help—and that of 5. This gap, its dangers and their remedy, are allegorically depicted by the late Mr. Byam Shaw in an interesting frontispiece. Turning to the text, we find Miss Margaret Macmillan dealing inspiringly with principles and ideals and courageously with the question of finance. Miss C. E. Grant points out very clearly the evil features of the present infant school system; Dr. W. J. Howarth and Miss Grace Owen, B.Sc., contribute practical suggestions from the medical and educational points of view respectively, and the crucial difficulty—the training of the nursery school teacher—is fully discussed in a chapter by Miss Freda Hawtrey.

Rear Admiral STITT's little book on the *Diagnostics and Treatment of Tropical Diseases*⁶ has now reached a third edition. As when the second edition was published, less than a year ago, a very thorough revision was made, no material changes have been made in the third. The subject of trench fever has been rewritten, a number of changes have been made in paragraphs of various sections, and two new illustrations and a plate of the malarial parasites have been added. There are some new observations that have appeared, however, between the two editions, and as these are important it would have been better had they been incorporated. For example, in the account of schistosomiasis (page 422), no mention is made of the febrile invasion that has been recently noted in infections by *S. haematobium* and *S. mansoni*. Again, in the remarks on ova in faeces (page 503), it is stated: "It is in the faeces we examine either for the parasites or for their ova in connexion with practically all the flukes except the lung fluke and the bladder fluke"; but the latter are often found in the faeces, and the former are sometimes met with there also. There are some other similar statements throughout the book which require emending. New discoveries and new work on tropical medicine succeed each other with such rapidity at the present day that we can sympathize with any author for not getting them all collated for his new edition. The book is a very useful one and deservedly popular.

The latest addition to the Notable Trials Series is the *Trial of Hawley Harvey Crippen*,⁷ edited, with notes and an introduction, by Mr. FILSON YOUNG, who has previously shown his aptitude for this kind of task. It may be said that he has done the work well, though we wonder why he should take so much trouble to show that there is a spiritual side to the Crippen affair "which is good and heroic"; nor can we quite agree as to the "extraordinary human and dramatic interest with which the story is packed." Why Crippen murdered his wife, why he left any of the remains under the cellar floor, and why

when he had thrown the police off the scent he suddenly lost his nerve and bolted, will never be known for certain. To the medical reader, however, the main interest in this sordid story lies in the medical and scientific evidence, and Mr. Filson Young does not exaggerate when he speaks of the brilliant and laborious analysis which proved that those few pieces of flesh and skin had been part of a body which had contained a fatal dose of hyoscine. As for the suggestion that has been so often made, that Crippen was a qualified medical practitioner in the English sense of that phrase, it may be well to quote from the paragraph in *Truth Cautionary List for 1911*: "He had been engaged at one quack establishment or another for many years, having first come under the notice of the editor of *Truth* in connexion with the Drouet Institute. At the time of his flight from justice Crippen was in the employment of one of the largest quack advertisers in the kingdom, a man named Marr, who has carried on business under the aliases of Keith Harvey, Erasmus Colman, Ohrsorb, and the Aural Remedies Co., for the purpose of victimizing the deaf." There is no doubt that for twenty-seven years Crippen picked up a living by the practice of various low forms of nostrum-mongery.

MATERNITY HOMES AND HOSPITALS.

THE publication by the Ministry of Health of a *Memorandum on Maternity Hospitals and Homes*¹ is timely, for in many districts there is a movement to establish such institutions, and hitherto there has been no publication to which the promoters could be referred. The Memorandum is illustrated by plans for buildings of various sizes, to provide from 8 to 120 beds.

Maternity Homes.

The limit for a maternity home is put at from six to twenty beds; maternity hospitals having from twenty-five to fifty beds, or a greater number, will be required in the large towns. Maternity homes will be chiefly required in the smaller towns and rural districts. Their size must be determined by a consideration of the needs of the district. Homes will be needed also in outlying districts of large towns to supplement the maternity hospital. The opinion is expressed that while an ordinary domestic building may, without great difficulty, be converted into a maternity home for six or eight patients with a fairly satisfactory result, when the requirements are greater considerable difficulties will arise, among them the provision of adequate sanitary accommodation and facilities for isolation and separation. Such homes may have an out-patient department to serve as a maternity centre for the neighbourhood, and also as a centre for district nursing, district midwifery, and for the training of pupils and students.

Maternity Hospitals.

A maternity hospital, it is said, should in the same way become the centre of the midwifery service of the town and be made available for training. Such hospitals should be fully equipped for the treatment of all complications and disorders of pregnancy and labour, and for clinical teaching. Their primary purpose should be to provide for abnormal or difficult cases, but not to the exclusion of straightforward confinements. Each should have an out-patient department for the treatment of patients referred by doctors or midwives, or sent from antenatal clinics.

Medical Staff.

The medical staff of a maternity hospital used as a training hospital for students must be competent to teach as well as to conduct the ordinary medical duties of the institution. Such a hospital of twenty-five or thirty beds, or over, especially when admitting mainly abnormal cases, should have one or more resident medical officers, as well as a visiting medical staff, on which paediatrics as well as obstetrics should be represented. A maternity home will not as a rule require a resident medical officer, but two or more medical practitioners having special experience of midwifery should be available when required. Normal cases should be treated by the nurse midwives on the staff unless the patient desires to be treated by her own doctor. It is suggested that one woman doctor should be associated with a maternity hospital or home whenever possible, and

⁷ *The Trial of Hawley Harvey Crippen.* Edited, with Notes and Introduction, by Filson Young. Notable Trial Series. Edinburgh and London: W. Hodge and Co., Limited. 1920. (Demy 8vo, pp. xxxv + 211; 7 illustrations. 10s. 6d. net.)

¹ H.M. Stationery Office. Through any bookseller, price 9d. net.

also that a medical officer attached to a maternity home or hospital should have held a resident post in an obstetric hospital.

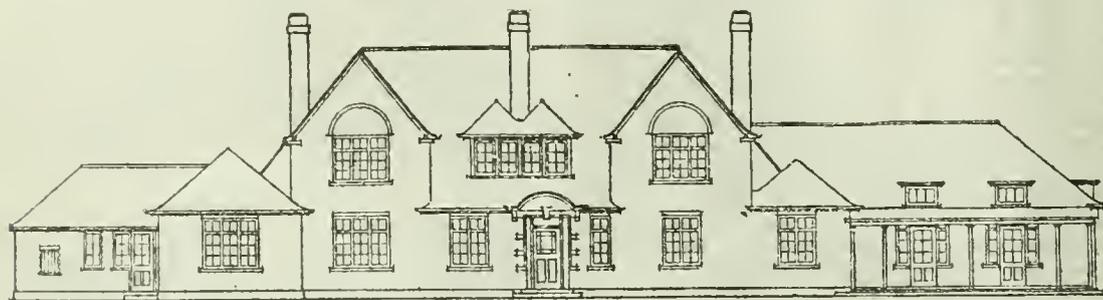

Nursing Staff.

It is recognized that adequate trained supervision is essential, and it is laid down that the matron should be a trained nurse and an experienced midwife, and that the sisters should also have had training in general nursing as well as midwifery. The number of nurses will depend on whether pupil midwives are taken, but as a general estimate it is said that the minimum staff should be such as will provide on the average one nurse for every three mothers and their babies by day, and for every eight to ten mothers and their babies by night. Small homes as well as maternity hospitals must be provided with a labour ward or wards, for which a special nursing staff will be needed. It is urged that all maternity institutions should have a detached isolation block, or at least an isolation or separation room. The practice of treating cases of puerperal fever in ordinary isolation hospitals is deprecated; such cases should remain under the supervision of the maternity hospital, for skilled obstetrical treatment is needed, and the

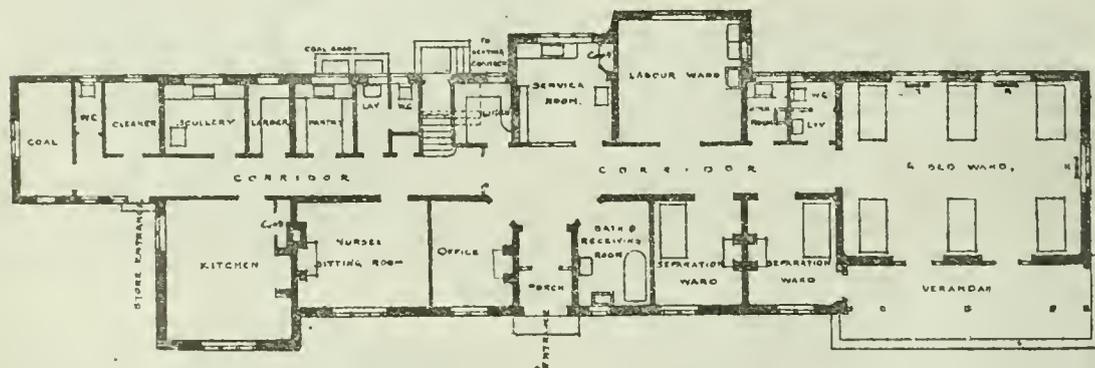

On the ground floor of the central building is a labour ward and two separation wards, as well as a nurses' sitting-room and office. The first floor provides bedrooms for matron and nurses. A plan is given also for a maternity home to provide twenty-two beds comprised in a single building. It contains on the ground floor ordinary offices, kitchen, a nurses' dining room, a nursery, a ward with four beds, two wards with two beds, two wards with one bed each, a labour room, and a receiving room. On the first floor there is a ward with four beds, three with two beds, and two with one bed each; a labour room is shown on the one side of the building, and on the other rooms for matron, sister, and maids; on the second floor is a series of bedrooms for nurses.

An elevation and plan for a one-story double pavilion with thirty beds to form part of a maternity hospital shows two labour wards, a ward with eight beds, another with six, two with four beds, two with two beds, a separation ward with two beds, as well as a receiving room and service room. This is apparently intended to form part of a larger hospital, for which a sketch plan is provided, showing four pavilions, providing altogether 120 beds, with

MATERNITY HOME FOR EIGHT BEDS.

Elevation.

Plan of ground floor. Scale $2\frac{1}{8}$ inches to 60 feet.

midwives should observe the course and conduct of the septic as well as of the normal cases. It is recognized, however, that a special nursing staff, as well as separate accommodation, will be required, and the smaller maternity homes, therefore, are not encouraged to retain such cases. While all institutions should be prepared to admit normal cases a maternity hospital should be fully equipped from the point of view of nursing and treatment to deal with all types.

Site.

It is recommended that a maternity home should be on a secluded site, with a garden, but yet reasonably central and easily accessible. In towns the site should be fairly central, but with quiet and clean surroundings, away from a road with heavy traffic. The area of a site for a hospital of twenty to thirty beds should be not less than two acres; for a home or hospital of twelve to eighteen beds not less than an acre and a half.

Buildings.

A plan, with elevation, is given for a self-contained maternity hospital for eight beds, and we reproduce the elevation and the ground floor plan. The building consists of a two-story building with two wings; in the wing on the one side is a ward for six beds opening on to a veranda, in the other wing a kitchen and domestic offices are provided.

vacant space for the erection of one other pavilion, which would raise the total to 150 beds. It is recommended that the nurses' quarters should form a separate unit, and that a separate isolation block should also be provided for a large hospital. Sketch plans are given for both of these buildings, and also for a combined children's hostel and maternity and child welfare centre in one building. The hostel part would provide a night nursery and a day nursery, opening on to a veranda; the maternity and child welfare part, a waiting room, doctors' room, and also a room for dental treatment.

The area of wards to contain patients with their infants should, assuming ventilation to be adequate, be calculated on the basis of 96 square ft. per bed, with a height of 10 ft., giving 960 cubic ft. per bed. In the case of lying-in wards to contain only mothers at night, the area per bed may, it is thought, be reduced to 80 square ft., and in the case of wards to contain antenatal cases only to 60 square ft., with the same height of room in each case. An ordinary labour room, it is said, should be not less than 14 ft. by 14 ft. It is noted that the labour room must be suitably warmed, and for this purpose, as for other rooms in the hospital, radiators or suitable gas fires are to be preferred to coal fires. It is noted also as desirable that in every maternity home there should be a separate room available as a second labour room in an emergency.

British Medical Journal.

SATURDAY, FEBRUARY 28TH, 1920.

THE FOOD SUPPLY OF GERMANY.

IN August last we published an article giving some account of a report on the food position in Germany made by Professor E. H. Starling, F.R.S., with the assistance of Mr. Guillebaud and Mr. McDougall, after a visit to that country. The significance of the statistics it contained was pointed out. Professor Starling, in a paper read at a meeting of the Royal Statistical Society on February 18th, on the food supply of Germany during the war, did not give much additional statistical information, but took the opportunity of recording his final judgement on events which will deeply interest the historian of civilization.

The material facts are these: Before the war the food supply of Germany was abundant; it is probable indeed that the peace time estimates of the Imperial Statistical Department were exaggerated, partly because their commissioners, who were particularly competent farmers, judged others by themselves, partly because of the competition of local representatives to put the best possible face upon their results. Further, in estimating the effects of a stoppage of imports, the consequences of a loss of manures and concentrated fodders were not sufficiently attended to. These disadvantages might have been predicted; but, in addition, unpredictable disasters occurred in consequence of the bad weather conditions which, even in normal times, must have impaired the agricultural yield, and in the state of war were especially prejudicial.

But even when all these discounts are allowed there should still have been available some 3,054 calories per "man" in 1917-18. Such a diet, "if evenly and equitably divided according to the actual needs of the population, should have been sufficient to keep them from semi-starvation, although the low content of fat would have given rise to discomfort, and the protein, which was also necessarily low, might not have been enough to maintain full mental and bodily activity." But no such equitable distribution took place. The producing class consumed their full peace-time ration and did not even release the surplus for equitable distribution. From a quarter to a third of the surplus was disposed of at enormous prices in illicit trade. The result was that the farmers thrived, the very rich ate as much as they chose, and the urban poor and middle classes starved.

In so far as lack of food brought Germany to her knees, the German nation may attribute its ruin to the lack of patriotism of its own citizens. There is a grim irony in the thought that the very nation which made of nationalism a god, which bragged of its patriotism as nobler than that of all other peoples, should be ruined by class and individual selfishness. We need not, however, attribute the greater efficiency of our system of food control and distribution altogether to our superior civic virtues or genius for organization. To control the apportionment of food supplies, the bulk of which comes from abroad to a small number of great ports, is a very much easier task than to deal with home producers. A secondary inference is that, if the Germans had been as patriotic as they supposed themselves to be, the war could not have been ended, or at least could not have been ended in 1918, by mere famine.

With regard to the future, we cannot do better than quote Professor Starling's words: "As might have been expected, three years on a diet insufficient as to quantity and quality, indigestible, tasteless, and monotonous, had a marked influence on the vitality and efficiency of the great bulk of the urban population, which finally resulted in that changed mentality which rendered impossible any further efforts of attack or even resistance. In the condition of dull apathy and mental prostration resulting from the deprivation of food the course of the war no longer seemed of importance. Food filled their thoughts by day and their dreams by night, and the only desire was to end the war by any possible means that might lead to a slackening of the blockade and the free entry of food into the country. No means could have been more effective in breaking the spirit of a nation, which had been regarded as a danger to European civilization. Nor need we believe that the effects will be only transitory. Many years with plentiful supplies of food must elapse before the previous conditions of nourishment and health can be restored, and this recovery will be rendered difficult by the diminished fertility of the soil, and the impossibility, for a long time to come, of raising again the industrial productivity to the height necessary in order that the requisite supplies can be obtained by purchase from foreign countries. It is not surprising, therefore, that the German people, essentially docile and industrious, sick of war and of the rulers who led them into a painful enterprise, are seeking only methods by which they can restore to some extent their economic conditions and the health and comfort of the population. It will be long before this nation will be in any condition to be regarded again as a menace to the peace of Europe."

This passage starts a train of thought which is not particularly reassuring. Is it not possible that we too, although not so far advanced along the road to destruction as Germany, are nevertheless treading the same path? The problem of feeding a nation such as ours mainly dependent upon overseas supplies, burdened with debt and distracted by domestic controversy, is at least a very grave one. We should like to see some indication that this really vital problem is receiving the attention it deserves. The sort of evidence that has been tendered by both sides to the Commission inquiring into the standard of living of dock labourers is sufficient proof that we have much to learn. Before the armistice Professor Starling and other scientific men pointed out how radically defective was our knowledge of national dietetics, and on several occasions attention was forcibly drawn to the matter in our columns. Since then hardly any additions have been made, and nothing more has been heard of the proposal to create a national institute of research into the problems of nutrition. We should like to feel sure that the ends that institute was intended to compass will really be attained.

THE DOGS' PROTECTION BILL.

THE Dogs' Protection Bill, entitled "A Bill to Prohibit the Vivisection of Dogs," introduced by Sir Frederick Banbury (City of London) and supported by Sir John Butcher, K.C. (York), and Mr. Frederick Green (Leicester, West), reproduces the text of the bill of last year as it left the Standing Committee on April 3rd, 1919.

The course of the bill of 1919 was fully reported in our columns at the time. As originally introduced by Sir Frederick Banbury last year, the penalty

clause proposed that a person guilty of an offence against the provision of the first clause of the bill, which would have forbidden any experiment of a nature causing or likely to cause pain or disease to any dog, either with or without anaesthetics, should for a second offence be liable to imprisonment for three months, and for any subsequent offence to imprisonment for one year. The penalty clause as amended in Standing Committee omitted special penalties, and provided that a person violating the enacting clause should be considered guilty of an offence under the principal Act, and punished accordingly. When the bill as amended by the Standing Committee came up in the House of Commons on the report stage on May 23rd, Sir Hamar Greenwood moved an amendment on behalf of the Government to insert the words "except as hereinafter provided" in the first clause. There was a long debate, during which Sir Hamar Greenwood's proposals were supported by, among others, Mr. Rawlinson, Captain Elliot, and Sir Auckland Geddes. When winding up the debate Sir Hamar Greenwood, speaking not only as a representative of the Government but as "a willing champion of the honour of the noble profession of medicine," appealed to the House to support the amendment. To pass the bill as it stood would, he said, cast an undeserved stigma on that profession; he invited the House to make it possible for experiments to be continued because in the past they had done great good, and would in the future, he believed, do even greater good. On a division the amendment was agreed to by 147 to 69.

Another Government amendment was then accepted without a division, omitting the words in the first clause forbidding any person or place to be licensed for the purpose of performing experiments on dogs in any circumstances, and providing that such experiments might be performed on a special certificate containing a statement of reasons why the object of the experiments would necessarily be frustrated unless performed on a dog, and that no other animal was available for such experiment. The title of the bill was altered also, and as thus amended by the House of Commons the bill came up for third reading on June 27th, when its adoption was moved by Sir Frederick Banbury. Sir Watson Cheyne moved the rejection of the bill, inviting the House to decline to proceed further with a measure which would impose an unnecessary and vexatious obstacle to medical research. The motion, which was seconded by Sir Philip Magnus, who had throughout taken an active part in opposing the bill, was carried, and the bill was rejected by 101 votes to 62, but not before Sir Frederick Banbury had appealed to the House to accept it, on the ground that the bill had been greatly changed during the report stage on May 23rd. In the interval the Ministry of Health had been established, and speaking as Minister of Health Dr. Addison said that the Government, after fully and carefully considering the measure, recommended the House to reject the bill. He enumerated the precautions enforced under the principal Act; certificate (A) provided that the animal experimented upon must be fully anaesthetized and remain under the anaesthetic. That provision might be suspended by certificate (B), under which the animal might be allowed to recover from the anaesthetic. Further, in the case of a dog another certificate (E) must be obtained. It was not, he said, to the interests of science or for the promotion of the health of the people that the bill should be passed, even in its present form. The damage which would have been done had been minimized as much

as possible on the report stage (May 23rd), but the Government still felt that the words as they stood would make research difficult and embarrassing, and so be contrary to the best interests of the well-being of the people. On that account the Government had no hesitation in asking the House to reject the bill, and, as already stated, it was rejected by a substantial majority.

Sir Frederick Banbury now brings up the bill again in exactly the form in which it left the Standing Committee, before the Government amendments were introduced. This fresh attempt to impede research in medicine and preventive medicine will be opposed as vigorously as last year, and Sir Frederick Banbury has placed himself, as it appears to us, in opposition not only to public opinion, but to the Government and the House of Commons. Sir Frederick Banbury was very angry when Dr. Addison said that he had concealed facts with regard to the safeguards against possible cruelty contained in the provisions of the principal Act, but he accepted the substituted phrase "failed to mention." The opponents of research habitually not only fail to mention but deliberately conceal benefits derived from it.

About the opinion of the medical profession on the matter there can be no doubt whatever. As an example of what is really thought we may recall the resolution adopted at the Clinical and Scientific Meeting of the British Medical Association in London last April. It was adopted at a conjoint meeting of the Sections of Medicine and Preventive Medicine and Pathology, over which Colonel Haven Emerson, of the Medical Corps U.S.A., presided. It was proposed by Sir William Osler, seconded by Professor C. J. Martin, Director of the Lister Institute, and supported by Sir George Makins, President of the Royal College of Surgeons of England. In putting it to the meeting Colonel Emerson said that though the bill was British the success of faddists here would encourage their kind in other countries. The same resolution was put to the Section of Surgery by its chairman, Sir Anthony Bowlby, on the proposition of Professor Bayliss, seconded by Dr. H. H. Dale. At both these meetings it was carried unanimously. The resolution affirmed that the possibility of the passage through the House of Commons of a bill to prohibit experiments on dogs was viewed with dismay, and proceeded to point out that the anatomical structure and omnivorous habit of the dog, together with the fact that it can be kept in health and comfort under the conditions imposed by laboratory work, render the larger sort the only available subject for experiment in important fields of physiological and pathological investigation. The prohibition of experiments upon dogs, in the opinion of the meeting, would have the deplorable effect of hampering the progress of medicine, and of rendering Britain alone, among the civilized nations of the world, unable to contribute to progress in a department of medical research in which it has hitherto played a distinguished part.

Sir Frederick Banbury's bill is down for second reading on Friday, March 19th, as the second order. The first order is the Shops (Early Closing) Bill, introduced by Mr. F. Briant. It may happen that this measure will absorb the time of the Friday sitting, and in any case it seems improbable that with discussion Sir Frederick Banbury will get a second reading for his bill within this sitting. If he does not its prospects of going to Grand Committee will be distinctly unfavourable; but it must be remembered that he is a past master of strategy and procedure, and that last year the bill he then brought forward made unexpected progress.

HARD HIT.

THE medical War Emergency Fund is administered by the Royal Medical Benevolent Fund, but it is a distinct fund. It is not a charity, but exists to help men to carry on who have suffered through the service they have given to the country during the war—in which the very existence of the country was at stake. The position may be expressed in the terms in which the purpose of the special parliamentary grant in aid of universities, colleges, and medical schools are set out—namely, "to meet the need of special assistance in order that they may, as far as possible, resume their full work under favourable conditions, and may not be hampered by extraordinary expenditure involved by the prolonged interruption of their activities and development caused by the war." Let it be repeated that the fund is not a charity, but an attempt to discharge the country's debt to men who have served it, and that its purpose is to help them to get back to their active part in the country's life. The fund has recently received a grant from the National Relief Fund. The medical War Emergency Fund grants will, as before, be limited to persons who have held commissions in the medical services during the war, but the contribution from the Prince of Wales's Fund will enable the committee of management to make more liberal allowances, especially for the education of children, the payment of insurance premiums, and of interest on loans. We are given to understand that the medical men for whose benefit this war tribute exists are not applying as they should for assistance in these three respects. Those who have hitherto failed to do so are invited to communicate with the secretary of the War Emergency Fund, 11, Chandos Street, London, W.1.

SPECIAL DIPLOMAS.

THE change which is coming over the organization of the practice of medicine in its several departments or specialties must be obvious to everyone who will compare the present with even the recent past. The change began before the war, and we are not sure that it can be said to have been accelerated by it, but the needs of local authorities, due only in the smaller part to State regulations and legislation, have undoubtedly intensified it. The D.P.H. has become practically essential for all undertaking public health work. Long before the war the need of specialization in tropical medicine and hygiene for the members of the medical services of tropical colonies led to the establishment of special tropical medical schools, and eventually to the institution of a diploma in tropical medicine and hygiene. The need for a similar diploma in psychiatry was for a time met by the certificate of the Medico-Psychological Association of Great Britain and Ireland, but it will be replaced eventually by diplomas granted by the universities and examining bodies. The same sequence of events is occurring with regard to tuberculosis officers and radiologists, and the policy will, without doubt, presently be extended. Thus we find that in the Ministry of Health's *Memorandum on Maternity Homes and Hospitals*, of which we give some account at p. 299, it is proposed that a medical officer attached to a maternity home or hospital should have held a resident post in an obstetric hospital; and this in all probability will eventually lead to the demand, and before long to the institution, of an advanced diploma in obstetrics for graduates. It is understood that the licensing bodies are disposed to meet the need which appears to be arising out of the new activities of the Ministry of Health and its related local authorities. Already the University of Cambridge has established diplomas in psychiatry and in radiology, and we shall be surprised if the Conjoint Board of England does not presently institute diplomas in these and other specialties as the demand grows. For some few years past Oxford has granted a diploma in ophthalmology. One moral obviously is that the need for post-graduate, or,

as we should prefer to say, graduate medical schools must steadily increase. For such instruction in tropical medicine provision is made by the London School of Tropical Medicine and the sister school in Liverpool; at the Maudsley Hospital, under the direction of Sir Frederick Mott, a course of instruction, including lectures and practical work, has been instituted, based on the requirements for the Cambridge diploma in psychological medicine. Courses for the diploma in radiology instituted by the same university are being given in Cambridge and London. These enterprises are signs of the times.

SMOKE ABATEMENT.

THE Ministry of Health has resolved to make further inquiry into the smoke nuisance. There have been many such inquiries and some good has followed, but as the recent experience of London—which for several mornings this week has been smothered in a yellow fog almost as bad as a typical November infliction—shows, there is still much to be done. The law as it stands gives considerable power to check pollution by factories, and when there are a sufficient number of public-spirited persons in a district to enforce it much can be done; but it leaves the pollution of the atmosphere by domestic fires untouched. As to the relative importance of pollution by factories and domestic fires there is a difference of opinion, but the ordinary observer is driven to the conclusion that the factory chimney is not everywhere the chief offender. The Ministry of Health in another connexion has recently stated that open fires at the present time are expensive luxuries, wasteful in fuel, the cause of unnecessary noise and dust, and ineffective as sources of heat. At the present time the best substitute is gas; electricity, convenient and clean as it is, must be put aside owing to the cost of installation and current. Much more progress would have been made in using gas for cooking had the gas engineers realized that a gas cooking stove does not warm the kitchen, and that on this account people who use the kitchen much prefer the coal cooking range. This has often been pointed out, but nothing is done. In 1914 the then President of the Local Government Board (Mr. Herbert Samuel) appointed a Departmental Committee to inquire into the subject of the pollution of the air by smoke and other noxious vapours, and it had made some progress in taking evidence when the war broke out, and its proceedings were discontinued. The new committee, which has a similar reference, will have Lord Newton as its chairman; the other members are Captain Hamilton Benn, C.B., D.S.O., M.P., Professor J. B. Cohen, F.R.S., of Leeds, Mr. W. S. Curphey, chief alkali inspector Ministry of Health, Sir John Lithiby, late legal adviser to the Local Government Board, Mr. J. F. McCabe, of the Local Government Board in Ireland, Mrs. Gilbert Samuel, Mr. E. D. Simon of Manchester, Bailie W. B. Smith of Glasgow, and Mr. F. J. Willis, C.B., chief assistant secretary, Ministry of Health. The secretary is Mr. E. C. H. Salmon, to whom all communications should be addressed at the Ministry of Health, Whitehall, S.W.1.

EUSOL IN SUBTERTIAN MALARIA.

THE beneficial results that attended the intravenous administration of eusol in septicaemia inspired Lieut.-Colonel P. S. Vickerman to test it in the treatment of subtertian malaria, with highly gratifying results. Some cases were cured by one injection, others required two or sometimes three.¹ In none of the cases was quinine used whilst the patient was under treatment, nor did they require it afterwards. The number of injections had no apparent relation to the number of rings and crescents found. During treatment the crescents seemed to disappear first and the rings rather later. It was found

¹ *Journal of the R.A.M.C.*, January, 1920

to be essential that the esul should contain at least 5 per cent. of available hypochlorous acid; it should be freshly prepared, boiled, filtered, or distilled water being used, with bleaching powder containing not less than 22 per cent. of free chlorine. The best results were obtained with the "Eupad" prepared at Edinburgh University and sent out in stoppered bottles. The technique of injection is very simple. Using an ordinary intravenous saline apparatus, the funnel and tube are first filled with saline and the needle introduced into the vein, and then 40 c.cm. of well filtered esul are run in, sufficient saline being afterwards poured into the funnel to ensure that all the esul enters the vein. In a case of malaria a typical attack of fever with rigor follows on the same day, and then the temperature settles down at once, although the organisms may not all disappear from the blood until ten days afterwards. In the meantime the patient feels well and has no fever attacks. Colonel Vickerman has also found esul very efficacious in the old chronic type with large spleen and pronounced cachexia and anaemia, often showing very few or no parasites in the blood microscopically. He considers that 60 c.cm. of esul is the maximum that can be given with safety.

THE NAVAL MEDICAL SERVICE.

DURING the past few months reference has been made, both in the JOURNAL and SUPPLEMENT, to the work of the Naval Subcommittee appointed by the Naval and Military Committee of the British Medical Association to examine and report on the new regulations for pay and retirement of naval officers. The chief matter before the subcommittee has been the position in which senior surgeon commanders find themselves under the new scheme. The new pension for these officers works out at less than 10 per cent. above the old rate fixed more than forty years ago. There is even a possibility of a deduction of 20 per cent. from this increase, giving finally an actual reduction of pension by some 10 per cent. In its letter to the Admiralty on December 2nd, 1919, the Association made representations also as to the new ages for compulsory retirement, and the consequent loss of full-pay service and chance of promotion to higher rank. We recorded last week that the Admiralty has replied declining to deal with the case of medical officers apart from the rest of their comrades in the other branches of the service. In this connexion we are asked to draw the attention of retired naval surgeons to the fact that an Association of Retired Naval Officers exists to safeguard the interests of naval officers and their dependants, and that its policy includes an appeal that the whole question of pensions shall be reopened and reconsidered. The committee of this body is composed of representatives of the various branches of the service. Surgeon Captain E. H. Meaden, C.M.G., R.N. (retired), who is the medical member, informs us that he is bringing forward more especially the injustice done to the senior surgeon commanders. The Naval and Military Committee of the British Medical Association has referred the Admiralty's letter to the Naval Subcommittee with certain suggestions; the subcommittee feels that this matter should not be left where it is; and the Naval and Military Committee is about to consider it further with a view to taking steps to bring it again to notice. Some additional information has been received within the last few days, but we would repeat the invitation to any naval medical officer who considers that he is seriously affected to send particulars to the Medical Secretary of the British Medical Association, 429, Strand, W.C.2.

OXFORD MEMORIAL TO SIR WILLIAM OSLER.

A PUBLIC meeting will be held in the Lecture Theatre, The Museum, Oxford, on Saturday afternoon, March 6th, at 3.30 o'clock, to consider what steps should be taken to perpetuate in some appropriate manner the memory of the

late Sir William Osler, Bt., Regius Professor of Medicine in the University of Oxford for the past fifteen years. The notice of the meeting is signed by the teachers in the Medical Faculty at Oxford, including Professor Arthur Thomson (anatomy), Professor G. Dreyer (pathology), Professor C. S. Sherrington (physiology), Professor J. A. Gunn (pharmacology), Dr. William Collier (Litchfield lecturer in medicine), Dr. H. C. Bazett (Welsh lecturer in clinical physiology), the lecturers in pathology, applied anatomy and morbid anatomy, and the reader in ophthalmology. The meeting will be attended by the Vice-Chancellor, the heads of colleges, Bodley's librarian, and the treasurer of the Radcliffe Infirmary. The action taken in Oxford will, we believe, command the approval of the profession generally, for William Osler was a man who had not only held a commanding position in medicine in this country during the fifteen years of his work here, but had also won the affectionate regard of members of his profession of all ages and schools. Communications should be addressed to Dr. J. A. Gunn, Professor of Pharmacology, The Museum, Oxford, who is acting as interim secretary.

PENSIONERS' RECORDS.

THE Ministry of Pensions has prepared a pensioner's record card (M.P. x9) in respect of every pensioner for whom treatment at a hospital is arranged. This should prove of much value to the medical officer in charge of the case, as on it will be entered a brief but accurate record of the man's past medical history. The card will be issued through the Commissioners of Medical Services to the secretaries of hospitals which are not under the Ministry's control but which treat pensioners. Besides giving a summary of the pensioner's medical history, spaces are provided for the findings and recommendations of medical referees. The record card is for the information of medical officers of hospitals, but is not intended for their clinical notes; it should be kept in the special envelope provided. A medical case sheet (M.P. x10) has also been designed to furnish medical officers with a convenient means of keeping current notes of progress and treatment. As the value of each pensioner's medical record depends largely upon its continuity, the Ministry of Pensions expresses the hope that medical officers will regularly write short notes of the cases under their care in the spaces provided. These documents—the record card, the case sheet, and the envelope with instructions—seem to us well designed for the purpose in view. In return for the valuable information given him on the card the medical officer of the hospital may not unreasonably be expected to make brief notes of progress and treatment upon the case sheet. All three documents, on completion, are intended to be returned at once to the Deputy Commissioner of Medical Services for the area.

BRITISH HONOUR FOR PROFESSOR TUFFIER.

THE announcement that the King has appointed Professor Tuffier to be an Honorary Knight Commander of the Order of the British Empire will give great pleasure to the profession in this country. Professor Tuffier is one of the most distinguished of French surgeons and is held in the highest esteem by British surgeons, not only for his learning and skill, but also for his character, in which geniality and strength are blended. During the war he rendered conspicuous services to the medical corps of the French Army, and his advice was of the utmost value in guiding the organization of the surgical hospitals from front to base. But the King's act is doubtless a recognition of Professor Tuffier's work for the wounded British officers and men brought into Paris during the early phases of the war and of his kindly and untiring efforts to make the Inter-Allied Surgical Conferences a success. It will be regarded with general satisfaction by all those who enjoyed the pleasure and privilege of working in

association with him. The appropriate insignia have been forwarded to His Majesty's Ambassador at Paris for presentation.

THE INTERNATIONAL SOCIETY OF SURGERY.

The fifth meeting of the International Society of Surgery will be held in Paris from July 29th to 23rd, under the presidency of Professor W. W. Keen of Philadelphia. The following subjects will be discussed: (1) Surgery of the heart and great vessels. (2) Treatment of tumours by x rays and radium, introduced by Dr. Neville S. Finzi. (3) Analysis of the blood and biological reactions in surgical affections. (4) Treatment of fractures of the thigh, introduced by Major Maurice Sinclair, C.M.G., D.S.O., R.A.M.C. (5) Prophylaxis and treatment of tetanus, introduced by Professor S. L. Cummins, C.B., C.M.G., Colonel A.M.S. A tour of seven days has been organized to visit the battlefields, at an inclusive cost of 815 francs a person. Surgeons who wish to be nominated for election to the society are requested to communicate with Sir D'Arcy Power, K.B.E., F.R.C.S.Eng., 10A, Chandos Street, Cavendish Square, W. The subscription is 50 francs.

CHADWICK LECTURES AND MEDALS.

LIEUT.-GENERAL SIR JOHN GOODWIN, K.C.B., Director-General A.M.S., will next month give three Chadwick public lectures on military hygiene in peace and war. The first will deal with army hygiene prior to the recent war, the second with army hygiene during the recent war, and the third with the future of army hygiene. The lectures will be given at the Royal Society of Arts, John Street, Adelphi, on Mondays, March 8th, 15th, and 22nd, at 5.15 p.m. The Chadwick trustees have awarded Chadwick gold medals and prizes of £100 to Surgeon Commander Edward L. Atkinson, D.S.O., R.N., and Brigadier-General W. W. O. Beveridge, C.B., D.S.O., A.M.S., for services in promoting the health of the men of the navy and army. The nomination for these presentations has been made by the Directors-General of the naval and military medical services respectively.

The honorary Fellowship of the Society of Medical Officers of Health has been conferred on Brigadier-General Sir William Heaton Horrocks, K.C.M.G., C.B., M.B., D.P.H., "in recognition of his invaluable services as chief of the Army Sanitary Department throughout the great war"; and on Dr. Henry Edward Armstrong, formerly Medical Officer of Health for Newcastle-upon-Tyne, "for his long and distinguished services in connexion with public health administration and the advancement of sanitary science."

Since the beginning of this year the Registrar-General's weekly returns of deaths from influenza in the ninety six great towns of England and Wales have been as follows: 52, 73, 62, 85, 66, 93, 109, 161. The figures for London, which are included in the foregoing totals, have been 19, 16, 19, 24, 15, 20, 25, 37.

On January 20th the second centenary of the death of the famous Roman physician Giovanni Maria Lancisi was celebrated in the hall of the Bibliotheca Lancisiana in Rome. Marchiafava, as official orator, pointed out that Lancisi was the herald of many modern discoveries in the fields of malaria, syphilis, and alcoholism.

The first general meeting of the association formed by the amalgamation of the Fellowship of Medicine and the Post-Graduate Medical Association was held last week and a general council formed, nominated partly by various medical schools and hospitals and partly from the original council of the Fellowship of Medicine. The first meeting of the general council will be held on March 5th for the election of officers and the executive committee.

Medical Notes in Parliament.

Census.—Dr. Addison announced on February 18th that he hoped shortly to introduce a bill for the census of next year.

The Registrar-General's Department.—Dr. Addison stated, on February 18th, that the reorganization of the Registrar-General's Department had been receiving close attention, but no increase in the statutory fees payable by the public was contemplated. It would in any case require legislation.

The Dogs' Protection Bill.—The bill to "prohibit the vivisection of dogs," introduced into the House of Commons by Sir Frederick Banbury, with the support of Sir John Butcher and Mr. Frederick Green, is the second order of the day for March 19th. The first order of that day is the Shops (Early Closing) Bill, introduced by Mr. Briant, which may or may not occupy a large part of the session. The text of the Dogs' Protection Bill is as follows:

A Bill to Prohibit the Vivisection of Dogs.

Be it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. *Prohibition of Experiments upon Dogs.*—Notwithstanding anything in the Cruelty to Animals Act, 1876 (hereinafter referred to as "the principal Act"), it shall be unlawful to perform any experiment of a nature calculated to give pain or disease to any dog for any purpose whatsoever, either with or without anaesthetics, and no person or place shall be licensed for the purpose of performing any such experiments.

2. *Penalties.*—Any person performing or assisting or taking part in performing any such experiment on any dog shall be guilty of an offence against the principal Act and punishable accordingly, and the provisions of this Act shall have effect as though they formed part of that Act.

3. *Short Title.*—This Act may be cited for all purposes as the Dogs' (Protection) Act, 1920, and the principal Act and this Act may be cited together as the Cruelty to Animals Acts, 1876 to 1920.

Experiments on Animals.—In reply to Sir Frederick Banbury, the Home Secretary said that the form of the returns relating to experiments on animals would be considered in due course. He hoped it might be possible to give nearly the same information as was given before the war, but he must have regard to the requirements of the Select Committee of the House on Publications.

Maternity Homes.—In reply to Mr. Clough, Dr. Addison said that his department had for some time pressed upon local authorities, both in general circulars and in individual letters, the importance of providing and maintaining maternity homes, and had obtained Treasury sanction for a grant of half the approved expenditure on these purposes. During the last year or so about twenty-five such homes were established by municipal authorities, and about twenty by voluntary bodies, who as a rule received financial assistance from local authorities. Many similar homes had been planned, and were likely to be established in the near future. (An account is given at page 299 of the Memorandum issued by the Ministry on the planning and organization of maternity homes and hospitals.)

Proposed Dental Legislation.—Asked by Mr. Raffan, on February 19th, whether legislation would be introduced this session to carry out the recommendations of the Departmental Committee on the Dentists Act, 1877, Dr. Addison said it was hoped to introduce legislation during the session, but he could not yet make a definite statement.

Retired Naval Officers' Pensions and Income Tax.—Mr. Long, in answer to Rear-Admiral Adair, on February 18th, said that retired naval officers who were called out during the war were not eligible to count such service for increase of retired pay, but, in lieu thereof, were granted a bonus of 25 per cent. upon their full pay during service. All such officers, however, were eligible to have their retired pay in respect of service before retirement re-assessed upon the revised scale introduced last year. The Government had decided that as from April 1st next income tax was to be charged on the assessable service emoluments of naval officers at the ordinary rates applicable to the rest of the community. The principle was decided upon when the new increased rates of pay were sanctioned. Viscount Curzon asked whether in Admiral Halsey's report it was recommended that if the service rate of income tax were no longer to be charged the question of pay would have to be reconsidered. Mr. Long replied that when the question was finally considered that recommendation was not adopted. Sir E. Carson put it that in some cases the income tax would nearly swallow up the increased pay. Mr. Long did not accept this, and said that new rates always at first affected some old conditions.

Precautions against Influenza.—In reply to Lieut.-Colonel Raw, Dr. Addison, on February 23rd, said there had been a slight increase in the number of deaths from influenza during recent weeks and a few outbreaks in schools and other institutions, but otherwise there was no evidence of unusual prevalence of the disease in this country comparable to the definite new waves of influenza which were occurring in American cities and on the Continent. The Ministry of Health kept a constant watch on the occurrence of influenza at home and abroad. Information was derived from returns, from consular agents, and other

official sources all over the world. Information as to the prevalence of the disease at home was obtained from the weekly return of influenza mortality in the ninety-six great towns, issued by the Registrar-General, and from returns of cases of acute influenza pneumonia, the notification of which was now obligatory in England and Wales. Returns of cases of influenza were also furnished voluntarily every week by a number of schools, institutions, and representatives of industrial firms throughout the country. All data on the subject, statistical as well as scientific, came before an Influenza Committee, a medical standing committee of the Ministry of Health, holding frequent meetings, and on which sat medical representatives of various Government departments. A vaccine against influenza was now being issued on demand to medical officers of health for distribution free of charge among medical practitioners. All practicable means of protecting the country from the introduction of influenza through the ports had been considered. The knowledge and experience accumulated during recent epidemics had been collected and issued to local authorities. A memorandum had been issued to local authorities explaining the measures (both administrative and personal) which were deemed best calculated to prevent the spread of the disease and lessen its mortality. A popular leaflet had also been issued and widely circulated to local authorities setting out the best measures of guarding against infection, with advice to patients as to the best known means of securing a speedy return to convalescence and the avoidance of those complications which constituted the special danger of influenza. Special inquiries were being pursued in selected districts into such questions as immunity, the effects of overcrowding, and incidence according to age. In certain of these areas arrangements had been made, in consultation with the Medical Research Committee, for the co-operation of medical officers of the Ministry, medical officers of health, and bacteriologists, in the investigation of the origin, the spread, and the best means of combating the disease.

Ministry of Health Expenditure.—Dr. Addison, in reply to Mr. Godfrey Locker-Lampson on February 18th, said that the recent establishment of the Ministry of Health obviously made it impossible to reduce the staff. Every effort, however, had been made, to the satisfaction of the Treasury, with whom the detail of the organization was worked out, to secure the utmost economy in the staffing arrangements.

Vaccination Statistics.—Mr. Charles Edwards, on February 18th, asked the Minister of Health if he were aware that more than half the children born at the present time were withheld from vaccination; whether the proportion of unvaccinated children of each year's birth was steadily increasing; whether nearly 40 per cent. of the births each year were exempted from vaccination by the statutory declaration of objection by the parents; and whether in the circumstances the compulsory clauses of the Vaccination Acts should not be repealed. Dr. Addison replied that the figures were approximately as stated. He was, however, of opinion that the repeal of the compulsory clauses would result in a still larger proportion of children remaining unvaccinated, and thus the whole community would be less protected. Small-pox was prevalent at the present time in various parts of Europe, Canada, and America, and in view of the risks of the introduction of the disease into this country he was not prepared to take any action which would tend to increase the number of persons in this country who were unprotected.

National Insurance Finance.—In answer to Captain Coote, on February 18th, Dr. Addison said that the revision of Health Insurance contributions and benefits had been under consideration for some time, and he hoped to introduce an amending bill at an early date.

Treatment in Army Mental Hospitals.—In reply to Major Steel on February 18th, the Secretary of State for War said that strict inquiry had been made into every complaint, whatever its nature, made with regard to the treatment of men in army mental hospitals. In no case had it been found that there was ground for serious complaint, and the suggestions of careless treatment and of deliberate ill treatment in these hospitals were unjustified. The utmost care had been taken in the treatment of soldiers suffering from early mental disorders, and the system of treatment followed, which was adopted after consultation with the most expert authorities on the subject, had been acknowledged by those best qualified to judge to be in some respects an improvement on the system generally adopted in civil mental hospitals. The results had been highly satisfactory, as was evidenced by the higher recovery rate and lower death rate as compared with civil institutions of similar type. The general allegations made against the officials of the army mental hospitals and the Army Medical Service were entirely unjustified, and he saw no occasion for ordering an inquiry of the nature suggested. The matter was raised again during the debate on the Army Estimates on February 23rd, when the Financial Secretary (Sir Archibald Williamson) said that the War Office was prepared to offer every facility for the fullest inquiry and investigation on a prima facie case being shown. It was not prepared to hold inquiries without some grounds for such action being shown, but if any responsible body of people could bring forward an allegation which seemed to have some basis the War Office would at once order an investigation. In the course of the debate on the Army Estimates in the House of Commons, on February 23rd, Mr. Spoor (a Labour member) raised the question of the treatment by the War Office of mental cases. He quoted a statement from a newspaper to the effect that between twenty and thirty thousand shell-shock patients had been treated in the military hospitals, and that many of the

brave men sent back from France, speechless or witless for the time being through shock, were given the treatment of prisoners in gaol. The paragraph went on to say that many of the men spent long weeks or months in solitary confinement, in cells destitute of furniture, and not even provided with a chamber utensil; further, that all letters written were subject to severe censorship, and that the patients were "at the mercy of callous and arrogant warders, who punished the least complaint or reluctant obedience by physical violence of an inhuman kind." Asked the name of the journal he was quoting, Mr. Spoor stated it was the *Daily Herald*, and this announcement being greeted with laughter, Mr. Spoor said he could not understand that there was any reason for that laughter. If there was the slightest element of truth in the allegations—and other papers had also quoted examples—there was every justification for an immediate inquiry. Sir Archibald Williamson (Financial Secretary to the War Office), replying, said that he had a document before him which dealt with the whole treatment of neurasthenic and mental cases in detail. In 1915 the President of the Royal College of Physicians, at the invitation of the Army Council, arranged for a Committee of Members of the College to visit the various military hospitals in which nerve shock and mental cases were being treated, and to submit a report on the adequacy or otherwise of the arrangements made for the care and treatment of the patients. There was a report which was satisfactory, and further supervision had been had of these hospitals and asylums and patients.

Service Women's Compensation.—Mr. Stanley Baldwin, Financial Secretary of the Treasury, made a statement on February 19th as to compensation to women disabled and discharged from Queen Mary's Auxiliary Corps, the Women's Royal Naval Service, and the Women's Royal Air Force. The women who entered these corps were enrolled, like other persons engaged in ancillary services, on a footing that differed little from that of ordinary employment, except in the case of those enrolled for service overseas, for whom a special scheme of compensation, under the Injuries in War Compensation Act, was framed. Under the Workmen's Compensation (Addition) Amendment Act, recently passed, an addition of 75 per cent. instead of 25 per cent. was being made to the weekly amount payable under that Act, and this applied to the three women's corps whose employment brought them within the scope of that Act, and who were disabled by injuries sustained in the United Kingdom.

The Professional Training of ex-Service Men.—In reply to Mr. Alfred Davies, on February 23rd, Sir Robert Horne said that assistance in training for the professions was given to disabled and able-bodied ex-service men by the Appointments Department of the Ministry of Labour, in conjunction with the Board of Education and the Agricultural Department. Advice was given as to appropriate training, vacancies or classes, and the payment of maintenance grants to suitable candidates. Grants had been made by the Labour Department to 1138 men training as solicitors and to 1,920 training as accountants. The President of the Board of Education had sanctioned grants to some 2,408 men training for the medical and dental professions.

Pensions Medical Officers' Remuneration.—In answer to Major Henderson, Sir James Craig, on February 23rd, said that in the London area half-time medical officers employed by the Ministry of Pensions were paid a fee by session of 2½ hours. The fee varied from 1½ guineas to 2 guineas according to the class of work required. Whole-time medical officers in the London area were paid annual salaries ranging from £750 to £1,200.

The Cost of Quinine.—Asked by Mr. Glanville, on February 23rd, why an official of the Ministry of Munitions was on the Profiteering Committee, and whether all tiles and documents appertaining to quinine in the Foreign Office, Ministry of Munitions, and the War Office were submitted to the Committee, Mr. Kellaway replied that an official of the Ministry conversant with the dealings in quinine was asked by the Board of Trade to serve on the Committee of Inquiry. So far as the Ministry of Munitions (War Office contract section) was concerned, no information was withheld. Mr. Glanville inquired whether Mr. Kellaway had any statement to make as to the quinine transaction conducted by his department with the British Quinine Corporation, criticized in the Board of Trade Profiteering Report. Mr. Kellaway thought that the report did not call for any statement.

Army Masseuses.—Sir A. Williamson (the new Financial Secretary to the War Office), on a question by Major Hurst, said war gratuities, broadly speaking, were given to commissioned officers and enlisted soldiers, and were not given to the very large numbers of civilians, men and women, who in various ways worked for the army during the war. An exception to this rule was made in the case of Queen Alexandra's Imperial Military Nursing Service and other staff performing similar duties, for special reasons and in accordance with precedent; but after full consideration he was not prepared to extend this exception.

Hospitals in India.—In reply to Colonel Yate, the Secretary of State for India stated, on February 16th, that the extra hospital accommodation and equipment and the appointment of fully trained nurses for family hospitals formed part of an extensive programme for the improvement of hospitals in India which had been accepted on the recommendations of the Makins Committee, and was being undertaken as funds permitted.

England and Wales.

DISTRICT NURSING IN LONDON.

The annual meeting of the Central Council for District Nursing in London is being held in London this week. The chairman is Sir William J. Collins, and the vice-chairman Sir Thomas Barlow. The executive committee has elected as its chairman Mr. E. B. Turner, F.R.C.S., who, together with Dr. T. W. H. Garstang and Dr. M. G. Biggs, represent the British Medical Association upon the Council. The fifth annual report states that the year 1919 was full of new problems and of fresh needs and opportunities brought about by the advent of peace and the abnormal state of the country. Amongst the sections of the community in need of assistance at the present time are the so-called "new poor." The attention of the executive committee was drawn afresh to the needs of "visiting nurses" for persons of limited income by letters in the press from Sir Richard Douglas Powell, who, at the request of the committee, has now joined the Council; with his aid it is hoped that effective action may be taken in the matter this year. The release of numbers of nurses from military service has done much to ease the pressure of work on the staffs of the District Nursing Associations, but the difficulty of meeting emergency and special cases by their regular staffs is still very great. The time was therefore thought ripe to organize a panel of nurses willing to undertake temporary work. The report states that from the surplus funds of the British Red Cross Society £10,000 will be entrusted to the Council for distribution to the metropolitan nursing associations, special consideration being given to the work done on behalf of ex-service men. Further steps will be taken to supply nurses for the areas in London still unprovided with nursing services. The Council records its sense of severe loss in the departure of Sir Arthur Downes, who has left England and can no longer give further active assistance, but his interest in the work is unchanged.

HOSPITALS AND CLINICS AT CARDIFF.

The financial position of hospitals, which renders acute the need for a settled policy for their future development and maintenance, is engaging attention in every part of Great Britain. It was discussed last week at a meeting of the Health Committee of the Cardiff City Council, when Dr. Edward Walford, Medical Officer of Health for Cardiff City and Port, and lecturer in public health in the Welsh Medical School, referred to the difficulty of housing the clinics. The premises of the tuberculosis dispensary maintained by the Welsh National Memorial were, he said, unsuitable; the sanitary authority hoped that the clinics supported by it might all eventually be conducted in connexion with the out-patient department of King Edward VII Hospital, Cardiff; Dr. Walford suggested that the hospital authorities should be asked to include the tuberculosis clinic. If this were done all the clinics supported or subsidized by the sanitary authority would be under the same roof. It was, however, clear that the hospital authorities were not at present in a position to offer facilities for this plan. Alderman Dr. J. Robinson, who was in the chair, expressed the opinion that the King Edward VII Hospital should be converted into a casualty clearing station to receive emergency cases, and to serve as head quarters for the various clinics, all other cases being provided for in a building somewhere outside the town. It was objected that the provision of another building would necessitate an expenditure of three-quarters of a million; but Dr. Walford observed that the sanitary authority would contribute largely, and that there would be a saving to the ratepayers in cost and a gain of efficiency in the working of the various clinics. Dr. Robinson, in suggesting the establishment of a hospital for all save emergency cases outside the city, was no doubt thinking of the Rookwood scheme, which was initiated in September, 1918, for the benefit of wounded soldiers and sailors requiring prolonged treatment, and afterwards for pensioners, but with an eye to its use for civilian patients in the future. The estate, which extends to some twenty-five acres, is situated on the outskirts of Cardiff, and is easily accessible from the centre of the city. It would provide a site sufficiently large to allow differentiation of buildings so as to adapt them to various classes of cases.

Correspondence.

MEMORIAL TO THE OFFICERS AND MEN OF THE R.A.M.C. WHO FELL IN THE WAR.

SIR,—May I venture to bring to the notice of any of your readers who may be unaware of the active prosecution of the above project the following particulars:

A committee representing every branch of the R.A.M.C. has been formed under the presidency of the Director-General Medical Services. This committee has decided to erect a memorial bearing the names of all officers and men who fell during the war, and place this upon a prominent site in London, and if funds permit to erect replicas in Edinburgh and Dublin.

The monument will stand in honour of the entire profession, and the project should also appeal to the many who received help at its hands in the hour of strenuous need.

A sum of some £10,000 has been already collected by army commands, but it is estimated that at least £30,000 will be required if the monument is to be made worthy of the men to whose honour it is to be dedicated.

Subscriptions may be sent to army commands or direct to the treasurers of the fund, Messrs. Holt and Co., 3, Whitehall Place, S.W.1, marked "R.A.M.C. War Memorial Fund."—I am, etc.,

London, S.W., Feb. 20th.

G. H. MAKINS.

THE INDIAN MEDICAL SERVICE: IS IT WORTH WHILE?

SIR,—In your issue of September 13th last there is an announcement that the Secretary of State for India requires 206 men for the Indian Medical Service, and that 33½ per cent. increase in the grade pay had been sanctioned. Since then (see SUPPLEMENT TO BRITISH MEDICAL JOURNAL, November 8th, 1919, p. 105) the interesting information has been elicited that, according to India Office calculations, an average increase of 22 to 26 per cent. only is being received by I.M.S. officers—that is, taking their whole pay into account.

This is brought about by the conferring of a flat rate of pay irrespective of the work done by the officer, and the abolition of all allowances for charge of followers, cantonment hospitals, or vacant regiments. The result has been the creation of a sense of grievance in the service, for the general belief was that as grade pay only was affected by the increase, the allowances would remain as before, or when the station hospital system was introduced, that compensation for these allowances would be given, so that officers should not suffer loss through change of system.

For many years before the war, owing to insufficient cadre, it was the rule for officers to have charge of other regiments than their own, and often more than one during the hot weather, and so to draw Rs. 100 a month extra on the average throughout the year.

Let us take an actual concrete case—a major of thirteen to fourteen years' service in medical charge of a cavalry regiment. At the old rates of pay this officer received:

Grade pay	Rs. 650 per mensem
Staff pay	150 " "
Horse allowance	90 " "
Estimated average of extra charge allowance	100 " "
Total	Rs. 990 per mensem

When the first revision of pay was made in December, 1919, on the introduction of the station hospital system, which allowed charge pay for command and second in command of station hospitals, the above officer received the following:

Grade pay	Rs. 750 per mensem
Charge pay for first-class station hospital	240 " "
Total	Rs. 990 per mensem

It will be clear, then, that this officer drew exactly the same pay under the station hospital system as he did under the regimental system. The second revision of pay which is now in force allows this officer a consolidated pay of Rs. 1,000 per mensem, however he is employed. Thus this officer has received an increase of Rs. 10 a month only, and not an increase equal to 33½ per cent. of his old

grade pay. When such a case is possible can you wonder, Sir, that the service grumbles.

Let us now examine the financial position of the above major. If he is a bachelor he can manage comfortably on his pay. If recently married or has no family, then he can probably just clear expenses. But let us suppose he married at 30, after five years' service, and has now three children, aged 8, 6, and 4 years respectively. Two of these children must be kept in England, the elder probably at a preparatory boarding school.

The father must remit money for these two children, and this may be put at £300 a year as a minimum. At present, of course, this remitting is more easily done than formerly, owing to the fall in exchange, but for the sake of argument let us take the value of the rupee at 1s. 8d. His monthly expenditure will probably be:

Deduction for income tax and family pension fund	Rs. 78 per mensem
Home remittance at £300 a year	„ 300 „ „
Insurances, say £22 a year	„ 22 „ „
Total	Rs. 400 per mensem

This leaves a balance of Rs. 600 a month for the living expenses of himself, wife, and youngest child in India. Now it is doubtful whether, with the present increased cost of living in India, this family could live in a plains station on this amount, but we will suppose that with rigid economy it is just possible. There remains to be considered how our friend is to meet the expenses of sending his wife and child to the hills for, say, four months in the hot weather. This is an essential minimum in most parts of India.

Cost of wife and one child in a hill station	Rs. 450 per mensem
Expenses of husband in the plains	„ 300 „ „
Total	Rs. 750 per mensem

That this is not an exaggerated estimate may be judged by the fact that only the hotel expenses of wife and child are taken into account; nothing is allowed for expense of journey, provision of warm clothing for child and servants, pocket money, social duties, etc.

The husband must keep on the house in the plains and most of the servants, so that to keep within the Rs. 300 he will have to live more or less the life of a hermit. You yourself say that, "We are advised that an officer without a family should be able to live on 400 rupees a month in India" (BRITISH MEDICAL JOURNAL, January 17th, 1920, p. 93). It is evident, then, that during the four months of hot weather separation he has to spend at the lowest estimate Rs. 750 a month with only Rs. 600 available. In four months he will be 600 rupees in debt. The position of this officer—and the case is an actual one—is financially appalling, yet it is a common one. Instead of being forced into debt he ought to be saving up money for home passages and the cost of keeping himself and family during his furlough.

That this stringency is not confined to the I.M.S. is evident from the recent revision of pay sanctioned for all other officers of the Indian army and various of the civil services in India. The following comparative table shows these revised rates. It will be seen that the I.M.S. is the lowest paid of any.

Rank.	Indian Cavalry.	Indian Infantry.	Supply and Transport	I.M.S.
Lieutenant	Rs. 625	Rs. 575	Rs. 725	Rs. 550
Captain	850	800	950	700
Captain after nine years ...	950	950	1,050	800
Major	1,150	1,100	1,300	1,000
Major after five years, second in command	1,250	1,200	1,450	1,150
Lieut. Colonel in command.	1,850	1,750	1,700-1,950	1,500-1,650

The Educational and Forest Services have also had revised rates of pay sanctioned for them. The former begins on Rs. 550 and the latter on Rs. 450 a month, and both receive annually an increase of fifty rupees a month. Thus an educational officer after eight years' service draws Rs. 1,000 a month, and a forest officer does so after ten years. The I.M.S. officer does not do so till after twelve

years' service. At twenty years' service the educational officer draws Rs. 1,500, while the I.M.S. officer is still drawing only 1,150. Why is this difference made? Does this represent the comparative values of the services as estimated by the Government of India?

It thus appears that the medical officer is the worst paid of any of the principal services in India. This fact should be known to the profession, and when it is known it does not appear likely that Mr. Montagu will get the recruits he is asking for, and which are so urgently required to allow of the overwrought officers getting their overdue leave. Is the public aware that over 120 I.M.S. officers are at present home on sick leave, and that only eight months' leave is being granted to anyone at present serving in the I.M.S. in India? Many officers have not been home for ever ten years, and yet these same officers were promised furlough every five years when they joined.

Facts like the above should be made known to intending recruits so that men may realize what they are letting themselves in for. Nothing less than the terms stated by Colonel Elliot before the Secretary of State at the India Office on October 30th last will satisfy the I.M.S. These terms are: (1) Increase of pensions; (2) free passages to and from India; and (3) an increase of pay of 50 per cent. on the total pre-war pay.—I am, etc.,

"I.M.S. RETIRED."

PUBLIC HEALTH VERSUS THE STATE.

SR.—I am obliged to Dr. Davies for his criticism. If he admits that destitution has been a large factor in tuberculosis mortality he has gone far towards accepting my position. If destitution destroys then surely privation predisposes. Destitution is a comparatively simple problem if you may spend public money lavishly. But "what the State gives to the working class it first takes from the working class, and returns it *minus* the cost of collection and of (far more important) distribution." The problem of the borderland class, not actually but easily becoming destitute, is of an infinite complexity. It is they who feel taxation, especially indirect taxation, most acutely. If real wages have been reduced in their case by paternalism, Dr. Davies cannot argue that the cost of municipal and State benevolence falls on the rich. His admission that they have been so reduced is the concession of my position. It is but a question of degree.

My paper had to be condensed else he would have known that housing was one part of my indictment. I had compared the conditions of twenty years ago—landlords competing for tenants—with to-day when tenants are competing for landlords. Let him compare the successful work of agencies like the Peabody, which cost the public nothing, with the municipal schemes involving a heavy burden on the rates, and ask himself how far the pre-war checking of private enterprise has been the cause of the frightful *impasse* of to-day. Given high real wages the houses would have been built, and were, while they were high, in excess.

The chief causes of the present rise, he says, are alcoholism, bad housing, and the like. He boasts that all these have been ameliorated, which necessarily means they were worse while the rate was falling. He cannot have it both ways.

The gravamen of my charge is that meddlesome legislation aims at stamping out the disease rapidly—in vain: it can only be by patient service of natural law. It is not reasonable to accuse me of pursuing the lightning tactics. Infection probably plays some, if not a great, part; with a drop of well on to 2,000 per million in fifty years, we had a right to expect an accelerating fall. But I left it at the arithmetical progression. If the rate had steadily fallen for so long by 200 in each five years, by now it should have been in the neighbourhood of 400. We are entitled to ask officialdom, now that it can control us so much more than ever it did before, why it should be about 1,200. It is no answer to plead the continuance of old conditions when in the same breath you boast that they have been vastly improved.

The "cult of the child" began long before the State and municipality adopted it as their own. Dr. Davies is hardly fair to ignore the immense effect of voluntary effort. Paternalism came too late into the field to be able to claim the entire credit of the advance in the

tuberculosis of childhood; but it is already possible, if you relentlessly track it down, to trace some of the mischief it has done in other directions, while perhaps relieving individual children.

Condensation again has given an erroneous impression of what I had said. I submitted that two to three years was not an excessive estimate for the length of time in fatal cases from the date your patient first comes to you to his death. It is about the average in my own experience, and the submission met with no objection from my audience. I am ready to admit that adverse influences may act more quickly to depress than favouring to raise. But we are dealing with thousands of cases, and it can scarcely be a coincidence that the charts bear out so many men's experience.

Of the list of diseases he gives, except for cancer, I cannot believe that any would fail to be influenced for the good by the more equable distribution of wealth which has been proved in England and America to accompany *laissez faire*. The cause of cancer we do not know; let me remind Dr. Davies that we do know that of tubercle, and that at one time it was plainly being checked.

He says that the rate of the fall of tuberculosis was not appreciably checked before 1913. It is sufficient, since the Registrar's figures do not convince him, to remind him that Professor Karl Pearson pointed out the fact, certainly before 1913. If it was appreciated, it must have been appreciable.—I am, etc.,

B. G. M. BASKETT.

Rayleigh, Essex, Feb. 22nd.

P.S.—Since writing this I have received from a correspondent in the United States, who is leading the opposition to a stupid attempt to introduce an "Insurance Act" into America, some additional tuberculosis charts. It therein appears that in Massachusetts the rate from 1890 to 1913 has fallen by 57 per cent.; that New York had by 1913 passed Berlin, Massachusetts, Prussia, Newark, and Leipzig; and that over the United States registration area the general rate had fallen in 1912 to 1,370 per million. Surely, with all the other facts, this should be conclusive. If we are no longer to set examples, in the name of common sense let us imitate the voluntarism of Denmark with its lowest of all rates, or of the United States with its rapides of progress.

THE TERRITORIAL FORCE.

SIR,—A campaign is commencing, having for its object the formation of the new Territorial Army. Many doctors will be debating mentally the advisability of joining, and perhaps the experience of some of the older T.F. officers will help them to make up their minds. Early in the present war it was a common thing for the Boer war men to say that the War Office would find some way of doing the volunteer out of his pay and gratuity; in fact, I know of one man who sold his gratuity for £5. He made a bad speculation certainly, but, now that the war has officially ended, one can definitely say that the R.A.M.C. officer who was a Territorial was shabbily treated. One cannot criticize the matter of honours, for they are given, deservedly or not, only on the recommendation of one's superior; but hard cash as received by the individual officer forms a definite means of comparison. During the war the question of T.F. pay was always hidden by the answer that at the end of the war everything would be evened up.

My experience has been this. In August, 1914, I was a specialist on the staff of a general hospital, and had held a commission in the T.F. for five years. I pushed off with my field ambulance, and in November, 1914, was promoted lieutenant-colonel (temporary). I commanded a field ambulance for nearly two and a half years, and was then transferred to a certain post, and, of course, reverted to my permanent rank of captain. In March, 1919, I was demobilized. My pay, *plus* allowances at the end of the war, was exactly 4s. a day less than the lieutenant R.A.M.C. qualified in 1918. My gratuity was that of a captain, and, in spite of Army Order 117 of 1919, I cannot draw the higher rate because, like all the early promotions, mine was gazetted as "temporary," whereas later, to avoid confusion between temporary commission and temporary promotions, the wording was altered to "acting," and in the Army Order "acting" is referred to.

Now, Sir, if I had, instead of joining the T.F., remained at my hospital I should have held the same rank (at least) and I should have retained my practice, and been able to keep my house instead of having to sell it for £1,500 less than I can now buy it back for. Incidentally, I should have been doing useful work instead of absolutely wasting five years, at work that any competent civilian could have done, in a field ambulance. My colleagues on the hospital staff automatically became lieutenant-colonels and majors, drawing the pay and also the gratuity of their ranks. It may be asked, why did I not ask for special work at my hospital? In August, 1914, I was told no specialists were required, and in 1917, when I applied to the D.D.M.S. Western Command for my appointment no answer was received. My advice to any young doctor who thinks of taking a commission in the Territorial Force is that it will pay him far better to wait until he is conscripted.—I am, etc.,

February 24th.

"T.F."

PROTECTIVE INOCULATIONS AGAINST INFLUENZA.

SIR,—Sir William Leishman's article upon the results of protective inoculations against influenza raises many interesting points. First, it seems to prove that Pfeiffer's bacillus, as I have consistently maintained on the strength of my own bacteriological investigations, is the essential cause of influenza—the parallelism of the intensity of the epidemic and the dominance of the influenza bacilli, and the protection apparently afforded by the increased strength of the influenza "vaccine," greatly strengthening the claims of this bacillus to this doubtful honour. Further, there may be some justification for extending these observations in the army, because efficient control can be exercised, and the incidence of the disease is likely to be greater among soldiers congregated in masses than in the general population.

Even these army records disclose some striking dissimilarities. The Western Command, the Scottish Command, and the London District, aggregating over 8,000 soldiers, show 600 cases of influenza and not a single death, and the incidence of influenza is even greater among the inoculated. Again, the great majority of deaths occur in two districts—York and Maidstone—among 7,297 units—that is, among 11 per cent. of the total (59,144). What local influence was at work to explain this high death rate? Was the influenza bacillus working in virgin soil? It is most important to determine whether the soldiers have ever suffered from influenza.

It cannot be argued that these inoculations protected unless we know for certain that the said soldiers had not been protected by an attack of influenza at some previous period; and it is conceivable that those who had had influenza already would be the more ready to submit to inoculation. The value of antityphoid inoculations could not be proved by inoculating those who had had typhoid fever before inoculation. The immunizing effect of anti-typhoid and anticholera vaccines can be demonstrated in the guinea-pig. I know of no experiments in animals which show the immunizing action of specific vaccines in influenza and its streptococcal complications. It is quite possible that Sir W. Leishman has positive evidence of this kind. If so, it should certainly be published in the interests of science.

However, I am not concerned with the wisdom of this procedure for the safety of soldiers. I wish to view the problem as it affects the civil population. The Ministry of Health has given its approval in a Memorandum, and its action is open to serious criticism. Ordinary people accept the approval of the health authorities as a substantial argument in favour of wholesale inoculation, and well-to-do people are keeping their doctors busy. I cannot think that doctors fully explain the reasons for and against inoculation. Perhaps they have not thought them out. The public have a right to know the common sense of wholesale inoculations, and then can decide for themselves.

If the policy of the Health Department is sound, inoculations should be widely practised among the poorer classes, because they suffer most and die most from influenza. If it is in the nature of an experiment, the experiment would be far more useful and instructive in hospitals and schools, when the patients could be controlled and supervised, than in private practice, when the work is casual

and uncontrolled. At hospitals there is also the control of the laboratory and the mortuary.

I will now briefly state the obvious objections to preventive inoculations against influenza:

1. Not I, but many, hold that the cause of influenza is not known. Non-specific "vaccines" are of no avail. But it is urged that the streptococcal complications are the cause of death. Perhaps sometimes, not always. But granted they are, what experiments upon animals prove that specific streptococcal "vaccines" protect against a virulent attack of the haemolytic streptococcus? In the case of typhoid fever, cholera, diphtheria, and tetanus the protective agent is specific, and its virtues can be demonstrated in animals. Not so with regard to the "vaccine" of either influenza or its complications.

2. What is the chance of an epidemic of influenza appearing in such a form and spreading so widely that protective inoculation would justify itself and its advocates? Very small. The epidemic is not likely to be even as severe as the epidemic of 1917. In 1917 influenza caused 750 deaths in London with a population of 4,000,000, measles 1,900 deaths in children under 5, whooping-cough 550 in children under 5, diphtheria 350 deaths in those under 5, puerperal fever 873 deaths in a select group of women. Now, if the policy of protective inoculation is sound, there is far greater reason for applying the principle to these restricted groups than to the protection of the whole population against influenza. Why is this "plunge in the dark" justified in the case of influenza if it is not made to protect the individuals belonging to a far smaller and more easily defined group, and suffering from diseases of a similar nature? The experts will find it difficult to supply an answer.

3. But there is another point, which should give this protective inoculation, as a public health measure, its quietus. In London's population of 4,000,000 persons there were 750 deaths from influenza in 1917. Thus, if protective inoculation is perfect, it is necessary to inoculate 5,330 persons—once, twice, or thrice—to save one life. To save one life a single doctor would have to give 100 inoculations a day, or double or treble that number, and work continuously for two months, not counting Sundays. He himself might die in the attempt, or—still worse—one or more of the inoculated multitude might die from the inoculation itself. Personally I think that if the doctor has to become a slave of this sort the risk of one or more deaths in 10,000 or more inoculations is more than probable. And what a waste of energy and money! At least £10,000 spent on the advice of the Ministry of Health for such a futile object as the inoculation of 5,330 persons out of a population of 4,000,000 in a vain effort to save one life.

If physicians are still inclined to recommend protective inoculations to their patients who are afraid of influenza, I trust that the patients may learn for themselves the common sense view of this proposal, and think twice.—I am, etc.,

W. CAMAC WILKINSON, M.D., F.R.C.P.

London, W., Feb. 19th.

NASAL DRILL.

SIR,—Dr. Hickling's interesting paper in the JOURNAL of January 31st will, it may be hoped, lead to improved methods in this increasingly popular mode of treatment; but I feel that sufficient stress has not been laid upon the two essential features of the drill—namely, not to close the nostrils when blowing, and to breathe in. The old tradition of mothers and nurses that children should be taught to blow their noses thoroughly is responsible for an immense amount of damage to nasal mucous membrane. A handkerchief used in the ordinary manner does much harm to the nose, and yet the majority of people seem to think that nasal drill consists mainly of forcible nose-blowing. The ordinary method consists of alternately closing and opening the nostrils during a forceful expiratory effort. The effect of this, in addition to expelling the excretion, is to fill up with blood the turbinated bodies and the nasal mucous membrane generally. This causes further secretion. Then follows more nose-blowing, and a vicious circle is established. Forcible inspiration depletes the nose of blood and stops secretion.

Almost anyone can produce a chronic nasal catarrh by continued nose blowing in the ordinary way, and the majority of nasal catarrhs can be stopped by a course of deep inspirations, blowing the nose only when absolutely

necessary and then without closing the nostrils. For instance:

I saw a girl who was in constant misery on account of an old-standing nasal catarrh. The turbinated bodies were engorged, and secretion was pouring from her nose in an almost constant stream. I horrified the child's mother by saying that the chief thing she needed was not to possess a handkerchief. I was told that she would not be fit to be seen without a handkerchief, so I advised her to shut herself up in her house for a few days and follow the instructions I laid down with regard to blowing and deep inspirations. Three weeks later I saw the child again, when the mother said that an extraordinary change had come about. Before I saw her she used twenty-four handkerchiefs a day and never had a dry one; now she had only one handkerchief a day and never had a wet one.

In another case a lady complained that all her children suffered from severe nasal catarrh which no remedies or nose-blowing would relieve. All were very susceptible to taking fresh colds, and one boy had frequent nose-bleeding. Recently the lady told me that for two years after following my directions all the catarrh and nose-bleeding had ceased, and the children had remained entirely free from fresh colds until a few weeks ago, when all the troubles returned as badly as ever. It was then found that a new governess had instituted a system of nasal drill every morning before beginning lessons. When this was stopped the nasal troubles ceased at once.

It is doubtful whether any benefit is derived from induced sneezing, and I am sure that Dr. Hickling makes a mistake in including menthol in the snuff she uses. The continued use of any preparation containing menthol is harmful. The immediate effect is pleasing, but there follows a hyperaemic reaction which ultimately becomes the predominating factor. The only other commonly used drug, which has a more deleterious effect, is adrenalin.

I believe that Dr. Lapage is mistaken in his opinion that "the majority of tonsils and adenoids are due to infection" (BRITISH MEDICAL JOURNAL, January 31st, p. 148). There is, I consider, convincing evidence that enlarged tonsils and adenoids are mainly due to orthodox nose-blowing and too much night air, which produce a constant hyperaemia and increased activity of the adenoid tissue.—I am, etc.,

London, W., Feb. 9th.

ALEXANDER FRANCIS.

TICKS AND RELAPSING FEVER.

SIR,—I can confirm the statements made by Colonel Mackenzie, in his letter of February 7th, and by Captain Nicholson, in his original article of December 20th, that spirochaetes were scanty and often difficult to find in the British cases of relapsing fever contracted in Palestine.

I was at the Military Laboratory, Port Tewfik (Suez), during two seasons of relapsing fever. Among the British cases occurring in that neighbourhood the parasites were rarely abundant, and they were never present in such numbers as were frequently found in Egyptian cases; there was, however, no difficulty in detecting them. But while I was at the Military Laboratory, Kautara, in the winter of 1917, as soon as British cases of relapsing fever began coming down the line from Palestine, a marked difference in this respect was noticeable. The parasites were nearly always extremely scarce, and sometimes could not be found at all until the second or even third examination. While I was at Jaffa, during the following spring, the same condition obtained. Indeed, I had such difficulty in finding the spirochaetes that I adopted the "thick drop" method for their detection (*vide* BRITISH MEDICAL JOURNAL, May 25th, 1918).

On the other hand, this difference was not noticeable in the Egyptian Labour Corps cases in Palestine. The spirochaetes in these patients could be found as readily as they were in the Egyptian cases dealt with at Kautara or Suez. Of course it happened now and again that the parasites were not numerous, but often they were swarming. May one offer the suggestion that the relapsing fever amongst the Egyptian Labour Corps in their camps in Palestine was louse-borne, while the British cases—to some extent, at any rate—were infected by ticks in the Judean caves?

This scarcity in number of the parasites, in the British cases from Palestine, was noticed, I think, also in other laboratories; in fact, I recollect that a memorandum dealing with the matter and emphasizing the necessity for repeated examination in the Palestine cases was officially circulated. As the same human host was concerned, it appears, on the ground of this difference alone, not to refer to other points, as though there were a

distinction somewhere in connexion with the parasite or its transmission in the two sets of British cases. It is quite true, as Colonel Balfour has pointed out (February 14th) that on the present data the question cannot be regarded as settled; still, I remember thinking at the time that the circumstances attending the particular infections detailed by Captain Nicholson did support strongly his view that these owed their origin to *Argas*.—I am, etc.,
London, Feb. 21st. H. M. WOODCOCK.

PREVENTION OF VENEREAL DISEASE.

SIR,—Lately the Women's Medical Federation has expressed its fear that the application of certain methods of prevention of venereal disease would rot the very foundations of society, and already that fear seems justified by Dr. McWalter's experience (February 21st, p. 273). His reference to "the seeming security of the packet" expresses what some of us have feared since such schemes were advertised. We foresee an increased demand for prostitution, with increased pressure brought upon young women and girls to surrender their chastity. Should not the medical profession pause before it gives the weight of its authority to a propaganda which may bring such dire results? Without discussing deeply what is necessary or unnecessary to the males, we may say at once that not only is sexual irregularity unnecessary to women, but that unchastity in her is most gravely and deeply harmful to the triple aspect of nature—body, mind, and spirit. Degradation, through sexual immorality, in her more sensitive and complex organization, is always painfully obvious. Nay more, we may say with fair confidence that the only two states in which she may develop in grace and favour are virginity and marriage. Seeing that this is the case with woman, is it not a grave thing for our learned profession to risk the encouragement of her sacrifice and prostitution? Could not the whole medical profession consider the question before such serious steps are taken? There must be many men who would scorn to admit their own defeat, even though in circumstances of such difficulty and complexity. A great number of men are led by public opinion, and possibly the incidence of venereal disease would not have been so great had medical men taken a different attitude in earlier days. Is it not possible to appeal to those higher instincts, which are the gift of humanity, and which can rule to the subjection of the lower? If the Church has failed, so much greater is the opportunity of our profession now!

The psychic effect of any new venture might probably be more accurately gauged by woman than by man, and she may therefore possibly be the best judge as to the mental development of a young man equipped with a prophylactic apparatus and fully instructed in its uses, and also as to his mentality and behaviour in the married state at a later period.

In the last sentence of his letter Dr. McWalter states that he has found the result that women feared—sexual depravity. His discovery that venereal disease increased with the prophylactic system was also foreseen by medical women among others.

I should like to add that, in my view, the above remarks apply to any propaganda designed to teach men how sexual irregularity may be indulged in with a lessened risk of venereal infection. Increased indulgence in man, causing increased degradation to woman, must react at last in degrading man. Man's nature, too, can be stunted in a certain development by indulgence in vice.—I am, etc.,
FLORENCE E. INGLIS, M.B., Ch.B. Edin.

Portsmouth, Feb. 22nd.

CLINICAL RESEARCH.

SIR,—If the first step towards knowledge be the knowledge of our own ignorance, there is some hope that the address of Sir James Mackenzie, delivered at the opening of the St. Andrews Institute for Clinical Research, will be epoch making, for no confession of ignorance could be more complete. Sir James, I think, wastes his time in trying to trace the origin of different diseases. The only difference I recognize is the difference between health and disease. When the environment of every individual is perfect there will be more chance of health being preserved as regards the macrocosm; but what of the microcosm? When the slums are all done away with, and the breath of heaven blows round every house: when drainage

is perfect and our water supply pure; when our rivers once more become silvery streams instead of sewers, as some are at present; when, indeed, there is nothing but accident or climatic influences left even in our largest cities to interfere with health, will there be an end of disease? There will not; for when we have a perfect macrocosm and a perfect microcosm at birth, how long will it be before the microcosm is upset? Pythagoras, wisest of the Greeks, said a man ought to be ashamed of being ill—meaning that he alone, through ignorance or folly, was to blame; and the proverb that "a man is either a fool or a physician at forty" points to food as a cause of disease. In his classification of symptoms Sir James Mackenzie made three groups: (1) structural, (2) functional, and (3) reflex. He confesses that, although we can detect neither change of structure nor function, we can recognize the particular disease with great accuracy, and he mentions gastric ulcer as an illustration; and then comes what seems to me the most important sentence in his long address. He says (January 24th, p. 110):

There may be no structural sign, nor sign of functional disturbance. Such symptoms (as those of gastric ulcer) are produced by an irritation of a limited portion of the central nervous system, in a reflex manner, the source of irritation being in the ulcer.

That is just the theory that I have been preaching for years. Many years ago, at a clinical meeting of the Edinburgh Branch of the British Medical Association, when the late Professor Gibson read a paper on angina pectoris, regarding it as a structural disease, I ventured to say that it was not structural but reflex, due to some irritation in the stomach, or intestinal canal. He would not believe me, and I do not wonder, for medical faith handicaps us all; but what are we to do when we have made up our minds that we have to do with an ulcer in the stomach? Send the patient to the surgeon to have it excised? I suppose that is what Sir James Mackenzie would do, and what is being done daily; but in spite of the success of the operation, so long as the primary cause of the ulcer is not discovered and removed, what guarantee can anyone have that another ulcer, or something worse, will not supervene? In my book published in 1911 I prove that food is the chief cause of disease, and there can be no doubt that improper food causes many symptoms reflexly before any structural, or perhaps even functional, change can be detected in the stomach. How food causes disease is the question which this century will see solved. Meantime I would suggest that it does so by spoiling the environment of some cells in the body, and with abnormal environment there will be abnormal functioning.—I am, etc.,

Hawick, Jan. 23th.

JOHN HADDON, M.D.

INTRASPINAL PRESSURE IN ACUTE DISEASE.

SIR,—I desire again to direct the attention of the profession to the injurious effect of intraspinal pressure in many acute diseases. In an article published in the BRITISH MEDICAL JOURNAL of May 5th, 1917, on the cause of death in acute pneumonia, I attempted to show that the physical conditions, such as consolidation of the lung, were not the cause of the symptoms, for the former persist after the acute symptoms have disappeared, often quite suddenly. I also pointed out that increased intraspinal pressure was well known to be present in a large proportion of cases. In spinal meningitis the immediate relief resulting from tapping is another instance of benefit derived from the temporary removal of pressure from the vital centres.

In the Epitome of Current Medical Literature, January 10th, 1920 (paragraph 29), there appears a note by Herrick and Dannenberg on the subject of increased intraspinal pressure in acute diseases; they emphasize its frequency, and infer that "the increased pressure in the subarachnoid system may be a protective reaction in the early stage of infection," and warn against the possible danger of reducing it. But if their theory and their deduction from it be true, and the increased pressure is due to increased secretion of spinal fluid as the result of a "protective reaction"—that is, to prevent invasion of the meninges by the active toxin—it is not effective, and does not affect the argument that intraspinal pressure is injurious and may be relieved beneficially by tapping, as in the case of spinal meningitis, in which the injurious toxin is removed and the pressure at the same time reduced, which many reliable observers consider to be as beneficial, without the subsequent intro-

duction of serum, or even more so. I have no wish, however, to raise controversial points, but I hope, in view of the disastrous results to the community, both military and civil, of the last outbreak of influenza, that attempts will be made in the next epidemic to reduce the mortality by judicious tapping in suitable cases; this will, I believe, include the majority of bad ones; if properly done it is without risk.

Increased pressure on the vital centres in the medulla, if severe or prolonged, cannot be anything but disastrous, and if positive and reliable evidence is required in support of such an obvious proposal, no stronger fact can be adduced than the immediately beneficial effect of a satisfactory flow from a spinal puncture in spinal meningitis.

As a profession we are conservative, and rightly so, for by following those lines we exclude quackery; but it is well to remember that it took 300 years to apply a ligature to a bleeding vessel, and with all respect to authority we are prone to repeat in our textbooks fallacies which have been handed down year after year, to the detriment of the public and also to the reputation of the profession.—I am, etc.,

Broadstairs, Feb. 1st.

H. V. DREW, F.R.C.S.

WAR HONOURS.

SIR,—I am quite in sympathy with your correspondent upon the above subject. I acted for nearly two years as A.M.O. to one of our largest county council mental hospitals, as did others of my friends, like myself upwards of 70 years of age, and was responsible at night for 1,000 patients, several of them shell-shock cases. The Army Council decline to bestow any medal upon the doctors, as they were not appointed by it but by the county council. I consider this rather straining a point. Soldiers were received daily and at all times, and examined on the spot. I press this, being one who contracted illness, which has nearly cost me my life, as was the case with others at my age (some died). It is a great satisfaction to have done something by way of help in this unprecedented war; nevertheless I think the authorities should bestow some sort of decoration upon those who volunteered for some duty at the onset.—I am, etc.,

February 18th.

ANOTHER M.R.C.S.

SIR,—May I ask a question—namely, how is it that one never sees or hears mention of the excellent services rendered by the Admiralty surgeons and agents during the war—men whose care in the selection of recruits for the navy accounts to a great extent for its physical and mental constitution? Surely those men who have rendered such conspicuous service to the nation deserve some recognition from the Government. Not being connected with the navy, I have no other interest beyond wishing for fair play.—I am, etc.,

February 22nd.

EXPOSTULATOR.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on February 20th the degree of M.D. was conferred upon T. E. Sandall, E. E. Paget-Tomlinson, and J. T. Fox.

UNIVERSITY OF ABERDEEN.

AMONG those upon whom the Senatus of the University of Aberdeen has decided to confer the honorary degree of LL.D. are Dr. William Bulloch, F.R.S., professor of bacteriology in the University of London; Major-General Sir Robert Jones, K.B.E., C.B., inspector of Military Orthopaedics, A.M.S.; Dr. David Nicolson, C.B., Lord Chancellor's visitor in lunacy; Sir Daniel Hall, K.C.B., F.R.S., secretary of the Ministry of Agriculture; Mr. J. H. Jeans, secretary of the Royal Society; and Sir J. C. Bose, D.Sc., founder director of the Bose Research Institute, Calcutta.

THE Finnish medical journal *Duodecim*, which has hitherto been published monthly in Finnish, will in the future appear as *Acta Societatis Medicorum Fennicæ Duodecim*. Contributions to this journal will be published in English, French, or German. This change in the Finnish journal is in response to the growing determination on the part of Finnish scientists to publish their investigations under their own auspices and yet to make them accessible to the world at large.

The Services.

ROYAL ARMY MEDICAL CORPS.

STRENGTH AND ARRANGEMENTS FOR THE FUTURE.

A MEMORANDUM¹ giving details of the work of the various departments of the War Office in connexion with the reconstruction of the Army since the armistice has been issued, amplifying the speech of the Secretary of State in introducing the Army Estimates for 1920-21 on February 23rd. In a note attached to the memorandum Mr. Churchill says that the work of demobilizing the large forces on foot at the armistice and of bringing into being the army of the future was so gigantic that he had been compelled to confine himself in his speech to the larger issues.

Territorial R.A.M.C.

In dealing with the Royal Army Medical Corps, the memorandum notes that a Territorial Section has been added to the War Office, which it is hoped will be a permanent section to deal with medical questions and personnel of the new Territorial army. The medical section of that army will be reorganized on its pre-war basis, with such additions and alterations as the war had shown to be necessary. The war showed the importance of casualty clearing stations, and it is proposed to form and maintain these medical units. Regimental medical officers will be appointed to battalions and will be carried on a Divisional List, which will include also officers of field ambulances and casualty clearing stations, and will show their seniority. Field ambulances will be organized with a head quarters and two sections. Sanitary Sections will be allowed to each Division; it is proposed to form them into companies and place them under the Director of Hygiene for technical training. Specially qualified medical officers, such as pathologists, x-ray specialists and hygienists, will be allowed for in the organization. General hospitals will be formed in connexion with universities and medical schools. A large number of physicians and surgeons of universities and hospitals will be required, and will be given the opportunity of training in the military duties of hospital administration. They will be carried on a special list.

Dental Corps.

It is proposed to form a dental corps, consisting of 110 officers and 132 other ranks (mechanics and orderlies).

Directorates of Pathology and Hygiene.

Reference is made to the establishment of Directorates of Hygiene and Pathology, according to the plan we announced some time ago. For each there will be a Director and Deputy at head quarters, and Assistants and Deputy Assistants in the important commands and districts at home and abroad. Officers will henceforth be able to continue to work in these special subjects throughout their service, instead of being compelled, as has hitherto been the case, to abandon them in order to take up administrative duties on attaining a certain seniority. Promotion to the higher ranks is now open to such specialists, and it is hoped that this will attract to these branches men from whose labours the army may expect to reap constantly increasing benefit. Each Director will have the aid of a strong Advisory Committee of experts, both civil and military, which will not only strengthen his hands in technical matters, but help to secure effective collaboration with other workers in these subjects, whether in a civil profession or in the medical branches of other departments of the State.

Strength: Officers.

The pre-war establishment of officers R.A.M.C. was 1,068; on the date of the armistice the strength was 14,461, and in addition 1,524 civil medical practitioners were employed. At present 3,338 officers and 322 civil medical practitioners are employed, and the number is continually being reduced in conformity with the reduction in hospital population. At the armistice the number of patients in the military hospitals in the United Kingdom was 316,000; on May 1st, 1919, it had been reduced to 112,000, and on February 1st, 1920, to 28,000. The policy had been to close the smaller hospitals and transfer the patients to hospitals which could be retained, and in this way the number of vacant beds had been kept as low as possible. In order to

¹ [Cind. 565.] Price 3d.

replace wastage of officers and to provide for garrisons in Mesopotamia and Palestine permanent commissions in the R.A.M.C. had been offered to Territorial, Special Reserve, and temporarily commissioned officers, and in this way a number of most valuable and experienced officers had been added to the Corps. As far as possible the higher appointments in the Corps will, it is stated, be made by selection from amongst the officers who have proved themselves on active service.

Other Ranks.

The pre-war establishment of warrant officers, non-commissioned officers and men R.A.M.C. was 3,895; at the armistice they numbered 131,361. In addition there were 18,660 Voluntary Aid Detachment general service women in hospitals and other formations in the United Kingdom. Large numbers of such women were employed also in France, Salonica, and Malta. The strength of other ranks in February, 1920, had been reduced to 18,412 and the number of Voluntary Aid Detachment general service women to 4,771, considerable numbers of them being employed in the Rhine army, Black Sea, and Malta. After the armistice measures were taken to enrol further numbers of Voluntary Aid Detachment general service women in order to set free other ranks who were demobilizable, and the system is being followed to the utmost extent.

Vaccine Department.

The Vaccine Department of the Royal Army Medical College produced more than thirty-three million doses of vaccines against typhoid, cholera, dysentery, and other conditions during the war. The success of the vaccines was most conspicuous against the typhoid group of fevers, and is believed to have been a large, if not the largest, factor in the remarkable freedom of the British armies from this scourge. From the beginning of the war down to the end of 1918 there were only 7,423 cases of typhoid and paratyphoid fever, with 266 deaths, in the British armies in France. In the French army before it was fully protected by anti-typhoid vaccination there were from the beginning of hostilities to the end of October, 1915, 95,809 cases, with 11,690 deaths. Afterwards the rates of the French army were more comparable with the British. Recent German statistics of mortality in their armies during the war mention 7,751 deaths from typhoid fever.

HONOURS.

C.B.E.

Temporary Lieut.-Colonel Richard Jones Morris, R.A.M.C., has been appointed C.B.E. (military) in recognition of valuable services rendered in connexion with the war.

FOREIGN DECORATIONS.

The following decorations have been conferred upon officers of the R.A.M.C. by the Allied Powers for distinguished services rendered during the war:

By the President of the Republic of China.

Order of Wen-Hu (4th Class): Temporary Majors (acting Lieut.-Colonels) William Harold Graham Aspland, and George Douglas Gray, O.B.E. Temporary Majors Stafford Mouritz Cox and Thomas Norton, F.R.D. (5th Class): Temporary Captains Percy Campbell Leslie, Henry Delahunt Matthews, Ernest John Pell, John William Pell, and William Robert Reeds.

By the Government of the Republic of Panama.

Medal of La Solidaridad (3rd Class): Captain and Brevet Major (acting Major) William Leckie Webster; Captains (acting Majors) William Kealty Campbell, D.S.O., M.C., and John Murray Weddell.

The name of Dr. E. A. Montgomery has been brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the war.

OUT of the 130,000 men in the Italian navy, 2,936 were wounded and 3,169 died during the war; 2,524 of the deaths were due to drowning. These figures are in accordance with the fact observed in previous wars that in naval forces the number of deaths exceeds the number of wounded. Three per cent. of the losses were due to tuberculosis. There were twelve cases of small-pox with three deaths among 125,000 men. The incidence of gonorrhoea and soft sore was 38.8 per cent., and of syphilis 19.4 per cent. In the period preceding the system of prophylaxis now in force the figures were 55.3 and 24.5 per cent. respectively.

Obituary.

DR. JAMES ADAMSON, who was an outstanding figure among the general practitioners in the North of England, died on February 13th at Houghton-le Hole. He was born at Ballydoughan, co. Down, in 1843, and received his medical education at Belfast and Glasgow, graduating M.D. of the University of Glasgow and taking the L.R.C.S. Edin. and L.M. diplomas in 1869. He went to Hetton in that year as assistant to Dr. Edgar; afterwards he became his partner, and succeeded him in 1878. Dr. Adamson was surgeon to the Hetton and North Hetton Collieries up to the time of his death; for the last ninety-four years these collieries have only had two surgeons—probably a record in its way. Dr. Adamson took the keenest interest in, and was one of the pioneers of, ambulance work in the county of Durham. He started his first ambulance course in 1877, and continued the classes until within the last few years. The Hetton Division of the St. John Ambulance Brigade was founded by him in 1901, and he acted as first honorary surgeon and superintendent. He held the appointment as M.O.H. for Hetton Urban District Council, resigning his position in 1914. At the time of his death he was medical officer and public vaccinator for Hetton-le-Hole district Houghton-le-Spring Union, and medical superintendent of the Houghton and Hetton small-pox hospital. He was an ex-president of the Sunderland and North Durham Medical Society and of the Northumberland and Durham Medical Society.

WE regret to record the death, in his seventy-fifth year, of Dr. JOHN WILLIAM HEMBROUGH, M.O.H. for the county of Northumberland, which took place on February 13th, at Newcastle-on-Tyne. Dr. Hembrough was the son of a doctor, and was born in Lincolnshire. He received his medical education at St. Bartholomew's Hospital, where he was a fellow student with the late Sir Richard Thorne-Thorne and Sir William Power. He obtained the L.S.A. diploma in 1865, and the M.R.C.S. in the following year. In 1885 he graduated M.D. Durh., and in 1890 he obtained the D.P.H. diploma. After some years of general practice he devoted himself to public health work, and twenty-six years ago was appointed medical officer of health to the Northumberland County Council. He was a member of the council of the Society of Medical Officers of Health, of which he had long been an active member, and was a member of the Newcastle-on-Tyne Division of the British Medical Association. He was an examiner in public health to the University of Durham, and a member of the examining board of the Royal Sanitary Institute. Dr. Hembrough was well known among his colleagues for his devotion to duty and the thoroughness of his work. Notwithstanding ill health and much pain during recent years, he remained at his post up to the day of his death. His wife died many years ago, and he leaves a married daughter.

WE regret to announce that Dr. JAMES PINKERTON, of West Kirby, died on February 16th. After studying medicine at Queen's College, Belfast, he graduated M.D. (with honours) and M.Ch. at the Royal University of Ireland in 1881, and won the Malcolm and Coulter exhibitions at the Belfast Royal Hospital. He began practice in Birkenhead about thirty-two years ago, and was for twenty-one years honorary medical officer to the Wirral Children's Hospital; he was also honorary surgeon to the Birkenhead Eye and Ear Hospital. On his retirement in 1909 Dr. Pinkerton removed to West Kirby, where he held the post of honorary medical officer to the Children's Convalescent Home; during the war he acted as school medical officer under the Liverpool Corporation. He was a member of the Cheshire Panel Committee, and of the local Division of the British Medical Association. He is survived by his widow, a daughter, and two sons, one of whom, Dr. P. B. Pinkerton, served in German East Africa as a captain in the R.A.M.C. (S.R.).

DR. THOMAS McCUBBIN of Gillingham, who died from pneumonia and cerebral haemorrhage on February 14th, aged 40, was educated at St. Mungo's College, Glasgow, and took the Scottish triple qualification in 1902, after which he acted as house-surgeon and house-physician to

the Glasgow Royal Infirmary. He practised in Liverpool for ten years before going to Australia, whence he returned on the outbreak of the war and took a temporary commission in the R.A.M.C. After serving in France Dr. McCubbin began practice in May, 1917, at Gillingham, where he made many friends. He was a member of the local Division of the British Medical Association.

DR. JOHN ALEXANDER BOYD, of Upper Gloucester Place London, died in Ireland on January 22nd, where he had gone in the hope of regaining strength. He was the son of the late Nathaniel Boyd, of Carnall, co. Antrim, Ireland. Through his mother he was grand-nephew of Dr. James McHenry, physician, playwright, novelist, whose book, *O'Halaran, the Insurgent Chief*, contains an account of the Irish rebellion of 1798, which is, we are informed, incorporated in the official history of Ireland. He graduated M.B., B.Ch., B.A.O. in the Royal University of Ireland in 1907. After spending four years in various hospitals he began private practice in 1911. To those who knew him intimately his loss is as great as was the privilege of his acquaintance.

LIEUT.-COLONEL JOSHUA DUKE, Bengal Medical Service (retired), died at Guernsey on February 13th, aged 72. He was the third of eight sons of the late Dr. T. O. Duke of Clapham, and was born in 1847. He was educated at St. Paul's School and at St. Thomas's and Guy's Hospitals, and took the diplomas of M.R.C.S. and L.S.A. in 1868. He subsequently went as a ship surgeon to Melbourne and served as resident assistant surgeon to the Bendigo Hospital. On his return to England he joined the L.M.S. in 1872, retiring with the rank of brigade surgeon lieutenant-colonel in November, 1902. He was very unfortunate as regards promotion, for he had been officiating in the administrative grade as full colonel for several months, when he attained the age of 55, on June 14th, 1902, and was thus barred by age from further promotion, though the next vacancy for promotion to full colonel took place only two days later, when the next on the list got the step. He was allowed an extension of service up to November 1st, 1902, and received one of the extra compensation pensions of £100 a year. The last twenty years of his service was spent chiefly in political employment; he was for several years residency surgeon in Kashmir, and accompanied a special mission to Gilgit. He served in the Afghan war of 1878-80, taking part in the action at Charasiah, in the operations at and around Kabul, in the famous march under General Roberts from Kabul to Kandahar, in the battle of Kandahar, and in the operations against the Marri tribes; was mentioned in dispatches, in G.C.O. No. 137 of 1879, and received the medal with three clasps and the special Kabul-Kandahar bronze star. He rejoined for service in the recent war on December 3rd, 1914, and served in York Place Indian hospital at Brighton from that date till it was closed on December 31st, 1915, and afterwards in a hospital at Bermondsey. He was the author of several works: *Queries at a Mess Table: What shall I Eat? What shall I Drink? 1878*; *Banting in India: Recollections of the Kabul Campaign, 1883*; *The Prevention of Cholera, 1900*; and also rewrote and edited the fourth, fifth, sixth, and seventh editions of Ince's *Kashmir Handbook, 1888 to 1903*, the two last being published under his own name. He is survived by his widow, one son—Dr. H. L. Duke, of the Colonial Service (Uganda)—and three daughters. He was buried in Guernsey Cemetery on February 17th, his coffin covered with the flag, and the "Last Post" given by a detachment of the Loyal North Lancashire Regiment.

SURGEON-GENERAL JAMES ALBERT CLERY, C.B., A.M.S., died at Blackheath on February 10th, aged 73. He was born on December 21st, 1846, the son of the late Thomas Clery of Ballynahinch House, county Limerick, and was educated at Stonyhurst and at Trinity College, Dublin, where he graduated M.B. and M.Ch. in 1870. He entered the army as assistant surgeon in 1871, and reached the rank of surgeon-general in 1902. He was placed on temporary half pay at the end of 1905, and retired at the end of 1906. He served in the Sudan campaign of 1884-85; in the Nile expedition, receiving the medal with a clasp, and the Khedive's bronze star; in the Sudan

campaign of 1898, when he gained the medal, with the special Khedive's medal, and was mentioned in dispatches; and in South Africa, where he was principal medical officer on the lines of communication, took part in the relief of Ladysmith, and in operations in the Transvaal, the Orange River Colony, and in Natal; was twice mentioned in dispatches, and received the Queen's medal with six clasps, the King's medal with two clasps, and the C.B. He rejoined for service in the recent war on July 17th, 1915.

CAPTAIN ALLAN WATSON, D.S.O., R.A.M.C., died on January 18th at Tembura, in the Southern Sudan. He was the eldest son of the late Rev. William Watson of Kilbearn, Ross-shire, and was educated at Edinburgh University, where he graduated M.B. and B.Ch. in 1909 and M.D., with high commendation for his thesis, in 1914; he took the diploma in tropical medicine and hygiene in 1910, and the D.P.H. of the Edinburgh Colleges in 1912. After filling the posts of house-surgeon of the Royal Bucks Hospital at Aylesbury, of assistant house-surgeon of the Guest Hospital at Dudley, and of senior house-surgeon of the East Suffolk Hospital at Ipswich, he entered the R.A.M.C. as lieutenant on January 30th, 1914. While going through the R.A.M.C. school he gained the Herbert prize as the first student of his term, the De Chaumont prize in hygiene, and the second Montefiore prize in surgery. He was promoted captain on March 30th, 1915, and received the D.S.O. on March 10th, 1917, for service in Mesopotamia.

Medico-Legal.

A DRUGLESS HEALER SENTENCED.

AT Stafford Assizes, on February 18th and 19th, Arthur Barker of Tunstall, aged 34, described as a quack doctor, was indicted before Mr. Justice Sankey for the manslaughter of Mrs. Sharples at Burslem on September 30th. The prisoner pleaded not guilty. Mr. Vaehell, K.C., alleged for the prosecution that the woman's death was due to Barker's incompetence and insufficient attention to her when he had undertaken the sole duties of medical attendant. Three years ago the deceased woman was attended by a regular practitioner for jaundice and later for pleurisy. In the spring of 1919 she was attended by Dr. Garvey, who saw her last in May, but might have sent her medicine during June. Mr. and Mrs. Sharples then heard of the prisoner, who was generally known as "Dr. Barker"; he was not qualified, and had no hospital practice or training. For five years or so he had been undertaking treatment of medical and surgical cases in Tunstall. For ten years before that he had been a miner working in the pits, and when he quitted that work he put up a brass plate on which he described himself as a professional hypnotist and drugless healer. Among the letters he put after his name were "M.T.," which counsel gathered stood for mechano-therapy, the system by which he professed to cure people. He was consulted by the husband, and paid his first visit to the wife on July 3rd, continuing to attend about twice a week until her death; he was paid 7s. or 10s. a visit. He had the sole medical care of the woman, and never suggested that anyone else should be called in, or admitted the case was beyond his powers. A fortnight before her death the woman's condition became very serious, and the accused gave her injections, and afterwards used an unsterilized rubber catheter. Towards the end he took the husband to his dispensary, told him that he had no medicine to offer him owing to the railway strike, and added that he would not stand in the way of further help being sought. The husband at once sent for Dr. T. W. Richmond, who attended with Dr. Blackie; they found the woman dying. A *post-mortem* examination showed extensive bed-sores, growths in various organs, and eighty-one gall stones in the gall bladder; but the immediate cause of death was acute cystitis. Dr. Richmond was closely questioned by Sir E. Marshall Hall for the defence, with regard to the prisoner's practice, the cause of death, the exclusion of the prisoner from the *post-mortem* examination, the proceedings in the coroner's court, the communication with the Director of Public Prosecutions, and "bloodless surgery" and "the profession of osteopathy." Dr. John Russell, who made the necropsy, said in cross-examination that he took no steps to acquaint the medical authorities of the circumstances of the case, and denied that he and other members of the medical profession had got their knives into the accused, either consciously or unconsciously; he believed that whatever action had been taken was in the interests of the public. He maintained that the use of an unsterilized catheter caused the cystitis from which the woman died; the treatment by the accused amounted to gross negligence. Dr. E. C. Myott, pathologist to the North Staffordshire Infirmary, said the woman had cystitis, and the catheter produced was not a proper instrument to use owing to the extreme difficulty of sterilization. Dr. B. H. Spilsbury said he had no reason to doubt the conclusion drawn by the medical witnesses that death was due to cystitis. External pressure was an improper mode of treatment, and it was gross negligence to try it. The catheter produced, if unsterilized, would suffice to account

for the introduction of micro-organisms from without, under the existing conditions of the case. Neglect of any of the recognized remedies for cystitis would tend to shorten life. Death was due to cystitis, and not to malignant disease. Sir E. Marshall Hall, after an unsuccessful submission that there was no case to go to the jury, intimated that he would call no evidence. Having objected to the expression quack doctor, he argued that this was an attempt to burk any form of medical practice not carried on by a duly registered member of the medical profession. The whole principle underlying this prosecution was "Down with the unregistered man! Protection for the members of the medical profession!" In the course of his summing up the judge said that the law was that when a person, licensed or unlicensed, dealt with the health of another he was bound to use competent skill and give sufficient attention, and if the patient died from want of either, the person was guilty of manslaughter. The jury found the prisoner guilty, and in sentencing him to four months' imprisonment with hard labour, his Lordship said he quite agreed with the verdict; had they not returned it the jury would have been doing something quite wrong and against the public interest. The real danger of unqualified men was when they got a really dangerous case and they did not know much about it, and the patient kept on getting worse, and a proper doctor was not called in until it was too late. He could not help thinking the prisoner was more misguided than anything else. He knew the effect of this conviction would be to destroy the prisoner's practice.

Medical News.

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, London, W.1. on Tuesday, March 16th, at 5.30 p.m.

A Society of Medical Officers of Maternity and Child Welfare Centres has been formed, and a draft constitution will be submitted to a meeting at Bedford College, Regent's Park, London, on Friday, March 26th, at 5 p.m. Medical officers in charge of centres who have not received an invitation to join the society are asked to communicate with the secretary, Miss Halford, National League for Health Maternity and Child Welfare, 4, Tavistock Square, London, W.C.1.

AT a meeting of the Central Midwives Board for England and Wales held on February 19th, Sir Francis Champneys in the chair, it was announced that Sir Francis Champneys, Dr. W. S. A. Griffith, and Mr. C. Sangster had respectively been re-elected as their representatives on the Board by the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London.

A SECOND post-graduate course of instruction in the diagnosis and treatment of venereal disease is being arranged by Mr. K. M. Walker at St. Bartholomew's Hospital Clinic, Golden Lane, E.C., established by the Corporation of London. The course will be held on Thursday afternoons at 5.30 p.m., commencing Thursday, March 4th. The beds attached to the clinic are available for the reception and study of suitable cases in addition to work in the out-patient department. There are still a certain number of vacancies. Any medical practitioner wishing to attend is invited to send his name to the Secretary, National Council for Combating Venereal Diseases, 81, Avenue Chambers, Southampton Row, London, W.C.1.

STEPS have been taken to form a properly constituted Old Students' Association at King's College, London. A committee was lately formed which has drawn up a provisional constitution, and a general meeting will be held on Thursday, March 4th, at 6 p.m., at the College, to ratify it. It has been possible to send notices of this meeting only to those old students whose names are on the register, but it is hoped that the meeting will be made widely known, and that as many old students as possible will be there.

A DEPARTMENT for diseases of children and a child welfare consultative centre will be opened at the Great Northern Central Hospital, Holloway Road, N., on March 1st. There will be two sections—medical and surgical—and patients, who must be children under 12 years of age, will be received on Monday afternoons at 2.30 p.m.

A PRACTICAL advanced course in operative ophthalmology will be given during May and June at the Hôtel-Dieu, Paris, by Professors De Lapersonne and Terrien, with the assistance of the heads of the clinic and laboratory. The course is open to foreign as well as French doctors and students. The class will be limited to forty and the fee is 100 francs. Communications should be addressed to the Secrétariat de la Faculté de Médecine, Paris.

THE Huddersfield Royal Infirmary has received an anonymous gift of £1,000 for the endowment of a bed in memory of the late Dr. Peter MacGregor of Huddersfield.

THE Senate of the University of London has appointed Dr. James McIntosh to the University chair of pathology tenable at the Middlesex Hospital Medical School, and Dr. Sidney Russ to be the first incumbent of the Joel chair of physics at the Middlesex Hospital Medical School.

THE Brighton Division of the British Medical Association has arranged a series of six clinical demonstrations, beginning March 4th, to be held at the Sussex County Hospital and the Children's Hospital. The demonstrations are open to all members of the profession.

QUEEN ALEXANDRA'S Field Force Fund, which was brought into existence in November, 1914, was demobilized last month. During the five years of its existence it sent out parcels to the number of nearly a quarter of a million to regiments in Europe, Asia, Egypt, Africa and the Cameroons. The surplus in hand is £3,000, and Queen Alexandra has decided that the annual interest shall, with certain limitations, be paid to the Village Centres Council for the benefit of the disabled ex-service men at the Village Centre, Enham, Hampshire.

IT is proposed to hold a reunion dinner in London, towards the end of April, for all ranks, men and women, of No. 34 (the Welsh) General Hospital and the Welsh Hospital, Netley. No. 34 General served as an Indian hospital of 3,000 beds, under the War Office, and the Welsh Hospital, Netley, was supported by Wales throughout the war. Colonel A. W. Sheen, A.M.S., formerly officer commanding successively the two hospitals, will preside at the dinner. Those wishing to attend are asked to notify Dr. R. L. Mackenzie Wallis, 55, Townshend Road, N.W.8.

AT a meeting of the Vienna Medical Society on January 30th Professor K. F. Wenckebach delivered a eulogium on the late Sir William Osler, the audience rising from their seats as a token of mourning.

THE Ministry of Health have been notified of a case of plague on the ss. *Alps Maru*, which arrived in the Port of London on February 9th from Japan, and entered the Millwall Dock on February 14th. One of the crew fell sick on February 15th, and as he was suspected on February 17th to be suffering from plague he was removed to the isolation hospital. The diagnosis of plague has been confirmed by the Bacteriologist of the Ministry from material obtained from the patient. The vessel has been removed to the Port Mooring Station for infected ships, and all necessary precautions have been taken by the port sanitary authority to prevent spread of infection.

PUBLICATION of the *Revue de la Tuberculose*, suspended during the war, is about to be resumed. It is the organ of the French tuberculosis society (*Œuvres de la Tuberculose*), and publishes its scientific proceedings. The *Revue* will be enlarged, and will in future publish original articles, as well as abstracts from other periodicals.

THE second number of *Discovery* (London: Murray, 6d. net; 7s. 6d. a year post free) is an advance on the first. It contains articles by Professor W. L. Bragg on crystal structure and by Mr. C. G. Darwin, of Cambridge, on the number of the elements, which seem to us exactly to fulfil the need which the periodical is intended to meet.

DR. MARCEL LABBÉ has been nominated professor of pathology and therapeutics in the Paris Faculty of Medicine.

THE Prussian Diet has appointed a commission consisting of Abderhalden, Lubarsch, Morawitz, Posner, Schittenhelm, Stephan, Stolte, Uhlenhuth, and others, to investigate the value of Friedmann's remedy for tuberculosis.

THE Hague bookselling firm of M. Nijhoff has celebrated the third centenary of the foundation of Batavia by issuing a catalogue of books concerning Netherlands India. It includes a section on medicine and on anthropology, containing books chiefly in Dutch, many of them on subjects concerned with tropical medicine.

AT a session of the "Gesellschaft für soziale Medizin, Hygiene und Medizinalstatistik," Professor Kayserling of Berlin proposed that a tuberculosis law should be enacted in Germany. It should aim exclusively at the prevention of tuberculosis, and no clause should be accepted which did not take into consideration the welfare of the patient. His principal points were (1) compulsory notification of every infectious case; (2) official organization of a network of dispensaries through which the law could be administered on a provident basis; (3) provision of hospital accommodation, free of charge, for advanced cases, dangerous to their home surroundings; (4) exclusion of infectious cases from employment bringing them into intimate contact with children; and (5) introduction of general measures affecting occupations and public health.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that **ALL** letters on the editorial business of the **JOURNAL** be addressed to the Editor at the Office of the **JOURNAL**.

The postal address of the **BRITISH MEDICAL ASSOCIATION** and **BRITISH MEDICAL JOURNAL** is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. **EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. **FINANCIAL SECRETARY** and **BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. **MEDICAL SECRETARY**, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

QUERIES AND ANSWERS.

INCOME TAX.

"W. B. C." inquires as to the assessment of income entirely derived from service on pensions boards.

As the appointment is not held directly under the War Office it would presumably be impracticable to support a claim to the special "service" rates of tax, and the income would be liable at the ordinary earned rates—that is, 2s. 3d. in the £ if the total income does not exceed £500, and 3s. if it is between that amount and £1,000. A reasonable sum to represent the additional cost of hotel board and residence would be an admissible deduction if the duties of the appointment—it is assumed that there is only one appointment—involve travelling from place to place.

"J. S." has been residing abroad as a missionary, and has been in this country on full salary since last June. What is his liability to income tax?

We assume that our correspondent has not maintained a residence in this country during his absence abroad. He is liable for the financial year ending April 5th, 1920, as a British resident. The appropriate form for his declaration is No. 12, and he can obtain one from the local inspector of taxes. He will be assessable on the amount of his salary so far as received in this country, less the abatement according to the usual scale, wife allowance of £50, provided that the total joint income of himself and his wife does not exceed £800 per annum, and life assurance allowance; the rate of tax will, of course, be on the earned scale, and he will apparently have a right to set off some excess tax suffered on his income from investments. A personal call at the office of the inspector of taxes might serve to clear up these questions conveniently.

LETTERS, NOTES, ETC.

A WARNING.

DR. W. J. O'SULLIVAN (16, William Street, Limerick, Ireland) writes to put medical men on their guard against a scheme for extracting money from their pockets. A well dressed man, he says, calls upon a medical practitioner (usually an Anglo-Irishman), stating that he has just been released on parole from an English prison, where he was interned for a seditious utterance, or tells some such story. He expresses great anxiety to get back to Ireland to resume his practice. In two cases in which Dr. O'Sullivan says his name was used, money was obtained, but not repaid as promised.

TREATMENT OF PSOROPTIC MANGE (PSOROPTES COMMUNIS, VAR. CUNICULI).

MR. J. E. M. MELLOR, B.A. (Gonville and Caius College, Cambridge), writes: The following note on a simple and successful treatment of psoroptic mange in a rabbit may be of interest.

On February 11th, 1919, a laboratory attendant brought me a rabbit, one ear of which was in the condition described by Crunston Low in 1911 (*An Investigation into Scabies in Laboratory Animals, Journ. of Path. and Bact.*, vol. xv, p. 338). The whole of the inside of the ear was filled with a mass of dry crusts like flakes of pastry. There was an offensive smell and the ear was tender and warmer to the touch than the unaffected one. There were a few dry scurfy scales on the outside of the ear, but these contained no acari. The head was sometimes carried slightly inclined to the side of the affected ear which hung down limply. The rabbit was observed to scratch occasionally and shake its head, when portions of the scaly debris would be shaken out.

On February 11th, portions of the pastry-like flakes were carefully removed from the ear with forceps (one piece removed measured 1.5 inches long and was 0.5 inch thick). Below these dry scales there was a soft whitish-yellow substance. This material and the crusts were examined under

the microscope and found to contain large numbers of acari. A small bunch of acari was placed on a slide under the microscope and a drop of a solution composed of 1 per cent. creosote oil mixture, 0.25 per cent. bile, and 10 per cent. soft soap was run in. All the mites were dead in four minutes. (For the composition of creosote oil mixture see "Investigations on the Prevention of Nuisances arising from Flies and Putrefaction," by F. W. Foreman and G. S. Graham-Smith, *Journ. Hygiene*, 1917, xvi, 2, pp. 109-226.)

A few drops were therefore applied to the inside of the rabbit's ear with a small pipette. On February 12th and 13th the same treatment was repeated. Only a few drops of the solution were used, as it was not certain whether it would irritate the tender surface of the animal's ear. On February 14th mites found were sluggish. Since no signs of irritation were observed and the animal did not seem worried by the treatment, more solution was used on February 14th and 15th. The ear was held up by an attendant, and a few cubic centimetres of the liquid kept in for four minutes on both occasions. No mites were found on February 15th. On February 18th the ear was quite clean, save for two lump-like scabs on the outside and back of the ear. These scabs were slightly raised off the surface of the skin and treated with a few drops of solution.

On March 5th the rabbit was again examined carefully. No parasites were seen, and the ear was clean, though it still felt a little warmer than the unaffected one.

The cure was therefore effected in four days. After the first treatment on February 11th the rabbit was placed in a clean hutch. The infected hutch was cleaned out and all the scrapings burnt. The inside of the hutch was then thoroughly sprayed with creosote oil mixture undiluted. A healthy rabbit placed in the disinfected hutch and rabbits in the adjoining hutch remained clean.

A mangy rabbit taken from another hutch was later completely cured by similar treatment administered by an attendant when I was away. Less than 50 c.c.m. of solution were used, so that the cost of treatment of the rabbit amounted to less than a penny.

These mites are very active; one mite dragging its mate *in copulo* was timed with a stop-watch on the small striations on the back of a linen-covered book. It was found to cover 6 mm. in five seconds.

A GRATEFUL COUNTRY.

A CASE recently brought to notice is that of a medical officer who sustained a serious wound of the head causing hemiplegia. He recovered sufficiently to return to military service, but was again wounded, this time in the foot. He has been discharged with a pension of £170 a year. He is a married man with children. The National Relief Fund exists to help men who have thus suffered for the country, and it has recently made a grant to the medical War Emergency Fund, and from this fund something may be done for this individual medical officer. But is it right, and is it in accord with the intention of the country, that men who have served so well and suffered so much should have to seek help to supplement their pension? Ought not the pension itself to be adequate? It may be said that this officer's pension is nearly as much as a man in the ranks will receive if totally disabled. But is it good national economy to put a professional man in such a position that he cannot educate his son to succeed him in his profession?

ERYSIPELAS: A CORRECTION.

DR. F. S. ARNOLD calls attention to an error in his reply to "X.Y.Z." in last week's **JOURNAL**. The word "eczema" (p. 278, col. 1, line 5) should, of course, be "erysipelas."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 38, 39, 40, 41, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 36, 37, and 33.

The following appointments of certifying factory surgeons are vacant: Belturbet (Cavan), Berkeley (Gloucester), Bruff (Limerick), Clonakilty (Cork), Halstead (Essex), Lochgilphead (Argyll), Romford (Essex), Stock (Essex), Stourport (Worcester), Toddington (Bedford).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

DYSPEPTIC AND OTHER REFERRED SYMPTOMS ASSOCIATED WITH DISEASE OF THE GALL BLADDER AND OF THE APPENDIX.

A BRITISH MEDICAL ASSOCIATION LECTURE GIVEN TO THE
NORFOLK BRANCH AT NORWICH, DEC. 19TH, 1919.

BY

SIR HUMPHRY ROLLESTON, K.C.B., M.D., F.R.C.P.,
EMPHYSICUS PHYSICIAN, ST. GEORGE'S HOSPITAL; PRESIDENT OF
THE ROYAL SOCIETY OF MEDICINE.

By referred symptoms is meant those that do not at once suggest local disease of the organ really responsible or that are remote in point of place; they might be described as masked or, as they are often the first manifestations of disease, inaugural, or as larval or *fruste*.

The discussion of this subject has its difficulties; to consider separately the gall bladder and the referred symptoms caused by its disease and then appendicitis and its referred symptoms might be the simplest course; but as this would lead to some tedious repetition it appears advisable to take the symptoms and to refer incidentally to their causation. Most of the infective complications of gall bladder and appendix disease, such as the various forms of hepatic suppuration, empyema and fistulae, and intestinal obstruction due to adhesions, bands or gall stones, will not be mentioned. Except when specially stated, the disease of the gall bladder and appendix is not acute but either the result of a past attack of acute inflammation, such as fibrosis, adhesions or calculi, or a recurrent or chronic inflammation. Further, it may be pointed out that what we commonly call a "chronic appendix" is more often the result of a past attack than a progressive and chronic inflammatory process.

Mechanism of the Production of Symptoms.

The question how morbid changes in the gall bladder and appendix induce symptoms in other viscera and distant parts will be touched on in connexion with these manifestations, but the various mechanisms that may be at work in different cases may be tabulated here as (1) Reflex, (2) Mechanical, (3) Toxic, (4) Infective.

1. *Reflex*.—Irritation in the appendix or gall bladder may cause hypertonus of the stomach and spasm of, or failure to relax on the part of, the pyloric or ileo-caecal sphincter, leading to gastric or ileal stasis and so to excess of acid or to toxæmia. Vigorous contraction of the stomach extending to the pylorus has been watched by Moynihan, during the course of laparotomy on patients with appendix dyspepsia, and Hurst¹¹ has seen visible spasm of the middle of the stomach when the appendix is manipulated under the *x*-rays. The pyloric spasm or want of relaxation of the pylorus has been regarded as a protective mechanism. In the case of chronic appendicitis failure of relaxation of the ileo-caecal sphincter is thought by Hurst to be commoner than spasm. Caecal stasis from inhibition of peristalsis or from enterospasm (spastic constipation) may be due to chronic appendicitis; when situated in the pelvis a chronically inflamed appendix may reflexly inhibit defaecation (dyschezia, Hurst¹⁰). Appendicitis may reflexly lead to increased frequency or inhibition of micturition through an irritated focus in the spinal cord (Mackenzie); and chronic irritation of the appendix may be responsible for cardiac irregularities.

The reflex pain in the epigastrium, which is so common in appendix and gall-bladder dyspepsia, has given rise to some discussion; Mackenzie maintains that it is in the peripheral terminations of the sixth and seventh dorsal nerves in the abdominal wall, and that this depends on the irritated focus in the spinal cord, whereas Hurst¹¹ argues that the pain is visceral, in the pyloric end of the stomach, and due to the peristalsis. They both, however, agree that the epigastric tenderness is due, not to pressure on the stomach, but to the irritated focus in the spinal cord which causes an exaggerated sensory effect when the skin, and especially the muscles and the underlying subperitoneal tissues, are pressed on. The referred cutaneous pain in gall-bladder disease may occasionally spread to the top of the right shoulder, and extend down the outside of the arm, so that patients may for years be treated for "neuritis"

until the passage of a gall stone at once brings relief (Mackenzie).

Very often the appendix when removed shows little naked-eye change to correspond with the prominent symptoms that then disappear; microscopic examination may be necessary to reveal the evidence of past inflammation in its walls, especially fibrosis in the submucous coat, and often, as I have seen in many sections, the changes are very slight. The ganglion cells of Auerbach and Meissner's plexuses have been found to show degeneration (Pfeiffer). Stimuli generated in the appendix travel by the sympathetic to the spinal cord, and by constant repetition give rise to a persistent irritable focus in the spinal cord, and so to a reflex extension of impulses. In women the right ovary and tube are very often matted together with the appendix, infection readily passing from one to the other. Ovarian and uterine dyspepsia, analogous to those now under consideration, have been described.

2. *Mechanical*.—Pericholecystitic adhesions may embarrass the movements of the stomach, interfere with the passage of food through the pylorus, or even lead to an hour-glass stomach. Though often the legacy left by cholecystitis, these adhesions may be due to duodenal or gastric ulcer. Peri-appendicular adhesions may cause intestinal stasis and so toxæmia, and the same result, only in a more marked degree, may be produced by an appendix adherent across the lower part of the ileum. In some cases adhesions about the appendix or the gall bladder may possibly alter the radiation of pain; adhesions around an inflamed gall bladder have been thought to cause left-sided pain, and adhesions between an inflamed gall bladder and the peritoneal coat of the appendix to explain the pain referred to the right iliac fossa (Tripiet and Paviot).

3. *Toxic*.—Absorption of bacterial toxins from the gall bladder or appendix may set up general toxæmia, cause myocarditis, and damage the mucous membrane of the stomach and intestines, thus giving rise to hæmorrhage. Toxic absorption from the inside of the organ is probably more often an important factor in the case of the gall bladder than of the appendix.

4. *Infective*.—Micro-organisms from the appendix or gall bladder may infect the kidneys, especially the right. Infection of the gall bladder is prone to spread to the pancreas, and local thrombo-phlebitis of branches of the iliac veins, secondary to appendicitis, may give rise to small pulmonary emboli and pleurisy; malignant endocarditis has been found to be associated with gall-bladder infection (Leva collected nine cases as long ago as 1892) and with appendicitis. As is well known, inflammation of the appendix and gall bladder are often associated; although the true relations of the two infections may vary, it seems probable that most commonly the appendix is the earlier affected and that from this focus the gall bladder becomes infected. The changes left in the appendix may be comparatively slight while there is considerable cholecystitis.

Dyspepsia.

The general recognition that disease of these two appendages of the alimentary canal may produce definite symptoms of gastric and duodenal disorder with few or no localizing symptoms is comparatively recent and is due to the observations on "the pathology of the living" (W. J. Mayo, Moynihan, Paterson, S. Fenwick); though had abdominal surgery been active in his time there can be little doubt that John Hilton would have expanded his conclusions on "sympathetic pains on the surface of the body connected with derangements of the internal viscera," and would have laid stress on the connexion between reflection of pain from the gall bladder to the stomach and duodenum on the one hand and the origin of the hepatic diverticulum from the foregut on the other.

As the dyspeptic symptoms in a certain number of cases depend on an organic lesion, resist symptomatic treatment, but yield to operative interference, the term "surgical dyspepsia" has arisen.

This attractive explanation, however, must not lead to the conclusion that dyspepsia is always, or, indeed, usually, due to an organic cause, and that the short cut to a cure is by way of the knife. A high estimate, at least for a physician, is that of M. J. Lichty, among whose 1,500 patients with gastro-intestinal disorders 600, or 40 per cent., were found at operation to have disease of the gall

bladder or appendix. It is, moreover, important to consider how far medicine can re-assert its position by in its turn preventing infection of the gall bladder and appendix. With regard to the gall bladder we know that cholecystitis is due to various foci of infection: from the vermiform appendix, from the intestines, particularly in enteric fever, from the stomach and teeth, and from the tonsils by the blood stream; for Roseow and Brown have shown the great frequency of haemolytic streptococci in inflamed gall bladders, argue that *B. coli*, formerly considered as one of the two commonest causal organisms of cholecystitis, is often a secondary invader, and from experimental observation believe that these streptococci in the tonsils have a special tendency to settle down in the gall bladder. The aetiology of appendicitis has been much debated; probably several causes are at work; but the elimination of septic foci in the mouth, tonsils, and nasopharynx, the supervision of food supplies, and early attention to signs of intestinal infection and constipation would diminish the frequency of this surgical disease. In connexion with the prevention of tonsillitis it is appropriate to refer here to Dr. G. I. T. Stewart's observations showing the causal relation of bad teeth to inflammation of the tonsils.

Gall-bladder dyspepsia is sometimes spoken of as the result of gall stones rather than the exclusion of cholecystitis, whereas a broader view holds the field as regards appendix dyspepsia, which is ascribed to appendicitis, and not solely to the faecal concretions. The correct view is that in the main the cholecystitis causes both the symptoms and the gall stones. It is of course true that single cholesterol calculi may form without any antecedent inflammation of the gall bladder, though they may subsequently favour the occurrence of cholecystitis. These calculi are much less common than those due to cholecystitis, and, I believe, may form an exception to Sir Berkeley Moynihan's dictum that gall stones always cause symptoms.

The evidence that referred dyspepsia is due to disease of the appendix or gall bladder rests on the disappearance of the symptoms after removal of a chronic inflamed appendix or gall bladder, and is analogous to the familiar relief of headache by removal of a decayed tooth. Cases not relieved by gastro-enterostomy have subsequently been cured by appendicectomy, and it has been urged that no laparotomy for disease of the stomach or duodenum, especially if no obvious disease in these organs be found, is complete without examination of the gall bladder and appendix. It was noted by Soltan Fenwick that patients with a peculiar form of gastric hypersecretion were prone to die from appendicitis, the real explanation apparently being that the hypersecretion was due to latent appendicitis which subsequently flared up. The diagnosis of gall bladder or appendix disease as the cause of dyspepsia in a given case may be very difficult; in both instances the primary lesion may be latent, there may be an absence of any history of an acute abdominal attack, and there may be no local tenderness over the gall bladder or appendix.

The dyspeptic symptoms associated with chronic disease of the gall bladder and appendix, which are commoner in women, show considerable variation, and it is very doubtful if any differential diagnosis as to which organ is primarily at fault can be made on the characters of the subjective manifestations only. Pain and tenderness on pressure in the epigastrium and flatulence are the most constant symptoms; the pain may be persistent, but is often at once made worse by food; or it may come on after an interval of hours, as in duodenal ulcer; possibly the pain directly after a meal in cases of cholecystitis or gall stones may be caused by vigorous contractions in the gall bladder as well as in the stomach. Heartburn is common, and vomiting may follow. The symptoms are often of long duration, and their obstinate resistance to remedies, such as bismuth, alkalis and food, that relieve ordinary indigestion, is a prominent feature. The prolonged pain and toxæmia, especially in cases with appendicitic adhesions, may induce neurasthenia and recurrent headaches. The condition of the gastric juice varies; there may be hyperchlorhydria, a normal or a much diminished amount of hydrochloric acid. Among 156 cases of gall-bladder disease, J. A. Lichty found that 84, or 54 per cent., showed hyperchlorhydria; 41, or 26 per cent., a normal; and 31, or 20 per cent., a diminished amount of HCl. Among Shierren's 20 cases of gall-bladder disease there was an absence of free HCl in 16.

There is a similar variation in appendix dyspepsia, and Fenwick considers that the condition of the appendix is an important determining factor; when there is active irritation, such as an enterolith or ulceration, hyperchlorhydria results, whereas with a merely thickened, adherent, or kinked appendix the symptoms are those of chronic gastritis with diminution or absence of HCl. He regards the hypersecretion as reflex, but there is the alternative view that spasm, or failure to relax on the part, of the pylorus leads to retention of food and accumulation of HCl. In a comparatively small number of cases there is haematemesis, which may be considerable and suggest gastric or duodenal ulcer. In my limited experience this has seemed less rare in appendix than in gall-bladder dyspepsia, but in a large series of cases operated upon in the Mayo clinic gastric haemorrhage and symptoms were present in 5 per cent. of gall-bladder infections and in 2 per cent. of appendicitis cases (Crispin). It is tempting to regard the haemorrhage as due to toxæmia, but the source of the poison is not always obvious, as the appendix may be merely obliterated. It is true that Paterson and others ascribe the symptoms of appendix dyspepsia to toxæmia due to intestinal stasis, and on this hypothesis an exacerbation in the intestinal toxæmia might be postulated as the exciting cause of haematemesis. But considerable gastro-intestinal haemorrhage is rare in acute appendicitis in which the toxæmia is so much more obvious. It is somewhat fanciful to imagine that there is sufficient reflex dilatation of the vessels in the gastric mucosa to produce weeping, but this is perhaps suggested by the peritoneal flush over the pylorus in these cases of appendix dyspepsia. Soltan Fenwick's explanation of gastric haemorrhage is probably more satisfactory—namely, that as a result of long-continued exposure to gastric juice with two to five times the normal percentage of free hydrochloric acid the gastric mucous membrane becomes inflamed, acutely congested, and shows haemorrhagic erosions. In some instances a gastric or duodenal ulcer is associated with appendicitis or gall-bladder disease. Among 1,078 cases of gastric and duodenal ulcer at the Mayo clinic 40 per cent. showed disease of the appendix and 9.7 per cent. disease of the gall bladder (Eusterman). These figures perhaps explain my impression that haematemesis is less rare in appendix than in gall-bladder dyspepsia. In rare cases gastro-intestinal haemorrhage may be due to ulceration of the gall bladder or of the ampulla of Vater when a gall stone is impacted there, but in the latter instance the symptoms would be those of intermittent hepatic fever.

Diagnosis.

The differential diagnosis of appendix and gall-bladder dyspepsia from gastric and duodenal ulcer presents considerable difficulties, but an x-ray bismuth or barium meal may give valuable assistance in providing the positive evidence of gastric or duodenal ulcer on the one hand, or of appendix or gall-bladder disease on the other. Hurst² has tabulated the x-ray results in favour of the presence of a chronic lesion of the appendix, and points out that the tenderness of the appendix—the most important sign—may be missed without the guidance of x-rays, as the organ may be displaced when pressure is applied; other signs are those of adhesions, ileal and caecal stasis, and though hypertonus of the stomach, which empties itself with abnormal rapidity, may be present, this is both much less frequent and less well marked than in duodenal ulcer, the spasm due to chronic appendicitis being more commonly in the middle of the stomach. From careful examination of a large number of cases Spriggs finds that the following indications of chronic disease—namely, partial filling of and stasis of barium in the appendix, constrictions, dilatations, and concretions—can be demonstrated by the x-rays. Adhesions around the gall bladder are characterized by a high position of the stomach, displacement of the pylorus to the right, distortion of the duodenal cap and of the hepatic flexure of the colon, and retention of food in the stomach for six to eight hours. Opinion differs as to the value of x-rays in the detection of gall stones; some American skiagraphists claim that 75 per cent. of gall stones can be thus diagnosed, and Pancoast and Pfahler regard 50 per cent. as a conservative estimate.

Turning to the other means of diagnosis, the pain of gastric ulcer is relieved by food and by alkalis, and in

duodenal ulcer there are usually periods of complete freedom from symptoms and hyperchlorhydria; in both these conditions occult blood in the faeces is much more likely to be present than it is in the referred dyspepsias. In favour of an appendicular origin are radiation of pain towards the right iliac fossa, with local tenderness there or on rectal examination, and Bastedo's sign—namely, localized pain and tenderness on pressure in the right iliac fossa on inflation of the colon. Deep tenderness to the right of the spine between the seventh and eleventh ribs is regarded as pathognomonic of pericholecystitic adhesions by Friedman, who considers it more valuable than x-rays. The tenderness has been ascribed to extension of inflammation to the chest wall so as to set up a mild neuritis.

It must of course be borne in mind that both the appendix and the gall bladder may be diseased, and that removal of one may not cure the symptoms. A few words may be said about the way in which disease of the gall bladder and appendix may imitate each other. An elongated gall bladder with a Riedel's lobe or peritoneal adhesions between the two organs may explain why in some cases of cholecystitis a diagnosis of appendicitis is corrected only at laparotomy. The converse mistake is less common, but may be due to an appendicitis close to the right lobe of the liver so that it becomes adherent to the gall bladder, or to other less obvious causes. In this connexion the following case is interesting.

A man aged 32 years had jaundice when 14 years of age, and since then had had repeated attacks of jaundice, much flatulence, and general ill health. Two months before I saw him he had had an acute abdominal attack regarded as appendicitis, and was much jaundiced. When seen there was tenderness over the gall bladder, and there was nothing palpable or any tenderness on the right side per rectum. The pre-operative diagnosis was recurrent cholecystitis, but the gall bladder was found to be perfectly normal, and there was a tense mucocoele of the appendix. He then completely recovered, went through the war, and was reputed to be well in December, 1919. Possibly the attacks of jaundice were due to disturbance of Meltzer's law of contrary innervation. The sphincter at the lower end of the common bile duct and the muscular fibres of the gall bladder are antagonistic; when the gall bladder contracts the sphincter relaxes; if from reflex disturbance the sphincter fails to relax during contraction of the gall bladder, the pressure of bile in the ducts will rise, and jaundice, and even colic, will result.

Chronic Colitis.

Chronic colitis with exhausting diarrhoea is occasionally due to continued infection from the gall bladder or appendicitis. This diarrhoea and serious wasting may occur without any localizing symptoms, and with little in the history to suggest the responsible focus. Martiu reported one of the first cases of this kind in a man without any signs pointing to appendicitis; exploratory laparotomy showed a thickened appendix with a dilated cavity communicating with the caecum; the appendix contained one or two enteroliths and extremely foul-smelling material, resembling in this respect the motions. Frequent bulky offensive motions with excess of fat occur in chronic pancreatitis, which may result from gall-bladder infection, or from a stone in the common duct.

Glycosuria and Diabetes.

It is now recognized that glycosuria or diabetes, if, indeed, any real distinction between them should be drawn, may be due to pancreatitis set up by infection associated with gall stones. It is not a common sequel, and, though a calculus may get into the common bile duct without obvious symptoms, it must be very rare for gall stones to cause diabetes when their presence is entirely unsuspected. The surgical treatment of certain cases of diabetes practised by Sir A. W. Mayo-Robson is an illustration of preventive surgery, as it aims at the removal of the cause before the resulting pancreatitis has reached an extreme stage.

Cardiac Symptoms.

The dyspepsia due to appendix or gall-bladder disease may be associated with palpitation, irregularity, and sub-sternal distress. M. J. Lichty found that in appendix cases the cardiac disturbance was usually functional only, whereas in gall-bladder disease, either alone or combined

with appendicitis, the resulting cardiac disease was more serious. Absorption of toxins from an inflamed gall bladder or ducts may cause myocarditis, anginoid symptoms, and cardiac failure. In a paper on chronic cholecystitis as a cause of myocardial incompetence, Babcock records thirteen cases, medical advice being sought, with two exceptions in which biliary colic occurred, for cardiac disorder without any suspicion of gall-bladder trouble. Angina or anginoid symptoms in patients with gall bladder disease may be due to exhaustion of the poisoned myocardium; a specially interesting case, as it raises the question of Graves's disease as a result of gall-bladder infection, is reported by Sears: a woman had intense precordial pain spreading to the left shoulder, a raised pulse rate, an enlarged thyroid, and other symptoms suggesting Graves's disease; an attack of biliary colic led to operative removal of two gall stones and disappearance of all the symptoms. Babcock described a group of his cases in which attacks of angina preceded cardiac failure. The pain of biliary colic sometimes imitates angina, and cases in which attacks of angina have cleared off after frank biliary colic are on record; it has been suggested that as the result of adhesions the pain of biliary colic may be felt on the left side. The symptoms of existing valvular disease may be intensified; or compensation may be broken down by toxic myocarditis due to gall-bladder infection. It is important to remember this, and also that the cardiac weakness is often entirely due to the gall-bladder disease, and will be cured by surgical treatment; for operation may be considered to be contraindicated by the condition of the heart. Janeway spoke hopefully of operation in these cases if performed under a local and not a general anaesthetic, the danger being more often from post-anaesthetic pulmonary complications. By waiting time may be lost without improvement in the cardiac condition; but in one case of this kind a vaccine made from organisms isolated from the faeces appeared to do good.

Pyelitis and Pyelonephritis.

Pyelitis and pyelonephritis may be due to infection with *B. coli*, either from the gall bladder or from the appendix: as far as I know, this usually occurs in the right kidney and then suggests a local extension of infection. I have seen right-sided pyelitis in a patient with chronic gall-bladder disease and from the comparative severity of the symptoms suggest acute cholecystitis; the difficulty in such cases is to be sure that both conditions are not present. By becoming adherent to the right ureter an inflamed appendix may cause pyelitis and the aspect of the case may be chiefly renal, and from the free haemorrhage even suggest a calculus; cases of this kind, usually after acute appendicitis, have been described by Hunner. I have been told of a case in which the appendix perforated into the ureter. An inflamed appendix situated high up and close to the kidney may possibly infect the pelvis of the organ.

Synovitis and Arthritis.

In common with other infective conditions of the stomach and intestines, appendicitis and cholecystitis very seldom give rise to a chronic or subacute arthritis such as is associated with oral sepsis. Dysentery is the disease in which the most extensive destruction of mucous membrane and opportunities for absorption occur, and yet synovitis is neither common nor, as a rule, severe. Arthritis in enteric fever is somewhat rare, and might be explained as the result of the early septicæmic stage. It seems plausible to suggest that the liver may protect the joints from damage due to intestinal infections. This hypothesis would naturally at once raise the objection that oral sepsis is an, if not the most, important cause of arthritis, and probably acts by infecting the stomach. On this point I would urge that the discharge of pus from the gums into the mouth, though a frequent cause of gastritis, is not so effective in producing arthritis as infection at the roots causing absorption into the blood stream. In rare instances appendicitis, usually acute, is associated with synovitis; this at first gave rise to the view that inflammation of the appendix, like that of the tonsil, both of which are rich in lymphoid tissue, was rheumatic in origin. But some years ago Poynton in discussing the association of

appendicitis with arthritis came to the conclusion that the articular affection was probably secondary to the appendicitis.

The Lettsonian Lectures

ON

TUMOURS COMPLICATING PREGNANCY,
LABOUR, AND THE PUERPERIUM.

DELIVERED BEFORE THE MEDICAL SOCIETY OF LONDON,

BY

HERBERT R. SPENCER, M.D., B.S., F.R.C.P.,

OBSTETRIC PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.

(Abstract.)

LECTURE III.—CANCER OF THE UTERUS COMPLICATING PREGNANCY, LABOUR, AND THE PUERPERIUM.*

THE lecturer presented two tables, reproduced on page 323, giving brief particulars of the ten cases of cancer of the cervix complicating pregnancy, labour, and the puerperium which he had had under his care at University College Hospital. He had not met with a case in private practice. He related the details in each case, but it appears sufficient here to reproduce those with regard to the three cases, observed in advanced pregnancy, in which the patients, after high amputation of the cervix, survived for twenty-five, twenty-two, and nineteen years respectively.

Patient Alive 25 Years after Operation.

E. W. (Table F, No. 1), aged 33 (children 4, abortion 1) was delivered on March 25th, 1893, by forceps through a cancerous cervix, of a full-term living child, which died of whooping cough when 11 months old. The labour was slow. The patient had had a discharge of blood for eight months. There was no *post-partum* haemorrhage.

On April 8th, 1893, high amputation was performed with the Paquelin cautery (see Figs. 1 and 2). On June 6th, 1894, she became pregnant in the body, which had been left behind. On March 6th, 1895, I delivered her by Caesarean section, terminated as a Porro's operation, with extra-peritoneal treatment of the stump. This child grew up and served as a soldier in the great war, 1914-18. In 1918, twenty-five years after the high amputation, the mother was examined by me and found to be in excellent health.

Patient Alive 22 Years after Operation.

A. C. (Table F, No. 2), aged 35 (children 8, abortion 0), was admitted to University College Hospital on January 3rd, 1896, when seven months pregnant. She had had haemorrhage on coitus for seven months, and a thin, watery offensive blood-stained discharge for six months. There was a large cancerous growth on the posterior lip and left side of the cervix. Labour was induced by de Ribes's bag; the child (3 lb. 7 oz.) lived only thirty-eight minutes.

On January 28th, 1896, I removed the cervix by the high amputation with the Paquelin cautery (see Figs. 3 and 4).

I have seen this patient many times since the operation. I examined her in 1918, twenty-two years after the operation, and found her free from recurrence and in excellent health.

Patient Alive 19 Years after Operation.

M. S. (Table F, No. 3), aged 38 (children 9, abortion 0), was delivered in the maternity of University College Hospital on January 25th, 1896, naturally, of a living child. She had had no bleeding during the pregnancy, but blood and shreds were passed every day afterwards. On June 5th—four months and eleven days after delivery—she was examined and found to have cancer of the cervix. High amputation was performed on June 30th, 1896.

* Delivered March 1st.

(See Figs. 5 and 6.) In 1915—nineteen years after the operation—I examined the patient and found her free from recurrence and in excellent health. The child lived at least to the age of 8 years. I have no further note about her, and the mother's present address is unknown.

(These three cases were published in the *Obstetrical Society's Transactions*, vol. xi, 1904.)

The rarity of the combination of cancer of the uterus with pregnancy is shown by the fact that few gynaecologists have published a list of even ten cases. Moreover, their cases have not been all personally treated by the authors, but are often the collected cases of clinics published in inaugural dissertations and theses, the inexperienced writers of which are wanting in the intimate knowledge which only personal attendance can give. In the clinic of Professor Wertheim, who has had such an extensive experience of this disease, amongst 250 cases of cancer of the cervix, only six were complicated with pregnancy, and some of these were not treated by him. The largest series attended at one clinic I have been able to find is that published by Glockner,¹ consisting of seventeen cases from the Zweifel's Gynaecological Clinic at Leipzig, followed by a series of ten cases from the same clinic by Aulhorn.² In 1904 Sarwey³ had been able to collect from the literature only 240 cases of this combination which had been subjected to operation, and gives the frequency (84,000 labours) as 1 in 1,600 labours.

AGE.

Of the ten patients two were between the ages of 20 and 30 (20 per cent.); seven between the ages of 30 and 40 (70 per cent.); and one was aged 40 (10 per cent.). Of Sarwey's collected series 17.8 per cent. were between 20 and 30, 64.4 per cent. were between 31 and 40, and 17.8 per cent. were between 41 and 50. From the ages of 3,442 cases of cancer not complicated with pregnancy, Sarwey shows that only 3 per cent. were between 20 and 30, 22.4 per cent. were between 31 and 43; 34 per cent. were between 41 and 50.

These figures indicate that in the child-bearing period of life cancer not combined with pregnancy is at its maximum in patients over 40, but when combined with pregnancy, under 40; and that below 30 the frequency of cancer is six times as great in the pregnant as in the non-pregnant.

The youngest of my patients was 26 years of age. I have never met with cancer of the cervix at an earlier age than this. Of Sarwey's collected cases the youngest was only 22; the oldest was 47.

NUMBER OF PREGNANCIES.

Cancer of the cervix is very rare in women who have not been impregnated. Olshausen and Döderlein have published cases of cancer complicating the first pregnancy. Cancer even in the second pregnancy is rare, having been found only six times in Sarwey's 180 cases. To these may be added my Case 3. My 10 cases had had in all 70 children and 11 miscarriages—that is, an average of 7 children and over 8 pregnancies. Six out of the 10 patients had had 8 children, and half of them had had 9 or more children, the greatest number of pregnancies being

FIG. 1.—Case 1, Table F. Cervix just before the operation. From a drawing by the author. (Natural size.) *Obstet. Soc. Trans.*, xlvii.

15 (Case 9). The influence of multiparity is thus shown, as in all other statistics dealing with this combination.

The reason why cancer of the cervix should be almost confined to parous women and so extremely rare in virgins has been much discussed. Lacerations during labour and abortion have been supposed by many to be the causes, but observations on this point are few; Sir John Williams published a striking case in which the laceration was the only part of the os not affected. It seems probable that lacerations, by exposing the cervical mucous membrane to external irritation, may tend to favour the development of cancer, but its influence is probably small; for cancer often develops in cases in which there is no sign of previous laceration, and in situations where lacerations do not occur; and, moreover, cancer of similar structure occurs in the body of the uterus, where lacerations do not arise.

Erosions have been thought by some to be a pre-cancerous condition, and very radical methods of treatment have been suggested. As erosions are very common in virgins, in whom cancer of the cervix is extremely rare, it is quite certain that erosions rarely develop into cancer. Nevertheless, in erosions are sometimes found both metaplasia and hyperplasia and even slight downgrowth of the epithelium, so that occasionally the differential diagnosis from early carcinoma is difficult. To the naked eye a case of this kind sometimes shows papillary, club-like, or finger-like processes, or even extensive papillomatous growths which may closely resemble cancer. These growths are, I think, sometimes the result of excessive sexual irritation and of venereal infection. And I am inclined to think that when the question of the causation of cancer of the cervix is solved it will be found that the reason why this disease is almost limited to women who have had coitus is that local venereal infection is almost limited to them. I do not know of a series of scientific investigations into the relations of syphilis, soft sores, and gonorrhoea to cancer of the cervix, but I believe it will be found to be close. I have twice seen cancer of the cervix develop in patients who had previously had a chancre of the cervix.

FIG. 3.—Case 2, Table F. Cervix just before the operation. From a drawing by the author. (Natural size.) *Obstet. Soc. Trans.*, xlv.

Influence of the Cancer on the Pregnancy.

Cancer of the cervix, by obstructing the canal, by the haemorrhages and discharges to which it gives rise, and the infection and inflammation which often accompany it, tends to prevent the occurrence of pregnancy, and, when it occurs, to produce abortion or premature labour.

Of my ten cases two aborted spontaneously at the fifth and sixth month. Both were septic on admission to the hospital, and it is probable that the infection brought on the abortion. Apart from this there does not appear to be

a great tendency for abortion to occur in the early months. Of the six cases of pregnancy in the eighth and ninth calendar months in no fewer than three labour came on prematurely; this seems to show a great tendency to premature delivery. The growth may in some cases be so extensive as to prevent the delivery of the child, and "missed labour" may occur. In one case the uterus ruptured during labour. The high mortality is due to haemorrhage, sepsis, and rupture of the uterus.

FIG. 2.—Case 1, Table F. Microscopical drawing, low power, showing squamous-cell carcinoma. *Obstet. Soc. Trans.*, xlv.

Influence of the Pregnancy on the Cancer.

The influence of the pregnancy on the cancer has varied in different cases. The three cases which were inoperable survived from seven to twelve months, which does not show any marked rapidity of growth after delivery, seeing that in all the cases the growth had reached an advanced stage at the time of delivery, which was difficult (forceps, Caesarean section, forceps for rupture of uterus).

SYMPTOMS.

Of the three chief symptoms of cancer of the cervix—haemorrhage, discharge, and pain—the most important is haemorrhage. When the cancer complicates pregnancy the haemorrhage may lead the patient to think she is not pregnant or has miscarried.

Haemorrhage as a result of coitus is a symptom of the greatest importance. It occurred as the first symptom in Case 6 (Table F, No. 2) and was followed by a characteristic thin watery, offensive, blood-stained discharge, which after it had existed for six months led the patient to seek advice. In some cases, however, the growth does not bleed as a result of pressure upon it. An instance of this was Case 9 (Table F, No. 5), and Kreps has published a similar case (*Inaug. Diss.*, Berlin, 1905). In some cases haemorrhage occurs at approximately monthly periods and thus leads the patient into error with regard to the presence or duration of pregnancy.

Discharge is often the earliest symptom, but is unnoticed by the patient, owing to the frequency with which it occurs from other causes. When, however, it is watery and discoloured, or bloodstained, it should at once arouse

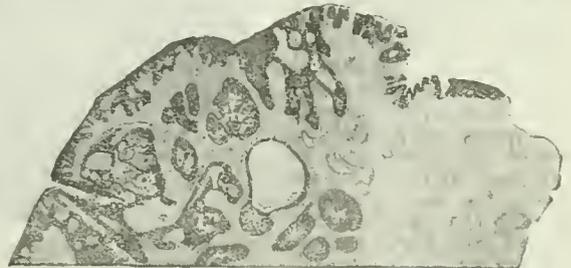

FIG. 4.—Case 2, Table F. Microscopical drawing of edge of growth showing squamous-cell carcinoma. *Med. Soc. Trans.*, xliii.

suspicion; an offensive discharge is due to necrosis, and often occurs only in the later stages of the growth.

Ordinarily pain does not occur in cancer of the unimpregnated uterus until the growth has extended beyond the organ; occasionally inflammation resulting from bacterial infection will cause it to appear while the growth is limited to the cervix. In cases complicated by pregnancy, pain may occur at an earlier date; it is due to contractions of the uterus or to a threatened or actual abortion, as well as to septicæmic infection, which is very prone to occur in these cases. The secondary symptoms—wasting, malaise, cachexia, pressure symptoms—do not differ from those met with apart from pregnancy.

DIAGNOSIS.

Cancer of the uterus complicating pregnancy always affects the cervix; there is, so far as I know, no case recorded of cancer of the body complicating pregnancy which will stand investigation. The cases formerly published were either cases of chorion-epithelioma or sarcoma.

In the early months it may be difficult to make out the condition of the pregnant uterus on account of the presence of the growth and the bleeding to which bimanual examination may give rise. On the other hand, the uterus is not rarely distended by pus (pyometra) in cases of cancer of the cervix, and it may then closely simulate a pregnant uterus, especially if menstruation has stopped. This will rarely occur apart from pregnancy until the age of the menopause (47), and pregnancy at this age is so exceedingly rare that only one case was recorded in Sarwey's collection.

On vaginal examination, either a growth or an ulcer will be felt, both differing markedly from the normal cervix by being comparatively hard and brittle, breaking down under the finger, and bleeding on pressure with the finger or the point of a sound. In later stages the uterus may be fixed by inflammation or growth in the cellular tissue; this is most easily made out by rectal examination.

On inspection through a speculum—a large Ferguson speculum, with the patient in the lithotomy position, is best for this purpose—an irregular growth with nodular or club-like processes, with or without ulceration, may be found. The colour of the growth is livid red, often sloughy on the surface, and may contrast with the purple colour of the vaginal cervix. The surface of the growth should be dried with absorbent cotton-wool, and the overhanging edge, the bleeding, and breaking down on pressure noted. If ulceration be present, the only conditions likely to be mistaken for it, namely, tubercle and syphilis, are rare.

In some cases only a hard, smooth enlargement of the cervix is met with: there is neither a projecting irregular breaking-down growth nor ulceration, the growth being in the wall of the uterus. In these cases the finger is easily passed into the cervical canal and recognizes the bleeding growth. A piece of this should be removed for microscopical examination in all cases. This is especially necessary, because the syphilitic and tuberculous affections cannot be distinguished by clinical methods, but are easily recognized under the microscope.

In ordinary cases the diagnosis of the growth is quite easy; the marked contrast of the brittle, bleeding growth with the soft tissues of the cervix of pregnancy leaves no doubt. There are, however, certain diseases of the cervix which closely resemble cancer and certain cases of cancer which lack the usual signs.

Conditions Resembling Early Cancer of the Cervix.

Hypertrophied papillary or nodular erosions, hypertrophied and inflamed glandular erosions, and papillomata (simple and diffuse) may closely simulate cancer.

By *hypertrophied papillary or nodular erosions* I mean a growth with club-like processes or lobules made up of thick connective tissue centres, often containing dilated glands, covered with a single layer of columnar or cubical epithelium. I have not met with this form during pregnancy, but the diagnosis would be difficult without microscopical examination. This form, however, is not friable,

By *hypertrophied and inflamed glandular erosion* I mean a granular condition similar to the ordinary glandular erosion, but much larger and more vascular; it sometimes measures as much as $1\frac{1}{2}$ in. across, and can be broken into with the point of a sound, and bleeds readily on examination. It does not break down to the extent that cancer does, and the growth does not project from the surface, but in some cases it is necessary to excise a piece in order to exclude cancer. I have not met with this condition in pregnancy, but in the impregnated uterus have several times mistaken it for cancer until the microscope showed the nature of the condition.

Papillary growths are met with in several forms. The pedunculated papillomata of gonorrhoea are occasionally found on the cervix, but rarely, I think, without being present on the vulva or vagina. This scattered distribution is an aid to diagnosis. Broad flat papillomata with a finely granular surface may be met with both in gonorrhoea and soft sores, and, I believe, as a result of masturbation. They bleed and break down under the finger, are generally softer and more friable than cancerous growths, and can be often pinched off the surface of the

cervix with forceps, leaving a raw red surface fairly smooth and bleeding freely. Under the microscope a central vascular stem supported by connective tissue is seen surrounded by a mass of large epithelial cells often oedematous or vacuolated.

More solid isolated polypoid or sessile nodules in the cervical canal and at the external os occur occasionally; they consist of stroma of the cervix covered by many layers of squamous epithelial cells (metaplasia of cervical columnar epithelium). In the substance of these growths gland spaces may be cut across of which the epithelium has also undergone metaplasia, so that the spaces are filled

with squamous epithelium. If these growths be cut without the subjacent and adjacent tissue the appearance is not distinguishable from squamous-cell carcinoma, although a deeper section shows no such invasion of the deeper tissue of the organ as occurs in true carcinoma. In excising a portion of the cervix for microscopical examination a wedge-shaped piece should be removed including the edge of the suspected growth; care should be taken that the microscopic sections are cut vertically to the free surface and not parallel to one side of the wedge.

Lastly, I would like to direct attention to the unusual features of Case 5, Table F, which led to an erroneous diagnosis. The peculiar features were (1) the smooth surface of the growth pitted by several holes from which a pus-like fluid escaped

in considerable quantity; (2) the fact that the growth did not bleed at all, although it was dressed almost daily for nearly two months; (3) that the growth did not break down under moderate pressure; (4) that it did not apparently increase at all during two months' observation, and in the puerperium at first diminished in size. I do not remember to have seen another case of cancer of the cervix in which these "pus" holes were present, although I have seen several in cancer of the vulva. In this case it is to be regretted that a piece was not excised; this would at once have shown that the growth was a columnar-cell carcinoma, and that the pus was the liquefied central epithelial cores.

Although the microscope is of the highest value and is

5	39	15	8th	Lived	Died 12 months later	Lived	Living 6 mths. later	Per vaginam, forceps; rupture of uterus	No; too far advanced for curative operation. Rupture packed with iodoform gauze.
6	34	11	8th	Lived	Died 7 months later	Lived	Died 15 days later	Per abdomen, by Porro-Caesarean section, with use of serre-noeud	No; too far advanced for curative operation.

indispensable for the diagnosis of certain cases, clinical examination is also of great importance. For want of this I have known a distinguished pathologist decide, as the result of the examination of a microscopical section, that only normal cervical glands were present, when clinical examination showed a deeply invading cancer. In this case the rare form of cancer, "carcinoma adenomatodes," in which the glands are lined with a single layer of columnar epithelium, would have led to a serious error if reliance had been placed on the microscopic examination alone and the clinical signs had been neglected.

STATISTICS.

I have published tables of cancer of the cervix in advanced pregnancy—that is, in the eighth, ninth, or tenth month—treated by vaginal or combined abdominal and vaginal hysterectomy, from the papers of Glockner (10 cases), Olshausen and Knusmann (8 cases), in the Obstetrical Society's *Transactions* (vol. lvi, pages 369-371). The percentage of cures in the 18 cases, operable and inoperable, is 5.5. The total immediate mortality is 33.3 per cent., operation mortality 16.6 per cent.

E. Aulhorn's 10 cases from Zweifel's clinic give the results of abdominal hysterectomy: 1 of 3 cases in "advanced" pregnancy remained well after "a good five years"; of 7 early cases 2 recurred and 5 remained free from recurrence after two to three and a quarter years.

E. Wertheim⁸ gives 6 cases: 1 advanced case, operated on by Micholitsch, remained well after five years. Of the 5 early cases 1 died of embolism, 1 recurred, the other 3 were "cured."

P. Glarner⁶ has recorded 8 cases: 3 in advanced pregnancy were treated by Caesarean section; 5 early cases were treated by abortion and vaginal and abdominal hysterectomy. All the cases recurred.

Trotta⁷ gives a list of 26 cases (1879-1905) in advanced pregnancy treated by Caesarean section and total abdominal hysterectomy. The maternal mortality was 33 per cent., the fetal 22 per cent. Of cases operated on in labour the maternal mortality was 53.3 per cent. He showed that the maternal mortality after abdominal operation was more than double and the fetal mortality only half that of the vaginal operation.

Sarwey,⁸ in 1908, gave a list of 29 cases of extended abdominal hysterectomy in all of which the mothers survived; it is made up of cases published between 1900 and 1903, but does not contain Wertheim's case of fatal embolism (1905).

Vitanza⁹ published in 1898 a paper on amputation of the cervix of the cancerous pregnant uterus. Of 7 cases seen, 4 were treated by high amputation of the cervix: the pregnancy continued and the patients bore living children. Two years later, in a paper on high amputation for cancer, he stated that of 15 early cases only 2 recurred; 9 remained free from recurrence for three to twelve years. In 6 of them pregnancy occurred from 6 months to three years after the operation. The Paquelin canterly was used in all cases after the amputation.

The preservation of the fetus and the possibility of pregnancy following high amputation, as shown by Vitanza's cases and one of mine, are valuable advantages of high amputation which should not be overlooked in considering the question of treatment.

TREATMENT.

The treatment of cancer of the cervix complicating pregnancy varies according as the case is "operable" or "inoperable" and the child is viable or not. The question of operability is usually decided by the absence of fixation of the uterus and of thickening in the parametric tissue, though operation, both vaginal and abdominal, permits the removal of the uterus in certain cases where these conditions are found. The age of viability of the child may be taken for practical purposes as in the last three lunar or two calendar months of pregnancy, in this paper called "advanced pregnancy," pregnancy of shorter duration being called "early pregnancy." In advanced pregnancy the interests of the child and the large size and vascularity of the uterus introduce special problems of treatment and increase the danger of the operation, which is especially great during the course of labour.

Modes of Treatment.

The chief modes of operative treatment which have been employed for cancer complicating pregnancy are by high amputation, vaginal hysterectomy, extended vaginal hysterectomy, abdominal hysterectomy, extended abdominal hysterectomy, and combined abdominal and vaginal hysterectomy.

In the course of the last ten years great advance has been made in the treatment of cancer of the cervix by radium, mesothorium, and x rays, and for the last five years in several of the chief clinics of Europe operation has been almost entirely abandoned in favour of radiation treatment. It would seem to entail some risk to the fetus, and I am not aware that it has been employed during the course of pregnancy.

The patients are on the average younger, and therefore presumably stronger than non-pregnant patients, but the disease is apt to be more malignant in the young. The glands are, however, comparatively rarely affected (Wertheim).

Treatment during "Early Pregnancy."

(a) "Operable" cases should be operated on at once. The opinion once held that cancer complicating pregnancy was inevitably fatal can no longer be maintained. The best results have been obtained by the extended abdominal hysterectomy, Wertheim's results having been unequalled by any other method. In view of the fact that the glands are rarely affected, vaginal hysterectomy (preferably performed with the cautery) may be employed in feeble or fat patients, as it has a much lower mortality than the abdominal operation, and amputation of the cervix may be performed in early cases of squamous carcinoma, in which there is a desire to preserve the life of the child and the fertility of the mother. During labour or abortion the same operations may be performed if the case is not infected; if infected, the whole womb should be removed.

(b) "Inoperable" cases. If the case is not accompanied by bleeding or infection, the patient should be kept at rest and Porro's operation with the *serre-nœud* be performed when the pregnancy is "advanced." During labour or abortion the case should be treated on general principles, with a view of preventing infection, and subsequently treated during the puerperium with the cautery, radium, and x rays.

Treatment during "Late Pregnancy."

(a) "Operable" cases should be treated by Caesarean section, followed by extended abdominal hysterectomy. If the patient is in fair condition, the operation is indicated equally on the ground of science and humanity.

If the patient is feeble or the growth infected, it might be preferable to remove the cervix by the cautery, and then remove the child by the vagina or by the abdomen, and apply radium after, or without, the removal of the uterus. This procedure would probably be safer to the mother than the performance of abdominal Caesarean section and the removal of the uterus (or the cervix after amputation) by the vagina, but would involve some increased risk to the child. Vaginal Caesarean section entails too great a risk of implantation of cancer cells, and no case is recorded in which it has been followed by cure.

During labour the risk to the patient is greatly increased. In the early stages of labour Caesarean section, followed by the extended abdominal hysterectomy, will usually be the best treatment. But if the labour be advanced and the growth not extensive, it may be safer to deliver the patient *per vias naturales*, and afterwards, at an early period of the puerperium, to treat the diseases by one of the methods mentioned. It is noteworthy that five of the seven advanced cases "cured" were operated on after delivery.

(b) "Inoperable" cases should be treated by Porro's operation with the use of the *serre-nœud*. It has the advantage over the conservative Caesarean section that it removes the placental site from the risk of infection, and over Caesarean hysterectomy with intraperitoneal stump that, in case of infection, discharges will readily escape by the side of the wire, which can be placed on any height above the growth, provided the placental site be removed. In the case of a dead or putrid child it would be possible by the Porro method to close the peritoneal wound above

and around the uterus before the body of the organ was opened or amputated.

During the puerperium the treatment does not differ essentially from the treatment of cases of cancer in the unimpregnated.

At the present time there is a great tendency abroad to treat these cases with radium, mesothorium, and x rays, a reaction having set in against the extended abdominal hysterectomy on account of its high rate of mortality. The late Dr. Pozzi¹⁰ proposed a restricted vaginal hysterectomy completed by radium therapy in cases of cancer of the uterus. Although such an operation is unsuitable for some cases of cancer during pregnancy, I believe that in the puerperium vaginal hysterectomy, or high amputation, performed with the cautery and completed by the application of radium and x rays, will be found to give better results than the extensive operations now usually practised.

The three cases of high amputation described in this lecture which have remained free from recurrence for twenty-five, twenty-two, and nineteen years, are instances of the possibility of cure by simple operations, which are free from danger. As far as I know only two other cases of cancer complicating labour in advanced pregnancy are recorded which have remained well for five years after operation—namely, Olshausen's (five and three-quarter years), and Von Ott's (eight and a half years) both operated on by vaginal hysterectomy in the puerperium. Two additional cases have been cured—namely, Micholitch's (five years) and Aulhorn's (five years), both operated on by the extended abdominal hysterectomy. The former was in advanced pregnancy but not in labour; no information as to the presence of labour was given in Aulhorn's case. I attribute the result in my cases to the use of the cautery (in two of the cases) and of antiseptic douches, and also to the fact that the operation was performed after delivery when the tissues were involuting.

The rarity of cure of cancer complicating labour in advanced pregnancy seems to justify the republication of these cases with a later after-history.

Sarwey, in Veit's *Handbuch der Gynäkologie*, while mentioning the title of my former paper in the bibliography, does not allude to the cases in the text. Perhaps the after-history of Case 5 may lead the next German writer on the subject to consider the cases worthy of mention.

THE THERAPEUTIC VALUE OF OXYGEN
IN PULMONARY LESIONS.

PRELIMINARY NOTE.

BY

JONATHAN C. MEAKINS, M.D., F.R.C.P. EDIN.,
CHRISTISON PROFESSOR OF THERAPEUTICS, UNIVERSITY
OF EDINBURGH.

It has been demonstrated by Stadie¹ that in cases of pneumonia with cyanosis there may be a considerable deficiency in the oxygen content of the arterial blood. He determined this by examining blood taken from the radial artery, using the technique of Van Slyke.² Using due precautions during collection against exposure to air, he estimated in one sample of the blood the oxygen content and in another sample the total oxygen capacity of the blood; then by comparison of the two results he determined the degree to which the arterial blood was unsaturated with oxygen.³ In normal persons he found this to average 5 per cent. His results showed that there was a close relation between the degree of unsaturation of the blood with oxygen and the degree of cyanosis; while in addition there was a direct relation between the intensity of the cyanosis and the condition of the patient. In other words, the greater the degree of oxygen unsaturation of the arterial blood the more critical was the patient's condition.

The value of oxygen administration in pneumonia has been a subject of much controversy, and the present

investigations were undertaken to determine whether oxygen adequately administered would increase the oxygen saturation of the arterial blood in this condition.

Effect of Oxygen Inhalation in Lobar Pneumonia and in Bronchitis.

The following cases illustrate the results which may be obtained when oxygen is administered in an efficient manner. The method of administration was that devised by Haldane.⁸ No difficulty was experienced by the patients provided the apparatus was in efficient working order.

Dr. Haldane's apparatus, reproduced from his paper in the BRITISH MEDICAL JOURNAL, July 19th, 1919. The gauge shows the amount of oxygen in the cylinder. The reducing valve reduces the pressure to a small amount, which remains constant till the cylinder is empty. The regulating tap shows the flow of oxygen in litres per minute. The tube is of thick-walled rubber. The face-piece is provided with elastic straps and a rubber pneumatic cushion which can be removed for disinfection. The collecting bag, of flexible rubber, is small, and is connected with the face-piece through a mica valve which prevents expired air from entering it. The face-piece has a rubber flap to cause a very slight resistance. During expiration the oxygen collects in the bag and is sucked into the face-piece at the beginning of inspiration. From the movements of the bag it can be seen at any moment whether the patient is receiving the oxygen. The apparatus is put into action by opening the main valve freely and adjusting the tap to give two litres a minute, or whatever greater or less amount may be desired. With a delivery of two litres a minute a 40-foot cylinder lasts nearly ten hours.

The blood of the patients so treated was obtained by the procedure described by Hürter.⁴ The method for estimating the oxygen content and the oxygen capacity of the arterial blood used in the present observations will be described in a future communication. The main principle of the method was to determine the amount of oxygen which a known quantity of arterial blood would take up,

taking proper precautions to avoid exposure to air before the estimation was made. Then the total oxygen capacity of the same sample of blood was determined by the ferricyanide method, and the ratio between the two gave the percentage of saturation or unsaturation with oxygen of the arterial blood.

EXAMPLE OF METHOD.

Amount of blood taken, 2.025 c.cm. Haemoglobin = 103%.
 Amount of gas absorbed, 0.039 c.cm. Bar. 29.76 in. of mercury; temperature 16° C.
 Amount of gas absorbed, 0.03697 c.cm. at 760 mm. Hg and 0° C.
 Amount of gas physically dissolved, 0.0186 c.cm.
 ∴ Amount of oxygen taken up by haemoglobin of 100 c.cm. of blood = 0.907 c.cm.
 Total oxygen capacity of 2.025 c.cm. of blood = 0.410 c.cm.
 Total oxygen capacity of 2.025 c.cm. of blood reduced to 760 mm. Hg and 0° C. = 0.38704 c.cm.
 ∴ Total oxygen capacity of 100 c.cm. of blood reduced to 760 mm. Hg and 0° C. = 19.11 c.cm.
 ∴ Unsaturation of arterial blood with oxygen = 4.8%.
 ∴ Saturation of arterial blood with oxygen = 95.2%.

CASE I.—Lobar Pneumonia.

The patient came under observation on the fifth day of the disease. He was suffering from lobar pneumonia, which involved the whole left lung except for a small portion of the apex of the upper lobe. The respirations were 42; there was no orthopnoea, but slight cyanosis. The degree of oxygen unsaturation of the blood from the radial artery was 15 per cent. of the total oxygen capacity.

On the eighth day of disease the cyanosis was more evident, and the arterial blood was 17.9 per cent. unsaturated with oxygen. At 3 p.m. of this day oxygen was first given to the patient by the Haldane apparatus. It was set to deliver 2.5 litres of oxygen a minute. At 5 p.m. another sample of arterial blood was examined and was found to be only 9.08 per cent. unsaturated with oxygen. During the night the oxygen administration was continued at 2 litres of oxygen per minute, and on the ninth day of disease the oxygen unsaturation of the arterial blood was 9.0 per cent. The oxygen was continued till 11 a.m. on the tenth day of disease, when it was stopped. Blood was drawn from the radial artery at 3 p.m., and it was found to be 15.5 per cent. unsaturated with oxygen. Cyanosis was present at this time. Oxygen amounting to 3 litres a minute was now administered and continued until next day, when it was found that the cyanosis had disappeared and that the arterial blood was only 3.05 per cent. unsaturated with oxygen. During the next night the patient had the crisis.

It is evident from this case that the degree of cyanosis and arterial blood unsaturation with oxygen may be readily regulated by the administration of oxygen in sufficient quantities by the Haldane apparatus.

CASE II.—Lobar Pneumonia.

This patient had pneumonia which involved the left lower lobe and part of the right lower lobe. There was slight cyanosis, and the arterial blood unsaturation with oxygen was 10.6 per cent. This was on the sixth day of the disease. The patient was given oxygen, amounting to 2 litres a minute, until the next day, when all signs of cyanosis had disappeared, and the arterial blood was found to have an oxygen unsaturation

amounting only to 1.85 per cent. The oxygen was continued, and the next day the patient had the crisis.

CASE III.—*Acute Exacerbation of Chronic Bronchitis.*

This patient was suffering from an acute exacerbation of a chronic bronchitis associated with moderate cardiac failure. There was slight orthopnoea and cyanosis, with an irregular distribution. The hands and ears were purplish in hue, while the lips were only slightly so. The arterial blood was unsaturated with oxygen to 10.9 per cent. Two litres of oxygen a minute were administered by the Haldane apparatus during the next twelve hours, when the cyanosis had completely disappeared, and the orthopnoea was practically gone. The arterial blood at this time was unsaturated with oxygen to 3.01 per cent.

EFFECT OF OXYGEN INHALATION IN HEALTH.

The degree of unsaturation with oxygen of the arterial blood of five normal cases was determined. It was found to average 5.1 per cent., ranging from 4.4 per cent. to 5.6 per cent. It will be noticed that in the pathological cases outlined above the arterial blood oxygen unsaturation showed an appreciable decrease from normal when a sufficient oxygen concentration of the inspired air was administered. Therefore it was considered of importance to determine whether the administration of oxygen would reduce the oxygen unsaturation of the arterial blood of a normal person. Arterial blood of a normal adult was examined and the oxygen unsaturation was found to be 4.4 per cent. Two litres of oxygen a minute were administered by the Haldane apparatus for 100 minutes and the arterial blood again tested for the arterial oxygen unsaturation, which was then found to be only 1.87 per cent. This confirmed the previous observations in the abnormal cases that the inhalation of inspired air sufficiently enriched with oxygen may diminish the oxygen unsaturation of arterial blood beyond the normal limits.

CONCLUSIONS.

1. In certain respiratory diseases where there is anoxaemia of the arterial blood the efficient administration of oxygen will diminish this anoxaemia and so relieve the cyanosis.
2. If the oxygen be given in sufficient concentration in the inspired air the arterial saturation with oxygen may be raised above normal.
3. This result may be obtained both in normal individuals and also in certain of those suffering from certain respiratory diseases.

CUTANEOUS MANIFESTATIONS IN A CASE OF CERVICAL FISTULA.

BY

ALFRED EDDOWES, M.D., M.R.C.P.,

LONDON.

THE following case raises some points of general importance:

In September, 1919, Nurse M., aged 30, consulted me for loss of hair, and complained of being "run down." I found falling of the hair of the scalp and eyebrows and some loss of eyelashes. The skin generally was dry and rather scaly; the cheeks were not flushed, but the complexion was muddy and the face wanting in expression; the voice was normal. The front and sides of the neck, as well as a V-shaped exposed portion of skin over the sternum, were very red, suggesting at first slight sunburn, but on closer inspection the redness was seen to be due to dilated venules without heat, swelling, oedema, or pigmentation. On the right side above the head of the clavicle was a very white patch 2 in. in diameter and nearly circular; it resembled leucoderma, but there was no trace of excessive pigmentation at its margin as occurs in true leucoderma.

Below and internal to the centre of this white area was a round puckered patch of thin skin about 1.5 cm. in diameter, situated about 1.5 cm. above the head of the right clavicle and nearly 3 cm. from the middle line of the neck. On deglutition, this bit of overstretched skin was drawn in and formed a tubular dimple, half an inch deep. Several medical men had, the patient stated, seen it and been unable to explain it. Passing upwards, backwards, and inwards, I felt a firm round

band apparently as large as a No. 2 gum-elastic catheter. She said she was liable to occasional regurgitation of matter into her mouth "like the discharge from a gumbot." The diagnosis was obvious—a pouch at the upper end of a cervical (branchial) fistula. She stated that her father told her that her "grandmother had something like it." I prescribed a lotion for the scalp, and internally iron and one grain of thyroid extract at bedtime.

When seen on November 17th she looked and said she felt much better, had found benefit quickly from the treatment and release from nursing a mental case. Her complexion was clear, colour good, and the hair had much improved. The redness of the neck had nearly gone, and there was now no contrast between white and red. The overstretched (often so-called atrophic) skin had become red, as if recovering normal nutrition. The round, firm, rod-like band was thinner and more distinctly fibrous. The dimpling on deglutition was not so marked, only a quarter of an inch.

A few years previously the patient had the appendix removed and after the operation was told that she had better never take another anaesthetic, as she had then taken it badly. Seven years ago she had "faintings" and a suspicion of hyperthyroidism and mitral disease. She believes the cervical fistula discharged, until the age of ten years, through a little lump the size of half a pea. Sometimes, if she leans forward on a stiff collar, "a discharge is felt coming from the throat into the mouth." I think the right thyroid was more prominent than it was in September (two months earlier).

I do not think I ever met with such a change in nutrition before and in such a short time; the oddest point to me being the change found in the round ligamentous band and its attachment to the skin. Is Nature trying to absorb the band or reopen it as a sinus? It is so obvious that the patient, whose physique is otherwise good, is having her health ruined by the filthy pouch that I have passed her on to a surgeon's care.

The red area of skin on the sides and front of the neck, already referred to, was too peculiarly localized and delimited to be attributable solely to exposure to light and weather. It corresponds to the area of referred "choking pain" described by Head in connexion with the passage of an oesophageal bougie.¹ It is also a blushing area, as is well shown in some young women. That vasomotor pathological changes should take place there is not so surprising when we consider that it is probably at the "seaming-up of the segments" that such affections as linear naevi, ichthyosis hystrix, linear papillomata, and even occasionally lichen planus (in lines) occur. In one very rare case I have seen a line of lichen planus reached from the hip to the foot. No one nerve or blood vessel will account for such changes of distribution, but "the seaming-up of segments" and the closing of clefts during fetal life give a clue. During last year I called attention to a rare form of tuberculide, and suggested for it the clinically descriptive term "lichenoid." It closely imitates lichen planus and tends to develop in lines.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SUBCUTANEOUS RUPTURE OF THE SUBCLAVIAN ARTERY.

ON January 16th, 1918, a heavy, muscular man, aged 48, weir keeper at one of the up-river locks, was hurriedly pulling up one of the sluices during rising water when he suddenly felt a severe pain in the right arm and at once experienced considerable loss of power. There was no mark of injury and no swelling to be detected, but the whole hand and forearm felt cold, numb, and weak, and he had to stop work at once. Five weeks after the injury I found that the right arm was quite cold and pale. There was no muscular wasting, and all ordinary movements could be carried out with precision. No pulse at all could be detected anywhere in the arm from the axilla downwards, but the subclavian pulse was readily felt and appeared to be equal to that on the other side. No aneurysmal or other swelling could be detected, and, in fact, beyond the absence of pulse and the pallor and chilliness of the arm, nothing abnormal was to be found. There was no evidence of any cardio-vascular disease.

I saw the man again on May 4th, sixteen weeks after the injury, and by this time colour, warmth, and a good deal of power had returned. The right radial pulse had reappeared but was smaller than the left, and could not be traced up the arm beyond a point about one inch above the bend of the elbow.

I did not see him again until January, 1920, exactly two years after the injury, and the pulse by this time could be felt throughout the limb, but appeared to be weaker than on the other side from the middle of the brachial artery upwards. There was no sign of aneurysm and, in fact, the patient was normal in all respects, except that he found himself unable to use the arm in cold weather without discomfort.

The history of this case seems to make it quite clear that what occurred was a rupture of the subclavian artery at the point where it crosses the first rib, and from the absence of haematoma or other evidence of extravasation it seems probable that only the inner and middle coats of the vessel had suffered. The mechanism of the injury is probably explained by powerful muscular contraction bringing the clavicle into forcible contact with the first rib and so crushing the artery. I find, from experiments upon myself, that contraction of the shoulder muscles while in such an attitude as would be adopted in pulling up a heavy sluice gate does cause obliteration of the radial pulse. Whether this is a common phenomenon, or whether it is present only in those of a particular build or particular degree of muscular development, I am unable to say.

CECIL ROWNTREE, F.R.C.S.,

Surgeon to the Cancer Hospital and to the Dreadnought Hospital.

LOCALIZATION OF FOREIGN BODY.

IN the review of Captain Harold C. Gage's book in the BRITISH MEDICAL JOURNAL of January 31st, p. 154, it is said that the author had convinced himself "that the usual report from the radiographic department—that a foreign body was situated so many centimetres under a certain mark made on the skin—was insufficient for the operating surgeon."

But provided the mark on the skin is correctly made and the depth properly calculated by any method of localization, and provided an atlas of sectional anatomy of the body is at hand, there is a very simple method of conveying sufficient information in anatomical form to the operating surgeon. Suppose, for example, in the case of a chest the mark on the skin is made at the level of the eighth dorsal vertebra on the right side posteriorly 10 cm. from the middle line, and that the depth perpendicularly in therefrom is calculated to be 15 cm., and that the antero-posterior thickness of the chest at the level of the mark is 30 cm., then we have only to work out these data by simple proportion (the rule of three) on a drawing of the transverse section of the normal anatomy of the chest at the level of the eighth dorsal vertebra, on the same side in any reliable atlas of sectional anatomy. If the corresponding thickness of the chest at this level in the atlas is 7.5 cm., then the depth in from the surface point corresponding to the mark on the patient's skin becomes 3.75 cm. at a proportional distance from the middle line of 2.5 cm., and we can at once actually demonstrate to the surgeon in charge of the case the probable anatomical position of the foreign body in question, and its relation to the organs and tissues around, on the section as on a chart.

The atlas latterly supplied to the British x-ray departments in France unfortunately did not portray the limbs. The principles of what may be called the "tri-graphic" method of localization could evidently be applied to all parts of the body in suitable (mostly quiescent) cases. The dimension in the patient chosen for comparison with the corresponding dimension in the chart might be thickness, or circumference, or the distance between recognizable prominences of bone.

This method had long been in my thoughts; I managed in the press of other duties to verify it in 1918 when abroad. It enables the radiographer to answer without mere guessing the oft-repeated questions: "Is the foreign body within or without the ribs?" "Is it below or superficial to the blade of the scapula?" and the like.

Reports of Societies.

EYESIGHT OF MINERS.

A DISCUSSION on illumination in mines, with special reference to the eyesight of miners, arranged by the Illuminating Engineering Society and attended by many ophthalmic surgeons as well as mining representatives and lighting engineers, was held at the Royal Society of Arts on February 24th, with Mr. J. H. PARSONS in the chair.

The discussion was opened by Dr. T. LISTER LLEWELLYN, who, in dealing with the photometric values of the lighting in use to-day in mines, said that the lighting values were extremely low owing to two factors—first, the insufficiency of the light generated; secondly, very feeble illumination that entered the eye of the miner owing to the high proportion of light absorbed by the blackness of the coal face. These two conditions presented the problem to be overcome. Of the light given by a naked tallow candle about one-tenth reached the coal face, and one-tenth of this, or one-hundredth part of the original source of light, entered the miner's eye. In the safety-lamp mines only one-fiftieth of the value of the illuminant reached the coal face, and only one-five-hundredth part the eye of the miner. They needed to increase the value of the lighting in the safety-lamp mines five-fold, and then it would equal in value the light in the naked-light mines. He showed the various forms of light in use and compared their values and relative advantages. Of those shown, the best appeared to be of the head lamp variety. The electric battery was carried on the belt of the miner and the current carried by a flexible wire to the lamp fitted to the miner's cap. The lamp in this position gave a good field of light, close to the miner's work, and therefore in far greater power than was possible with a hand lamp, and, further, a light quite free from shadows. Calculating the injury and loss sustained by miner's nystagmus he showed that on pre-war values the economic loss to the country from this disease was at least £1,000,000 per annum.

Dr. H. S. ELWORTHY communicated some researches into the different values of light as affected by colour relief. The coal was nearly black, and there was a total absence of colour relief. He believed this of itself accounted for much eye fatigue. Whitewashing the posts and roofs of the workings would give much relief. Various tests which he described indicated that the rich yellow light with a tinge of red in it given by the oil lamp was a most comfortable light, but that in the bad air of a deep working this light became bluish. This blue light and the bad air were particularly irritating. Further observations indicated that there was more nystagmus in mines, where the coal face was of a bluish tint—for example, in the steam coal mines.

Dr. J. S. HALDANE said that he did not think that the quality of the air in mines had much to do with nystagmus. The air on the coal face of a decently ventilated mine (and they were mostly so now) was very pure. He considered the disease was a local neurasthenia induced by the fatigue of trying to see in darkness. He instanced the analogy of certain respiratory troubles following gas injuries at the war.

Mr. ARMITAGE, a representative of a Yorkshire colliery company, said a prize of £1,000 was offered by the Government in 1911 for the best electric lamp; £600 was awarded to the C.E.A.G. lamp and smaller sums to others. His company ordered 10,000 lamps; they had been working since then, and the facts obtained seemed to warrant a definite decision being arrived at. The use of the lamp was followed by (1) reduction of nystagmus, (2) fewer accidents, (3) quicker movement of the men from the pit bottom. The whole costs of their use for six years worked out at 1.29d. per shift—a very reasonable figure.

Dr. F. SHUFFLEBOTHAM commented on the great increase of interest in the disease shown in recent years. He thought Dr. Llewellyn underestimated the loss caused by the disease; the number of certified cases did not give the full tale. He considered it a general nervous disease and not an eye disease.

Mr. FUDGE, the secretary of the committee of inquiry now sitting, stated their chief object was the improvement of the miner's lamp, and he thought they were getting on.

Lamp makers had taken great interest in the matter. But there was a limit of improvement possible on present lines. The weight of the battery limited it, and one line of improvement might be better batteries. Flame lamps had been made to give $2\frac{1}{2}$ candle power, but they were found to get so hot that they could not be held. He thought there were possibilities in the extension of white-washing. Mr. ELLWOOD commented on the fact that there had been a great increase in the disease since the war, notwithstanding that the electric lamp was more in use than ever. He thought this must indicate some causation other than light. A member of the audience, who stated he had been a working miner, spoke of the benefit of the electric lamp, and believed his testimony was not biased by the fact that he was now an agent for a lamp company.

Dr. LEYTON DAVIS of Cardiff thought there must be some condition other than bad light as a cause of these cases. He had taken observations on the fields of vision, and found a striking similarity between those of miners and those of the subjects of toxic diseases. He thought that chronic gas poisoning had a serious influence. Mr. HARRISON BUTLER said miner's nystagmus took some ten to twenty-five years to develop, therefore they could not expect great improvement in this generation of miners. Dr. HARFORD stated that miners who were free from disease on enlistment had subsequently, under the stress of war, developed the symptoms, so that there was evidence of latency. His inquiries amongst Belgian and French miners showed their great belief in the efficacy of the better electric lamps.

Dr. H. POOLEY stated that miners did not give up and claim compensation until they could not work. He thought the disease was a cerebral irritability caused by bad light and bad air. He confirmed the evidence of latency. Dr. ETTIE SAYER spoke of the comfort of yellow light, particularly as evidenced by the use of very powerful lights in the treatment of skin diseases. Dr. BERNARD CRIDLAND thought there was room for a joint inquiry by ophthalmic surgeons and lighting engineers. Dr. WHITEHEAD said the problem was not an easy one to solve. But he had no doubt that the disease was due to trying to see under disadvantageous conditions.

Mr. BISHOP HARMAN asked if the head lamp shown by Dr. Llewellyn would be considered safe in fiery mines; the length of flex seemed vulnerable. Further, he commented adversely on the trend in improvements in electric lamps being limited to more powerfully glowing filaments. Why did not inventors turn their attention to the vapour lamps, which in experimental form were remarkable? He thought that the work of Josiah Court had long ago demonstrated that bad light was the one important cause of the disease, and that to spend time on adjuvant factors until the light was bettered was to draw a red herring across the trail.

Dr. LEWELLYN, in reply, thought that the future lay with the head lamp; he believed it to be as safe as any lamp (there were expressions of dissent from the mining representatives). Finally he called attention to an experiment which had been carried out before their eyes; during the meeting the oil lamps had burned out, but the electric lamps were glowing as well as ever.

ACCESSORY FOOD FACTORS IN INFANT FEEDING.

A DISCUSSION on the influence of vitamins in infant feeding took place at a meeting of the Section for the Study of Diseases of Children, of the Royal Society of Medicine, on February 27th, Mr. J. P. LOCKHART-MUMERY presiding.

Dr. E. MELLANBY, who opened the discussion, confined himself to the question of fat-soluble A. Its distribution in foodstuffs, he said, rendered it the most important factor from the point of view of child nutrition. It had not been decided whether fat-soluble A and the anti-rachitic factor were the same, but he believed that this was the case. The results of his experiments on dogs differed from those of some workers who had experimented on other animals, notably on rats. This factor did not appear to be necessary to growth, and he had found a distinct amount of anti-rachitic factor present in some, not all, vegetable fats. The relation of the anti-rachitic factor to the age of the animal was clearly brought out. It was

practically impossible to produce rickets in dogs more than four or five months old by the methods he had adopted. With increasing age the animal became less dependent upon an anti-rachitic factor, and any rickets which had previously developed tended to cure itself. The relation of the anti-rachitic factor to the energy-producing power of the diet was also sharply defined. In animals which were fed on a deficiency diet under exactly the same conditions, the only variable element in the diet being bread, which was given *ad libitum*, it was found that the animals which ate most bread got most pronounced rickets. The carbohydrates appeared to accentuate the rachitic tendency, while protein diminished it. Exercise had the same effect as protein; it increased the energy output, while carbohydrates increased the laying on of tissue. Dr. Mellanby cited certain statistics collected some years ago by Dr. William Hall, of Leeds, upon the comparative conditions as to rickets among Jewish and Gentile children. A much smaller percentage of Jewish children showed evidence of rickets and bad teeth, and this was true alike of a poor district and a better-class district. The evidence that diet was the deciding factor in this instance was very strong. In Jewish households large quantities of oil were used in cooking; potatoes were never boiled in water, but in milk, or were fried in fat, and the ordinary beverage was cocoa made with milk. He considered that diet was the most important element in child nutrition in the first year of life, and that the anti-rachitic factor was an important part of this diet. It was assisted in its action by anything which increased the energy output of the child, such as increased protein or exercise, and was prevented by increased carbohydrates or anything which tended to make the child put on flesh.

Professor NOEL PATON held strongly that evidence was still lacking for the theory that rickets was due to dietary deficiency alone. No far-reaching conclusions could be drawn from such evidence as was at present available. He considered that to compare animals of different litters and to group puppies of different ages was unjustifiable. More experimental evidence, the value of which could be definitely estimated, was wanted. Further work on the association of fats with energy values must be undertaken. The evidence was far from being complete that milk contained an accessory factor protective against the development of rickets. A series of inquiries which he had addressed to the larger hunts in the country, the returns covering 600 whelps, failed to support the idea that deficiency of fat-soluble substance was a causal factor. He recapitulated the observations which, with Findlay and Watson, he had already published in the *BRITISH MEDICAL JOURNAL* (December 7th, 1918, page 625), and said that to his mind more and better co-ordinated investigation was necessary before the etiology of rickets could be adequately discussed. The possibility that it might be primarily an infective disease, due to some non-specific organism, must be borne in mind. Certainly in experiments on puppies, the more scrupulously clean the kennels were kept the less did rickets develop.

Dr. ROBERT HUTCHISON thought that most clinicians would agree that the dietetic factor was essential in rickets, but he was not convinced that the fat-soluble accessory factor was alone concerned. The fault that produced rickets was an ill-balanced diet, in which there was a relative excess of carbohydrates. By cutting down the carbohydrates, even though the rest of the diet was left much as it was before, the clinical cure of the condition could be effected. It seemed to be unnecessary, therefore, to evoke as an explanation some elusive thing named a vitamin. The vitamin theory must not be overdone. It was the latest dietetic "stunt." There had been previous "stunts," each of which had had its day. He did not dispute that there were such things as vitamins, but to make far-reaching application of the theory was not yet justifiable.

Dr. C. J. MARTIN held that there was no doubt that rickets was a dietetic disease. From the epidemiology of the disease and the clinical results obtained by altering the diet it was difficult to come to any other conclusion. Dr. Mellanby's experiments were of the first importance to orientate future inquiry. He did not think Professor Paton had made a serious assault upon the position taken by the opener, which, in his opinion, was a moderate one. What was really wanted was to put the vitamin question on a quantitative basis. For many years

at the Lister Institute his colleagues had been endeavouring to place this question on such a basis so far as beri-beri and scurvy were concerned. He described the work on the antiscorbutic vitamine, showing how widely the results varied with different animals. If the work were done on rats, the conclusion might be that there was no such thing as an antiscorbutic vitamine; if on guinea-pigs, that it was the most essential thing in the diet. The quantitative line of investigation had made it possible to estimate the value of certain foodstuffs; for example, if the value of lemon juice from the point of view of antiscorbutic factor were taken as 100, that of equal weights of cabbage juice would be the same, that of swede juice 60, that of carrot juice 7.5, a lightly cooked potato and beef juice 7.5, and that of fresh milk 1.0 or 1.5.

Dr. E. A. BARTON exhibited two preparations which had proved of considerable use in the Child Welfare Department of University College Hospital during the war when the raids and deficient food disturbed lactation. Dried milks seemed to satisfy the children, but the diet was devitaminized, and the question was what should be added. Orange juice was used, the whole orange being minced, with pulp and rind, the latter containing the essential oil of orange which acted as a preservative of the juice. The mass was passed through a tincture press, and one teaspoonful of the juice expressed was given twice a day to infants under three months and two teaspoonfuls to those over three months. When oranges were scarce and juiceless he tried vegetable juices, but as these seemed to be culture media, the result was a good deal of diarrhoea. The other substance he brought forward was an artificial cream made of beef suet. The trouble in making this was that suet had a very high melting point, but by adding about 12 per cent. of inert olive oil it was got down to a suitable emulsion. The children took it very well, and it was now being made commercially as "university cream." This cream had the same percentage of fat as skimmed cream, would keep for months, was free of tubercle, and would mix with any dilution of milk. It was not expensive, and quite palatable.

The method of manufacture is as follows, quoted from Mr. Hampshire and Mr. Hawker in *Transactions of the British Pharmaceutical Conference, 1919*:

Beef suet	40 oz.
Olive oil	5 oz.
Syrup	25 fl. oz.
Benzoic acid	35 gr.
Decoction of Irish moss	70 fl. oz.
Water	to 1 gallon

The oil is added to the melted suet and the benzoic acid dissolved in the mixture. The decoction is heated to about 60° C. and placed in the emulsifier, and the fats are then added at about the same temperature. The emulsion is then worked up and the syrup and water added last.

Dr. ERIC PRITCHARD also exhibited a form of artificial cream made with oils containing a rich supply of fat-soluble A factor, and of chemical composition closely analogous to human butter-fat. He objected to the application of the word "anti-rachitic" to any particular vitamine. The particular symptoms of malnutrition which followed from deprivation of this accessory factor ought to be ascertained. The majority of cases of malnutrition were due not to deficiencies but to excesses. To label any one accessory factor the anti-rachitic factor was a retrograde step, because it induced people to think that rickets was a perfectly simple disease only due to one cause, and capable of being cured by a teaspoonful of cod-liver oil.

Dr. LAWSON DICK called attention to the geographical distribution of rickets. The area from 40 deg. N. to 58 deg. N. across Europe and America included the whole of the rickets zone. This was the temperate zone, the zone of deciduous trees, the wheat-growing zone, but, above all, it was the great industrial zone of the world. Four hundred millions of Asiatics lived on rice, under ideal conditions for diseases due to want of vitamins, but rickets did not develop.

Dr. MELLANBY, in reviewing the discussion, said that he wished to disclaim any responsibility for the excessive importance attached to vitamins by some people. In reply to one speaker who had suggested a hereditary element in rickets, Dr. Mellanby said that heredity was the very last hypothesis he was going to adopt. It was true that some of his animals were more susceptible to rickets than others under comparable conditions, but he took it that this was because some animals grew more rapidly.

EARLY SIGNS OF SCURVY.

At the meeting of the Section of Medicine of the Royal Society of Medicine on February 24th, Dr. A. F. VOELCKER presiding, a paper was read on "Early manifestations of scurvy," by Colonel RANSOM PICKARD and Dr. G. W. LLOYD. The authors described a group of cases which they encountered in the middle of 1915 at a divisional rest station in France. Thirty-two cases in all were observed, but the authors devoted most of the paper to a detailed discussion of the appearances seen in twenty of them. Out of a first series of twelve cases anaemia was present in ten, pyorrhoea in seven, bleeding gums in three, muscular pains in nine, ecchymosis in two, rash in three, and night blindness in nine. Out of a second series of eight cases, all had a definite anaemia, four had pyorrhoea, six had bleeding gums, six had muscular pains, and seven had night blindness. Special attention was drawn to the symptom of night blindness, as this was the symptom which finally decided the diagnosis. The authors described in detail the tests they made of the night vision of these patients, compared with controls. The circumstances in which the cases arose were that during the summer of 1915 the troops of the division from which these men were drawn were in the trenches from four to six days at a spell, during which time they had no fresh meat or vegetables, though when out of the trenches they had an ample supply. All but one of the cases investigated belonged to infantry battalions, which had these spells of trench work, and consequently diet which intermittently was deficient. By the autumn of that year (1915) the cases had practically ceased, and on inquiry it was found that the men were able to obtain fresh provisions locally, and afterwards arrangements were made for an ample supply of fresh meat and vegetables while the men were in the trenches. In the first half of 1916 a few isolated cases occurred; after that practically none.

Dr. FREDERICK LANGMEAD noted that no mention had been made of slight symptoms of peripheral neuritis, which some regarded as among the early symptoms of scurvy. Peripheral neuritis was a symptom of beri-beri, and he believed that when it occurred in scurvy it was because there was a deficiency of both varieties of the accessory food factor. Dr. VOELCKER was struck with the rapidity with which the condition developed in these cases; in stories of expeditions the occurrence of scurvy seemed much more tardy.

Colonel PICKARD said, in reply, that the men were several months overseas before the symptoms appeared; it was not a matter of one spell of four or five days, but of a succession of spells of deficient diet. The diet in the trenches was the ordinary ration *minus* fresh meat and vegetables; it consisted of bread and butter or margarine, "bully," sugar, and other oddments. Dr. G. W. LLOYD said that there were no symptoms of neuritis. He added that although, when recited, the symptoms struck one as a perfect picture of scurvy, out in the field they were by no means so clear. The symptoms were all minor manifestations, quite different from the appearance in pronounced scurvy.

Dr. S. DUTTON read a paper on "Some deficiency diseases and leprosy," in which he suggested that leprosy was, to some extent at least, a deficiency disease. The fish diet of the people who were particularly subject to the disease did not contain—except in the form of shellfish, and there probably in insufficient quantities—any carbohydrates. A diet chiefly composed of fish was not efficient, especially when the fish was salted. Dr. H. THURSFIELD agreed that there were in leprosy many features of a deficiency disease. Possibly the sporadic cases occurring in this country might be explained more easily on this ground than by the chance infection of a leprosy bacillus.

THE annual meeting and conversazione of the Harveian Society was held at the Medical Society's Rooms on Thursday, January 22nd. The following were elected officers of the society for the ensuing year: President, Dr. William Hill; secretaries, Dr. C. D. B. Hale, Mr. Kenneth Lees. The retiring President (Dr. James Taylor) then delivered an address entitled "Neurological Jottings," printed in last week's JOURNAL. The Harveian Oration will be delivered by Sir Thomas Horder on Friday, March 12th, at 8.30 p.m., on "The diagnostic significance of nerve symptoms in acute infections."

Rebielus.

MAN, PAST AND PRESENT.

THE Cambridge University Press has been well advised to bring out a new edition of *Man, Past and Present*,¹ by the late Dr. KEANE, for it is the standard English book on human races and peoples. The first edition appeared in 1899 and much has been added to our knowledge of mankind in the twenty years which have elapsed since then. Every year our information regarding the geographical distribution and physical characteristics of native races becomes more exact; scarcely a week passes without an addition to our knowledge of ancient civilization, and occasionally comes authentic news of a discovery of the remains of fossil man.

It is clear, then, that the preparation of a new edition of a work which embraces all of these subjects—not to mention a knowledge of languages, of writing, religion, folklore, marriage customs, primitive culture, palaeoliths and eoliths—requires an editor with an uncommon range of qualifications. No one in England is so well fitted to supervise such a task as Dr. A. C. HADDON, round whom a strong anthropological school has grown up in Cambridge. Dr. Haddon was trained as a zoologist, but fully thirty years ago, when he held the chair of zoology in the Royal College of Science in Dublin, he became interested in the zoology of mankind, and organized anthropological expeditions to the West of Ireland and thereby laid the foundation—one which has been but little built upon—of an accurate knowledge of the Irish people. Then at a later period he led an expedition to Torres Straits and showed the world how a successful and profitable survey of native peoples should be made and how a sound science of anthropology should be built up. Clearly he is the man to continue the great work commenced by that very remarkable man who, living a secluded and penurious life in Hampstead, wrote the first edition of *Man, Past and Present*. Dr. Haddon was fortunate in having a very able pupil—Mrs. HINGSTON QUIGGIN—to relieve him of the toil involved in the revision of such a work, for the task of incorporating into the old text the discoveries of twenty years is one that very few are qualified to undertake. Mrs. Hingston Quiggin has performed her task most ably, and by giving references to all recent literature has produced for serious students of ethnology just such a reference work as they now need. In such a book we must not expect, or look for, new or revolutionary doctrines: the aim of the editors, as it was of the original author, has been to give a faithful, perhaps a somewhat cautious, reflection of the opinion held by leading experts.

The groundwork of this book is the geographical distribution of the various races and peoples of the world—a careful analysis of the physical and mental characters, and of the religion and culture of each variety being duly noted. The classification of human races originally adopted by Dr. Keane has been retained in the present edition with only minor alterations. That system was one founded on the characters of the hair; for Dr. Keane mankind fell into three main stocks or types—the woolly-haired, the straight-haired, and the wavy haired. He began his survey with the most sharply differentiated type—the woolly-haired, or negro. Planting himself, in imagination, in Ceylon, he looked southwards and saw that his woolly-haired black-skinned stock was split into two great divisions—a western, centred in the heart of Africa, and an eastern, lying scattered in the islands north and east of Australia. He drew the legitimate conclusion that these two branches were growths from a common human stem which had been rooted in Southern Asia when land distribution and climate were very different from what they are to-day.

Then, turning his back, as it were, on the Indian Ocean, he took up a stance on the Himalayas and looked northwards over the Tibetan plateau. That plateau he supposed to be the cradle of another human stock—the Mongolian, which had ultimately found its chief centre in China, and had spread until it extended from Lapland in the West to Japan in the East, from the Siberian coast in the North to the warm islands of the Pacific in the South.

Next passing to the American continent, he seems to have hesitated for a moment, uncertain as to the place of the American Indian in his scheme of classification. But he boldly faced the circumstances of the situation. He came to the conclusion that the native peoples of America were descendants of Northern Asiatics who had made their way to the new continent before the differentiation and spread of the Mongolian type. He therefore placed American aborigines in a separate group. Dr. Haddon and Mrs. Hingston Quiggin have done Dr. Keane's prescience less than justice by substituting Dr. Hrdlicka's ultra-cautious statements regarding the origin of the American Indian for the well-reasoned conclusions of the original author.

Having marked off these three stocks of humanity—the Negro, the Mongol, and the Red Indian—Dr. Keane swept the remainder into a fourth stock—the Caucasian. How heterogeneous this stock is we see by bringing together its extremes. The fair-haired Norwegian finds himself side by side with the black-skinned native of Central Africa; the Prussian, the Slav, the Englishman, are bracketed with the Egyptian, the Afghan, the ebony-skinned native of India, and the Easter Islander. Clearly Dr. Keane's Caucasian group is a hotch-potch of humanity, and certainly should have undergone a radical revision in the preparation of the present edition.

But where are we to draw the line between a member of the Masai in Central Africa and a fair-haired Highlander of Scotland? If we start from the north of Europe and make towards the Mediterranean, the tall and fair-skinned people gradually change in type until a short, dark-haired, and bronzed type is reached in the southern shores of Greece. Nor does the change stop there, for if we follow the coast lands of the Levant all the way from Greece to Egypt, we shall find no sharp break to form a border-line between one type and another, and yet at every stage of our progress the physical characters of the people are some degree different. If we ascend the Nile for some distance, and then pass to Central Africa by the Red Sea littoral and Somaliland, we shall find all the grades which link the Egyptians to the Masai and Bahima, and even then we shall have difficulty in finding a break in the line which leads us on to the Zulu. Now, the Hamitic tribes of Uganda may be most estimable people, but there must be something wrong with the scheme of classification which sets them side by side with so different a type of humanity as that found in north-west Europe.

In its ultimate solution the differentiation of mankind into races and varieties is a medical problem. Unless we agree that evolution is constantly at work and has been in operation since living things appeared on the earth, we can give no explanation of the present state of the zoological kingdom of which man is a part. We do see that under certain disordered conditions of the glands of internal secretion the physical characters of the human body can be altered, and we are therefore justified in presuming that the endocrine system is part of Nature's mechanism for manipulating the body and mind, and thus adapting mankind to his surroundings. We should expect, if Nature's mechanism for the differentiation of mankind into races is of the kind we suspect, that the most clearly evolved types should be found as the nuclei or centres of the most densely populated areas of the world. We find the purest Negro in the heart of Africa, the purest Mongolian in the real heart of Asia, and the round-headed Caucasian in the heart of Europe. Then there should be, and there are, subsidiary and intermediate centres—some of them waxing, others waning. It is when we apply such a theory to the distribution of human types and varieties that we reach a satisfying explanation of the present geographical arrangement of racial types. Sooner or later medical men, or men with a full training in the basal subjects of medical education, must apply themselves to the task of arranging mankind in natural groups, and they must begin, not by attempting to mark out the world as sharply defined areas, but start at the centres where types are being evolved and work from the clearly marked human type in the centre of evolution to the more generalized varieties at the circumference.

In such a system we shall not find the impossible mixture of human types presented to us at present under the name of Caucasian.

¹ *Man, Past and Present*. By A. H. Keane. Revised and largely rewritten by A. Hingston Quiggin and A. C. Haddon. F.R.S. Cambridge University Press. 1920. (Roy. 8vo, pp. xi + 582; 16 plates, 50s. net.)

A MANUAL OF VENEREAL DISEASES.

DR. MAGIAN in his *Manual of Venereal Diseases*² follows the usual practice of dividing the volume into two parts, the first part dealing with gonococcal infections, the second with syphilis. It is essentially a practical textbook, and this is as it should be, for we are told in the preface that it has been written for the use of the general practitioner. Whether all the elaborate mechanism required for the modern treatment of these disorders—and this is particularly true of gonorrhoea—is likely to be available for those dealing with occasional cases may be open to question; but the author has rightly taken the view that this does not absolve him from describing them and their use.

The first section contains much sound advice; the criticism on page 32 of the routine treatment of gonorrhoea by santal, cubebs, or copaiba, followed by some favourite astringent injection, will be endorsed by those accustomed to see the results of these methods. In the second and larger part syphilitic infections are considered; on page 169 is given a complete scheme for an average case seen shortly after the primary sore. It is recommended that a combined course of mercury and salvarsan—or one of its substitutes—extending over fifty days, should be followed by the administration of potassium iodide for a further six weeks. While such a plan is advocated by some authorities, general opinion now rather favours the continued employment of mercury over longer periods, up to two years in some cases, even where the Wassermann reaction is negative. Since relapse is by no means infrequent after the short "intensive" methods, these long courses appear to be justified.

Apart from this criticism, with which all may not agree, the views set forth should meet with general acceptance. The author's pleasant and entertaining manner of presenting his facts makes reading easy and adds to the value of the book.

NOTES ON BOOKS.

A VOLUME containing the *Minutes* of the General Medical Council³ and of its various committees for the year 1919 has been issued. The proceedings of the Council were reported from time to time in our columns. In appendices, occupying about half the volume, reports presented by various committees are given, together with the usual financial statement and report. The Council has also issued a *General Index*³ to its minutes for the years 1903-1919. The convenience of these periodical indexes is well known to all interested in the work of the Council.

The new number of *Medical Science*⁴ (March, 1920) contains reviews of recent literature on typhus, dysentery, alimentary diseases, and diseases of the liver, and on the surgical treatment of bronchiectasis and pulmonary abscess, and the management of unreduced obturator dislocations of the hip. These reviews are followed by some seventy pages of abstracts. It is announced that an index to Volume I will be issued with the first number of Volume II.

The *British Journal Photographic Almanac* for 1920,⁵ now in its fifty-ninth issue, is full of information essential to working photographers all the world over. The amateur photographer also will find much to instruct him in this volume. We wish the *Almanac* continuance of the wide circulation and success it deserves and has enjoyed.

The Letters of a Widowed Physician to his Daughter,⁶ issuable to her at puberty, maturity, marriage, and motherhood, contain a quantity of sound advice conveyed with adequate emphasis and excellent brevity. There is a great demand nowadays for the early education and enlightenment of boys and girls in all sorts of matters that not so many years ago they were left to learn by chance. These *Letters* appear quite suitable for the perusal of the many girls for whom they have been written.

² *The Practitioner's Manual of Venereal Diseases*. By A. C. Magian, M.D. London: William Heinemann (Medical Books), Limited. 1919. (Demy 8vo. pp. viii + 215; 61 figures. 10s. 6d. net.)

³ London: Constable and Co., Ltd. (12s. and 2s. 6d. respectively.)

⁴ Annual subscription 21s.; a single number 2s.

⁵ *The British Journal Photographic Almanac and Photographer's Daily Companion*, 1920. Edited by George E. Brown, F.I.C. London: Henry Greenwood and Co., Ltd. 1920. (Paper cover, 1s. 6d. net; cloth bound, 2s. 6d. net.)

⁶ *The Letters of a Widowed Physician to his Daughter*. London: Baillière, Tindall, and Cox. 1919. (Fcap. 8vo, pp. 64; 2s. 6d. net.)

The fourth edition of DA COSTA'S *Principles and Practice of Physical Diagnosis*⁷ has been revised and enlarged. It is designed for the use of medical students, is clearly written, conservative, and covers the ground adequately. The first seventy pages deal with the methods and technique of physical examination in general; then follow two chapters on the examination of the thorax and broncho-pulmonary system, and after that the various diseases of this system are described in detail from the point of view of physical signs. The next two chapters are given to the examination of the cardio-vascular system and its diseases; the last seventy pages of the volume describe the examination of the abdomen and its viscera. The description of the physical signs is assisted in many cases by photographs of *post-mortem* specimens admirably reproduced, and by photographs of typical cases taken from the life. We doubt, however, if it is really desirable to employ so many photographs of the nude in exhibiting mere diagrams of physical signs as is the author's practice in this volume.

⁷ *Principles and Practice of Physical Diagnosis*. By John C. Da Costa, Jr., M.D., Ex-Associate Professor of Medicine, Jefferson Medical College, etc. Fourth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Co. 1919. (Med. 8vo, p. 602; 225 figures. 20s. net.)

A PHYSICAL CENSUS OF THE MALE POPULATION.

VOLUME I is published this week of the Report upon the Physical Examination of Men of Military Age by National Service Medical Boards, covering the period from November 1st, 1917, to October 31st, 1918.¹ In order to understand the genesis of this important work it is necessary to recapitulate briefly the recent history of recruiting in this country, and the phases through which it has passed.

THE PRE-WAR STANDARD.

Before the war we had a voluntary army, and only men of good physique and free from any physical defect were accepted for enlistment. Recruits were required to possess all the following physical qualifications:

Good intelligence; a high standard of vision with either eye; good hearing; speech without impediment; no glandular swellings; capacious and well formed chest; sound heart and lungs; freedom from rupture in any degree or form; well formed and fully developed limbs; free and perfect action of all the joints; well formed feet and toes; no congenital malformation or defects; no sign of an impaired constitution; and a sufficient number of sound teeth for efficient mastication.

Men presenting any of the following conditions were rejected:

Indication of tuberculous disease; constitutional syphilis; bronchial or laryngeal disease; palpitation or other diseases of the heart; generally impaired constitution; under standard of vision; defects of voice or hearing; pronounced stammering; loss or decay of teeth to such an extent as to materially interfere with efficient mastication; contraction or deformity of chest or joints; abnormal curvature of spine; defective intelligence; hernia; haemorrhoids; varicose veins or varicocoele if severe; inveterate cutaneous disease; chronic ulcers; fistula; traces of corporal punishment; or any disease or physical defect calculated to unfit them for the duties of a soldier.

It was laid down that the height, weight, and chest measurements of each recruit should accord with each other and with his age in conformity with the official table of standards.

It will thus be seen that the medical examination of recruits was a simple and straightforward matter, as the examiner was only required to certify that the candidate was possessed of certain definite physical characteristics and was free from other equally definite defects. Each recruit who fulfilled these conditions was passed "fit" and accepted for service. Each recruit whose physical condition did not conform to these standards was regarded as "unfit" and not accepted for service. In short, the army only accepted for service the best human material judged by a high standard and declined all recruits who did not conform to this criterion. The examination itself was carried out by medical officers of the Regular Forces and of the Special Reserve and Territorial Forces (under certain conditions) and by civilian practitioners specially appointed for the purpose; it is evident that theirs was a simple task which required only ordinary attention to the

¹ Cmd. 504. H.M. Stationery Office, 1920. To be purchased through any bookseller. Price 2s. 6d. in paper covers; 6s. bound.

regulations and a straightforward physical examination for its efficient performance; the definite question "fit" or "unfit," without qualification, was capable of a definite answer in each case.

The Outbreak of War: Recruiting Chaos.

Such was the position of affairs at the outbreak of war in August, 1914. Immediately there was a tremendous rush of recruits to the colours, and it was inevitable that they should be dealt with on the existing, almost ingenuously simple, system, which had to be expanded precipitately in order to cope with the immense requirements of the situation. The result was chaos; tens of thousands of recruits were besieging the recruiting offices to get into the army; the army was in urgent need of men, and doctors were called upon to "examine" as many as 200 recruits per diem; the whole tendency of the situation was to expedite and reduce to a minimum the medical examination. The medical problems involved had been visualized no more than the purely military problems. It is becoming difficult now even to remember the immensity of our unpreparedness for the war, and in no department was this unpreparedness greater than in that of recruiting. In these circumstances thousands of men were passed "fit" into the army every week without any medical examination worth the name. As the weeks went on the army itself began, as was inevitable, to realize that it was confronted with a new problem—that the old simple standard by which the authorities had selected fit recruits was no longer applicable, and that they were being flooded with men who after a few weeks' or months' military service broke down and contributed an ever-growing quota to the sick return and casualty lists.

In October, 1915, the "Derby scheme" came into operation; men were placed in groups according to their age and marital status, and the different groups called up as required. By this time public enthusiasm for military service had cooled down considerably, and instead of pressing for admission to the army men were beginning to raise the question whether they were or were not physically "fit." In response to the public criticism of the methods of medical examination, medical boards were established by the War Office at the end of 1915 to replace the examination by single medical officers. Early in 1916 appeared the first instructions for the classification of recruits by categories; this marked a great advance in the realization of the recruiting medical problem, though the fact that it was proposed that 200 examinations should be carried out per diem by each board shows clearly how much there still remained to be learnt upon the subject.

On January 27th, 1916, the first Military Service Act, which provided for the compulsory service of unmarried men between the ages of 18 and 41, became law; this was followed on May 25th by Session 2 of the same Act, which extended the obligation to all married men. Throughout that year various modifications of the categories were introduced, and their number was increased. On looking back, however, it is evident that there was no real uniformity in the practice of different recruiting boards, and little real appreciation of the difficulties and importance of the problems presented by the medical examination and classification of recruits. The inevitable dissatisfaction with this state of things was brought to a climax by the Review of Exceptions Act, April 5th, 1917. Under this Act a very large number of men previously exempt from military service were called up for examination, the methods of which called forth a storm of adverse criticism. The result was the appointment of the Shortt Committee, which in due course recommended to the House of Commons that recruiting medical boards should be placed under civilian control.

The National Service Organization.

By this time the difficulties attending the provision of recruits for the army were recognized, and also the existence and vital importance of the man-power problem. The great fundamental industries of the country, including munition works, had to be adequately manned, and it was evident that one of the principal factors in deciding the issue of the war would be the extent to which each of the belligerents succeeded in allocating every available man to the work in which he would be most useful. A special civilian department—the Ministry of National Service—was reconstituted under Sir Auckland Geddes to regulate

the man-power of the country, and entered upon its task on November 1st, 1917, with Sir James Galloway as Chief Commissioner of Medical Services, at the head of the Medical Department. Great Britain was divided up into ten regions as follows:

Northern, North-Western, Yorkshire and East Midland, South-Western, South-Eastern, London, East Anglian, West Midland, Scotland, and Wales.

In each region a commissioner of medical services was appointed to administer the medical work. These regions were further subdivided into areas which generally corresponded to counties, and a deputy commissioner of medical services was appointed to administer the medical work in each area under the commissioner of the region. The requisite number of boards was set up in each area to examine recruits, the doctors of the board being drawn from a panel of selected local practitioners so as to spread the work, and, by employing local doctors on a part-time basis, to economize to the utmost the medical man-power of the country.

Each board consisted of four members and a chairman, each of whom saw every recruit at some stage in his examination. It was recognized that much of the difficulty of the past had been due to the complex nature of a category which was partly medical and partly administrative; the new recruiting boards were therefore instructed that every recruit was to be placed in one of the four grades in accordance wholly and solely with his physical condition, without regard to any administrative consideration, such as his fitness for any particular arm or branch of the service. It is evident that this definition of the duties of the medical boards—namely, to grade the men brought before them solely in accordance with their physical condition—laid the foundation of a physical census of the men of military age throughout the country, and it is the collective result of these examinations that forms the basis of the present report.

SCOPE OF THE REPORT.

The first volume of the Report consists of 159 quarto pages, with a frontispiece, many charts and graphs throughout the text, a map, and five beautifully executed large coloured graphs. There is ample material to justify division of the Report into two parts, for the present volume contains an enormous mass of information obviously representing a still larger mass of crude material which has been condensed, sorted, and tabulated. The second volume will analyse in detail the disabilities for which a quarter of a million men were found totally and permanently unfit for military service, and the reasons for which men were placed in Grades II and III; it will present also anthropometrical observations upon large numbers of men in the various parts of the country, together with such information as is available upon the physique of women examined for the various women's corps.

The frontispiece shows examples of men in each of the four grades; this, with the glossary of medical terms, will enable the general reader to follow the argument of the text and give him at the outset a correct idea of the main characteristics of the men in each grade. The prefatory letter, addressed by Sir James Galloway to Sir Auckland Geddes, explains briefly the origin of the whole inquiry; by reading between the lines it is sufficiently evident how much valuable work lies behind this report. The concluding paragraph observes truly that it represents the only survey of the physical fitness of our male population in the history of our country, and should stimulate interest in the vital problem of the health of the nation.

The actual contents are divided into two main parts. The first consists of an introduction, describing briefly but clearly how it came about that every man called up under the Military Service Acts after November 1st, 1917, was placed by National Service Medical Boards in one of four grades in accordance with his physical condition alone. Then follow four chapters upon (1) grading as a criterion of health, (2) the comparison and analysis of grading results, (3) the relations of occupation and health, (4) the causes of low grading and rejection.

Grading and Health.

Immediate difficulties arise in considering grading as a criterion of health. Physical fitness is a complex quality

incapable of exact measurement. Furthermore, certain disabilities, such as deformities of the feet, are serious from the standpoint of grading for military work but of slight account in considering physical fitness as regards life insurance. This necessity for looking upon disabilities in their military aspect has to be kept in mind throughout a perusal of the Report, and whilst the general fitness of recruits from a civilian standpoint is also fully investigated and commented on, it must be remembered that a certain number of men were necessarily placed in lower grades than would have been the case had the grading been based solely on their capacity for carrying on efficiently their own civilian employment. Nevertheless, even after allowing for this factor, it is sufficiently depressing to find that only 36 per cent. of the men could be placed in Grade I as being up to the full normal standard of health and strength for their age, and that rather more than 10 per cent. were judged to be totally and permanently unfit for any form of military service, even when it was assumed that if a man was physically fit for any civilian work he was fit for some sort of army work.

Broadly, the men examined during the last year of the war were either those combed out of protected industries, those refused further exemption by tribunals, and youths attaining the age of 18, or, on the other hand, men previously rejected or between 43 and 51. The standard of physical fitness of the former and larger group will be above the average and of the latter below the average, so that the argument that the results of these examinations give a fair picture of the manhood of military age seems to be justified.

It is clearly a first necessity in such an inquiry to have some definite idea as to what ratio the different grades should bear to each other in a community of satisfactory average physique. In order to attempt an accurate estimate of this required ratio the reports of the work for the first eight months were submitted to Professor Arthur Keith, whose memorandum is included in the Report. The general result of his most interesting study of the problem is that a normally healthy community should produce 70 per cent. Grade I, 20 per cent. Grade II, 7.5 per cent. Grade III, and 2.5 per cent. Grade IV men. The actual percentages for these grades, as shown in the total results of 2,425,184 examinations, were 36, 22.5, 31.3, 10.2, indicating only too plainly the widespread prevalence of a physique much below that which ought to exist in a healthy community. Expressing these percentages in actual figures we find a shortage of 825,000 Grade I men and an excess of 575,000 Grade III men, and of 190,000 Grade IV men—truly a disquieting result.

The general physique of any group of men may be expressed by the estimation of what Professor Keith calls the "index of fitness." Without detailing the method by which this index is calculated it may here be stated that for a normally healthy group this index should be 89.3. The actual index for the whole of the United Kingdom was found to be 70.9, a deficit of 18.4 on Keith's standard. A table of graphs is given showing the total grading, numbers, and percentages for each region, and from this it is seen that the lowest index of fitness was in the London and South-Eastern Region—namely, 66.7—and the highest in Wales—namely, 76.3.

Chapter III contains an able summary of the relations of occupation to health, miners and agriculturists being specially considered. These two occupations head the poll in grading results, and give indices of fitness closely approximating to Keith's standard; whereas tailors, for example, are far below this standard. The application of this standard of fitness to various trades is very illuminating in its results and affords a valuable method of expressing clearly and concisely the relation of occupation to health.

The causes of low grading and rejection are considered from a general point of view in Chapter IV, especial emphasis being laid on the deplorably low standard of health found amongst youths. From the examination of 260,000 lads of 18 it was found that, in contrast with the results to be expected from Keith's standard, there was a deficit of nearly 13,000 Grade I and an excess of over 6,000 Grade IV youths. In other words, there were almost twice as many youths totally and permanently unfit for any form of military service as there should have been.

Comparison of Regions.

The second part of this Report gives the detailed information upon which the general conclusions of the first are based; it consists of statistical and general reports furnished by the Commissioners of Medical Services and other medical officers of the various regions into which the country was divided for administrative purposes. Each regional report contains a valuable collection of statistical and general medical detail judiciously selected and arranged from the bewildering mass of isolated facts which accumulated in the course of the work. The sifting of the grain from the chaff in order to present the essential facts in clear and intelligible form must have involved immense labour on the part of the medical officers concerned, and they are to be congratulated on the clarity of the statistical tables and graphs and on the way in which they have brought to life these dry bones of figures, infusing them with the vital energy of their own zeal for research.

The report of the Commissioner of Medical Services for the London and South-Eastern Region is conspicuous for the wholly admirable series of coloured charts with which it is illustrated, reflecting great credit on the foresight and enthusiasm of the Commissioner of Medical Services and his staff. So comprehensively and clearly do these charts bring out the salient features of the inquiry that but little textual elaboration is necessary, and they constitute a masterpiece in the art of graphic presentation of complicated facts.

An analysis of about 230,000 consecutive examinations was made in this region, the basis of the analysis being a division according to occupations, diseases, and ages, the inter-relation of these factors being exhaustively worked out. It was found necessary to limit the more detailed analysis to men placed in Grades III and IV only, but important figures are also given relative to Grades I and II.

Special attention was directed in the London areas to any evidence obtainable as regards a correlation between particular diseases and overcrowding associated with bad hygienic conditions. An area in the East End of London, comprising Mile End, Whitechapel, Stepney, London Docks, Bethnal Green, and Bow was mapped out as a "Black List" area and all facts relative to this area were separately analysed. The area thus delimited corresponded closely with the distribution of the alien population, and thus an indication of the effect of racial factors was also obtained. In general it was found that the "Black List" area compared with other areas showed a higher percentage of all diseases, and especially of pulmonary tuberculosis and other respiratory diseases. This is according to expectation, and affords further evidence, were such required, of the urgent need of drastic action in regard to housing and sanitation. A further disquieting, though less commonly appreciated, fact brought out in these statistics is the unhealthiness of the group of trades comprised under the heading "barbers," and including Turkish bath attendants, masseurs, manicurists, chiropodists, and complexion specialists. This trade group showed the highest percentage in relation to almost every disease—an unwelcome thought when one recalls the many opportunities afforded to these trades for conveying infection by close contact with their customers.

Veneral Disease among Recruits.

Veneral diseases are seen to have exerted only a very slight influence as a factor in relegating a man to Grade III or IV, and it is noticeable that the impression given by the reports from all regions is that the prevalence of venereal disease is small. It must be observed at once that these returns furnish no real evidence on this point; men were examined primarily with regard to diseases and disabilities which limit or abolish military efficiency. Active venereal disease, granted that appropriate treatment is given, rarely has such an effect except for a short while, and men with active venereal disease were placed in the grade for which they were otherwise suited, and recommended to have their disease properly treated; if they were called up for service at once, they were admitted straight away into a military hospital. Furthermore, it must be remembered that, except in its acute stages, the diagnosis of venereal disease requires considerable time and skill, with the aid of a fully equipped pathological laboratory, and rapid accuracy in its diagnosis, even by such methods, has only

been attained since the beginning of the war. It was no part of the duty of medical recruiting boards, faced with the urgent necessity of examining and grading tens of thousands of men as rapidly as possible, to make any special investigation into the general prevalence of such diseases. In fact, it is evident that this Report furnishes as little direct evidence of the prevalence of venereal disease, as it does of the exanthemata or other acute infections.

The real evidence regarding the prevalence of venereal disease, as brought to light in this Report, is to be found in the statistics as to the health of older men, in the frequency with which they were found to be suffering from diseases of the circulatory and nervous systems, and other disabilities in the causation of which venereal disease plays an important part. Further, the records of venereal disease in the army show clearly the extent to which latent disease, which could not be detected by the boards, became manifest under army conditions.

In the section devoted to the London and South-Eastern Region an interesting report is also furnished in regard to a period prior to the Military Service Acts. This is important in connexion with the question as to how far the men examined during the last year of the war may be regarded as a fair sample of the population. Defective feet were found in 23.8 per cent. of these recruits, at least 18 per cent. of which were apparently due to causes easily preventable in early life. No fewer than 42.5 per cent. suffered from dental defects affecting their general health, again largely as the result of early neglect. An instructive table is given, showing the relative grading percentages of Russian Jews as compared with British recruits, 70.1 per cent. of the latter being up to Grade I or II, whereas only 30.4 per cent. of the former attained that standard.

"Overtime" Research.

The Commissioner of Medical Services for the North-Western Region, comprising Lancashire and Cheshire, presents in his report a long series of most detailed and comprehensive statistical tables. These deal chiefly with the work of the Liverpool Boards, and the medical officer in charge of them may be complimented on the minute accuracy with which his records were kept. In reading these reports on the work of National Service Medical Boards it is easy to forget the circumstances under which the work was done. The primary, and indeed from the official War Office point of view the only, duty of the Boards was to extract from the male population a maximum number of men physically capable of fighting, or assisting to fight, the Germans. The compilation of any other statistical returns beyond those dealing directly with this necessity (and they were no small number in themselves) was subsidiary and outside the ordinary daily work. No official time or place was recognized for research of a general medical or statistical nature; "there was a war on," and research must take a back place. Such was the general and natural attitude of the authorities; though Commissioners of Medical Services were directed to concern themselves with the local conditions and social circumstances of the population in regard to their bearing on the health and physical fitness of the people, it is manifest that this unique and fleeting opportunity of collecting and collating invaluable information was seized only when the personal energy and enthusiasm of individual medical officers led them to devote their scanty leisure to this work. It is therefore the more remarkable that, with but two exceptions, all the regions are able to show results which must have cost much labour out of office hours, and show that the medical officers concerned realized the unique opportunity presented for research. In the North-Western Region, for example, the age-incidence of tuberculosis, pulmonary and non-pulmonary, is fully worked out, and an elaborate investigation into the frequency distribution of height, weight, and chest measurements is set forth in full.

The fact that, by specially analysing the statistics relative to youths who had just attained military age, information could be obtained in regard to a soil which had not been dug over by previous recruiting was fully made use of, and the details given of physique and disabilities in youths provide a basis upon which the general health of the young men in this region can be accurately gauged. The results of this analysis are sufficiently deplorable.

"Out of 1,070 recruits of 18 years of age no fewer than 451 (equal to 42 per cent.) were less than 112 lb. in weight, and 142 of them (equal to 13 per cent.) were less than 100 lb. in weight." Such figures only need to be mentioned to bring home with full force the alarming and widespread existence of a youthful C3 population.

The sad results of so low a standard of health amongst youths are further exemplified in a memorandum on the health of men over 43 years of age in Manchester and Stockport. Here again a "virgin soil," unaffected by previous recruiting, was studied, and the conclusion was arrived at that "the average man here is, for military purposes, an old man before he reaches the age of 40." Very severe varicose veins were exceedingly common, as were also rheumatic troubles and cardiac disabilities. In Salford, out of 1,877 cases, only 8 per cent. showed no disability of any sort! The writer of the memorandum suggests that the root cause of this low standard in health is to be found in the early age at which boys commence hard and exhausting work, no opportunity being given for any form of physical culture either as games or otherwise. Unfortunately, these lads accept this state of affairs with dull contentment, and appear to take almost a pride in their disabilities.

The Commissioner of Medical Services for the West Midland Region made a special study of military age in its relation to weight, height, and grading, and also the details of occupation and disease, with special analysis of tuberculosis and venereal disease, amongst the men rejected (Grade IV). The results are shown in a series of tables and graphs, each being subdivided into the ten main areas of the region—namely, Birmingham, Burslem, Dudley, Worcester, Coventry, Shrewsbury, Hereford, Leamington, Walsall, and Wolverhampton. Nearly 233,000 men were examined during the twelve months (November, 1917, to November, 1918) to which the report refers. Reference must be made to the tables and graphs themselves in order fully to appreciate the intricacy of the investigation and the admirable way in which the essential points brought out therein are discussed. In regard to the figures for weights and heights comparison is made with previous work on the subject by the Anthropometrical Committee of the British Association in 1883, and it is regrettably clear that the standard of weight and height in this region falls far short of that previously worked out (in much smaller figures) for the average general population by that Committee. The conditions of labour in the Potteries and in the brass and allied trades in Birmingham are discussed at some length, and the conclusion is reached that the general conditions in these trades are definitely inimical to health, and, combined with overcrowding in houses which are damp and dirty, produce a high percentage of diseased and disabled individuals. The need for organized physical culture is emphasized here as in the North-Western Region. A report is given from a tuberculosis officer who examined 874 cases referred to him. He calls attention to the large proportion (15 per cent.) of those suffering from tuberculosis who were unaware of the fact, though in a good many the disease was fairly advanced, and considers that there is a serious danger to the community in this ignorance.

The report on the Yorkshire and East Midland Region is chiefly concerned with the work done in the Leeds and Barnsley areas, the D.C.M.S. of Leeds commenting especially on the bad housing conditions in that area, there being no fewer than 60,000 "back-to-back" houses. He considers that the Jews in Leeds are becoming "a menace to the welfare of the city," on account of their lack of sanitation and the prevalence of tuberculosis amongst them. An interesting note is made on the prevalence of an artificially produced glycosuria amongst recruits. He estimates that there must be 10,000 to 12,000 sufferers from tuberculosis in Leeds. As regards the Barnsley area, an exhaustive analysis was made of the mental and physical disabilities of 1,844 men placed in Grade IV. Here again pulmonary tuberculosis is very prevalent, accounting for over 25 per cent. of the rejections, and amongst them 2 were found to be retailing milk, 35 were clerks, 4 hairdressers, and 5 school teachers, all presumably propagating infection through their work. The Commissioner of Medical Services of the region makes a detailed criticism of the memorandum by Professor Arthur Keith, given in Part I of the Report, and specially discusses the

causes of difference in the gradings in Leeds and Sheffield. The criticism is interesting and relevant, and an alternative method of estimating physical fitness is given at some length.

The report on the Eastern Region, though comparatively short, is very concise, and contains much useful and interesting information in regard to the areas of the region. Tuberculosis here accounted for about 13 per cent. of the rejections, whilst cardiac disabilities were responsible for 11 per cent. As was found in the London and South-Eastern Region, there is here also evidence that the majority of cases of defective feet could have been prevented by intelligent footwear and treatment in early life. Housing conditions in the Oxford area are described as very unsatisfactory, and in Buckinghamshire it was remarked that whereas the young farm labourer of 18 to 21 is usually of splendid physique, the same class of man at 40 is middle aged, and suffers from such disabilities as myalgia, arthritis, varicose veins, hernia, and flat feet. The statement made that Buckinghamshire is "remarkably free from venereal disease," though possibly true, is not, however, supported by any adequate evidence.

No written report is given on the work in the Northern and South-Western Regions, but graphs showing the gradings, actual numbers and percentages for each month of the period November 1st, 1917, to October 31st, 1918, are given in respect of both regions.

The Scottish Findings.

Scotland, on the other hand, is dealt with in a full and comprehensive report. Visual defects were analysed in regard to 16,000 examinations in the Edinburgh area, and, taking $\frac{1}{2}$ and better in both eyes as an average standard of efficient sight, it was found that 23.8 per cent. fell below this mark. High myopia was common and chronic blepharitis widespread; ten cases of trachoma were recorded. Special stress is laid on the progressive nature of myopic defects, a factor of importance in subsequent claims for pension, and the large number of eyes damaged by corneal nebulae and scars following on the common ezeematous keratitis of childhood, furnishing another example of adult disability due to preventable disease in early life. One thousand entries in the recruiting register of Glasgow were summarized, and, as in other industrial areas, the prevalence of poor physique and the need for systematic physical culture is strikingly shown.

The recruits from Ayrshire and Wigtownshire, 18,432 in number, were studied as regards the relation of age and occupation to grading, and full tables of the results obtained are given. It is a pleasant contrast to the usually depressing results of these investigations to find that, at least as regards the Ayrshire miners, there is a predominance of high mental and physical efficiency, due, it is considered, to improved conditions of labour. In general the standard of physique in these areas was fairly good, and, apart from their fitness for military life, it was considered that 67.6 per cent. were fit for ordinary civilian occupations, 23.5 per cent. moderately handicapped, and 8.8 per cent. seriously handicapped. Severe varicose veins are again noted as very common.

A chairman of a medical board dealing with industrial areas in Scotland, notably Dundee, Perth, Fifeshire, and Stirlingshire, records his impressions, and once more the widespread occurrence of preventable disabilities, the bad influence of early full-time labour amongst boys with a lack of good housing accommodation and opportunities for recreation and sports, are emphasized. Dealing with a period prior to the institution of National Service Medical Boards, namely, from August, 1916, to May, 1917, a lengthy analysis is given of the physical defects found amongst 10,000 men between 18 and 41 years of age in Scotland, drawn from both agricultural and industrial districts. Only 20 per cent. were found free from noteworthy physical defect. Valvular defects of the heart were found in 2.4 per cent., varicose veins in 5 per cent., pulmonary tuberculosis in 1.07 per cent., and deformities of various kinds in 7.4 per cent. These are only a few samples of the diseases considered. An interesting note on malingering is added showing that it usually consisted of the exaggeration of a slight defect.

Wales: the Healthy Miner.

The Commissioner of Medical Services for Wales, in dealing with recruiting during the period November 1st,

1917, to June 30th, 1918, divides it into four phases according to the order in which miners and other men in protected industries were called up. Miners as a whole proved to be an excellent type of recruit. They were, however, whilst otherwise fit, very subject to affections of the metatarso-phalangeal joints, hypertrophy of the heart, the results of old trauctures, and miners' nystagmus. The occurrence of nystagmus varied with the type of mine, being very prevalent when safety lamps had been used, the light being then more or less fixed, with the result that the miner constantly changes his visual accommodation as he moves about, in contrast to what occurs when a steady illumination is provided by a naked light carried about by the miner. The Commissioner considers that it is extremely doubtful whether a man suffering from any degree of nystagmus should be passed as fit for combatant work on account of its liability to become severe at any time and the great difficulty in vision experienced in dim light.

Agriculturists in Wales provided a good type of recruit, especially those from the pasturage farms. In spite, however, of the good general physique of recruits from Wales, as far as mining and agriculture are concerned, there appeared to be good evidence that diseases of blood vessels and valvular disease of the heart were alarmingly common, while the industrial regions again demonstrated the evil effects of long hours and too severe labour at an early age in producing premature age and general deterioration of physique. The results of grading of this region are clearly set out in graphic form, enabling them to be easily and rapidly comprehended.

THE ASSOCIATION OF CERTIFYING FACTORY SURGEONS.

THE Council of the Association of Certifying Factory Surgeons, of which Sir Thomas Flitcroft of Bolton is now President, has published a report for the years 1914-19 inclusive. As with other associations of a similar character, active operations were suspended to as great an extent as possible during the war; Dr. J. Hedley occupied the position of president for three years in succession, and Dr. Thomas Watts for two years in succession. The Council, however, despite war handicaps involving the whole profession, was compelled to resume its activities on three separate occasions.

In 1916 a very strenuous resistance was made to the abolition of accident reports when the Police, etc. (Miscellaneous Provisions) Bill was brought before Parliament. With the assistance of the British Medical Association and many members of Parliament, the objectionable clause was fought in the House of Commons through each stage of the bill, and, although it was somewhat modified in order to retain the investigation of poisonings due to accident and to allow the Secretary of State to schedule any particular class of accident for investigation, when the bill was passed this important function of the certifying surgeon had practically disappeared. The British Medical Association organized an opposition in the House of Lords, but the spirit of economy was even stronger in that House, and no further alteration was made in the clause as it left the House of Commons. The case for compensation was subsequently laid before the Home Secretary, who, however, stated that the terms of appointment precluded compensation. By this action of the Government certifying surgeons as a whole lost £12,000 per annum, and those responsible were no doubt able to congratulate themselves on effecting a very valuable war economy. Nevertheless, it was rather a severe tax on a small section of the medical profession.

In 1918 the Council were stimulated to further action, owing to the diminishing value of the fees paid for certifying and other work. It was felt that the basis of payment for certifying, which was fixed in 1833 at 6d. a case, was woefully inadequate to meet the present day increase in cost of commodities. A conference with the Chief Inspector of Factories was held in July, 1918, when the circumstances were fully laid before him. Since then it is pointed out that the Home Secretary had made no move whatever to assist these doctors by raising this ancient scale of fees or by ordering a bonus. It is admitted that certifying surgeons can, under Section 124 of the Factory Act of 1901,

make agreements with employers respecting the amount of fee to be paid, and it is stated that such arrangements have in many cases been made. This power is, however, not regarded as sufficient, in face of the fact that employers have the right to adhere to the minimum scale scheduled in the Act, and it is held that there should not be any variation of fee in different parts of the country, the necessity for increase being equally pressing everywhere. The Council is of opinion that the financial stress is much greater at the present time than was the case when the interview with the Chief Inspector took place, and that the suggested increase of fees then made would be quite insufficient to meet the needs of to-day. It is pointed out that the Civil Service scale of grants for local Government technical officials now amounts to a bonus on ordinary remuneration of £60, plus 30 per cent. of the income, and that it cannot be regarded as fair that certifying surgeons, who are undoubtedly Government officials, should be expected to carry on with fees established in 1833. At the recent annual meeting, when the position was laid before the members, the opinion was practically unanimous that nothing less than doubling of the statutory amounts allowed would meet the situation, and we are informed that representations on these lines have now been made to the Home Office.

The report describes the action taken by the Council when the Ministry of Health Bill was before Parliament, and expresses satisfaction with the intention of the Government to transfer the Factory Department to a Ministry of Employment.

The honorary secretary is Dr. W. F. Dearden, 168, Trafford Road, Manchester.

PURE AND CLEAN MILK.

THE medical profession is in a dilemma with regard to the prescription of milk. The dilemma is this, that, on the one hand, it is generally agreed that for infants fresh cow's milk is the best available substitute for mother's milk, and that it is a most valuable, almost indispensable, part of the diet of young children. On the other hand, cow's milk, as ordinarily available, has dangers of its own; there is the risk of tuberculosis and the risk of contamination by other organisms, especially those of the *B. enteritidis sporogenes* and organisms of the food-poisoning group, but including the enteric group, during milking and the subsequent manipulations. It is difficult to eliminate these risks. The fact that tuberculosis is exceedingly common among our herds has to be admitted, and the difficulty of eliminating it faced. Under ordinary dairy farm conditions milk is always subject to faecal contamination and almost without exception contains *B. coli*, the contamination being often heavy, even in the early stages, and rapidly increasing under trade and domestic conditions. Though difficult, it is not impossible to eliminate these risks; scientific management is necessary, a herd free from tubercle must be obtained, and every one employed on the dairy farm must be imbued with the principles by the observance of which success can alone be attained. In practice the difficulty hitherto has been, as a rule, so great that the medical profession has been compelled to advise boiling, pasteurization, or sterilization as the only safe course. By bringing milk to the boil a certain number of the organisms in it are destroyed, and by boiling for two or three minutes all harmful organisms are destroyed, though some spores may survive. There is evidence that if the milk is of good quality and free from gross contamination to begin with, and if the distribution and method of feeding is under careful medical supervision, infants will grow at about the normal rate after the fourth month if fed on milk which has been brought to the boil. But these are serious "ifs," and there are questions as to nutrition of the infant or child, and as to the relation of such diseases as rickets to the condition of the milk given, at present undecided. It is obvious that if contamination of the milk could be avoided—that is, if it were both clean and free from the infection of tubercle—it would be in every way better. No risk need be run if the collection and distribution of milk is so conducted that the need for submitting it to such processes as boiling is avoided.

It is possible to supply a clean fresh milk, free from the virus of tubercle or any other disease, and certain public-

spirited milk producers in this country have succeeded in doing so, and are anxious that other dairy farmers all over the country should follow their example. A meeting called by a few of the leaders in the matter a short time ago was attended by a number of farmers all keen to observe the conditions required to be fulfilled and to increase the supply of pure clean milk until it becomes sufficiently large to be within the reach of all classes.

The Food Controller, acting in consultation with the Ministry of Health and the Scottish Board of Health, has been granting licences permitting the use of the designations "Grade A" and "Grade B" in connexion with the sale of milk of high hygienic quality. This system will come to an end on March 14th, and will be replaced by a modified plan comprising regulations not less strict. The Food Controller will in future issue licences for two sorts of milk—"Grade A milk" and "Grade A (certified) milk"—and no person will be permitted to use these designations except under licence by the Ministry of Food.

Grade A Milk.

Grade A milk is milk produced under specially clean and hygienic conditions from a herd free from tuberculosis. The licence requires that the herd from which the milk is obtained must contain no cow or any bovine animal kept in contact with the herd which has not passed the specified tuberculin test, and certain other prescribed requirements. While the licence is in force every facility must be afforded for taking samples of the milk of any cow in the herd, or of the mixed milk of the herd, or of any milk sold under the licence at any time or place that may be thought necessary during the progress of the milk from the producer to the consumer. The farm must be open to inspection by a representative of the Ministry of Health or in Scotland of the Board of Health, or a local authority acting on behalf of the Ministry or Board, and must attain a certain standard in respect of equipment and methods. The licence in the first place is granted after such an inspection, and if at a later inspection the standard is found to have deteriorated the licence may be withdrawn. The milk must be cooled on the farm and consigned in a sealed container having a label giving the address of the farm, the day of production, and whether from the morning or evening milking. Dealers, other than producers, who desire to obtain a licence to sell milk under the designation Grade A milk must show that their equipment and methods are found satisfactory on inspection, that the milk is delivered to the consumer in the vessel in which it is received, or in bottles sterilized by steam, filled on the premises of the retailer and closed by discs or caps, showing the day of production.

Grade A (Certified) Milk.

In the production of Grade A (certified) milk certain additional precautions are enforced, and it is this certified milk which will probably have most interest for members of the medical profession. The milk after cooling is bottled on the producer's premises in sterilized bottles, and labelled to show the day of production and the time of day. The milk on examination at any time before delivery to the consumer must not contain *B. coli* in one-tenth of a cubic centimetre (in each of two tubes) or more than 30,000 bacteria per cubic centimetre. Further, the milk must not be delivered to the consumer as Grade A (certified) milk more than two days after the day of production. We are told, however, by an independent observer that milk fulfilling these conditions will in fact keep sweet much longer. This Grade A (certified) milk must be delivered to the purchaser in the bottles in which it has been received from the producer, with caps intact.

Tuberculin Tests.

The conditions with regard to the application of tuberculin tests on the health of the herd laid down by the Food Controller with the concurrence of the Ministry of Health and of the Scottish Board of Health are rigid; they include careful record of the temperature after injection

* One of the first dairy farms conducted on the principles governing the production of Grade A (certified) milk was that of Mr. Wilfred Buckley, Director of Milk Supplies, Ministry of Food. Milk of this quality is known to some physicians as Moundsmere milk, from the name of his farm, but milk is now being produced under the required conditions at a number of dairy farms, including those of Viscount Astor and Lord Elveden. It is hoped that the number of farms producing Grade A (certified) milk will soon be largely increased.

as compared with the normal. The name of the manufacturer of the tuberculin must be stated, and no animal injected with tuberculin within the previous thirty days is to be included in the test. The report must contain a statement with regard to any cow that appears to be suffering from tuberculosis, induration, or other chronic disease of the udder, and as to any bovine animal suffering from tuberculous emaciation, or from chronic cough, and showing definite clinical signs of tuberculosis. Should any animal react to the tuberculin tests it must immediately be removed to another farm or otherwise disposed of. Animals which show no reaction at the first test must be retested after an interval of three months, and should any animal then react it must be removed and the remainder of the herd again tested after another interval of three months. When, after two successive tests of a herd at intervals of three months, no animal reacts, the test must be reapplied at intervals of six months, except when only home-bred animals from a clean herd are introduced, when the interval may be twelve months. Every animal added to the herd must be retested. Certificates, accompanied by temperature sheets, must be sent to the Ministry of Food immediately after completion of each test. Finally, herds must be subject to periodical veterinary examinations at intervals of not less than six months, and a report of each such examination forwarded to the Ministry of Food.

DINNER TO LORD DAWSON.

THE Federation of Medical and Allied Societies met at dinner at the Café Royal on February 25th for the purpose of congratulating one of the original members of its Council, Lord Dawson of Penn, G.C.V.O., K.C.M.G., on his recent elevation to the peerage. Sir MALCOLM MORRIS, Chairman of the Federation, presided, and amongst those present were Dr. Addison, M.P., Lord Astor, Lord Charnwood, and Sir Robert Morant. Between fifty and sixty sat down at the tables.

THE CHAIRMAN, in proposing the health of the guest, said that Lord Dawson went to the House of Lords with a very big reputation behind him as a practising physician, who intended to go on practising his profession. The nation to-day was suffering from great prostration as a result of the war. Its mentality was wrong; its system deranged. Lord Dawson was going to take his share in bringing the nation back again to its proper moral and physical condition. The medical profession in the past had not done all that it might have done for the nation, and one of the objects with which the Federation was started was to encourage medical men to take a larger share in the work of the State. Some were found declaring that the only duty of the doctor was by the bedside, but a new conscience was manifesting itself and medical men were responding to the higher claims of citizenship. He urged medical men to give of their best to the local councils of their town and county; work at the periphery was important as well as work at the centre.

LORD DAWSON, in reply, said that there was for any man scarcely a delight in life greater than that of having earned to some degree the confidence and approval of the members of his own profession. It was a special pleasure to him to be the guest of that Federation. He regarded it as remarkable that a body so young should show such vigour, but he attributed that to the fact that it met the needs of the time. He himself would be an egoist indeed if he looked upon the honour which had come to him merely in the light of personal recognition. It was a recognition of the great profession to which he had the honour to belong. It was also an invitation from the State to the medical profession to take that bigger share in national life from which hitherto it had held aloof. And, yet again, it was in line with the tendency towards vocational representation as a factor in national government. Such vocational representation was an inevitable result of the progress of knowledge. The greater the progress of knowledge, the more technical did life become. And as civilization advanced and knowledge played an increasing part, it seemed to him absolutely essential that that knowledge should in some way be at the State's disposal. Matters of government must not be left entirely to amateurs, however brilliant. Each skilled calling in the land should find some collective expression in national councils. The Federation was an

effort to bring together the collective voice of the medical and the professions allied to it, and its other function was to educate the profession in public affairs. Dr. Addison as Minister of Health had not only set up a consultative medical council in association with his Ministry, but had given it a generous measure of freedom. That was only a beginning, but it did bring the profession in some organic relationship with administration, and for this the profession owed a debt to Dr. Addison, the full extent of which it did not yet appreciate. In a short time the council would issue an interim report, and the Minister was going to publish it substantially as received by him, so that there again the profession would be given an opportunity of expressing its view on constructive policy. The profession was about to enter on a new era of opportunity.

THE CHAIRMAN proposed the health of Dr. Addison. He said that he was not the first of his name to be Minister of the Crown. The other Addison, the essayist, won his position by Court influence and the writing of essays for his party. Their own Dr. Addison had won his position by sheer hard work and parliamentary ability.

DR. ADDISON, after a reference to the housing question, in which he said that he was certain that the Ministry of Health would win through its present difficulties, went on to speak of the consultative council of which Lord Dawson was the head. It was the first time that any body of medical men in any country had been asked to give its advice to the State on matters such as those which the consultative council was envisaging. But if Lord Dawson thought that what he and his council were going to recommend for the health organization of the nation would meet with universal approbation, he could only tell him, as an old hand, that he was a very sanguine man. The Ministry of Health looked to the Federation, amongst other agencies, to bring a considered opinion to bear upon the proposals which would be published. One of the grave defects in the profession in the past, which it was sought tentatively to remedy, was the absence of any body of men who could be appealed to for judgement on a great public issue. The Ministry of Health was determined on a programme of health service which, although it might take a generation to accomplish in full, would at least commit the State to a course of action from which it could not turn back. If this work could be started on the right lines and with a bold plan, the Ministry would have done well.

COLONEL C. J. BOND proposed the toast of "The Federation," and commented upon its achievements. The fact that it had forty allied societies behind it gave it a great driving force. The former conditions of medical work had fostered a crude individualism, and a true perspective of public duty must be obtained. The Federation would make up for this deficiency, and give the profession itself a sense of solidarity and of public duty and citizenship.

DR. HOWARD MUMMERY, the general secretary, who responded to the toast, said that the Federation stood in no rivalry to any existing body. Nor was it party-political in character. At a recent by-election it supported a Labour candidate, and at another a Coalition Unionist. Out of the ten medical members of Parliament (excluding the two Cabinet ministers) seven were on the council. He regretted that certain organizations whose co-operation was sought had not yet seen their way to render it.

MR. E. B. TURNER, in felicitous terms, proposed the health of the Chairman, and Sir MALCOLM MORRIS, in responding, said it was a great privilege at three score years and ten—the last lap of life—to be allowed to take some part in such a big cause.

WE announced a fortnight ago that the first meeting of the General Council of the League of Red Cross Societies would begin on March 2nd, and that the thirty Red Cross Societies now comprising the League had been invited to send representatives. The Hon. Sir Arthur Stanley left for Switzerland at the close of last week in order to take part in the conference on behalf of the British Red Cross Society. The Japanese Red Cross is represented by the Marquis Kuniloshi Tokugawa, with Dr. A. Ninagawa as his adviser. We take this opportunity to correct a slip. In announcing the appointment of Mr. Charles R. Hewitt as librarian to the League of Red Cross Societies, he was stated to have been assistant librarian of the Royal Society of Medicine, whereas he was in fact librarian, having held that post since 1907.

British Medical Journal.

SATURDAY, MARCH 6TH, 1920.

PHYSICAL EDUCATION.

INTEREST in physical education has increased of late, and the medical profession has been rightly urged to take an active part in its development and extension. Physical education is, indeed, one of the various instruments to be used in the prevention of ill health among children, and it is most important that doctors, and especially those engaged in the school medical service, should bring the light of their knowledge and experience to bear upon the physical education and training which is now in vogue in the state schools.

Broadly, there are two periods when facilities for physical training are needed: first, during school life, and secondly, during adolescent and adult life. Obviously a wholly different organization is required during each of these periods. During school life physical education can be imposed upon the child as part of the school routine; the instruction should not only be based upon correct physiological principles, so as to promote the healthy all-round bodily development of the growing child, but it should be given a sufficiently wide interpretation and application to make it interesting to children of different tastes, and thus implant such a genuine love of physical exercise, in one form or another, for its own sake, that the individual will seek opportunities of wholesome outdoor recreation, games, and sports in after-life. Upon the "compulsory" foundation which is laid in the school will depend the permanent success of any "voluntary" organization of adult recreation, and it is therefore important that the opportunities thus provided shall be utilized to the greatest advantage.

Physical training in the schools under the Board of Education was first organized in 1909, though physical "drill" had been carried out in a haphazard way in elementary schools for many years before this. The influence of the training on the health of the children was considered to be so important that the responsibility for the arrangements was in that year placed upon the chief medical officer, Sir George Newman, who was assisted by one of his medical officers and a staff of expert inspectors. For ten years past report has been made to Parliament in the Board's medical reports.

The essentials of a national scheme of physical training as conceived by the Board of Education have included: (a) An official *Syllabus* of physical exercises, by means of which reasonable uniformity of instruction might be secured in all schools; (b) a minimum of training in physical exercises for all students attending training colleges, special classes, and holiday courses for school teachers desiring further instruction; (c) supervision, advice, and constructive criticism from expert gymnastic teachers acting as "organizers" in local areas under the education authorities; and (d) reasonable facilities (including sufficient time) and equipment in schools for games, play, dancing, and swimming, as well as for the more formal gymnastic exercises. A revised syllabus, issued in 1909, was adopted by practically all schools throughout the country. This *Syllabus* was based in a general way on the Swedish system, the exercises were simple to perform and

teach, and were graded for children from 7 to 14 years of age. Model lesson tables and many excellent illustrations were included for the guidance of teachers, and the teaching of games and dance steps was introduced. The volume soon secured an immense circulation.

During the war the teaching of physical training naturally suffered, especially in the boys' schools, but progress was made, nevertheless, and a few weeks ago the Board's Medical Department issued a new, revised, and enlarged *Syllabus of Physical Training*, accompanied by two separate pamphlets dealing respectively with the teaching in infants' schools and with games.¹ The experience gained in the schools during the previous ten years, and the results of recreational training given in the army during the war, have made it clear that the lessons in physical exercises should be made less formal and more recreative, and that greater attention should be given to games and free exercises. In the new lesson tables, therefore, it is suggested that half the time shall be given to easy Swedish movements and the remainder to gymnastic games, dancing, "general activity exercises," and so forth. It is considered important to have a nucleus of formal exercises, in order to obtain the corrective, disciplinary, and mental effects of such training, but it is now recommended that gymnastics should be supplemented by vigorous, enjoyable free movements. In addition to physical training lessons, many schools have provided swimming instruction or organized games in parks or playing fields. The value of evening play centres has been recognized, and their number is rapidly increasing. Boy Scouts and Girl Guides have become associated with the schools in many cases. School Camps have been started and are likely to multiply. This organization has applied mainly to elementary schools, but in 1911 and 1914 the Board of Education issued advisory memoranda on the subject to secondary schools. The establishment of schools which provide whole-time education up to the age of 16, and of day continuation schools, where part-time education will be compulsory until 16, and eventually until 18, will lead to the extension of physical training organization to an age-period when it is most important to supervise the health, to attract the interest and arouse the enthusiasm of the growing adolescent. Further, under the Education Act of 1918 education authorities have wide powers to promote social and physical training by means of holiday and school camps, centres and equipment for physical training, playing fields and school swimming baths, and by providing other facilities for social and physical training in the day or evening. The importance of providing class teachers in elementary schools with expert guidance was recognized, and the Board has encouraged the appointment of well qualified organizers of physical training (men and women) to supervise the teaching in the schools, to demonstrate, advise, encourage, and stimulate. Special grants in aid are given towards the salaries of these organizers. Several well known physical training colleges exist for women—at Dartford, Bedford, Chelsea, and elsewhere; no suitable training school for men teachers of physical training has hitherto existed, but a special course has been instituted at Sheffield Municipal Training College.

It is thus evident that considerable progress has already been made towards a national system of

¹ The publications referred to are the *Syllabus of Physical Training for Schools, 1919*, price 2s. net; *Suggestions in regard to Games*, price 4d. net; and *Physical Exercises for Children under 7 Years of Age, with Typical Lessons*, price 3d. net. The pamphlets are published for the Board of Education by H.M. Stationery Office, and can be obtained through any bookseller.

physical training, and that when Local Education Authorities fully utilize the powers they now possess there will be a continuous system through childhood and adolescence, combining the advantages of formal gymnastics with recreative activities, and including facilities for games, sports, social intercourse, etc., after school hours. Then comes the break. After school days no systematic provision is made. What now seems to be needed is the effective organization of physical exercises and recreation for the great mass of the people. That such provision is practicable has been proved at the front during the war, but there seem to be divided counsels as to ways and means. Some things, however, are evident. Any organization of adult physical recreation must be voluntary and free from Government control. A directorate under the Ministry of Health or Board of Education appears to be both unwise and inexpedient. What seems to be required is a voluntary representative body of experts and others, prepared to work in co-operation with the Local Education Authorities, and willing and able to continue their schemes beyond the age of 18. The duties and powers of Education Authorities should be fully realized by the promoters of all arrangements for providing adult recreation, and advantage should be taken of the existing school organization to induce young people to continue after school life the outdoor games and pursuits for which they have already acquired taste and talent.

THE PHYSIQUE OF BRITISH MANHOOD.

WE print elsewhere this week (p. 331) a full account of the Report upon the physical examination of men of military age by National Service medical boards during the last year of hostilities. This most important document had its origin in the work of a committee set up in March, 1918, by Sir Auckland Geddes when Minister of National Service. Sir James Galloway was the chairman, and Dr. H. W. Kaye the secretary of the committee. Its reference was to consider the best method of utilizing the data obtained from the work of recruiting medical boards, with the intention of making these data readily available for the use of officials of the Ministry, and of placing the information as to the physical fitness of the nation so obtained on record for future use and reference. When the medical department of the Ministry of National Service was transferred to the Ministry of Pensions a year ago, it was decided that this work should be continued by the staff which had been engaged upon it for the previous year, and the responsibility of carrying on the committee's investigations devolved entirely on the secretary, to whose enthusiasm and perseverance a well-earned tribute is paid. The volume now issued represents the first portion of the completed work; the two together will furnish an elaborate physical census of the men of military age, and much more besides. The first volume, amplifying the preliminary communication which we published on September 28th, 1918, throws a flood of light upon the physical condition of the people of Great Britain. The material is analysed in such a way as to reveal the nature and distribution of disabilities among our manhood, and to show how far the national health falls below an attainable standard. This information, compiled with great pains and skill, will, no doubt, form a logical starting-point for future efforts to improve the national health.

It must be said at once that the Report is far from pleasant reading; the message it conveys as to the physical fitness of the British stock will shatter any

feeling of complacency. The chief lesson for the future seems to arise from the large proportion of defects clearly due to preventable disease and unhealthy modes of life. As the result of nearly 2,500,000 examinations less than 872,000 men were placed in Grade I—that is to say, only 36 per cent. attained the full normal standard of health and strength and were judged capable of enduring physical exertion suitable to their age; 250,000 were judged to be totally and permanently unfit for any form of military service, and accordingly placed in Grade IV. The method of grading was such that the conclusions drawn from the figures are more likely to err on the side of overrating than underrating the physical fitness of our manhood. It is especially disquieting to find that the physique of the youths called up as they reached the age of 18 was far below the standard of health we had a right to expect. There were twice as many lads totally and permanently unfit for any form of military service as there should have been. If such be the state of physique amongst our youths, what are we to assume as to the condition of older men who have had to undergo the full stress of industrial life? Such facts as are recorded in the Report bring out with startling clearness the magnitude of the need for social, economic, and medical work before the country can take to itself credit for having attained even a normal standard of national physique.

The Report contains a vast amount of hitherto unknown or unclassified information relating to the general physical condition of the male population of the United Kingdom. It forms, as we have already implied, a foundation upon which it should be possible to base sound projects for the amelioration of preventable disease and for the extension of an effective health organization. As a work of reference, as a handbook essential to social and health work, and as a landmark in the history of medical investigation, the Report occupies a unique position. It demands careful study, and should be at hand for frequent reference. We await with interest the publication of the second volume, which, it is understood, will give in yet further detail the statistical and other facts embodied in the Report now before the medical profession and the public.

THE OPIUM QUESTION AND THE PEACE TREATY.

THERE is every prospect that during this year substantial progress will at last be achieved towards putting into operation the International Opium Convention which was signed at the Hague in 1912. In an article which appeared in the *JOURNAL* on September 20th, 1919, on "The international control of drugs of addiction," Sir William Collins indicated the advance which had been made towards bringing that Convention into effect under Article 295 of the Treaty of Peace and Article 23 (c) of the Covenant of the League of Nations. By the former all signatories of the Peace of Versailles who had not ratified the Opium Convention were held to be bound by a Special Protocol, opened at the Hague after the third Opium Conference, and to be under obligation to enact the legislation required by the Convention within twelve months. By the latter the general supervision over the execution of the Opium Convention was entrusted to the League of Nations.

In a letter which appeared in *The Times* on January 3rd last Mrs. Hamilton Wright showed that the United States, which is one of the five Powers party

to the Special Protocol binding its signatories to enforce the Convention without waiting for other Powers, had enacted its own legislation for that purpose as well as for its consular districts in China. The so-called Harrison Bill, it appears, was largely the work of the late Dr. Hamilton Wright, who represented the United States at the Shanghai Commission as well as at the first and second Hague Conferences.

Whatever fate may attend the League of Nations at the hands of the American Senate, there is, as *The Times* recently pointed out in a leading article, "no necessity to wait until the League is fully at work. In fact, if legislation is to be passed within the prescribed period, the Governments concerned must begin at once." We gather from a letter from Sir William Collins in the same newspaper of January 6th that our own Government takes the view that Article 295 implies that Powers like Great Britain, Belgium, Italy, and some eleven others which had ratified the Opium Convention, are also bound by the Special Protocol. Thus it would appear that France, Japan, Greece, Serbia, Rumania, Bolivia, Haiti, Panama, Peru, and Germany, are now under obligation to enact pharmacy laws, within twelve months from January 10th last, to give effect to the restrictions on traffic in noxious drugs laid down by the Opium Convention. And further, that these Powers are now to be supported by Great Britain, Belgium, Brazil, Denmark, Ecuador, Guatemala, Italy, Nicaragua, Portugal, Siam, Spain, Sweden, Uruguay, and Venezuela in proceeding to enforce the Convention without waiting for the few remaining Powers which are neither parties to the Treaty nor to the Protocol.

It is clearly high time for Great Britain to get ready her pharmacy legislation as required by the Opium Convention. The Home Secretary has stated that he is sanguine that the necessary Bill will be introduced early this session. It would ill become this country, whose delegates at the Hague were instructed to press—and did press successfully—for the inclusion of strict regulations of the traffic in morphine and cocaine as well as in opium, to be backward in giving effect to the requirements of the Convention. Should any Power be slack in carrying out its obligations it would apparently rest with the Government of the Netherlands, under Article 24 of the Convention, or the Council of the League of Nations, under Article 23 (c) of the Peace Treaty, to put the necessary machinery in operation.

When we remember that the Convention requires the Powers which are parties to it so to supervise the manufacture, import, sale, or export of these potent drugs as to restrict their use to medical and legitimate purposes only, and when we recall the wholesale abuse of these drugs, as disclosed in the daily papers, we cannot fail to be impressed with the urgent need for action.

Only last week it was officially stated on behalf of the Board of Trade in the House of Commons that more than 300,000 ounces of British-made morphine were exported from these shores last year. It requires a large draft upon our credulity to believe that any considerable portion of this can have been utilized for medical and legitimate purposes only. In years prior to the war British morphine, it is believed, found its way, by the ton, into China, while the import of Indian opium was being religiously precluded. Recent reports from China show that the poppy is being again extensively cultivated in parts of that country, while the area under poppy cultivation in India appears also to be extending. Indeed, the need for the restric-

tions laid down in the Convention in 1912, which were amply justified then, is even more imperative to-day, and we look to the Government to lose no time in handling this question effectively.

THE ANNUAL MEETING AT CAMBRIDGE.

We are now able to give some further details with regard to the programme that is being drawn up by the local committee for the Annual Meeting of the British Medical Association to be held in Cambridge next summer. The Annual Representative Meeting will, as already announced, begin on Friday, June 25th, at 10 a.m., and the members of the Representative Body will dine together that evening. The session will be continued on Saturday morning at 9.30, and, if necessary, on the Monday and Tuesday. The Examination Halls will be available for the Representative Meeting, and also for the statutory Annual General Meeting, which will take place at 2 p.m. on Tuesday, June 29th. On that evening Sir Clifford Allbutt, after his presidential address to the Association in the Senate House, will receive distinguished foreign guests, and a reception will be given by the local branch in King's College. The sectional scientific meetings will be held in the New Museums on Wednesday, June 30th, Thursday, July 1st, and Friday, July 2nd; the mornings from 10 till 1 being devoted to discussions, and the afternoons from 2.30 to laboratory and clinical demonstrations, which will form a special feature of the meeting. On Wednesday, at 5 p.m., religious services will be held in the University Church—Great St. Mary's—and in the Roman Catholic Church. On the same evening the Vice-Chancellor of the University will give a soirée at Emmanuel College, and the honorary secretaries of Branches and Divisions will hold their conference and dine together. On Thursday evening, at 7.30 o'clock, the annual dinner of the Association will be held in the hall of St. John's College, the numbers being limited to 200. On Friday evening there will be the popular lecture, by Dr. G. S. Graham-Smith, F.R.S., a soirée given by the Master and Fellows of Trinity College, and an entertainment for Freemasons. According to present arrangements the Guildhall, which has been placed at the disposal of the Association by the Mayor and Corporation, will be used as the reception room for members and guests; it is situated in the Market Square at the centre of the town. The Corn Exchange, near at hand, has been secured for the Annual Exhibition, and the Art Schools will be used for offices. Local entertainments—garden parties and the like—will be given on several afternoons, and a visit is being arranged to the tuberculosis colony at Papworth. Saturday, July 3rd, the last day of the meeting, has been set apart for excursions to places of interest in the neighbourhood. The various college authorities have generously offered bedrooms for a thousand visitors, and to provide them with meals at an inclusive daily charge; this will ensure accommodation for all members unaccompanied by ladies. There are also a large number of university lodgings in the town, and the local committee will engage as many of these as are needed by visitors for whom private hospitality cannot be provided. An announcement will be made in due course in this JOURNAL when arrangements are sufficiently advanced for the acceptance by the local authorities of names of those proposing to attend the meeting.

TEACHING OF OPHTHALMOLOGY.

CONSIDERABLE interest is being shown at the present time in this country in schemes for what is called "post-graduate" medical teaching. It is not a new subject in this country, but it has recently received an impetus, owing partly to the wish shown by many civil practitioners to have an opportunity of refreshing their knowledge,

partly to the demand arising among medical men who served during the war, and partly no doubt to the observations on the subject in Sir George Newman's Memorandum on Medical Education in England, and the developments expected to arise out of the policy the Ministry of Health is shortly to make public. The subject has many aspects: one of them is discussed in the *Archives of Ophthalmology*, which contains three papers on the subject—by Verhoeff of Boston, Wiener of St. Louis, and Duane of New York. The former concerns himself with the whole teaching of his subject in the case of undergraduates and graduates; the two latter deal with graduates only. Verhoeff divides those who desired to be taught into four groups: (1) medical undergraduates, (2) general practitioners who wish to take up this special subject, (3) practising ophthalmologists anxious to repair deficiencies in their training, (4) recent medical graduates who propose to qualify themselves for the practice of ophthalmology. For the first group he recommends a short comprehensive general course; the men in the second group, he says, are usually persons who have not succeeded in other branches of the profession, and think that a six weeks' course in eyes will render them fit to practise ophthalmology, for these he advises a complete graduate course; for the third group special courses of short duration, say, in the summer months; for the fourth group, the most important of all in his view, a thorough training spread over four years, in two parts. In the first part, lasting two years, there should be degree work in higher algebra, trigonometry, physics, chemistry, plane and solid geometry; practical clinical experience in general medicine and surgery; and such an acquaintance with special subjects, neurology and dermatology, as can be gained in the out-patient clinics of a large general hospital in a period of six months. Verhoeff insists that in this preliminary part of the course there must be elasticity of detail, as he considers it undesirable to try to cast all students in the same mould. This preliminary course should be the first step towards the degree of Doctor of Ophthalmology, and the succeeding two years should be spent, for the first year, from 9 a.m. to noon, three days a week, in practical clinical work in the out-patients' room, and three days a week in the study of in-patients and operations; the afternoons should be given to laboratory work, anatomy, physiological optics, set operations on animals' eyes, and so on. During the second year the student would act as house-surgeon to an eye hospital, and might be allowed to take part in elementary teaching, for it is in the teaching that the chief difficulty lies at present. Wiener's paper is a plea for more thorough graduate teaching in the U.S.A.; so is that of Duane, who outlines a plan on which a post-graduate course could be worked; he advocates "quizzing" in all stages of training. Verhoeff's scheme appears ideal, but difficult to work at present; it is obviously impossible for one man, or even a body of men, to see all the patients and at the same time do all the teaching. A good deal depends upon the type of student to be taught. Some assimilate the theory by "spoon feeding"; others prefer the more laborious method of getting their experience from a long service of drudgery, doing the actual work in out-patient rooms; generally speaking, this has been the method of most of us. It may be taken as a fact that the man recently qualified, who starts at an eye hospital, saying that he is specially interested in, say, fundus cases, will not go very far unless he is also willing to undertake the preliminary part of the examination of an eye case, by which the fundus examination must be preceded. Most ophthalmic surgeons have taken to their special subject fortuitously, as it were; we all have to live, and unless adequate remuneration is forthcoming for the teacher, a man cannot be expected to give up much of his time to this form of work, unless, of course, he happens to possess private means.

THE SCIENTIFIC STUDY OF RADIOLOGY.

WE welcome the announcement that a chair of medical radiology has been established in the Middlesex Hospital Medical School to work in conjunction with the Joel chair of physics there, because we believe that radiotherapy must be got out of the empirical rut into which it seems to have slipped in this country. With regard to the treatment of new growths alone, it seems clear that progress can only be achieved if a definite plan of research is carefully thought out by the therapist and physicist in consultation and carried through by them conjointly. The efficacy of radium in the treatment of rodent ulcer is well established, but with regard to both sarcoma and carcinoma we are still in the empirical stage. Why is it that some cases of sarcoma are either cured or kept at bay for many years, while in others the treatment totally fails? Again, why is it that in some few cases radium seems to arrest and, in exceptional instances, to cure carcinoma, whereas in the majority it fails entirely? There must be some difference in the mode of application of the radium or in the growth itself, or in the general condition of the patient. The importance of the matter is illustrated by the statement Dr. Herbert Spencer makes in his third Lettsonian Lecture (p. 324), to the effect that owing to the great advance made in the treatment of cancer of the cervix of the uterus by radium, mesothorium, and x rays, operation for this condition has been entirely abandoned in favour of treatment by radiation in several of the chief clinics of Europe. The chair of radiology at the Middlesex Hospital Medical School was formally instituted by the Senate of the University of London on February 25th. The authorities of that hospital have, we learn, felt for some time that if real progress is to be made in radiology in this country an expert in this branch of medicine and therapeutics should be able to devote his whole time to the department and to the work of education and research. The hospital affords great opportunities for the investigation of the possibilities of radiotherapy. Over one hundred beds are constantly occupied by cases of cancer. The hospital possesses a large supply of radium, and in the physics department there are special laboratories for the investigation of the physiological and pathological problems that arise. We recorded a short time ago the endowment of a university chair of physics in the Middlesex Hospital Medical School by Mr. J. B. and Mr. S. B. Joel. The new department and the professor of radiology will work in close association with the Joel professor (Dr. Sidney Russ) and the department of physics, and it is hoped that some other millionaire will seize the opportunity to associate his name with the medical chair.

MACKENZIE DAVIDSON MEMORIAL FUND.

A COMMITTEE has been formed to establish a memorial to the late Sir James Mackenzie Davidson. His death while still in the full vigour of life deprived radiology of one of its pioneers whose single-hearted devotion to its advancement never abated. His name is especially associated with the development of radiographic methods, particularly stereoscopic radiography, and with the perfecting of the use of x rays for the localization of foreign bodies. He was rightly regarded as the head of his department in this country, but his reputation was international. Throughout his career he was unsparing in his efforts to raise the status of radiology among the sciences and was insistent on the fundamental value of physics in the study and application of radiology to medicine, particularly in regard to methods of measurement and the designing of equipment. Of his ingenuity in designing, of his enthusiasm for every scheme to advance the subject, and of his readiness to impart his knowledge to others, all who came into contact with Mackenzie Davidson are well aware. We have no doubt that the appeal, made by many occupied in his own branch of the profession, by

physicists, and by a number of his personal friends, to found another University Chair of Radiology will meet with a ready response. Had he lived Mackenzie Davidson would himself have been among the first actively and generously to support the foundation of an institute for research and teaching in radiology, and it is hoped, if funds permit, to establish such an institute to which the chair might be attached. It would not be confined to purely medical questions, for research has shown that the x rays may be of value to a number of industries. It has already been employed in detecting faults in wood and slovenly workmanship in the building of aeroplanes and other appliances. Only recently it has been found to offer great possibilities for the examination of the internal structure of metals, and has been turned to account by the steel manufacturer, the metallurgist, and the engineer. A chair of radiology at an x ray institute may be expected to play a great part in the development of these new branches of radiology. The appeal is signed by, among others, Mr. Bonar Law, Sir J. J. Thomson (President of the Royal Society), Sir Clifford Allbutt (President of the British Medical Association), Sir Alexander Ogston (who was associated with Mackenzie Davidson during his life in Aberdeen), Sir Robert Hadfield, Dr. Christopher Addison, Lord Harcourt, Lord Dawson, Sir W. Watson Cheyne, Sir F. W. Mott, Sir Anderson Crichtett, Professor Sir Ernest Rutherford, and many others associated with the study and application of the principles of radiology. Subscriptions will be received by Dr. Robert Knox, 38, Harley Street, W.1. Cheques should be made payable to the London Joint City and Midland Bank, crossed and marked "The Mackenzie Davidson Memorial Fund." There is plenty of room both for this proposed radiological institute and for the radio-therapeutic scheme now to be carried out at the Middlesex Hospital. There will be ample work for both.

MEDICAL ENDOWMENTS IN AMERICA.

MR. BALFOUR, in his reply to the deputation from the British Medical Association and the British Science Guild, which laid before him reasons for the provision by the State of suitable rewards for scientific discoverers, referred to the liberality with which American millionaires had given money to universities, especially to meet the ever-advancing needs of medical education and research. We cannot profess to give anything like a complete list even of recent benefactions, but we may quote a few instances which happen to be at hand. The medical school of Harvard University has received an anonymous gift of £10,000 for the establishment of the James C. Melvin fund for tropical medicine. The income is to be used in research. The school has also received the income of the residuary estate of Horace Fletcher, to be used to "foster knowledge of healthful nutrition." The university proposes to adopt this year a programme of compulsory athletics or physical training, in view of the fact that 40 per cent. of the young men of the United States were turned down after examination by medical boards as unfit for military service. The basis of the programme is expressed in the formula "Get everybody into the game." The Washington University Medical School, in addition to several small sums for special researches, has received £60,000 for the endowment of the department of pharmacology. The trustees of the University of Tennessee have decided to erect a building for the department of medicine at Memphis, at a cost of £20,000. The medical department of the University of Louisville has received from one of the members of the faculty a gift of £1,000, payable in instalments of £100 annually. The first will be expended in the equipment of a research laboratory in which medical and surgical diagnostic problems are to be worked out. The University of Cincinnati has established in its medical school a department of industrial medicine and public health.

The training is intended to make students competent social and medical engineers and to enable them to educate the public in the importance of sound health. Yale University Medical School has enlarged its library. It now contains 26,000 volumes, including 14,000 bound volumes of medical journals and translations. It has over 250 medical periodicals, including European as well as American journals. Though not strictly germane it may be noted that the Michigan State Legislature recently appropriated £200,000 towards the erection of a new hospital with 800 beds, to be connected with the Medical School of the University of Michigan. It is estimated that the building and equipment will cost between £400,000 and £600,000.

CHARLES MERCIER.

For the memoir of Dr. Mercier, printed in the *JOURNAL* of September 13th, 1919, we were fortunate in securing the ready help of Sir Bryan Donkin, who wrote an appreciation of his friend as psychologist, physician, and logician. We were able to publish also a brief but illuminating note sent to us by Sir William Osler, who was then on a holiday in Jersey; this was, we believe, his last published writing; within a few weeks he, too, passed into the valley of the shadow. So unlike in so many respects, Osler and Mercier had yet much in common that shone out in the genial after-dinner talk at Oxford: each personified in his own way the union of medicine and letters. We are pleased to find in the current number of the *Journal of Mental Science* a longer notice in memory of Dr. Mercier, written by Sir Bryan Donkin from his full knowledge of the man and his work. He notes the likeness in intellectual power and gifts between Charles Mercier and Henry Maudsley. Both, he says, possessed in a large measure the scientific mind, and their works were marked alike by dominant determination to search out as thoroughly, and explain as clearly and fully as their powers allowed, the subject they had chosen for the chief labour of their lives. Both men were trenchant and alert in controversy, and both excelled in their wide and intimate knowledge of the best of English literature. Both, too, had a mass of readily quotable knowledge of the Bible, Shakespeare, and many other classics, to an extent not often attained even by purely literary specialists. From this apt comparison Sir Bryan Donkin passes to sketch in bold outline Mercier's life of strenuous effort, and his special qualities as an alienist, a scientific philosopher, and a man of letters. He enlarges on one matter in order to clear up a misunderstanding for which Mercier himself was partly to blame. It has been sometimes implied that Mercier looked upon disease of the mind as the result of disordered conduct; but even in his early writings he maintained that disorder of mind could and did exist without insanity; the gist of his teaching was that a man is rightly judged as insane from evidence of what he says and does, not from what one may infer or guess that he thinks or feels. This sympathetic and discerning obituary notice is rounded off with a note on Mercier's literary style by the secretary of the Casual Club; with Osler's tribute quoted from our columns; and with a fitting extract from one of Henley's *Echoes*, which must often have passed through the minds of those aware of Mercier's indomitable courage "under the bludgeoning of chance."

INFLUENZA.

Too late for notice in our last week's issue, the Ministry of Health issued a statement as to the present position of influenza in this country. The weekly returns of deaths from influenza (which we believe include all deaths in the certification of which the diagnosis of influenza as a primary or associated cause occurs) have increased since the beginning of the year, but the actual numbers are small, indeed smaller than during the period following the

epidemics of 1890-92, so that the Ministry does not think they need give rise to apprehension. On the other hand, there has been a fairly large increase of the notifications of pneumonia; these, however, cannot be checked by comparison with previous years, owing to the recent introduction of compulsory notification. The Ministry has information of epidemics of influenza in certain large schools situated in the south and south-west of England, and, although there are no immediate indications of a general recrudescence, it again directs attention to the general warning previously issued, and re-emphasizes the importance of attention to the measures therein advised. The Ministry goes on to report that public health authorities and the medical profession have already widely availed themselves of its assistance or advice in concerting appropriate measures to deal with a possible emergency. At the time of writing we have no information which would lead us to modify the official diagnosis of the position. It is true, we believe, that the increase of notifications of pneumonia has been arrested, but the deaths from both influenza and all forms of pneumonia are still increasing. It is, of course, normal for the mortality from respiratory diseases to increase through the first quarter of the year, but whether the actual rate of increase is within the limits of probable chance fluctuation is a question only to be answered after a minute inquiry, which is no doubt being carried out by the official committee. In most of the American cities which have experienced severe epidemics the disease is now subsiding. In New York, where 24,385 cases were notified in the week ending January 31st, and 21,674 in the following week, only 8,637 were returned for the week ending February 14th. Chicago reached its maximum as early as the week ending January 24th, Detroit in the following week. The American epidemics seem to have been widespread but less fatal than in the last wave. In New York the largest number of deaths was 956, in the week ending February 7th. Of course, these figures (as indeed those of notifications) are mere indices and have no pretension to be exact. Information as to the European position is vague, but at Copenhagen the notifications declined from 11,038 in the week ending February 7th to 8,368 in the following week. In the official statement it is said that competent American medical authorities consider the disease to be the same as that which was prevalent eighteen months ago, but of a less severe type. From the epidemiological point of view a most interesting feature is the fact that, despite the wide dissemination of the disease in epidemic form in America and the intercourse between the two countries, the only manifestations here so far have been in communities little exposed to foreign importation. This is not, indeed, a novel point, but it is none the less remarkable.

THE PORTAL FOR ACUTE POLIOMYELITIS.

The low morbidity of acute poliomyelitis, even during severe epidemics, has been ascribed to a relative insusceptibility which is no real explanation, or to a specific protection, due to an unperceived active immunization by the virus, of the community. No systematic study of the blood of exposed persons who have remained free from poliomyelitis has been published; some observations on the blood of doctors, nurses, and others repeatedly exposed during the epidemic of 1916 were made by Flexner, but they did not yield definite evidence of the presence of specific antibodies. In 1917 Amoss and Taylor showed that in man the nasal mucous membrane exerts a local protective action and neutralizes or destroys the virus of acute poliomyelitis. In order to throw light on this defensive power Flexner and Amoss¹ have carried out a number of experiments on monkeys. Although the intranasal introduction of cotton-wool containing the

active poliomyelitis virus may infect the monkey, all the monkeys thus treated are not affected, and the successes are less than by the intra-cerebral route, and it appears that an efficiently acting nasal mucosa both prevents the passage of an energetically applied virus to the brain and spinal cord and also leads to the disappearance of the virus from the nasal mucosa in a relatively short time, whereas an inefficient mucosa allows the virus to persist for an undetermined period. The incidence of healthy and chronic carriers of the poliomyelitis virus is probably determined by the protective power of the nasal mucous membrane. It is important to recognize that the application to the mucosa of chemical antiseptics does not exert any beneficial influence and may, indeed, do harm by unfavourably modifying the protective powers of the mucous surface. Some further experiments showed that infection with the virus of poliomyelitis, applied to the nasal mucosa under conditions favourable to extension to the central nervous system and to multiplication there, can be prevented by the intravenous injection of poliomyelitis immune serum, the meeting place of the virus and the serum being probably in the subarachnoid space.

NATURE AND TREATMENT OF HYPERPYREXIAL HEATSTROKE.

To the first number of the *British Journal of Experimental Pathology* Dr. W. Cramer contributes the results of an investigation on the mode of action of a chemical substance, beta-tetrahydronaphthylamine, which produces fever. He found that it caused prolonged sympathetic stimulation associated with over-activity of the thyroid-adrenal apparatus, and that the increased production of heat and diminished loss resulting from this induces pyrexia, which from its origin he called "sympathetic fever." If experimental animals are kept in a cool atmosphere the increased loss of heat diminishes the height of the fever and may even prevent the body temperature from rising. Exposure to a warm atmosphere or crowding the animals together, by interfering with the rate of cooling, elicits a rapidly fatal hyperpyrexia. The circumstances under which it is produced and the conditions found *post mortem* present a striking resemblance to hyperpyrexial heatstroke in man. The explanation of hyperpyrexial heatstroke in man suggests that an extrinsic factor (deficient cooling due to conditions of environment) acts upon an organism which is under the influence of prolonged sympathetic stimulation due to the excessive activity of the thyroid-adrenal apparatus. In the treatment of the condition in man the first essential is to reduce the temperature by drastic cooling, which should be instituted during the prodromal stage described by Hearne in our columns (vol. i. 1919, p. 516). The principal symptom in this stage is suppression of sweating, which may be present from one to forty-eight hours before the attack. In discussing accessory methods of treatment Cramer condemns the injection of saline or other fluids, and observes that it is not clear how venesection can combat the condition, though it may relieve the symptoms. Morphine was found useless to arrest experimental heatstroke. A chart of the effect on a rat shows an initial fall of temperature, followed within two hours by a rapid rise, which, however, was not accompanied by excitement; the temperature eventually rose higher than in another animal which had not received morphine, and both died at about the same time within four hours of the beginning of the experiment. Chloral was found a much more suitable drug in experimental heatstroke. In mice and rats it was found possible to delay the onset or prevent heatstroke altogether by a dose of chloral, which produces slight anaesthesia if given alone. It was necessary, however, to repeat the dose, for as soon as the narcotic effect passed off the temperature began to rise. The effect of chloral is

¹S. Flexner and H. L. Amoss, *Journ. Exper. Med.*, Baltimore, 1920, xxxi, 123-134.

thought not to be specific, but to be due to the condition of anaesthesia it produces, for there is evidence that in anaesthesia the effect of a given dose of adrenin is less than in a normal animal. Whether this observation can be applied to man is not known.

PROPOSED ALL INDIA RESEARCH INSTITUTE.

PROFESSOR E. H. STARLING, F.R.S., has sailed for India to advise as to the locality and equipment of an All India Research Institute. The Government of India already maintains several research institutes, but the Director-General stated a year ago that it was a matter of urgency to establish an additional research institute in a central position, where opportunities for clinical investigations would be available. Delhi, the new capital of India, was suggested as a site for a new institute to serve as the head quarters of the research organization, but other places have been mentioned. It may be added that the Indian Medical Research Fund Association, which has an income of five lakhs (approximately £35,000) a year, will continue to organize research in India by engaging, financing, and equipping men for special research work. The bacteriological department, a central organization under the Government of India in the Department of Education, has a staff of thirty officers employed to staff the research institute at Kasauli, the Pasteur Institute of India, the provincial laboratories, the provincial Pasteur institutes, and for pure research work. The Imperial Research Institute, which it is now proposed to establish, will be directly under the Central Government, but it is hoped that provincial governments will develop existing facilities for research by establishing additional research institutes of their own. Professor Starling, we understand, expects to be absent from this country for about three months. It was understood some time ago that Sir D. J. Tata, senior partner of Tata, Sons, and Co., of Bombay, contemplated the foundation and endowment of a large independent research institute in medicine as a complement to the chemical and physical research institute at Bangalore. Nothing has been heard recently of this proposal.

THE NOTIFICATION FEE AND THE END OF THE WAR.

WE announced at the time that the Ministry of Health, in a circular dated December 20th last, stated that the medical practitioner's fee for notification of a case of infectious disease would revert to 2s. 6d. on the date of the termination of the war as fixed by Order in Council. There is as yet no indication when that Order in Council is likely to be issued. As long ago as last July the War Office assumed that the official date of the termination of "the present emergency" would be August 4th, 1919. It may be a convenience to the bureaucracy, but we cannot see that it is in the public interest to delay fixing the official date of the end of the war until the formalities of peace have been ratified with countries which ceased to be in arms against us sixteen months ago. It is to be hoped that this matter will soon be raised in Parliament. It is possible that the real motive, whatever it be, for postponing the issue of the Order in Council will, even so, not be brought to light; but if the House of Commons presses for an explanation the bureaucrats may find it convenient to stop further inquiry by getting the Order issued before the last solemnity is concluded with Turkey or Bulgaria, or whichever of the warring nations happens in theory to be still at war with us. Unless awkward questions are put in public, the continuance of frontier skirmishes with some hill tribe in North-West India will, perhaps, seem to the official mind a good enough pretext for holding civilian doctors in the army abroad, and for paying a shilling for notification of infectious diseases at home.

THE REGIUS CHAIR OF MEDICINE AT OXFORD.

THE King, on the recommendation of the Prime Minister, has approved the appointment of Sir Archibald E. Garrod, K.C.M.G., M.D., F.R.S., to be Regius Professor of Medicine in the University of Oxford, in the room of the late Sir William Osler. We congratulate Oxford on securing for its chair of medicine so distinguished a scientific physician, and a teacher held in such affection by his pupils. Sir Archibald Garrod is physician to St. Bartholomew's Hospital, and consulting physician to the Hospital for Sick Children, Great Ormond Street. He served during the war as consulting physician to the Mediterranean Forces with the rank of Temporary Colonel, A.M.S., and after his return was appointed Director of the newly formed medical "element" in the clinical teaching unit at St. Bartholomew's. He was Bradshaw lecturer in 1900 and Croonian lecturer in 1908 at the Royal College of Physicians of London, and was elected a Fellow of the Royal Society ten years ago, largely in recognition of his work in chemical pathology. In 1914 he gave the address in medicine at the Annual Meeting of the British Medical Association at Aberdeen, and received the LL.D. of that University *honoris causa*. His war services were rewarded with the C.M.G., and later the knighthood of the same Order; and the University of Malta conferred on him the honorary M.D. degree. All who have been associated with him at home and in the army will welcome Sir Archibald Garrod's appointment to be the head of the medical school in his own great University, and will wish him success and happiness in a post so well suited to his character and attainments.

WE understand that Captain W. E. Elliot, M.C., has succeeded Dr. A. C. Farquharson as Secretary of the Committee of Medical Members of the House of Commons. We understand also that Lord Dawson of Penn has consented to co-operate with the committee.

THE lectures and practical instruction for a diploma in psychological medicine at the Mandsley Hospital, Denmark Hill, S.E.5, having now been arranged, Sir Frederick Mott will be glad to meet medical officers of asylums and practitioners desirous of attending the course on Wednesday, March 10th, at 2 p.m., at the hospital, in order to arrange the days and hours to suit the convenience of the greatest number.

AMONG those recommended by the Council of the Royal Society for election as Fellows are Dr. E. P. Cathcart, professor of chemical physiology in the University of Glasgow, and Dr. J. J. W. Stephens, professor of tropical medicine in the University of Liverpool. The other new Fellows include Dr. F. H. A. Marshall, lecturer in agricultural physiology, Cambridge, Mr. A. W. Hill, assistant director, Kew Gardens, and Dr. Robert Robinson, professor of organic chemistry in the University of Liverpool.

THE appointment of the Right Hon. Sir Auckland Geddes, K.C.B., M.D., as His Majesty's ambassador extraordinary and plenipotentiary in Washington, is announced this week. The broad details of his career, both as teacher of anatomy before the war, and as administrator and statesman during the past five years, are well enough known to our readers. No member of the medical profession, so far as we are aware, has hitherto served as British Ambassador to a foreign country. In consequence of this appointment Sir Auckland Geddes has resigned the post of Principal of McGill University, accepted by him last year with the intention of returning to Montreal on his release from Cabinet office in London.

Medical Notes in Parliament.

National Insurance Amending Bill.—Dr. Addison, on March 1st, formally introduced the National Health Insurance Bill "to amend the Acts relating to National Health Insurance." It was backed by Mr. Munro (Secretary for Scotland) and by Mr. Macpherson (Chief Secretary for Ireland), and ordered to be printed. The main provisions were stated in the SUPPLEMENT of January 24th, page 20.

Insurance Administration.—In reply to Mr. Charles Edwards, Dr. Addison said, on February 24th, that in response to representations received from a large number of approved societies he hoped at a very early date to introduce a bill to revise the present scales of insurance benefits and contributions, and this would make it possible to increase the amount for administration.

Infectious Diseases at British Ports.—In reply to a question by Lieut.-Colonel Raw, Dr. Addison, on February 26th, said detailed consideration was being given to the danger of the introduction of infectious diseases through the ports of this country in view of the widespread prevalence of small-pox, typhus, and of other epidemic diseases abroad. Special arrangements have been made with the Foreign Office and the Colonial Office whereby periodical and continuous information was received and appropriate action taken. A weekly bulletin was forwarded from the Ministry to the medical officers of health of the Port Sanitary Authorities in this country, and special bulletins when occasion required. The powers at present possessed by Port Sanitary Authorities were inadequate. Regulations would shortly be issued with the object of obtaining a greater security against the introduction of infectious diseases in this country from abroad and of increasing the efficiency of Port Sanitary Administration, and arrangements had been made with the Treasury for the provision of special financial assistance.

The Welsh Board of Health.—Dr. Addison, on February 26th, informed Mr. A. T. Davies that the Welsh Board of Health did not include a woman representative. An increase in its membership was being considered, and the point referred to would be borne in mind.

The Training of the Blind.—Dr. Addison, in reply to Mr. R. Young, on February 25th, said it was not possible to give figures as to the expenditure of the Poor Law authorities on the training of the blind, as no separate record was kept by the authorities. On March 1st Mr. Lloyd George said that the Minister of Health was giving special consideration to the matter of the training of the blind, in consultation with the Advisory Committee on the Blind, and it was hoped that some satisfactory steps might be taken in the near future to deal practically with the matter.

Morphine, Morphine Salts, and Opium.—In a written reply to Mr. Gilbert, on February 24th, Mr. Eridgman stated that the quantity of morphine and morphine salts registered as exported from the United Kingdom in the year 1919 was 322,970 oz., of which 121,474 oz. went to the United States. The records show that no morphine and morphine salts were exported to Japan. No particulars were available with regard to consignments by post. The quantities of opium registered as imported in the United Kingdom during 1919 from British India, Persia, and Turkey respectively were as follows: British India, 466,475 lb.; Persia, 30,558 lb.; Turkey (European), 204,966 lb.; Turkey (Asiatic), 133,157 lb.

Naval Medical Service Promotions.—Sir Watson Cheyne asked the First Lord of the Admiralty, on February 25th, if he was aware that the proportion of surgeon captains to surgeon commanders was 1 to 19, of paymaster captains to paymaster commanders was 1 to 11, of engineer captains to engineer commanders 1 to 9½, and of executive captains to executive commanders 5 to 9; and whether he realized that this point was a serious matter for the Naval Medical Service and might markedly increase the difficulty of recruiting for that service; and whether any steps were being taken to remedy this disparity between the various branches of the service and at least to place the surgeon captains on the same basis as the paymaster and engineer captains. Dr. Macnamara gave a written reply as follows: "The proportions are approximately as stated, though the proportion of surgeon captains to surgeon commanders is more correctly 1 to 17.4. At the present time, however, there is a considerable surplus in the number of surgeon commanders and a shortage in the junior ranks, so that normally the proportion of surgeon commanders would be very much less. The question of the number of higher ranks in the Naval Medical Service has been under consideration, and it has been decided to increase the number of surgeon rear admirals to 6, and the number of surgeon captains to 16, excluding one officer specially promoted to that rank for service during the war. The numbers will be further considered as necessity arises, dependent in all cases on the requirements of the Naval Service. It may be pointed out that the conditions of service of medical officers in the Royal Navy have been very appreciably improved as a result of the recommendations of the Ferram-Halsey Committee, as not only have the rates of pay been increased but the period of service for promotion from

surgeon lieutenant to surgeon lieutenant commander has been reduced from eight years to six years and similarly that for promotion from surgeon lieutenant commander to surgeon commander, a reduction of four years in all. The earlier advancement to surgeon commander thus authorized has increased the apparent disparity of numbers of the higher ranks."

Naval Officers' Income Tax.—Mr. Long, replying to several questions on February 25th, said it was considered by the Government that there was no justification for treating naval officers in the matter of income tax differently from the rest of the community, and it was therefore decided that tax at the ordinary civilian rate should be charged as from the beginning of the ensuing financial year. The rates of pay approved were substantially those recommended by the Halsey Committee, and were deemed adequate, notwithstanding the Committee's report that any increase in the rate of income tax would necessitate increased scales of pay. Mr. Long demurred to Viscount Curzon's suggestion that owing to the present position of naval officers with regard to income and the withdrawal of children's allowances the increase of pay would all be absorbed.

Officers' Pensions on Continued Service.—Mr. Long, on a question by Rear Admiral Adair, on February 25th, said that a naval officer due to retire during the war, but who was kept on, could count such kept-on time for increase of pension, in accordance with pre-war regulations, if it were to his advantage. Alternatively, he might under the concession recently granted to these officers, as the result of a recommendation of the Officers' Pay Committee, receive a bonus of 25 per cent. on his full pay in lieu of counting such kept-on time for increase of pension. Officers retired before the war, on the other hand, were entitled only to receive the bonus of 25 per cent. on their full pay in lieu of counting their service for increase of retired pay. The 25 per cent. bonus was calculated on the full pay of an officer's rank on the retired list and not upon his pension. It was granted in lieu of counting service for increase of retired pay, and was not in the nature of compensation for disturbance.

Disability Partly Due to Military Service.—Sir L. Worthington-Evans, on February 26th, in reply to Captain Loseby, said that in the case of a man suffering from two disabilities, one of which was attributable to or aggravated by service and the other not so attributable or aggravated, pension was awarded in respect of that disability which was connected, either wholly or in part, with military service. In the case of a man who suffered from a disability prior to enlistment, and on or after discharge was found to be suffering from the same disability in an aggravated form, the increase in disablement was considered attributable to military service, and pension was assessed on the total extent of the disability.

Army Officers in India.—In answer to Lieut.-Colonel Brickley, on March 1st, Mr. Churchill said there were in India forty-one officers of the Royal Army Medical Corps whose tour of service had expired. Twenty-four regular officers were under orders for India, and would be employed for the relief of tour-expired officers and towards completing the permanent establishment of the Royal Army Medical Corps in India.

Territorial and Special Reserve Officers R.A.M.C. in Mesopotamia.—Sir Watson Cheyne asked, on March 2nd, whether the War Secretary was aware of the grave discontent among the Special Reserve and Territorial Force officers of the Royal Army Medical Corps in Mesopotamia, owing to the fact that they could not be relieved, some having spent two or even three hot seasons in Mesopotamia without leave, and especially in view of the prospect of having to spend another hot season, and whether steps would be taken to give relief to them. Mr. Churchill replied that some of these officers, in common with the regular Royal Army Medical Corps and the Indian Medical Service, had leave due to them. This was a matter for the local military authorities, but the granting of leave necessarily interfered with the release of officers eligible for demobilization. Regular officers of the Royal Army Medical Corps were being sent out as they became available to replace officers of the Special Reserve and Territorial Force where demobilization had been applied for.

Lunacy Statistics.—Major Baird (Under-Secretary to the Home Office) on March 1st informed Major Wedgwood that on January 1st, 1920, there were in public or private lunatic asylums in England and Wales 96,344 patients (42,294 males and 54,050 females). The total included 3,739 ex-service men classified as "service" patients, and a small number of ex-service men, whose classification as "service" patients the Ministry of Pensions had found themselves unable to sanction, or whose classification as such was pending. There were on the same date 270 persons (males 108, females 162) voluntary boarders in private asylums, but none temporarily detained. Dr. Addison, in reply to Mr. Hurd on March 1st, said there was no legal authority under which boards of guardians should be repaid at least one-half of the actual cost to them of every pauper lunatic maintained in a county asylum. Dr. Addison added, in reply to another question, that in view of contemplated Poor Law reform legislation could not now be undertaken.

The Administration of the King's Fund.—The Minister of Pensions, on February 26th, stated, in answer to Captain Cooté, that the total number of grants made from the King's Fund was 36,303 and the payments amounted to £1,137,459 0s. 3d.

The cost of administration did not fall on the fund, but was borne as part of the general administrative expenses of the Pensions Minister. It was estimated at about £35,000, exclusive of an additional administrative expenditure by Local Committees.

Treatment of Syphilis.—On February 24th Mr. Waterson asked a question with regard to the deaths recorded by Colonel L. W. Harrison in his paper on army medical experience of venereal disease during the war, contributed to the Special Clinical and Scientific Meeting of the British Medical Association in London last April, and published in the *Proceedings* of that meeting. (It appeared that there had been 36 deaths among 39,377 cases treated.) Dr. Addison said that a special committee had been appointed by the Medical Research Committee, and that part of its reference was to inquire into the toxic effects of arsenobenzol compounds. Mr. Waterson then made an inquiry with regard to the report of the German Commission, the substance of which we published some time ago. Dr. Addison said that he intended to procure the report, and would consider whether a translation should be made.

Hospitality for Austrian Destitute Orphans.—The Prime Minister, in answer to Mr. Ormsby-Gore on February 26th, stated that a scheme had been submitted by responsible persons to the Home Secretary for bringing a number of Austrian children to the United Kingdom, where they could be placed in suitable surroundings. Subject to the Ministry of Health being satisfied that the proper precautions would be taken to safeguard the health of the people in our own country, the scheme had been approved, and the details were now being worked out in consultation between the Home Office and the Ministry of Health. He understood that large numbers of Austrian children had been sent to other countries, but he had no information as to the arrangements made for their reception. Asked by Sir Clement Kinloch-Cooke if care would be taken to see that there was enough milk to go round, Mr. Lloyd George said that was a consideration that the Health Ministry would take into account.

Insanitary Conditions at Theatres.—In answer to Mr. Jesson, on February 26th, Dr. Addison said he had received communications from the Actors' Association complaining of insanitary conditions in some provincial theatres, and he had told them that if they failed to get such conditions remedied by the local authorities of the district, and would bring the case before him, he would consider whether he could take it up with the local authority.

The Taxation of Invalid Chairs (Motor Driven).—Mr. Maclean asked, on February 26th, whether the revenue authorities were levying a tax on all disabled persons who attached a motor to their invalid chair; and whether, in view of the number of disabled soldiers compelled to use this method of conveyance, the Chancellor of the Exchequer could see his way to exempt them from taxation. Mr. Chamberlain subsequently replied that mechanically-propelled invalid chairs, if used upon the public highway, were liable to motor car licence duty. The whole question of the taxation of mechanically-propelled vehicles was under the consideration of a departmental committee appointed by the Minister of Transport, and a particular point raised must await the report of the committee.

Drunkenness Statistics.—Mr. Shortt, on March 1st, gave the following figures for England and Wales:

	1913.	1914.	1919.
England	177,971	174,451	54,947
Wales	—	—	2,964

The figures for Greater London during the month of January for seven years were:

January, 1914	5,066	January, 1919	1,037
January, 1918	1,015	January, 1920	2,762

Small-pox in Germany.—At the instance of Mr. Lunn, Dr. Addison, on March 1st, gave the following information as to small-pox in Germany: There was an epidemic during 1917 comprising some 3,000 cases, the origin of which was traced to infection brought into Germany by Russian prisoners. During 1918 cases continued to occur, and numbered (so far as his information went) to about 300. In December of that year there was a recrudescence of the disease, and down to the end of 1919 about 4,344 cases had been reported. Of these some 800 occurred at Dresden and about 164 in Danzig. Amongst the other places at which small-pox was prevalent in 1919 were Oppeln (311 cases), Königsberg (83), Stettin (24), Breslau (58), Berlin (25), and Cassel (34), but the number of deaths had not been reported. In 1917 and 1918 there were many foreigners in Germany—prisoners, refugees, and others, including Russians, Poles, Austrians, Italians, Belgians, and French—and it was more than probable that many of these foreigners were unprotected by vaccination. Separate statistics as to Germans and foreigners attacked were not available.

THE book on *The Chamberlains and the Midwifery Forceps*, by the late Dr. Aveling, published in 1881, has become rare. Mr. Alban Doran has recently presented to the Library of the Royal College of Surgeons of England a copy in memory of the late Charles Louis Taylor, Assistant Editor of the BRITISH MEDICAL JOURNAL, from whom he had received it as a gift some years ago.

STATE GRANTS FOR SCIENTIFIC INVESTIGATION.

DEPUTATION TO THE LORD PRESIDENT.

A JOINT deputation from the British Medical Association and the British Science Guild waited upon the Right Hon. A. J. Balfour, Lord President of the Council, at the offices of the Privy Council on March 2nd, to place before him certain considerations with regard to State awards for scientific research. Sir WATSON CHEYNE, Bt., M.P., introduced the deputation, which included Sir Clifford Allbutt, K.C.B. (President of the British Medical Association), Sir Ronald Ross, K.C.B., Professor Benjamin Moore, F.R.S., Mr. E. B. Turner, F.R.C.S., Sir Richard Gregory, F.R.A.S., Dr. R. T. Leiper, Lieut.-Colonel W. A. J. O'Meara, M.Inst.C.E., Dr. D. Sommerville, and Dr. G. C. Anderson, Deputy Medical Secretary of the British Medical Association. The following members of Parliament were present: Sir Philip Magous, Dr. Nathan Raw, and Dr. W. E. Elliot. Mr. Balfour was accompanied by Sir George Newman, K.C.B., M.D.

Sir WATSON CHEYNE said that the object of the deputation was to bring forward the question of State awards for scientific work after such work had been done. Scientific workers were assisted by scholarships and so forth while doing their work, but after it was done there was at present no provision for them, although, excited by the interest of their investigation, they had often neglected to make any provision for themselves. Moreover, it was the tradition that a scientific man should immediately publish his discoveries, making no attempt to conceal any knowledge in order to secure personal advantage.

Sir CLIFFORD ALBUTT referred in particular to the conditions under which medical men worked. Those conditions were governed by the very high standard of ethics maintained in the profession. No medical man could have honour in the profession if he descended to any kind of direct or indirect advertisement. No medical man was permitted to take out a patent. The large hospitals no doubt gave a field to the clinical worker which might offer considerable indirect reward, but that did not apply to the research worker, who was rather hidden behind his work. He knew men of very high academic attainments working enthusiastically at research who were declining lucrative appointments in order that they might finish—which they never did, of course—their experimental investigations. It was from such disinterested research—not utilitarian nor aimed at sensational or immediate results—that the greatest benefits accrued to mankind. He himself was chairman for some years of the Scientific Relief Committee of the Royal Society. Mr. Balfour would perhaps be surprised if he were to tell him privately the names of the very distinguished scientists who, or whose representatives, came forward to ask for grants in order to tide over a time of great difficulty. It was desirable to attract a great many more potential workers. The field of comparative pathology, for example, lay untilled; at present it offered no reward, direct or indirect. It would be said that the Treasury must be careful about expenditure, but he feared that the expenditure under this head would not be very great. He was afraid that the highest kind of intellectual research was rather scarce, and consequently the demands for grants would not be so heavy as might be anticipated.

Sir RICHARD GREGORY said that in medicine the great experimental work was rarely done by the successful practitioner or consultant. It was carried out in the research laboratories by men who occupied posts carrying only moderate salaries. There was the further consideration that the highest type of worker—the genius—in medicine or any other department of science was precisely the man who was not amenable to control—the free worker who followed up a clue in some department of knowledge to the willing sacrifice of himself. There should be a fund of some kind for making suitable awards, to be considered as payment for results achieved, and not as grants for favours to come. The scientific worker (he added), unlike the worker in literature or art, could not dispose of his achievement to the public for profit.

MR. BALFOUR'S REPLY.

Mr. BALFOUR said that he had always been an advocate—even a vehement advocate—of two things which, until quite recent years, the British public had been very slow to realize: the one, that the material progress of mankind depended upon the applications of science, and the other, that there must be pure science before these could be applied. While that was still worth saying even now on the public platform, it was a commonplace to everybody sitting around that table. They were all agreed that the State—which, after all, represented the people of the country and could not be in advance of them by more than a certain amount at any given time—had been backward in the past in its support of science. The only difference among them, if there was any difference, was as to the way in which the stimulus could best be given to those brains in the country best qualified to further scientific research and the subsequent industrial research based upon it. The view of the deputation, as he understood, was that when a man whose opportunities and genius permitted him to work at research had turned out some brilliant discovery the State should give him a reward.

Everybody must feel that the straits to which many distinguished men of science were reduced after devoting their whole lives to research without any desire for pecuniary reward were rather pathetic, and in many cases discreditable. For his own part he thought it most desirable that some remedy should be found. But he wondered how many such people would get the reward under the scheme which in rough outline had been laid before him that day. He thought the truth was that in the case of the very great discoveries, while it was often possible to go back to the individual who started the train which led to the great result, he himself had not directly produced that result. Faraday did not discover the telephone or wireless telegraphy or a practical method of electric lighting; what Faraday did was to make all those things possible, to lay the scientific basis of them. It was not easy to see how the reward was always or even commonly to be got into the right pocket. The amazing progress which medical science had recently made in stamping out certain forms of zymotic disease was, indeed, a wonderful triumph; but it was very hard to pick out the individuals to whom that triumph was due. If he might put himself in the unfortunate position of a Prime Minister, the difficulty of saying that A. should have the money which was available, or that B. should have it, would be very great, even though he took the best advice obtainable. There would be certain dramatic cases in which the whole public would be behind the Prime Minister in apportioning a particular reward, and yet when the historian came to look back upon the long labours which had made the triumph possible, might not he have to say that the genius to whose intuition and inspiration the achievement was really due had died unrewarded? Did anybody think that Maxwell, for instance, would ever have come in for any share of this parliamentary grant, seeing that his discoveries were such as very few were capable of comprehending in the form in which he gave them to the world? Yet his discoveries lay at the root of much of the subsequent progress in physical science. Sir Clifford Allbutt had pointed out that this was not asking very much from the taxpayer, because the number of people who would actually get the reward was so small. But, looked at from the point of view of the encouragement of research, that meant that a young man, going into research, and surveying the possibilities of reward, would find he had the chance only of one in ten thousand. He might contribute himself as a collaborator to the great discovery for which somebody else, quite properly, got the chief credit. The collaborator, on this plan, got nothing, yet without the collaboration of people not in the first rank could progress be made? Germany had never excelled this country—he would like to use a stronger phrase, but he would be nationally modest—in the production of those geniuses who started original discovery; but it had surpassed this country in the organization of men not of the front rank whom it had brought together in co-operation towards a common end. He did not see how the investigations of a body of co-operative workers could be stimulated by rewarding a few isolated individuals. At any rate,

he saw difficulties. Was there not more to be said for some attempt to stimulate research by improving the position of the researchers while they were doing their work? He was told the other day that there were people carrying on research work at Cambridge for a smaller remuneration than the town council of Cambridge paid to its unskilled employees. This showed that there was still a great deal to be done in the way of aiding research while it was proceeding. He agreed entirely with Sir Richard Gregory that while the State might aid research it would only destroy research if it were resolved to control it. The best men would not be controlled. The State was incapable of forming a judgement on the merits of an abstruse physical or physiological inquiry. That must be left to the genius of the men themselves. But he hoped it did not follow that it was quite impossible to combine with that independence of the worker some better reward for the work he was doing. He was afraid, however, that if the Treasury were represented at that assembly, it would say it preferred the original scheme laid before him by Sir Watson Cheyne. The framing of any such ideal scheme would require a great deal of thought.

In conclusion, Mr. Balfour said that while he had spoken for himself alone, he was also there in some sense as representing the Prime Minister, and he would like to add that there was no man living who had shown a greater sympathy with scientific development than Mr. Lloyd George, who had been responsible for some of the greatest advances which had been made in the direction of State aid for scientific and medical research. When he reported to him what had passed that day, they might be sure the Prime Minister would give it the most sympathetic consideration. He was far from laying it down that the State should not on occasion imitate our forefathers in the case of Jenner and offer a pecuniary reward to some great man of science whose services had been exceptional and whose achievements were obviously his own. But he would not wish that to be a part of the regular system of dealing with discovery in this country. He hoped that what the Government had already done would be found to be far greater in its ultimate results than perhaps the public at large, or even men of science, as yet had realized. He feared that they had not been supported as they might have been by men of great wealth in this country. There had been admirable exceptions, but either we had fewer millionaires than the Americans or we were less lucky in them, for there was no doubt that private individuals across the Atlantic had contributed on a scale which did justice to their generosity and was likely to produce great results for the whole world. Probably it was out of the question to hope completely to emulate them, but he did not despair that among the wealthy men in this country some might be found, in addition to those who had already shown themselves generous benefactors, who would do much to aid and stimulate that research into the laws of nature and that application of those laws upon which our main hopes for the amelioration of the lot of the human race must depend.

Sir RONALD ROSS said, with regard to the difficulty of selecting men for these prizes, that the proposal of the deputation was that the £20,000 suggested should be divided into ten pensions of £1,000 each and twenty pensions of £500 each, or, of course, it could be further subdivided. The selection of participants was simply a matter of thorough examination of details. The Royal Society gave, not pensions but honours, and the most careful examination was made. The Nobel prizes also were given with very great care, a register being kept even more elaborate than that of the Royal Society. He suggested that a committee be appointed, preferably consisting of the medical members of the House of Commons, to draw up the best possible scheme for giving these prizes.

Mr. BALFOUR said that he took it that what was proposed was in the nature of an addition to the Civil List Fund. The deputation was asking the Government to take a course with regard to the medical profession; but it could not stop at the medical profession. The provision must cover all branches of scientific research. Sir RONALD ROSS agreed.

Sir WATSON CHEYNE having thanked Mr. Balfour, the deputation withdrew.

England and Wales.

DISTRICT NURSING IN LONDON.

THE annual meeting of the Central Council for District Nursing in London was held on February 26th, Sir William J. Collins presiding. The fifth annual report (summarized in our last issue) was adopted on the motion of Mr. E. B. Turner, chairman of the Executive Committee. In reply to a question by the Rev. G. Bell Doughty with regard to the sum of £10,000 entrusted to the Council by the British Red Cross Society, Mr. Turner said that the distribution was still under consideration. The decision would be announced at the earliest possible moment. Replying to a further question regarding the grant of £500 from the London Insurance Committee, Mr. Turner said that it was hoped it was only a beginning, and that approved societies also would help. The nurses controlled by the various associations affiliated with the Council nursed insured persons in the same way as others. As the funds at disposal increased it was hoped to add to the staff of nurses and to improve the general service. The meeting resolved to make arrangements with the District Nursing Association for securing home nursing services for insured persons in all parts of London, and to continue the negotiations with a view of obtaining contributions from approved societies for the nursing of their members. The meeting approved the decision of the Executive Committee informing district nursing associations that a condition of a grant would be that the minimum salary of a resident nurse should be not less than £50 clear, and of a non-resident nurse not less than £50, with a reasonable allowance for board and lodging. It was reported that an informal conference on maternity nursing had been held with the medical officers of health of the metropolitan boroughs. The matter was inextricably connected with the provision of midwives. The fact that medical practitioners were abandoning midwifery work except as consultants made the demand for nurses for cases attended by doctors smaller. A fully-trained nurse would not work under a midwife with six months' training, yet the midwife was frequently unable to nurse all her patients adequately. Dr. D. S. Roxburgh suggested that the attention of the Minister of Health should be drawn to the serious result of recent legislation in diminishing the attendance of medical practitioners in midwifery cases. The Chairman promised a further report on the matter, also on the adequacy and efficiency of the district nursing provision in London, and on the desirability of extending the work of the Central Council beyond the county area.

EARLY CARE OF MENTAL CASES IN SOUTH WALES.

The movement to establish a clinic in psychiatry in Cardiff is making progress. The Committee which has the matter in hand contains representatives of the Cardiff City Mental Hospital at Whitechurch and the University College of South Wales; it recently asked the Board of Management of King Edward VII Hospital (formerly known as the Cardiff Infirmary) to allow the out-patient department of the clinic to be instituted at the hospital as part of the present out-patient department. The Medical Board recommended that the request should be granted, and the Board of Management has now unanimously agreed. The effect of this will be that as soon as the necessary arrangements have been made, cases of mental disorder in their early phases will receive advice and treatment in the out-patient department of King Edward VII Hospital. When in due course an in-patient psychiatric clinic is established, it is intended that the out-patient department shall still remain at the hospital. Cardiff is the centre for a very large part of South Wales, including many of the mining districts, so that the advantage of this new out-patient clinic will be enjoyed by a large population. The progress of the movement will be watched with interest by all who know the importance of early treatment of mental disorder, and realize that the arrangements at present existing are inadequate. We have no doubt that the new out-patient clinic will eventually, and we hope before long, lead to the establishment of an indoor clinic.

MEDICAL PRACTITIONERS' FEES IN MIDWIVES' CASES.

The Midwives Acts Committee of the London County Council has reported its general agreement with the amended scale of fees to medical practitioners called in by midwives to assist in cases of emergency, as given in the circular letter which the chief medical officer of the Ministry of Health has addressed to the local supervising authorities under the Midwives Acts. The principal representations which the Ministry of Health has transmitted to these bodies for consideration are (1) that it is undesirable to distinguish between operative and other confinements; (2) that a special fee should be prescribed for certain operations usually performed after the birth of the child for which the fees for ordinary subsequent visits do not afford a sufficient remuneration; and (3) that in view of the rise in prices the fee for visits should be increased. The Midwives Acts Committee, however, does not agree with the proposal in the circular letter to fix the fee for all attendances at parturition at a flat rate of £2 2s. In some cases this would not be adequate; in others it would be comparatively high. The Committee proposed to ask the Ministry to allow the scale in this respect to remain as at present, but that local supervising authorities should have a discretionary power to pay a higher fee in operative or difficult cases.

Scotland.

THE EDINBURGH BRANCH.

THE winter clinical meeting of the Edinburgh and some other Scottish Branches of the British Medical Association was held in the Royal Infirmary in Edinburgh on February 27th, and proved a conspicuous success. The museum, in the pathological department, was visited by a great many members during the day. From 11 a.m. until 3.15 p.m. a number of excellent demonstrations, arranged by Dr. John Eason, were given in the wards and special departments by Mr. D. Lees, Dr. William Sym, Dr. Dawson Turner, Dr. Hope Fowler, Dr. A. McKendrick, Dr. Norman Walker, and Professor Meakins. At the clinical meeting in the afternoon the large surgical theatre was almost completely filled. Lieut. Colonel John Keay, President of the Branch, was in the chair, and a number of interesting cases were shown. At 5 o'clock Dr. Alexander Blackhall-Morison gave an address on "The passive mechanical factor in heart disease: its influence and management," which we hope to print in a subsequent issue. A cordial vote of thanks and appreciation of the lecture was passed, on the motion of Dr. James Ritchie, a former president of the Branch. In the evening a dinner was held in the Royal College of Physicians, with Colonel Keay in the chair. At this enjoyable function fifty-two were present, including eight guests, among them being Dr. Blackhall-Morison, the Scottish Medical Secretary (Dr. J. R. Drever), the Chairman of the Scottish Committee, and representatives from other Branches in Scotland. The toast of the Imperial Forces was proposed by Dr. Playfair, and responded to by Surgeon Lieutenant-Commander Wilkie, R.N.V.R., and Colonel Wade, A.M.S. The toast of the British Medical Association was proposed by Dr. George Mackay, President of the Royal College of Surgeons, Edinburgh, and acknowledged by Dr. Drever. The health of the guests was submitted by the President, and responded to by Dr. Blackhall-Morison and Dr. Matheson, President of the Royal Medical Society. The President's health was proposed by Dr. G. M. Robertson, professor of mental diseases in the University. Earlier in the proceedings Dr. A. H. F. Barbour, Vice-President of the Royal College of Physicians, in the unavoidable absence of the President, expressed the kindly welcome of the College to the Edinburgh Branch, and on the motion of Mr. F. M. Caird, emeritus professor of surgery, a former president of the Branch, a cordial vote of thanks was passed to the Royal College of Physicians for hospitably placing its hall at their disposal for the dinner. Many appreciative letters on the success of the whole day's programme have been received by Dr. John Stevens, honorary secretary of the Edinburgh Branch.

GRADUATE COURSES, EDINBURGH.

Short advanced courses for graduates will be held in connexion with the University and Royal Colleges in Edinburgh during the summer and autumn terms and the summer vacation if a sufficient number of graduates enter for the several courses. In certain instances a maximum limit will also be imposed. The courses will be conducted by teams of teachers and the following subjects will be included, namely: Clinical therapeutics, tuberculosis, diseases of the blood, diseases of the renal system, diseases of the alimentary system, diseases of the circulatory system, diseases of the ductless glands, abdominal surgery, genito-urinary surgery, surgery of children, clinical gynaecology and clinical obstetrics; diseases of the larynx, ear, and nose; ophthalmoscopy and errors of refraction, venereal diseases, advanced bacteriology, advanced medical anatomy, advanced surgical anatomy, child welfare. Arrangements will also be made, if necessary, for special instruction in antenatal maternity work, psychiatry, and dermatology. Full particulars may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Correspondence.

ADENOIDS, NASAL CATARRH, AND INFLUENZA.

SIR,—Recent discussion in your columns as to adenoids and nasal catarrh seems to have taken one of those humorous turns which occasionally brighten the austerity of science, for it has tended to resolve itself into the question of to blow or not to blow the nose, and if the answer be in the affirmative, whether or not the drill master be required. Some laryngologists remember the suggestion made years ago that adenoids could be cured by respiratory exercises. Of course most of us knew that this was impossible, but we realized that where the amount of lymphoid tissue was small training in nasal respiration might turn the balance in doubtful cases and make operation unnecessary. The immediate result of the suggestion was, however, that breathing exercises began to be taught and the teachers developed systems. Now it followed that the simple became complex, and all sorts of unnecessary movements were introduced, this being required on behalf of the systems. As a matter of fact, breathing exercises are quite simple, but as we do not desire to produce good tone in one set of muscles only, they should form part of a course of physical culture; the instructor should at the same time be directed to devote special attention to nasal respiration.

Untold harm may be done if, owing to recent publications as to the efficacy of any form of breathing exercise or medicinal treatment, well marked adenoids which cause symptoms are not removed. We all realize that those symptoms vary from time to time, and this may have misled the more sanguine believers in nasal drill and medicinal treatment.

The striking letter of Dr. Wilkinson in your issue of February 28th touches a question of great interest. We hear and have heard a great deal about vaccines both for colds and influenza, but it has always appeared to me that the proof of their efficacy leaves much to be desired. We all know what is meant by influenza from one point of view, but to prove that one patient has a feverish catarrh and that another has influenza seems wellnigh impossible. I have taken more than a purely academic interest in this matter, for, after some years of leading an open-air life, I went back to hospital work during the war. In one year I suffered from three attacks, each presenting the features of influenza. One of my medical friends suggested the use of a vaccine, but I argued that probably immunity might have ensued from these attacks. During the remainder of my period of work I was not again affected, but had I been inoculated my case might have been quoted in favour of this method of prophylactic treatment.

The question of the definite diagnosis of influenza seems to present great difficulties, and as our confrères are but human may there not be a tendency to catalogue indefinite acute cases as influenza in the same way as the word "gout" is by some employed to embrace many chronic

troubles? Years ago, when Pfeiffer's bacillus seemed to have an assured position as the etiological factor, I was confronted by this difficulty of diagnosis when I desired to make some observations on the effects of influenza.—I am, etc.,

Harrogate, March 1st.

P. MCBRIDE.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—Dr. Baskett and I are agreed that poverty due to low wages was the chief cause of tuberculosis. We also are both of opinion that free trade was a main cause in the diminution of poverty and cheapening of food which produced the remarkable reduction in the death-rate. But while Dr. Baskett fixes his attention on this one factor, I cannot forget the numerous other causes—more or less independent of wages—which produce consumption. Take infection. Sir A. Newsholme has shown the close connexion between isolation in Poor Law infirmaries and the diminution of this disease, and this was due to paternal legislation and not to *laissez faire*. Then there are alcoholism, housing, workshop conditions, smoke, etc., which cannot be remedied by increased wages alone; they can only be dealt with by paternal legislation.

But Dr. Baskett is far from being an anarchist as one might have feared from his choice of watchword. He approves of Truck Acts and other legislation which does not increase taxation. He also, I take it, approves of voluntary insurance by friendly societies. Granted that such societies can do for 1d. what the State charges 1½d. for, does not the 1d. diminish real wages, even if to a lesser extent, and is it no compensation to the masses that for the extra ½d. the improvident are compelled to be provident?

Surely Dr. Baskett does not wish to abolish municipal isolation hospitals, public health departments, notification of disease, municipal sewers, water supplies, etc. But there are other means of insurance against disease, equally costly, and they must lower real wages just as much as the Insurance Act. Granted the Act is very imperfect and wants amending; but once admit—and I am sure Dr. Baskett admits—the brotherhood of man and the co-operative motto, "Each for all and all for each," I utterly fail to see that an Insurance Act is necessarily wrong in principle.

And do not Trusts increase the cost of living? Would Dr. Baskett apply *laissez faire* to these?

I am, Sir, appalled by the complexity of the question which Dr. Baskett finds so simple—"Oh, what a dusty answer gets the soul when hot for certainties in this our life." Dr. Baskett has made out an ingenious case for his theory, but I submit that it is not as simple as he would have it. He is too hot for certainties.—I am, etc.,

Worthing, March 2nd.

SIDNEY DAVIES.

MALE STERILITY.

SIR,—In writing the brief article that appeared in your issue of January 3rd, under the heading of "Sterility in the Male," I little anticipated any danger of being drawn into the dust and turmoil of the battle at that time being waged in your correspondence columns over the subject of prophylaxis and venereal disease. But apparently the writers of the letter that appeared in your number of February 21st have discovered grave moral issues in my statement that prolonged and absolute continence has been said to produce a temporary azoospermia or oligospermia. Surely my critics have overlooked the word in italics, for I cannot believe that the fear of incurring a temporary azoospermia or oligospermia is likely to drive continent males from the paths of rectitude. However, lest such should happen, I would hasten to add that the evidence in favour of such a disability is very slender, for opportunities of proving or disproving the statement are naturally rare.

My article being on the subject of sterility in the male, and not on the relation of continence to health, I do not propose to be drawn into a discussion on the advantages and disadvantages of leading a virtuous life. Apologizing for trespassing on your valuable space, I am, etc.,

KENNETH WALKER, F.R.C.S.

Medical Officer in charge of V.D. Department,
St. Bartholomew's Hospital.

London, March 1st.

THE TERRITORIAL FORCE.

SIR.—I was pleased to see "T.F." in the *BRITISH MEDICAL JOURNAL*, February 28th, p. 309, speaking out. While working in the weary Macedonian wilderness it was always a consolation to be assured in the belated *BRITISH MEDICAL JOURNAL* that remuneration to T.F.'s would in the end be righted by an increased gratuity. Alas! for hopes. It was disgusting enough there to see temporary medical officers leaving again and again "on leave," while the T.F. stuck year after weary year; never mind if paid less than temporaries and conscripts for his patriotism. The former cannot be undone, the latter can. I think it is certainly up to the able-bodied British Medical Association to organize all war-serving T.F.'s to strike against any other service save "conscript" (other medicals joining issue), the minimum demands being that every T.F. officer should have back pay for every day of service to bring his pay equal to that of equal temporary rank. Calculation is easy enough—for example, every T.F. captain received 15s. 6d. a day and 3s. 6d. field allowance while at home some of the time and extra allowances while abroad. These are recorded. The difference to bring it up to an average of 24s. a day should be paid. There never was any lack of patriotism on the part of medical men and there is no need to fear any in the future, on equal footing of payment, in time of England's distress. Personally I intend to resign my commission as soon as may be and refuse to have anything whatever to do with any Territorial service until I am paid for past services. It will not avail much, however, unless all do so. After four and a quarter years' service the "extra gratuity" held out to me (as a hope) would, if matured, have been a merciful boon, and to many others, to retrieve scattered fortune. Personally it was tragic (after comparative pre-war affluence) to commence over again almost beggared. I have always received from the Editor of the *BRITISH MEDICAL JOURNAL* courteous replies and helpful suggestions on whatever matter I have asked his help, and am grateful to his institution. When demobilized in March, 1919, and only beloved ones a preventive to considered self-effacement, the Editor of the *BRITISH MEDICAL JOURNAL* suggested applying to war benevolent funds. I did so. I cannot reconcile his article, "Hard Hit," in the same issue as "T.F.'s" letter, with the verdict in my case that "no grant could be made." Damn all charities! Pay the T.F.'s what they have earned first! Meanwhile my own right arm and own "left" brain, with still an overdraft of £450, arc, I rejoice, slowly making good.—I am, etc.,

February 28th.

"HARD HIT."

SIR.—While sympathizing with the bitterness of "T.F." (February 28th, p. 309), I venture to demur to his "advice to any young doctor who thinks of taking a commission in the Territorial Force, that it will pay him better to wait until he is conscripted." Nobody is more alive than I am to the inequitable treatment meted out to the Territorial during the war; probably in hard cash it paid better to be a conscript. But the consciousness that he did freely his duty to his country should go far to compensate the Territorial; while the treatment meted out to him by a soulless Government department should make him determined that the duty shall be carried out in future under better conditions.

The small Territorial army contemplated by the Government will require only a very small minority of practitioners as medical officers. Consequently the Government will again be in the position in any future emergency, of being able—or compelled—to offer more favourable terms to civilians, unless a Conscription Act is introduced at the beginning of the emergency. But Conscription Acts appear to be so distasteful that few Governments are likely to take the risk of conscription until driven to do so. We shall be wise, therefore, if we take forthwith such measures as are possible to prevent a repetition of the inequitable conditions at the beginning of the war without discouraging the soul of patriotism by advising men to refrain from joining the Territorial Army. It is probable that the Territorial section now added to the War Office will have some effect in this direction. But I have always maintained that representation of particular interests in a Government Department is not in itself sufficient. I believe it to be essential that outside the Department there should be a strong voluntary body which

shall weigh the views of the various parties concerned; shall watch the proceedings of the Department; shall give friendly advice when necessary; but shall be prepared to act firmly and forcibly when need arises.

Such a body should be found in the Naval and Military Committee of the British Medical Association, which has already taken up questions connected with the reconstruction of the Territorial Army, and contains men capable of speaking on the views of the regular, the territorial, and of the civil profession. With such a body in existence it appears to me that we may advise all young doctors whose position allows it, and for whom room can be found, to join the new Territorial Army.—I am, etc.,

London, W., March 1st.

CHAS. BUTTAR.

PROPOSED MEMORIAL TO SIR VICTOR
HORSLEY.

SIR.—As an old colleague and friend of Sir Victor Horsley, the most scientific surgeon of our day, I heartily support the proposal of Mr. Downie.

A combination, and a form indeed,

To give the world assurance of a man.

He was a man; take him for all in all

I shall not look upon his like again.

—I am, etc.,

London, W., Feb. 25th.

W. CAMAC WILKINSON.

Obituary.

D. J. WILLIAMS, F.R.C.S.,

Llanelly.

WE announce with deep regret, a regret which will be felt throughout the profession in South Wales, the death on February 27th of Dr. D. J. Williams of Llanelly. He was a man of marked character and unusual ability, who, almost in spite of himself, won the respect and affection of a large circle of friends within and without the profession. A strong Welsh patriot, he did not display all the characteristics of his race. Retentive by temperament, he took little part in public life, but his high standard of professional conduct and attainment was evident, though seldom specifically expressed. When he was President of the South Wales and Monmouthshire Branch of the British Medical Association in 1909 he gave an address, the purpose of which was allegorically shown in the title, "Hercules and the Wagoner." In it he gave utterance to the conviction of his life that the profession of medicine was something greater than the passing show of politics and must work out its own salvation through the increase of its efficiency in the prevention and cure of disease. In this way only, he believed, could it surely reach and keep the position of influence in the community which in the best interests of all it should hold.

His life had few incidents. He was born sixty-eight years ago, received his early education at Llandovery College, and later entered University College, London, where he early showed a disposition to devote himself to science; he was a good histologist and held the post of demonstrator of physiology. Shortly after taking the diploma of M.R.C.S. in 1877 circumstances rendered it necessary for him to go immediately into practice, and he settled at Llanelly, where he already had some friends. There he remained for the rest of his life, going through, at first, all the hard work of a young medical man in a growing industrial town. Success encouraged him to take the diploma of F.R.C.S. in 1894, and afterwards he did much surgical work at the Llanelly Hospital. During his time Llanelly became a chief centre of the tin plate trade, and works and factories rapidly multiplied. It speaks well for his surgical acumen and the independence of his mind that he was among the first to appreciate the genius and apply the methods of Hugh Owen Thomas, the founder of the Liverpool School of Orthopaedics. In his later years failing health limited his activities and he gradually curtailed his practice, but his opinion continued to be sought far and wide throughout the area of which Llanelly is the centre.

He was a loyal member of the British Medical Association, and represented Wales on the Central Council for several years at the time when the Insurance Act caused

so much anxious discussion. The whole conception of that measure was distasteful to him, running counter as it did to his belief that the profession must remain master in its own house if it was to do its duty to the people. He never wavered in that belief and never worked under the Act.

His boyhood was spent in a remote Welsh valley with a trout stream at the bottom of the garth. His fishing hand never lost its cunning, and down to a few years ago he could charm trout to his fly on a day when others, accounted good fishermen, would go home with empty creels. His other recreation was literature; he was well read in Welsh, and his capacious memory held vast stores of the best of the English poets.

He was married but leaves no children. To his wife, the constant comrade of many years, the sympathy of many friends goes out.

DR. ROBERT J. BANNING, of Shoeburyness, who died on February 10th, was born in Liverpool in 1833. He received his medical education at the Liverpool Royal Infirmary, where he was a medallist and scholar, and at the Middlesex Hospital, taking the diploma of L.S.A. in 1854. He was a civil surgeon during the Crimean war, 1854-55, acted as surgeon on the Crimean transports, and saw fighting at Sebastopol. In 1857 he graduated M.D. St. Andrews, and in the following year took the diplomas of M.R.C.S., L.R.C.P. He began private practice at Gateshead in 1858, and subsequently removed to Shoeburyness, where he took great interest in local affairs, and held the post of medical referee under the Workmen's Compensation Act till May last. He was president of the West London Medico-Chirurgical Society in 1894-5.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Compulsory Greek.

THE statute modifying the regulations with regard to the Responsions Examination in respect of Greek was passed in Convocation on March 2nd by 434 votes to 359. The effect is that Greek is no longer a compulsory subject, except for candidates for classical and theological honours.

Medical News.

THE next Oxford Ophthalmological Congress will be held on July 15th and 16th. On the first day a discussion on perimetric methods will be opened by Dr. Luther C. Peter of Philadelphia. The Doyne lecture on "The nerve paths and centres concerned with sight" will be given on July 16th by Mr. F. Richardson Cross. Further particulars can be obtained from the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton.

A REPORT made by the honorary secretaries to the first general meeting of the Fellowship of Medicine and Post-Graduate Medical Association shows that altogether 663 graduates took advantage of the emergency courses instituted by the Fellowship of Medicine at the beginning of 1919, and continued to the present time. Of those attending 221 belonged to the United Kingdom, 215 to the Dominions, 30 to India, 179 to the United States, and 18 to the various European countries, Japan, and South America. The hope is entertained that one of the existing medical schools in London may become a graduate medical school, but it would be premature to make any announcement on this subject.

THE first number of the *British Journal of Experimental Pathology* has been issued. It is a quarto of seventy pages. The first paper is contributed from the Institute of Physiology, University College, London, by Professor W. M. Bayliss, who gives a negative answer to the question, Is haemolyzed blood toxic? His experiments lead him to the conclusion that the serious results of the transfusion of incompatible blood are not to be ascribed to the haemolysis as such, but are rather an aspect of the action of foreign serum-protein analogous to that responsible for anaphylactic shock. Other papers are contributed by Dr. James McIntosh and W. A. M. Smart on the determination of the reaction of bacteriological culture media, by Dr. H. MacLean and O. L. V. de Wesselow on the testing of renal efficiency, and by Dr. Crauer on hyperpyrexial heatstroke, to which we refer elsewhere more at length. In an appendix are some notes on laboratory methods.

THE annual meeting of the North-East Essex Division of the British Medical Association will be held at the Red Lion Hotel, Colchester, on Thursday next at 2.30 p.m.

AT the meeting of the Hunterian Society in the School of Oriental Languages, Finsbury Circus, E.C., on Wednesday next, at 9 p.m., papers will be read by Dr. Howard Humphris on "Modern physiotherapy," and by Mr. J. E. H. Roberts on "The treatment of septic fingers."

THE proposal to admit women to be Fellows of the Royal College of Surgeons of Edinburgh after examination, on the same conditions and with the same privileges as men, has been accepted.

AT the court of governors of the London Hospital on March 3rd it was decided to ask in-patients to pay 10s. a week towards the cost of their food; the alternative was said to be closure of one-half of the wards. The chairman, Lord Knutsford, urged that the proceeds of the Amusements Tax should be allotted to the hospitals.

VISCOUNT SANDHURST has accepted the presidency of the annual congress of the Royal Institute of Public Health to be held in the University of Brussels from May 19th to May 24th. The scientific work of the congress will be conducted in seven sections. The Harben lectures of the Institute will be delivered during the congress by Professor Maurice Nicolle of Paris.

SIR WILLIAM HALE-WHITE will open a discussion on idiosyncrasy to drugs at the meeting of the West London Medico-Chirurgical Society to be held at the West London Hospital, Hammersmith, this day (Friday, March 5th) at 8.30 p.m.

THE Home Secretary has appointed Dr. William C. Sullivan, medical superintendent of the State Criminal Lunatic Asylum, Rampton, to the post of medical superintendent of Broadmoor Asylum, vacant by the retirement of Sir John Baker, M.D. Dr. Sullivan was scientific adviser to the Central Control Board (Liquor Traffic) throughout the period of its existence. He has been associated with the prison medical service for many years, and is known for his authoritative writings on alcoholism.

THE Mayor of Kensington, Dr. A. J. Rice-Oxley, C.B.E., and Mrs. Rice-Oxley, held a very successful mayoral reception recently in the Kensington Town Hall. The function was attended by Princess Louise Duchess of Argyll, and Princess Beatrice, and a large number of his colleagues were present to support the first medical mayor of the royal borough.

AT a conference of medical superintendents of sanatoriums, training colonies, and hospitals for tuberculosis held in London on February 23rd it was decided to form a new society which should have as its aim the advancement of the standards and the improvement of the methods of administration, diagnosis, and treatment of tuberculosis in residential institutions. Membership was limited to medical men and women the chief part of whose duties lies in the medical charge of residential institutions mainly devoted to the treatment of tuberculosis. "Associate members" may be elected from among those who formerly held such posts, and from present junior officers of such institutions. The annual subscription was fixed at 10s. 6d. for members and 5s. for associate members. It is intended to hold quarterly meetings, and to circulate full reports of the conclusions and recommendations of the society and its committees. Dr. Jane Walker was elected president and Dr. James Watt secretary and treasurer.

THE full programme of the meeting of the International Society of Surgery, to be held in Paris on July 19th-23rd, has been issued. In the discussion on the surgery of the heart and great vessels M. Tuffier (Paris) will deal with the heart, M. Sencert (Strasbourg) with the great vessels, and M. Jembraux (Montpellier) with the transfusion of blood. The discussion on treatment of tumours by x rays and radium will be opened by M. Régaud of Paris, and Dr. N. S. Finzi of London. The discussion on analysis of the blood and biological reactions in surgical affections will be opened by Drs. A. Depage and Govaerts of Brussels. In opening the discussion on fractures of the thigh Major Maurice Sinclair, C.M.G., D.S.O., R.A.M.C., will be associated with M. Patel of Lyons, and in that on the prophylaxis and treatment of tetanus Colonel Cummins, C.B., C.M.G., A.M.S., will be associated with M. Donati of Modena. Professor W. W. Keen of Philadelphia will preside over the meeting, and the names of American contributors to the discussions will be announced later. Particulars are also published of the visit to the battlefields after the congress; it will be made partly by train, partly by motor car. The first place visited will be Rheims, and the party will separate at Ostend seven days later.

A DEATH from lethargic encephalitis is reported from Donington, Lincolnshire. The patient was a young man who had been ill for ten days.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE "BRITISH MEDICAL JOURNAL."

The charges for advertisements in the BRITISH MEDICAL JOURNAL will be increased at the end of March. The new charges will apply to all advertisements for insertion in the JOURNAL of April 3rd and subsequently. The rates will be as follows:

Six lines and under	7s. 6d.
Each additional line	1s. 3d.
Whole single column	£6 0s. 0d.
Whole page	£16 0s. 0d.

An average line contains six words.

From the issue of April 3rd the charge for announcements of births, marriages, and deaths will at the same time be increased to 7s. 6d.

QUERIES AND ANSWERS.

ERYSIPELAS.

"D. O. W." writes: I have read most of the treatments suggested for this ailment in the "Notes," but I have found that the administration of liq. ferri perchlor. nxx or mxxv thrice a day, or added to other appropriate ingredients in the mixture at the time and not already made in a stock mixture, always acts almost as a specific. Collodion applied locally, especially in facial erysipelas, helps. Even with temperatures of 103° and 104° I have never seen a fatal case.

LETTERS, NOTES, ETC.

THE TAGLIACOTIAN DOCTRINE.

COLONEL J. SMYTH, I.M.S. (Clifton, Bristol), writes: If Lient-Colonel Mills, R.A.M.C., will read the Puranas, especially the Brahmaravarta and Matsya varaha, he will not only find the correct version of the account he gives of the manner in which Ganesha got an elephant's head, but several other different versions as well. One statement common to them all is that an elephant's head was substituted on Ganesha for his own head after it had been either burnt or cut off, and he remained quite happy ever after; these are the only points of any interest to us. The version of the story quoted by me I received from Mr. M. K. Lakshmana Chariar, a well known Brahman gentleman of Madras, and is doubtless as true as any of the others. According to the Puranas, the head is variously described as "clapped on" and "fixed" on.

WAR HONOURS.

"MAJOR R.A.M.C.(T.)" writes: The exclusion from any recognition is not confined to Territorial medical officers who served in the general hospitals at home. Similar treatment has been meted out to medical officers who were compelled (through no fault of their own) to serve in the field units of the Home army.

SURGICAL WAR HONOURS.

M.R.C.S. AND SURGICAL SPECIALIST" writes: My letter, published in the BRITISH MEDICAL JOURNAL, February 14th, p. 238, has been misunderstood. Recognition by the Government can only be by appointment to the Order of the British Empire—a compliment many of us have no desire to receive. My suggestion was that the Royal College of Surgeons of England should make a careful survey of the surgical work done by its members "and confer the higher diploma or some written appreciation." I fear the conservatism of the Council will prevent them entertaining such a proposal. Many members or "Stuff Governors" have done the work of "Silk" or Fellows. The latter body might be strengthened by electing to the higher diploma men who have proved

themselves capable surgeons and good general practitioners. The man makes the value of the diploma; no diploma has ever created a capable man.

THE PRICE OF PETROL.

THE Board of Trade has issued the report of the subcommittee appointed to investigate costs, prices, and profits at all stages in respect of petrol, benzol, and other motor fuels. The report states that the present high prices for motor fuel are mainly due to the demand which is tending to outstrip the world's present supply, but that powerful financial interests are taking advantage of this tendency to raise prices. Practically all the sources of supply, transport, and distribution of petrol are under the influence of two groups—the Standard Oil and the Royal Dutch Shell—which control a large number of companies. Rather more than half the petrol imported in 1919 came from the United States. It is believed that the price, free on board, at New York should be about 6d. a gallon, and the price of 1s. 4.6d. a gallon actually charged is held to show a grossly excessive profit. It is suggested that the production, price, and distribution of motor fuel should engage the attention of the League of Nations or, that failing, be made the subject of international agreement between the Governments of the principal importing nations. The importation from Persia was rather less than a fifth of that from the United States, but the British Government has a controlling interest in the Anglo-Persian Company, and when contracts by which it is bound expire two years hence it will be in the power of the British Government to give substantial protection to users of petrol in this country. The transport rates are considered to be at the present time double, or more than double, what they ought to be. The committee also considers that the profits made by the retail distributor are excessive. It finally advises that the retail price of No. 1 petrol should be fixed for the present at 2s. 10½d., and of No. 3 petrol at 2s. 8½d. a gallon. The price of benzol is regulated by agreement among the producers through the National Benzol Association, and is based on the price of petrol, not on the cost of production. It is recommended that the price of petrol or any spirit containing an admixture of benzol or of toluol should be fixed at 2s. 8d. a gallon, and that the export of benzol or toluol should be prohibited. The committee, however, recognizes that all these recommendations are merely palliative, and that the real remedy is to develop the production of power alcohol in this country or within the empire. The committee urges that its recommendations should immediately be put into force, and we note that the Automobile Association and Motor Union is very actively engaged in obtaining signatures to its petition asking the Prime Minister that strong Government action be taken.

PREVENTION OF VENEREAL DISEASE.

DR. FREDERICK H. PICKIN (London, S.W.) writes: The preacher of morality is a necessity, and plays the most important part in the campaign against venereal disease. But he only plays a part; he cannot succeed unaided. Venereal diseases are "dirt diseases" consequent upon immorality, and to prevent them all that is necessary, next to godliness, is cleanliness. If every brother who has had the misfortune to be tempted and fall would immediately afterwards thoroughly and repeatedly wash with plenty of soap and water and then perform the act of micturition venereal disease would rapidly become a negligible factor in the life of the community. Further, if every frail brother, in addition to using soap and water freely, would visit within twenty-four hours a doctor who understands these things and submit to an efficient irrigation, there would soon be no venereal disease to prevent.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 44, 45, 46, 47, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 42, 43, and 44.

THE following appointments of certifying factory surgeons are vacant: Caldbeck (Cumberland), Hull (York, East Riding), Shaftesbury (Dorset).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

				£	s.	d.
Seven lines and under	0	6
Each additional line	0	0
Whole single column	4	0
Whole page	12	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posto restante* letters addressed either in initials or numbers.

An Address

ON

WAR LESSONS FOR RADIOLOGY.

DELIVERED BEFORE THE ELECTRO-THERAPEUTIC SECTION
OF THE ROYAL SOCIETY OF MEDICINE.

BY

C. THURSTAN HOLLAND,

HONORARY MEDICAL OFFICER, ELECTRICAL DEPARTMENT, ROYAL
INFIRMARY, LIVERPOOL, ETC.

WHEN war broke out so suddenly in 1914 no one recognized the strain it was going to impose on every branch of the service. The rapidity with which one event followed another upset all calculations, so that measures taken to deal with conditions as they arose rapidly became obsolete, and others had to be improvised to take their place. In July, 1914, the schedule of army *x*-ray apparatus was practically that which had been in use during the Boer war, and few or no army medical officers were expert in *x*-ray work. No extra pay was granted for such work, and there was no special organization in the medical branch of the War Office to deal with it.

While it has been easy to criticize War Office administration adversely, it should be remembered that there had been nothing in previous wars, nothing in the army work during peace, and nothing done by any radiologist in this country to suggest to the authorities that an elaborate department should exist. The radiologists themselves had not realized what would be the necessities of *x*-ray work in a great European war.

Criticism of the War Office, though it found expression early, was more justly directed to want of action at a later date. Long before 1917 it had become evident that *x* rays were a prop on which much of the successful war surgery was being built up. Surgeons, especially the younger ones, were everywhere realizing that efficient *x*-ray work was essential to them; and yet, down to this time, and indeed even later, nothing had been done officially to ensure that the *x*-ray work, equipment, and organization should be controlled by an expert board or committee, and that the whole control and management of this branch of medical work should be in expert hands. It is in this direction that the permanent medical staff of the War Office failed badly. I recognize of course that my friend Sir Archibald Reid (Captain Reid then) had been attached to the War Office in an advisory capacity as early as November, 1914, and that later on certain physicists were called in to help him, and a small committee was formed. I recognize also very fully the splendid work he did for so many years, and rejoice in the honours which have been conferred upon him; but this does not alter what I consider to be the fact, that the expert radiologists of this country, as far as giving advice and helping to organize and control *x*-ray work, were entirely ignored.

It is possible that the War Office chiefs were not alone to blame. At that time many of the older surgeons were almost the only members of the profession who were consulted as advisers. Many of us are well acquainted with the attitude of many eminent surgeons towards radiology—it exists, in London especially, even to-day—the attitude which may be summed up as follows: "All we want is a good radiograph; this can be taken by a layman quite as well as by a medical expert, even better perhaps; give us this and we can read the plates ourselves, make our own diagnoses, draw our own conclusions." The committee of eminent surgeons which met at the War Office never had associated with it even one expert radiologist, and Reid did not sit upon this committee. In other words, advice on *x*-ray matters was a question for surgeons, and for surgeons alone. It is an open secret that the consulting surgeons reported to the War Office that "all was well with the *x*-ray work throughout the Home Commands." I have no doubt whatever that if, at this time, the expert *x*-ray men working in army hospitals at home had been asked to report, certain grave defects in the *x*-ray work, then existing, would have been pointed out. Most certainly if I had been asked—to make it a personal matter—my own experiences of the early years would have given me ample grounds for proving that things were anything but satisfactory. I will give some examples.

During the first year of the war an Army Order came to the hospital to which I was attached instructing me to receive two young students of physics, to give them one week's *x*-ray training, and then to report upon them as to their suitability for *x*-ray work. I would emphasize the fact that they were physicists, and not medical students. They spent a week with us—wrecked several tubes, and incidentally the temper of the sister-in-charge. I then reported that I found them pleasant and intelligent students who had put in a week's work in the department. I did not commit myself further than this. Very shortly afterwards I received two letters of grateful thanks from two young gentlemen who had been appointed to take charge of two hospital *x*-ray departments at a salary of £250 per annum each.

A similar instance illustrating the official attitude towards *x*-ray work was that in which an elderly medical man came to me with a request for intensive instruction, as he had been ordered to take charge of the *x*-ray work on a very large hospital ship. For all practical purposes he knew nothing about *x*-ray work. There was no time to give him any instruction of value before his ship sailed; the day before it sailed the *x*-ray equipment arrived and was dumped on board. I saw this equipment at his urgent request; it was as beautiful as elaborately polished wood and metal work could make it; on the other hand, I do not know to this day what some of it was meant to be used for, and I am equally certain neither does the gentleman placed in charge. He had also been supplied with about £20 worth of 15×12 plates, and no dishes in which they could be developed.

Appointments of these kinds were common, and their direct results can be illustrated by the following:

1. I saw a man who had a large healed operation wound, 6 in. in length, to the left of his sternum and directly over his heart. He told me that he had been *x* rayed, and that a bullet had been seen and located, and the surgeon had attempted its removal. As a matter of fact the said bullet was exactly one inch deep in the muscles of the back.
2. I saw another man who had been trephined after an *x*-ray examination had shown a small foreign body inside the head. The man told me that he had had no symptoms whatever except a slight headache, and that at the time of the operation the original wound was quite healed. Now it seems to me fairly certain that no surgeon would have attempted such an operation if the *x*-ray report had been to the effect that the piece of metal, very small, was two inches deep in the frontal lobe, which was where it was.
3. An officer I once saw had a fairly large foreign body behind the upper part of the left lung; he had no symptoms calling for its removal; the wound was healed; we were not certain whether it was just inside or outside the pleura. Later on I saw this officer again, and this after an eminent surgeon, who had made his own screen examination, had decided upon the anterior route by means of a large incision in front just below the collar bone. I need hardly say that he did not find and remove the foreign body.

These are merely examples of what we were all of us more or less frequently seeing. They were inevitable under the circumstances, but they show quite clearly that all was not well with the *x*-ray work at the time when so favourable a report was furnished to head quarters. Later, in 1918, *x*-ray experts were appointed to the various commands as advisers to the D.D.M.S.'s, a sufficient acknowledgement of error, inasmuch as it showed that at this period the War Office had become alive to the fact that *x*-ray work should be organized and officered by experts, who should be responsible for the *x*-ray work to the heads of departments. I look upon this change of attitude, tardy though it was, as a very distinct recognition of the claims, which had all along been made, as to the status of radiology in the army.

This recognition was due to two causes—the sympathy extended towards *x*-ray work by Sir John Goodwin, and the support which the three surgical members of the advisory board (Sir Berkeley Moynihan, Sir Harold Stiles, and Sir Robert Jones) gave him in this matter. We radiologists owe a very great deal to these four men, more, perhaps, than many may be aware of.

These expert appointments the addition of several experts to the War Office X-Ray Committee; the grading of all R.A.M.C. officers as regards their *x*-ray knowledge and abilities—came too late, for it was well on in 1918 before any of them became effectual, and events moved so rapidly from this time onwards that no great amount of reconstruction or reorganization was possible; still the

recognition of important facts will undoubtedly have a distinct bearing on the future.

Some recollection of what happened to ourselves in the first few years owing to the attitude of the authorities are not devoid of interest. Most of us older radiologists were, when the war broke out, *à la suite* Territorial officers, others joined up in a similar capacity as it became evident that there was a great deal of *x*-ray work to be done. Many of us were too old to go abroad or had already been damaged by *x* rays to such an extent as to make this impossible.

I joined in 1908, when the Territorial hospital staffs were first appointed. I took the junior rank of captain, looking upon it as merely honorary, and on the distinct understanding that I should, if ever required, perform such duties in a military hospital as I performed in civilian hospitals. Mr. Macpherson, then Under Secretary of State for War, in November, 1917, in the House of Commons, to all intents and purposes admitted that this assurance had been given; qualifying it only by saying that the "clinical" duties should not necessarily be identical. He further stated that he was not aware of any case in which *à la suite* officers were compelled to perform duties other than clinical, and later on that he was not aware that any of these officers were called upon to inspect hospitals administratively.

As he seemed to be so ignorant of what we all knew was going on in every Territorial hospital in the country, I wrote him the following letter in December, 1917:

"Sir,

"I beg to inform you that officers of the *à la suite* staff have been ordered to perform duties other than either clinical or medical. Ever since the war began many officers on the staff of the 1st Western General Hospital have been ordered to do (1) orderly duty, (2) inspect auxiliary hospitals.

"Consulting hospital physicians, specialists, such as physicians attached to general hospitals in the capacity of throat specialists, skin specialists, anaesthetists, *x*-ray specialists, and even dentists, have been detailed for these duties. Most of these men may be described without prejudice as well known leaders of the profession in their various lines—most of them men of about 50 years of age. These men, for the most part, took their commissions with a view to being able to offer their country skilled professional services of the most valuable kind in the event of national emergency. They were willing and anxious to render these services. They accepted the junior rank of captain to enable them to perform these services.

"(1) Orderly duty consists in, amongst other things, re-classifying wounded and sick discharged from the attached hospitals and already classified by the medical officers attached to these hospitals. In admitting cases sent to the base hospital by other hospitals. In signing railway warrants and the letters of the O.C. and the registrar of the hospital. In doing odd duties of all kinds.

"(2) Inspecting auxiliary hospitals they are instructed to report on the keeping of books, the condition of ashpits, the condition of kitchens, and many things entirely apart from clinical work.

"I would most respectfully point out that these officers were, and are, entirely ignorant of, and quite incapable of reporting on and doing much of the work required, and that in these respects much of the work they have done is absurd. Additionally, the waste of time valuable to the army and to the general community is obvious"—and so on.

I suppose I was fortunate to get any reply at all, but the fact remains that I did get one—from "the great man's" secretary. It read as follows:

Dear Sir,

I am requested by Mr. Macpherson to acknowledge your letter of the 18th instant.

What has been the Effect of the War on the Production of X-ray Apparatus, on the Invention of New Instruments, etc.?

The only outstanding advance in apparatus has been the American production of the standard mobile transformer unit with its radiator type of Coolidge tube. This may be said to be the direct result of the war, and it marks a distinct advance in apparatus. An *x*-ray generating outfit of this kind, working from a petrol engine or a lighting circuit, constructed to work at practically a fixed milliamperage through the tube, almost fool proof—and this notwithstanding the recent lamentable accident to our French colleague—capable of doing all the work required at casualty clearing stations, advanced hospitals, and, indeed, most base hospitals, would have been invaluable had it been available at the

beginning of the war as a standard apparatus for general use. An outstanding fault of our equipment, and a fault it appeared to be impossible to remedy, was that no standardization seemed to be possible. At the beginning the shortage was such that it was necessary to take almost any apparatus which the instrument makers could supply. Many attempts were made later on to get some of the things standardized; but the difficulties in manufacturing and the difficulties of labour, which got worse and worse as more and more men were called up, made such ideals impossible. Though the outbreak of war found out the weak points in our home *x*-ray industry, on the whole our manufacturers met the situation splendidly; and as far as concerned coils, interrupters, couches of various kinds, and most, if not all, of the minor accessories, the supply was reasonable and the quality very good.

Under the direction of the War Office Committee the petrol engine sets, chiefly for use abroad and in places where an electric current supply was not available, reached a high level of excellence and efficiency. Later the mobile car units were turned out in good numbers, and were remarkably useful and efficient. Their design and equipment left little to be desired, and they accomplished a great deal of most useful work, especially at casualty clearing stations. Plates and printing paper suffered somewhat in the earlier years. In the later part of the war both were excellent. Tubes threatened at first to be a serious question. We all know to what an extent we had relied upon Germany for our tube supply. The difficulty, however, was overcome, and whilst importations from America helped to a considerable extent, our own manufacturers rose to the occasion. Taking into consideration the position of the home industry in 1914, the glass difficulty, and the almost entire absence of any skilled tube makers, the results obtained were tremendous, and great credit is due to all those who took this matter in hand.

It is for us all, I think, to see that we give all possible support to our own manufacturers in the future, and do not buy foreign-made tubes. At the same time my personal experience is that some makes of home-manufactured tubes have not been so good or reliable during the past six or eight months as they were during the later years of the war. The faults I have had to complain of are: (1) An undue tendency to puncture, (2) a liability of the cathodal terminal inside the tube to loosen, and in some cases to break off, and (3) the very serious fault of the regulating device being quite inefficient. A word of warning to the manufacturers may be uttered that such faults must be overcome if we users are not to be driven by bitter experience, at a cost to both our pockets and our tempers, to buy in other markets. I have said that the plates and printing paper rose to a high degree of excellence during the war, but here again, and especially during the past six or eight months, *x*-ray plates, in my opinion, have undergone a serious deterioration in quality. I have been finding it necessary to increase times of exposure very considerably, and even then have not been able to obtain the same quality of negative as I did before the war. It is not only slowness but loss of quality of which I personally complain. Complaints to the makers produced at first only lame excuses, but eventually some improvement was noticeable.

What has been the Effect of the War on X-ray Work and on X-ray Workers?

Those who were already experienced in *x*-ray work were not taught very much by the war; they gained great experience of the localization of foreign bodies and had many opportunities of perfecting the *x*-ray examination of bone injuries, but, without claiming to make a complete list, I may say that the following classes of cases seem to me to be those in which radiology proved of very great advantage, and in which the science and art of radiography was advanced:

1. In diaphragmatic hernia, a condition recognized occasionally before the war as within the scope of *x*-ray diagnosis, owing to the comparative frequency with which this condition has been seen following wounds of the diaphragm, our *x*-ray knowledge of the appearances, and of the methods of examination, and the diagnostic points has been advanced.

II. In "gas gangrene" an entirely new x ray advance was made. The possibilities of x ray diagnosis in this condition were first of all established by my friend, Dr. Morrison, when serving with the Liverpool Merchants' Hospital (1915). Later, radiology became of great importance in the diagnosis and prognosis of gas gangrene, as is well shown in a masterly paper by Miss Ivens (1916).

III. The opportunities of examining cases of tropical abscess of the liver by x rays have increased enormously, as men returning from the East who have had dysentery, and have apparently completely recovered, later on develop these abscesses, in which an x ray examination is often very definite.

IV. In therapeutic work the treatment of keloid condition by both radium and x rays has been much advanced, and the depilating power of x rays has proved of the utmost value after plastic operations on the face following war injuries. I would especially mention the work of our colleagues, Robert Knox, and Stevenson of Dublin.

I do not intend to say much about localization and the many and various instruments elaborated in its cause. Some little bits of apparatus were invented or designed with a view to facilitating either actual localization or the operations for the removal of foreign bodies; but when we come down to bedrock it is as well to pause and consider the position. In a paper by Dr. Remy of Paris in the *Archives of the Röntgen Ray* in August, 1900, and published still earlier in France, he showed the method of screen localization from below up by means of a tube shift—that is, the triangulation plan nearly all of us have used as the basis of our methods. Remy also used metal directors from above to indicate the paths of the x rays, and to point to the spot where the foreign body actually was—the forerunner of the Hirtz compass and all similar devices. Localization work during the war has been interesting; it has brought out much ingenuity, but I do not consider that it has brought about any real great advance in the science and art of radiography.

The Great Effects of the War on X-Ray Work.

The war brought radiology into very great prominence, and this notwithstanding the attitude of the authorities during the early years.

The enormous number of laymen and women who became interested in, and who took part in, the work of our war hospitals, both abroad and all over this country, altogether apart from the enormous number of wounded who were radiographed, means that the eyes of the general public have been very much opened to the importance of x ray work in medicine and surgery, and in the large home hospitals the cases were by no means limited to war injuries.

The effect of this will tell in many ways. It will mean a large increase in x ray work, as members of the lay public either themselves, or on account of the advice of friends, will increasingly insist upon having x ray examinations made.

The whole of the medical profession also has had the same thing impressed upon them. It is really only within the last twelve years or so that the x ray position as regards the kidneys, the stomach, and the thorax has gradually become firmly established. To the majority of the general practitioners scattered all over the country this work was not well known. All of them have now served in war hospitals at home or abroad, or have been intimately associated with the work in these hospitals, and they have been able to see and to realize the advantages to themselves and to their patients of an x ray examination conducted by an expert. Thus, again, the direct result of the war will mean a great increase in x ray work.

Surgeons and physicians, especially perhaps the former, have had it forcibly impressed upon them by what they have seen day after day—"the importance and scope of radiology." This again means increased work.

We may therefore in the future—indeed, I know from my own work, both hospital and private, that this is the case now—look forward to a greatly increased use of radiology for diagnostic purposes, and also to a demand that this work shall be of the very best quality.

There is, however, an important fact which should not be overlooked, whilst medical men generally who do not intend to practise radiology—have seen for themselves the value of x ray work, from two other classes of workers there is a possibility of harm resulting.

In the first place a very large number of lay assistants,

males and females, have learnt a smattering of x ray work; some of these have become really very efficient, but for the most part this is very far from having been the case. Many of them, however, efficient or otherwise, have a very exalted idea of their capabilities, and there is a danger that a certain number of these people may set up as unqualified practitioners to carry on the "art" of " x ray photography." It is for the medical profession generally to see that, if this happens, success shall not be the result.

In the second place—and, to my mind, this is even more serious—a large number of qualified medical men have learnt certain parts of x ray work very well. They have become very efficient at looking after coil outfits, in taking and interpreting radiographs of injuries to bones, in the localization of foreign bodies; but as to their general knowledge of radiography and its interpretation as regards the kidneys, the thorax, the abdomen and its contents, bone diseases and x ray treatment, their knowledge is so small that they may rightly be described as knowing nothing whatever.

It is also quite evident, from some of the communications recently published, that many of them know nothing of the past literature of the subject. Some of them have already, I believe, started work as x ray specialists; others are contemplating such a step. I would utter a word of warning and of advice. The University of Cambridge has published the syllabus of a comprehensive course in radiology and electro-therapeutics. At the end of six months' teaching an examination will be held and a diploma issued to those who are successful in passing it. My strong advice to all those who have learnt their x ray work during the war is to take up this course of instruction, and to obtain the diploma, before starting on their x ray careers. The six months sacrificed in learning will be as nothing; the advantages to themselves and to their future clients will be enormous. They will not then learn their x ray work at the expense of much anxiety to themselves and of much harm to their patients, whether hospital or private.

This Cambridge diploma has been instituted at a very opportune time, and it should assist materially to raise the status of x ray work and of x ray workers.

CONCLUSIONS.

Let me briefly sum up the chief points.

In the first place, the war has taught us the tremendous value of radiographic work in war—that war surgery depends very largely for its success on efficient x ray work which must be directly controlled by expert medical radiographers; that such work should be recognized by the army as expert work; that it has shown most conclusively that there is a necessity for a permanent staff at the War Office to organize (1) the teaching of x ray work to officers, (2) the teaching of trained nurses and orderlies who should be available as assistants, (3) the standardization of army x ray equipments; and with this goes the further point, that such equipment should be kept well abreast of the times.

In the second place it is our duty to see that in the future the teaching of radiology is put on a proper basis in all our medical schools; that not only should post-graduate work be firmly established, and that all who wish to practise as experts should of necessity be forced to undergo special training and take a special diploma, but that in addition a certain knowledge of x ray work should be part of the ordinary curriculum of medical students; that teaching should be organized in view of this, and that in the examinations qualifying for practice x ray work should not be ignored.

CHADWICK naval and military prizes, each of £100 and a gold medal, were presented by Sir William Collins, chairman of the Chadwick Trustees, on March 8th. The naval recipient was Surgeon Commander Edward L. Atkinson, who was a member of the Scott Antarctic Expedition. In 1914 he was one of an expedition sent by the Admiralty and Colonial Office to investigate diseases occurring in river gunboats in the tropics, and later introduced a system of electrolyzing sea water for use as a disinfectant. In 1915 he was appointed a health officer to the Royal Naval Division ashore. The army medal was presented to Brigadier-General W. W. O. Beveridge, C.B., who was assistant director for sanitation, and responsible adviser to the D.G.A.M.S., France, on all matters connected with sanitation and the prevention of disease. He is a permanent delegate for Great Britain to the Inter-Allied Sanitary Conference.

An Address ON SOME POINTS IN CONNEXION WITH RENAL DISEASE.

DELIVERED BEFORE THE LAMBETH DIVISION OF THE
BRITISH MEDICAL ASSOCIATION.

BY

CHARLES R. BOX, M.D. LOND., F.R.C.P., F.R.C.S.,
PHYSICIAN TO ST. THOMAS'S HOSPITAL AND TO THE LONDON
FLYER HOSPITAL

SOME of the recent investigations on nephritis are of practical importance, and I have been fortunate in having the opportunity of proving their value both in treatment and prognosis. The opportunity arose from the fact that Dr. Hugh MacLean and Dr. De Wesselow have been and are still engaged at St. Thomas's Hospital in an investigation on war nephritis. With the greatest readiness they have collaborated in the investigation of my ward cases and placed their knowledge at my disposal. Before going further I hasten to express my indebtedness to their published results and to them personally for many facts gleaned during conversations with them.

It is well known that the predominant symptoms of renal disease fall into two main groups—the oedematous and the cardio-vascular. In acute nephritis both sets of symptoms may be present, although not always in equal degree; in chronic nephritis the predominance of symptoms of one or other of these groups enables us to recognize two distinct types—the chronic parenchymatous or tubal and the chronic interstitial or granular form.

Nephritis of the chronic parenchymatous type is characterized by profuse albuminuria and diminution of the quantity of urine passed, coupled with obtrusive oedema and effusions into the serous sacs, but cardio-vascular changes are not at all a pronounced feature. The chronic interstitial form, on the other hand, is distinguished by scanty albumin, increased excretion of urine of low specific gravity, cardiac hypertrophy, and raised arterial tension. Oedema is not present in this type until the terminal stages, and then is not of the renal distribution, but of that variety which is attributed to cardiac failure.

Whether these two forms of chronic nephritis originate as such or develop from the continued selective action of an antecedent attack of acute inflammation we will not now linger to discuss. I propose rather to direct your attention to some interesting facts which have a bearing on the symptomatology and treatment of the two types. For many years we had to be content with the results of urinary analysis alone when investigating cases of renal disease. Estimation of the quantity of albumin, the detection of blood, measurement of the amount of water passed, determination of the specific gravity, and, it may be, an estimation of the urea and chlorides, were the points to which, in conjunction with a microscopical examination of the sediment, attention was chiefly directed, and there is no doubt that in this way most instructive information may be obtained.

But a much clearer insight into what is happening may be gained by a combination of urinary analysis with periodical examinations of the blood. Improved methods now enable the clinical pathologist to estimate with accuracy the urea content, the chloride content, and the amount of protein in a small sample of the blood, and so to throw a flood of light on some of the problems of renal disease. The methods are laboratory procedures, and it is not my province to describe them, but they have important clinical bearings and it is important that we should be acquainted with the main facts which have come to light, and see how they fit in with our clinical knowledge.

THE PERCENTAGE OF UREA IN THE URINE AND IN THE BLOOD IN NEPHRITIS.

In the early stage of acute nephritis all the functions of the kidney suffer, among them the power of excreting urea, so that there is generally a marked defect in the elimination of this body, together with a diminution of the amount of urine passed. In favourable cases this retention is transitory, and normal elimination is sooner or later re-established.

In chronic nephritis, however, observations on the urea excretion have led to discordant results. Attempts to correlate the urea excretion of chronic nephritic patients with their clinical condition met with no success. The reason of this failure gradually became obvious. The renal mechanism is such that under circumstances of stress the kidneys are capable, even though much damaged, of eliminating a quantity of urea which is approximately normal, but they do so—and this is the important point—by secreting an additional quantity of water. We must therefore, in attempting to gauge the renal efficiency, take into consideration both factors; in other words, the percentage of urea in the urine or the urea concentration is our criterion, and not merely the amount of urea excreted in the twenty-four hours.

The urine of a normal individual on ordinary diet contains about 2 per cent. of urea. For patients under observation in hospital an average of 1.6 per cent. is found to be nearer the mark if the kidneys are healthy. When the kidneys are damaged the concentration falls below this figure.

That the specific gravity of the urine is consistently low in cases of advanced granular kidney is a well recognized fact, and these are precisely the cases in which difficulty of urea excretion is particularly marked. It may be asked, therefore, Why not take the specific gravity of the urine as a criterion of renal efficiency in place of the more troublesome urea estimation? Although the determination of the specific gravity of one sample might not be reliable, the average over a week or longer might yield useful information. An objection to this method lies in the fact that the chlorides and sulphates form heavier solutions than does urea, so if these salts are deficient the specific gravity will fall, and also the specific gravity will be low if excessive fluid is being ingested and excreted, quite apart from urea defect. None the less there is a marked tendency for a low specific gravity to accompany low urea concentration, and it is difficult for an extremely granular kidney to secrete urine of a greater specific gravity than 1012 at the highest. I have several times found this test valuable in making the distinction between the granular kidney and the kidney of arterio-sclerotic heart failure.

The late Dr. Foxwell of Birmingham paid especial attention to the subject of urea excretion in conjunction with the amount of urine passed, and he concluded that an increase in quantity to 60 oz. per diem or more was indicative of renal fibrosis, just as was a specific gravity below 1012. Combining the specific gravity, the quantity of urine passed, and the percentage of urea, his analyses led him to the following formulæ:

	Specific Gravity.	Quantity.	Urea Percentage.	Total Urea.
		Ounces.		Grains.
Healthy male	1019	39	2.1	—
Healthy female	1019	28	1.8	—
Moderate work possible	1012	50	1.4	310
Occasional light work	1011	45	1.3	238
Confined to bed	1010	40	1.0	175

Although a patient suffering from chronic nephritis may, with the aid of polyuria, excrete as much urea in the twenty-four hours as does a patient with normal kidneys, examination of the blood brings to light a marked difference in the two cases. The normal individual on ordinary diet will have in his blood a urea content of 20 to 40 mg. per 100 c.c.m., whereas in that form of chronic renal disease which leads to the retention of non-protein nitrogenous bodies, of which urea is the chief and is taken as the index, the urea content of the blood may rise to 100 mg. per 100 c.c.m. or higher. A similar retention may occur in acute nephritis also, and in some cases of renal disease the percentage has been found to rise to 300 or even 600 mg. It appears that any rise above 300 mg. is of fatal prognostic import.

In all forms of acute nephritis urea retention is a very constant feature, but in chronic nephritis it is only characteristic of cirrhotic, granular, or fibrosed kidneys, as opposed to the chronic parenchymatous or chronic tubal variety of the disease.

On the facts which they have ascertained with regard to urea retention and urea excretion MacLean and De Wesselow have based a new and simple test which promises to be of much practical value in nephritis. Fifteen grams of urea are dissolved in 100 c.cm. of water. This draught, which may be flavoured with tincture of orange, is administered the first thing in the morning on an empty stomach, the urinary bladder at the same time being emptied. Two hours later the bladder is again emptied, and the concentration of urea in the specimen is determined. With normal kidneys the concentration will be from 2 to 3.5 per cent. With a concentration of 1.5 per cent. the kidney is only moderately efficient, whilst a concentration of 1 per cent. or less indicates that the kidneys are severely damaged. Low concentration is generally correlated with urea retention in the blood. There is one fallacy which must be guarded against—urea may cause considerable diuresis in some normal individuals. So, if the specimen obtained two hours after administration shows a low concentration, a further specimen should be obtained an hour later, by which time diuresis should have ceased. If the concentration is still low the kidney is not normal.

It may be mentioned that in cases in which urea retention occurs this substance is also found in excess in the cerebro-spinal fluid. The normal content of this fluid ganged by the hypobromite method is said to be 0.006 per cent., whilst in renal impermeability to urea it may rise to 0.1 per cent., and in some instances is as high as 0.6 per cent. In this fluid concentrations above 0.3 per cent. are said to indicate a fatal issue.

From what has been said it is evident that a knowledge of the amount of urea present in the blood, and incidentally also in the cerebro-spinal fluid, affords two important indications: In the first place, it tells us that a certain type of renal inadequacy is present, and in the second, it affords prognostic indications which, in a certain number of cases, cannot be arrived at by other means.

That urea itself produces toxic symptoms it is not possible to assert. The general opinion hitherto has been that urea itself is a comparatively harmless substance. We must not forget that urea retention goes hand in hand with the retention of other non-protein nitrogenous bodies such as uric acid, creatinin and prin bases; and we must also remember that those renal cases which have urea retention are sooner or later characterized by raised arterial pressure and cardiac hypertrophy. Some interesting considerations bearing on the absence of renal dropsy in cases of this type will be mentioned presently. That uraemic convulsions may occur when urea retention is present the following case well shows; but Dr. MacLean tells me that his investigations have led him to the conclusion that it is not possible to predict uraemic convulsions from the amount of urea found in the blood. Indeed, the chronic cases with the highest amount of urea retention are more likely to be characterized by uraemic twitching and coma than by explosive convulsion.

J. G., a delicate-looking lad of 12 years, was admitted under me in December, 1919, with oedema of face and ankles, and a history of two days' obvious haematuria. Five years ago he was laid up with pneumonia, and he went through a sharp attack of acute rheumatism twelve months before his present illness. A fortnight before admission he complained of sore throat, but had no pyrexia, rash, or other signs of scarlet fever.

On examination he was found to be pale, with moderate oedema of the face and ankles. There was evidence of a little fluid at the bases of the pleural sacs, and the heart was slightly enlarged. The blood pressure was 120 mm. The urine was diminished in quantity, an average of 30 oz. being passed in the twenty-four hours. Much albumin was present, also blood. The sediment contained epithelial, blood and hyaline casts in some quantity. The blood urea was 140 mg. per cubic centimetre, and the urine contained only the smallest trace of chloride, so both urea retention and chloride retention were marked. The temperature was slightly febrile; the tonsils were chronically enlarged.

Six days after admission he had, without warning, a series of severe convulsive fits followed by a state of semi-coma. Venesection to the amount of one pint followed by saline infusion of 30 oz. caused immediate improvement, and the fits did not recur. Profuse sweating was induced by hot packs, and nothing but milk and barley water allowed. Four days later the blood urea was found to have fallen to 54 mg. and the blood pressure to 112 mm. A week later still the blood urea was 35 mg. Coincident with this fall, and no doubt responsible for it, was an increasing polyuria rising to 70 or 80 oz. per diem. At the same time the albumin in the urine, which at first amounted to 7 grams per litre, had fallen to $\frac{1}{2}$ gram, the fall being gradual. He is still under observation.

SALT RETENTION AND ITS RESULTS.

It has long been known that retention of chlorides in the body can produce oedema of the tissues and serous effusions, water being retained to keep the salt concentration in the tissues down to the normal limit of 0.6 per cent. sodium chloride solution. In other words, for every 6 grams of salt retained, the body will store up 1,000 c.cm. of water. A very important function of the kidney is the regulation of the concentration of salt in the plasma. In certain forms of nephritis the kidney appears to lose the power of excreting chloride in the normal manner; these forms of nephritis are those which are associated with oedema; they may be acute or chronic in character, but their essential characteristic is that they are parenchymatous or tubal in type.

Blood examination does not throw much light on chloride retention, because diminished chloride excretion does not produce an increased concentration of the salt in the blood and tissues owing to the simultaneous and inseparable retention of water, which acts as a diluent.

It may be mentioned in passing that a primary retention of water would also lead to a compensatory retention of salt, and it is believed that under certain circumstances this may occur, although, generally speaking, it may be said that in oedema water is retained to dilute the salt and not salt to salinate the water.

A normal kidney excretes the day's intake of salt (15 to 20 grams) within the next twenty-four hours, and in the non-oedematous forms of renal disease—that is, the granular kidney—salt is excreted equally well, the capability of excreting salt being quite independent of the power of excreting many other substances, such as urea, uric acid, and potassium iodide. The power of excreting phosphates and sulphates is, unlike that of excreting chlorides, roughly parallel with the capability of excreting urea. Salt retention is a characteristic of the oedematous or tubal type of nephritis, just as urea retention is characteristic of the chronic interstitial or cirrhotic type.

The accurate determination of salt retention is not such a simple matter as the estimation of urea retention. The amount of salt which will be excreted after a weighed dose of sodium chloride depends a great deal on the amount of fluid present in the tissues of the body at the time of administration. If the body is low in fluids, the salt may actually be retained, the body fluids correspondingly augmented, and the weight raised. So, for the estimation of salt retention, an equilibrium must first be established between intake and output by careful dieting, and then large doses of salt must be repeated on successive days. If salt is retained, an increase in weight at once takes place, owing to the retention of fluid; but in a healthy individual this increase is limited to a few days; it then ceases, and there is excreted in the urine a quantity of salt equivalent to that taken by the mouth. On the other hand, if salt retention is present, dropsy should ensue, and perhaps also serous effusions. The test obviously is a difficult one to apply, so for ordinary purposes reliance is placed simply on the estimation of the chlorides in the urine.

The following case, although not one of nephritis, is a striking example of the results of flooding the tissues with an excess of salt:

On November 4th, 1916, a girl aged 2½ years was brought to St. Thomas's Hospital on account of oedema of the feet and face. Her only previous illnesses were whooping-cough and chicken-pox.

For three weeks she had shown slight nasal catarrh; recently her face had been swollen in the mornings, and latterly her feet had become swollen also.

Physical examination revealed nothing to account for the oedema. The urine was free from albumin, its specific gravity was 1020: it was concentrated and full of urates. No sugar. As the oedema persisted and the urine remained non-albuminous, she was admitted for further observation. But meantime an important fact had come to light—it had been ascertained that the child was inordinately fond of salt, and would, when opportunity offered, empty the salt cellar as if it were a sugar basin.

On admission the temperature was 100°, but fell to normal before night. Slight bronchitis with some respiratory acceleration was present. The urine was still concentrated, but free from albumin. The child was placed on milk diet.

In a day or two sharp crepitation made its appearance in the lungs and gradually extended in area and intensity. The temperature became febrile. There was still no albumin, and the quantity of urine averaged 6 or 7 oz. a day—that is, at least a third, or possibly a fourth, of what it should have been.

The pulse and respiration rates gradually increased, the

Only three tapings of the abdomen were necessary after commencing the diet, and the oedema of the legs, thighs, scrotum, and penis gradually subsided; the lumbar cushion also disappeared. A marked loss of weight, due no doubt to the elimination of fluid, was later succeeded by a steady gain as nutrition improved. Nothing could be more satisfactory than the way in which the fluid which waterlogged this patient was induced to disperse. His subsequent history is, however, well worth noting. It is over a twelvemonth since his last tapping. He continues his diet on much the same lines, remains free from ascites and oedema, has put on flesh and looks and feels much better, but his urine is still highly albuminous, and his blood pressure has gradually risen until the systolic pressure is 220 mm. of mercury.

There can be no doubt that the institution of a diet on Epstein's lines was completely successful in restoring this man to a condition of comfort when the ordinary means of treatment combined with salt deprivation had failed. Now, Epstein, as a result of his investigations on renal disease, came to the conclusion that the amount of protein in the blood was very seriously diminished in chronic parenchymatous nephritis, and that this diminution was the direct result of the loss of albumin in the urine. As the result of this there is a diminution in the osmotic pressure of the blood—that is, of the power of the blood to attract fluid from the tissues—a state of affairs which favours the imbibition and retention of fluid by the tissues themselves. Thus he accounts for the oedema and serous effusions met with in chronic parenchymatous nephritis, a form of renal disease in which it is well known that albuminuria is profuse.

Before specifying his diet another point has to be mentioned: Not only did he find blood protein deficient in these cases, but he also detected a remarkable increase in the lipid—that is to say, the cholesterol content of the blood, which he attributed to the mobilization of the fatty deposits in the body, and perhaps also to tissue degeneration. Epstein's diet, therefore, is rich in protein and poor in fat to meet these conditions.

EPSTEIN'S DIET.

The daily food value is from 1,280 to 2,500 calories.

Protein from 120 to 240 grams.

Fat (unavoidable) 20 to 40 grams.

Carbohydrates 150 to 300 grams.

The articles used are lean veal, lean ham, whites of eggs, oysters, gelatin, Lima beans, lentils, split peas, green peas, mushrooms, rice, oatmeal, bananas, skimmed milk, coffee, tea, and cocoa.

Of fluid, 1,200 to 1,500 c.cm. are allowed, and the amount of salt is in quantity sufficient to make the food palatable.

Fortunately, at the time when this patient was in St. Thomas's Hospital, Drs. MacLean and De Wesselow were already engaged in their investigation on war nephritis which is being carried on there, and I obtained their ready assistance for the investigation of my case.

Two striking facts emerged: first, during the period of diuresis the already low protein content of the blood plasma tended rather to diminish than to increase; secondly, the urea content of the blood became augmented. The actual figures were as follows:

Date.	Protein in Blood Plasma.	Urea in Blood.
	Per cent.	
October 15th, 1918	6.29	27 mg. per 100 c.cm.
November 20th, 1918	6.20	64 mg. per 100 c.cm.
December 3rd, 1918	6.00	56 mg. per 100 c.cm.
January 3rd, 1919	—	81 mg. per 100 c.cm.
January 22nd, 1919	5.95	63 mg. per 100 c.cm.

These results led Dr. MacLean to infer that, in this instance at all events, Epstein's explanation of the disappearance of the dropsical effusions could not apply, and that the diuresis and consequent disappearance of the effused fluid from the subcutaneous tissues and the serous sacs which resulted from the adoption of the rich protein diet was to be attributed, not to an increased richness of the blood in protein, but to an increase in its urea content, which rose from 27 mg. per 100 c.cm. at the beginning of the new diet to an average of about 60 mg. per 100 c.cm. Urea is known to be a powerful diuretic, and the administration of fairly large doses of urea to patients who suffer

from renal oedema has been found to set up a diuresis similar to that which occurred in the case just narrated.

Whether patients who are the subjects of oedematous renal disease can be injured by the adoption of the high protein diet is a question which calls for serious consideration. The institution of such a diet does not appear to increase in any appreciable degree the amount of albumin which is being lost by the kidneys, and which in itself must be a serious drain. but, as we have seen, it does undoubtedly increase the amount of urea, and presumably also the other non-protein nitrogenous bodies, in the blood. The administration of urea in large doses occasionally induces headache, but apparently, in healthy persons at all events, has no appreciable effect in raising the blood pressure. My patient, although free from oedema and serous effusions and making no complaint of headache or other discomfort, shows a gradually increasing blood pressure, which at the last observation has reached 220 mm. of mercury. It is tempting to associate this rise of pressure with the retention of the non-protein nitrogenous substances in the blood, and it is important to determine whether increased blood pressure is the usual sequel of a rich protein diet in such cases. There is some reason to suspect that it is.

At the same time it is well to bear in mind that patients with large white kidneys who survive the oedematous stage are described as passing into a condition comparable to that induced by contracted granular kidneys—that is to say, a condition in which increasing polyuria is associated with pronounced cardio-vascular changes. It might well be urged, therefore, that the present condition of my patient is but the natural result of the evolution of his disease. Whatever be the explanation, the fact remains that the adoption of the high protein diet enables these patients to survive the waterlogged stage and its associated dangers, a survival which experience has shown was rare before this type of diet was adopted.

As regards diet in acute nephritis we remain much where we were. A low protein supply is obviously indicated in the early stage of the disease owing to the presence of urea retention. Should dropsy be present, it is also advisable to restrict or eliminate salt, and not to allow excessive ingestion of fluids. The old warning against beef-tea and meat extracts is justified since they are rich in both salt and nitrogenous derivatives, whilst the idea that toxic products might be eliminated by considerably increasing the fluid intake is not supported by what we know about the mechanism of the oedema. Milk still remains our staple article of food at this stage, not because it is a non-nitrogenous diet, which it assuredly is not, but because it is easily assimilated, slightly diuretic, and by experience found to be least harmful. When the acute stage is passed, a rather more liberal protein diet appears to do no harm. The addition of some protein to the carbohydrates usually allowed at this stage does not appear to increase the albumin or produce other harmful effects.

As to chronic nephritis of the hydraemic type, Epstein's diet certainly affords slow and steady relief to the dropsical symptoms, but the ultimate outcome is still *sub judice*, whilst in that form of which the granular kidney is the type and urea retention the rule, the established treatment by reducing the protein and extractives is fully corroborated.

THE LIFE-HISTORY OF THE FIRST CASE OF MYXOEDEMA TREATED BY THYROID EXTRACT.

By GEORGE R. MURRAY, M.D., D.C.L., F.R.C.P.

PROFESSOR OF SYSTEMATIC MEDICINE IN THE VICTORIA UNIVERSITY, AND PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER; LATELY COLONEL A.M.S. AND CONSULTING PHYSICIAN IN ITALY.

THE development of the principles and practice of endocrinology during the last thirty years has been rapid and progressive. The practice of this branch of medicine has unfortunately not always been based on sound physiological principles, so that glandular extracts have been given indiscriminately in many conditions with disappointing results. In the case of some preparations there is little evidence that the hormones they are supposed to contain are able to exert their normal physiological action when given by the mouth. It therefore may be

of interest to complete the life-history of the first case of myxoedema successfully treated by thyroid extract—it has recently terminated at the age of 74—as the results obtained in this case not only afforded definite proof that the thyroid gland produced an internal secretion, but showed that the thyroidal insufficiency of myxoedema in man could be made good by maintaining an adequate supply of thyroidal hormones from an external source.

During the war we learned to appreciate more fully the value of the collective investigation of disease for which the aggregation of large numbers of men under military discipline and the co-operation of groups of medical officers provided the opportunity. A striking example of the results to be obtained by this method had, however, already been furnished by the publication, in 1883, of the report of the special committee which was appointed by the Clinical Society¹ in 1883 to investigate the relation of myxoedema and allied conditions to the thyroid gland. The history of the subsequent developments of the treatment of these maladies as a direct result of the work of this committee has just been so clearly given by Mr. Stephen Paget² that further reference to it is not necessary. It is, of course, well known that the experimental work of Sir Victor Horsley, which was undertaken at the request of this committee, first definitely proved that myxoedema, cretinism, and cachexia strumipriva were due to loss of function of the thyroid gland. Although at that time it had not been proved that this function was to provide an internal secretion, he suggested that grafting a portion of healthy thyroid gland would be a rational method of treating these maladies.³ The striking improvement which followed the adoption of this suggestion in Bettencourt and Serrano's⁴ case led me to suggest and carry out the treatment of myxoedema by thyroid extract in the case whose complete life-history I now wish to record as an example of the value of observation of individual cases over long periods of time in the elucidation of certain problems in medicine.

Mrs. S., aged 46, was shown at a meeting of the Northumberland and Durham Medical Society on February 12th, 1891.⁵ She had had a family of nine children, of whom six were living. At the age of 40 she had a miscarriage, after which she had menstruated once, at the age of 42. When she was 41 or 42 years of age her relations had noticed that she was becoming slow in speech and action, and she herself began to find that it required a great effort to carry on her ordinary housework. The features gradually became enlarged and thickened and the hands and feet increased in size and changed in shape, so that at the time of this meeting she presented the typical features of an advanced case of myxoedema of at least four years' duration. After showing the patient, I stated my intention of treating her with thyroid extract, and described the principles upon which this treatment was based and the reasons for expecting that it would be successful. The treatment was not commenced until two months later, and the following note taken on April 13th, 1891, describes her condition at that time:

She complains of languor, a disinclination to see strangers, and great sensitiveness to cold. The temperature is subnormal, and varies between 95.6° and 97.2° in the month. The pulse varies between 60 and 70. The face is blank and expressionless and the features are notably thickened. This change is well seen in the *alae nasi* and lips. The subcutaneous connective tissue of the eyelids is so swollen that she finds it difficult to look upwards. There is also considerable swelling beneath the eyes and of the cheeks. The hands and feet are both enlarged; the former have that peculiar shape which has been described as spate-like. The skin is very dry, there is no perspiration, and the superficial layers of the epidermis are continually being shed as a fine white powder. The hair is very fine in texture, and a considerable quantity of it has been lost. She is slow in answering questions; all her actions are slow and are performed with difficulty. The speech is remarkably slow and drawing and the memory is bad. No thyroid gland can be felt in the neck. The urine contains no albumin or sugar.

The experimental nature of the treatment was explained, and the patient, realizing the otherwise hopeless outlook, promptly consented to its trial. In order to ensure that the extract was properly prepared, the thyroid gland was removed from a freshly killed sheep with sterilized instruments and conveyed at once in a sterilized bottle to the laboratory where the glycerin extract was prepared, as elsewhere described.⁶ This extract was after-

wards included in the *British Pharmacopoeia* of 1898 as "liquor thyroidei".

At that time care in obtaining the actual thyroid gland was necessary, as was shown by the experience of the late Dr. Michell Clarke, who, in the course of a discussion on a paper read by me at the annual meeting of the British Medical Association at Nottingham in 1892,⁷ stated that he had carried out the treatment without any benefit in two cases. Several years later Dr. Clarke kindly told me he had subsequently discovered that his want of success was due to the fact that the butcher had been supplying thymus instead of thyroid gland for the preparation of the extract. Even in recent years some thyroid preparations have proved to be inactive. In the treatment of this first case a hypodermic injection of 25 minims of the extract was given twice a week at first, and later on at longer intervals. The patient steadily improved, and three months later, on July 13th, the condition was thus described:

The swelling has gradually diminished, and has practically disappeared from the backs of the hands, the skin over them being now loose and freely movable. The lips are much smaller. The swelling of the upper eyelids has diminished so much that she can look upwards quite easily. The swelling beneath the eyes and of the cheeks has also much diminished. The face consequently, as a whole, has greatly improved in appearance and has much more expression, as many of the natural wrinkles, especially about the forehead, have returned. The speech has become more rapid and fluent, the drawl being scarcely noticeable at the present time. She answers questions much more readily, the mind has become more active, and the memory has improved. She is more active in all her movements, and finds that it requires much less effort than formerly to do her housework. She now walks about the streets without any hesitation without a companion.

She has menstruated normally during the last six weeks at the regular interval. For the last four weeks the skin has been much less dry and she perspires when walking. The hair remains as before. She is no longer so sensitive to cold. Unfortunately owing to circumstances a daily record of the temperature has not been kept, but out of four observations that have been made lately, about 11 a.m., three times the temperature has been 98.2° F. and once 97.4°.

After this the injections were given at fortnightly intervals, and later on, when the oral administration had been shown by Dr. E. L. Fox and Dr. Hector Mackenzie⁸ to be equally efficient, she took 10 minims by the mouth six nights a week, so that 1 drachm was consumed in the course of each week. On this dose she remained in good health, and free from the signs of myxoedema. I have only seen this patient once during the last eleven years, but Dr. Helen Gurney, medical registrar at the Royal Victoria Infirmary, Newcastle, has kindly kept her under observation, and has informed me that she continued to take liquid thyroid extract regularly until early in 1918, when it became difficult to obtain, so that she was given dry thyroid extract in a tablet instead. She enjoyed excellent health until early in 1919, when she developed oedema of the legs, and died in May of that year at the age of 74 from cardiac failure.

This patient was thus enabled, by the regular and continued use of thyroid extract, to live in good health for over twenty-eight years after she had reached an advanced stage of myxoedema. During this period she consumed over nine pints of liquid thyroid extract or its equivalent, prepared from the thyroid glands of more than 870 sheep.

The results obtained in this case show that:

1. The thyroid is purely an internal secretory gland.
2. The symptoms of myxoedema can be entirely removed, and the patient maintained in good health, by the continuous administration of thyroid extract.
3. The functions of this gland in man can be fully and permanently carried on by the continued supply of thyroidal hormones obtained from one of the lower animals.
4. The duration of life need not be shortened by atrophy of the thyroid gland provided this substitution treatment is fully maintained, and so under these circumstances the prognosis of myxoedema is very good.

THE USE OF ANTISTREPTOCOCCIC SERUM IN QUINSY.

By NOEL C. FORSYTH, M.D.,
MALTON.

Five years ago it fell to my lot to treat a case of double quinsy which did not run the usual course. The report on a swab from the throat was: "Diphtheria bacilli not present; abundant growth of streptococcus." The patient, a man aged 32, was very ill; 2,000 units of antidiphtherial serum were injected when he was first seen. The second tonsil developed an abscess on the third day, and there was an abscess of the soft palate. Eventually the right cervical glands suppurated; he developed also extensive neuritis of the upper and lower limbs. He was invalided for eight months, and ultimately recovered. The ordinary treatment of quinsy was unavailing.

On the assumption that the primary cause was a streptococcus, it was determined to treat any subsequent cases of quinsy with antistreptococcic serum. Cases were selected in which the abscess had not perforated and in which the conditions were definitely acute.

The following routine was adopted: Serum (10 c.cm.) was injected at once; if there was any doubt of diphtheria 2,000 units of antidiphtherial serum were added. The injection was made in the thigh, hypodermically. As regards drugs, the usual initial purge was given; and thymol, carbolic lotion, and hydrogen peroxide were used for washing out and swabbing the mouth and throat. Ten cases only were treated.

A.-S. = Antistreptococcic serum, 10 c.cm.
A.-D. = Antidiphtherial serum.

CASE I.—Double Quinsy.

J. C., aged 31, farm wagoner, gave a history of quinsy once before. He had been ill one day. The temperature was 103.8° F. Both tonsils were much enlarged, the left most markedly; they met in the middle line. The soft palate was swollen and congested. A glairy translucent membrane covered the inflamed surfaces. A.-S. was injected.

Next morning he was improved. He could swallow his saliva and drink tea with some difficulty. He said that the acute pain over the tonsils and at the angles of the jaw had appreciably lessened some six hours after the injection. He had perspired freely throughout the night.

The left tonsil discharged twenty-four hours and the right forty-eight hours after the injection. The soft palate perforated and discharged a short time after. He went out for the first time on the seventh day. Between six and seven days after the injection urticaria developed all over the body and limbs. The throat was examined some months later; both tonsils were enlarged and pitted; operation was advised, but was refused.

CASE II.—Double Quinsy.

A farmer, aged 38, had had quinsy on one previous occasion. He had been ill one day. Both tonsils were enlarged and inflamed, as also were the fauces and soft palate. There was a translucent glairy membrane over the inflamed surfaces. The temperature was 103.8° F. A.-S. injected at 5 p.m.

Next morning he had improved. He could swallow fluids with some difficulty. He had perspired freely, and complained of a frontal headache. The acute pain in the throat had been appreciably eased during the night. The tonsils discharged some thirty-six hours after the injection. The rash appeared on the seventh day after the injection. He was out in the harvest field on the sixth day superintending his men.

CASE III.—Double Quinsy.

A soldier, aged 23, with no previous history of quinsy, had been ill two days. The temperature was 104° F. Both tonsils, the fauces, and soft palate were swollen and inflamed. The teeth were very septic—stumps with an overlying dental plate. A.-S. injected.

There was appreciable relief of pain in about ten hours. The tonsils discharged on the second day after the injection, the fourth day of the illness; the congested soft palate did not form an abscess. Urticaria developed on the seventh day after the serum. The man was not able to get about until the tenth day from the onset. The mouth was very much inflamed, with gingivitis and sordes.

CASE IV.—Double Quinsy.

F. P., aged 28, gave no history of a previous attack. He had suffered from "sore throat" for two days, but he had been able to go about. The temperature was 103.6° F. There was marked swelling of both tonsils, and of the soft palate; there was a glairy membrane over the inflamed surfaces. A swab was sent for cultivation. A.-S. 5 c.cm., with 2,000 units of A.-D., were injected at about midday. He experienced some slight relief by 7 p.m.

Next day the temperature was 101.8° F., and he was in great distress. A similar dose of both serums was injected. By the evening, eight hours later, there was marked relief. The

abscesses were discharging pus on the fifth day of the illness. Urticaria developed in about six and a half days after the injection. The rash spread over the arms and thighs—first appearing there—thence over the whole body and head. It was apparent on the lips, and the eyelids were said to have been oedematous. The result of the swab was: "Diphtheria bacilli not present; a growth of streptococcus."

The man was able to do light office work on the eleventh day after the onset of his illness.

CASE V.—Double Quinsy.

A farm labourer, aged 24, had had no previous attack. Both tonsils were enlarged and reddened. A.-S. injected.

He said that the pain was much relieved some hours afterwards. Both tonsils discharged on the second day after the serum, the fourth of his illness. Urticaria appeared round the injection site and over the abdomen on the seventh day after injection. Operation later was refused.

CASE VI.—Right Quinsy.

Housemaid, aged 25, had had quinsy once before. She was first seen on the second day of her illness. The right tonsil was much swollen; the left swollen and inflamed, but not so markedly. The pain was on the right side. The temperature was 104° F. A.-S. was injected.

She said that the pain was appreciably relieved some ten hours afterwards. The right tonsil discharged on the fourth day of her illness. The left tonsil did not suppurate. Urticaria was said to have appeared on the seventh day after injection, but I did not see the rash. She left her situation on the eighth day after her illness and went home to another locality.

CASE VII.—Right Quinsy.

A lad, aged 17, who had had no previous attack, had been ill one day. The temperature was 104.2° F. A.-S. injected. The pain was much improved next morning. The tonsil discharged on the third day after injection, and urticaria appeared on the seventh day after.

CASE VIII.—Left Quinsy.

A lad, aged 16, was seen first on the third day of his illness. The temperature was 104.6° F. A.-S. injected. The pain was appreciably relieved some hours afterwards. The left tonsil discharged on the fourth day of his illness. Urticaria appeared on the seventh day after the serum; the rash was "out" for about twelve hours.

CASE IX.—Right Quinsy.

A fireman, aged 24, who gave no previous history of quinsy, had been ill one day. The temperature was 103.8° F. A.-S. injected. The tonsil discharged on the third day of his illness. The pain over the tonsil was much relieved before the abscess discharged. Urticaria appeared on the sixth day after the injection; it was confined to the right thigh and leg. He was off work for fourteen days.

CASE X.—Left Quinsy.

J. C., the same patient as recorded in Case I, two and a half years after his last attack developed an abscess of the left tonsil. He was seen the day after the onset, when the temperature was 103.6° F. Ten c.cm. A.-S. serum was injected. The left tonsil discharged on the fourth day of his illness. He again experienced definite relief of his pain some hours after injection. Urticaria appeared on the sixth day afterwards, but he thought the rash was not so acute as on the previous occasion.

This man agreed to have his tonsils removed, but he left the district shortly after without submitting to the operation.

It would appear that the most definite result obtained in these cases was the relief of pain—if an opinion may be formed from the small number treated with antistreptococcic serum. In all, pain was appreciably relieved in from six to twelve hours; the more or less acute pain when swallowing was eased some hours after that, but within a definite time before the abscess ruptured.

In no case was incision of the abscess required by reason of the severity of the symptoms, and in all so treated there was pus discharging from the abscess on the fourth day of the illness; except in Case IV, in which the discharge was on the fifth day.

The temperature was as a rule taken in the axilla, when there was marked distress. The temperature approximated to the normal one or two days after the serum injection. A four-hourly chart would have shown the serum reaction, but it was not possible to construct one because not one of the cases had a nurse sufficiently trained.

It is to be regretted that calcium lactate was not given three or four days after the serum, so as to have prevented or modified the urticaria, but at the time I did not know of the proper method of its administration.

The serum used throughout was antistreptococcic, polyvalent, manufactured at Evans and Webb's laboratory.

THREE CASES OF ACUTE PERFORATION OF DUODENAL ULCER: LAPAROTOMY: RECOVERY.

BY

E. HUNTLEY, B.S.LOND., CAPTAIN R.A.M.C.(T.C.),
SURGICAL SPECIALIST, MILITARY HOSPITAL, TIDWORTH,
SALISBURY PLAIN.

THE notes of these cases illustrate the importance of early operation to secure a successful issue.

CASE I.

B. M., aged 32, a private A.I.F., was brought into hospital in the early hours of the morning of October 13th, 1919, cold and collapsed; he vomited some coffee-grounds fluid as he was being put to bed. He gave a history of being first taken ill with pains in the upper part of the abdomen on October 6th, and being sick once or twice. The pains came on worse two to three hours after taking food. He reported sick on October 7th, and was given a "dose of medicine." On October 8th he felt better, but vomited several times during the day, the vomiting relieving the pain in the epigastric region. He seems to have dragged about until the evening of October 12th, when he had a sudden acute pain just above the umbilicus, to the right of the middle line, and was very sick. On admission the whole abdomen was very hard and rigid, and abdominal respiratory movements were absent. There was acute tenderness above the umbilicus, distinctly greater towards the right of the middle line. There was no distension of the abdomen. Liver dullness was absent.

He was prepared for operation, and as soon as possible laparotomy was performed through the right rectus muscle. Immediately on opening the peritoneum gas escaped, as well as a certain amount of bile-stained fluid. The perforation was soon found in the first part of the duodenum, on its anterior aspect, through which gas and fluid were escaping. As much fluid as possible was mopped out of the right kidney pouch of the peritoneum and the perforation closed, a small tag of omentum being sutured immediately over the opening to strengthen the closure. A wick drainage tube was placed in the right kidney pouch and the incision closed. A second opening was made in the middle line, below the umbilicus, and a considerable quantity of thick bile-stained fluid was mopped out of the pelvis, into which a second wick drain was passed and the incision closed. This ulcer was found to be of quite recent origin, there being no marked hardness of its edges and very little recent lymph about.

This patient made an uninterrupted recovery; he did not vomit once after the operation down to his departure to a convalescent home on November 21st, 1919.

CASE II.

C. T. W., aged 22, a bombardier in R.F.A., was admitted to hospital on the evening of November 27th, 1919, in a mildly collapsed condition with pain in the upper part of the abdomen. He gave a history of having had "indigestion pains" of a gripping nature for a week, but with no vomiting. He had taken aperient medicine which had acted. The pains were worse about four hours after food. On the morning of November 27th, 1919, they became suddenly more severe, and he reported sick. Marked rigidity of the whole abdominal wall was found with tenderness above and to the right of the middle line. During the examination he vomited some thin greenish fluid. There was no distension of the abdomen, but the liver dullness was absent.

Laparotomy was performed the same evening, but only after some delay, owing to patient refusing operation, as he said he did not feel ill enough and would give permission, if necessary, in the morning after he had had a good sleep. An incision was made through the right rectus muscle; on opening the peritoneum, gas escaped and a large quantity of fluid had to be mopped out of the right kidney pouch and elsewhere before any perforation could be found. It was seen to be situated at the junction of the first and second portions of the duodenum. There was much recent lymph about and the ulcer was hard edged and difficult to get at, partly owing to its position and partly to bile-stained fluid constantly welling up through the perforation. After closing this and soaking up as much fluid as possible in the right pouch and pelvis, both these regions were drained with wick drainage tubes and the incisions closed. A very large quantity of fluid had gravitated into the pelvis in this case.

The patient was very troubled for several days following the operation with vomiting and distension. Once the bowels had acted, however, he progressed quite happily, and was discharged from hospital on December 31st, 1919, to convalesce.

CASE III.

J. B., aged 34, a gunner, R.G.A., was brought into hospital at about 6 p.m. on January 17th, 1920. He stated that he had abdominal discomfort for three weeks, with pain, a feeling of nausea, distension above the level of the umbilicus, and occasional attacks of vomiting. The pain was worse several hours after food. He was able to carry on his duties until the morning of January 17th, 1920, when he was seized with violent pain about the epigastric region whilst he was sweeping out his hut. He vomited and went to lie down. The pains got worse, and he began to feel ill and reported sick. On examina-

tion the abdominal wall was very rigid all over, with considerable tenderness in the epigastrium almost directly in the middle line. There was decided distension of the abdomen, with dullness marked towards the right loin. The liver dullness was completely absent. He vomited some greenish fluid.

As soon as the patient could be got ready laparotomy was performed through the right rectus muscle above the level of the umbilicus. When the peritoneum was opened gas escaped, followed by a large quantity of thickish green fluid, which welled up from the right kidney pouch as well as from the lower part of the abdomen. The ulcer was soon found in the first part of the duodenum and closed. It was of recent origin, the edges being free from hardness, and hardly any lymph was about except on the liver and omentum. Both the right kidney pouch and the pelvis were drained as in the other cases.

Except for some slight suppuration at the upper end of the main incision, this patient recovered extremely well, considering the history he volunteered of a profound liking for alcohol. He is now quite convalescent.

The recovery of these three patients was, in my opinion, largely due to the great care and skill bestowed on them by the nursing staff, to whom I am greatly indebted.

For permission to publish these notes I have to thank Lieut.-Colonel Langford N. Lloyd, C.M.G., D.S.O., R.A.M.O., commanding Military Hospital, Tidworth.

PAPILLIFEROUS CARCINOMA OF THE THYROID GLAND.

BY

BASIL HUGHES, D.S.O., M.A., M.B., B.CH.CAMB.,
B.Sc.LOND., F.R.C.S.,
ASSISTANT HONORARY SURGEON, CHILDREN'S HOSPITAL, BRADFORD;
PATHOLOGIST, ROYAL INFIRMARY, BRADFORD.

PAPILLIFEROUS CARCINOMA is uncommon at any age, and must be extremely rare in a child of 13. It presents also certain clinical features of importance in prognosis to which attention may be called.

C. S., a girl aged 13, was seen first at the out-patient department of the Bradford Children's Hospital in October, 1918. Her mother stated that three years earlier a swelling appeared in the middle line of the neck; for ten months it had been noticed that not only was the swelling getting bigger but that additional swellings had appeared on the right side of the neck, and these had grown larger. There had been no pain, cough, dyspnoea, change in the voice, or difficulty in swallowing, and no loss of weight.

Examination showed a tumour confined to the right half of the thyroid gland, moving on deglutition, but adherent to the trachea. It appeared to surround the carotid sheath rather than displace it. It was peculiarly hard and knobby to the touch, and was wholly above the sternum. In addition there were three large easily movable and discrete lymphatic glands in the right side of the neck. The pupils were equal, and the vocal cords moved normally.

The patient was admitted to hospital and the enlarged lymphatic glands were removed without difficulty, as they shelled out with the greatest ease. Sections examined microscopically were remarkable in that there was no trace of any true lymphatic tissue to be seen, the whole gland substance being replaced by metastases from the primary growth in the thyroid gland.

A month later the right lobe of the thyroid gland was removed through a transverse incision. This procedure was more difficult as the growth was firmly adherent to the trachea and carotid sheath. The superior thyroid artery was first secured and ligatured, and the tumour was then attacked from below. With difficulty it was separated from the trachea and carotid sheath; during the process some of the contents of the tumour escaped. The whole area of operation was well protected with sterile gauze so that soiling of the wound was prevented. Branches of the inferior thyroid artery were ligatured as they were divided and the recurrent laryngeal nerve was carefully preserved. The resection completed, the wound was approximated with buried outgut sutures and the skin brought together with a subcutaneous stitch of fishing gut. Drainage was not employed. The wound healed by first intention and the subcutaneous stitch was removed on the sixth day.

Microscopical examination of the tumour showed it to be identical in structure with that in the lymphatic glands—that is, it was a true papilliferous carcinoma. The tumour itself was hard to the touch and contained on its surface numerous dark-coloured irregularities resembling cysts into which hæmorrhage had occurred. On opening these a sanious fluid escaped, and slight pressure caused the exudation from them of a yellowish caseous material, which proved to be intracystic papilliferous growth. This was the naked eye structure of the tumour throughout, and in it no normal thyroid tissue appeared to exist. It was evidently these tense cystic structures that gave the knobby, irregular feel to the tumour.

In places where the tumour was firmly adherent to the trachea and carotid sheath this seemed to have come about in the following way. The cyst wall had ruptured and the papilliferous growth had directly grafted itself on to these structures.

The naked eye appearance of the lymphatic glands was interesting. On cutting them across they presented a peculiar arborescent appearance, and on squeezing them their contents escaped as a caseous, yellowish material.

It is now three months since I operated upon the child, and at present there is no sign of any recurrence and she is perfectly well.

The only other case I have seen of this disease was that of an elderly lady over 70 years of age. A portion of the thyroid gland had been removed eight years previously, and proved on section to be a papilliferous carcinoma.

Eight years later she had an extensive enlargement of the lymphatic glands on one side of her neck. They were easily removed, and on section proved to contain metastases from the growth removed eight years previously. This case was under the care of Mr. James Berry, who very kindly asked me to assist him at the latter operation.

During the six months in which I was Mr. Berry's house surgeon, and in which period I saw many cases of goitre, this was the only instance of papilliferous disease. Very little has appeared in the literature about this condition, and the chief points of interest with regard to it, in addition to its extreme rarity, are that it usually occurs in patients over 40 years of age, and that it is usually far less malignant than the ordinary carcinomata, the history often extending over many years. For a long time these tumours show very little tendency to infiltrate; the metastases are local and situated in the glands of the neck, and they may appear years after the removal of the original growth. The infected glands remain movable and discrete, and their removal is easily accomplished. The original tumour, if removed before infiltration has occurred, shows little tendency to recur.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PROLONGED RETENTION OF FOREIGN BODY IN THE CORNEA.

A MAN, aged 21, applied for treatment at this hospital for pain in his right eye. There was some pericorneal injection, and situated in the central region of the cornea was a leucoma, which at the centre was brownish and looked necrotic. On further examination with the oblique light a metallic glitter was seen, and a foreign body of iron or steel $1\frac{1}{2}$ mm. long and $\frac{1}{2}$ mm. broad was removed from a distinct cavity in the centre of the leucoma.

The history showed that a hot metallic fragment entered the patient's eye in 1915, at which date the foreign body was not removed. This I have been able to verify by old hospital notes. Subsequent to this date no foreign body had entered the eye.

Between 1915 and 1920 the fragment remained in the cornea with no inconvenience to the patient except for the presence of the leucoma, which seems to have formed a fibrous capsule round the foreign body; ultimately the fragment became exposed by a natural process of ulceration.

I have not been able to find in the literature any case in which a metallic foreign body lay dormant in the cornea for so long a period as five years without causing any inconvenience to the patient.

I am indebted to Mr. C. Walker, F.R.C.S., surgeon to the hospital, for permission to publish this case.

House-Surgeon, Bristol Eye Hospital.

A CASE OF CERVICAL ABORTION.

A B., aged 29, was admitted to Dundee Royal Infirmary, under the care of Dr. R. C. Buist, with bleeding of one week's duration, following a two months' period of amenorrhoea. She had had three miscarriages, the last nine months previously. On this occasion two days before admission she had pain in the lower part of the abdomen and back, and sharp bleeding came on.

On examination the cervix appeared in the vagina as a soft cystic swelling, about 2 in. in diameter, and above it the body of the uterus could be felt, empty and contracted. The external os was closed; only a very small part of discoloured blood-clot was protruding.

The os was dilated instrumentally to admit the finger, which entered a smooth cavity containing a soft mass. Beyond the cavity the finger entered a passage, which opened to meet it. This was recognized as the cavity of the uterus, the contracted body of which could be felt also bimanually. The soft mass was loose, except for a strand of slender tissue, which continued into the cavity of the uterus. As this strand did not separate easily, the cervix was plugged with flanne gauze. This was removed at the end of twenty-four hours. On examination twenty-four hours later again the cervix was found to be empty and flaccid, and the examining finger in the cervical canal could feel the cavity of the uterus leading off from it. The ovum had escaped unobserved.

The case is peculiar in the comparative infrequency of this form of abortion, and in that the patient was not a primipara, and there was no stenosis of os.

Reports of Societies.

CHRONIC HALLUCINATORY PSYCHOSIS.

At the quarterly meeting of the Medico Psychological Association of Great Britain and Ireland, held at 11, Chandos Street, London, on February 24th, under the presidency of Dr. BEDFORD PIERCE, Professor R. HUNTER STEEN, M.D., read a paper on chronic hallucinatory psychosis, founded upon a series of cases in which the principal symptom was the presence of hallucinations. As the hallucinations caused slight depression, some of the cases might be included under melancholia, while the development of delusions of persecution might lead to a provisional diagnosis of paranoia. Others, again, might be swept into the wide net of dementia praecox. He set out to show that there were hallucinatory cases that could be grouped together into a well defined clinical entity, for which he proposed the term "chronic hallucinatory psychosis." The most prominent of the hallucinations were auditory. The patient might for years recognize that his hallucinations were morbid and unaccountable. These patients could not be termed insane, hence he preferred the word "psychosis" to "insanity." In the absence of an explanation the patient tried to account for their presence, and a delusion resulted, mostly one of persecution. In the early stages such a patient was quiet and orderly and his memory was good. The author quoted several typical cases. In most of them—for it could not be regarded as a rare affection—careful research into the family history revealed a strong hereditary tendency to nervous instability. It seemed an affection of adult life, usually beginning between 30 and 50. It was met with mostly in women, and not those of the lowest rank of life. The special morbid anatomy of the condition was unknown. Not one of Dr. Steen's cases had died, and he knew of no published accounts of *post-mortem* examinations in such cases.

Etiology, Diagnosis, Treatment.

The phenomena could be best understood if approached from the psychical side purely, though theories had been advanced founded upon material conceptions. A hallucination was the result of dissociation of the mind, directly produced by a mental conflict which had been sternly repressed, perhaps for a long time, in a person of congenitally unstable mind. Sleeplessness was not prominent except in the later stages. The expression became anxious, a listening attitude might be noted, and the voices might be conversed with: violence was sometimes threatened, and suicide suggested. Though there were periods of remission, on the whole the disease steadily progressed in intensity, and having reached its zenith, remained stationary for several years. Dr. Steen discussed the differential diagnosis of the condition from general paralysis of the insane, the manic-depressive group, true melancholia, the secondary and organic dementias, and paranoia, the last named being the most difficult to differentiate. The earlier a case was seen the more hopeful the outlook. When delusions had developed, but little could be done to avert chronicity. The general health was not affected, and there appeared to be no danger of terminal

dementia. In the early stages change of environment sometimes did good. Rest from work, freedom from anxiety, and change of air and scene should be advised; plenty of nourishing food should be taken, and the bowels kept regular. In some cases it was well to give an occasional hypnotic to secure sleep. If, however, small doses of the bromides or hydrobromic acid led to no improvement, a thorough mental examination must be made; it would probably bring to light a mental conflict which had caused the dissociation. The present difficulty of getting into touch with these cases in the early stage was likely to be less in the future, with the multiplication of mental out-patient departments attached to large hospitals.

The PRESIDENT did not consider that Dr. Steen had quite established the claim to regard the malady he described as a separate disease from paranoia. Paranoia was shown by Dr. Percy Smith, in his presidential address, to be an exact clinical entity. Was it possible for a mental conflict to produce dissociation?

Dr. MENZIES said this type of case became very demented in the course of twenty or twenty-five years, the patients becoming ordinary chronic lunatics. At necropsy more or less thickening and chronic resolution was always found. The cases were first called paranoiacs, and then chronic maniacs. These matters were not, he thought, to be regarded purely from the psychical standpoint; unless the anatomical, and especially the chemical, aspects were also considered there would not be much advance.

Dr. PERCY SMITH said that observers in various countries who described paranoia had referred to acute hallucinatory paranoia and chronic hallucinatory paranoia, and included in the writings upon paranoia were almost all the kinds of acute psychosis met with—even acute delirious conditions, which was absurd. It would be too sweeping to assert that in no cases of paranoia were there hallucinations. In the address referred to, he had pointed out that chronic hallucinatory cases, to which the term paranoia was properly applied, often began with a serious emotional disturbance. Many cases of paranoia had hallucinations. He thought psycho-analysis might help in the early stages of the cases described.

Dr. STEEN, in reply, said he was not prepared to explain how a mental conflict produced dissociation, but he had no doubt of the fact, especially when the conflict was strongly repressed. In one of his cases revelation of the source of conflict was followed by three years' relief. He agreed there were hallucinations in some cases of paranoia, but that was a disease characterized by delusions, with, as a rule, absence of hallucinations; certainly the latter were not characteristic of paranoia, while they were in the cases now described. An approach from the psychical side gave a better insight into the condition than the assumption of a causal physical basis. Early psycho-analysis, he believed, would enable many cases to recover.

EARLY DIAGNOSIS OF SYPHILIS.

The third sessional meeting of the East Riding Division of the British Medical Association was held in the Board Room of the Hull Royal Infirmary on February 5th, with Dr. TURTON in the chair.

Dr. E. HARRISON, in the course of an address on the early diagnosis of syphilis, said that if a sore could be diagnosed within a few days of its appearance there was a very great probability that a course of "914" and mercury extending over six weeks would cure the disease. If, however, two or three weeks were allowed to pass before beginning treatment then one course of injections would probably not suffice, and if postponed until the commencement of the secondary stage much more prolonged treatment was necessary. He held that treatment should not be initiated until a diagnosis had been made. Early treatment following on early diagnosis was of importance to the community at large, as after a few injections the patient was no longer infective. Every sore found on the penis, however trifling in character, should be looked upon as a possible chancre. A genital sore might be syphilis, chancroid, scabies, herpes, or traumatic. The resources for arriving at a diagnosis were (1) the history, (2) the clinical signs, (3) the microscopic findings, (4) the Wassermann reaction, (5) the therapeutic test. The history was not often of much

value. The clinical signs, in spite of the existence of modern methods of diagnosis, still remained the most important means of diagnosis. It must be remembered that the existence of a soft sore did not rule out syphilis. From his experience at the clinic Dr. Harrison concluded that, in Hull at any rate, chancroid pure and simple was a rare condition; nearly always there was syphilis at the back of it. He next gave a description of the method of collecting serum for microscopic examination, the manner of examination, and points of distinction between the *S. pallida* and other spirochaetes. The microscope served to confirm the diagnosis made on clinical grounds; it was of great value in all doubtful cases; and in soft sores it often yielded early positive evidence of syphilis. Until serum for the microscope had been taken no antiseptic should be used locally. The Wassermann reaction was of no value in the early diagnosis of syphilis, as it did not become positive for from two to six weeks after the appearance of the sore. Thus a negative report did not exclude syphilis for six weeks after the manifestation of symptoms.

Dr. TURTON, in thanking Dr. Harrison for his very excellent address, emphasized the uselessness and even danger of trusting to the Wassermann test in early syphilis. It was, however, of great value in the late stage; but even here, when the blood gave a negative reaction, the cerebro-spinal fluid might be positive.

Dr. RITCHIE RODGER said that symptoms sometimes appeared in the throat before the primary sore had disappeared; and sometimes, especially in women, these signs were the first thing to be observed; in such cases the Wassermann test was of some value.

Mr. HOWLETT remarked that the work done by Dr. Harrison at the venereal clinic was of very great value. They had there an argument in favour of State aided as against voluntary hospitals.

Dr. DENYER, Dr. MOIR, Dr. MACKAY, and Dr. LILLEY also spoke, and Dr. HARRISON replied.

DIAGNOSIS OF GONORRHOEA IN THE FEMALE.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Liverpool on February 20th, Dr. W. W. KING (Sheffield) read a paper on the diagnosis of gonorrhoea, based upon an analysis of the first 500 cases under his care at the venereal clinic of the Jessop Hospital for Women, Sheffield. He divided the cases into two groups; those in which the gonococcus had been found—"proved" gonorrhoea; and those presenting the signs and symptoms of the disease, but where the specific organism had not been isolated—"clinical" gonorrhoea. The gonococcus was found in 60 per cent. of cases with clinical symptoms of gonorrhoea, but in a number of these was only isolated after repeated examinations. He estimated that from 70 to 80 per cent. of patients with the physical signs mentioned later were really suffering from gonorrhoea. Of the remaining 30 per cent. the majority were undoubtedly venereal, and in one case the infection appeared to be due to a diphtheroid bacillus present in the cervical and urethral discharge.

Clinical Diagnosis.

The symptoms complained of were discharge (yellow or white), pain on micturition, local pain and swelling, abdominal pain, menorrhagia, and irritation. Yellow discharge was present in over 70 per cent. and pain on micturition in about 30 per cent. of both "proved" and "clinical" cases. The physical signs noted were vaginal discharge, vulvitis, papillomata, leucoplakia, lesions of Bartholin's gland, urethral discharge or thickening, urethral caruncles, vaginitis, and affections of the cervix uteri. Vaginal discharge was present in 80 to 90 cent. of all cases. Acute gonococcal vulvitis was not often met with, most of the cases seen at the clinic being in the subacute or chronic stages. In about 80 per cent. of cases there was a purulent urethral discharge, but in a small number the discharge was white in colour and composed of epithelial cells, in which the gonococcus was sometimes found. Thickening of the urethra was most valuable evidence of past gonorrhoea in the female—comparable in this respect to stricture in the male. Infection of Bartholin's gland

was only met with in 10 per cent. of cases. The commonest evidence of cervical infection was purulent or mucopurulent discharge, usually associated with a patulous external os. The combination of purulent discharge and patulous cervix was a most helpful diagnostic sign, especially if the internal os was also sufficiently patent to admit a "dressed" probe into the uterine cavity. In more chronic cases the discharge consisted of a clear mucus, and this coming through a patulous external os, produced a bull's-eye lantern effect, which he had called a "magnifying" cervix. This was typically seen in nulliparæ, but occurred also, though less strikingly, in women who had borne children. This condition corresponded to the gleet stage of gonorrhoea in the male, and occurred in about 15 per cent. of cases. The inguinal glands were rarely found enlarged in uncomplicated gonorrhoea. When enlargement was present he always suspected the presence of syphilis. Salpingitis was the most frequent complication of gonorrhoea met with (18 per cent. "proved" cases, 12 per cent. "clinical" cases). No case of gonococcal cystitis was noted in the series, although generally stated to be of fairly frequent occurrence.

Bacteriological Diagnosis.

Detection of the gonococcus in film preparation was at present the only certain method of diagnosis. The method of preparation of these films was important; "dressed" wires were used for collecting the material, which was dabbed—not rubbed—on to the slides. In this way the leucocytes were preserved intact and the intracellular features of the gonococcus more easily observed. The importance of the urethra in the bacteriological diagnosis was shown by the fact that the organism, when found, was present in the urethral discharge in over 70 per cent. of cases. If found at all, the gonococcus was generally detected in the first five examinations, but sometimes not until the eleventh or twelfth. Cultural methods were extremely difficult to carry out with the highly contaminated pus present in the female. Some serum reaction was needed to put the diagnosis of the disease on a surer footing than at present. The technique of the complement fixation test for gonorrhoea was so faulty that the Lister Institute, after examining a dozen or more specimens for him, had finally refused to carry out further tests.

INTUSSUSCEPTION OF THE APPENDIX.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, held on February 6th, with the President, Mr. A. E. MAYLARD, in the chair, Mr. ARCHIBALD YOUNG described and showed a specimen removed by operation from a case of ulceration of the ileum, caecum, and ascending colon, with intussusception of the appendix.

The patient, a woman aged 34, had for two years suffered from progressive loss of weight and strength, and from persistent severe pain in the right iliac fossa. The bowels had for long been constipated, but latterly, when they moved, tended to be loose. On examination under an anaesthetic a tumour about the size of a chestnut was made out in the region of the first part of the ascending colon and suspected to be malignant. Laparotomy was performed, and as extensive glandular enlargement was found, the last four inches of ileum, the caecum, and ascending colon were excised. The mucous membrane of this portion of bowel showed extensive ulceration, typically tuberculous, both to the naked eye and on microscopic examination. Ulceration was specially marked in the caecum around the partly intussuscepted appendix. Convalescence was uneventful and the patient left hospital a month later greatly improved in health.

Mr. Young referred to three other cases of intussusception of the appendix, the first two of which he had reported to the society in 1911:

1) A child, aged 4½, operated on for a suspected partial and recurrent obstruction of the bowel; (2) a woman, aged 24, operated on because of highly acute symptoms suggesting acute appendicitis; (3) a woman, aged 20, operated on in 1917 on account of appendicitis of more chronic type with recurrent attacks extending over several months. The specimen from this case also was shown to the meeting.

In all four cases it was probable that the exciting cause of the intussusception of the appendix was the local irritation exciting excessive peristalsis of the organ.

Dr. W. S. SYME, in a communication on malignant disease of the larynx, pointed out that in this country this disease was much commoner in men than in women, whereas malignant disease of the lower pharynx was commoner in women. Intrinsic disease—that is, affecting the cords, anterior fornix, subglottis, and false cords—might remain as a local condition for a long time, and hence could frequently be treated by thyrotomy and removal of the growth and surrounding tissue. But in extrinsic disease, affecting other portions of the larynx, glandular infection was very common, and the patient was often seen by the surgeon too late for operation. Hence the importance of early diagnosis in cases of persistent hoarseness. Dr. Syme showed a patient whose larynx he had removed two years ago for extrinsic disease. There had been no recurrence and the patient had developed a quite intelligible pharyngeal voice. He reported also three cases of removal of a vocal cord by thyrotomy, one two and a half years and the other three and a half years ago, without recurrence, and a third more recent case.

Dr. ADAM PATRICK described a case of multiple oriental sores (leishmaniasis) infected in Mesopotamia early in 1919 and treated by intravenous injections of antimony. The injections, eleven in all, were given twice weekly, beginning with a dose of 0.04 gram of tartar emetic and increasing to 0.12 gram. The seven ulcers present on hands, legs, etc., had healed satisfactorily.

Dr. W. F. SOMERVILLE described the Bergonié chair—an apparatus for producing a painless alternating interrupted electrical current—and demonstrated its application in treatment.

BACTERIOLOGY OF MILK.

At a meeting of the Pathological Section of the Liverpool Medical Institution held on February 20th, with the President, Dr. J. F. GEMMELL, in the chair, Dr. R. STENHOUSE WILLIAMS read a note on the bacterial content and keeping qualities of clean milk produced for commercial purposes. He presented the results of work upon methods of milk production carried out by Miss K. Freear and Miss E. Knight at the Research Institute in Dairying at University College, Reading. A series of weekly examinations of clean bottled milk produced for commercial purposes, extending from November, 1916, to December, 1918, demonstrated that the bacterial content of such milk only rose above the 10,000 limit on three occasions, and was only really unsatisfactory in one instance. These results were obtained with milk taken in a special milking shed from washed cows, by clean workers, in steam-sterilized vessels. The cost and upkeep of a special milking shed was an added charge on the price of milk, and further experiments were detailed which demonstrated the possibility of producing clean milk in an ordinary cow byre. From these experiments the following facts emerged: (1) It was possible to produce clean milk in an ordinary cow byre; (2) to ensure success the cows should be clipped and washed, the workers clean, and the utensils steam-sterilized; (3) the covered milk bucket, when properly used, was of great assistance in keeping dirt out of the milk, but, in the hands of unskilled workers, might be an added source of contamination of the milk. This last observation was of special importance to the dairying farmer. Dr. Stenhouse Williams further contributed a paper on the presence of tubercle bacilli in the faeces of apparently healthy cows. He recorded an investigation carried out by himself, in collaboration with Mr. W. A. Hoy, on behalf of the Medical Research Committee. It was shown that about 2 per cent. of apparently healthy cows had been found to be excreting tubercle bacilli in the faeces. Five such cows had been found in four of the fourteen farms in which it had been possible to examine the faeces of nearly all the cows in milk. The results were subject to a considerable margin of error, inasmuch as each cow being examined on a single occasion only, a very small fraction of the daily excreta could be tested; and the method of examination (antiformin) adopted in the earlier stages of the work did not appear to be so satisfactory as the method (Petroff) finally utilized. He showed that the excreta of such cows, when kept in a dark cellar, remained infective for at least twelve months, and, when spread upon pasture land or added to liquid manure, remained infective for at least four months. The possible influence of such material upon the health of other beasts in the farm was pointed out. Both note and paper were copiously illustrated by charts.

MECHANO-THERAPY.

AT a meeting of the London Association of the Medical Women's Federation, on February 17th, the President, Mrs. FLEMING, M.D., in the chair, Dr. HEDDA ALSTROM read a paper on mechano-therapeutics in general—its past, its present, and its possible future. She traced its history from the most ancient times, showing how, at various periods, it had been held in high esteem; at others it had been looked upon with indifference, until the weight of eminent authority and the pressure of popular opinion had again raised it from oblivion. In many countries medical men and women, high in their profession, specialized in it, and its theory and practice were taught at the universities. Until the same was done in England, the best would not be got out of a good thing.

Dr. BARRIE LAMBERT, C.B.E., spoke on the need for medical personnel in mechano-therapy. She gave an account of the various kinds of gymnastic training given in England, and said that the present-day remedial gymnast was very fully trained and efficient, provided she held the Incorporated Society of Trained Masseuses' triple qualification of massage, remedial exercises, and medical electricity. The better qualified the gymnasts were the more they asked for medical supervision, and few doctors had sufficient knowledge to make progressive work in this line anything but extremely difficult. Most doctors, with the exception of the specialists, might roughly be divided into those who had too little faith and those who had too much. The latter were the more dangerous, as they were apt to order treatment in unsuitable cases. The difficulty of finding medical officers with sufficient knowledge to supervise made the organization of remedial clinics extremely difficult. Dr. Lambert urged the importance of a short course for all medical students in the theory and practice of massage, remedial gymnastics, and medical electricity, and in the after-care of orthopaedic cases.

Dr. A. KELLGREN-CYRIAX spoke of the need for the extended application of mechano-therapy. She said that mechano-therapy rested on a sound physiological basis, and that there was no danger in prescribing and applying it if its laws and technique were understood. It could accomplish much that medicine and surgery could not do—for instance, promoting circulation, developing muscle, removing pus from tissues at a distance from the lesion, re-educating the neuro-muscular circuit, aiding air entry into almost solid pneumonic lung, toning up enteroptosed viscera. Were mechano-therapy practised by some of the profession the public would not be driven to charlatans and bone-setters. The highest forms should be taught at medical schools, and it should take its place beside the great systems of medicine and surgery.

AT a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on February 27th, the President, Dr. E. W. GOODALL, in the chair, Dr. MATTHEW YOUNG read a paper entitled, "An investigation into the periodicity of epidemics of whooping-cough from 1870 to 1910 by means of the periodogram." An investigation of the statistics of London and ten other large towns had afforded evidence of definite periodicity in several cases. In London the maximum amplitude by the periodogram method was in the neighbourhood of two years, and further analysis suggested that there were really two periods involved of approximately 102 and 107 weeks respectively. In Bristol a two-yearly period was not found, the main periods being of 95 and 124 weeks. In Newcastle, Liverpool, and Salford periods of about two years were revealed. The main period at Birmingham was of 99½ weeks, and Glasgow, Edinburgh, and Sheffield all showed maximum at intervals of more than two years. In Dublin the main period was as much as 135 weeks. Manchester, unlike most of the other towns, showed no outstanding amplitude. In Birmingham and Salford the chief periods of measles and whooping-cough were nearly identical, but this did not occur elsewhere. The paper was discussed by Mr. TRACHTENBERG, Dr. BROWNLEE, Dr. MAJOR GREENWOOD, Dr. CHALMERS, Dr. JAMER, and the PRESIDENT.

AT a meeting of the Assurance Medical Society, held on March 3rd, Dr. T. D. LISTER, C.B.E., in his presidential address, said the society stood in a peculiar and isolated position: its members were not representatives of a special branch of medicine, but dealt with many special

branches. Their work was not concerned with the technology of any specialty; it was one of applied medicine only. Their function was to advise the great commercial undertakings employing them upon the medical considerations that had to be taken into account in assessing life risks. In their endeavour to hold the medical scales evenly in the assurance market between the public and the office they had to form a judgement on the importance of the medical facts as affected by the other facts, and vice versa.

AT a meeting of the Pathological Section of the Royal Society of Medicine, held on March 2nd, with the President, Dr. WILLIAM BULLOCH, F.R.S., in the chair, Dr. J. A. MURRAY gave a demonstration on the staining and constitution of mitochondria, illustrated by specimens and lantern slides. Dr. E. H. KETTLE demonstrated experimental aspergillosis in the rabbit. Dr. DA FANO gave a summary of the recent work on disseminated sclerosis.

Rebuelus.

SYPHILIS IN CHILDHOOD.

IN a handy little volume on *Syphilis in Childhood*. Dr. LEONARD FINDLAY¹ has given a concise and remarkably practical account of the disease, founded on his experience at the Glasgow Hospital for Sick Children. Most of the space is given to symptomatology and treatment. The text is lavishly illustrated, several of the figures being in colour. In the chapter dealing with the mode of infection the author says that the view that stillbirths and miscarriages are evidence of a mother being syphilitic is likely to lead to serious error. In 97 syphilitic families under his care 19 per cent. of 427 pregnancies ended in abortion or stillbirth, and in 19 definitely non-syphilitic families 19 per cent. of 123 pregnancies also ended in a similar way. The high incidence of syphilis in Glasgow, which by clinical and serum tests has been calculated to be 10 per cent., as compared with 2 to 6 per cent. among hospital children in New York, St. Louis, San Francisco, and Chicago, is accounted for by the delicacy of the method used in carrying out the Wassermann reaction, and by the fact that the cases examined came from the poorest neighbourhoods. Dr. Findlay agrees with other writers in emphasizing the low degree of infectivity of congenital syphilis; he has, he says, never seen a case in which infection could be ascribed to association with a syphilitic infant. On the few occasions in which such a method of infection had been suggested by the parents, he invariably found a positive Wassermann reaction on examination of the serum of the father or mother. He admits, however, that though the infectivity is slight and infection rare, it is a danger which should be borne in mind and guarded against.

In discussing prophylaxis, Dr. Findlay maintains that no antivenereal campaign will be successful without notification of the disease, which he feels confident will be adopted sooner or later. He thinks that marriage may be permitted when a negative Wassermann reaction has been obtained after early and thorough treatment with salvarsan and the reaction has remained negative for a year. The antenatal treatment of pregnant women with intravenous injections of salvarsan and mercurial inunction which was carried out in seven cases resulted in the birth of absolutely healthy children, and in no instance did the treatment interfere with the course of gestation. Dr. Findlay regards inunction as the most efficacious method of administering mercury. He has frequently seen children, treated with mercury and chalk without any benefit, immediately improve when inunction with mercury ointment was substituted. In many cases he had continued inunction for about a year without seeing the slightest evidence of toxæmia in the form of stomatitis or proctitis. Salvarsan, which in combination with mercury he regards as practically indispensable in the treatment of syphilis in children, should never, in his opinion, be given to infants

¹*Syphilis in Childhood*. By Leonard Findlay, M.D., D.Sc., F.R.F.P.S.G. London: H. Frowde, and Hodder and Stoughton, 1919. Cr. 8vo, pp. xii + 154; 37 figures. 8s. 6d. net.)

by the intramuscular or subcutaneous route, if these can be avoided, as in the majority of cases induration followed by necrosis and sloughing is apt to ensue. He regards the intravenous route as the method of choice; he makes use of the scalp veins, as first recommended by Noeggerath in 1912.

We have noted a few misprints, such as *per utero* (pp. 3 and 7), *olis* for *oris* (p. 84), and Argyll-Robertson (p. 62). Several of the names of lesser known foreign authorities are wrongly spelt (pp. 8, 21, 67, 137). The statement on p. 1 that there is no reputed example of transmission of syphilis even to the third generation requires qualification, and it is not correct to speak of an eruption as a "macula" (p. 35). These, however, are comparatively trivial blemishes in a book which should prove of value to medical practitioners, especially those concerned with child welfare, for whom it is particularly intended.

NEW EDITION OF CUNNINGHAM'S ANATOMY.

THE issue of the first volume of the seventh edition of *Cunningham's Manual of Practical Anatomy*,² revised and edited by Professor ARTHUR ROBINSON, marks a definite stage in the evolution of this well known and deservedly popular work. This volume is concerned only with the extremities, and we are told that the change which is being made from two to three volumes has been deemed advisable because of the increase in size caused by the addition of many new figures and the amplification of the dissecting instructions.

We are glad to note that the number of radiographs—a new feature of the sixth edition—has been increased, and their value greatly enhanced by their dispersal throughout the volume. The plates include a fine series of radiographs of young joints displaying the epiphyses, and also a few of injected vessels, to show their relation to bones and some of the anastomosing channels. Another welcome addition is the increase in the space and in the number of figures devoted to the lymphatics. It is well that the attention of the student should be specially directed to the groups of glands that he can readily display for himself, and that, while doing so, he should be given an account of the lymph paths involved, informed of their importance, and warned that they can be studied effectively only by special methods.

The Basle nomenclature has been retained, with many of the old terms still in brackets. Measurements formerly given in inches are now translated into millimetres, but an indiscriminate application of this change to the metric system leads to some curious results which are hardly likely to recommend it—as, for example, on p. 62, where the student is advised to tie the divided axillary vessels and nerves to a piece of wood about 37.5 mm. long!

We are not quite sure of the advantage of using special type for dissecting instructions, which could be sufficiently marked off from the text proper by a special heading. A short experience of the use of the present volume suggests that students may find the particular type employed somewhat tiring—a point worthy of the careful consideration of the editor and publishers of a book so widely used.

We have said before that *Cunningham's Manual* holds a unique place in this country. The new edition bids fair to consolidate that reputation by continuing in its enlarged form the high standard achieved by the original author and maintained in successive editions by the present editor.

WEIR MITCHELL TREATMENT.

THE volume by Dr. DERCUM in *Rest, Suggestion, and Other Therapeutic Measures in Nervous and Mental Disease*³ is concerned in the main with the application of the Weir Mitchell method for the treatment of the neuroses and psychoses. Following upon a brief survey on physiological lines of the process of fatigue, the author develops the view that neurasthenia, in so far as it is essentially a

fatigue neurosis, must be treated by the simple physiologic measures of rest associated with exercise and feeding. In this section the practitioner will find the fullest possible directions for the treatment of cases along these lines. Minute details as to rest, diet, exercise, medicine, baths, isolation, massage, and electricity are given, and will be found helpful. When, however, the author advocates the routine treatment of hysteria on similar lines it becomes difficult to harmonize his suggestions with current conceptions as to the significance of hysterical manifestations. If neurasthenia be regarded as adequately explained on the basis of morbid physical fatigue, Weir Mitchell methods of treatment for the cure of the disorder are scientifically sound, but in no sense would it seem possible to regard hysteria from a similar pathological standpoint. Hysterical symptoms in soldiers have been treated by active measures directly opposed to those rest methods which tend to fix and perpetuate them. It is interesting to note that Dr. Dercum recently admitted in a paper on "Shell-shock"⁴ that he would not adopt the methods he advocates in this volume for war cases, and it is therefore difficult to understand why he does so in respect to civil cases in which the mechanism is essentially the same. When he says that "Electricity also may prove of much value in given cases. . . . The slowly interrupted faradic current is conveniently used to stimulate the muscles. . . . It promotes the general nutrition and increases the general level of the muscular tone," is he not by this treatment unconsciously fixing the idea of illness in the mind of an hysterical patient?

Attention is given along similar lines to hypochondria—which is here regarded as a distinct entity—the drug habit and certain forms of mental disorder. The highly practical details in regard to treatment will be of value to the reader, though they suggest nothing particularly new. In discussing suggestion its use without hypnotism is advocated. In the last chapter consideration is given to shamanism, mesmerism, hypnotism, catharsis, psycho-analysis, metallo-therapy, mind-cure, Christian science and "mystic and religious methods generally." The inclusion of hypnotism and psycho-analysis in this group is sufficient to indicate the attitude of the author to these methods of treatment. Perhaps if he had criticized them with more restraint than is here the case his views would have exerted greater influence.

THE NURSERY SCHOOL.

NO one can have a greater claim than Miss MARGARET MACMILLAN to speak with authority of *The Nursery School*,⁵ and her book is a noteworthy contribution to the study of a problem which is of importance to every teacher and educational administrator, and concerns everyone who takes heed to the physical or moral welfare of the coming generation. Doctors (and not school doctors alone) are among those on whom this book should have a special claim for consideration.

In a congested urban or slum area the average household provides an atmosphere, physical and psychological, which is far from ideal for the development and unfolding of the child-mind; the function of the nursery school is to remedy this by providing for the "nurture" of the young child. At present nothing is done until the infant school claims the child at five, and Miss Macmillan thinks that this is too early an age for formal instruction, and makes out a strong case for the extension of nursery school training until the child reaches seven.

In the first chapters the author tells of her seven years' experience in Deptford; we learn with what appreciation and gratitude the mothers regard the work; we are shown how the material welfare and cleanliness of the children are cared for; the bathing, the feeding, the clothing, the breathing exercises, the afternoon sleep, are described, and we follow the "toddler" in the successive stages of his nurture until he becomes the seven-year old, differing from his brother of the well-to-do classes, we are told, only in his physical superiority and greater psychological advancement. The garden receives much attention, and Miss Macmillan's experience leads her to make an eloquent plea for open-air nursery schools. The second half of the

² *Cunningham's Manual of Practical Anatomy*. Revised and edited by Arthur Robinson. Seventh edition. Vol. I, Superior Extremity; Inferior Extremity. Edinburgh, Glasgow, and London: Henry Frowde, and Hodder and Stoughton, 1919. (Crown 8vo, pp. xxx + 451; 203 figures, many coloured. 12s. 6d. net.)

³ *Rest, Suggestion, and Other Therapeutic Measures in Nervous and Mental Diseases*. By Francis X. Dercum, A.M., M.D., Ph.D. Second edition. London: Kegan Paul, Trench, Trübner, and Co., Ltd. 1919. Med. 8vo, pp. ix + 395. 21s. net.)

⁴ *Archives of Neurology and Psychiatry*, January, 1919.

⁵ *The Nursery School*. By Margaret Macmillan. London: J. M. Dent and Sons. 1919. (Post 8vo, pp. 353; 16 illustrations. 7s. 6d. net.)

volume is chiefly devoted to the important question of the training of the teachers, and here the author's views, though founded on experience and clearly and decidedly expressed, will probably excite a good deal of contention.

This book is not written in the judicial manner of one who plans a textbook or frames a report, but is rather the work of a pioneer who seeks to inspire; its lack of strictly formal arrangement and the author's not infrequent digressions only serve to emphasize its purpose and mission, but it is a little irritating to find in Chapter xxviii nearly half a page of the text (p. 253) repeated, almost word for word, eight pages later.

NOTES ON BOOKS.

BOOKS ABOUT BABIES.

The Baby,⁶ by Dr. E. A. SAUNDERS, is a short and thoroughly practical little book on the care of infants, well paragraphed and printed, and very suitable for the study of nurses and mothers on the look-out for a sound elementary handbook dealing with the subject. Every circumstance of the feeding, clothing, airing, housing, and general supervision of the infant seems to have received the author's attention. The book is well written, and deserves success.

The sixteenth edition of *Our Baby*,⁷ by Mrs. LANGTON HEWER, provides mothers and nurses with an alternative handbook on the best ways of rearing infants and young children in a rational and scientific manner. The book has been before the public for thirty years, and really requires no other testimonial to its merits; it is full of practical and detailed advice, and undoubtedly deserves the success it has attained.

Mothercraft,⁸ a selection of twenty-six lectures on infant care delivered under the auspices of the National Association for the Prevention of Infant Mortality, is a volume for intelligent mothers, nurses, health visitors, members of infant care committees of all sorts, and general readers who wish to be well informed on prenatal and infant hygiene and the care of young children. It is in its third edition, and deals with every aspect of the prevention of infant mortality; the National Association is to be congratulated upon the excellence of these lectures, each written by a well known specialist in its subjects.

Dr. ROBINSON'S book on *Baby Welfare*⁹ is based on a series of lectures delivered at the Vincent Square Infants' Hospital, and is designed for the instruction of untrained nurses and mothers. Beginning with a brief account of the infant's anatomy and physiology, the author goes on to the subject of milk and its properties and adaptation to the needs of the child. The second half of the volume is given to the disorders of infancy and their general treatment. Dr. Robinson has succeeded in compressing a good deal of information and sound general advice into the book, which could be studied with advantage by well educated and thoughtful people; perhaps it would be found to try the intelligence of the average laywoman rather high.

The Baby's Food,¹⁰ by Professor ABT, is a collection of recipes for nurses and cooks who have to feed infants and children, based on the author's practice in America and culled from various pediatric manuals. It is intended for the use of mothers and nurses, and, if its directions are followed, should provide their charges with numerous delectable dishes.

The eighteenth edition of *Dr. Chauvass's Advice to a Mother*,¹¹ edited by Dr. LISTER, presents nurses and lay-

⁶ *The Baby*. By E. A. Saunders, M.A., M.B.Oxon., D.P.H.Oxon. London: Methuen and Co., Ltd. 1917. (Fcap. 8vo, pp. xi + 132; 15 figures. 1s. 3d. net.)

⁷ *Our Baby: For Mothers and Nurses*. By Mrs. J. Langton Hewer. Sixteenth edition, revised. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd.; Toronto: The Macmillan Company of Canada, Ltd. 1918. (Cr. 8vo, pp. 163, 2s. 6d. net.)

⁸ *Mothercraft*. Third edition, revised and enlarged. London: National League for Health, Maternity, and Child Welfare. 1919. (Cr. 8vo, pp. 324. 5s. net.)

⁹ *Baby Welfare: A Guide to its Acquisition and Maintenance*. By W. E. Robinson, M.D. London: T. Fisher Unwin, Ltd. 1918. (Fcap. 8vo, pp. xiv + 206. 7s. 6d. net.)

¹⁰ *The Baby's Food*. Recipes for the Preparation of Food for Infants and Children. By Isaac A. Abt, M.D., North-Western University Medical School. Philadelphia and London: W. B. Saunders Co., Ltd. 1917. (Demy 8vo, pp. 143. 6s. net.)

¹¹ *Chauvass's Advice to a Mother*. Eighteenth authorized edition, rearranged and rewritten by Thomas David Lister, M.D. London: J. and A. Churchill. 1920. (Cr. 8vo, pp. 336. 2s. 6d. net.)

women with a great deal of sensible advice about the care and ailments of infants and young children, and some good instruction on the hygiene and general management of older boys and girls. It is provided with an unusually good index, and may be commended to the attention of those who realize their need of a nursery manual.

ASSOCIATION OF PUBLIC VACCINATORS.

At the annual meeting of the Association of Public Vaccinators, held recently at Anderton's Hotel, London, when Dr. J. FOSTER PALMER, the President, was in the chair, the attendance was better than at any previous meeting since the war began in 1914. After formal business the financial statement, which was regarded as satisfactory under the circumstances, was adopted. It was stated that the decision of the extraordinary general meeting to increase the subscription had been favourably received by the members.

Dr. C. J. Palmer of Mansfield was, on the motion of Dr. A. E. COPE, unanimously elected president for the ensuing year.

On taking the chair, Dr. PALMER congratulated the Association on having obtained the Order of 1919 raising the minimum fee for vaccination. There still remained much to be accomplished in such matters as fixity of tenure and superannuation and the defence of vaccination. Endeavours in these directions would engage the constant attention of the association. The officers of the year were then re-elected, and three new members of the Council duly elected. Hearty votes of thanks were recorded to the editorial secretary (Dr. Arthur Drury) and the organizing secretary (Mr. Frank A. Briggs).

The Preparation of Calf Lymph.

Dr. H. S. FREMLIN, Assistant Pathologist, National Vaccine Establishment, Hendon, gave an address on the preparation of calf lymph for distribution. He described the difficulties which had been overcome and outlined the methods now in use. Great care was taken in the selection of calves. The animal, which must be perfectly healthy, was on arrival kept in quarantine and well away from those maturing vesicles. The process of vaccination of the calf, the variations in vesicles obtained, and the method of selection and collection of the resulting lymph were described. Experience had enabled the establishment to effect considerable improvements. Each calf was slaughtered after the collection of the lymph pulp and a certificate as to the condition of the carcass was sent to the establishment by the officer in charge. Next came the emulsion process previous to storage. A mixture usually four times the weight of the lymph was used; it consisted of:

Glycerin	50 per cent. by weight.
Water	50 per cent. by weight.
Clove oil	1 per thousand.

After numerous experiments Dr. Blaxhall had found this the most suitable vehicle for the purpose; it acted as a rapid eliminator of extraneous bacteria. The pulp was pounded in a sterile Chalybaus lymph machine and the mixture added, and an apparently homogeneous fluid obtained, to which bacteriological tests were applied. The method of storage was a matter of great importance. The length of time during which the lymph remained active depended greatly on the temperature at which it was kept. In 1898 this was not known, and consequently much of the lymph then circulated was found to produce negative results. This defect had been overcome. Each tube sent out was charged with about 30 mg. of the emulsion. Particulars of all calves were kept in a register, which showed also the lymph with which each calf was vaccinated. Every calf was given a number, as was also the lymph taken from each calf. This number was sent to each public vaccinator. Details were also kept in regard to each lymph, showing to whom it was distributed and the results obtained. During the ten years ending March 31st, 1919, public vaccinators had furnished the establishment with reports on 2,900,000 primary vaccinations with establishment lymph, and these showed a "case" success of 99.4 per cent. and an insertion success of 96.2 per cent.

A discussion followed, and Dr. Fremlin was cordially thanked for his instructive address.

OXFORD MEMORIAL TO SIR WILLIAM OSLER.

OSLER INSTITUTE OF GENERAL PATHOLOGY AND
PREVENTIVE MEDICINE.

THE meeting announced to be held in Oxford on March 6th to consider what steps should be taken to perpetuate there in some appropriate manner the memory of Sir William Osler was presided over by the VICE-CHANCELLOR (the President of Trinity College). It was attended by leading members of the University and representatives of the medical profession both in Oxford and London.

THE VICE-CHANCELLOR said that the meeting was held to show the respect and affection felt for the late Regius Professor of Medicine, not only by the University of Oxford, but by other universities on more than one continent and by the London hospitals. Osler's name would always be associated not merely with the history of the chair he occupied, but with its actual existence by reason of the generous benefaction, of which the speaker thought he was the first person to hear from Sir William Osler himself. Whether Osler's name would be associated with the future history of the School of Medicine in Oxford would depend upon the result of the meeting.

SIR CLIFFORD ALLBUTT, Regius Professor of Physic in the University of Cambridge and President of the British Medical Association, in proposing a resolution to the effect that the distinguished services of the late Sir William Osler were deserving of a permanent memorial in Oxford, said that it would be impossible to sum up what made the real charm of Osler's character, and he would present only one point of view, which was the universality of his experience and of his sympathies.

SIR HERBERT WARREN, in seconding, said that the most remarkable trait in Sir William Osler's character was the combination in an eminent degree of theory and practice.

THIS following resolution was then proposed by SIR WILLIAM CHURCH, Bt., formerly President of the Royal College of Physicians of London:

That in view of the intimate association of Sir William Osler's life work with the study of the origin and prevention of disease, the most appropriate form of memorial would be an Osler Institute of General Pathology and Preventive Medicine.

IN commending it to the meeting Sir William Church said that it would be fitting that some permanent memorial should exist in Oxford of one who had played so important a part in the life of the university.

Professor ARTHUR THOMSON, who seconded, said that an institution of the kind indicated in the proposal typified Osler's career, for he began life by studying the causes of disease and ended it as an ardent advocate of the means of preventing disease. The one depended on the other, and the proposed institution would typify that intimate and close association.

THE resolution was adopted, and, on the motion of the DEAN OF CHRIST CHURCH, seconded by Sir A. E. GARROD, Sir William Osler's successor to the chair of medicine, general and executive committees were appointed to issue an appeal. Professor GUNN, who is acting as interim secretary, said that he had been in communication with friends of Sir William Osler in America, and that a provisional committee had been appointed, consisting of Professors Welch (Baltimore), Harvey Cushing (Boston), Billings (Chicago), President Butler and Dr. Walter James (New York).

Among those who have expressed their sympathy with the proposal are the United States Ambassador, the British Ambassador to the United States, the High Commissioner for Canada, the President of the Royal College of Physicians of London (Sir Norman Moore), the Earl of Crawford, the Earl of Jersey, the Earl of Maclesfield, Viscount Harcourt, Lord Aberdare, Sir Donald MacAlister, Sir George Newman, Sir Walter Fletcher, Lieut.-General Sir John Goodwin, D.G.A.M.S., Sir Robert Hadfield, Sir William MacCormick, and the majority of the heads of houses in Oxford.

Communications may be addressed to Dr. J. A. Gunn, Professor of Pharmacology, The Museum, Oxford.

EIGHTY-EIGHTH ANNUAL MEETING

OF THE

British Medical Association, CAMBRIDGE, 1920.

WE print below the third of a series of historical and descriptive notes on Cambridge written for the benefit of members and guests attending the Annual Meeting of the British Medical Association to be held in Cambridge from June 29th to July 3rd, under the Presidency of Sir Clifford Allbutt, K.C.B., F.R.S. The first article, sketching the origin of the University and town, and describing the situation and climate of Cambridge, was printed in our issue of January 3rd, 1920, p. 17. The second article, on the development of the University, appeared on January 24th, p. 125. The fourth article will deal with the foundation of the professorships of anatomy and botany; and the history of these subjects, also of chemistry and physics, until the medical school was established on a satisfactory footing. Subsequent articles will be devoted to the medical school of to-day, and to the antiquities and architectural beauties of Cambridge and district.

EVOLUTION OF THE MEDICAL SCHOOL.

THE history of the Cambridge Medical School has not yet been written; it is therefore hoped that the following sketch, compiled from many sources, may be found interesting and may prompt some antiquary to write an adequate history of the school.

THE materials for construction of the history are scattered in many old records or their modern reprints, as well as in modern books and papers. For the great majority of references to documents from which this sketch has been compiled, we are indebted to the Rev. H. P. Stokes, LL.D., Litt.D., F.S.A., of Corpus Christi College, who by his researches and publications has contributed more than any man living to the history of Cambridge.

THE first hint of medical teaching is found in the thirteenth century, apparently between 1270 and 1279, when Nigel de Thornton, doctor of physic, bequeathed property to the university, including some buildings close to the Schools of Divinity and Law. Dr. Stokes suggests that among these buildings would be a medical lecture room.

IN early times the University conferred not only the degrees of M.B. and M.D., but also licences to practise surgery or medicine—"C.L." or "M.L."—which of course did not rank as degrees. An arts degree was always insisted on before the M.D. degree, nearly always before the M.B.; it was frequently taken by candidates for the M.L., much less so by candidates for the C.L.

FOR centuries the teaching consisted only of reading and exposition of theoretical works. The practice of medicine and surgery had to be learned by apprenticeship, and the student saw no hospital practice unless his master was attached to a hospital. Some of the medical students had learned the practice of the art beforehand, and came to the University to learn the theory and get a degree or licence. For a licence a very small knowledge of theory sufficed, the student being passed after oral examination on practical subjects and the production of evidence of practical instruction.

BY the Cambridge Statutes of 1396 the student of medicine after graduating in arts, was required to hear *once*, in the schools, the book of Johannicius Philaretus *De Pulsibus*, Theophilus *De Urinis*, the Antidotarium of Nicholas, with one of the books of Isaac (Israelita), whether *De Urinis*, *De Febris*, or *De Dietis Particularibus*, or *De Viatico*. He was required also to hear *twice* the works of Galen with their glosses or comments (known only by their Latin translation from the Arabic as the works of Tegnus Galienus¹), including his book of *Prognostics*, of *Aphorisms*, and *De Regimine*

¹ In passing through the Arabic the word *regimen*, the art of Galen, got mistaken for a part of his name, and the Latin translation of his works was known as "Liber Tezni Galieni." For further information on the early medical textbooks see lecture by Professor Alexander Macalister in the JOURNAL, October 22nd, 1904, p. 1094.

Acurorum. It was further required that he should read *cursorie*, within not less than three years of his readings in Arts, at least one book on the theory and another on the practice of medicine; that he should both oppose and respond in the schools of his faculty,¹ and should practise at least during one year; he was then admitted to his degree, after the usual deposition and forms.

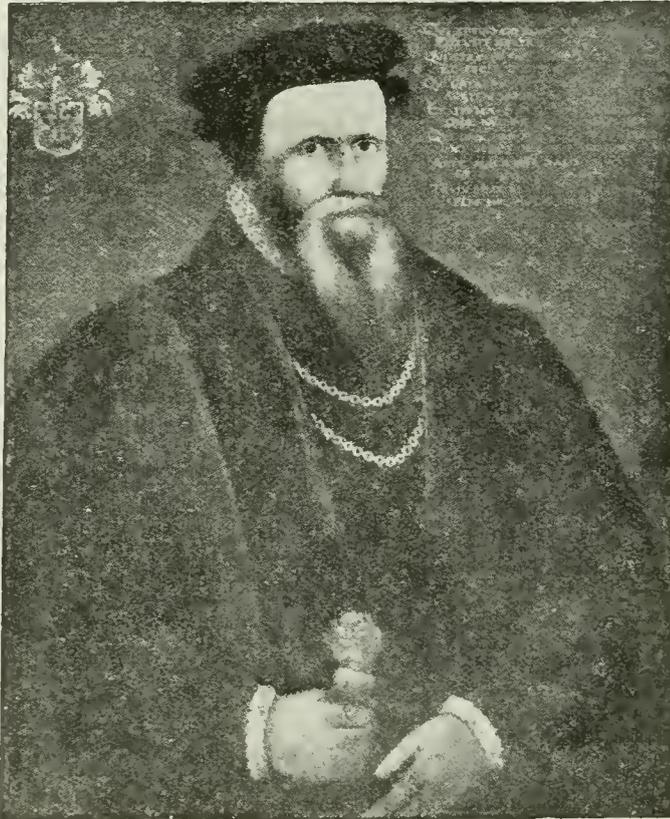

There is also an additional provision to the same statute, that no one shall be admitted *ad incipiendum in medicina*, unless he had practised medicine at least during two years, a condition apparently inconsistent with that which is contained within the body of the statute, though it is very possible that one might refer to the degree of Bachelor and the other to that of Doctor, or the distinction may be between licences and degrees.²

With all these and various other elaborate statutory provisions, the number of graduates and licentiates in early times was very small. This may be attributed to the almost total absence of practical teaching; there is no early record of dissection or of practical pharmacy with its adjuncts—botany and (in those days) alchemy. The town was not large enough to provide work for many apprentices, and there was no public hospital. The Hospital of St. John was a home for the aged and infirm rather than a sick-house, and the Starbridge Hospital was only for lepers, and therefore these institutions could provide only a limited field of study. The sick poor were treated in the several parish work-houses. But towards the end of the reign of Henry VIII there is a sudden increase in the numbers of licences and degrees conferred. This is possibly indirect evidence of the introduction of practical anatomy and other sciences.

In those days dissection, if done at all, must have been done secretly owing to popular prejudice; therefore it is no evidence, *pro* or *contra*, that there is no mention of it in the statutes of the University or the Colleges. But more enlightened times were approaching. In 1546 the King founded the Regius Professorship of Physic; and among the items proposed for the consideration of a Royal Commission in 1548, one was "To constitute a Medical College in some other fit place in the University" (after the foundation of a College of Civil Law) "by assigning one of the colleges for the study of medicine, and to make such of the fellows thereof as were willing to apply to that study and should be deemed fit, Fellows of the King's Medical College, and to transfer to other colleges those who were unwilling or should be considered unfit to follow that art, or to assign pensions to the Master or Fellows of such college."³

This scheme was not carried out; but the deficiency was met by the generosity of one of the great benefactors of English medical science, of whose life it is necessary to give an outline, for the better explanation of his work, influence, and bounty. John Keys, a native of Norwich, entered Gonville Hall in 1529, at the age of 19. There he latinized his name as Johannes Caius,⁴ graduated B.A. 1533, M.A. 1535, was elected Fellow in 1533. After studying classics and probably medicine in Cambridge, and becoming a very proficient Greek scholar, he went to Padua in 1539, and graduated there as M.D. in 1541. In 1543 he left Padua, visited Florence, Pisa, and other Italian towns, returning to England in 1544 or 1545. He was admitted Fellow of the College of Physicians in 1547, and practised in London for some years. Then in 1558 he refounded Gonville Hall under the name of Gonville and Caius College, making special provision for the pursuit of medicine by its students.

His reputation as a physician was great, but it is difficult

JOHANNES CAIUS, M.D. (DR JOHN KEYS).

to suppose that in the eleven years of his practice in London he made money enough to endow a college. Moreover, from 1529 to 1547, eighteen years, he was pursuing his education; and though he was receiving some payment as a scholar, and later as a Fellow, of what he calls "that pore howse" Gonville Hall, it seems improbable that this was sufficient to pay for his foreign travels and the books and manuscripts he bought. It is justifiable therefore to suppose that he inherited considerable property. His entrance to the university at the age of 19, four or five years above the usual age at that time, rather looks as if he had previously spent a few years assisting his father in some kind of business, from the profits of which he afterwards derived an income.

As a student at Padua he lodged in the same house with André Vesale (or Vesalius), with whom or from whom he acquired an enthusiasm for anatomy, though it is not certain that

he fully accepted the Vesalian innovations in the science. During his residence in London, and even before entering on medical practice, he gave lectures with practical demonstrations on anatomy at the hall of the Barber-Surgeons, who had a licence, by their original charter of 1540, to claim the bodies of four criminals annually for purposes of dissection.

In refounding his college he provided that two of the three new fellowships should be held by medical men. He also made elaborate arrangements for the study of anatomy, obtaining from Queen Elizabeth in 1564 a formal grant of bodies for dissection, to the effect that "they and their successors shall have for ever, at their free discretion and will, without the contradiction of anyone, two human

¹ This refers to the method of examination by questions and disputations in public. The term *opposal*, for a difficult question, was corrupted into *puzzle*. See Skoat's dictionary. *Cursorie legere*, Dr. Stokes informs us, was to read aloud in the schools the text of an author, with the customary glosses, but without comments of the reader's own.

² George Peacock, *On the Statutes of the University of Cambridge*, Appendix A, p. liii, footnote, in which other information on textbooks, etc., will be found.

³ Cooper's *Annals of Cambridge*.

⁴ His name occurs in ten different forms in the bursars' accounts of Gonville Hall; all the forms end with the sound of s. His college is always known as "Keys College," and the old spellings indicate that he was usually called Keys, in spite of his latinized name. But as the departure of English vowel sounds from the Continental type was not so complete in the sixteenth century as now, the names Keys and Caius were more nearly alike in his time. Key and quay were then pronounced *kay*; now both have degenerated into *kee*.

bodies for anatomy, condemned by law for theft or homicide, and dying in the town, castle, or county of Cambridge. And that they may freely dissect them at their will, with the reverence due to the human body, for the increase of medical knowledge; and this without any payment" (*Treasury*). He gave careful directions in his Statutes concerning these dissections, desiring that "every year, during the winter, there shall be spent by the students of our College, on anatomy and on the worthy burial of the dissected bodies at St. Michael's, 26s. 8d. The president and every one residing in college to attend the burial of the remains with as much respect and ceremony as if it were the body of some more dignified person; and this on account of the advantage they have thus received. And the master shall see that the students of medicine do not treat the body with any lack of respect or humanity.

Dr. Venn, from whose biography of Caius the above translation of the Latin statute is taken, expresses a fear that very inadequate use was made of this privilege. We take this opportunity to thank Dr. Venn for his courtesy in allowing us to make free use of his work in this outline of the life of Caius, and in particular for his permission to copy the portrait here presented. The biography will be found in the volume of the works of Caius, edited by John Venn, Sc.D., F.R.S., F.S.A., published by the Cambridge University Press.

Caius was admitted to the degree of M.D. at Cambridge, by incorporation from Padua, a few days after the opening of his new college. The master of the college dying a few months later, Caius was pressed by the Fellows and by other representative persons in Cambridge to undertake the mastership. He yielded unwillingly, refusing to accept a stipend or any other emoluments. He was master from January, 1558-9 until his death in 1573. His medical practice necessitated his spending much time away from Cambridge; but he did his duty conscientiously to the college, and continued to spend money upon it in building and in other ways.

His noble benefaction did not make as great an impression on the study of medicine as it deserved. It was a very long time before any thorough medical training was attempted. Students still sought their medical education at Padua, Montpellier, and other foreign universities, and, after graduating there in arts and medicine, were admitted to the Cambridge M.D. "by incorporation." But be it noted that in these cases Cambridge always insisted on graduation in arts, either at home or abroad. These incorporated doctors swell the list of graduates of Cambridge without adding much to her credit.

The first important result of the work of Caius was the attraction to his college of Harvey, who was followed about

twenty years later by Glisson. William Harvey graduated B.A. in 1597, and in the following year proceeded to Padua in search of the best medical education then obtainable. After graduating there as M.D. in 1602 he returned to England, was admitted to the degree of M.D. at Cambridge, and elected Fellow of the College of Physicians. Cambridge can only claim to have laid the foundation of his education. His interest in the circulation of the blood was awakened at Padua, and his researches on this and other subjects were carried on in his private laboratory in London.

But Glisson seems to have completed his education in England. He practised in Cambridge, and was Regius Professor of Physic from

1636 to 1677. Physic in those days included most of the subjects of medical study, and Glisson therefore taught, among other things, anatomy and the limited physiology of his day. So we find that by a Grace of the Cambridge Senate in 1646 the attendance at three dissections required by the University statutes (capp. 15, 17) as a qualification for M.D., and the attendance at two required from candidates for M.B., were revived, this exercise having fallen into disuse since the death of Caius.

During Glisson's professorship a great impetus was given to botany in Cambridge, and in England generally, by the work of John Ray, who was first a student of St. Catharine's Hall, then migrated to Trinity College, of which he became Fellow in 1649. He died in 1705.

Chemistry also became a popular study at Cambridge in the seventeenth century, but there is no record of lectures in the subject until, in the last twenty years of the century, it was successfully taught by a Veronese, John Francis Vigani. In 1702-3 his services were acknowledged by the University investing him with the title of Professor of Chemistry. Bentley, Master of Trinity College, soon after fitted

up for him a laboratory in the "lumber hole" eastward of Trinity Bowling Green.

Then experimental physics and physiology received an important impulse from the work of Stephen Hales, who became Fellow of Corpus Christi College (or Benet Hall) in 1703, and F.R.S. in 1718. He carried out remarkable experiments in his private "laboratory" in the College, also at Vigani's laboratory in Trinity College, and later during many years at his home at Teddington, of which parish he was incumbent. In later life he was admitted D.D. of Oxford. His chief publications were entitled: *Statical Experiments on the Sap in Vegetables*, and *An Attempt to Analyse the Air*, 1727, being vol. i of his *Statical Essays*; *Hydraulic and Hydrostatical Experiments on the Blood and Blood-vessels*; also the *Nature of Certain Concretions*, 1733, being vol. ii.

SATURDAY, MARCH 13TH, 1920.

ORGANIZATION OF IN-PATIENT TREATMENT.

THE future of hospitals and the need for extension of accommodation and the better organization of that already provided is very much before the public at present, and Lord Knutsford, with his happy knack of getting to the centre of the stage, has had a good "press" for his announcement that it is intended in future to ask in-patients at the London Hospital to contribute 10s. a week towards the cost of maintenance. Many correspondents, he announces, have asked him to set aside some of the wards for paying patients and make an adequate charge, but he declares this impossible, because all the thousand beds at the London Hospital are sorely needed by persons who could not pay even the moderate charges of a pay ward. But with that other knack of his, perhaps not quite so happy, which reminds us of the machine in the tube railways to keep the London Hospital going for one second, he has promptly produced a scheme for a paying hospital where there would be a "menu" of operations at inclusive charges done by a resident surgeon paid £1,000 a year. Lord Knutsford, in disclaiming any originality for this idea, assigns it to Mr. Danvers Power, but it is fairly old, and many attempts have been made to carry it out. The home for paying patients at St. Thomas's Hospital has been in existence for many years, and has done much useful work. The Home Hospitals Association also must not be forgotten, although the provision it makes is on a relatively small scale. A few weeks ago¹ we were able to give a description of St. Chad's Hospital at Birmingham, where a building was specially erected for the purpose, and the plan has been tested for five years. There 90 per cent. of the patients pay an inclusive weekly fee for accommodation, nursing, and all professional attendance. The difficulty created by the need for considerable capital expenditure to erect the buildings has been got over there, and could, we have no doubt, be got over elsewhere if the right people went about it in the right way. The need is undoubtedly great, but we hardly think that Lord Knutsford's plan of a £1,000 a year resident surgeon is going to meet the requirements of the public, even with the proviso that anyone requiring an operation outside the resident surgeon's skill should call in a specialist.

The British Medical Association, in its pamphlet on a Ministry of Health published a couple of years ago,² recognized the need for the full provision of consultative, specialist, or institutional services, and went on to point out that "the maintenance or establishment of the true relation between the patient and his chosen practitioner is essential to the best utilization of such additional services, and their proper development would encourage many general practitioners, as is very desirable, in the continued cultivation of skill in some branch of advanced or specialized

work or knowledge." Lord Dawson of Penn, in an address he gave at Birmingham a few weeks ago, said that hospitals must be more widely distributed and must be graded, a distinction being made between the primary institution, where a patient would be looked after by his own doctor, and the larger hospital to which he could be sent to be under the care of a staff of specialists when necessary. He asserted further that the present hospitals are not only insufficient in number, but are not performing the right functions, by which we understand him to mean that many of the large general hospitals are cumbered by cases which either from the first, or at the stage they have reached, could be as efficiently or more efficiently treated in less elaborate and expensive institutions. This belief, we think, is very widely entertained, perhaps more generally in the large provincial towns than in London. Lord Dawson referred to the importance from an economic standpoint of minor cases of injury or disease disabling for a time, but not dangerous to life nor calling for elaborate hospital treatment. It is obviously to the interests not only of the individual but of the community that the period of disability should not be lengthened owing to any want of skilled treatment; this was well exemplified during the war by the excellent results that followed immediate treatment of minor injuries to the eye in munition factories; the period of disability was reduced from weeks to days, with, obviously, a great diminution in the risk of serious complications.

There is another direction, however, in which the general hospitals might be relieved; it was well illustrated by the paper on "The Care of Crippled Children" contributed to our pages by Sir Robert Jones and Mr. Girdlestone last October. The treatment in such cases, the authors pointed out, is beyond the scope of the general hospitals, for it is impossible for them to provide the necessary conditions, which should include ample bed accommodation in open-air country hospitals. It is, they went on to say, characteristic of orthopaedic surgery that operation is often not an aim in itself, but one link in a chain of treatment, and that by early treatment operation may in many cases be avoided altogether. Somewhat similar considerations apply to a very considerable number of other classes of patients, including even many who, at the time of admission to the general hospital, are acutely ill, needing special treatment—perhaps operation and skilled nursing. The crisis passed, they ought to give place to the more serious or acute cases awaiting admission. It has therefore been proposed in several cities that the central general hospital should be linked with another institution in the outskirts of the town adequately equipped for after-treatment, and near enough to render it possible for the physician or surgeon who saw the patient through the acute stage to follow up and maintain continuity of treatment. The war has at least taught us that patients can be transported in properly appointed ambulances without immediate risk on the journey and with great eventual benefit to themselves by being nursed to recovery in more tranquil surroundings. We showed a fortnight ago that a scheme of this kind had made considerable progress at Cardiff, where the general hospital in the centre of the town has already been overbuilt on the site, and where an estate of five-and-twenty acres a few miles away has been acquired. As we have said, similar schemes, particulars of which we are not at liberty to give, are in contemplation, and we hope that this method of contributing to the solution of the hospital question will receive the full consideration it deserves.

PYREXIA OF UNCERTAIN ORIGIN AND ENTERIC FEVER.

THE Great War provided a rigorous test of the accuracy of bacteriological methods in their relation to the prevention, diagnosis, and to a lesser extent to the specific treatment, of infections of military importance. The remarkable success with which typhoid and paratyphoid fevers were prevented in the British army is generally admitted to be the most brilliant of the many medical achievements of the war. But in order that a due perspective may be maintained it is important to realize the gaps that still exist in our knowledge, and among the dark patches upon which light is greatly to be desired few are more important than the group of cases included under the label "P.U.O."

When attempting to ascertain the precise nature of the infection in a case of pyrexia of cryptic origin, no method is more satisfactory than the actual isolation and identification of the infective micro-organism from the blood, tissues, or excreta of the patient. Should these investigations fail, serology can sometimes be of material help, and in the case of fevers of the enteric group the presence in the blood serum of the patient of specific agglutinins for the typhoid bacillus or for those of paratyphoid A or B, the relative abundance of such agglutinin or agglutinins, and the fluctuation shown by them as time goes on, are points that have been insisted on by Professor Dreyer and others as of the utmost value in effecting a correct diagnosis.

In a recent report to the Medical Research Committee¹ Dr. W. W. C. Topley, Dr. S. G. Plates, and Dr. C. G. Imrie describe the result of their investigation of cases of pyrexia of uncertain origin invalided from the Western front between October, 1916, and January, 1919. The majority of the cases examined were under treatment in the wards of Charing Cross Hospital, but some were in the Ontario Military Hospital at Orpington, others in the Italian Hospital, and others in the Military Heart Hospital at Hampstead. The chief question investigated was the proportion, if any, of these cases actually suffering from enteric infection. Since bacteriological examination of the stools of 327 patients only yielded positive results with regard to bacteria of the enteric group in two cases, the investigation became perforce entirely serological, and it may be said that the elaborate care with which Dr. Topley and his colleagues set themselves to exclude errors in the diagnosis of enteric fever from the agglutinin index is worthy of all praise.

A study was made of the accuracy of the agglutination test when carried out according to Dreyer's technique, with special reference to the "reduction factor" and the "agglutinin unit" introduced by him for the purpose of obtaining accurate, uniform, and comparable records. Repeated estimations were made of the agglutinin titre of a large number of serums by this procedure, and the percentage of error determined. The agglutinability of standard cultures was compared against various serums with a view to ascertaining the accuracy of the reduction factor, and as a result of these observations the conclusion was reached that the complexity of the various strains in this group is too great to permit of constant quantitative results by this method. For that reason chiefly, but also because they are by no means persuaded that agglutinins are independent of certain other antibodies present in serum, Dr. Topley and his colleagues

prefer to record their results in terms of the dilution of serum which will produce a given result, rather than as agglutinin units.

An obvious source of error in an inquiry of this kind arises from the presence of "residual" agglutinin in the patient's serum, present as the result of previous inoculation with T.A.B. vaccine. It has been maintained by Dreyer and others that errors from this source can be excluded by making repeated observations and watching the fluctuation in the curve of agglutinin to the typhoid bacillus and to paratyphoid A and B respectively; the curve rising in the case of the particular organism infecting the patient, and subsequently falling. This matter accordingly was investigated, the effect of time and also of reinoculation being determined on the three agglutinins.

Having in this way prepared the ground and eliminated sources of error as far as possible, Dr. Topley and his colleagues made repeated examinations, usually at intervals of a week, of the serum of altogether 502 patients. The results obtained are fully recorded in tables attached to the report. A variation of 200 per cent. on the lowest reading was observed in 35 cases. After wisely considering all the other evidence available as well as the serological results, they conclude that out of 211 cases of atypical and undiagnosed pyrexia from the Western front examined by them agglutination tests pointed definitely to enteric infection in 10 cases, and more doubtfully to the same disease in 4 others. It would seem therefore that between 5 and 7 per cent. of the cases invalided from the Western front during the two and a half years in question with undiagnosed pyrexial illness were suffering from one or other of the enteric fevers. This proportion will strike most people as small; the etiology of P.U.O. has still to be adequately defined.

TUMOURS COMPLICATING PREGNANCY.

DR. HERBERT SPENCER'S Lettsomian lectures on tumours complicating pregnancy, labour, and the puerperium, the publication of which was concluded last week, form a characteristically valuable contribution to obstetrical and gynaecological literature, and one which, although dealing with rare conditions, should command the attention of practitioner and specialist alike. In them the profession is given the benefit of a considered statement of views that have ripened slowly in the light of a long and very full experience, and they possess all the soundness which such circumstances, combined with clear thinking, might be expected to bestow. His careful records and his habit of taking tracings of the size and situation of abdomino-pelvic tumours enabled him to present many illustrative cases in demonstrative detail. Indeed, this accuracy of record and the lengthy period over which his observations have extended in individual cases, are amongst the most valuable features of his review of the subject.

Fibroids are no rare complication of pregnancy and labour. Dr. Spencer estimates their frequency at one in a hundred and fifty cases, but in many their presence is entirely overlooked. With the exception of submucous tumours they do not, in his experience, tend particularly to produce abortion, although premature and also, curiously enough, post-mature—labour is not uncommon. Labour in a uterus with fibroids is often surprisingly simple and easy, and the main warning to be remembered is the danger of attempting to drag a child past an obstructing tumour by forceps or after version. Where operation is necessary Caesarean

¹ Medical Research Committee. Special Report Series, No. 48. A Report on the Probable Proportion of Enteric Infections among Undiagnosed Febrile Cases Invalided from the Western Front since October, 1916. H.M. Stationery Office. 1920. Pp. 88. Price 3s.

section at term, followed by hysterectomy, is generally the most advisable treatment. Incidentally it may be noted that Dr. Spencer lends the weight of his opinion to the view that fibroids are not so much a cause of sterility as is sterility a cause of fibroids.

Ovarian tumours, which formed the subject of the second lecture, are found to lead to abortion in 25 per cent. of the cases in which they complicate pregnancy. Dr. Spencer emphasized the value of pushing up the cyst out of the pelvis at the beginning of labour, and, once more, the risk of attempting forcible delivery past the tumour. Where laparotomy is necessary, complete dilatation of the cervix should first be secured, so that the child may be extracted with forceps while the ovariectomy is being finished and the patient is still under an anaesthetic. He pointed out also what has not previously emerged so clearly—namely, that the risk to the child is increased by operating during pregnancy, and that therefore operation should, if possible, be postponed until the child is at least viable.

The third lecture dealt with cancer of the cervix complicating pregnancy, labour, and the puerperium. The lecturer is dubious as to the part played either by lacerations or "erosions" of the cervix as etiological factors, and hazards the opinion that local venereal infection may prove to be a more adequate explanation of the fact that this condition is so predominantly an affection of parous rather than of nulliparous women. He related six cases of advanced pregnancy complicated by cancer of the cervix, which he had treated by high amputation of the cervix by the actual cautery with the extraordinarily proud result that three of the patients are alive and well after nineteen, twenty-two, and twenty-five years respectively. Unquestionably these results must give us reason to pause and think. The hopes based on the technique of Professor Wertheim, whose recent death the Vienna school is now mourning, have not been fulfilled, and throughout all gynaecological literature there is apparent a feeling almost of despair as to the powers of surgery in dealing with this particular form of cancer. Many gynaecologists have found in radium, either alone or in combination with hysterectomy—and here the lecturer's emphasis on the actual cautery as the instrument of amputation is to be noted—new promise of success. Recent reports from America contain a note of fresh and confident hope in regard to it. As yet, however, little systematized work on the problem has been done in this country, and it seems more than time that it should be undertaken. More and yet more radium should be obtained and made available at different large centres, where research on a definite plan could be instituted under the combined direction of competent physicists, pathologists, and operating gynaecologists and surgeons. Each of these points is essential, for not from more or less desultory work, controlled solely by the clinician or by the radiologist, can results be expected that will enable rapid and sure progress to be made. The matter is, indeed, a form of national debt, towards the extinction of which some of our wealthy philanthropists might well devote their attention and their means.

THE OXFORD MEMORIAL TO SIR WILLIAM OSLER.

The meeting held last Saturday in the University Museum, Oxford, under the chairmanship of the Vice-Chancellor, arrived at the appropriate decision that his memory should there be commemorated by the establishment of an Osler Institute of General Pathology and Preventive

Medicine. Professor Arthur Thomson justly said (p. 369) that an institute of this kind would typify Osler's life, beginning with the study of the causes of disease and winding up with increasing interest in prevention. Eloquent and sympathetic tributes were paid to the wide influence for good which Osler wielded—his unceasing and successful efforts to promote international amity, especially between America and this country, the wide range of his scientific and literary interests and attainments, his high ideals of the status and education of the medical profession, the unswerving optimism with which he looked back on the past and forward to the future, and, not least, the extraordinary charm and fascination of his own character, which laid under the spell of enduring friendship all those who were privileged to know him. It was unanimously felt that Osler was one of the "great men who mellow the whole age in which they live," and that it was just and salutary to do something, and something worthy, to carry down to future generations the fragrance of his memory and the brilliance of his achievements. To carry out the project a large sum of money will be required, but Oxford is in need of such an institute, and we do not doubt that the suggestion will thus make a double appeal—on the one hand to the multitude of friends that Osler gathered round him, and on the other to graduates of the university in all faculties. On the first head we are glad to learn that already some of the leaders of science and learning in the United States are forming a committee, and that a similar committee will shortly be established in Canada, where Osler began his career as a teacher of physiology, pathology, and clinical medicine. Oxford and its graduates all over the world are proud to have gained for their university the enthusiastic loyalty of one who had already earned his reputation as a great physician in Canada and the United States of America. The presence of the Vice-Chancellor in the chair and of many of the heads of colleges and other leading members of the university at the meeting last Saturday is evidence of this, and there are many other such evidences. The form the memorial is to take would have appealed to Osler himself; it will further the progress of two of his greatest interests in life. The building to be erected will in the first instance accommodate the University department of pathology, which is in need of expansion both for teaching and research. It is proposed that the present pathological laboratory shall be given over to pharmacology, now inadequately housed in temporary premises.

RARITY.

A VERY striking and rare condition is naturally prone to be reported relatively more often than a lesion of everyday occurrence. Accordingly confusion of at least two kinds may result: as the existence of such a condition is common knowledge, it is sometimes regarded as of common occurrence. On the other hand, a rare disease may come under the notice of several observers whose separate reports may go down to medical posterity as those of two or more distinct cases; thus a case of progressive myositis ossificans originally described by Dr. F. W. Burton-Fanning, subsequently visited most of the large London and some of the provincial hospitals, and accounts of this "brittle man" were published in two other medical papers and, it may be added, in the *Daily Mail* also. A case of hypernephroma with hirsuties, one of the earliest reported, in a girl aged 3 years, appears separately under the names of J. W. Ogle, W. H. Dickinson, and sometimes of H. Pitman, and so is apt to be counted twice or even thrice. References, too, have a knack of going wrong, and as a remarkable example of duplication in this way, Plass's¹ observation on the case of congenital obliteration of the oesophagus reported by C. K. Bowes

¹ E. D. Plass, *The Johns Hopkins Hospital Reports*, Baltimore, 1919, xviii, 259-286.

may be quoted. The title reads "By C. K. Bowes, Oxon.," and the Germans especially have taken the "Oxon." as the last name of the author, and by further corrupting it to "Axon" have created a place for it in their literature, so that frequent references are made to two cases, Bowes's and Axon's! In reporting a case of congenital atresia of the oesophagus associated with fused kidney, Plass has consulted and verified the references to 136 cases. The lesion consists of a cul-de-sac, representing the upper part of the oesophagus, and projecting from 1 to 5 cm. or more below the level of the larynx, while the lower part of the oesophagus is in communication below with the stomach and above with the trachea, just above the bifurcation. These two portions may or may not be connected by a thin strand of tissue; in 51 cases such a connexion was present, in 41 it was absent, and in 44 no note was made about its presence. Other anomalies are commonly present, the most frequent being atresia ani; among 94 cases in which the point was mentioned, 59 presented some anomaly, and atresia ani was present in 24. The developmental error occurs at a very early stage, and has been observed in a fetus 18 mm. long. The incidence in the sexes is equal, and the infant had usually been born at full term. The symptoms are asphyxiation due to nasal or pharyngeal mucus, choking attacks, prompt regurgitation of food, inflation of stomach with each respiration, breath sounds more audible than normal over the abdomen, and cyanosis which may be either constant or periodic; the urine, though passed as usual, becomes reduced to an extremely small amount after a few days. There is wasting, often accompanied by inanition fever, and life is never prolonged more than fourteen days. Gastrostomy in 16 cases and jejunostomy in one case have been unsuccessful, and the only hope of rational therapy lies in advances in intrathoracic surgery.

ETIOLOGY OF YELLOW FEVER.

In previous reports noted here Noguchi has shown that yellow fever patients in Guayaquil have a filterable organism, *Leptospira icteroides*, in their blood; that after recovery from an attack their blood serum agglutinates and dissolves this organism when introduced into the peritoneal cavity of a normal guinea-pig; and that the organism produces in some experimental animals the characteristic symptoms and lesions of yellow fever in man. For these and other reasons, the probability that *Leptospira icteroides* stands in causal relation to the yellow fever of Guayaquil is great. In his tenth paper Noguchi¹ records immunological experiments undertaken with the view of deciding the relation between *Leptospira icteroides* and *Leptospira icterohaemorrhagiae*, the causal organism of spirochaetosis icterohaemorrhagica. The serums of animals immunized against single and also against several strains of these two organisms respectively showed a high titre of neutralizing power for cultures of the homologous groups; but the action of the serums was not absolutely specific, for injection of a sufficient amount of the anti-icteroid serum apparently prevented a fatal outcome in a guinea-pig inoculated with multiple minimum lethal doses of a culture of *Leptospira haemorrhagiae* and *vice versa*. More or less (though not absolute) specificity was shown also by the complement fixation reaction. On the other hand, guinea-pigs infected with *L. icteroides* may after recovery resist a subsequent inoculation with a virulent strain of *L. icterohaemorrhagiae*. It appears, then, that these two organisms, though closely allied, are distinct in their immunological reactions, the difference perhaps amounting to that between subspecies or races. Their pathogenic action also is somewhat different, inasmuch as *L. icteroides* produces chiefly jaundice and nephritis, and *L. icterohaemorrhagiae* haemorrhage and nephritis. In a further

paper² Noguchi states that a multivalent anti-icteroid serum of high potency when given to guinea-pigs infected with *Leptospira icteroides* checked the progress of the disease; when administered intraperitoneally during the period of incubation it completely prevented its development, although subsequent examination of the guinea-pig when killed after recovery showed haemorrhagic lesions in the lungs; when given early in the course of the disease the fatal outcome was prevented, but when administered several days after the onset of jaundice and nephritis, the serum did not exert any beneficial effect; it appears probable that the serum would fail also in human yellow fever when the stage of multiple haemorrhages, cholaemia, and uraemia has been reached. In a clinical report on about 70 cases of yellow fever at Guayaquil by another member of the Rockefeller Commission—C. A. Elliott³—it is pointed out that although the mosquito has been regarded as the chief, if not the only, means of transmission of the disease, other means, such as direct transdermal infection, seem possible, in view of the apparent similarity between yellow fever and spirochaetosis icterohaemorrhagica. That many patients go habitually bare-footed; and that Noguchi produced the disease in experimental animals by inoculations through the unbroken skin, would seem to support this hypothesis.

THE PHYSIOLOGICAL ACTION OF INTRAVENOUS INJECTIONS.

In a recent number of *Le Monde Medical* (No. 560, p. 327) Dr. Laumonier discusses the effects of intravenous injections in general. The first and most salient feature is that the results, from a reactional point of view, are much the same whatever be the substance injected, whether of animal or vegetable or even of mineral origin—namely, shivering and a rise of temperature coinciding with more or less intense leucocytosis followed by a sweating stage, a fall of temperature, and copious diuresis. These symptoms are the same whether the vein be injected with an isotonic solution of sugar or with a metal in a state of fine division—for example, in a colloid state, with serum or plasma, with emulsions of living or dead bacilli, or with red corpuscles—and the therapeutical results, as manifested by an improvement of the patient's state, are similar. We are at liberty to infer that the reaction is not special to the substance injected, but is a protest on the part of the organism against the sudden introduction into the circulation of a heterogeneous something. Now the very fact that the organism reacts and resents the foreign invasion shows that it is in good posture for combating the septic or other pathogenic germ that has gained a footing in the tissues, and by refurbishing up its defences against the one it enhances its defensive powers towards the other. The more pronounced the reaction after intravenous injections of the colloid metals, for instance, the more hopeful the prognosis. This being so, it may be argued that the reaction merely demonstrates the integrity of the means of organic defence without our having exerted any influence in creating or maintaining the latter. More or less intense leucocytosis, corresponding to an increase of white corpuscles from 5,000 or 7,000 to 25,000, is the constant and no doubt the efficacious consequence of the intravenous injection. There is no uniformity in this respect, and the substance which proves most leucogenous in one case may be less so in another, so that when a first injection fails to determine the desired reaction the substitution of some other substance may be attended by more satisfactory results. The fact that the therapeutical results are consequent upon reactions common to all intravenous injections proves pretty clearly that the reaction is not in any sense specific, and this may explain why various substances have been recommended in the

¹ H. Noguchi, *Journ. Exper. Med.*, 1920, xxxi, pp. 135-158.

² *Ibid.*, pp. 159-168.

C. A. Elliott, *Arch. Int. Med.*, Chicago, 1920, xxv, 174.

treatment of a particular disease, and why one substance can be employed for all kinds of infection irrespective of their nature.

TREATMENT OF PERITONITIS.

In a recent paper¹ Crile has outlined the treatment of peritoneal infection as carried out in his clinic. He believes that the general symptoms of peritonitis (rapid pulse and respiration, raised blood pressure, and heightened temperature) are due to blood acidosis. The local symptoms (pain, rigidity, etc.) are the sign of the effort of the organism to prevent the spread of infection by securing immobility. Crile is as insistent a believer as ever in his anoci-association theory, and adheres to his old technique. The war has amply proved the almost unassailable brief that he holds for gas and oxygen anaesthesia. He has fought a good fight on this point. As regards local infiltration in the anaesthetized subject, there are grounds for thinking that he can have but few true disciples to-day. The time taken in anaesthetizing the incision is too long to make it a very practicable step. Exponents of the art have been seen cutting as fast as ever their assistants can inject the novocain or procain solution—apparently in blissful ignorance that these drugs need several minutes in which to act as anaesthetizing agents. Such methods are a travesty of the practice of anoci-association. Crile's after-treatment of peritonitis is interesting; it consists of vast hot packs over the entire abdomen spreading well down over the sides; injection of 5 per cent. sodium bicarbonate and 5 per cent. glucose solution into the rectum as long as tolerated; gastric lavage if vomiting continues; the subcutaneous injection of 2,500 to 3,000 c.c.m. saline solution every twenty-four hours till danger is past; and morphine by hypodermic injection until the respiration falls to 10 or 14 a minute. With this last point in treatment many will probably disagree. There is no definite dose; the drug is administered frequently until the respirations fall. It needs some courage in its application, but seems to act well in all save streptococcal cases. If the proof of the pudding is in the eating, Crile's recipe is the best yet made known, for at Cleveland they have treated 409 consecutive cases of acute appendicitis, with and without general peritonitis, without a death. He remarks that they have reduced their mortality by 67.6 per cent. for acute appendicitis alone. This was presumably their original mortality, but if so it was unduly high.

MANICURE INFECTION.

A serious indictment of manicure has lately been published by Körbl,² a Viennese surgeon, who has observed no fewer than 32 cases of infection, some very alarming, resulting from this practice. In most of his cases the infection led to severe inflammation, requiring prolonged treatment, and produced more or less serious functional disturbance. Most of his patients did not consult him till conservative treatment had failed, and even free incisions had proved incapable of limiting the disease. The history of these cases, and the observations he had the opportunity of making in early cases, convinced Körbl that in practically every case the disease began as a cutaneous whitlow. In three cases it began in the finger-tips; in all the others it began in the tissues near the nail. It is pointed out that every step in the practice of manicure is liable to produce infection. First the protecting epidermis is opened, and the thin film connecting the base of the nail with the skin is incised and trimmed. Then, in the act of polishing the nail with pastes and powders, micro-organisms which have gained access to the subcutaneous tissues are securely soiled in. Finally, the manicurist massages and polishes the nail, driving the infectious material deeper into the lymphatic system. Examination of the pus showed that the staphylococci usually associated with whitlow were seldom present; in most cases the infection was mixed. The most preva-

lent micro organisms were streptococci, and anaerobic bacilli; colon bacilli, as well as influenza bacilli, were also comparatively common. In four cases, three of which developed erysipelas, streptococci were found in pure culture. Infection may occur either during the manicuring or afterward. Of the two, primary infection is thought to be by far the most important. In a family of four persons, all under his treatment, the patients had used the same manicure instruments, but only in nine of his cases had the patients manicured themselves; all the others, including the three patients with erysipelas, had been treated by professional manicurists. All three patients were Hungarian merchants staying at a hotel where they were manicured in turn by the same person. No cultures could be obtained from the instruments used (they had probably been cleaned with alcohol), but the paste employed yielded pure cultures of streptococci. Körbl, who observes that the popularity of manicure has increased enormously, concludes his case against it with a reference to the possibilities of the conveyance of tuberculosis and syphilis to the devotees of this rite.

CONVALESCENT HOME FOR PROFESSIONAL CLASS CHILDREN.

THE Convalescent Home for Children, established at Broadstairs some years ago by Sir Alfred Yarrow, was taken over as a military hospital during the war, but has now been restored to its original purpose, which is to help the children of professional and well educated people whose means will not allow them without assistance to give their children the change of air needed on recovering from illness. The youngest children received are 4 years of age; boys continue to be eligible until the age of 12 and girls until the age of 14. The usual period of residence is four weeks, but may be extended on the advice of the medical officer of the home. Two wards—one for boys and one for girls—are set apart for the reception of a limited number of cases more serious than are usually admitted to a convalescent home, and to these a lengthy stay in exceptional cases is granted. Children suffering from pulmonary tuberculosis, advanced heart disease, or from incurable complaints or liable to fits are not eligible. Nor can children be admitted who have within a recent period suffered from scarlet fever, ringworm, or any other infectious or contagious disease, or who have been in homes or schools where such diseases exist or have existed within four weeks. The contribution made by the parents of the child is 15s. a week. An efficient new nursing and domestic staff has been got together, and the whole home will be working to its full capacity very shortly. It stands in beautiful grounds close to and facing the sea; it is open all the year round, being well adapted for winter as well as for summer residence. The London offices, at 6, Holborn Viaduct, E.C.1, are in charge of a former matron of the home, and full particulars will be supplied on application to the Secretary. Yarrow Home appears to us to meet the needs of classes who are suffering through the present high cost of living, and we believe that the advantages it offers have only to be more fully understood by the medical profession for it to be constantly full, and even tempt the generous founder to enlarge it.

THE MAUDSLEY COURSES IN MEDICAL PSYCHOLOGY.

THE final arrangements for the courses of lectures and demonstrations at the Maudsley Mental Hospital, Denmark Hill, S.E., of which some particulars have already been given, are now being completed. It is intended that the lectures and demonstrations shall be given in the afternoon between 2 and 5; the final arrangements will be announced shortly. The course will consist of two parts: Part I will be conducted by Sir Frederick Mott, Dr. F. Golla, and Dr. J. V. Lowson. Sir Frederick Mott will give twelve lectures on the anatomy of the nervous system,

¹ *Journ. Amer. Med. Assoc.*, 1919, 73, 1655.

² *Wien. Klin. Woch.*, February 5th, 1920.

followed by practical instruction and demonstrations occupying eight sessions of two hours each. Dr. Golla will give twelve lectures on the physiology of the nervous system, accompanied by demonstrations in practical physiology intended to put students in possession of methods employed in minor research work in mental diseases; they will occupy ten sessions. Similarly Dr. Lawson, who is demonstrator of psychology in the University of Cambridge, will give ten lectures on psychology and eight sessions of practical work and demonstrations in the subject. Part II will consist of a series of lectures and demonstrations by several other authorities. Thus Dr. Hubert Bond will give twelve lectures on the diagnosis, prognosis, and treatment of mental diseases, followed by demonstrations of clinical cases by the medical superintendents of the London County Council mental hospitals and the medical officers of the Maudsley Hospital. Sir H. Bryan Donkin will give two lectures on crime and responsibility; Dr. F. C. Shruballs two lectures, with demonstrations of cases, illustrating the practical aspect of mental deficiency; Dr. William MacDougall will give eight lectures on the psychology of conduct, and Dr. Bernard Hart six on the psycho-neuroses. In this part of the course Sir Frederick Mott will give six lectures with demonstrations on the pathology of mental diseases, including the symptoms and treatment of brain syphilis, and, in association with Dr. Golla, twelve clinical demonstrations in neurology. Further information and full prospectus can be obtained on application to the Secretary of the Fellowship of Medicine and Post-Graduate Medical Association, 1, Wimpole Street, W., or to the Asylms Officer, 13, Arundel Street, Strand, W.C.2. The fee for Part I or Part II separately is ten guineas each; for both parts fifteen guineas. The course has been arranged to meet the requirements for the Cambridge diploma in psychological medicine.

THE GENEVA RED CROSS CONGRESS.

THE first general council meeting of the League of Red Cross Societies opened in Geneva on Tuesday, March 2nd, and closed on March 9th. The proceedings began with a general assembly of the delegates at the Hôtel de Ville, followed by the inaugural meeting. The various sections met in the mornings and afternoons for detailed discussion of their separate subjects. In the evenings there were receptions of the delegates by the chairman of the Board of Governors, Mr. Henry P. Davison; by the Director-General, Sir David Henderson; by the Secretary-General, Professor Rappard; by the city and canton of Geneva, and by the International Red Cross Committee. A general meeting open to the public was held on Sunday evening under the presidency of M. Motta, President of the Swiss Confederation, when M. Georges Milsom gave a lecture on the origin, organization, and purpose of the League. The British delegates attending the Congress were the Hon. Sir Arthur Stanley, Sir Robert Philip, P.R.C.P. Edin., Dr. F. N. Kay Menzies, Sir Arthur Lawley, and Mr. Baddeley. On February 16th the Secretary-General of the League of Nations, Sir Eric Drummond, addressed a letter to the Director-General of the League of Red Cross Societies, expressing his council's lively interest in the forthcoming meeting, and welcoming the idea of the closest co-operation in the future between the two leagues. It will be recalled that under Article 25 of the Covenant the members of the League of Nations agreed "to encourage and promote the establishment and co-operation of duly authorized, voluntary, national Red Cross organizations." During the congress a letter was received from Mr. Balfour, President of the Council of the League of Nations, appealing for the organization of an effort to relieve the terrible distress in Central and Eastern Europe. It was decided to formulate plans for extension of voluntary relief upon receipt of an assurance from the League of Nations that food, clothing, and transport would be furnished to the afflicted peoples.

SIR GEORGE MAKINS, G.C.M.G., C.B., President of the Royal College of Surgeons of England and Consulting Surgeon to St. Thomas's Hospital, has become President of the Fellowship of Medicine and Post-Graduate Medical Association, in succession to the late Sir William Osler.

Medical Notes in Parliament.

Hospital Provision in the Future.

LIEUT.-COLONEL FREMANTLE asked, on March 3rd, whether the Minister of Health was aware that the present uncertainty as to the future utilization of existing Poor Law infirmaries was hampering boards of guardians in their endeavours to make adequate provision for the needs of the sick, either by way of extension or improvement of their institutions; whether, in the interests of an early reorganization of health services, he would inform boards of guardians what was the policy of the Ministry with regard to these particular institutions, and the use to which they were destined to be put under the new scheme of health services which was contemplated; and whether the Minister was aware that the various health authorities in London and boards of guardians were particularly handicapped in making proper institutional provision for tuberculous persons owing to the failure of the Ministry as yet to carry into effect the declared policy of the Government with regard to the Poor Law. Dr. Addison replied that he was aware of the matters stated, but they involved questions of local government and other subjects of the first importance that could be dealt with only by legislation; and it was obviously necessary that he should lay proposals before Parliament and obtain its sanction thereto before he could properly adopt towards local bodies the attitudes suggested in the question.

Mr. Briant asked if the Minister of Health would take steps to co-ordinate the work of the Poor Law infirmaries and voluntary hospitals, so that persons requiring treatment should be sent direct to the most suitable institution, and should thus be saved the delay and danger of seeking admission at two or more institutions before obtaining the necessary treatment. Dr. Addison replied that he was aware of the case which Mr. Briant had in mind, and he would consider the question; but he had no jurisdiction over voluntary hospitals. Mr. Briant asked whether Dr. Addison did not realize that no effective medical administration in the country could be obtained if he did not draw a distinction between Poor Law infirmaries and hospitals. Dr. Addison responded that he was not quite sure that any effective administration would maintain that distinction. Mr. Briant invited Dr. Addison to introduce legislation to make it effective. The latter replied that no one was better acquainted with the complications of the subject than Mr. Briant.

Colonel Newman asked whether the Minister was aware that, owing to heavy taxation and the increase in the cost of living, large numbers of the middle class were unable to afford the expense of treatment and nursing in their own homes; whether he was aware that they were unable and unwilling to obtain admission to and further overcrowd the large hospitals maintained by voluntary contribution for the pre-war poorer classes of the community; and what action he proposed to take to meet their necessities. Dr. Addison said he was fully aware of the pressure upon the voluntary hospitals. The general question of the provision of hospital treatment had for some time been engaging the attention of the Medical Consultative Council, from whom he was expecting a report shortly.

The Revised Service Pensions.

The Government decisions on the second special report from the Select Committee on Pensions were announced, on March 4th, by Sir L. Worthington-Evans in a written answer of much detail to questions addressed by several members. This reply is given in full in Hausard of the date named, but cannot be understood without reference to the report already mentioned, which has been issued as a White Paper from the Stationery Office.¹

The Government has accepted the majority of the forty-nine recommendations made by the Committee. The estimated cost of the committee's recommendations, including the continuance of the 20 per cent. bonus, would have been £3,000,000. The estimated cost of the improve-

¹ Parliamentary paper 247. H.M. Stationery Office. Price 3s.

ments accepted by the Government is £1,900,000. In particular it has accepted the whole of the recommendations as to the disability scales of pay of regular and temporary officers, contained in paragraphs 16 to 27 of the report. There were two methods by which a scale could be constructed where allowance was to be given both for service and rank, and for disability: (1) a service-and-rank scale, with additions for disablement, or (2) a disablement-and-rank scale, with additions for service. Broadly speaking, the first method was adopted in 1917, and the departmental committee hold that the existing scheme is appropriate and equitable; but they reviewed it to advise various alterations and alternatives providing for composite rates, and in some cases large additions to the scale. The recommendations with regard to officers' widows' pensions and allowances for children have been accepted with slight modifications. It is pointed out that officers and their dependants need not apply to the Ministry for the increased rates of retired pay or pension. The work of reassessment will be carried through as rapidly as possible, and payment will be made as from April 1st, with arrears from that date.

The suggested increases for matrons and nurses are approved. Proposals made to the Treasury on behalf of the Special Grants Committee that aid may be given where a service nurse's relatives are dependent on her for support are approved. It is agreed also that if existing powers under the Dispensing Warrant for dealing with civilian nurses disabled on war service are insufficient further consideration will be given to cases of hardship. The question of compensation to the general service section V.A.D.—that is, to women engaged on ancillary duties—will be considered by the War Office.

Part 3 of the report—dealing with treatment and training—has been referred to the Ministry of Labour. It raises the question of providing more buildings and land quickly by Government purchase.

National Insurance Arbitration.

In reply to Sir Philip Magnus, on March 8th, the Minister of Health stated the result of the arbitration on the rate of remuneration (reported in the SUPPLEMENT this week). Proposals, he said, would be submitted to Parliament in due course to give effect to the finding. The utmost goodwill existed on both sides, and he expressed sincere appreciation of the impartiality and services of the arbitrators.

Insurance Practices.—Major Prescott asked the Minister of Health, on March 3rd, when the Regulations 16, I.C. of the Government Insurance Act came into operation, medical panel practitioners would be deprived of the advantage of the capital values of their practice; whether a promise was given in 1913 to the effect that such an interest would be assured to the medical practitioner; whether panel practitioners were apprehensive of the effect of these regulations upon the disposal of their practices, and if so, would he take into consideration the expediency of reviewing the situation? Dr. Addison replied that he was not aware that any promise had been given in 1913 or, indeed, any time of the character indicated in the question. He was aware that some insurance practitioners were apprehensive—unnecessarily so—of the effect of the Regulations referred to, and he was sending Major Prescott a copy of a reply he had addressed to representations made to him on the subject on behalf of the Conference of Panel Committees.

Work of the Ministry of Health.—On a supplementary vote of token value for the Ministry of Health, on March 9th, Dr. Addison gave a short review of the work of the Ministry of Health. During demobilization Great Britain, like other countries, had been exposed to the risk of the introduction of diseases rampant in some of the famine districts in Europe, and it appeared that the Port Sanitary Authorities, owing to lack of funds, were unable to provide the necessary staff and apparatus. The scheme proposed would authorize the Ministry of Health to contribute 50 per cent.—probably a total of several thousand pounds—in next year's vote towards the approved expenditure of Port Sanitary Authorities for the purpose indicated. The Ministry had been encouraging the employment of nurses and health visitors at child welfare centres. During the past year 400 additional centres had been set up, and he hoped many more would be provided during the next financial year. Midwifery centres also were being extended, and additional midwifery services had been provided for populations of 200,000, and fifty additional maternity homes had also been established. The infant mortality rate last year was 93 per 1,000—the lowest on record. Turning to medical service under the Insurance Act, he said that medical men recognized that many patients were not getting good enough services, and the profession had heartily co-operated with the Ministry in seeking to attain a standard which would make it certain that insured persons would get as good treatment as ordinary patients. In conclusion, Dr. Addison referred with pleasure to the intended appointment of medical referees and consultants.

Small-pox in East London.—Sir Alfred Yeo asked the Minister of Health, on March 4th, what steps he proposed to take with

regard to the serious state of affairs in connexion with the Government stores being dumped at Bell Wharf, Bromley-by-Bow, E., and the reported death of one woman working in the wharf and the isolation of five other persons from the same place, one of whom was in the service of the medical officer of health of the Poplar Council, and what steps he proposed to take to rid the neighbourhood of the cause of the outbreak. Dr. Addison replied that the Minister, in conjunction with the sanitary authorities, had been taking active steps for some time past in endeavouring to check the spread of infection from the different centres to which it had been traced from the source indicated amongst the population largely unvaccinated. The value of the stores dumped was about £250,000. The small-pox had now spread to various other places in the district. Burning it up would not remove the danger.

The Inspection of Dairies.—Lieut.-Colonel Fremantle inquired, on March 3rd, on what date the Milk and Dairies Consolidation Act, 1915, and the Tuberculosis Order of 1913 should come into force; and whether under both the Acts and the Order whole-time veterinary surgeons were to be appointed to carry out the requisite inspections. Dr. Addison said that the question of the appointment of whole-time veterinary officers was under consideration in connexion with the bill which it was proposed to introduce to amend the Milk and Dairies Act before bringing that Act into operation. The part of the question relating to the Tuberculosis Order should be addressed to the Ministry of Agriculture and Fisheries. Operations must be delayed until the modifications proposed in the new bill are in force. Lieut.-Colonel Fremantle: Is there any chance of the bill being brought in this session? Dr. Addison: Yes, I hope so.

Death Rate of Illegitimate Infants.—Dr. Addison, asked on March 3rd by Mr. Raper whether the death rate of illegitimate children was double that of other children, stated that the death rate of children under one year of age during 1913 was 91 per 1,000 in the case of legitimate children, and 186 in the case of illegitimate.

Government Lymph.—In a written answer to Mr. R. Young, Dr. Addison, on March 4th, said he was not aware that a sample of calf lymph submitted to the Wassermann test had given a strong syphilitic reaction; he would be glad if the hon. member would give him full particulars of the case referred to.

Retired Surgeon Commanders.—Sir C. Kinloch-Cooke asked, on March 3rd, whether the First Lord of the Admiralty was aware that some twenty-five surgeon commanders (fleet surgeons) had been placed on the retired list after reaching the ages of 55, or completing thirty years' service, and notwithstanding that many of them were called up in August, 1914, and had served throughout the war, some as surgeon captains, their retired pension was only 10 per cent. higher than the rate fixed for surgeon commanders forty years ago; and whether the First Lord would consider the possibility of increasing the pensions as had been done in the case of officers in other branches of the service. Mr. Long replied that a number of surgeon commanders (fleet surgeons) who retired before the war on reaching the age of 55, or on completing thirty years' service, were called up during the war and served in the rank they held on the retired list, whether surgeon captain or surgeon commander. The exact number could not, however, be ascertained without examining each case separately. While re-employed, such officers received, in addition to the full pay and allowances of their rank, a bonus of 25 per cent. of their full pay, in lieu of counting the additional time served towards increase of retired pay. Under these conditions of service, they would not have been entitled to increase of retired pay; but, in accordance with the general arrangement made in the case of retired officers, who served in a service capacity during the war, their retired pay was reassessed on the new scale at the rates applicable to their age and rank at the date they originally retired. In the majority of cases the rate of retired pay was thus raised from £547 10s. to £500 per annum. The procedure adopted in reassessing the rates of retired pay of surgeon commanders called up for service in the war had been exactly the same as that adopted in the case of officers in other branches called up for service. It was true that the increase of retired pay was proportionately not so great in the case of the surgeon commanders in question as in the case of certain other ranks, but some dissimilarity in this respect was inherent in any scheme which was framed to put the different branches of the Naval Service as far as possible on the same basis.

National Service Medical Board.—Mr. Doyle, on March 3rd, asked the Minister of Health what action he proposed to take on the report of the National Service Medical Board, analysed in our issue of last week (p. 331) on the physical examination of men of military age in the year ended October 31st, 1918. Dr. Addison replied that it was quite impossible to set out within the limits of a reply to a parliamentary question the very large variety of ways in which the causes and the treatment of diseases were being taken up. The number of houses for which the acceptance of tenders had been approved had increased during the last three months from about 12,000 to about 60,000.

Pensions Medical Officers' Salary.—In reply to Captain Loseby, Sir L. Worthington-Evans said, on March 4th, that the salaries of all medical officers who had been duly appointed to the staff of the Ministry of Pensions were punctually paid at the end of each month. In some cases there had been delay in the formal appointment of medical officers who had taken up duty in advance of appointment, and were thus temporarily without pay. He was making inquiry into this.

England and Wales.

HEALTH OF LIVERPOOL.

THE Medical Officer of Health for Liverpool, Dr. Hope, considers that the Registrar-General's estimate of the population of the city, based on the last decennial census, is at least 70,000 below the real number. He goes on to express the opinion that a quinquennial census would be much more satisfactory from a public health point of view. Dr. Hope's return for the same week was 24.7 per 1,000 as compared with the Registrar-General's figure, 27.2. Measles is unfortunately prevalent in the city, and many of the patients are infants of 12 months old, whose removal from the mother to the hospital might endanger their recovery. The hospital accommodation is not sufficient to meet the requirements. Last week there were 842 cases of measles, and the previous week 720.

THE SPECIAL NEUROLOGICAL BOARD, LANCASTER GATE.

At a dinner held in the Great Central Hotel on February 28th Dr. W. A. Brend was the recipient of a presentation consisting of an inscribed album, a silver rose-bowl, and a complete edition of *Pepys's Diary*, from over sixty past and present members of the Special Neurological Board and Clinic. In making the presentation the Chairman (Dr. Muirhead Martin) expressed the personal regard of the staff for Dr. Brend and their admiration of his work during the term of his presidency of the board, now brought to a close by his appointment as Neurological D.C.M.S. for the London Region. Dr. Brend, in reply, referred to the difficulties overcome before the board attained its present influential position, and commented on the growing importance of its treatment branch and clinic in the development of psychotherapy. Dr. H. E. Davison, who succeeds to the post of President, was also a guest, and the other speakers were Drs. Charlton Briscoe, P. Bousfield, Danvers-Atkinson, Drucau, David Forsyth, Laing Gordon, and Travers-Smith.

MEDICAL STAFF OF THE LONDON COUNTY COUNCIL.

It was reported to the London County Council on March 2nd that the present medical staff of the Public Health Department was insufficient to meet the growing requirements of the work. It is proposed to have for the general work nine instead of seven divisional medical officers. Five of these nine will be in charge of the five geographical divisions, and the other four will be in charge of special departments of work—namely, one in the bacteriological laboratory in connexion with infectious diseases; another in connexion with venereal diseases, infant life protection, midwives, and lying-in homes; a third on tuberculosis work; and a fourth on special school medical work (treatment of ear cases). The special staff engaged on school medical work is also to be increased by creating eight whole-time officers in place of seven part-time ones. The salaries of the divisional medical officers are to be readjusted. The maximum will be £700 a year instead of £600; this increase is to take effect from January 1st, 1920. These figures are on the pre-war basis; with the temporary additions or war bonus the annual remuneration will be £650 to £875.

THE HOSPITAL QUESTION IN KENT.

We gather from the *Kent Messenger* that the question of hospital accommodation in the county of Kent is engaging attention. There are two aspects: in the first place the voluntary hospitals are in financial straits, and in the second place the accommodation is said to be insufficient. There are voluntary hospitals at Ashford, Folkestone, Canterbury, Margate, Tunbridge Wells, Maidstone, Rochester, Gravesend, and Sevenoaks. At the annual meeting of the West Kent General Hospital, Maidstone, an appeal was made for a sum of £100,000 to make additions to the present buildings so as to raise the number of beds to 105. Dr. Travers, in supporting the appeal, said that the hospital at present had fifty-five beds occupied, but that as many as seventeen urgent cases had been sent to the hospital in a single week, and there was at present a waiting list

of seventy. He considered that a convalescent home at a distance would not meet the need, as many of the cases sent to the hospital required active surgical and medical treatment, and many could not be moved out to the country for some weeks. In a letter to the newspaper Dr. Barclay, who was formerly in charge of a state hospital in New Zealand, has suggested that the disused aerodrome buildings at Detling Hill should be utilized. The buildings, he says, are about to be sold; after visiting them he came to the opinion that they could be adapted without serious alteration for chronic cases and those needing chiefly nursing, fresh air, and good food. The hospital at Maidstone could then remain for the reception of acute cases. The proposal, as we have indicated elsewhere in this issue and on several other occasions, seems in principle on the lines of proposals made for several other towns.

Scotland.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a meeting of the Central Midwives Board for Scotland, under the presidency of Sir Halliday Croom, a number of disciplinary cases were considered. In two instances certified midwives were charged with failure to notify ophthalmia neonatorum; one was suspended for three months and the local supervising authority instructed to report thereafter with reference to her ability to take and record the temperature and pulse. In the other case the Chairman said that such offences could not be adequately dealt with by censure or caution, but that the midwife would be allowed an opportunity of proving amendment, the local supervising authority being requested to report at the end of three months. A midwife who had failed to notify stillbirth was reprimanded, and judgement on other breaches of the rules was deferred, the local supervising authority being requested to furnish a report within three months. The name of another midwife, who was charged with having been in contact with a patient suffering from puerperal fever and failing to make the required notifications and take the necessary precautions, was removed from the roll of midwives and her certificate cancelled. The names of three other women were directed to be removed and their certificates cancelled. In one instance the woman had been convicted of keeping an improper house, another had been sentenced to three months' imprisonment for theft and fraud, and a third had been sentenced to eighteen months' imprisonment for using instruments with intent to procure abortion.

Ireland.

ULSTER MEDICAL SOCIETY.

At the meeting of the Ulster Medical Society on February 26th, when the President, Mr. Andrew Fullerton, C.B., C.M.G., F.R.C.S.I., was in the chair, Dr. Thomas Houston read a paper on the classification of streptococci, in which he related the observations made by himself and Dr. J. McCloy in the Base Hospital, Etaples. Dr. H. P. Malcolm described his experiences of streptococcal septicæmia in France, and Dr. W. J. Wilson gave an account of the various organisms isolated in cases of gas gangrene. Before the close of the meeting one of the members referred to the purchase of "Graymount," Belfast, by the Corporation, as a sanatorium for surgical tuberculosis. Considerable discussion ensued, and dissatisfaction was expressed that the profession and the public had not been informed about the matter.

THE Ministry of Health has issued a handbook, entitled *Maternity and Child Welfare Centres in England and Wales* (H.M. Stationery Office, through any bookseller, 1s. net), which is a directory to such institutions. It appears that there are in London 203, in the county boroughs 391, and in the counties 1,124. Of the total, 679 are maintained by voluntary societies.

Correspondence.

DYSPEPSIA.

SIR,—As methods of precision in diagnosis develop the treatment of dyspepsia is falling increasingly into the hands of the surgeon. That tendency may prove a permanent or a passing phase. The diagnosis also, in obscure cases at least, of dyspepsia is being more and more laid on him, and he feels the need of help from physician, physiologist, and pathologist. The columns of the JOURNAL have recently contained two important articles, the one entitled "Disappointments after gastro-enterostomy," from the pen of Sir Berkeley Moynihan (BRITISH MEDICAL JOURNAL, July 12th, 1919), and the other, "Dyspeptic and other referred symptoms associated with disease of the gall bladder and of the appendix," from that of Sir Humphry Rolleston (BRITISH MEDICAL JOURNAL, March 6th, 1920). Both articles indicate the somewhat widely separated sources of origin of the symptoms of dyspepsia—the biliary apparatus, the appendix, the duodenum, etc., in addition to the stomach itself.

In the JOURNAL of November 15th, 1919, in an article entitled "Remarks on the frequency, diagnosis, and treatment of chronic pancreatitis," I indicated the pancreas as an important source of dyspeptic symptoms, and in that article, and the correspondence that followed, pled for systematic examination of the pancreas as possibly the sole or the associated source of obscure dyspeptic symptoms. Such systematic examination, by means of microscopic examination of a *fresh* portion removed by the surgeon from the living gland, has, as I indicated, convinced me that chronic or subacute pancreatitis is the sole or the associated source of the symptoms in many cases of dyspeptic troubles, and, further, that certain supposed signs of pancreatitis on which we have hitherto relied are either unreliable or present so rarely as to be valueless, more especially in the early stages of the trouble.

The structure and the functions of the pancreas are apparently complex and at present ill understood. It stands, as I recently pointed out (BRITISH MEDICAL JOURNAL, January 24th, 1920), somewhat alone amongst the tissues in the rapidity and intensity of *post-mortem* changes. Autolysis is so rapid that examination of fresh specimens taken from the living gland, in the course of an abdominal operation, alone yields reliable results as to the presence or absence of morbid changes, and therefore of the value of the various alleged signs of, and tests for, the existence of pancreatitis.

I venture to renew my plea for the routine examination by the surgeon of the pancreas in all cases operated on for actual or supposed gastric, appendicitic, duodenal, and biliary symptoms, and to suggest certain of the questions awaiting answer:

1. What proportion of cases of pancreatitis is accompanied by cholelithiasis? My results give it as small.
2. What proportion of cases of pancreatitis is accompanied by catarrhal gastric, duodenal, and biliary apparatus affections? My results give it as large.
3. What proportion of cases of pancreatitis is accompanied by excess of dextrines in the urine? Except in cases of advanced pancreatic cirrhosis, my results give it as negligible.
4. Is excess of dextrine confined to cases in which the islands of Langerhans are affected?
5. Does the pancreas, in addition to its digestive secretion, produce an "internal secretion," and, if so, of what nature and function?

I am, etc.,

Glasgow, March 6th.

JAS. H. NICOLL.

"INTRAVENOUS PROTEIN THERAPY."

SIR,—Dr. A. E. Gow rightly laments the confusion which has arisen in applying such a nomenclature as "protein" or "protein shock" therapy to the various cases under consideration. The latter term was first coined in America, and seems to have stuck more or less. The protein is used in two forms—(1) as bacterial emulsions (to which, indeed, the application of the term "protein" is utterly unscientific), and (2) as cleavage products of the simple protein nucleolo (proteoses). Each of these substances is used therapeutically in two distinct and opposing ways—

namely, (a) in minute doses for immunizing purposes, and (b) in single (or more) massive doses for the purposes of the pyrogenic reaction ("shock" of American writers). From this it is evident that the expression "protein therapy" may mean anything, and the addition of the word "shock" conveys a false impression. It is therefore necessary to indicate so far as we can, by some nomenclature, which of these methods of treatment is specified.

Dr. Gow apparently seems to think the term "pyrogenic therapy," as applicable to the massive reaction, is defective for two reasons. The first is that certain non-protein substances may produce fever, and the second, that the clinical improvement cannot be ascribed to the pyrexia. I venture to think that these objections may be fairly met. If a non-protein substance can produce the desired reaction it may be just as good for use as a protein. The experiments with non-protein substances have hitherto only been made on animals, but the effects appear to differ in no way from those of proteins. Quite recently, however, the typical reaction seems to have followed the use of hydrogen peroxide in the human subject, as described in the *Lancet* (vol. i, 1920, p. 432) by Drs. Oliver and Murphy. Even if the non-protein substances were not suitable clinically, this does not affect the issue. We use only such pyrogens as are therapeutically appropriate, just as for purposes of purgation (to take an example) we use only certain purgatives, though many poisonous drugs are likewise capable of acting as purgatives.

As regards Dr. Gow's second objection—that the clinical improvement cannot be due to the fever—it is an instructive fact that all other workers at this subject are unanimous that the temperature production is the essential factor. Without the pyrexia no good can be effected. It also may be pointed out that the term "pyrogenic" does not refer to a possibly chance production of the symptom pyrexia, but refers to those substances themselves which act as pyrogens—a name given them by the late Sir J. Burdon-Sanderson. Nor is their capacity to produce fever a secondary or subsidiary one, caused by the liberation and mobilization of toxins in diseased conditions, as the fever is equally produced in the healthy subject, showing the substance to be a pyrogen in the true sense.—I am, etc.,

London, W., March 1st.

A. G. AULD.

THE TRANSMISSION OF RELAPSING FEVER.

SIR,—With reference to the remarks by Dr. W. H. Willcox in your issue of February 14th, p. 222-3, on the possibility of there being methods of transmission of relapsing fever other than the louse, I quote some evidence to support his suggestion.

During the years 1906-7, and part of 1908, I carried on an extensive investigation of Indian relapsing fever, which resulted in the discovery of the body louse as the natural transmitter of the disease.

In the earlier part of the inquiry many possible sources of infection were studied, and in particular the blood, to see whether the disease required the interposition of an insect vector, or whether it could be transmitted by simpler methods, such as by contamination with one or other of the excretions.

It was shown in various ways that the blood during the febrile period (and less so during the apyrexial) was very infective to monkeys. Such blood, when brought into contact with the healthy uninjured skin, did not produce the disease, but if a few hairs were pulled out or minute abrasions made on the skin, the application of infective blood invariably resulted in the infection of the experimental animal.

Similarly, if an infected and a healthy monkey were laid side by side and several passages made from the one to the other by pricks with a grooved needle, the healthy monkey became infected on each occasion.

It was found also that when a few cubic centimetres of infected blood were introduced with a soft, well-greased rubber catheter into the oesophagus of a monkey, the disease was regularly transmitted by this means, even though the risk of abrasion of the surfaces was almost certainly excluded.

During the course of these investigations two of my assistants developed relapsing fever in the laboratory after doing autopsies on infected animals. They had no recent cuts or abrasions visible to the eye, so that the spiro-

chaetes must have gained entry by means of microscopic abrasions such as may generally be found around the nails.

A case is on record from another laboratory in which an investigator received a spurt of blood into his eye from a cut vessel whilst operating on an infected animal. Notwithstanding the fact that the conjunctival sac was washed out, he developed relapsing fever after the usual incubation period.

These facts show that the spirochaete has no obligatory cycle of development before it becomes infective after leaving the mammalian host, though this does not disprove the possibility of an alternative cycle of development in its arthropod vector.

When my investigations had reached this stage and when a year's close study of the supposed potentialities of the bed-bug had yielded negative results, a series of cases of relapsing fever were observed to be occurring amongst the staff of a big lying-in hospital in Bombay, which I was directed by Government to investigate. It was shown that these cases were almost certainly being infected by contact with fresh blood. What happened was briefly as follows:

1. There was a small but widespread epidemic of relapsing fever in Bombay at the time.
2. This disease almost invariably produces abortion in pregnant women.
3. Women suffering from abortion and miscarriage were coming to the hospital in a highly infective state to be treated.
4. Spirochaetes could be found in the placental blood.
5. Doctors, students, and nurses who came into contact with fresh blood became infected. Cotton gloves (or none at all) were in use in the theatre.

None of the surgical staff of the big general hospital in the same compound contracted relapsing fever. This may have been due either to the fact that rubber gloves were worn at operations or more probably to the fact that operations would not be undertaken on patients who were suffering from relapsing fever or other pyrexial diseases.

It is true that at this time the real insect transmitter was not known, and it was not until some months later that I had the opportunity of investigating another epidemic with quite different epidemiological features, as the result of which I was able to point to the body louse as the true vector of relapsing fever. On reconsidering my evidence as to blood transmission in the light of these new facts, I was still able to adhere to my opinion that the series of cases in the lying-in hospital were due, not to insect transmission, but to contact with fresh blood.

Dr. Willcox's clinical acumen has led him to the same conclusion in his experience in Mesopotamia. His suggestion as to the transmission of relapsing fever through human faeces is not supported by experimental evidence, nor in my considerable experience by clinical evidence. I have repeatedly tried, but always failed, to infect monkeys by the subcutaneous injection of faeces, urine, and vomit taken from patients at the height of their infection. Microscopical evidence on this point would be valueless, as all these excretions contain spirochaetes under natural conditions. Experiments on monkeys, however, provide a very delicate test, as not one of my series of over a hundred monkeys failed to become infected even when the dose of virus was minute.

The practical point is that though the ordinary carrier of relapsing fever in Europe, Asia, and Northern Africa is assuredly the louse, a more direct transmission from person to person does take place under exceptional circumstances—namely, by the contact with, and subsequent absorption of the virus from, freshly shed infective blood.

Whilst on this subject I venture to refer to the question of priority of the discovery of the louse as the carrier of relapsing fever. This should fairly be placed to my credit (vide "The part played by *Pediculus corporis* in the transmission of relapsing fever," BRITISH MEDICAL JOURNAL, December 11th, 1907). This reference appears to have been overlooked by some writers on the subject, whilst some have referred to it merely as a "suggestion." The observations made in that paper were confirmed by Sergeant, Graham Smith, and others, but particularly by Nicolle and his associates, who extended and amplified the original observations. The latter also corrected me as to the exact method of transmission by the insect, showing that it was brought about by the crushing of the body of the infected louse into an abraded skin surface rather than

by the insect's bite. Other observations of mine showed that the buccal secretions of some infected lice swarm with spirochaetes, and the significance of this has yet to be explained.

It should be remembered that the transmission of relapsing fever was known before the louse hypothesis was applied to the transmission of typhus fever, and the close epidemiological similarity between the two diseases suggested their being carried by the same agency.—I am, etc.,

F. P. MACKIE,

Bristol, Feb. 29th.

Major, I.M.S.

THE TREATMENT OF MALARIA.

SIR,—In the expressions of opinion in your columns on the treatment of malarial fever in the tropics there seems to be little variance, but what concerns the general practitioner is the anti-relapse treatment in this country where reinfection is unlikely.

My experience of the treatment of malaria in tropical Africa from 1900 until recently is similar to that of Drs. Taylor, Law, and Collett, and, like the last-named, I have seldom had to resort to other than the oral method of administration. Cases do occur, but they are distinctly rare.

Since demobilization I have treated many hundreds of ex-soldiers suffering from recurrent malaria in this country. In the majority there has been little or no clinical evidence of the disease, but at the same time a considerable number show some splenic enlargement. The improvement in practically every genuine case is so marked that there can be no two opinions about the efficacy of the routine treatment which has been adopted by several of us working alongside each other. The treatment is simple. Every genuine case is given 10 grains of quinine sulphate in solution daily before breakfast; this is continued for a month. The patient is then seen again, when the same daily dose is repeated for another month or increased to 15 grains should the case require it. The treatment is completed at the end of three months should no relapse have occurred during that time. The patient is then given a tonic for as long as he requires it. Under this treatment I have only met with one case in which the spleen did not return to normal within three months. In the large majority of those who take their daily dose of quinine regularly no relapse occurs, but it has been found that in a small minority of the regular quinine takers slight relapses will occur, but that these will soon cease if the treatment is persevered in.—I am, etc.,

R. E. DRAKE-BROCKMAN, M.R.C.S.

London, S.W., Feb. 26th.

SIR,—As I find that the treatment of malaria by *intramuscular* injections of quinine salts is still recommended for certain classes of cases by some authorities, I wish to point out that this method was condemned by the medical service of the E.A.E.F. ("German" East Africa).

The intramuscular injection of quinine causes extensive necrosis of muscle, and its therapeutic value is negligible when compared with the other methods of administration, oral, intravenous, or subcutaneous.—I am, etc.,

AUGUSTUS R. BALMAIN, M.B., B.S. Lond.,

Captain R.A.M.C. (S.R.), late of E.A.E.F.

London, S.W., Feb. 28th.

MEASUREMENT OF EMOTION.

SIR,—The experiments of Professor A. D. Waller on the above subject (February 21st, p. 259) are very interesting to me as corroborative to a very small extent of the epoch-making work of my friend Dr. Albert Abrams of San Francisco.

It is quite eight or ten years since Abrams showed that the electric discharge from the human body chiefly occurs at the tips of the fingers and toes; the discharge is greater in the light than in the dark, and, contrary to generally accepted opinions, greater in dry than in damp weather. As an absolutely dry atmosphere is a more or less perfect insulator, he legitimately concludes that human electric potential is high. He has also shown that the polarity in the normal male—I say normal because there are a good many asexual individuals about—is positive in the right hand and foot and negative in the left; in the normal female during the child-bearing age the polarity is

reversed; the polarity can also be reversed by throwing a yellow handkerchief over the head of the subject. In some highly strung individuals the discharge from the right hand in the male and the left in the female is sufficient to neutralize the south pole of a six-inch bar magnet.

Abrams ascribes these effects to electronic energy, not simply in the cell but in the atoms of which the cell is composed, and he holds that radio-activity is a universal property of matter, and not simply confined to the dozen elements or so to which physicists limit it.

I think it is within the experience of very many individuals that any painful or disagreeable emotion causes tingling or the so-called "pins and needles" at the tips of the fingers. In your own case, when Dr. Waller aroused a disagreeable memory, there was a great deflection in the mirror galvanometer. There must be a great many disagreeable reminiscences stored up in the substrata of your encephalon; get someone to rake them up, and you may be able to corroborate my observation at your fingertips without any Wheatstone bridge or galvanometer.

In executions it has been long known that emissions of semen not infrequently take place. This has always been ascribed to the effects of strangulation congesting the penis and testicles, but it occurs as frequently in fracture of the neck as in the slow process of strangulation, and in my opinion takes place before the execution in the dread anticipation of what is going to happen.

In epileptics the high electric potential can be drawn off from any part of the cranium, and in order to lessen the electrical resistance of the scalp in such cases I have been lately having it rubbed night and morning with a 5 per cent. solution of acetic acid. I could easily fill several journals with an account of Abrams's valuable work, but this will perhaps suffice to whet the appetite of the curious for something new.—I am, etc.,

Liverpool, March 1st.

JAMES BARR.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—In the argument which has followed the publication of Dr. Baskett's paper, I admire greatly the author's persistence in keeping his critics to the point. As I read it, the statement of his case is this: State "paternalism" is designed to assist the poorer classes; "paternalism" is costly; the larger part of the cost is passed on to the poorer classes in the increased price for commodities (the poorer classes being the largest consumers owing to their enormously preponderating numbers); thus the cost of "paternalism" tends to reduce "real" wages; reduction of real wages means destitution, or at all events privation.

As a corollary the mortality from any disease which depends on privation or destitution is bound to increase—or to fail to decrease as rapidly as it otherwise might—under any system of State "paternalism." Hardly any happening in Nature is due to one factor alone; and it is probable that in emphasizing—quite justly—what seems to him the most important factor, Dr. Baskett may be under-estimating the value of other factors. But the arguments of his opponents seem to me so unconvincing that I venture to make a deduction from Dr. Baskett's conclusions.

The financial difficulties of the country are supposed to be very great. Yet we are overwhelmed with the schemes of "reconstructionists." All these schemes are costly; nearly all involve interference by the State. There is a crusade in contemplation against a C3 population. In this crusade the Consultative Medical Council of the Ministry of Health is not unlikely to find itself involved. It is permissible, therefore, to hope that every member of that Council has duly weighed the argument put forward by Dr. Baskett, and that no scheme of medical services will be put forward in the report shortly to be published unless it is reasonably certain that the results will be in some measure commensurate with the costs involved. It seems too often forgotten that the greater part of State activity is unproductive, although we are assured on all hands that the need of the hour is production. If unproductive work is necessary, let it not be unreasonably costly. I am, etc.,

London, W., March 5th.

CHAS. BUTTAR.

TREATMENT OF THE RUNNING EAR.

SIR,—The object of my original letter (August 23rd, 1919, p. 253) was to emphasize the fact that non-operative treatment will produce surprisingly good results in many cases if thoroughly carried out. In my opinion the essence of such treatment is the cleansing and drying of the meatus, and in that respect Dr. MacGibbon (February 28th, 1920, p. 294) apparently agrees with me. Syringing is not a "modern" method, although probably more so than "sponging out the discharge." The object of each is the same, and they are probably equally effective, but, while the former can be carried out by others, the latter, to be efficient, requires the attendance of the surgeon twice daily. This I have found a practical bar. The figures I gave were based on the duration of discharge, because, under the circumstances, the records which I was able to keep did not allow of a classification into true clinically chronic cases and those of prolonged acute conditions. The former, however, predominated. I had no intention of implying that operative treatment had no place in the treatment of cases of suppurative otitis media, as that would be absurd. In my opinion the antrum is involved at some stage in all cases of otitis media. The important factor is the freedom or otherwise of drainage from this cavity. Failure of resolution in an acute case is usually due to deficient drainage from the antrum, and the drainage provided by an operation is necessary, and in my opinion increasingly employed. The results of operation in unresolved acute cases are almost uniformly successful. As to operation in chronic cases, the results of the radical operation are not nearly so good, discharge recurring or persisting in nearly 50 per cent. of cases. In my opinion this operation should be reserved for cases in which some decided indication exists.

No mention was made of the great importance of any necessary treatment to nose or nasopharynx, as this is generally recognized, and the object of the letter was to emphasize a particular point rather than to write an essay on the treatment of suppurative otitis media. Space and the tolerance of your readers limited me then and do so now.—I am, etc.,

Bristol, March 1st.

A. J. WEIGHT, F.R.C.S.

COMMISSIONS IN THE INDIAN MEDICAL SERVICE.

SIR,—Would you kindly allow me to add my testimony to what has been stated by Lieut.-Colonel R. H. Elliot, I.M.S., in your issue of February 7th, and in a previous communication, regarding temporary commissions in the Indian Medical Service for young medical men? The conditions offered by the Government of India to approved candidates are as good, if not better, than those of any other Government service in India at present. It is possible that those conditions will be further improved. There are some of us who can remember drawing Rs. 286.10.8 for a year or so after joining the service. Notwithstanding the greatly decreased purchasing power of the rupee the pay now offered is in every way higher than it was.

There is, I believe, a desirable temporary career open in the Indian Medical Service to young men with the best professional attainments at the present time. I write with a knowledge of the arguments for and against such a career.

There are several special reasons for accepting temporary commissions. If at the end of two years the officer finds the Indian Medical Service unsuitable he has been through a useful experience. It may be that before long permanent Indian Medical Service officers after serving for seven or eight years will be allowed to relinquish their commissions with a substantial gratuity, as is the case in the Royal Naval and Royal Army Medical Services.

At the present moment no prudent person would have the temerity to prophesy what the Indian Medical Service is likely to be, say, ten years hence, or what changes may take place in the Medical Services of India as a whole during that time; if the improvements one has in mind regarding leave, study, duty, free passage home periodically, etc., are published, then I would strongly recommend the Indian Medical Service as a permanent career. These opinions are entirely personal.

I would advise young medical officers going out to join the Indian Medical Service not to purchase more clothes and boots than is absolutely necessary, as most articles of wear are cheaper in India than at home at present. I have recently returned from India, and regret not coming home with a replete wardrobe.—I am, etc.,

P. HEHR,
Major-General I.M.S.

London, March 7th.

THE TERRITORIAL FORCE.

SIR.—I am in entire agreement with "Hard Hit" in his pungent criticism of the Territorial Medical Service. Dr. Buttar either takes things lying down or has not been a T.M.O. During the recent war I started as captain, saw four years nine months' service and was demobilized, still in the same rank, all for 5s. a day less than the conscripts. I am told that I cannot resign, but I mean to resign at the first opportunity and have done with such niggardly treatment, and I shall advise all my friends not to join the T.F. until patriotism is not counted for evil.

I am a specialist in a particular region of the human anatomy, but was I given a special job? Oh, dear no. For the greater part of my service I was doing work which any clerk could have done. Was this the case with the A.M.S.? Oh, dear no. A great many of the London men were made major-generals with corresponding emoluments, honours, and titles. Was any Territorial M.O. made a major-general? I think not. At any rate, I was not. I was only one of the poor fools who joined up twelve years ago. But "Hard Hit" and I both look to the British Medical Association to see for us our arrears of pay.—I am, etc.,

March 8th. CONSULTING SURGEON.

. So far as we can ascertain eight temporary colonels were promoted to be major-general, and one colonel of the Medical Service of the Territorial Force Reserve, Major-General Sir R. H. Luce, K.C.M.G., C.B.

THE END OF THE WAR.

SIR.—Judging by the article on the "Notification Fee and the End of the War" in your issue of the 6th instant, you appear to be ignorant of the fact that the termination of the war has been fixed by Order in Council as occurring on January 10th, 1920; at least, it was so announced in the press. I presume, therefore, that the medical practitioner's fee for notification of a case of infectious disease will revert to 2s. 6d. from that date.—I am, etc.,

Atleborough, March 7th. G. S. KEELING.

. Our correspondent is mistaken. The Order in Council dated February 9th, 1920, and published in the *London Gazette* of the following day, declares January 10th, 1920, to be the date of the termination of war with Germany, and not that of the termination of the present war. We quote the last two paragraphs of the Order so that there may be no doubt about the matter:

"And whereas treaties of peace with other belligerents not having yet been ratified, it is desirable to declare the date which is to be treated as the date of the termination of war with Germany before declaring the date which is to be treated as the date of the termination of the present war:

"Now, therefore, His Majesty, by and with the advice of His Privy Council, is pleased to order, and it is hereby ordered, that the said tenth day of January shall be treated as the date of the termination of war between His Majesty and Germany."

EPIDEMIC DISEASES IN MAURITIUS.

SIR.—Your reviewer in criticizing (February 28th) my book on the *Epidemics of Mauritius* finds fault with the statement that the *Phlebotomus papatasi* is the carrier of dengue fever, and refers me to the recent work by Clelland and others in Australia who say that the *Stegomyia fasciata* is the carrier of that fever. Long before Clelland, Bancroft (of Australia) had accused the *stegomyia*, but both Daniels (*Tropical Medicine and Hygiene*, Part III, p. 130) and Manson (*Tropical Diseases*, p. 254) consider the experimental evidence inadequate, whilst Brumpt (*Précis de parasitologie*, p. 449) makes a distinct statement, which may be translated as follows:

The *Phlebotomus papatasi* transmits into man the pappataci fever, usually called dengue fever.

The researches of Doerr, Franz, and Taussig have shown that the phlebotomus after biting a patient with dengue fever

can transmit the disease eight days after. They are the intermediary host of this affection.

The virus of dengue is transmitted by the phlebotomus, and also, according to Graham of Beyrouth and Ashburn and Craig of the Philippines, by certain mosquitos.

In *Memoranda of Medical Diseases in the War Areas* (Edition 1919, p. 199) it is stated that "dengue, undulant fever, etc., may be mistaken for phlebotomus fever"; and again (p. 48) that "the differential diagnosis between dengue and phlebotomus fever is not always easy, as both may assume atypical forms. Indeed, there are not wanting those who both in India and in Macedonia declare the two diseases to be identical. It must be admitted that the arguments adduced are very powerful, so much so that we are led to ask if the same disease may be transmitted by totally different insect vectors." Finally, Manson (pp. 324 and 326) draws attention to the possibility of mistaking three days' fever, seven days' fever, undulant fever, dengue, etc., for one another. Of course, I agree with the reviewer, the species' names should have been written in small letters. It was a lapsus.—I am, etc.,

London, W., March 1st.

D. E. ANDERSON.

Medico-Legal.

DRUNKENNESS IN MURDER CASES.

THE House of Lords on Friday last delivered their reserved judgement in the Beard case which was argued towards the end of November and which raised points of considerable interest and importance.

Beard had been sentenced to death for the murder of a girl of 13 whom he had ravished and accidentally suffocated by placing his hand over her mouth, his object being to prevent her calling for help.

His defence had been that he was drunk, and on that ground his counsel had pleaded that the verdict should be one of manslaughter. Mr. Justice Bailhache, in leaving the case to the jury, had directed them that this defence could only prevail if as the result of his condition the prisoner did not know what he was doing or did not know that what he was doing was wrong. The jury, however, returned a verdict of murder and there was an appeal to the Court of Criminal Appeal.

It should perhaps be explained that a criminal intent or, as it is described in legal language, *mens rea* is of the essence of every crime, and this being so a lunatic is obviously incapable of committing a crime and the test which at law has long been accepted as determining the question as to a man's mental condition is that which Mr. Justice Bailhache applied when he summed up the case of Beard to the jury.

Now there had been a case in 1909—Meade's case—in which the defence of drunkenness to a charge of murder had been considered by the Court of Criminal Appeal. In that case the prisoner had, whilst drunk, so brutally ill-treated a woman that she died, and on his appeal against the sentence of death which was passed upon him the Court of Criminal Appeal pointed out that a man is taken to intend the natural consequences of his acts, but that in the case of a man who is drunk this might be rebutted by showing that his mind was so affected by the drink he had taken that he was incapable of knowing that what he was doing was dangerous. "If this is proved the presumption that he [Meade] intended to do grievous bodily harm is rebutted."

Here again it is necessary to explain, because of its bearing upon the view which the House of Lords took of the decision in Meade's case, that there are many crimes in English law in which an intention to do a specific act forms an essential element of the crime. A man charged with the murder of a woman upon whom he has performed an abortion cannot successfully plead that he did not intend to kill her. According to English law everyone is presumed to have intended the natural consequences of his actions.

But there are many crimes in which there is an element of what may be called a specific intention. Wounding with intent to kill is one, attempted suicide is another. As Chief Justice Jervis once said, "If the prisoner was so drunk as not to know what she was about how can you say that she intended to destroy herself?"

Beard's case came before the Court of Criminal Appeal and that court, considering itself bound by its own previous decision in Meade's case, held that Mr. Justice Bailhache had dealt with the case in his summing up to the jury as one of insanity, and that the defence of drunkenness had not been properly left to

the jury, and reduced the verdict to one of manslaughter, and from this decision the Crown appealed to the House of Lords.

In that House the Lord Chancellor pointed out that according to the law of England as it prevailed until early in the nineteenth century, voluntary drunkenness was never an excuse for criminal misconduct; and indeed the classic authorities had broadly asserted that voluntary drunkenness must be considered rather as an aggravation than a defence, and referred to a case reported in 1562, in which it was said:

If a person that is drunk kills another, this shall be felony, and he shall be hanged for it, and yet he did it through ignorance, for when he was drunk he had no understanding nor memory; but inasmuch as that ignorance was occasioned by his own act and folly, and he might have avoided it, he shall not be privileged therefor.

The Lord Chancellor then reviewed the cases on the point, remarking that the old rigid rule of the nineteenth century appeared gradually to have been relaxed, from which he drew three conclusions:

First, that insanity, whether produced by drunkenness or not, afforded a defence. He pointed out that the insane could not be convicted of crime, but on a verdict of insanity were ordered to be detained during His Majesty's pleasure. If actual insanity in fact supervened as the result of alcoholic excess it furnished as good an answer to a criminal charge as insanity induced by any other cause: he quoted Mr. Justice Stephen, who said, in deciding a case in 1881:

Drunkenness is one thing, and the diseases to which drunkenness leads are different things, and if a man by drunkenness brings on a state of disease which causes such a degree of madness, even for a time, as would have relieved him from responsibility if it had been caused in any other way, then he would not be criminally responsible. In my opinion in such a case the man is a madman and is to be treated as such, although his madness is only temporary. . . . If you think there was a distinct disease caused by drinking, but differing from drunkenness, and that by reason thereof he did not know that the act was wrong you will find a verdict of not guilty on the ground of insanity.

Secondly, that in cases where a specific intention formed an essential element of the crime, evidence of drunkenness which rendered the accused incapable of forming that intention should be taken into consideration, in order to determine whether he had the intention or not; and

Thirdly, that evidence of drunkenness, falling short of a proved incapacity in the accused to form an intention necessary to constitute the crime, and merely establishing that his mind was affected by drink so that he more readily gave way to some violent passion, did not rebut the presumption that a man intended the natural consequences of his acts.

He then came to Meade's case and, after referring to the facts of that case and to the judgement, pointed out that the crime charged in that case was that death arose from violence done with intent to do grievous bodily harm, so that it was necessary to prove the particular intention. In the case under consideration, on the other hand, the death arose from a violent act done in furtherance of what was in itself a crime of violence. Drunkenness could be no defence unless it could be established that Beard at the time of committing the rape was so drunk that he was incapable of forming the intent to commit it, which was not the fact and, manifestly, having regard to the evidence, could not be contended. He then dealt with the way in which Mr. Justice Bailhache had left the case to the jury and remarked that the judge's direction was one applicable only to a plea of insanity which had of course never been raised. The summing up was, in fact, unduly favourable to the prisoner, and he was not prepared to say that the jury was disabled from reaching a true conclusion upon the matters which required decision. He doubted whether there was any sufficient evidence that the prisoner was in the only relevant sense drunk at all. There was certainly no evidence that he was too drunk to form the intention of committing rape, and it was proved that death was caused by an act of violence done in furtherance of the felony of rape. This was, by the law of England, murder, and the appeal should be allowed and the conviction of murder restored.

In this conclusion the other lords concurred.

It is right to add that although the conviction of murder has now been restored, the House of Lords intimated at the close of the argument in November that whatever their decision the death sentence would not be carried out.

A VENEREAL "PROFESSOR" SENTENCED.

In the Glasgow High Court of Justiciary, on February 24th, before Lord Salvesen, A. S. Eastburn was charged with having contravened the Venereal Diseases Act, 1917, by treating men for venereal diseases, he not being a duly qualified medical practitioner. The indictment contained twelve counts. His Lordship upheld objections raised against six of the counts, by counsel for the defence, and a plea of not guilty was raised in the other six counts. The counts dismissed were for "offering" to treat which was held not to come within the Act.

Lord Salvesen explained to the jury that the question was whether in each of the six cases in which evidence would be tendered the men were treated for venereal diseases by the accused; that used not to be an offence in common law, but it was so now for an unqualified man to treat such diseases. The question was whether the accused treated for venereal disease each of the six persons and prescribed for them, and also if he did so for reward. The amounts paid for treatment by one witness were read from the accused's ledger produced in court.

Between March 1st, 1915, and September 20th, 1919, he paid £189 in five sums. He returned for further advice to the "professor," who asked for a fee of £265 for a new special treatment. This sum, the witness declared, he had paid over to the accused in full in September last; no entry for it was found in the ledger, but a slip from a bundle of documents relating to cases treated by the accused and seized on his premises by the police contained the words "£250 paid," and a clerk in Eastburn's employment, who kept the books, told the court this entry was in the accused's handwriting. Professor Glaister, called for the Crown, stated that samples of the blood of this man had lately been examined by himself and two other experts, and the result showed that he was not free from the disease for which he had apparently been treated. Another witness stated that he had paid £58 in all to the accused, and a third—a seaman from Liverpool—declared he had paid Eastburn £66 in five sums, and was then advised by him to undergo his "compound treatment," which would cost £42. At the end of two years he still felt very ill and went into a Liverpool hospital for free treatment. The medical evidence was to the effect that no signs of a previous treatment suitable to the disease could be found, but that if properly treated at the outset the man would almost certainly have been restored to health. Professor Glaister further stated in evidence that the tablets supplied to witnesses for treatment were shown on analysis to contain neither arsenic nor mercury, but some vegetable substance which the analyst could not determine.

In the course of his summing up Lord Salvesen said that for many years the accused had been making a livelihood by the treatment of these diseases in men; he had advertised himself as a specialist, had given private consultations, and prescribed treatment to any person who paid him his fees. The jury returned a unanimous verdict of guilty on three of the counts, and by a majority on one count; by a majority in the other two counts their verdict was "not proven." Lord Salvesen, in passing sentence, said he entirely agreed with this very discriminating verdict. It was obvious that the accused had for profit contravened the Venereal Diseases Act, well knowing what its provisions were and that it was applicable to him. His Lordship felt that he would not be doing his duty to society if he did not impose a sentence which, at all events, would be a deterrent. In the circumstances he could not make the penalty less than six months' imprisonment.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

DR. HENRY HEAD, F.R.S., has been elected an honorary Fellow of Trinity College.

At a congregation held on March 6th the following medical degrees were conferred:

M.B.—L. G. Jacob.

B.Ch.—R. Stansfeld, E. V. Gostling.

UNIVERSITY OF LONDON.

WAR MEMORIAL.

A COMMITTEE, of which Lord Rosebery Chancellor is president and Sir Edward Busk (Chairman of Convocation) vice-president, has issued an appeal for contributions to a war memorial to members of the University of London Officers' Training Corps who were killed or died on service. It is proposed to erect the principal memorial in the standing camp of the contingent at Great Kimble, near Princes Risborough, Buckinghamshire, and to arrange for the dedication of personal memorials there. It is intended to erect a memorial in London also.

The Military Education Committee of the University has in preparation a *Roll of War Service, 1914-19*, of the University of London Officers' Training Corps. The Roll will be in three sections, the first containing particulars of the 657 officers who fell in the war; the second will record the honours and distinctions gained in the war, to a number exceeding 1,600; in the third section the names of officers will be arranged in alphabetical order to an estimated number of 4,200. The subscription price for orders received on or before June 30th, 1920, is £1 ls., with 1s. extra for packing and postage. Any profit on the publication will be devoted to the War Memorial Fund.

The V.C. was won by five former cadets of the contingent, and the two survivors are among the honorary secretaries of the fund. The number of distinctions gained in the war is 1,650, including V.C., 5; D.S.O. and Bars, 54; D.S.C., 8; M.C. and Bars, 588; D.F.C. and Bars, 10; A.F.C., 9; Mentions in Dispatches, 707; *Croix de Guerre* (French 27, (Belgian) 15; Silver Medal for Military Valour (Italian, 5; Distinguished Service Medal (United States), 2. In addition, a number of former cadets served in the ranks.

Contributions should be sent to the Honorary Treasurer, 46, Russell Square, London, W.C.1.

UNIVERSITY COLLEGE.

F. J. Fitzmaurice Barrington, M.S., F.R.C.S., assistant surgeon to University College Hospital, and T. H. C. Stevenson, M.D., C.B.E., superintendent of statistics, General Register Office, joint secretary of the Royal Statistical Society, have been elected Fellows of University College, London.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following were admitted (after examination) as Fellows: A. Allison, T. B. Gilchrist, J. C. Middleton, R. C. Robertson.

Dr. Thomas Forrest (Glasgow) has presented to the Royal Faculty a case of surgical instruments which had been the property of and were used by the late Lord Lister while he was a surgeon in the Glasgow Royal Infirmary. Dr. Freeland Ferguson, president, accepted the gift with very great pleasure, and stated that it would be placed in the archives of the Faculty.

The Services.

ROYAL ARMY MEDICAL CORPS WAR MEMORIAL.

A COMMITTEE has been formed to deal with this question; this committee contained representatives of the Regular, Special Reserve, Territorial, and Civilian Medical Services, the Presidents of the Colleges of Physicians and Surgeons of England, and past and present Director-Generals of the Army. Ireland, Scotland, England, and Wales are all represented.

At a large and representative meeting the following decisions were agreed to:

1. That a permanent memorial should be erected in London, with replicas in Edinburgh and Dublin, if funds were available.
2. That the names of officers, non-commissioned officers, and men who had fallen in the war should be inscribed on the memorial.
3. That funds "ear-marked" for the benefit of families should be devoted to that purpose.
4. That it should be open to the public to subscribe such sums as they wish.
5. That subscriptions should be sent to the Honorary Secretary, R.A.M.C. War Memorial Fund, Captain A. R. Wright, D.S.O., War Office, Cornwall House, Stamford Street, S.E.1.

TREATMENT FOR DISABLED OFFICERS AND NURSES.

IN pursuance of the policy of decentralization, the Minister of Pensions has entrusted to the Commissioners of Medical Services in the various regions of the Ministry the responsibility of obtaining for disabled officers and nurses the medical or surgical treatment to which they are entitled under the Royal Warrant. A discharged officer or nurse who is claiming retired pay or pension on the ground that he or she is suffering from a disability which is either attributable to or aggravated by service, and who is in need of treatment for the disability, should also make application to the Commissioner of Medical Services at the regional office with a view to the necessary treatment being provided. Appended is a list of the addresses of the Regional Commissioners and the counties comprised in each region, but the local War Pensions Committee will supply any officer or nurse with the address of the appropriate regional office upon request.

1. Scotland.—All Scotland. Address: Adelphi Hotel, Cockburn Street, Edinburgh.
2. Northern.—Northumberland, Durham, Cumberland. Address: 14, Clayton Street West, Newcastle-on-Tyne.
3. North-Western.—Lancashire, Cheshire, Westmorland, Isle of Man. Address: 13, Piccadilly, Manchester.
4. Yorkshire.—Yorkshire. Address: 7, Boar Lane, Leeds.
5. Wales.—All Wales and Monmouthshire. Address: Angel Building, Cardiff.
6. West Midlands.—Staffordshire, Shropshire, Warwickshire, Worcestershire, Herefordshire. Address: Bethany Buildings, Loveday Street, Birmingham.
7. East Midlands.—Leicestershire, Lincolnshire, Nottinghamshire, Derbyshire, Northamptonshire, Rutlandshire. Address: Black's Building, Stoney Street, Nottingham.
8. South-Western.—Gloucestershire, Wiltshire, Dorsetshire, Somersetshire, Devonshire, Cornwall. Address: Clifton Down Buildings, Bristol.
9. Eastern.—Norfolk, Suffolk, Cambridgeshire, Huntingdonshire, Essex, Bedfordshire, Hertfordshire, Buckinghamshire, Oxfordshire, Berkshire. Address: 80, Westbourne Terrace, W. 2.
10. London.—Metropolitan Area. Address: Crown Agents' Annexe, Westminster House, Millbank, S.W.1.
11. South-Eastern.—Kent, Surrey, Sussex, Hampshire, Isle of Wight, Channel Isles. Address: 48, Grosvenor Gardens, S.W.1.
12. Ulster.—Ulster. Address: Grand Central Hotel, Belfast.
13. Ireland South.—Muinster, Leinster, Connaught. Address: Dunlop House, Abbey Street, Dublin.

The Regions in the above list are printed in italics.

Officers and nurses are advised that in the event of their making their own arrangements for treatment without the prior approval of the Commissioner of Medical Services of the Ministry of Pensions, it may not be possible to refund to them any of the expenses thereby incurred. Communications with regard to the award of retired pay or pension should be addressed to the Officers' Awards Branch, Cromwell House Annexe, Millbank, S.W.1.

HONOURS.

FOREIGN DECORATIONS.

THE following decorations have been conferred by the Allied Powers for distinguished services rendered during the course of the campaign.

By the King of the Belgians.
Ordre de la Couronne.—Officer: Temporary Major Cathbert Christy, R.A.M.C.

Ordre de Leopold II.—Chevalier: Lieut.-Colonel Sir David Prain, C.M.G., C.I.E., F.R.S., I.M.S. ret.

Médaille du Roi Albert.—Captain Oswald Ryle Horwood A.A.M.C.

By the King of Italy.

Order of the Crown of Italy.—Commander: Colonel Charles Alfred Hodgetts, C.M.G., C.A.M.C. Officer: Major Charles Bramhall, O.B.E., R.A.M.C. Cavalier: Captain Perc. R. Bolus, R.A.M.C. (T.F.).

By the President of the United States.

Distinguished Service Medal.—Lieut.-Colonel and Brevet Colonel Sir Edward Scott Worthington, K.C.V.O., C.B., C.M.G., R.A.M.C.

By the President of the Portuguese Republic.

Military Order of Aviz.—Commander: Colonel Alexander D. Sharp, C.B., C.M.G., A.M.S. (T.F.), Captain John William McNee, D.S.O., R.A.M.C. (S.R.).

By the King of Serbia.

Distinguished Service Medal.—Lieut.-Colonel and Brevet Colonel Sir Edward Scott Worthington, K.C.V.O., C.B., C.M.G., R.A.M.C.

Order of St. Sava (5th Class).—Captain Charles Gunn Skinner, R.A.M.C. (T.F.).

By the Emperor of Japan.

Order of the Rising Sun (3rd Class).—Surgeon Captain George T. Broatch, C.B.E., R.N.

By the Sultan of Egypt.

Order of the Nile (4th Class).—Surgeon Commander John Thornhill, R.N.

By the King of the Hedjaz.

Order of El Nahda (4th Class).—Temporary Captain Graham Colville Ramsay, R.A.M.C.

Surgeon Lieutenant Henry Cyril Conwy Joyce, R.N., has been mentioned in dispatches for services in Siberia, 1919.

A HANDBOOK FOR THE DEMOBILIZED.

THE Service Handbook, compiled by Captain H. C. Baird, D.S.O., should prove a valuable guide for demobilized officers, and their dependants. It summarizes in a convenient form information as to the qualification for all available grants, pensions, and allowances, the method of application and the quarter in which it should be made, and includes brief notes on the several voluntary funds and organizations existing for special purposes. The Handbook can be obtained from the office of the *Ex-Service Man*, 11, Regent Street, S.W.1, price 1s.

Obituary.

SAMUEL WEST, M.A., M.D. OXON., F.R.C.P.

Consulting Physician to St. Bartholomew's Hospital; President of the Royal Medical Benevolent Fund.

WE much regret to record the death on March 2nd. at his house in Wimpole Street, of Dr. Samuel West, consulting physician to St. Bartholomew's Hospital, the Royal Free Hospital, the New Hospital for Women, King George Hospital, and King Edward VII Sanatorium.

Samuel Hatch West was born at Carlisle in 1848; his father was John West, Deputy Inspector-General of Mails to the General Post Office. He was a Queen's scholar of Westminster, and a junior student of Christchurch. At Oxford he gained first-class honours in the natural science school, was demonstrator of anatomy for a short while, and later Radcliffe Travelling Fellow. From Oxford he went to St. Bartholomew's, graduating M.B. of his University in 1875, and proceeding M.D. in 1882. He obtained the membership in 1877, and was elected a Fellow of the Royal College of Physicians of London in 1885. His tenure of the Radcliffe Fellowship enabled him to continue his studies at Berlin and Vienna.

Dr. Samuel West was appointed assistant physician to St. Bartholomew's Hospital in 1887, and full physician in 1903, retiring in 1913; for some years he was lecturer on the principles and practice of medicine in the medical school. During the earlier part of this period of service

on the active staff at St. Bartholomew's Dr. West was physician also to the Royal Free Hospital and to the City of London Hospital for Diseases of the Chest. He was for long an examiner in medicine to the English Conjoint Board, and to the Universities of Oxford, Cambridge, London, and Birmingham. At the Royal College of Physicians of London he was Bradshaw lecturer in 1887, councillor from 1904 to 1906, censor in 1911-12, and senior censor in 1917. In the Royal Society of Medicine he had held office as president of the Medical Section and of the Clinical Section. He was a former president of the Medical Society of London, and delivered the Lettsomian lectures in 1900 on the subject of granular kidney. Dr. West's long and great services to the Royal Medical Benevolent Fund as honorary secretary, treasurer, and president are recorded below by Dr. Newton Pitt. This charitable work occupied a very great share of his time and thought. During the war he represented the Council of the Fund upon the Professional Classes War Relief Council, bringing to this duty his experience, energy, and good will.

Of Dr. Samuel West's writings his book on *Diseases of the Organs of Respiration*, in two volumes, is, perhaps, the best known. It was first published in 1902, and a second and revised edition appeared seven years later. Both editions were characterized by careful observation and analysis of contemporary work happily blended with the personal impress of the author's ripe experience. In 1900 he revised and amplified his Lettsomian lectures and published them in a book with the title *Granular Kidney and Physiological Albuminuria*—a well-planned treatise of much practical value, clear and concise in its theoretical parts, and full of useful suggestions on the practical management of cases. Many years before he had produced a small handbook, *How to Examine the Chest*, which several generations of students found helpful in forming methodical habits of bedside investigation; it was, we believe, reprinted several times. Dr. West was the author of the article on "Treatment of Acute and Chronic Nephritis" in *Wright's Index of Treatment*. His many contributions to current medical literature included a paper on "Sulph-Haemoglobinaemia," printed in the *Medico-Chirurgical Transactions*; two papers on "Nitrogen Excretion," printed in the *Proceedings of the Royal Society*; several addresses—including one in 1906, on "Dilatation and Hypertrophy of the Heart,"—printed in this JOURNAL; and a series of "clinical jottings" which appeared from time to time in *St. Bartholomew's Hospital Journal*. His literary style was clear and easy, without affectation.

Dr. West was fond of outdoor sport and country pursuits, and, above all, of music. He had an agreeable well-trained tenor voice, and in former days no students' smoking concert was allowed to close without a song by him. He married a daughter of Sir Edward Frankland, K.C.B., F.R.S., and had three sons and three daughters. The first part of the funeral service was held on March 5th at St. Martin's in the Fields. He was a member of the Governing Body of Westminster School, and the Dean of Westminster conducted the service, which was attended by the President and other representatives of the Royal College of Physicians and by many colleagues representing the hospitals and other institutions with which he was connected. With great appropriateness the musical part of the service was very beautiful.

We are indebted to Dr. JAMES CALVERT for the following appreciation:

My earliest recollections of Dr. West date from the time when I was a student and he medical tutor. His classes were very well attended; every earnest student learnt a great deal from them, and he may be considered to be the pioneer of the present medical tutorial system at St. Bartholomew's. When I was house-physician to Sir Dyce Duckworth Dr. West was the corresponding assistant physician; and when, in the course of time, I became assistant physician, he was my chief. So that for many years we worked together, I am glad to say, in perfect harmony, for he was easy and pleasant and most kindly to work with. I shall always hold in grateful remembrance his unvarying consideration and helpfulness. He was a very accomplished physician and a very practical one, with a leaning, naturally enough, to chest diseases, but certainly not limiting his activities to them, as his

record shows. He was devoted to his wards, and he never allowed, as some are inclined to do, the scientific aspect of the case to interfere with the personal interests of the patient. An excellent teacher, and with great experience in teaching, he was popular with the students; his clinical clerks were many, and he always had a substantial following round the wards. Outside the hospital he had a large consulting practice of the best kind, and I am sure there are many, especially among his old pupils, who in his death feel, as I feel, a sense of personal loss.

Dr. G. NEWTON PITT writes as follows:

Dr. Samuel West was intimately associated with the Royal Medical Benevolent Fund for thirty years, and under his skilful direction the funds of the society have steadily increased in amount, so that the annual income now exceeds that in 1900 by £3,000. From 1899 he held the office of Treasurer in succession to the late Sir William Broadbent, and was mainly responsible for the reorganization of the finances. From the first he insisted that all legacies should be invested and the income expended on the annuitants, while the current income from annual subscriptions and donations should be awarded as grants to necessitous cases. The amounts last year were £3,200 and £2,800 respectively. For the past three years he has been President and acting Treasurer of the Fund.

The profession also owes a deep debt of gratitude to Dr. West, for it was mainly through his initiative that the War Emergency Fund was started, and this has already made grants to the amount of £10,000 to assist doctors on their return from the war to re-establish themselves in practice. One of his last acts was to obtain a grant of £10,000 from the National Relief Fund for the same purpose, which will enable even more liberal grants to be made in the future.

COLONEL DENIS FRANCIS KEEGAN, I.M.S. (retired), who died recently, took the diploma of M.R.C.S. in 1861, and graduated M.B. of Trinity College, Dublin, in 1862, and M.D. three years later. He obtained the F.R.C.S. Eng. in 1891. Lieut.-Colonel Henry Smith, I.M.S., writes: "The death of Colonel Keegan removes one of the grandest figures in the history of the Indian Medical Service. If you named the three biggest surgeons which the Indian Medical Service has produced, you must include the name of Keegan. The grand work he did will live for generations yet unborn, and he will be more honoured in his urn than he was when alive. This is the fate of all great pioneers. Death removes them from the field of jealousy. When he was doing the spadework he had to fight the world, and he did it and established his case. We all—or some of the older members of the profession rather—still remember how he and Freyer fought the controversy on litholapaxy. We are all familiar with the grand work Keegan did in rhinoplasty, and how he established the Indian operation as the operation for all time. He was a powerful, clear, and incisive though courteous controversialist. Keegan was a man with a fine imagination, a powerful and versatile intellect and a strong character. It is only a very able man in any public service who can go his own way and live as an official. Keegan did this. As a man he was one of the most kind-hearted, the most generous, and the most genial of men. As a friend he was one of the few capable of that genuine friendship, as distinguished from fair-weather friendship, who would life itself resign at the sacred call of friendship. He had too much pride for servility and too little prudence for selfishness. He was the finest type of Irishman. He did most of his service in Central India, where his fine personality was a political influence of the first magnitude. He died at the age of 80 years. The Government of India did not do themselves the honour of honouring him with a decoration. A man like Keegan does not require a decoration as his passport. He made no pretension to be what, in popular language, is called an "aristocrat." He belonged to a much higher order. He was an aristocrat of the moral code of the New Testament. He leaves a grand heritage to his son and his two daughters."

The medical profession and the public of Middlesbrough-Tees have to regret the loss of Dr. W. J. WILLIAMS, who was a prominent practitioner in the town for over fifty years. William Jones Williams was born in Tremadoc,

North Wales, in 1841, the son of a Baptist minister. He was educated in Liverpool, Glasgow, and Edinburgh, and graduated M.D. at the latter university in 1866. He then sought experience in the wards of some of the London hospitals, and afterwards spent many months in Paris. He spoke French with ease and facility, and was familiar with German and German medical literature. He was appointed house-surgeon to the North Riding Infirmary, Middlesbrough, in 1867, and two years later commenced practice in the town. He was elected to the medical and surgical staff on the first vacancy, and for forty years filled this position with conspicuous ability. He then became vice-president and honorary consulting surgeon. Dr. Williams was an ardent Freemason, was the Past Provincial Senior Grand Warden of the North and East Ridings, and was also Past Master of the Ferrum Lodge, Middlesbrough. He was twice married, and leaves a widow, the daughter of the late Dr. Longthorpe of Middlesbrough. He was a justice of the peace for the borough and a patron of most of the institutions of the town. Such (writes a colleague) is a brief summary of one who went about his work with a conscientious diligence and devotion which won for him the admiration of the whole of his professional brethren and the affection and respect of a whole community. He was a man of high character, of most amiable disposition, and leaves a great number of friends to regret his loss.

THE death has occurred of Dr. JAMES EMERSON REYNOLDS, F.R.S., the eminent chemist, who was a member also of the medical profession. He was the son of Dr. James Reynolds of Booterstown, co. Dublin, and received his medical education at the Royal College of Surgeons and the Ledwich Medical School, Dublin, obtaining the L.R.C.P. and L.R.C.S. Edin. diplomas in 1865, and the L.R.C.P.I. in 1873. Soon after qualifying he returned to pure science, was appointed Keeper of Minerals at the National Museum, Dublin, in 1867, professor of analytical chemistry to the Royal Dublin Society in 1870, and professor of chemistry in the Royal College of Surgeons in Ireland three years later. From 1875 to 1903 he was professor of chemistry and chemical philosophy in the University of Dublin. That university conferred upon him its honorary M.D. and D.Sc. degrees, and in 1880 he was elected Fellow of the Royal Society, becoming Vice-President in 1902; in the latter year he was elected president of the Chemical Society, having previously served as president of the Society of Chemical Industry, and president of the chemical section of the British Association. Dr. Emerson Reynolds's researches were recorded in a series of papers in the *Journal of the Chemical Society* and the *Proceedings of the Royal Society*, and other scientific publications. He published a volume of lectures on experimental chemistry in 1874, and his book on general experimental chemistry appeared in 1880. In former years he was examiner in chemistry to the Universities of Cambridge and London. Thus, save for his early medical studies in Dublin and his collaboration in a manual of public health for Ireland, Dr. Emerson Reynolds had little direct contact with the practice of medicine, devoting his working life almost wholly to chemical research and to the teaching of chemistry. After his retirement from the chair of chemistry at Trinity College, Dublin, he went to live in Kensington, where he died suddenly last week in his 77th year.

DR. ROBERT MORRIS WILLIAMS of Menai Bridge died on March 2nd, aged 52. He received his medical education at the University and the Royal College of Surgeons of Edinburgh and graduated M.B., C.M. Edin. in 1892, after which he acted as colliery surgeon at Ystrad Rhondda, where he won the esteem of all with whom he came in contact, and on his departure for Menai Bridge was presented with an illuminated address and a purse of gold. He was Commissioner of the Priory of St. John for the county of Anglesey, certifying factory surgeon, M.O.H. Menai Bridge Urban District Council, and medical officer to the Post Office and Education Department. He was chairman of the North Carnarvon and Anglesey Division of the British Medical Association and had served as Deputy Representative of the Division in the Representative Body. Only three days before his death Dr. Williams presided over a successful dinner given by the medical men of North

Carnarvon and Anglesey in honour of their colleagues who served in the R.A.M.C. On the following day alarming symptoms showed themselves, and Dr. J. E. Thomas of Bangor, who had so lately proposed Dr. Williams's health, was called in. An operation was performed, but death occurred from toxæmia.

Medical News.

THE London County Council proposes to exercise its powers under Section 18 of the Education Act, 1918, to provide medical treatment for fee-paying pupils attending its own secondary schools, and medical inspection and treatment for fee-paying pupils attending aided secondary schools if so requested by the governing body, provided that the medical treatment shall only be given at the Council's centres to pupils whose parents cannot afford to make private arrangements.

AT a meeting of the Marylebone Division of the British Medical Association to be held at the Hospital for Epilepsy, Maida Vale, on Tuesday, March 16th, at 4.30 p.m., Dr. Charles Porter, M.O.H. Marylebone, will read a paper on "The practitioner, public health, and preventive medicine." The meeting is open to all medical practitioners.

IT is proposed to hold a reunion dinner of officers who were attached to No. 5 General Hospital, B.E.F., in London on Saturday, April 10th. Those who wish to attend are asked to write to Dr. G. T. Loughborough, 3, Lexham Gardens, Kensington, W.8.

AT the next meeting of the Chelsea Clinical Society to be held on Tuesday, March 16th, at 8.30 p.m., in St. George's Hospital Medical School, Dr. D. M. Barcroft will open a discussion on "Is asthma a disease of the chest?" in which Sir Thomas Horder, Dr. Leonard Williams, and Dr. Herniman-Johnson will take part.

MR. C. A. MITCHELL recently read to the Society of Public Analysts a paper on the persistence of finger prints on documents, and showed specimens fifty-six years old. He discussed the various methods of detecting finger prints on documents, and also the persistence of stains on paper, including blood finger prints.

THE annual general meeting of the Medical Sickness Annuity and Life Assurance Society will be held in the rooms of the Medical Society of London, 11, Chandos Street, W.1. on Friday, March 26th, at 3 p.m.

THE annual general meeting of the London and Counties Medical Protection Society will be held at the offices, 32, Craven Street, Strand, W.C.2, on March 17th, at 4 p.m.

A FRANCO-JUGO-SLAV medical union has been formed in Paris with the threefold object of facilitating the medical studies of Jugo-Slavs in France, the diffusion of French science among the Jugo-Slav populations, and the establishment of direct professional relations between French and Jugo-Slav medical men.

AT a meeting of the Medical Officers of Schools' Association, to be held at the house of the Medical Society of London on Friday, March 26th, at 8 p.m., Dr. G. H. Lock will read a paper on the care of minor ailments in school children. Medical practitioners interested in the subject are invited to attend.

A MEETING of the North-Western Tuberculosis Society (formerly the Lancashire and Westmorland Tuberculosis Society) will be held on Thursday, March 18th, at the Houldsworth Hall, Deansgate, Manchester, at 2.30 p.m. Dr. T. H. Peyton will read a paper on the tuberculosis colony; the attendance of medical practitioners is invited. Information as to the society, the annual subscription to which is 5s., can be obtained from Dr. G. Jessel, County Tuberculosis Dispensary, Leigh, Lancashire.

THE annual general meeting of governors of the Royal Dental Hospital of London will be held at the hospital, Leicester Square, W.C., on Thursday, March 25th, at 5 p.m., when Sir Fisher Wentworth Dilke, Bt., will preside.

THE French Medical History Society, which was established in 1902, recently revised its constitution and renewed its activities. It admits members of either sex and any nationality, and is inviting British members to join; at present they are few in number. The society recently elected the late Mr. C. Louis Taylor, Assistant Editor of this JOURNAL, but the intimation arrived after his death.

AT the matriculation examination of the University of London in January there were 102 successful candidates in the first division and 807 in the second.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westminster, London*; telephone, 2531, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westminster, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westminster, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin, and of the Scottish Office, 6, Belford Square, Edinburgh.

QUERIES AND ANSWERS.

"P." relates a case of poliomyelitis affecting the quadriceps and peronei which for the first two years was treated by muscular rest and relaxation by means of a Thomas splint. During the succeeding two years it has been treated with massage and some electricity. He asks for suggestions as to any other treatment.

"H. H. P.," who has under treatment a factory girl suffering from hysterical paraplegia, asks whether there is a hospital or other place where treatment by psychotherapy could be got.

INCOME TAX.

"A. A. A." inquires as to the expenses he can deduct for income tax purposes from the salary received by him as an assistant school medical officer under a county council.

"1." "Running expenses of car when on duty where not covered by allowance from the council." If the allowance is at an annual rate or calculated in any other way other than for specific journeys we imagine that the revenue authorities would require very full proof before making a deduction that would in effect impugn the council allowance as insufficient; nevertheless our correspondent is entitled in law to any excess over the allowance of expenses incurred solely, exclusively, and necessarily in the performance of the duties of his office.

2. "Cost of purchase of car less price obtained for car sold on leaving practice to join the services during the war." Assuming that the council's allowance is intended to cover wear and tear, "A. A. A." will have to meet the difficulty mentioned above. Possibly he may be able to induce the local inspector of taxes to defer the question until he can show the results of twelve months' running of the car.

3 and 4. "Subscriptions to societies and cost of new books and subscriptions to medical library." It is necessary for "A. A. A." to expend something from year to year to maintain that degree of professional competence essential to the proper performance of his duties. So much of the subscriptions and cost of new books as can fairly be brought within that description he is, we conceive, entitled to deduct as expenses.

LETTERS, NOTES, ETC.

SUBCUTANEOUS INJECTIONS OF OIL OF CAMPHOR.

IN the EPITOME for January 31st (paragraph 111) the experience of Jensen in the treatment of sciatica by the subcutaneous injection of oil of camphor was noted. It was said that he injected 3 to 4 cm., which was raised in severe cases to 5 or 6 cm. daily. A correspondent asks as to the formula for this camphor oil. The preparation, though little used in this country, is largely employed in France and Germany in the treatment of heart failure, typhoid fever, and low forms of pneumonia. The usual prescription is 2 parts of camphor oil in 10 of sterile olive oil, and the dose is 10 minims, increased if necessary. Heroic doses up to 30 grains of camphor have been given but are dangerous. The firm of William Martindale supplies the oil for hypodermic use in sterules containing 1/2 and 3 grains in sterile olive oil.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 42, 43, 44, 45, 46, 47 and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40, 41, and 42.

SITES OF INOCULATION LESIONS IN SYPHILIS.

IN our issue of January 10th, p. 51, we gave some account of a report to the Medical Research Committee by Surgeon Lieutenant Commanders R. J. G. Parnell and P. Fildes, which dealt with the treatment of syphilis in the navy. Dr. Douglas White, honorary secretary of the National Council for Combating Venereal Disease, has obtained from Surgeon Lieutenant Commander Parnell statistics with regard to the site of inoculation in 2,745 consecutive cases at R.N. Hospital, Haslar. They are as follows:

Genital Inoculation Lesions:

In urethra (concealed)...	1
Within meatus (concealed)	25
At meatus (visible)	94
On glans penis	270
On corona glandis	86
In sulcus	420
On prepuce (skin 328, i.m. 346)	674
On fraenum preputii	192
Under phimosed prepuce (concealed)	121
				1,884 = 68.7%
Body of penis	209
Root of penis	50
Scrotum	20
Peni-scrotal angle	13
				292 = 10.6%
Site on penis not stated	238
Combinations of above	283
				521 = 19%

Extra-genital Inoculation Lesions:

Lip	20
Eye (palpebral conjunctiva)	5
Anus (at or near)	7
Thigh	2
Pubes	6
Chin	1
Finger	2
Umbilicus	1
Nose	1
Neck	1
Abdomen	1
Buttock	1
				46 = 1.7%

Remarks.

1. In addition 101 cases had manifest signs of syphilis or had cerebro-spinal syphilis, yet no site of the inoculation lesion was found; all the men denied a sore on the penis. A few of these men gave a history of "gonorrhoea." The majority denied having had venereal disease in any form, but admitted risks of infection. A very small number denied venereal disease, and stated that they had never exposed themselves to infection. Three of these had definite signs of congenital syphilis.

2. One case of both genital and extra-genital inoculation lesions occurred (lip and penis).

3. Of the 238 cases in which the site (on penis) was not stated, the vast majority were old infections giving a definite history of a sore on the penis, but no scar was found. In a few cases there was an indefinite amount of scarring at a site other than that at which the sore apparently had been.

THE following appointments of certifying factory surgeons are vacant: Currie (Edinburgh), Farnworth (Lancaster), Lynton (Devon).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

The charges for advertisements in the BRITISH MEDICAL JOURNAL will be increased at the end of March. The new charges will apply to all advertisements for insertion in the JOURNAL of April 3rd and subsequently. The rates will be as follows:

Six lines and under	7s. 6d.
Each additional line	1s. 3d.
Whole single column	£6 0s. 0d.
Whole page	£16 0s. 0d.

An average line contains six words.

From the issue of April 3rd the charge for announcements of births, marriages, and deaths will at the same time be increased to 7s. 6d.

Present Scale.

Seven lines and under	8 s. d.
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive postage restant letters addressed either in initials or numbers.

Observations

ON

THE ELEMENTS OF THE PSYCHO-NEUROSES.

A PAPER ADDRESSED TO THE SOCIETY OF MEDICAL
OFFICERS OF THE PENSIONS BOARD,
LANCASTER GATE, LONDON.

BY HENRY HEAD, M.D., F.R.S.

It would be an impertinence on my part to talk to you of the treatment of war pensioners, for each of you is more practised than I am in this class of work. But I venture to approach you to-day because I believe your experience will be of inestimable advantage in the more difficult task of understanding the psycho-neuroses of civilian life.

The conditions which evoked these morbid states in soldiers on active service were essentially simple. A man who had never engaged in any warlike or strenuous pursuit was called upon to undergo violent preparation under most unpleasant conditions to fit him to take part in disagreeable and dangerous operations calculated to arouse fear even in the bravest. The fundamental instincts of civilized man were outraged. What wonder that the not infrequent consequences were an anxiety neurosis, an obsessional state, or hysterical manifestations?

Now the war is over, the factors responsible for the continuance of these morbid states have altered. The active forces are still fear and a desire to avoid discomfort, but the objective of these emotions is changed. The patient has no longer to brave the horrors of the trenches, but the conscientious pensioner is still oppressed by dread that he may be unable to face his job, whilst the more obviously self-seeking recognizes that he is better off on a pension of a pound a week than when earning twice that sum by fatiguing toil. The first of these suffers from an anxiety neurosis, whilst the second remains firmly entrenched behind his hysterical symptoms.

No new morbid phenomena have been evoked by the war. The disordered functions of the human mind were manifested in exactly the same forms as under the stress and strain of peace-time civilization. But the task to be faced by every man in the army was a simple one. The one test of his conduct was "Can he fight?" and the only reality to which he was compelled to adapt himself was a state of war. On the other hand, in civilian life the factors underlying a psycho-neurosis are far more complex; they may lie in many different fields—thwarted ambition, business worry, or family anxieties, apart altogether from the disaccord between individual sexual desires and social convention.

In all attempts to solve a complicated problem it is important to choose examples which show the smallest number of variable factors. The functional neuroses of war have been of inestimable benefit in showing us these morbid states under the simplest causal conditions. We have been able to observe the various forms they assume under pressure of the same external forces, and could watch the diverse results which followed changes in the mental and physical environment.

Your task is to deal with these patients, who continue to need your care although the war is over, and you have the opportunity of watching their behaviour, when subjected to the more complicated conditions of civilian life. You can note the effect of disappointment on anxiety neurosis, originally due to fear and fatigue, or observe the return of obsessions and nightmares under the depressing effect of illness of wife or child. Let us then consider some of the chief processes at work in the production of the psycho-neuroses in the hope that we may be guided to some simple rules of prophylaxis and curative treatment.

In the past, psychology dealt mainly with the intellectual factors of mental activity; the instinctive and emotional aspects of the mind were disregarded and the unconscious entirely neglected. But we have learnt to recognize that, outside the limits of the experiences which can be recalled into consciousness by an effort of the will, lie impressions capable of producing an active effect upon mental life.

Throughout the vital activities of the nervous system, from the lowest reflexes to the highest neuro-psychical activities, functions of a lower order are controlled by

those higher in the scale. Thus, for example, the activity of the optic thalamus is normally controlled by that of the cerebral cortex. The thalamus is the centre for the more affective aspects of sensation; it is peculiarly associated with the pleasure or discomfort induced by afferent impulses, and is responsible for almost the whole of our sensibility to pain. When this centre is released from cortical control, the patient becomes more susceptible on the affected half of his body to any stimulus capable of exciting either pleasant or unpleasant sensations. The prick of a pin causes intense discomfort and immediate withdrawal, whilst contact with such a stimulus as warmth evokes exquisite pleasure. Moreover, general states of emotion can be produced more easily by stimuli applied to the abnormal parts; thus, an elderly man, one of my patients, fell in love on the affected half of his body, and had no desire to touch the beloved object, except with his affected hand. Gross organic disease may free the activities of the optic thalamus from the active control normally exerted over them by the cortex. The response from the affected parts becomes in consequence more vehement and impulsive. The patient can no longer deliberate whether or no to remove his hand when pricked; the reaction is an immediate defensive withdrawal.

The object of this control, exercised by higher centres over those of a more primitive activity, is to endow the animal with the power of choice between alternative courses. It can be demonstrated at every level of neural activity, from the simplest reflexes to the highest neuro-psychical functions. It consists, on the part of the higher centre, of a positive exercise of inhibiting energy over the reactions of those lower in the neural hierarchy. With the gradual evolution of its functions, the nervous system thus gains ever-increasing control over the reaction to painful and disagreeable stimuli. We acquire the power of choosing our actions, and cease to be the slaves to an impulsive and inevitable response.

From the psychical point of view, the reactions which civilized man must bring under control are those founded on the primitive instincts; of these, the most powerful are the pleasure of sexual gratification and the urgent desire to avoid pain and discomfort. They are therefore controlled by the more discriminative and logical aspects of the mind, exactly as the activity of the thalamus is subjected to that of the cortex. So long as there is harmony the mind exercises its functions in an orderly manner. The instincts are permitted to manifest themselves in an orderly manner on suitable occasions, and at other times are relegated to a subservient position. But any want of unison between the more impulsive and more discriminative activities of the mind becomes manifested in mental conflict.

Normal control is an automatic and not a voluntary act. The focus of interest changes, as attention moves over the varied objects presented to consciousness. Some point in the field arouses vivid mental activity, and then becomes submerged again with all its attendant psychical processes, as attention moves on to some other centre of interest. In order that the mind can function in a normal manner, attention must be free to range widely, and within certain limits we must be able to choose the mode of response.

Should this control cease to be automatic, the mind adopts several different methods of curbing the desires to which it has determined not to yield. Of all instincts, that of self-preservation is the most deeply innate; but the war has shown how completely it may be curbed by the forces of social tradition or implanted *esprit de corps*. A soldier recalls to himself that if he runs away he will certainly be shot at dawn, and dominates an instinctive wish by a terrifying concept. But this intermediate conflict is certain sooner or later to lead to morbid consequences. The private develops a conversion hysteria, and is carried from the danger zone paralysed from the waist downwards. The officer becomes the victim of an anxiety neurosis, and may resolve the conflict by suicide.

Such conflict may assume morbid proportions in several different ways. It may be that an attempt has been made by the sufferer to repress the desire it is inexpedient to gratify, and the emotional energy with which it is charged reappears in some other form, most commonly as a disturbance of some physiological function. Or the affective intensity of the experience may be so great that the normal powers of adaptation are inadequate to resist its impact.

Lastly, the patient may fall back on some previous and less efficient mode of reaction.

REPRESSION.

The importance of the mental conflict arising from the failure of automatic control was not recognized until Freud formulated his conception of the process of repression, and its bearing on the genesis of the psycho-neuroses. He laid down that forgetting was not a negative procedure, but was a positive act. Unpleasant experiences did not simply fade away, but were thrust out of consciousness as incompatible with its more intellectual content.

These instinctive desires or unpleasant impressions pass into oblivion in consequence of the positive inhibition exerted by the dominating influence of conscious activities of the mind, but are still capable of exerting a subterranean influence on the mental and physical life of the individual. It is this act of expulsion without facing the problem that is so dangerous to the harmonious working of the mind. If I have received an unpleasant letter and neglect to answer it because I am reluctant to deal with its contents, I may forget it for a time; but I shall probably be haunted by a sense of impending ill, my appetite may fail and sleep be troubled. For I have thrust into unconsciousness a highly affective process, which should have led to action, without discharging the energy with which it was loaded. This energy, forbidden the normal method of expression, finds some other outlet. It appears as a dyspepsia, headache, insomnia, or analogous disturbances of function. It is a significant fact that this suppressed energy often manifests itself on the physiological level when denied psychical expression.

This repression, under the influence of reluctance to face disagreeable memories, reaches its acme in the cases of amnesia, which were not uncommon during the war. Many patients could not remember that they had ever been in France, and one young officer under my care could recollect nothing after his seventeenth year. He lost all knowledge of his profession as an engineer, and knew nothing of music in which he had become unusually expert. An able pilot in the R.A.F., when returned to duty after a crash, was ignorant of the construction of an aeroplane, and denied that he had ever been in the air. Asked why he was wearing wings on his tunic, he was entirely at a loss to explain how they came to be there.

DEFECTIVE ADAPTATION.

It is a beneficent provision of Nature that a stimulus of uniform intensity cannot continue to produce a reaction of constant strength. Adaptation is one of the fundamental factors in the mode of response of the nervous system to the forces of the external world. Soak the right hand for a time in cold and the left in warm water; then plunge both of them into a vessel containing water at a temperature which, before the experiment, seemed neither hot nor cold—the neutral medium will now seem hot to the right hand and cold to the left. Each has become adapted to the temperature to which it was exposed, and the change is manifested in the different sensation produced in the two hands by the same, previously neutral, environment.

One of the most salutary results of this power of adaptation possessed by the central nervous system is the capacity to dominate pain and discomfort. This applies not only to the normal physiological processes of the individual, but also to those of his mental life. An apparently overwhelming sorrow loses its poignancy with time; a sound mind and healthy body become adapted to the environment. But any failure of physical health, or lack of that instinctive vital energy which lies behind the processes of consciousness may lead to failure of adaptation. The patient becomes easily fatigued, anxious, and depressed, finally passing into a condition spoken of by the old physicians as "irritable weakness." Should sleep be disturbed this process of exhaustion—physical and mental—is aggravated. The power of adaptation to the conditions produced by bodily fatigue or psychical discomfort is diminished, and the patient is said to be suffering from an exhaustion psycho-neurosis.

But some minds have a subtle method of side-tracking this want of adaptation by constructing fantastic conceptions of the external world. No better example could be given than the story of Cinderella. The despised youngest sister, sitting in rags amongst the pots and pans of the kitchen, imagines a coach and six horses, a footman and gorgeous robes; she too is present at the ball,

but she alone attracts the attention of the Prince. Such fantasies have been the comfort of many a Cinderella, and have served to make it possible to exist under otherwise impossible surroundings.

Such fantasy building has its dangers. Just as a repressed fear may come to the surface as a physical symptom, so such imaginings that have no connexion with reality may lead to curious aberrations of conduct. Privates masquerade as officers of high rank. A lieutenant, who was brought to me for an opinion about loss of power in his arm, was covered with ribbons of non-existent orders, one of which was said to be the "Serbian Victoria Cross." No one doubted his story that he had penetrated to Austrian head quarters disguised as an Austrian officer and had obtained information of vast importance; and yet it was easy to ascertain that this young cockney could not understand a word of German.

I believe that this fantastic method of thinking is responsible for some of the inexplicable disappearances known as "*fugues*." A lieutenant in the R.F.A. was wounded in France, but the injury was not severe. Whilst in hospital in England he obtained leave to spend a weekend with his parents. On Sunday afternoon he mounted his motor bicycle prepared to return to hospital, and disappeared. He subsequently confessed that during the ride he began to think with pleasure of the farm where he worked before the war; from that time he had only a hazy recollection of what happened, until he was discovered by his brother three weeks later. It appears that he turned up at the farm on Monday morning, occupied his old quarters, and set to work at once. When after some days the surprised farmer asked how long he intended to stop, he said he had been discharged from the army.

An airman who had returned from France was attached to an aerodrome to fly machines he particularly disliked. He was lurching alone in the neighbouring town at a restaurant where some of his colleagues were entertaining a merry party. He began to think how pleasant it would be to be free, and what a happy time he had spent with a friend and his wife who kept an hotel in the West of England. He went to the station feeling lonely and unhappy, intending to return to the aerodrome. A train came in going to the West; he got in and disappeared. Several weeks later he returned without explanation, having spent the whole time quietly with his friends. He had made no attempt to hide himself, nor had he offered any reason to his hosts for his presence.

These "*fugues*" are commonly attributed to amnesia, and the patient is said to remember nothing that happened. This is true in some instances; but I am certain that there are others in which memory is not completely lost, and sometimes a fairly coherent account can be obtained from the patient himself of how he spent his time. He may lose all sense of the cogency of the reasons against the line of conduct he adopts; but, as in the case of the airman just mentioned, he may not only remember the mental conflict, but also be able to give an account of his period of absence. Such fantasy building was responsible for many inexplicable aberrations of conduct in young officers during the war. It also lies at the bottom of some of those curious cases met with in civilian life, when a woman for a time leads a purely fantastic existence.

REGRESSION.

When Jung first described regression he intended the term to signify a falling back of psychical life to a more infantile or primitive mode of behaviour. This useful conception is, however, capable of far wider application.

An unexpected return to some previous habit is one of the commonest errors in all human mechanical activities. Innumerable instances can be gathered from games and from daily life. For example, an aviator slowly acquires complete facility in manipulating his machine. At first he laboriously flies by rule, and has to memorize the steps by which each evolution is induced. As he becomes more expert, he has but to desire some movement and it occurs; for a good pilot flies automatically and not by formula.

This power over the machine has been gained by conscious effort, during which a series of functional adaptations become engulfed in the automatic activities of the central nervous system. Movements laboriously learnt become unconscious reactions. But this supreme control can only be maintained by constant exercise and perfect

physiological efficiency. Any influence which tends to diminish the power of concentration, or to disturb the acquired mastery over sensory and motor impulses, will lower ability to fly. The pilot begins to be aware that he has lost his certainty in the air, and especially in the art of landing, but does not know why he is no longer master of his actions. In the same way a golf player, who is "off his game," discovers he has fallen back to some long conquered faults. This might be called mechanical regression; for some action, which has been acquired in perfection and become automatic, is executed in a more primitive and less efficient manner. An even more evident regression was responsible for some of the accidents which occurred to pilots flying rapid scouts. They had been trained on relatively stable machines, which, if they fell into a spin, would right themselves, provided the pilot centralized all his controls. But the fighting scouts were not only much more sensitive, but required a definite action to bring them out of a spin. Should the pilot inadvertently regress to his old habits, adapted to more stable machines, he would certainly get into trouble. The attempt to fly a fast scout by the manipulative actions, suitable to a more stable type of machine, ended inevitably in disaster.

Regression may also be manifested in a failure to control automatically impulses from the sense organs. Those of you who happen to have overcome a childish tendency to sea-sickness may have had the ignominious experience of falling back to the earlier mode of reaction, under the influence of some temporary malaise. In the same way, a tendency to giddiness and vomiting in the air passes away with the acquisition of ability to fly. If, however, the pilot's physiological resistance is subsequently lowered, or his power of mental concentration is diminished, he may regress to the form of reaction which troubled him when he first went into the air.

Mental regression is an exactly analogous phenomenon. Most soldiers suffering from the stress of fighting complained of nightmares, which assumed the most diverse and individual forms; after suitable treatment these terrors ceased, and ultimately the sufferer was able to sleep quietly, and undertake some form of light work. But suddenly all the old horrors returned, in consequence of some private anxiety or trouble. He did not dream of the cause of his recent worry: his nightmares were those of the trenches. He had fallen back on an earlier mode of reaction.

When dealing with the psycho-neuroses of airmen, I frequently had the opportunity of seeing all these aspects of regression in the same individual. A clever pilot would discover that he was no longer flying with certainty; he was obliged to think what he was doing, instead of carrying out the manoeuvre automatically. At the same time the tendency to become giddy, which he experienced when he first went into the air, began to show signs of returning. He slept badly, and nightmares occurred, which went back to some long-forgotten accident, or to his period of service in the trenches. In such a case regression had occurred in all forms of neuro-psychical activity, and was manifested in want of mechanical aptitude, defective sensory adaptation, and uncontrolled resurgence of unpleasant mental experiences.

Throughout this exposition I have spoken of the psycho-neuroses in terms of processes common both to the mind and to the physiological functions of the nervous system. The lower reflexes are controlled by the higher centres, exactly as the more discriminative aspects of the normal mind dominate those which are more instinctive and primeval. But the success of this relation is based on a harmonious give and take. When I tread on a sharp stone, the result is a complicated act of walking, which removes my whole body from the site of the disagreeable experience; if, however, the sole of my foot is pricked when I am prone in bed, all that is necessary is a simple act of flexion, withdrawing the stimulated limb.

Control, in as far as it is a harmonious automatic process, is an expression of the dominance exercised by higher over lower neuro-psychical activities. Abnormal consequences arise when there is declared conflict between the suppressed experiences and the repressing forces. Such emotional repression of some idea or feeling, on account of the dread or repulsion it excites, uniformly leads to harmful consequences.

Adaptation is the power possessed by the normal nervous system of responding to a stimulus of constant intensity, with a steadily decreasing reaction. If this faculty is diminished, we can no longer accustom ourselves to our surroundings, and fail to carry out automatically the functions necessary for such adaptation. Unpleasant mental experiences, or bodily discomfort, tend to be unduly prolonged and lead to exhaustion.

Regression is the act of falling back to a more primitive mode of reaction. Facilities which have been acquired by practice come to be exercised automatically, as the reactions of the child are transformed by increasing experience into those of the man. Any failure of this automatic control may lead to the phenomenon of regression, and the victim becomes subject to some disability he had previously overcome completely.

Face to face with the patient, it is futile to waste time in considering whether he is a case of neurasthenia, psychasthenia, anxiety neurosis, or hysteria. The war has unfortunately increased the universal love of labels. Medicine is popularly thought to be based on the principles of a penny-in-the-slot machine. Make a so-called "diagnosis" and the rest follows mechanically. Hysteria is treated with electricity and massage; an anxiety neurosis needs a "rest cure"; obsessions require fresh air and cheery companions. Nothing is more pitiful than the condition of the medical man who finds that these rules of practice break under him. He is filled with mingled anger and despair, which frequently lead him to vent his impotence on the patient; he expresses his opinion that "the fellow is a rotter," and he "would like to see all his sort shot on the parade ground." He has made no attempt to investigate the forces at work that produce the condition he does not understand. His "diagnoses" are but camouflaged ignorance. The only diagnosis that is of the slightest value, or is worthy of the dignity of our profession, is the laying bare of the forces which underlie the morbid state and the discovery of the mental experiences which have set them in action. Diagnosis of the psycho-neuroses is an individual investigation; they are not "diseases," but morbid activities of a personality which demand to be understood. The form they assume depends on the mental and physiological life of the patient, his habits, and constitution. That is why the psycho-neuroses of war were so much simpler than are those of civilian life. Moreover, in daily practice, the causes of much defective mental harmony are not only more complex, but are more difficult to elicit. A married woman is not likely to confess to her doctor that she is in love with another man, when the doctor's wife may any day drop in to tea with her. She may have absolute confidence in the discretion of her medical attendant, but the presence of his wife would instinctively remind her of her unpleasant conflict. On the other hand, she has no reluctance to confess what she knows in her heart to be the cause of her want of sleep and digestive troubles to a man living at a distance, whom she will in all probability never see again, after her morbid condition has passed away.

Provided we can determine the processes at work in the production of the psycho-neuroses, the causal factors underlying a large number of the phenomena can be discovered without elaborate technique. In many cases, especially during the war, the patient was conscious of the experience which was at the bottom of his trouble, but, because of the horror it engendered, he refused to face it. This was particularly evident in cases of obsession. A man who had seen some horrible or filthy sight naturally repressed it whenever it appeared in consciousness. In this he was encouraged by his medical attendants, who advised him to "go away and forget the war." "Don't think of anything you saw in France, but play games and be with cheery fellows." The evil of this advice has been wonderfully expressed by Siegfried Sassoon in his poem called "Repression of War Experience."

Now light the candles; one; two; there's a moth;
What silly beggars they are to blunder in
And scorch their wings with glory, liquid flame—
No, no, not that—it's bad to think of war,
When thoughts you've gagged all day come back to
scare you.

And it's been proved that soldiers don't go mad
Unless they lose control of ugly thoughts
That drive them out to jabber among the trees.

If the morbid state is accompanied by physical symptoms, such as loss of speech, deafness, or paralysis, these must be removed. The patient is first carefully examined so as to be certain that there is no structural cause for his loss of power. Then he is told that his disability is not based on any serious bodily condition, and that he can be cured without difficulty.

The majority of hysterical patients, like children, are unduly suggestible. But, in most instances, it is unnecessary to employ hypnotic suggestion. Provided the examination has been carried out carefully and sympathetically and nothing has been said or done to confirm the patient's belief in the severity of his disease, the physician will have acquired sufficient suggestive power to remove such physical disabilities as paralysis or loss of speech. Sometimes this suffices to produce a permanent cure; but it must not be forgotten that behind these obvious manifestations may lie a state of anxiety. This must be dealt with seriously and systematically, or the patient will relapse on the first occasion that his conflict is reawakened.

The number of lightning cures that were possible during the war was a measure of the ignorance of the bulk of the medical profession as to the nature of these maladies. Paralyzes of mental origin were mistaken or neglected, and the patient was not subjected to systematic psychological treatment.

All such loss of function can be easily recognized by its character. It follows a conceptual and not a physiological or anatomical distribution. A patient with hysterical loss of speech can write and read fluently, and one with complete aphonia can cough loudly. When all power of recognizing the position of one upper extremity appears to be lost, the patient has no difficulty in finding the tip of his affected forefinger with that of the normal hand; but he carries out the reverse operation with difficulty, because it seems natural to him to do badly with the "bad" hand and well with the "good" one. But, when the sense of position is disturbed from an organic lesion of the cortex, the condition is usually the exact opposite. The normal forefinger cannot be brought into contact with that of the affected hand because its position is not known, whereas the reverse movement can be carried out without difficulty, because the situation of the normal hand is accurately recognized. It is easy to make fair shooting with a bad rifle if we know the position of the target; but the best rifle in the world is useless if we are ignorant of the direction of our aim.

The following difference between two apparently allied signs is equally significant. When a patient with *tabes dorsalis* or any disturbance of the functions of the posterior columns is made to stand with his eyes closed, he tends to sway or fall. In many psychopathic states he also becomes unsteady under similar conditions; this has been called by the outrageous name of "pseudo-Romberg." But the true nature of this sign is evident from the following procedure: Let the patient stand on both feet and tell him to close his eyes; he tends to fall. Then tell him you are going to examine his eyes; stand him facing the light, and close first one eye with your hand and then the other; he will remain steady on his feet. By the first method of examination, attention was attracted to his power of standing with his eyes closed, but, on the second occasion, he was told that his eyes were under examination and no question of equilibrium arose in his mind. All these conditions may be classed together as "paralysis by idea."

Most of these defects of function arising during the war have long ago been removed by treatment, and the few patients of this class who remain are of a poor mental type. The large bulk of the functional neuroses which now demand attention are those consisting of states of anxiety and obsessions. This corresponds to the normal experience of civilian life. An ex-soldier is troubled about his work or is anxious about the illness of his wife and the difficulty of obtaining a lodging. Officers returning to their pre-war employment find it uninteresting and badly paid. Moreover, they have not the mental stamina to work long hours, and then return home in an intolerably overfilled train. Old nightmares recur and sleep is troubled; their general efficiency goes down, and they are in real danger of finding themselves without employment.

It is the business of the physician to investigate these conditions with the greatest care. An unfavourable environment must, if possible, be changed. The sleep of

one of my patients improved enormously as soon as quarters were found for him in London, so that the railway journey at the beginning and end of the day's work became unnecessary. Abnormal mental experiences must be brought into the main stream of the individual personality, and, if possible, the patient must be induced to regard them from a more favourable point of view. A terrifying object, that can be logically examined, tends to lose its fearful aspect. We dread the unknown; and to drag these half-appreciated horrors into the light may discharge the greater part of their emotional energy. If possible, a sorrow must be sublimed; the loss of some dearly loved person should not be repressed, but be brought up to form an integral part of the sacrifice at the altar.

Obsessional states are the hardest to remove permanently; for any want of physiological or mental fitness is liable to lead to regression. If, however, the patient can be taught to recognize the significance of this re-appearance, its explosive force can be greatly lessened.

I have entered a plea for regarding the psycho-neuroses as a disturbance of functions, common both to the nervous system and to the mind. The form they assume depends on the personality of the patient, and the nature of the emotions and ideas with which he has had to deal; it has nothing to do directly with the effect of external physical forces. Such expressions as "shell shock" and "neurasthenia" do not correspond categorically to the manifestations of the functional neuroses, which are in reality the forms assumed by the reaction of the patient to his individual mental experiences.

THE NATURE, PREVENTION, AND TREATMENT OF HEAT HYPERPYREXIA.*

THE CLINICAL ASPECT.

BY

W. H. WILLCOX, C.B., C.M.G., M.D., F.R.C.P.,

PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON; LATELY CONSULTING
PHYSICIAN TO THE MESOPOTAMIAN EXPEDITIONARY FORCE.

The three summers of 1916, 1917, and 1918 spent on active service in Mesopotamia as Consulting Physician to the Mesopotamian Expeditionary Force gave me the opportunity of seeing a very large number of cases of illness due to exposure to high atmospheric temperature, and I made a careful study of the clinical manifestations of the different types of disease due to this cause.

Heat hyperpyrexia was the most striking and most dangerous form of illness met with, and as this was likely at any period to occur as a complication in the milder types of these effects of heat, it was chosen as the title of the paper.

ETIOLOGICAL FACTORS.

Climate.

Mesopotamia and the country round the Persian Gulf have been well known for many years as having an unenviable reputation for danger from "heat-stroke." The sun's rays seem to have a peculiar deadly power in this part of the world, and the risk of heat-stroke appears to be much greater than in countries like India, where the temperature is equally high.

Probably the explanation is to be found in the extreme flatness of the country, and the absence of trees and vegetation except in the small cultivated areas. The clearness of the atmosphere also and the absence of dust and moisture in the upper strata undoubtedly contribute, so that the full force of the sun's rays was encountered, with scarcely any absorption from dust or moisture in the air and unrelieved by shade.

The soil of Mesopotamia is really the dried alluvial mud deposited by the river floods, and this forms a light brown dry barren deposit, which radiates and reflects to a great extent the sun's rays, so that one is exposed not only to the direct rays of the sun but to those reflected and radiated from the surrounding soil.

* Papers read in introducing a discussion on heat hyperpyrexia at a meeting of the Medical Society of London on March 8th.

Temperature.

A maximum shade temperature of 110° F. appeared to be the dangerous limit. When this was reached some cases of "effects of heat" were sure to occur, and each degree rise above this limit was attended by an increasingly larger number of cases. Temperatures of 120° or over were exceedingly dangerous, and on these days, in spite of all precautions, large numbers of heat-stroke cases occurred.

A comparison of the temperature records of 1917 and 1918 for Baghdad (see atmospheric temperature curves) shows the reason of the far greater number of cases of heat-stroke in the former year. In 1917, on six days in July the shade temperature was 120° and upwards, and on fifteen days it was 115° and over. In 1918 the temperature did not reach 118°, and on only two occasions was it 115° or over.

The curves showing the temperature and cases due to effects of heat illustrate the influence of temperature.

Cumulative Effect of Heat.—The effect of heat was undoubtedly cumulative in action; thus one or two very hot days were not necessarily followed by a large number of cases of heat-stroke; it was the succession of several hot days which was dangerous. The case incidence curve followed the temperature curve, with a delay of a few days in the rise of the former. The cumulative effect of heat was shown on the individual; a man might be exposed to heat for one or more days and then develop an attack of heat hyperpyrexia in the night or early morning after the atmospheric temperature had fallen considerably.

Humidity of atmosphere undoubtedly predisposed to heat hyperpyrexia, owing to the diminished heat loss from a lower rate of evaporation from the skin, and also from the greater heat conductivity of a hot, damp atmosphere. The effect of a high relative humidity was shown by the

greater case incidence of effects of heat at Basrah than at Baghdad (see tables), the relative humidity being considerably higher at Basrah, as shown by the wet and dry bulb records.

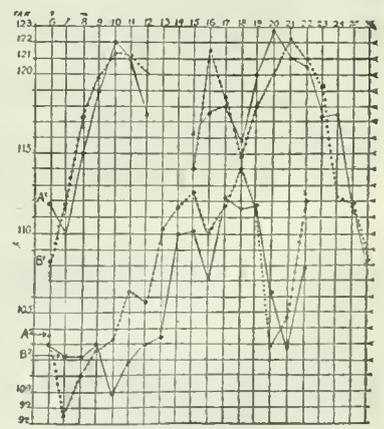

Special Rays as Causes of Heat Hyperpyrexia.—There is no evidence that other rays than the heat rays from the sun cause heat hyperpyrexia. The influence of actinic or ultra-violet rays as possible causes was investigated, with negative result, by Mackenzie and Le Count in America.¹

Night Temperature.—In Mesopotamia the month most dangerous as regards heat-stroke was July, since the maximum shade temperature was for a great part of the time over 110°. August was also a dangerous month. Even in these months, however, the night temperature fell considerably; thus, on the hottest day in my experience (July 20th, 1917) the maximum shade temperature was 122.8°, but at night the temperature fell to 81.6°, a drop of 41.2°. The relatively cool nights even in the hottest months render Mesopotamia a possible country for the white man; were it not for this, the incidence of heat hyperpyrexia would undoubtedly be much greater.

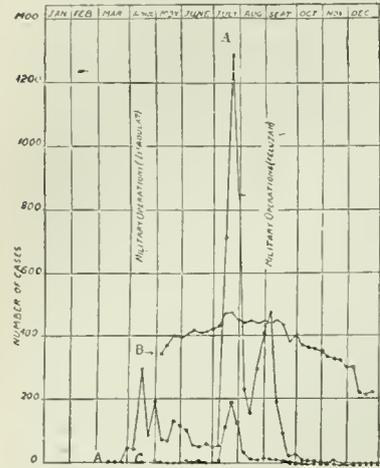

Stagnation of Air.—Free currents of air have a great value in protection by promoting evaporation from the skin and loss of heat. Electric fans and punkahs were largely used in Mesopotamia in hospitals and dwellings occupied by troops from 1916 onwards. They were a vital necessity to the British troops during the hot months. In this connexion it is interesting to note that when the temperature was very high the air from a fan would be like a hot blast, and unless the body was covered with a moist sheet, or a moist screen intervened, the fan would be of little value as a cooling agency and indeed might do more harm than good. The Arabs do not appreciate the value of air currents; in the native quarters of the towns the narrow streets and houses with little window space, show that they are designed with the object of shutting out the hot air rather than promoting free ventilation. In July, 1917, on some days the heat was so intense that when a slight breeze arose it was necessary to take shelter

temperature was very high the air from a fan would be like a hot blast, and unless the body was covered with a moist sheet, or a moist screen intervened, the fan would be of little value as a cooling agency and indeed might do more harm than good. The Arabs do not appreciate the value of air currents; in the native quarters of the towns the narrow streets and houses with little window space, show that they are designed with the object of shutting out the hot air rather than promoting free ventilation. In July, 1917, on some days the heat was so intense that when a slight breeze arose it was necessary to take shelter

in a covered dwelling to escape the hot wind. On July 20th, 1917, at Knt such an instance occurred when people ran for shelter to escape the scorching blast, and several fatal cases occurred.

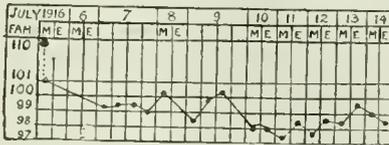

CURVE II.—Effects of heat, 1917 (Mesopotamia—British). A=Cases per week; B=Temperature; C=Deaths.

1918, and was very valuable in estimating the degrees of stagnation of air, and thus the risk from heat-stroke. For example, in a hospital ward by its means the suitability of the beds for cases liable to heat-stroke could be tested.

Dwellings for Protection against Heat.

Dwellings must be constructed of very thick walls of non conducting material—for example, of stone, bricks, or dried mud—and it is of special importance that the roofs of huts should be thick. A coating of at least six inches of

CHARTS 1 AND 2.—Heat hyperpyrexia.

dried mud on a roof is the minimum protection against the sun's rays. Tents afforded poor protection, and in the double fly E.P. tents the temperature would often reach 135° or 140°. During the hot days it was necessary to wear in them a head protection—for example, a topee.

A further protection to a tent was an additional roof of rush matting, but the difficulty of fixing this rendered it impracticable for general use.

Dug-outs with mud walls around and a tent roof, which were used in some cases for troops, were unsatisfactory,

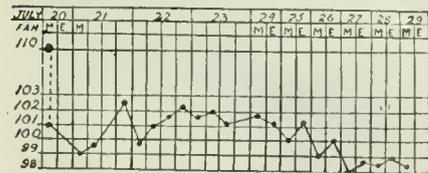

CHART 3.—Heat-stroke.

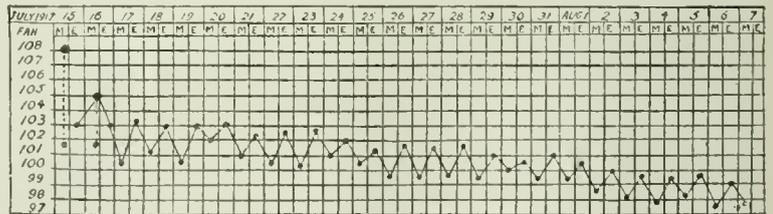

CHART 4.—Heat-stroke; prolonged pyrexia. Blood tested on July 17th and 20th, was negative on each occasion.

since, though cooler in the daytime they were too hot at night; further, the dug-out earth was a favourable breeding ground for sand-flies, and sand-fly fever was always prevalent under such conditions.

Camps under palm trees were tried, but the stagnation of air caused thereby, and the greater prevalence of mosquitos and other insects, outweighed any advantages derived from the shade of the trees.

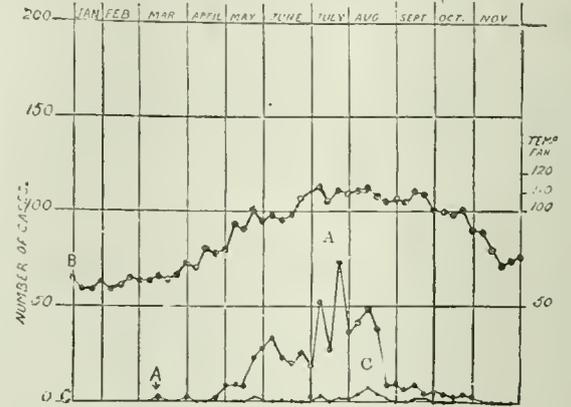

It appeared that on the open desert double fly tents, due precautions being taken as regards personal protection during the day, were on the whole best suited for troops if huts or buildings were not available,

Fans.—The best use of fans in very hot weather was obtained by keeping the rooms closed as far as possible so as to keep out the hot air, the fans providing the necessary air currents in the cooler air within. Aron has shown by experiments on monkeys that still air is a potent cause of heat-stroke.

The "kata" thermometer, introduced by Dr. Leonard Hill, F.R.S., was used in Mesopotamia in

Age and Race.
The risk of heat hyperpyrexia depends largely on personal protection, and if care be not taken any age is subject to it. The case mortality was undoubtedly greater in men over 40.

Race is very important. Heat hyperpyrexia due to heat

CURVE III.—Effects of heat, 1918 (Mesopotamia—British). A=Cases per week; B=Temperature; C=Deaths.

alone, and not to the complication of other diseases, was very uncommon amongst Arabs and Indians; indeed, when it occurred in them almost always some complicating disease such as malaria was found as the cause. White races are much more susceptible to the effects of heat, and in British troops a large percentage of the cases were due to heat *per se*.

Alcohol.—If alcohol is taken during the heat of the day it undoubtedly predisposes to heat-stroke. Numerous individual examples of this came to my notice.

Exertion.—Exertion during the heat of the day is a great predisposing cause, especially if heavy kit is carried. Numerous examples of this occurred; perhaps the best instance is that shown in the 1917 curve of heat effects, where the two accessory rises in April and September were due to military operations at Istabulat and Felujah respectively. (See Curve II.) A tragic example was the sad death of Sir Victor Horsley, which was undoubtedly due to his having to walk long distances during the heat of the day in the performance of his duties as consulting surgeon.

Water.—Absence of a large supply of drinking water is a cause of heat hyperpyrexia. During the hot weather

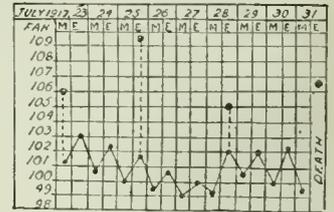

CHART 5.—Recurrent hyperpyrexia.

from two to three gallons a day are necessary for a man exposed to heat. In military operations this was in some cases impossible, and cases of "effects of heat" occurred in consequence.

Personal Protection.

Clothing.—The use of efficient heat protection from the sun's rays, as by thick pith topees or an efficient service helmet, was very important. The service helmet appeared to give adequate protection, and as it was capable of withstanding rough usage, it was perhaps better adapted for troops than the pith topee. Spinal pads 9 in. wide were necessary for the protection of the spinal cord from the

sun's rays. Light loose clothing, not too thin, was desirable.

Constipation was undoubtedly a predisposing cause, and Army Orders were issued warning against this. The high percentage of indicanuria in cases of heat-stroke is confirmation of the importance of promoting free elimination from the bowel.

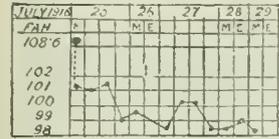

CHART 6.—Malaria and heat-stroke. July 25th, quinine gr. vi intramuscularly.

Umbrellas afforded protection to those compelled to walk in the heat of the day, and were used with advantage.

Hand fans were of value in promoting loss of heat and in keeping off flies.

Predisposing Diseases.

Any disease causing pyrexia predisposed to heat-stroke in the hot weather.

Malaria was one of the commonest of these, and in Indians was almost always the cause of heat hyperpyrexia. (See Charts 6 and 7.)

Sand-fly Fever.—During an attack of this fever in the hot months hyperpyrexia sometimes occurred, and I have notes of cases of heat hyperpyrexia occurring in the apyrexial period following sand-fly fever. Captain H. C. Sinderson has suggested² that sand-fly fever was a common cause of heat hyperpyrexia. I cannot agree with this, because in the great majority of cases there was no evidence of sand-fly fever, and in the great incidence of heat-stroke in July and August, 1917, sand-fly fever was entirely absent.

The enteric group diseases, if occurring in the hot weather, were not uncommonly complicated by heat hyperpyrexia (see Chart 8).

Typhus fever, both in the acute stage and apyrexial period, might be complicated by heat hyperpyrexia (see Charts 9 and 10).

Small-pox.—I have seen heat-stroke occur during the early stages of small-pox before the appearance of the rash.

heat-stroke occur during the early stages of small-pox before the appearance of the rash.

heat-stroke occur during the early stages of small-pox before the appearance of the rash.

naphthylamine will cause hyperpyrexia in animals, and it is likely that similar chemical bodies produced as the result of the effects of heat on the tissues in man may have a like effect.

No evidence of bacterial infection was obtained in a numerous series of blood cultures in cases of pure heat hyperpyrexia.

Suppression of sweating has been stated by Dr. K. G. Hearne⁴ to be the cause of heat-stroke. Undoubtedly suppression of sweating is a most important predisposing cause in many cases, especially those of Group IV in my classification, and in this connexion Dr. R. J. Love⁵ has called attention to the risk of giving atropin injections, since he had observed hyperpyrexia follow the administration of atropin before an anaesthetic.

Suppression of sweating did not, in my experience, always precede heat hyperpyrexia, and though it is undoubtedly an important predisposing cause, it cannot be regarded as the primary cause. Thus some cases of heat hyperpyrexia occurred suddenly in exposed men who were in good health, without any previous evidence of lack of skin action, and in cases of the gastric type of heat hyperpyrexia no previous suppression of sweating was observed, though they had been under observation in hospital for several days.

Though entirely agreeing with Dr. Hearne's conclusions as regards treatment, I cannot accept his explanation as the cause of heat hyperpyrexia.

Morbid Anatomy.

In the *post-mortem* examinations made in Mesopotamia oedema and general hyperaemia of the brain and leptomeninges were observed, and cloudy swelling of the liver, kidneys, and myocardium was found; petechiae of the skin and mucous membranes were seen in some cases.

No definite signs beyond these were observed beyond those indicating intercurrent diseases, such as malaria with enlarged spleen, etc.

CLINICAL TYPES OF ILLNESS CAUSED BY EXPOSURE TO HEAT.

1. Heat exhaustion (mild type).
2. Gastric type.
3. Choleraic or gastro-intestinal type.
4. Heat hyperpyrexia (heat-stroke or sunstroke).

In Types 1, 2, and 3 heat hyperpyrexia might suddenly develop unless great care were taken in their removal from a hot atmosphere. Types 2, 3, and 4 were all dangerous and the prognosis grave. Of 80 severe cases of "effects of heat" of which I made careful notes, 13 (16.2 per cent.) were of the gastric type, 9 of the choleraic (11.2 per cent.), and 58 (72.5 per cent.) were hyperpyrexial.

1. Heat Exhaustion.

This would commence suddenly with weakness, giddiness, faintness, and inability to walk; the pulse was rapid and weak. The majority of these cases were associated with a mild pyrexia of 102° or 103°, which lasted two or three days and then the temperature became normal, the patients requiring a few days' rest before being fit for duty. A small proportion of the cases were associated with cardiac failure, the temperature being subnormal.

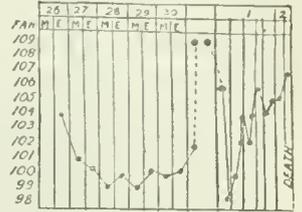

CHART 7.—Malaria and heat-stroke. From the 26th to 30th quinine gr. x t.d.s. by mouth; on the 23th and 30th intramuscular quinine.

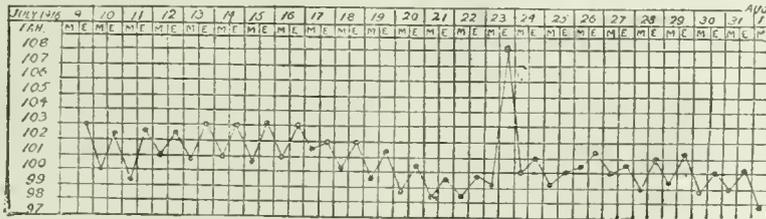

CHART 8.—Paratyphoid A, malaria, and heatstroke. July 24th, quinine gr. x intramuscularly.

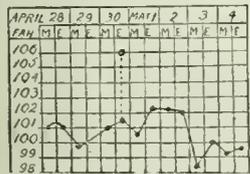

CHART 9.—Typhus and heat hyperpyrexia.

PATHOLOGY AND MORBID ANATOMY.

I have no doubt whatever from my experience that heat hyperpyrexia is a clinical entity and occurs apart from intercurrent diseases. The influence of these has already been considered.

The clinical history of cases of pure heat hyperpyrexia and the course of the symptoms after the acute stage, which often exhibit prolonged pyrexia and profound toxæmia in the absence of any bacteriological infection, strongly indicate that the cause is an autointoxication as the result of the effect of heat on the body tissues. My experience led me to believe that this is the cause of heat hyperpyrexia.

The autointoxication occurring in heat stroke was found to be associated with the presence of acetone and diacetic acid in the urine in only a small proportion of cases (about 12 per cent.), and in these the reaction was of only moderate intensity. It thus appears that heat hyperpyrexia is not due to an acid intoxication. The presence of indican in excess in the urine in acute cases is of importance and is an evidence of the autointoxication present.

Dr. W. Cramer³ has shown that beta-tetrandro-

the skin cold and clammy, the face pale, and the pulse very rapid and feeble.

During military operations in hot weather large numbers of cases of heat exhaustion occurred. The mortality from this type of case was very slight.

2. Gastric Type.

This was one of the most interesting and treacherous forms; it constituted 16.2 per cent. of my series of severe cases. The patient would have a flushed face and be restless and irritable, with marked nausea and occasional vomiting.

The month temperature and pulse would be normal for several days. The rectal temperature showed often a rise of about 2°. Usually there was fatty enlargement of the liver. The knee-jerk was lost in all of nine cases in which it was specially tested. This was a valuable diagnostic sign. The knee-jerk reappeared when convalescence was established, the time varying with the severity of the case. Many of these cases, after four to ten days' premonitory symptoms, suddenly developed fatal heat hyperpyrexia. The following are notes of two typical cases:

CASE I.

H. Onset July 15th, 1917; the patient was morose and irritable, with a feeling of nausea. When admitted to hospital on July 17th the face was flushed, the tongue very furred, the temperature normal; vomiting occurred daily, and the liver extended two inches below the right subcostal border. On July 22nd the mental condition was somewhat muddled, and the temperature was 99.2°; nausea was present, and vomiting occurred once. At 11.45 p.m. the temperature suddenly rose to 108° F., and the patient died on July 23rd, at 1.30 a.m.

CASE II.

K. Onset July 13th, 1917. The patient became faint and collapsed and vomited, some cyanosis being present. When admitted to hospital the temperature was normal, the face flushed, the tongue furred, and nausea and daily vomiting occurred; the liver extended three inches below the right subcostal border. The mental condition showed depression and irritability, with some mental confusion. On July 23rd stupor and coma developed, the temperature suddenly rose to 108° F., and death occurred a few hours afterwards.

3. Gastro-intestinal Type (Choleraic).

In this type (which constituted 11.2 per cent. of my series) the onset was sudden, marked collapse occurring. The patient usually had a temperature of 101° to 103°. Vomiting was marked, and there was diarrhoea. Cramps in the abdomen and legs occurred in some cases. The face was pale, the eyes sunken, and the skin pale and clammy. The knee-jerks were generally lost; in four cases specially examined they were absent in three and diminished in one. The general appearance of the patient was similar to that of cholera.

This type was of uncommon occurrence, but the mortality was high, death often occurring within three or four days.

4. Heat Hyperpyrexia.

In this type, which accounted for 72.5 per cent. of my series of eighty severe cases, the onset was often quite sudden, the patient being taken ill when on duty, with a sudden high rise of temperature and loss of consciousness.

In some cases the patient when off duty would be found by his comrades unconscious and dying.

CASE III.

In one such case a soldier complained of headache in the morning; he returned to duty and was apparently better in the afternoon, and was last seen playing with a dog, but about 5 p.m. was found unconscious and dying. He died at 5.30 p.m. before medical aid could reach him, and 1½ hours afterwards the rectal temperature of 116° indicated that heat hyperpyrexia was the cause of death.

Heat hyperpyrexia frequently occurred in the very hot weather in hospital patients suffering from another disease. In them the temperature would often suddenly rise to 110°, coma and convulsions supervening. (See Charts 1 and 2.)

In many cases, however, the onset was more gradual, malaise, headache, and restlessness occurring, accompanied sometimes by nausea and vomiting. Frequency of micturition was a characteristic early symptom, and was sometimes associated with urethral pain. The temperature would be somewhat raised—100° to 102° or so—and the skin be hot and dry. The preliminary symptoms usually lasted for a few hours, sometimes as long as forty-eight. Then mental excitement and delirium would supervene and the temperature rapidly rise to 110° or so. With the hyperpyrexia coma and stertorous breathing occurred, and the face was flushed and cyanosed, the conjunctivae being congested. The pupils were often dilated in the early stage and contracted in the comatose condition. Fibrillary twitchings of muscles, and convulsions were very common in this stage, and the breathing might have the Cheyne-Stokes character. Incontinence of urine and faeces occurred with the coma. Unless the temperature was reduced by treatment death rapidly occurred from hyperpyrexia, the mode of death usually being asphyxial in type.

Marked cardiac dilatation, often associated with a systolic murmur, occurred in the severe cases. This remained for a few weeks after the attack and needed special care.

Bronchitis and congestion of the bases of the lungs occurred in some cases.

Air hunger was definitely observed in one case, and in another a spasmodic type of breathing like uraemic asthma.

Pulmonary oedema was a terminal event in the fatal cases.

The Urine.

Indican was present in excess in all of six acute cases in which a special examination was made. Acetone and diacetic acid were present in small amount in one out of eight acute cases specially tested. Albumin was found present in small amount in three out of eight acute cases. No casts were present.

Nervous Symptoms.

Restlessness and delirium occurred with the onset of hyperpyrexia and were quickly followed by stupor and coma with incontinence of urine and faeces. Muscular twitching and convulsions were very common with the high temperature.

The knee-jerk was almost always absent in the pure heat-stroke cases during the acute stage. Out of thirty-two cases specially tested the knee-jerk was absent in twenty-seven, diminished in two, and normal in three; in these latter cases the hyperpyrexia was probably malarial in nature. In the severe cases the knee-jerk did not return for three or four weeks, in the milder cases earlier. The presence of knee-jerks was a valuable prognostic sign, for when they had returned there appeared to be much less risk of a relapse, and the patient might then be evacuated with safety. This sign was of great practical help in deciding on the disposal of heat-stroke cases.

After the acute stage in the severe cases marked mental symptoms often remained for some weeks; irritability, mental confusion, and delusions were not uncommon. Usually these symptoms cleared up.

Defective articulation (anarthria) occurred as an after-symptom in four of the severe cases of my series. Nystagmus occurred in one case, and squint with diplopia in one.

Multiple neuritis associated with weakness and marked wasting of the legs, the tibialis anticus muscles being most affected, occurred in two cases.

Lumbar puncture was performed in several cases; the cerebro-spinal fluid was clear and sterile and the pressure was above normal.

Parotitis occurred in three cases of my series.

Petechiae were observed in a few of the cases showing marked toxæmia.

Many of the severe cases showed, after the hyperpyrexia had subsided, a pyrexia, for several days the temperature being about 102° or 103° (see Charts 3 and 4). In one case the fever lasted three weeks. Numerous blood cultures were made in these pyrexial cases, with negative results. Recurrences of hyperpyrexia were very likely to occur after an attack of heat-stroke unless the patient was kept in a cool atmosphere, which was often impossible. There were several instances of two and three recurrences (Chart 5).

After convalescence from hyperpyrexia attacks of headaches were common, and exposure to slight heat would induce them. These patients for a long time were very sensitive to heat, and evacuation to a cool climate was essential. In some of the severe cases showing marked persistent nervous symptoms it was clear that permanent organic changes had resulted from the effect of heat on the brain cells. Dr. R. M. Stewart⁶ has described a case with persistent cerebellar symptoms following an attack of heat hyperpyrexia in Egypt.

TREATMENT.

1. *Heat exhaustion* required no special treatment beyond rest, keeping cool, and aperient medicine.

2. *The gastric type* was dangerous, and required great care in treatment. Free purgation, great care in protection from heat, large doses of sodium bicarbonate (30 grains every three hours), and rectal injections of cold solution of the same salt (2 drachms to the pint) gave the best results. The diet in all "heat" cases was chiefly lacto-vegetarian, the fat and protein being reduced as far as possible.

3. *The choleraic type* required treatment on the lines of cholera cases, including normal or hypertonic saline subcutaneously, and cardiac stimulants—for example, digitalin, strychnine, adrenalin, pituitary extract given hypodermically. Protection from heat was most important.

4. *Heat hyperpyrexia* demanded immediate application of measures to reduce the temperature. Thus, the stripping of the patient and constant application of a spray of cold water, or rubbing with blocks of ice, were essential until the rectal temperature fell to 102°, the patient being under a fan during the process. In the hospitals in Mesopotamia special heat-stroke wards were established, with overhead fans and portable electric fans for each acute case. Ice-cold water was supplied to each bed, so that the patient could have a constant spray of this; there was also an ample supply of ice. At my suggestion the acute cases were treated on an ordinary iron bed, a rush mat, with a smooth Japanese reed mat above it, being placed over the iron framework. This allowed a free current of air all round the patient, from below as well as above.

By these means the hyperpyrexia could be controlled. If enlargement of the spleen was observed, or if there was a previous history of malaria, quinine bichloride gr. x was given either intravenously or intramuscularly without delay, and during the carrying out of the hydrotherapeutic measures. An injection of quinine gr. x was given if the temperature was not readily controlled by the above methods. Blood films were made at once and examined for malaria, and if the result was positive, active quinine treatment was continued.

Convulsions, which were of very common occurrence, were treated most satisfactorily by venesection, 10 to 20 oz. of blood being withdrawn. Intravenous saline after venesection was not found beneficial, since it tended to cause recurrence of the convulsions. Rectal injections of ice-cold water or of ice-cold solution of sodium bicarbonate (2 drachms to the pint) were beneficial.

Cardiac failure was treated by digitalin, strychnine, adrenalin, or pituitary extract hypodermically.

Failure of respiration was treated by artificial respiration and oxygen, or oxygen bubbled through alcohol.

Some cases with violent delirium and convulsions were treated by morphine hypodermically, and chloroform inhalations, but these methods were usually inferior to venesection.

PROPHYLAXIS.

Every care was taken by the army authorities in the prevention of heat-stroke. As far as possible no military operations were carried out during the hot weather, and

as far as possible also troops were relieved from any duty between 10 a.m. and 4 p.m. Head and spinal protection were ensured by the issue of efficient helmets and topees, and spinal pads. Special light summer clothing was issued to troops in the hot months. A free supply of water was allowed to troops, and every man had a 1 gallon canvas *chagul*, so that by keeping drinking water in it efficient cooling was obtained by evaporation.

Army Orders were issued, on the advice of the D.M.S., warning against the risks of constipation and the taking of alcohol.

Billets and huts for troops were supplied with electric fans. In the case of troops under canvas special care was taken as regards the management of tents so as to ensure maximum heat protection.

Hospitals were equipped with an ample supply of electric fans and ice. In hospitals where patients suffering from other diseases showed a tendency to hyperpyrexia it was found advisable to place them in the coolest part of the wards under a fan and to cover them with a sheet kept wet with cold water.

Heat-stroke stations, with all facilities for treating cases were established in each of the base areas, and each division of troops had six such stations, so that every facility was provided for the treatment of emergency cases.

My thanks are due to Major-General A. P. Bleukinsop, C.B., C.M.G., D.M.S., of the Mesopotamian Expeditionary Force, for statistical figures in this paper, and for the interest and active measures he took for preventing and dealing with heat hyperpyrexia.

THE PHYSIOLOGICAL ASPECT.

BY

LEONARD HILL, M.B., F.R.S.,

DIRECTOR, DEPARTMENT OF APPLIED PHYSIOLOGY, MEDICAL RESEARCH COMMITTEE.

HEAT-STROKE results from the rise of body temperature to a height incompatible with the maintenance of the equilibrium of the physico-chemical reactions in the cell on which life depends. Such rise may result from inability of the heat-regulating mechanism to control the body temperature under the atmospheric conditions, or from exhaustion of this mechanism. Infection, drink, fatigue, by weakening the mechanism, enhance the risk of heat-stroke.

Heat-stroke may occur in either dry or moist hot shade conditions, or from exposure to sun on close, warm days. While sunburn is an inflammation of the unacclimatized and untanned skin resulting from the sun rays, sunstroke is only another form of heat-stroke. There is unreasoning fear of exposure to the sun in this country; so long as the body is exposed to cooling breeze, exposure to the sun cannot produce sunstroke. The heating effect of food, especially of protein-rich food, must be borne in mind in the tropics. Alcohol is contraindicated if taken in place of natural foods. It contains no vitamins or protein-building groups, but is a fuel to the body. Monkeys fed on a light diet of bananas and rice and given plenty of water can be trained to stand exposure to the tropical sun out of doors for many hours a day. The sweating mechanism becomes more efficient by training.

The effect of enclosure and still air is very important. When surrounded by stagnant moist air in an enclosure at body temperature, any loss of heat by convection, radiation, or evaporation of sweat becomes impossible; as heat production continues, the body temperature inevitably rises. The rise of temperature accelerates the rate of combustion in the cells, and a vicious circle is established. In the Black Hole of Calcutta the air entangled between the bodies and in the clothes of the victims became saturated with water vapour and heated to body temperature; thus heat-stroke, not suffocation, put an end to their sufferings. As the body, weighing some 60 to 70 kg., takes time to heat up several degrees to the critical temperature, people withstand temporary exposure to the heat of a

crowd or immersion in a hot bath. The weakly with feeble circulations, heart disease, or vasomotor instability, are the first to suffer.

It is easy by a few minutes' immersion in a very hot bath (107° to 110° F.) to accelerate greatly the pulse and respiration, lower the systolic pressure and raise one's rectal temperature to 103° F., to a point where one feels dizzy on standing up owing to the dilatation of the cutaneous blood vessels and the influence of gravity on the circulation. A cold douche gives immediate relief by constricting the cutaneous vessels, the rectal temperature still remaining at 103° F.

Normally, in comfortable cool surroundings, we are cooled mainly by convection, cool moving air carrying away the body heat from the skin, loss by evaporation from the skin being kept at a minimum, while that from the respiratory membrane is kept at a maximum by the breathing of cool air of low vapour tension. The vessels of the skin are toned up, activity and metabolism kept at a good level by the cool touch of moving air. In warm stagnant air the emergency method of cooling by sweating is brought into play.

The power of the air to hold water vapour, its evaporative power, increases rapidly with rising temperature; thus saturated air—

At 30° F.	holds 1.94 grains of water per cubic foot.
At 50° F.	.. 4.08
At 70° F.	.. 7.98
At 80° F.	.. 10.9
At 90° F.	.. 14.7
At 100° F.	.. 19.7

Wind enormously increases the evaporative power so long as the air is saturated at a temperature below body temperature by continually bringing fresh unsaturated layers of air in contact with the body.

As every gram of water evaporated from the skin or respiratory membrane carries away 0.59 calorie, the emergency method of body cooling is very effective. It is brought into play when men do hard physical labour and increase their rate of heat production five or even ten times. A high cooling power, due to cool air and wind, is required to stop sweating in such workers. There is an imperative need to so adjust the cooling powers of the air by fan ventilation in workshops that men may be saved from body heat stagnation or needless sweating, and from loss of physical vigour such as is evident in cotton spinners when contrasted with miners.

The limits of an Englishman's power to keep himself cool is passed when the wet bulb exceeds 88° F. in the still air of a chamber, even when he is stripped to the waist and resting (Haldane). When muscular work is performed a wet bulb temperature of 80° F. may be the limit. Walking in a tropical climate—wet bulb 75° to 80° F., dry bulb 80° to 90° F., may raise the rectal temperature 2° to 3° F., and send the pulse rate up to 140 to 160. Breathing hot air may so heat the blood as to produce exhaustion, even when the skin is exposed to a cool atmosphere.

The effect of wind in promoting the cooling of the body is illustrated by measurements taken with the "kata" thermometer. This is a big-bulbed spirit thermometer which is warmed up so that its rate of cooling—from 100° to 95° F.—can be taken in seconds. The cooling power of the "kata" surface at body temperature is then deduced by means of a factor in millicalories per square centimetre per second. Readings are taken with the "kata" bulb dry and wet (covered by a wet knitted cotton glove). To take an example: On a certain day the temperature out of doors in India was dry bulb 89° F., wet bulb 73° F. Now the cooling powers are as follows:

	Still Air.	Wind 1 Metre per sec.	Wind 9 Metres per sec.	
Dry "kata" ..	1.3	3.6	6.7	With dry bulb 89° F.
Wet "kata" ..	9.8	22.4	36.7	With dry bulb 89° F. and wet bulb 73° F.

The cooling powers in still air are intolerably low, those with wind 1 metre per second quite tolerable for a sedentary person, those with wind 9 metres per second quite cool.

Suppose the air were saturated, the wet bulb also standing at 89° F., then the wet "kata" readings become:

Still air	3.3
Wind 1 metre per second	8.0
Wind 9 metres per second	15.1

and a wind of 9 metres a second (20 miles an hour) is required to secure comfortable cooling. In ordinary work-rooms in this country a dry "kata" reading of 6 and wet "kata" reading of 18 to 20 are commonly found, and appear to be comfortable for light work. Out-of-door workers in this country are exposed to far higher cooling powers, chiefly owing to the far greater movement of the air. The stimulating effect of the cooling powers of outdoor air on metabolism is of great importance to health.

In Borneo the wet bulb temperature not uncommonly reaches 90° F., and if there is no wind the conditions must be met by punkabs and electric fans and bathing in cool water. For such conditions compressed air douches would be of value. Water condenses out of air when it is compressed, and the air escaping from compression is both cool and dry. Such air offers a method of cooling far more practicable than any method of cooling by freezing machines. It is a method used in mines where the tools are driven by compressed air.

Now let us consider warm dry air at temperatures near to blood heat. So long as the sweating mechanism remains active and there is a breeze, there is no danger of heat-stroke. On the other hand, with hot dry air (well above body temperature) and a wind, the cooling power due to evaporation of sweat may be overpassed by the heating power of the air. The simoon kills by the hot wind drying the skin quicker than it can be kept wet by perspiration, and so heating the blood. The Arab crouches down on the ground and covers himself with clothes to avoid the drying and heating effect of the simoon, and hopes it will pass before his body becomes overheated. If a hot desert wind dries the skin absorption of sun heat takes place, which is normally checked by the layer of sweat. So long as the skin is thoroughly wet with sweat the sun heat is mostly expended in evaporation and is kept from the blood.

The glistening wet skin reflects the sun rays to a large degree. The black, with his tissues protected by pigment from the lethal effect of the sun, can have a thinner skin and blood vessels closer to the surface. Thus the cooling of shaded parts of his body is better secured. The pigment on absorbing the sun rays heats the cutaneous nerve endings, and these activate the sweat glands, dilate the cutaneous blood vessels, probably through "axon" reflex, and with very little delay.

While the "kata" thermometer indicates conditions of the atmosphere which are likely to cause heat-stroke, the surface temperature of a piece of black fur (taken by stroking it with the bulb of a sensitive thermometer) gives a simple measure of the radiant heat of the sun.

The loss of heat of a resting man may be taken as about 1 millicalorie per square centimetre of body surface per second; the extra heat production due to work may put this up to 3 millicalories. The exposure of half the body to the sun may result in the absorption by the clothes of 5 to 10 millicalories per square centimetre per second. Exposure to the sun, then, greatly increases the strain on the sweating mechanism. Hence the conditions for causing heat-stroke are given by soldiers heavily clothed marching in close column in the sun on a calm day. The air surrounding their bodies becomes saturated and warmed, and the sun heat is absorbed by their clothes. The stripping off of clothes, open order, frequent rests, plenty of drinking water, and avoidance of the heat of the day for marching are the proper precautions. Clothes for the tropics should be of thin cotton material: a shirt open at neck and sleeves—the shirt worn outside the belt when conditions are trying—shorts, boots, and knitted puttees, and a light sun helmet well ventilated and impermeable to sun rays. The clothes must be light in colour to reflect the sun. The man should allow his skin to tan, so that he can wear thin material. He must avoid sunburn while tanning by wearing an opaque garment whenever the skin becomes tender. There is not only no advantage in red linings, but disadvantage owing to the double layers. The work of Hare, L. Rogors, Haldane, Pembrey,

and others established that heat-stroke is caused by overheating the body. It is not an infectious disease, as Sambon has suggested (supported by Manson's authority), but is more liable to occur in those whose vasomotor mechanism is unstable, in the constipated, the drunken, the fatigued, or infected. Heat-stroke can be produced in normal men by appropriate conditions in the experimental chamber of the physiologist. Many cases occurred in fresh troops sent straight from England and certified free from malaria on their arrival at Basra. It can be prevented by simple treatment based on the physical laws of cooling. 107° to 108° F. seems to be the critical rectal temperature at which grave effects such as unconsciousness and convulsions result. Speedy reduction from such a temperature is demanded to avoid not only a fatal termination but tissue degenerations.

Men vary in their capacity of sweating, and thus, when in Mesopotamia in 1917, the temperature rose in stages, groups of cases occurred at 105°, 110°, 115°, 120° F. Such shade temperatures out of doors meant 130° to 140° F. in the still air of a tent on the hottest days! Thick walls, double roofs, and wide verandahs well ventilated, and fans are required to make such conditions tolerable. There were none of these things to start with. The treatment often recommended in 1917 appears to have been the rubbing of the skin with ice and ice enemata. Venesection and infusion were also tried as a last resource.

While evaporation of water at body temperature carries away 0.59 calorie per gram, the melting of ice only takes away 0.08 calorie per gram; rubbing the skin with ice, moreover, obstructs evaporation. Again, 70 grams of water evaporated from the skin takes away as much heat as 1,000 grams of iced water used as an enema.

The direct cause of heat-stroke in a hot, dry atmosphere such as Mesopotamia seems to be exhaustion of the sweating mechanism, hence diaphoretics are useless; the one treatment to immediately apply is artificial sweating, established by means of a water spray and fan. Such a method of treatment was, as Director-General Goodwin tells me, well known and practised in India before the war, but it had not become generalized and taught in the books. Fans and sprays were wanting to meet the fierce heat of the summer of 1917 in Mesopotamia.

G. K. Hearne found that he could pick out in his wards at Basra all cases in danger of heat-stroke by their dry skin; cessation of sweating, generally coupled with increased micturition, in every case preceded the rise of body temperature. Those who ceased to sweat asked for the roof fans to be turned off, because they, like the dry "kata" thermometer, were heated up by the wind—the air temperature being above body temperature. Those who were sweating, on the other hand, begged for the fans to be kept on because they were cooled by evaporation, just as the wet "kata" thermometer was cooled.

Hearne used the "kata" thermometer at Basra, and so secured a demonstration of these facts. Finding out the "dry" cases by frequent visits to each patient in his wards, he put on the water spray and fan treatment; by these simple means, so he tells me, he was able to stop all further cases of heat-stroke both in the wards and in the troopships. The great thing is to recognize the danger of the dry skin and get treatment in time. People must be warned of the danger of the skin going dry. Hearne found no signs of general exhaustion of the sympathetic system; it is the sweating mechanism in particular which fails. In the final stage of heat-stroke the patient lies cyanosed and comatose, with signs of respiratory embarrassment. The quick shallow breathing excited by heat washes CO₂ out of the blood, and so increases the alkalinity of the tissues. There is no acidosis then and no indication for the intravenous injection of a sodium bicarbonate solution. Gum saline may be tried for cases which come under treatment when collapsed, but the spray and wind treatment must first be set going.

Post mortem the organs of a case of heat-stroke show capillary congestion, as in wound-shock. Cramer lays stress on the signs of hyperaction, followed by exhaustion of the thyroid and adrenal glands. Either infection or exposure to over-warm atmosphere has these effects. Hyperadrenalism leads to increased change of glycogen into sugar and greater heat production. Injection of a small dose of tetrahydroamphylamine into mice produces pyrexia with signs of increased activity of the sympathetic system. If the mice are kept in a cool room

they survive, but if crowded in a warm place they die of heat-stroke. The drug causes intense congestion of the thyroid, with changes in the colloid and very active secretion of adrenalin. It dilates the pupil, constricts the blood vessels, causes rapid respiration, restlessness, and spasms, changes liver glycogen into sugar, and increases the respiratory metabolism and heat production. Narcotics such as chloral counteract this experimental heat-stroke, and an animal kept narcotized long enough recovers from a fatal dose. It is obvious that, while narcotics might delay, they cannot stop heat-stroke when the air temperature is above body temperature and the patient cannot sweat.

Cramer's experiments show how infection and a hot atmosphere may have an accumulative effect in producing heat-stroke by each over-stimulating and exhausting adrenal action. Observations on lower organisms show that death from excessive heat is due neither to coagulation of proteins nor to want of oxygen, for the change produced by heat is reversible if not carried too far, and is not affected by increased oxygen tension. The ultra-microscope shows an augmentation in the number of granules in the living cell and a growth in their size as the temperature rises; the increasing aggregation, reversible up to a certain point, stops the reactions of life.

NOTE ON THE DIETETIC TREATMENT OF DIABETES MELLITUS.

BY

R. T. WILLIAMSON, M.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE ROYAL INFIRMARY, MANCHESTER.

IN an article in the BRITISH MEDICAL JOURNAL in 1915 (March 13th) I recommended a line of treatment for certain cases of diabetes mellitus which I had found of much service in checking the glycosuria, temporarily at least. In cases uncomplicated by "acidosis" and certain other secondary affections, when the ordinary restriction of carbohydrates in the diet failed promptly to check the glycosuria, I advised complete rest, and for seven days a diet composed of a mixture of casein, cream, and water, given every two hours from 8 a.m. to 10 p.m. without any solid food. In many cases this diet promptly checked the glycosuria when other treatment had failed. At the end of the seven days a change was gradually made to a suitable solid diet, the amount of carbohydrates which the patient could tolerate being carefully noted.

During the war period, in place of the casein and cream solution I often used a diet composed chiefly of eggs and milk, given every two hours for seven days,¹ or a diet chiefly of suitable vegetables and jelly.² Both of these are more palatable, and are often useful, but not so frequently successful as the casein and cream solution. At the end of the war period the casein obtainable was often very unsatisfactory in taste and odour, and I have recently employed, with great success in many cases, the following mixture and course of treatment, which can be easily carried out. The mixture is a useful substitute for the casein and cream solution.

If "acidosis" and other serious complications can be excluded, and if an ordinary diabetic diet, with restriction of carbohydrates, fails to check the glycosuria promptly, then the patient is advised to rest on the sofa for seven days (or for a shorter period) and to take a mixture of eggs, cream, and water, prepared as follows: Three eggs are beaten up with 3 oz. of cream and a little water. More water is then added gradually until the mixture measures four pints. Of this mixture the patient takes half a pint (a tumblerful) every two hours from 8 a.m. to 10 p.m. (that is, eight times in the day). In addition he takes coffee or tea at 8 a.m. and 4 p.m., and also beef tea (warm) half a pint at 12 noon, 6 p.m., and 10 p.m. No bread, no meat, and no other foods are taken during this period.

In many cases the glycosuria is promptly checked in from four to seven days. This diet is not continued longer than seven days, and is then slowly changed to a solid diet containing only a small amount of carbohydrate food, the amount of bread and other carbohydrates which can be tolerated being carefully noted.

It is often found that not only has the glycosuria been temporarily arrested, but the power of carbohydrate

destruction in the system has been increased, so that the patient can take for a short or a long period (without glycosuria occurring) an amount of carbohydrate in the diet which would have been attended with glycosuria before the treatment.

If the glycosuria returns only after a long period, the week's treatment with the egg and cream diet may then be repeated. If the glycosuria returns in a few days after the first week's treatment with the egg and cream diet, then a satisfactory course is to advise this diet for one or two days every week-end, and to allow an ordinary solid diabetic diet, containing only a small quantity of bread and carbohydrate, during the other five or six days of the week.

A useful practical course, in these cases, is to advise that the urine should be tested every Friday; if it is found to contain sugar, then the egg and cream diet should be taken on the Sunday or Saturday, or on both days. If the Friday's urine is free from sugar, then the egg and cream diet is unnecessary on the Sunday.

This line of treatment is of great service in many cases, but unfortunately not in all. In some cases it fails, like every other treatment. In other cases, after being successful for a long period, it finally fails. It cannot, of course, be regarded as a cure for diabetes, but it is often a very useful method of checking the glycosuria at least temporarily, and of enabling us to keep it under control for a long period.

The grounds for the satisfactory action are the same as those I have described for the casein and cream diet. The treatment is unsuitable in cases with marked "acidosis," or with certain complications, such as phthisis and marked wasting, or cardiac failure.

Most patients can take the egg and cream diet for seven days quite satisfactorily. Some state that they feel remarkably well on it; others feel rather weak; only rarely do the patients complain of slight sickness, and in such cases the diet should be changed to the egg and milk diet or the vegetable diet previously mentioned.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

NEPHRITIS: ABDOMINAL HAEMORRHAGE:
DEATH.

I HAVE had lately under my care a case which, though investigated *post mortem*, remains a puzzle.

I was called to attend a spare woman who gave a history of overwork during the war in the absence of her husband on service, with the suggestion that the town in which she had been living had not agreed with her health. She had a slight rise of temperature, and complained of pain and difficulty of movement in her legs and back. There was no paralysis; the temperature was slightly raised and the pulse rather rapid. Examination disclosed no cause for the condition; there were no catarrhal conditions. Provisionally I diagnosed influenza, and for a day or two she seemed to improve. The pains in the limbs disappeared, but the pain in the lumbar region of the back persisted and seemed severe. After the menses, which were present at my first visit, had ceased, I obtained some urine, and found it to contain blood and albumin. She remained some three weeks in this condition, with small rises of temperature—sometimes better and free from backache, at other times much the same. My partner, Dr. Dick, saw her, but could find no cause for the disease. She was sent into the Cottage Hospital, where in the night she had a "collapse," from which she recovered with stimulants. The bowels had acted, but the severe pain was referred to the right hypochondriac and epigastric regions. She remained in a low state for forty-eight hours, but during the night had another attack of pain, with collapse, and died.

My colleague, Dr. Gordon Ward, made a *post-mortem* examination. The peritoneal cavity was filled with blood and blood clots, for which no source could be discovered after careful examination. The heart was hypertrophied, and the walls of the left ventricle much thickened. At the

right edge of the liver was a much tumefied area, rather smaller than the palm of the hand—red, soft and friable, like a blood clot. There was blood behind the peritoneum near the right kidney, and petechial spots on the mesentery. There was also blood tracking up behind the peritoneum and into the thorax. A portion of the affected liver and a portion of kidney were sent to the Clinical Research Association, who reported:

There is a good deal of leucocyte infiltration beneath the peritoneal surface of the liver extending some distance along the fibrous septa. There is also considerable fatty degeneration. There is no pyogenic membrane adjacent to the clot, but there are a good many polynuclear leucocytes and a little pus at one or two points in it. We think there must have been an abscess. The kidney shows some thickening of the capsule, and a slight increase of fibrous tissue in places. There is much swelling and disintegration of the renal epithelium, however, so that in addition to a slight chronic nephritis there are acute degenerative changes.

Granting that this was a case of acute nephritis grafted on a chronic condition, and that such condition may cause a haemorrhagic diathesis by causing or failing to excrete a toxin, it must, I feel sure, be rare to find death due to such extensive haemorrhage with so few symptoms of kidney insufficiency.

Sevenoaks.

JAMES E. BLOMFIELD, M.D.

A CASE OF ACUTE YELLOW ATROPHY OF
LIVER.

PRIVATE J. R. was admitted to the Military Hospital, Devonport, on December 26th, 1919. Four days before, without previous symptoms or any acute beginning, he noticed that his skin was becoming yellow, and that his urine was dark. He had had no previous serious illness. He served in France in 1918, but had not been anywhere else abroad.

On admission to hospital he was jaundiced, and had slight nausea, but no vomiting; the tongue was coated with white fur; the bowels were regular, the stools were solid and of a light slate colour. The temperature was normal; the pulse 64, regular, and of good volume. Nothing abnormal was found by palpation, percussion, or auscultation.

On December 30th the jaundice was intense, and he was very drowsy in the afternoon. The pupils were dilated. On the night of the same day he became very excited and violent, shouting, singing, and swearing. The pulse remained slow and of good volume, and the temperature normal. On the morning of December 31st he was semi-comatose; the pulse was rapid and feeble, and the pupils widely dilated; the temperature remained normal. A catheter specimen of urine was examined for leucin and tyrosin, which were not found. In the afternoon the coma increased, the temperature rose rapidly to 105° F., and the pulse was hardly perceptible. Cheyne-Stokes breathing supervened, and death occurred at 2.30 p.m.

Post-mortem Examination.—The liver weighed only 29 oz.; the capsule was wrinkled and loose, the substance of liver was limp and flabby, and bright yellow, with a few red patches. The heart showed numerous haemorrhages beneath the visceral pericardium. There were numerous haemorrhages also in the substance of both lungs. The aorta was bile-stained. The kidneys were soft and swollen, bile-stained, and showed many small haemorrhages. The spleen was apparently normal. The brain was not examined owing to objection of relatives.

E. C. WHITEHEAD, M.B., Major R.A.M.C.,
Officer in Charge, Medical Division, Military
Hospital, Devonport.

Plymouth.

NOTE ON A TUBERCULOUS COW.

RECENTLY the inspector called my attention to a cow which had been slaughtered in my district. The animal was a cross-bred one, apparently about 10 years of age, and had reached this particular slaughterhouse, by the present exceptional conditions of grading and sale, whereby the butcher is the only man connected with the transaction who has no "say" in the choice of the animals he has to pay for.

The carcass was that of a third grade animal weighing alive about 10 cwt., and could not be said to be emaciated, and even could be described as decent beef in these times, when all animals are sent to the market in an underfed

condition. The heart, the kidneys, the neck, the throat, the head and brain showed no signs of disease whatever. With these exceptions, however, the whole of the internal part of the carcass was affected throughout. In both lungs were nodules of the size of wren's eggs, the stomach was affected externally, and the pleura, diaphragm and spleen were in a bad condition. As a matter of course I had to condemn the whole carcass, and it was sent to the knackers, who gave a written undertaking to have it treated in such a way as to prevent its being used for human food.

The cow had evidently been milked up to within about a couple of months before being slaughtered; for some considerable time, therefore, there must have been a considerable quantity of highly infected tuberculous milk sold from it, and the question of better veterinary inspection of herds is once again brought to mind, for this cow could not have failed to be susceptible to the tuberculin test.

[Dr. Scales's description of the condition of the viscera is confirmed by two photographs he enclosed for inspection.]

Reports of Societies.

HEAT HYPERPYREXIA.

At the meeting of the Medical Society of London on March 8th, Mr. WARREN LOW, C.B., in the chair, a discussion on heat hyperpyrexia was opened by Dr. W. H. WILLCOX and Dr. LEONARD HILL, with the two papers printed elsewhere in this issue.

Dr. A. FELLING said that in his own experience in Mesopotamia, which almost synchronized with that of Dr. Willcox, he had found it comparatively rare for previously healthy men to be affected with heat hyperpyrexia. It was generally found that immediately before the onset the patient had had malaria or had been out of sorts as a result of constipation or some minor disorder. It was necessary for the medical officer to be on his guard, for some of these cases were very apt to mislead him. One morning in July, 1917, an officer in his own mess had a temperature of 100° F. He was advised to go into hospital straight away, but said he would keep his room for that day. Seen again at lunch, he appeared quite well, though he said that he would perhaps go into hospital in the cool of the evening, but at 4 p.m. he was found unconscious with a temperature of 110°, and died four hours later. This officer had been billeted under conditions as good as it was possible to get there at that time. Convalescence was extremely protracted in these cases. Many of the patients he had under treatment were not fit to travel at all for fully a month afterwards, as irregular pyrexia continued for a week or ten days or more, and required most careful watching. Such patients hardly ever sweated. The suppression of the sweat lasted for a week or longer, and the temperature went up to 104° to 106° on the least provocation. Since coming home, several patients had consulted him for what they described as the results of heat-stroke contracted in Mesopotamia. The principal symptom was intractable headache. As a prophylactic measure against heat-stroke, free currents of air were the one factor most essential. He had not had much success with venesection as a means of controlling convulsions. The spraying of the body with cold water and the use of electric fans was undoubtedly a desirable method of treatment, but in his experience it did not produce sweating at all. He did not regard the suppression of sweating as the cause of hyperpyrexia, but as the result.

Dr. E. KINGSCOTE said that in the Turkish bath the temperature might be up to 140° or more, and though the means of cooling down were close at hand, it was quite common for persistent headache to follow a Turkish bath and to continue for twenty-four hours. Any discomfort was more often relieved by a hot shower than by a cold douche.

Dr. CAMPBELL WILLIAMS said that the after-history of heat-stroke patients was important. He had had experience of two patients who had suffered heat-stroke in India and had both subsequently become inmates of asylums.

Mr. V. Z. CORE suggested that possibly the fact that the British ate more meat than the Arabs and Indians might account for the higher incidence of heat-stroke among them. He thought the absence of sweating one of the chief symptoms rather than one of the causes. Once while operating he found that the patient went off into a violent form of heat-stroke directly after the administration of the anaesthetic was begun; the anaesthetic was stopped at once, but the heat-stroke appeared to exaggerate and prolong the effect of what had already been given.

Sir W. HALE-WHITE described a sweat measurement test made upon himself. He took a hot bath at 108° F., remaining in it for fourteen minutes, which was as long as he could endure, then dried himself and lay down, and in fifteen minutes his temperature was 99° (it had risen in the bath to over 103°), and the sweat excreted was exactly eighty times what it was before he got into the bath. The cause of the pyrexia in these cases was undoubtedly a breakdown of the heat-regulating mechanism.

Dr. MANSON BARR referred to the difficulty of making a diagnosis between heat-stroke and pernicious malaria, the cause of confusion being the paucity or even the absence of parasites in the peripheral blood during the first thirty-six hours after the onset of malaria. In the Jordan valley, where the conditions were somewhat similar to Mesopotamia, it seemed that persons were able to harbour the malarial parasite for some days or weeks without any symptoms whatever; then in a spell of heat there was a crop of cases which simulated heat-stroke in their clinical aspect.

Dr. WILLCOX, in replying to the discussion, agreed as to the predisposing factor of previous disease, the effect of heat in actual damage to nerve cells and brain, and the difficulty of differentiation from malaria. In his own cases, if the temperature did not go down quickly, the patient was at once given quinine by intramuscular injection.

Dr. LEONARD HILL said that the interesting point in the discussion was whether the absence of sweating was a symptom or a precursor. The fact seemed to be that the sweating mechanism was not built to stand the extraordinary strain put upon it.

SURGERY OF THE CHEST.

At a meeting of the Medical Society of London held on February 23rd, the President, Mr. V. WARREN LOW, being in the chair, Sir CHARTERS SYMONDS read a paper on the surgical treatment of the later stages of gunshot injuries of the chest and of empyema. He said that as the result of war injuries there remained a considerable number of open pleural cavities requiring surgical treatment; these had followed either the drainage of a septic haemothorax or an open wound. The same was true of some of the empyemata which had not infrequently occurred after the pneumonia complicating influenza. He gave an account of the results of some recent attempts to close these old suppurating pleural cavities.

The main object of the investigation was to inquire how far the lung could be released by removal of the adventitious layer covering it—that is, by decortication. The number of patients submitted to operation was 19, and 24 operations had been performed, counting only those made after the primary drainage. In 14 one operation was sufficient to secure practical recovery; two required a further operation for removal of the second rib; one had three operations, all comparatively small; the remaining two were still under treatment, one had had two operations, and the other a single one; both promised recovery. Of the 19, one had had four operations and another six before coming under treatment. Of the cases dealt with, seven had been the result of ordinary empyema, one was a sterile haemothorax, six were examples of septic haemothorax operated upon soon after the wound, and the remaining five had open wounds of the chest.

Operations on Old Suppurating Pleural Cavities.

The operations consisted of resection of the ribs—in some to obtain access only, in others to bring about collapse of the chest wall as well; of decortication of the lung and removal of the thickened pleura from the thoracic wall; lastly, of the transplautation of flaps of muscle into the cavity. In most of the operations an attempt was made to detach the adventitious layer covering in and binding down the lung; in others the pleura was simply scored. Access was obtained by removal of the

fourth and fifth ribs from the front. The thickened pleura was removed from the thoracic wall in those cases where muscle flaps were used. In most of the cases, while the thoracotomy served to bring about closure by the falling in of the thoracic wall, he considered that some expansion did take place when the lung was found to be airless, and that when it had receded, as measured by the probe, some expansion took place later on.

At the operation four conditions were met with :

(1) The adventitious layer stripped off easily, exposing an unbroken and glistening pleura. The lung filled the cavity and recovery was rapid. (2) The adventitious layer could be removed and the lung freed, but expansion was not immediately permanent. In this form the air vesicles were torn and air escaped in many places. Expansion varied in extent and did not reach his expectations, though, on the whole, the procedure was full of promise. (3) Detachment of the layer was possible, but not without including some of the pleura. There resulted a dark red spongy, airless lung tissue, which rose, spongelike, into the cavity and gave promise of some permanence, but so far as could be judged no part became aerated and useful. (4) This type was found in most of the cases of old gunshot wounds, and in the empyemata long nuder drainage. The adventitious layer was part and parcel of the visceral pleura, and the two could not be separated. The lung was dark, firm, airless and smooth on section. When torn no air escaped, and there was little bleeding. The adventitious layer was thinned as though it had undergone organization.

In estimating the size of the cavity the best information was gained by a long curved probe or metal sound. With this the most complete exploration could be made, the swing of the antero-posterior curve giving the lateral dimensions. The end thrust against the chest wall could be appreciated by the hand outside. The x-ray screen came next in value, both with and without bismuth. In addition to exhibiting the cavity, evidence could be obtained as to the condition of the lung and the movements of the diaphragm, the latter a most important point in prognosis. Auscultation and percussion completely failed to demonstrate the dimensions of the pleural space.

Two methods of using bismuth were employed, first by filling the cavity and, secondly, by introducing a rubber tube containing bismuth. In the first Dr. R. Heath of Weymouth directs that the patient should be placed so that the orifice is uppermost and the bismuth (30 per cent. in paroleiole) injected through a rubber tube which reaches the deepest part of the cavity. The tube should be small so that the air can escape. The second, a convenient method, was to fill a thin-walled rubber tube two to three feet long with bismuth or barium, tie both ends and introduce it into the cavity; in this way a fairly accurate outline of the cavity could be demonstrated. Neither method, however, gave the lateral extent of the cavity unless a stereoscopic picture were made.

Having ascertained the position and dimensions of the cavity, the fourth and fifth ribs were removed from the front. In recent cases the ribs above and below were retracted, which gave sufficient room to decorticate the whole lung. It was necessary to remove the thickened pleura at the same time. If a little more room was required, division of the rib above added materially to the space. When the ribs were approximated, as was found in most of the cases, two ribs would require removal. The adventitious layer could, in a recent case, be broken through with the fingers in front and behind, and the lung set free. Then the lung itself was exposed, the adventitious layer coming away and leaving a normal pleura. In older cases the facility with which the adventitious layer could be removed varied greatly. In the fourth variety it could not be detached, and then the pulmonary pleura could be everted or divided into squares or cut in vertical lines. In addition to removal of ribs to permit collapse of the chest wall, flaps of muscle had been introduced, a procedure especially advisable when the apex was affected, for it was important to leave the first rib and dangerous to remove it. The cases related showed that by muscle transplantation the apex had been closed. When muscle transplantation was done the thick parietal pleura had been removed, except at the apex. In completing the operation the anterior wound had been closed and a drain left in the old sinus in all cases with extensive cavity. In some, when the cavity had existed chiefly in the upper part with a small track leading to the opening, the drain had been introduced where the cavity was largest. An important question arose as to whether, after the lung had been freed and filled the pleural cavity; it would have been wiser to excise the old drainage opening

and close the cavity. In small cavities resulting from open wounds the thick, hard pulmonary boundary was scar tissue and not a layer of adventitious material, and should not be disturbed.

The two risks in these operations were shock and septic infection of the recently divided structures. Since the use of bismuth injections had been resorted to before the operation, the danger of infection had practically disappeared. In only one of the twenty-four operations was there any anxiety. The temperature seldom reached 101° F. The men arrived, as a rule, with septic pus and small openings. When necessary the opening was enlarged without removal of bone and the cavity irrigated with saline and peroxide, and then filled with 30 per cent. bismuth in paroleiole daily for three to seven days. At the operation all exposed surfaces were rubbed over with this preparation. Shock had never been of sufficient importance to demand treatment, nor had haemorrhage given cause for anxiety. The anaesthetic employed had been warm ether. After-treatment was a matter of prime importance. Colonel Soltan, who carried this out, had varied the reagents. He used the Carrel-Dakin method when the cavity became septic or the discharge abundant, after a time substituting permanganate in some cases. Chloramine-T paste was also used, but on the whole proved troublesome and was difficult to remove when suppuration continued. Peroxide was the customary reagent for irrigation; when a bronchial fistula existed oxygen was employed. Another feature of his practice was early exercise, the patient being allowed up as soon as possible, sent out when the weather was suitable, and encouraged to walk about and do work in the wards. Finally, several wounds were closed by excising the sinus and suturing the muscle and skin. An important feature in the after-treatment was the use of elastic in the bandage in the form of an elastic lace, which obviated restriction of chest expansion and limitation of breathing.

Empyema.

Speaking of empyemata, Sir Charters Symonds said it would be agreed that the chief cause of delay and failure to recover after empyema operations was faulty drainage. There seemed to be an impression in a good many minds that a large tube kept up discharge and prevented closure. He narrated instances where recovery had been delayed by too early removal of the tube or employment of one too small. Prolongation of septic infection, as shown by continued pyrexia or the abundance of pus and recurrent pyrexia associated with increase of suppuration, were very important causes of delay. He was convinced that these drawbacks could be prevented and removed by irrigation of the pleura at the operation and removal of the fibrinous material. He did not think that there was any danger in irrigation when carried out in the recumbent position. He advocated early operation when an empyema failed to heal. The time had come to interfere and release the lung when a large cavity was demonstrable by a sound or by bismuth at the end of about four weeks. If periods of pyrexia had occurred the operation was then all the more necessary.

Mr. H. RAWLENCE, who had collaborated with Sir Charters Symonds in the treatment of these cases, said that the method contrasted very favourably with the older type of operation. When using bismuth the carbonate or the salicylate were easier to introduce than the subnitrate. Anaesthesia had been by oxygen bubbled through warm ether, employing one of the special forms of apparatus used, and preceded by morphine and atropine. Patients seriously ill had expressed themselves as relieved directly after the operation. There had been a remarkable freedom from secondary haemorrhage.

Sir CHARLES BALANCE advocated the removal of the haemothorax early in cases in which this occurred in connexion with gunshot wounds, for if left a foul empyema resulted. Before the war he had been disappointed in the treatment of chronic empyema by the operations of Estlander and Schede. From the point of view of obtaining expansion of the lung and recovery of the patient, he favoured the principle of no drainage and reliance on aspiration.

Sir GORDON WATSON said that he had found that in recently wounded men, if a hole were left in the chest the mortality was high, and he had endeavoured to get such a hole sewn up even at the advanced dressing

station. Of 3,000 cases of gunshot wounds of the chest met with during the Passchendaele fighting the mortality was 40 per cent. with an open "sucking" pneumothorax; 40 per cent. from septic pneumothorax which had been drained; and under 30 per cent. when the pneumothorax had been washed out and sewn up. On the Italian front the mortality was much better. Four or five cases of empyema in which he had sponged out the pleura with 1 in 1,000 flavine and sewn up the wound completely and thereafter aspirated daily did extremely well.

Mr. J. E. H. ROBERTS said that, provided all the solid adventitious material were removed from the chest, cases did best if the chest were closed and aspirated. It was a very ordinary occurrence for bacterial infection to disappear when this was done. Possibly the bismuth preparation would save time and be better than the Carrel-Dakin solution which he had used, but he thought that the solution had a softening action on fibrous tissue. It was advisable in empyema, when the patient's condition permitted, to clear out the fibrinous deposit both on the visceral and parietal pleura. With regard to the anaesthetic, the best results were obtained with gas and oxygen, which he combined with a local anaesthetic, believing that it increased the patient's comfort after the recovery of consciousness.

RENAL FUNCTION IN NEPHRITIS.

At a meeting of the Sheffield Medico-Chirurgical Society, held on March 4th, Professor J. B. LEATHES, F.R.S., gave an address on the function of the kidney in nephritis. He began by referring to results described to the Association of Physicians in July last (BRITISH MEDICAL JOURNAL, August 9th, 1919, p. 165) showing that two common failures in the cases of war nephritis examined were loss of diuretic response to the intake of water and absence of the matutinal alkaline tide, two independent phenomena either of which occurred without the other. The persistence of the nocturnal urinary acidity throughout the first hours after waking showed that it was not to inability of the kidney to remove acid that a tendency to dyspnoea in such cases should be traced. The normal acidity of the urine in the evening and at night was normally accompanied by a considerable increase in the output of phosphate, and the fact that a diuresis induced by phosphate, unlike that produced by other agents, was an acid diuresis suggested that the amount of phosphate excreted by subjects who exhibited no alkaline tide might be found to be high. But this was not the case; nor was the phosphate increased, as chloride and nitrogen output are, by the diuretic flood. Taking average figures from more than a hundred tests with the hourly output of water increased to four times as much as it was during the night, the hourly output of phosphate fell at the same time to two-thirds of what it had been before the diuresis, a proportion observed equally when there was and when there was no alkaline tide. Cushny had shown that a partial obstruction to one ureter, hindering the escape of urine, tended to diminish the volume and increase the acidity of the urine from that kidney as compared with the other. Obstruction in the tubules due to the presence of red blood corpuscles or blood clots conceivably might account for diminished volume with increased acidity in some of these cases; and it was observed that it was particularly in cases that persistently passed granular casts (which could be shown to contain altered blood pigment and from which haematin could be prepared) that this combination of small volume and high acidity was common. Another peculiarity common in cases of nephritis, the tendency for the retention of chlorides rather than of urea, might also be accounted for by films of blood clot on filtering surfaces if it were shown that clotted blood exhibited the properties in regard to permeability which characterized red blood corpuscles—namely, permeability to urea, but not to sodium chloride. Experiments with blood clotted in thin layers on dialyser membranes had been begun, and so far showed a remarkable impermeability of the clot to sodium chloride. How far this might account for the phenomenon common in these cases of nephritis the experiments were not yet sufficient to decide. The very great majority were clearly cases of acute glomerulitis in which haemorrhage from glomerular tufts was probably one of the very earliest disturbances, and in some degree was probably constant.

Professor HALL, Dr. BARNES, Dr. NAISH, Dr. ABERCROMBIE, and others took part in the discussion.

TOXIC IDIOPATHIES.

AN "occasional lecture" was delivered before the Royal Society of Medicine on March 15th by Dr. JOHN FREEMAN on the subject of the relationship between hay and other pollen fevers, animal asthmas, food idiosyncrasies, and bronchial and spasmodic asthmas. Dr. Freeman had grouped these apparently dissimilar affections under the name of "toxic idiopathies," and the purpose of his lecture was to justify the grouping and the name. He began with hay fever, which he had studied longest and most thoroughly.

Hay Fever.

The great majority of hay fever cases occurred between the last week in May and the first week in July, a period which corresponded with the presence of grass pollen in the atmosphere. In these abnormally sensitive persons trouble might arise whenever the pollen came in contact with their tissues. Generally hay fever affected the eyes and the mucous membrane of the throat, but subjects who had thin skins suffered also from an intolerable feeling of itchiness, and often a rash or urticarial wheals developed on the exposed portion. Hay fever, therefore, was not a local but a generalized affection. He had also found that people sensitive to the pollen were sensitive all the year round, not simply during the pollen season. Grass pollen did not stand alone among irritants of this order. Most people who reacted to grass pollen reacted also to sedge, and many of them would react to other pollens also, such as those of the daisy tribe. The pollen of the peony seemed to be a particularly powerful irritant. The reaction of hay fever patients to these other pollens, however, was by no means uniform; some would react to particular pollens, which produced no effect on others. Three factors were needed for a pollen to produce a definite disease: it must be toxic, producing sufficient irritation in the people who happened to be sensitive to it; it must be in sufficient quantities all over the country; and it must be wind-borne. In England only timothy grass pollen fulfilled all these three conditions quite well. In America, however, there was a daisy which was peculiarly toxic, very common, and also wind-borne, and as this flower pollenated in the autumn the Americans had an autumn fever which was rather worse than the American June fever corresponding to our hay fever.

Animal Asthmas.

Dr. Freeman said that about 60 per cent. of his horse asthma patients were also subject to hay fever, though others were quite insensitive to pollen. The parallel between the two conditions was noteworthy. Horse dandruff, when applied to the skin or, in weak solution, to the eye, produced reactions exactly like those obtained with pollen. The serum, flesh, urine, and dung of the horse alike seemed capable of producing the reaction. Other members of the equine family were responsible for similar effects. He had succeeded in producing on the skin of one subject reactions not only to the curry-combings of the horse, but also to those of the zebra, the ouega, and the kiang; in the case of the donkey the reaction was much smaller, possibly because this animal was further removed than the others, zoologically, from the horse. In animal asthmas, therefore, it was not only asthma which resulted from contact with the emanations of the animal, but every part of the body was sensitive. Other animals, not of the horse family, were also responsible for asthmas. A well known court official told him that he was subject to cat asthma, and on one occasion, in the royal presence, on a cat entering the room, he was seized with such an uncontrollable asthma that he had to bolt from the apartment without any opportunity of explanation or apology. Certain people were susceptible to goats, sheep, dogs, cattle, rabbits, guinea-pigs, and mice. He linked up these animal asthmas with the pollen cases, first on the ground that they were both selective, also that they both had much the same symptom-complex, and yet again, that they were both hereditary. Hay fever ran in families to an extraordinary degree, and this led him on to discover that the asthmas did also. On coming across cases of bronchial or spasmodic asthma he found that very frequently in the same family there were hay fever or animal asthma subjects, so that these conditions also were connected up, by the family link at any rate. He

also found, on getting the causal organism of the bronchitis which accompanied a case of bronchial asthma, making a solution, and getting out the endo-toxins, that it was possible to produce on the eye or the skin a reaction entirely comparable to the reaction in the pollen fevers or horse asthmas. The only difference was that in the case of bronchial asthma there was a longish period of delay before the reaction appeared. The reaction after the pollen appeared perhaps in a few minutes; that of the endo-toxins took some hours to develop.

Food Idiosyncrasies.

The Americans had lately done some work on food idiosyncrasies, and since the war he himself had turned his attention to this subject. He discovered that his hay fever patients had most startling stories to tell of aversion from particular kinds of food. One of them, for instance, could not eat apples. On one occasion, after eating an apple, he was seized with severe vomiting and diarrhoea, which lasted for a day. In another case serious effects followed the taking of a spoonful of honey; it immediately brought on a nausea so severe as to cause collapse. Apart from these well marked cases there was every degree of idiosyncrasy, down to quite minor discomfort, hardly referable to a particular article of diet. He thought it wise, when people came with dietetic troubles for which there was no obvious cause, to inquire whether there was hay fever or horse asthma in the family. Dr. Freeman believed that many other things came into this group of toxic idiopathies. He instanced a case of special sensitivity to gnat bites in a hay fever patient. As for spasmodic asthma, he thought that this ought to be called asthma of unknown origin. He believed that in this condition a similar irritant was at work to that of the pollen, and he was inclined to think that the emanations from moulds might very possibly be the cause. He discovered one man with spasmodic asthma who was specially susceptible to mushrooms. While it was too much to say that these ideas opened up a big new field in medicine, they yet threw light from an unexpected angle across an old field.

Sir ALBROTH WRIGHT said that they had heard some useful generalizations, and although he was of opinion that most generalizations were wrong, they served a temporary purpose as a basis of testing. Most of Dr. Freeman's audience would go away with a fresh set of questions to put to themselves and their patients when confronted with these anomalous cases. He thought it an admirable thing to have a lecture on generalizations rather than on those isolated facts of medicine which generally formed the substance of discussions in medical societies.

Dr. ARTHUR LATHAM said that in children under 10 asthma was not infrequently caused by white of egg and nothing else. He had often found asthma alternating with eczema; it was rather interesting if it was some foreign protein which was producing these conditions in the same individual. Sir JOHN BROADBENT said that the difficulty of supposing that all attacks of asthma were due to some special idiosyncrasy was that in quite a large number of cases there seemed to be no possible cause for the condition. He thought it likely that in purpura and haemophilia, research on the lines of endo-toxins might elicit further information.

Dr. PARKES WEBER was of opinion that some of the mysterious stories about attempts at poisoning during meals could be explained by food idiosyncrasies; and Dr. W. H. WILCOX also thought that food idiosyncrasy would explain many of the unusual types of food poisoning which were met with. Sir W. ARBUTHNOT LANE said that every family had got certain tissue disabilities, and the particular families with whom Dr. Freeman had been dealing had their disabilities in their bronchial tubes. They all, in answer to the same stimulus, reacted in the same way, to the disadvantage of the individual.

Dr. FREEMAN, in reply to Sir HUMPHRY ROLLESTON, who presided, said that these conditions most certainly were acquired as well as hereditary. He instanced among his patients an old man of 74 who had just developed hay fever for the first time.

THE IRRITABLE HEART.

At a meeting of the Bristol Medico-Chirurgical Society, held on March 15th, papers on the irritable heart syndrome were read and discussed. Dr. CAREY COOMBS, who dealt with the syndrome as seen in civil practice, gave an

analysis of 50 cases. He said that in 90 per cent. there was no evidence of organic heart disease, and gave other reasons for regarding it as a nervous disturbance. About half the patients showed evidences of temperamental predisposition; physical effort was not a cause. Infections of various kinds, especially influenza, might be regarded as causal in 44 per cent. Distressing emotion of a protracted kind was apparently responsible for the onset of the symptoms in at least 36 cases.

Dr. C. E. K. HERAPATH outlined his experiences in a cardiac clinic of the Ministry of Pensions. Of his first 57 cases 9 were examples of various organic lesions; the rest were irritable heart cases. Among these 48 men there were 28 who dated their symptoms back to convalescence from some acute illness—influenza, trench fever, malaria, etc. Of the remaining 20 there were 11 who ascribed the onset to some form of nervous disturbance. Dr. Herapath gave an account of his methods of investigation and treatment, laying particular stress on the value of optimistic "suggestion." He had, he said, already seen enough improvement take place to justify a further application of these principles. Dr. A. G. MORRIS detailed notes of cases of irritable heart in soldiers serving in this country and developing without any infective or other obvious cause, except anxiety as to their immediate future, which there was strong reason to regard as causal. He also described his experience on boards at an overseas base, which was to the same effect, that the "D.A.H." syndrome often sprang from pure "anxiety." Dr. J. A. BIRRELL read notes of four cases of severe tachycardia following influenza, in all of which the patients were under the influence of protracted anxieties at the time when the influenza attacked them. Analysis of this tachycardia had proved it to be of the supracardiac "nervous" type.

In the discussion which followed, Dr. J. A. NIXON described experiences in France which led him to suspect infection of the heart itself as a cause of some of the tachycardias. He had seen *post-mortem* signs of early aortic syphilis and also of an acute endocarditis of unknown origin in many men killed by wounding. Dr. R. G. GORDON, on the other hand, supported the nervous theory. The kind of emotion that was most productive of this syndrome, he thought, was that expressed by the French "angoisse." Influenza allowed of the development of the syndrome with undue ease because of its action in diminishing higher centre control of emotional expression. Dr. D. A. ALEXANDER suggested that functional disturbances might set up organic disease.

NERVE SYMPTOMS IN ACUTE INFECTIONS.

On March 12th, before the Harveian Society, Sir THOMAS HORDER delivered the Harveian lecture on the diagnostic significance of nerve symptoms in acute infections. The subject was dealt with from two aspects—the general or synthetic point of view, and the particular or analytical. The lecturer considered the different mechanisms by which nerve symptoms were produced as the result of infection of the body by micro-organisms. These mechanisms included (1) the interaction between the nerve tissues and toxins circulating in the blood (a) when absorbed from a focus, or (b) when resulting from a general infection; (2) the direct effect of infection of the pia arachnoid membrane, leading to meningitis, in which case there were subsidiary mechanisms concerned; (3) the direct effect of infection of the central nerve tissues themselves, again leading to secondary mechanisms. This last named mechanism came into play in cases of poliomyelitis in its different forms. The lecturer proceeded to refer each of the various acute infections leading conspicuously to nerve symptoms to one or more of these mechanisms. He pointed out that every virus tended to set going each one of these mechanisms, and that this tendency must be kept in mind, otherwise the occurrence of such a condition as "meningism" would not be understood. Passing to the analytical side of the subject, the main nerve symptoms and signs were discussed in turn, and comments were made concerning the particular significance of each in regard to the mechanisms already dealt with. Headache, delirium, coma, changes in the reflexes, the facies, pareses and paralysis, and other nerve manifestations received detailed consideration.

DRUG IDIOSYNCRASY.

A DISCUSSION on idiosyncrasy to drugs took place at a meeting of the West London Medico-Chirurgical Society, in the society's rooms at the West London Hospital on March 5th, with the President, Mr. HERBERT CHAMBERS, in the chair.

Sir WILLIAM HALE-WHITE, who opened the discussion, said that many idiosyncrasies were apparent, not real. Apparent idiosyncrasies were sometimes to be explained by impurities in the drugs; at other times they depended upon varying composition of the drug—the best instance of inconstant composition was ergot, which contained varying proportions of at least three powerfully active bodies—ergotoxin, tyramine, and histamine. The solanaceous plants were another instance, containing as they did varying proportions of alkaloids. Delayed excretion of a drug, causing its action to be cumulative, might cause a person to appear peculiarly susceptible to the drug, whereas in truth he was not. Examples were digitalis, lead, and opium. Again, the rate of absorption of a drug might explain some instances of idiosyncrasy. All were familiar with the profuse erythema which occasionally followed the administration of a soap enema; this was believed to be due to the soap leading to the solution of a faecal toxin. It was highly likely that variation in the intestinal contents might be the explanation of some cases of idiosyncrasy, for a drug, if it was usually slowly absorbed and soluble in the intestinal contents only with difficulty, might from abnormal alterations of the fluids of the intestine become readily soluble, and therefore quickly absorbed. Or, again, the drug might, in the intestine, become chemically changed, and the changed drug be more soluble and easily absorbed or have a different action and be readily poisonous. Apparent idiosyncrasies might again be caused by disease—for example, many cases of uraemia were benefited by morphine, yet, very rarely, the drug appeared to be a fatal poison. We were often disappointed in the relief of cardiac pain by nitrites; this might be because cardiac pain had a varying pathological origin. Passing on to the genuine idiosyncrasies, Sir William Hale-White said that no attempt could be made, in the present state of our knowledge, to state the cause in the majority of the more important examples. The most remarkable were the iodides—half a grain daily for two days had caused iodism; on the other hand, he had given 300 grains a day without any symptoms of it. Sometimes when the dose was diminished they would pass away; again, doubling the dose might lead to their disappearance. Drug rashes, sufficiently infrequent to cause idiosyncrasy, were caused by a large number of drugs. Cutaneous idiosyncrasies were seen also when drugs were applied externally; he knew personally a nursing sister who was unable to put her hands into mercury perchloride or handle mercurial gauze without getting general signs of mercurial poisoning. The selective action of lead, arsenic, and alcohol on nerves was most remarkable, and the explanation would be found, he thought, by the bio-chemist.

Sir ROBERT ARMSTRONG-JONES referred to the idiosyncrasy of some persons to aspirin, when the eyelids and face became alarmingly swollen, this lasting as a modified erythema or urticaria for nearly twenty-four hours. He spoke also of the cumulative effects of sulphonal and the appearance of haematoporphyrinuria after repeated administration of physiological doses, and mentioned the susceptibility of some persons to the pollen of the *Cupressi* and the *Thuja*s. The explanation of idiosyncrasy was not, he said, completed by calling it a matter of temperament, and biochemistry could not explain the phenomenon. The familial record of dipsomania would indicate some inherited frailty, and it was interesting that the selective affinity of alcohol in mental cases was not associated with hepatic cirrhosis.

Dr. P. A. HENDLEY put forward the theory that idiosyncrasy was, in a greater or less degree, nothing more than shock produced by an increased or decreased hydrogen ion concentration in the serum. Dr. SEYMOUR TAYLOR and Dr. HALLS DALLY emphasized the excellent results often obtained by increasing the dose of potassium iodide when the patient could not tolerate small doses.

Dr. RICKARD LLOYD said that no doubt varying states of health, strength, psychical condition, and the circumstances in which the vital functions were being performed influenced the toleration of individuals to the amount and rate of dosage of chloroform and other idiosyncratic drugs.

Mr. BISHOP HARMAN had experience of a case in which a few drops of zinc sulphate solution, a grain to the ounce, put into the eye caused acute symptoms. The solution used had been subsequently found to be innocuous on six other persons.

SURGERY IN EGYPT.

THE book entitled *The Surgery of Egypt*,¹ which Mr. FRANK COLE MADDEN, professor of surgery in the Egyptian Government School of Medicine, has written, possesses a special character. The stay-at-home has only to turn the pages and glance at the many curious and interesting photographs in which the work abounds to realize the fascination which foreign practice has—the wealth of what are here rare diseases and the opportunities for research and alleviation of suffering. Professor Madden has written primarily for the Egyptian student, and particularly the student of the Kasr-el-Ainy Hospital. The work is planned as an adjunct to a general textbook of surgery (Rose and Carless has been his model), the idea being to supplement such a European book in the places where it is deficient in its account of tropical diseases. The author has at times been unable to keep himself strictly to the letter of his intention, with the result that there is often a considerable overlap. He has, moreover, hardly used sufficient discrimination in his often tiresome quotation of other people's opinions word for word. Up to a point such acknowledgements are good and magnanimous, but his readers may object to Professor Madden allowing people to say things for him which, with a little more trouble, he could very well have said for himself. The book is for this reason somewhat ragged, and in its next edition will gain greatly by compression. With these reservations we have nothing but good to say. Professor Madden's surgical principles are absolutely sound, and the Egyptian student is fortunate in having so wise and able a mentor. The critic who wishes to quarrel with him over points in treatment will be disappointed, although he might well join issue on the use of cocaine, which he seems to prefer to novocain.

As might have been expected, the most valuable sections of the book deal with bilharziasis in its protean forms. The study of this disease is no insignificant memorial to the value of the European invasion of Egypt. The fatalism and indifference of the fellah, "around whom," says Madden, "much unmerited romance has been woven," are all against discoveries of the early stages of disease being made. Observations on these phases have recently been rendered possible by the disease appearing in our soldiers in Egypt. A summary is given of Leiper's interesting experiments on the mode of ingress of the parasite. Mycetoma and Madura foot are ably dealt with, as are filariasis, hepatic abscess, and the Egyptian enlargement of the spleen, with which Richards has familiarized us, so closely resembling Banti's disease. It is interesting to note that hydatid cysts are rare. Another interesting point is the rarity of gastric carcinoma, 4 cases in 2,906 admissions. It is noteworthy in this connexion that gastric and duodenal ulcer are equally rare, and the author says that the day of any operation on the stomach is marked with red in the student's calendar. Epithelioma of the tongue is common, syphilis being rife.

The book has been printed by the Nile Mission Press, Cairo. The Egyptian compositors have done their work well, though the method of breaking up the page into a number of spaced paragraphs has nothing to recommend it. The photographs, which are an admirable feature of the work, have been made by the photographic section of the Egyptian Survey. If more are being taken we might suggest that we could often spare full length pictures of fellahs if by that means the area actually diseased appeared larger.

We have no doubt that this book will achieve the popularity it so well deserves, and that it will find an honoured place on the shelves of most medical officers in our far-flung Eastern colonies and protectorates.

RADIOGRAPHY OF THE LIVER AND DUCTS.

*Radiography in the Examination of the Liver, Gall Bladder, and Bile Ducts*² is the title of a monograph by

¹ *The Surgery of Egypt*. By Frank Cole Madden, Professor of Surgery, Egyptian Government School of Medicine, Cairo. The Nile Mission Press, 1919. (Roy. 8vo, pp. xxxviii + 394; 63 plates, comprising 233 photos, 3 line drawings in text.)

² *Radiography in the Examination of the Liver, Gall Bladder, and Bile Ducts*. By Robert Knox, M.D. London: William Heinemann (Medical Books), Limited, 1920. (Sup. roy. 8vo, pp. 64; 64 figures. 7s. 6d. net.)

Dr. ROBERT KNOX. Hitherto little reliance has been placed on the *x*-ray examination of these organs as far as British radiography is concerned, but in America many workers have published numerous papers on the subject; this monograph is, therefore, opportune. The author first gives a concise account of the anatomical considerations, which should be of value to many radiographers; this is followed by a very complete account of biliary calculi, taken chiefly from Beattie and Dickson's *Pathology*. The radiographic method is described in great detail and illustrated by stereoscopic photographs. Details of the results of a large number of experiments on the *x*-ray appearances of gall stones are related.

Opinions vary as to the percentage of cases in which stones actually present can be shown by radiography, but there is no doubt that the larger percentage of successful results will be obtained by those workers who use a powerful apparatus and cut down exposure to a minimum. The shadows on which gall stones have to be diagnosed are often very small and very faint—so faint that they cannot always be printed out from the negative; the slightest movement of respiration may entirely prevent such stones being shown. Even when shown the question of differential diagnosis is often a matter of great difficulty; gall stones have to be distinguished from renal calculi, calcified mesenteric glands, and many other possible lesions. Perhaps the two points of greatest importance are (1) if a ring-like shadow is found (due to calcareous material being deposited on the surface of cholesterol) this is strong evidence in favour of the shadow being caused by a gall stone; (2) if the shadow is smaller and more sharply defined on the plate taken with the patient lying face down than on the plate taken with the patient lying on the back, this also is in favour of gall stone.

Much of the original work described is of the greatest importance; it comprises experiments on the absorption coefficient of the various constituents of gall stones as compared with the tissues around the gall bladder, and experiments on gall stones and kidney stones to show the variations in density and exposures from tubes of different vacuum, and to ascertain the absorption equivalent of gall stones themselves.

The final chapter deals with the historical side of the work and detailed abstracts from the literature of the radiography of the liver, gall bladder, and bile ducts are given. The *x*-ray investigation of the region of the liver and gall bladder should always be employed when symptoms point to a lesion in that region, and with increasing experience the individual value of the observer will increase.

THE MICROSCOPIC ANATOMY OF THE TEETH.

IF anyone is curious to find truths stranger than fiction he needs but to seek them in nature's workshop, nor need he go far afield to find them. In his fascinating volume on *The Microscopic Anatomy of the Teeth*³ Mr. HOWARD MUMMERY exposes nature in her most baffling complexity. Enamel formed by ameloblasts, enamel formed partly by ameloblasts and partly by a secreting gland, enamel laid down by epiblastic cells pouring a secretion into a mesoblastic groundwork, and claimed by some as enamel and by some as dentine, enamel perforated by tubes entering from the outside, by tubes entering from the inside continuous with the dentinal tubules, by both, or by none—such are some of the variations of enamel; and indeed, in no two animals does the histology of this tissue seem to be identical, nor does any order or meaning yet appear amid all its marvels; nature seems to be disporting herself, seeing how many ways there are of arriving at the same end. Dentine, by comparison, is rather an unexciting structure, and seems to fall fairly into line with bone in its main characters; but it may well be asked what nerve-end cells with axons and dendrons can be doing in the dental pulp. By his discovery of these cells and of the prolongation of their axons into the tubules of the dentine Mr. Mummery has solved the problem of the sensitiveness of dentine, and established himself as perhaps the foremost of dental histologists.

No one who reads current literature can fail to be struck

by the many and divergent opinions held on the same point in dental histology, and the author has done great service by bringing together these opinions for comparison and by adding to each chapter a full bibliography. Where possible he has made a definite pronouncement, but more often than not the student must take his choice, or remembering "quot homines, tot sententiae," will leave it to others to dispute. If, however, he is a wise man and has the leisure, he will himself follow Mr. Mummery into this fairland of science, of which only the edges are known. We heartily congratulate Mr. Mummery on his work; it is well arranged, well written, plentifully illustrated, and generally clearly expressed, though there are places—as, for instance, p. 135 et seq. (osmotic membranes)—where we are left in some doubt as to the author's meaning.

DISEASES OF THE MALE URETHRA.

Dr. I. S. KOLL's book on *Diseases of the Male Urethra*⁴ is altogether an excellent piece of work. The author states that he has aimed at conciseness, clearness, and simplicity, and these are the distinguishing qualities of his book, which on this account may be read with uncommon pleasure. The number and excellence of the plates undoubtedly contribute to its clarity. The coloured urethroscopic views are particularly good, and although the work is not primarily an exposition of endoscopy, these illustrations furnish a better gallery of urethroscopic views than many more ambitious works. The author, when he admits that some of his views are reactionary, probably had in mind his chapter on the bacteriology of gonorrhoea; it is, however, in accepting the bacteriological opinions of Dr. Carl Warden rather than in any of his own work that Dr. Koll shows a tendency to heterodoxy. According to these views, it is extremely doubtful whether the well-known Gram-negative intracellular diplococcus seen in urethral films is in reality the gonococcus. Dr. Warden suggests, and Dr. Koll is inclined to believe, that in the majority of cases these biscuit-shaped cocci are staphylococci that have lost their property of retaining the stain when the Gram method is applied to them. If this be so, then the old criterion—the microscopic appearance of smears—is to all intents and purposes useless, and cultural methods alone can have any value in the diagnosis of gonorrhoea. According to this theory, if biscuit-shaped Gram-negative cocci are found in a gonorrhoeal exudate a double infection is probably present, true gonococci being demonstrable only with difficulty, or possibly not demonstrable at all in such an exudate. As evidence in favour of this view is adduced the fact that the complement fixation curve for *Staphylococcus urethrae* runs directly parallel to that for the gonococcus. Dr. Warden's work, as quoted by Dr. Koll, is rather bewildering; whilst the necessity for the employment of cultural methods in the diagnosis of gonorrhoea may be fully accepted, we are not inclined to accept these revolutionary views without further evidence.

The author is not in favour of the routine resort to irrigation in the treatment of gonorrhoea, but relies on injections of albargin. He employs it in the strength of 1 per cent. in a base of gelatin and tragacanth. Of vaccine therapy he is decidedly sceptical. With the possible exception of arthritis no lesions due to the gonococcus have, in his experience, been benefited by the use of vaccine. In a chapter on urethral stricture he makes a strong appeal for conservative or non-operative treatment, as he considers that 98 per cent. of all organic strictures may be relieved without recourse to the urethrotome or knife. Patience and endurance are demanded on the part of both patient and physician, but the ultimate results obtained are better. We believe that this warning against the indiscriminate operating of some surgeons is not altogether unnecessary. The indications for urethrotomy are definite, and should be more closely observed.

The book closes with chapters on sterility and impotence, subjects too often neglected in English textbooks. These matters are as clearly and simply dealt with as the subjects of the previous chapters. Altogether we are disposed to think this book the best monograph on the subject yet produced.

³ *The Microscopic Anatomy of the Teeth*. By J. Howard Mummery, D.Sc. Penn., M.R.C.S., L.D.S. Eng. London: H. Frowde, and Hodder and Stoughton, 1919. (Demy 8vo, pp. viii + 382; 243 figures, 6 coloured plates. 25s. net.)

DR. HENRY QUIN OF DUBLIN.

MEDICINE is a profession in which a man may be extremely well known during his lifetime and yet leave so little behind that he rapidly becomes forgotten. Henry Quin (1718-1791) is a case in point, for though the most notable physician in Dublin and an eminent patron and connoisseur of art during the latter half of the eighteenth century, the only record of his life is in Dr. T. P. C. Kirkpatrick's *History of the Medical School in Trinity College, Dublin* (1912). Recently Dr. A. Blackhall-Merison's presentation of a bust of Dr. Quin to the Royal College of Physicians of Ireland has been the occasion of a scholarly Life of this Dublin physician from the pen of the Registrar of the College—Dr. KIRKPATRICK.⁵ The son of Thomas Quin, an apothecary and Master of the Guild of St. Luke, Henry Quin graduated M.B. in 1743 and then disappeared for six years; but as he came back to Dublin in 1749 with the doctorate of Padua he probably obtained his love of the fine arts in Italy. Shortly after his return he was elected, as the result of an examination, King's professor of the practice of physic in the medical school of Trinity College, Dublin, and immediately started on a fashionable and lucrative practice, no doubt helped thereto by his father's recommendations and a judicious marriage.

Perhaps as the result of this early success Quin never published any medical papers, and his name does not find a niche in the *Dictionary of National Biography*. But he had many other interests; he was an accomplished musician and had a private theatre in his house for concerts; he collected cameos and intaglios which he copied with his own hand, and was the generous patron of James Tassie, who afterwards gained fame and fortune in London, and of William Mossop, the pioneer medallist of Ireland. Had it not been for his help, probably neither of these artists would have emerged from obscurity. A medal struck in his honour bears the rather remarkable legend, "The human frame is, Quin, thy debtor, none but its Maker knows it better." On St. Luke's Day, 1758, four years only after his election as a Fellow, he was chosen president of King and Queen's College of Physicians in Ireland, an office he filled on six subsequent occasions. *The Gentleman's Magazine*, in recording his death on February 11th, 1791, in his 73rd year, at his house in St. Stephen's Green, refers to him as "a very eminent physician and uncle to the Marchioness of Waterford." He left an ample fortune, which enabled one of his sons to travel and collect art treasures on Italy; while the other, Charles William, president of the College in 1786, published an octavo of 227 pages, *A Treatise on Dropsy of the Brain and on the Use of Digitalis purpurea in Dropsies*, thus following the work of Robert Whytt (1760) and Withering (1785) respectively.

NOTES ON BOOKS.

THE Edith Cavell edition of *The Imitation of Christ*,⁵ by THOMAS À KEMPIS, is a facsimile of the copy which belonged to Edith Cavell, and which she had with her in the prison of St.-Gilles at Brussels in August, September, and October, 1915, up to the hour of her death. Reproduced in its pages are the markings she made against the passages she found of special help and comfort, some sixty in all. How poignant are these pages; what a clear light they cast on the training of a holy and humble life spent in the service of others! There must be many people in this country who would be glad to own a copy of this edition, for the sake of its association with the thoughts of a woman who sacrificed her life to help the wounded and fugitive. Its purchasers will also be helping to maintain the Edith Cavell Homes of Rest for Nurses, to which the proceeds of its sale will go. The possession of this volume will also serve as a reminder of the moral degradation to which the Prussian spirit leads in warfare, as exhibited by the type of man not unfairly characterized as *Pithecanthropus teutonicus* by a French writer.

Dr. HENRY J. WATT'S name is already familiar as that of an explorer of those almost unknown territories which

⁵ *Henry Quin, M.D., President and Fellow of the King and Queen's College of Physicians in Ireland, and King's Professor of the Practice of Physic (1718-1791)*. By T. Percy C. Kirkpatrick, M.D. Dublin: University Press. 1919. (Sup. roy. 8vo, pp. 66; 6 illustrations. 10s. 6d. net.)

⁶ *Of the Imitation of Christ. Four Books by Thomas à Kempis. The "Edith Cavell" edition.* London, Edinburgh, Glasgow: Humphrey Milford. 1920. (3¹/₂ × 6; pp. 229. 2s. 6d. net.)

lie where the domains of the physiologist, the psychologist, and the musician join, and which none of them has had the courage deeply to penetrate or survey. In his *Psychology of Sound* he addressed himself to the physiologist and psychologist; in his new work, *The Foundations of Music*,⁷ he applies the psychological groundwork of the previous one, so as to bridge the gulf between the psychological elements of music on the one hand, and on the other "the sensory stuff and functions of music as the musicians observe them." The present volume is thus interesting chiefly to the musician who is conversant with psychological methods, and to the psychologist who is not devoid of musical capacity; among such will be not a few medical men. The work is remarkable for its lucid and original exposition of a subject presenting very great difficulties.

The forty-second volume of the *Transactions of the Medical Society of London*⁸ contains the lists of past and present members and officers usual in these publications, and papers on subjects of medical education and medical interest (most of them reported in our columns at the time of their delivery) that are of no little importance to medical men anxious to keep up with the progress of medicine.

⁷ *The Foundations of Music*. By Henry J. Watt, D.Phil., Lecturer on Psychology in the University of Glasgow. Cambridge: University Press. 1919. (Med. 8vo, pp. 239. 18s. net.)

⁸ *Transactions of the Medical Society of London*. Vol. 42. Edited by Edmund Cautley, M.D., and Donald Armour, C.M.G., F.R.C.S. London: Harrison and Sons. 1919. (Demy 8vo, pp. liii + 253; illustrated.)

NEW STAFF OF OUTDOOR MEDICAL OFFICERS
OF THE MINISTRY OF HEALTH.

IN connexion with the appointments for medical officers which the Ministry of Health announces in our advertising columns this week, the Ministry supplies the following particulars, which may be of interest. The new staff will include both whole-time and part-time medical officers. Each whole-time officer will be stationed in the area in which he works. Particulars as to the part-time appointments will be announced later.

The duties of the whole-time officers will be partly clinical, partly administrative; of the part-time officers, clinical only. The clinical duties of the medical officers will consist in examining insured persons referred to them by approved societies or doctors, in advising the societies and doctors on questions of incapacity for work, and in advising doctors on questions of diagnosis and treatment. The clinical duties will thus combine those of referee and consultant. For cases of special medical difficulty specialist advice as to diagnosis or treatment will be made available for the assistance of the medical officers.

The administrative duties will include examining health insurance medical certificates, records, reports, and prescriptions, and making inquiries of insurance practitioners respecting any points arising on these, or arising out of the examination of insured persons. The medical officers will also make such other inquiries and take such action, in connexion either with the work of the insurance medical service or with other branches of the work of the Ministry, as the Ministry may from time to time require.

The Minister proposes to appoint in the first instance eighteen whole-time officers for England and three for Wales. In addition there will be a small number of supervisory posts. It is contemplated that this number of whole-time officers may be increased (with a corresponding reduction in the employment of part-time officers) as soon as sufficient experience has been gained of the working of the arrangements.

Although particulars of the part-time appointments are not yet available, it may be stated that the work of part-time officers will be arranged, so far as the nature of the case permits, in definite half-day sessions at fixed centres; in the more remote parts of the country it will be necessary to employ doctors specially for single cases. Sessions will be held at the various centres at such periods (weekly, fortnightly, or monthly) as may be found necessary to deal with the flow of cases. So far as it can be avoided, a practitioner working part-time will not be called upon to examine cases within the district in which he ordinarily practises.

The Minister is appointing a Selection Committee (of which the personnel will be announced shortly) to consider all applications for the appointments which are now advertised, and to make recommendations to him.

British Medical Journal.

SATURDAY, MARCH 20TH, 1920.

THE PSYCHO-NEUROSES.

WE commend to all interested in the working of the mind, whether healthy or disordered, the admirably clear and comprehensive address by Dr. Henry Head which we have the advantage of publishing this week. He presents the matter in a way which, we hope, may tend to diminish the bitterness imported into discussions on psycho-analysis—bitterness on the one side due to a revolt against the extravagances of Freud himself, who seems to have been so obsessed by his theory of the importance of the sexual content that he has been unable to do justice to other fundamental elements. Dr. Head makes all this very plain, but the address must be read and digested as a whole; isolated paragraphs must not be picked out to support this or that theory. The address in its conception irresistibly recalls the teachings of Hughlings Jackson, and we conceive that no higher compliment could be paid to a living neurologist. The comparison arises no doubt through the manner in which Dr. Head handles the doctrine of the control of the optic thalamus, the centre associated with the pleasure or discomfort induced by afferent impulses. The control exercised by higher centres over the more primitive activity of the thalamus endows the animal with the power of choice, but normally this control is automatic, not voluntary. If it ceases to be automatic the mind adopts several different methods of curbing the desires to which it has determined not to yield. It curbs the sexual desire and it curbs the other great basal factor—the desire to avoid pain and discomfort. Of all instincts self-preservation is the most deeply innate; it may, as in war, be curbed by tradition and education, but there ensues a conflict which may lead to morbid consequences. Thus the private may develop a conversion hysteria and is carried paraplegic from the danger zone, while the officer becomes the victim of anxiety neurosis.

The contrast is well illustrated in the course of an essay on the psychoses and psycho-neuroses contributed to the Naval History of the War by Dr. Thomas Beaton, lately temporary Surgeon Lieutenant R.N.¹ He states that of the psycho-neuroses of the navy, 95 per cent. were of the nature of anxiety neurosis, which, in his opinion, was the outcome of the perseveration and overaction of the fundamental biological defensive mechanism of the organism to the psychological stimulation by fear. The work of Cannon in regard to the relation between the activities of the endocrine organs, the sympathetic nervous system, and the occurrence of emotional mental states, is quoted, and Mott's conception of the "vicious circle"—the chronic emotivation producing a definite disturbance of the physiological balance of the endocrine system which, in its turn, sets up constant emotional unrest in the mind—is thoroughly endorsed. The strong clinical resemblance existing between anxiety neurosis and Graves's disease is noted; Dr. Beaton found that a remarkably high percentage of his cases of anxiety neurosis showed clinical evidences of thyroid hyperactivity. McCurdy's view that shell shock is purely a conversion hysteria belonging to the hysterical or suggestion type of neurosis is accepted. Men who served afloat were little affected

by this form of disorder; such cases of hysterical paralysis or loss of sensation as occurred arose in men serving in the naval division with the army ashore, or in individuals who gave a history of pre-war manifestations, and in whom the symptoms developed during training before they were exposed to any actual war stress. This freedom of the navy from the hysterical neurosis is attributed to two factors: First, the man in the navy was not subjected so frequently as his comrade in the army to the actual strain of battle, and consequently did not experience the vivid emotional disturbances accompanying imminent unavoidable danger. The sailor had to bear the stress of chronic anticipation rather than of immediate realization of vivid fear, and consequently developed the anxiety neurosis rather than the hysterical dissociation. Further, when the actual sea battle occurred, fear, however vividly felt, would tend to maintain full physical capacity rather than aid in the acceptance of a disabling loss of function. As the second factor the theory of Rivers as to the effect of the army training in producing a heightened suggestibility is considered, and it is pointed out that the naval training aims at producing a reasoning unit of a service, while army training tends to create the perfect but machine-like automaton, which can be un-faillingly set into motion by the word of command, but which has correspondingly lost the faculty of criticism of its own actions.

The treatment advocated is mainly the application of psychological principles in a common-sense manner, each case being treated as an individual problem. The psychoses met with in the navy did not differ in their clinical presentment from those of civil life. Complete and early recovery occurred in a large number of the cases, and a strong appeal is therefore made for the earlier treatment of the psychoses in civil life. The naval or military case is got under control and treatment from the earliest phase of the disorder, and the marked tendency to recovery was partly if not largely due to this circumstance. The classification of the psychoses adopted by Dr. Beaton cannot be regarded as satisfying, but probably it was dictated by the need for simplicity. His statement that recovery took place in 50 per cent. of his cases of dementia precox must be regarded with doubt, but the term is probably used to cover a wider range of case than present knowledge would perhaps justify. In discussing prophylaxis reference is made to the methods of the American authorities in making a psychological examination of the recruit as well as determining his fitness for service on purely physical grounds. The statistics from the Royal Naval Hospital at Chatham which Dr. Beaton gives show that there was a great increase in the cases as the war went on, and also bring out the curious point that they were always more numerous in the third quarter of the year than in any other.

To return, after this long digression, to Dr. Head's illuminating address, it is to be noted that he accepts Freud's conception of the process of repression and its bearing on the genesis of the psycho-neuroses, and also the opinion that forgetting is not a negative procedure but a positive act, although we gather that this doctrine is to be applied only to unpleasant experiences, and is to be qualified by what he goes on to say as to adaptation and regression. With regard to the latter, every one must have had experience of an unexpected return to a previous habit, and the regression which afflicts the soldier is an analogous phenomenon. One great merit of Dr. Head's address is that he speaks of the psycho-neuroses in terms of processes common to the mind and to the physiological

¹ *Journal of the Royal Naval Medical Services*, January, 1920.

functions of the nervous system, and in the concluding passages he has a message for every member of the profession. The psycho-neuroses of war are comparatively simple when compared with those of civilian life, and in the attempt to solve the complicated problem it is a great advantage to be able to choose examples which show the smallest number of variable factors.

THE DIAGNOSIS OF LETHARGIC ENCEPHALITIS.

THIS country has happily been spared any serious recrudescence of lethargic encephalitis or epidemic encephalitis. Other countries have been less fortunate. New York and some large cities of America have suffered recently, and it would appear that the disease has again become active in France also. As we have noted from time to time, the disease has been the subject of discussion both in its clinical and pathological aspects at several meetings of the Academy of Medicine. There was general agreement that the cardinal symptoms of the disease were somnolence, palsy of cranial, especially oculomotor, nerves, and fever; attention was fixed largely upon the question of the existence of lymphocytosis of the cerebro-spinal fluid, and the diagnostic value of its presence. Cases exhibiting lymphocytosis were reported by Achard, Netter, Vidal, and Marie,¹ and similar observations have been made by observers in this country. The opinion has generally been held that while lymphocytosis of the cerebro-spinal fluid may occur, it is the exception rather than the rule, and that its absence cannot be held to invalidate the diagnosis. With this opinion Marie, in his concluding remarks, concurred, and pointed out that while a moderate degree of lymphocytosis does not exclude the possibility of lethargic encephalitis, any very marked and lasting amount should lead to serious reconsideration of the question whether a condition of real meningitis, notably tuberculous or syphilitic, may not be present.

All are agreed that lymphocytosis, when found in cases of encephalitis lethargica, is a transitory phenomenon which clears up without treatment in all cases progressing to recovery. In this connexion we must remember that lymphocytosis may be found in the cerebro-spinal fluid in many different conditions. Tuberculous meningitis, syphilis of the central nervous system, including tabes and general paralysis, sleeping sickness, and the meningitis of mumps, are some of the more important of such conditions. Grévet² has even recorded a case in which swelling of the parotid glands, combined with a meningeal state and the existence of well-marked lymphocytosis of the cerebro-spinal fluid, led for a time to an erroneous diagnosis of mumps in a case which eventually proved to be one of lethargic encephalitis. Of all the conditions mentioned tuberculous meningitis and syphilis of the central nervous system are those most essential to exclude, particularly the latter, in which prompt and appropriate treatment may mean so much to the patient.

This occurrence of lymphocytosis of the cerebro-spinal fluid, as well as the general resemblance on etiological, clinical, and pathological grounds, at once torces a comparison with poliomyelitis and polio-encephalitis, with which the disease was for a time identified by many observers. Calhoun³ has recently defined the pathology of lethargic encephalitis as an acute infiltrative encephalomyelitis, the most marked

changes being found about the blood vessels of the thalamus, the floor of the fourth ventricle, and in the white matter of the spinal cord. While the changes are very similar to those occurring in poliomyelitis, he considers the absence of haemorrhages in the nuclei and grey matter a point of distinction. Mott⁴ has described four kinds of lesions—infiltration of the walls of the small blood vessels and especially of the veins with lymphocytes and plasma cells, foci of interstitial inflammation, lesions of the nerve cells in the shape of chromatolysis but only exceptionally neuronophagia, and foci of haemorrhages. The last named he considered the most obvious microscopic change.

Whether any very clear distinction can be made on microscopic grounds alone is perhaps still a moot point, but the clinical characters, as well as the seasonal incidence of the two, make it practically certain that we are dealing with two distinct infections, though similar in their nature and habitat in the body. The virus of poliomyelitis has been demonstrated to exist in the nasopharynx of both patients and contacts. The filtrate of such secretions has been used successfully to reproduce the disease in animals, and Noguchi and others claim to have cultivated the organism on special media. It appears that recent attempts to repeat the experiments with the virus of lethargic encephalitis have been successful. Strauss, Loewe, and Hirschfeld⁵ have filtered the secretions of the nasopharynx of patients, and by inoculation into monkeys and rabbits have reproduced a disease similar to that occurring in man. Further control experiments, however, are required. The similarity between the two diseases is therefore close, and what has been said of the lymphocytosis of the cerebro-spinal fluid in lethargic encephalitis may be held to stand as true of poliomyelitis. In the latter a meningeal variety of the disease has been postulated and may explain the rather rare cases in which marked lymphocytosis of the cerebro-spinal fluid is found. In connexion with these two conditions it is interesting to recall the observations of Gordon,⁶ who has described a fatal disease in children presenting the picture of a general infection of the nervous system and particularly of the bulb. These cases exhibited lymphocytosis of the cerebro-spinal fluid.

It is probable, therefore, that there may be many varieties of virus, as yet not clearly differentiated, which are capable of causing a diffuse inflammation of the central nervous system, and producing the clinical picture of an acute nervous disease. The different points in the nervous system attacked will naturally be responsible for the many different clinical shapes which such diseases may take, and the nature of the infection must be judged rather from its epidemiological and general characters than from the particular disturbances of function which it produces. We have already ground for hoping that further experience and research will aid us in differentiating such infections.

THE RECONSTRUCTION OF THE INCOME TAX.

The report of the Royal Commission on the Income Tax was issued on Wednesday evening. It is signed by all the surviving members of the Commission, subject to minority reservations on certain points. When the Commission was appointed it was announced on behalf of the Government that it was hoped that the report would be available in time

¹ *Bull. de l'Acad. de Méd.*, Paris, 3^e série, lxxxiii, Nos. 1, 3, 4, 5.

⁶ Gordon, *Lancet*, 1913, i, 553.

for its findings to be utilized in that thorough reconstruction of the income tax which is to be a leading feature of the ensuing parliamentary session: the substantial unanimity which has been achieved will materially strengthen the hands of the Chancellor of the Exchequer in dealing with what has become a pressing and important national problem.

The Commission has published seven volumes of evidence, including over 28,000 questions and answers in the course of the cross-examination of the witnesses, who between them have represented the difficulties and hardships of the present system from every point of view. The evidence given on behalf of the British Medical Association by the treasurer, Dr. G. E. Haslip, was reported in our issue of December 13th, 1919, p. 783. The publication of the detailed report has been awaited with keen interest by that large and increasing section of the community which is directly affected by the income tax and is concerned to see the present complicated system of rates, abatements, and various personal allowances reduced to a simpler form, which, while furnishing sufficient safeguard against dishonest evasion, will enable each taxpayer to understand his liability without the expert assistance that at present is almost universally essential.

The suggestions put forward by the Commission naturally fall into two classes, dealing first with the general scheme of the tax, and secondly with its administration. It is recommended that what has hitherto been called unearned income should be known as "investment income," and that earned income should be reduced by one-tenth to arrive at the assessment. From the assessable income—that is, the actual investment income, or the earned income reduced by one-tenth—should be deducted the allowances for the taxpayer himself, his wife, children, dependent relatives, etc., in order to arrive at the taxable income. When this taxable income does not exceed £225 the amount would be charged at half the standard rate of tax. If the taxable income exceeds £225, this amount, £225, would be charged at half the standard rate of tax and the excess over £225 at the full standard rate of tax. The effect of the recommendations is illustrated by a number of examples with which we cannot at present deal; we must content ourselves with saying that in the case of a married man with a family of three young children and an earned income of £500 and no investment income the taxable income would be £135, and the effective rate of tax would be equal to about 9½d. in the £. Another case given is that of a man with an earned income of £1,500, who owns his residence subject to ground rent of £6, and has £250 in taxed dividends. Assuming that he is entitled to allowance for wife and three children, his taxable income would be £1,335, and he would pay £368 11s. The real effective tax in this case would be equal to 4s 1d. in the £. The Commission considers that graduation of incomes exceeding £2,000 can best be effected by a super-tax in addition to the ordinary income tax, and it is advised that the super-tax rate should be increased in the case of an income of £2,500 from 1s. to 1s. 6d. on the extra £500, and so on. It is recommended that it should be open to any partner to claim that his share of the partnership profits should be separately assessed (at the place of business), so that his private concerns may no longer be known to his fellow partners. It is also advised that the profits of the year immediately preceding the year of assessment should be taken as the basis for assessment, and that all income from employments now assessable under Schedule D should be transferred to Schedule E. Under that schedule

the basis of assessment would be the remuneration of the employee for the year to which the assessment relates.

Other points dealt with are the elimination of the double liability to income tax within the Empire of income arising in a colony, dominion, or British possession, but receivable in the mother country, and the very vexed question of the liability to income tax of co-operative dividends; on this last there is a reservation by a minority of the Commission, supporting the present official view that such dividends do not come within the scope of an income tax.

On the administrative side the recommendations appear to be directed mainly to the elimination of locally appointed assessors and collectors, the inspector of taxes being made legally responsible for seeing that the work of assessment and collection is performed, presumably with such whole-time staff as the Board of Inland Revenue may be able to supply. This change would restrict the functions of district commissioners of taxes to the exercise of their judicial powers in the hearing of appeals. This is a matter which will, no doubt, be the subject of very full parliamentary discussion; *prima facie* the proposals imply a complete breach with the original theory of the tax—for example, that it was to be locally administered to avoid unfair pressure by the co-ordinating Government department, but the reply on the other side is that in practice the inspector is already performing the functions which in theory the district commissioners should perform. Whether the suggestion is ultimately adopted or not will presumably depend on the weight of evidence as to the present *de facto* position.

Further detailed comment on the Commissioners' voluminous and complicated report must be deferred.

THE JUNE MEETING AT CAMBRIDGE.

THE annual meeting of the British Medical Association at Cambridge this year begins at the end of June, not, as is customary, towards the end of July. The President's address will be given on Tuesday, June 29th, and the Sections will begin on the following day, June 30th. The College authorities have offered bedrooms for a thousand visitors, and married members will be able to find accommodation in the numerous university lodgings in the town.

MEDICAL AMBASSADORS TO THE UNITED STATES.

WE are indebted to Dr. Salusbury MacNalty for calling our attention to the fact that there is an interesting precedent for the appointment of a member of the medical profession to be the chief diplomatic representative of this country in the United States of America. Sir Auckland Geddes, K.C.B., M.D., has just been appointed Ambassador Extraordinary and Minister Plenipotentiary in Washington. Sir Charles Vaughan, G.C.G.H., M.D., was appointed Envoy Extraordinary and Minister Plenipotentiary to the United States in 1825. He was the son of Dr. James Vaughan of Leicester and was born in 1774; he was thus eight years younger than his brother, Sir Henry Halford, physician to George IV, and for twenty-four years President of the Royal College of Physicians of London. Henry Vaughan inherited a large property on the death of Lady Denbig, widow of his mother's cousin, Sir Charles Halford, and changed his name by Act of Parliament to Halford. Charles Vaughan, like his brother, was intended for the medical profession, and was educated at Rugby and Merton College, Oxford. He graduated B.A. in 1796 and M.A. in 1798, and became a Fellow of All Souls in the same year. He attended lectures on medicine

both in Edinburgh and London, and took the degree of M.B. in 1800. In the same year he was elected Radcliffe Travelling Fellow in the University of Oxford. He was thus able at an early age to indulge his master passion for seeing other countries. He got as far east as Baghdad and Persia, and after a winter in Russia reached England in 1806. Two years later he entered diplomacy as a member of Lord Stuart de Rothesay's mission to Spain. He carried dispatches during the Peninsular war, and in 1809 published a *Narrative of the Siege of Saragossa*. In the same year he became private secretary to the Secretary for Foreign Affairs, and in the following year was Secretary of Legation (later of Embassy) in Spain. In 1820 he became Secretary of Embassy in Paris, and in 1823 was made Minister-Plenipotentiary to the Confederated States of Switzerland. In 1825 he was appointed Envoy-Extraordinary and Minister-Plenipotentiary to the United States, becoming at the same time a Privy Councillor. In 1833 he was created Knight Grand Cross of the Guelphs of Hanover. He left Washington in 1835. Of these years the *Dictionary of National Biography* says: "His services in the United States covered one of the most interesting periods in American history. He was intimate with such men as Story and Clay, and he had to watch such burning questions as that of the boundary with Canada, the position of the South American republics, the slave trade, and the tariff." He was sent on a special mission to Constantinople in 1837, and much of the remainder of his life was spent in travel. He died in London in 1849.

SIR WILLIAM OSLER AT THE BODLEIAN.

ONE of the latest of the tributes to Sir William Osler's memory and services is published in the *Bodleian Quarterly Record*, signed with the well known initials of Bodley's librarian, who only retired from that position last year. "F. M." says that Osler was a firm and constant friend to the Bodleian; the library was his admiration and delight, and as a curator and a member of the standing committee he had considerable influence on its administration. He promoted the establishment of the room for musical students, as well as the science research room at the Camera, and when a good opportunity for a special purchase presented itself he was among the first to offer liberal support and to engage the interest of friends. This was notably the case when the original Bodleian First Folio of Shakespeare was repurchased in 1906. The foundation of the *Bodleian Quarterly Record* itself was due to Osler's suggestion and initiative, while his generous action in guaranteeing to pay for some years out of his own pocket such deficit as might occur, enabled the Curators to launch it with confidence on its career. He heartily agreed with its three-fold object—to interest friends of the library, to supply classified lists of recent acquisitions, and to print documents and records of importance. The wonderful collection of books, grave and gay, massive and light, out-of-the-way and trivial, which came to the Bodleian under the will of Robert Burton, the author of the immortal *Anatomy of Melancholy*, made, we are told, a special appeal to Osler's feelings. The collection contains the sources of a work which more than any other combined Sir William Osler's chief interests—humanity, literature, and medicine—and we learn that it was Osler's intention, had he been spared, to prepare a final edition of that great work, based on a collation of the early editions (to be undertaken by a committee of friends), and furnished with annotations by the master's hand. The notice from which we are quoting concludes with the following words: "If he came to you as a friend, he had a way of drawing up his chair to yours, as though all his time were at your disposal, with looks and words of infinite compassion if you were in ill case, of helpful encouragement if you were striving against hindrances, and sympathetic comprehension if you were in

doubt or difficulty. These qualities are akin to the divine. Sir William's friends all over the world feel his loss with personal pain and imperishable regret, not only from his great and varied gifts of mind and intellect, but more than all because those gifts were combined with real human kindness of heart, and because his whole life was devoted to the welfare and betterment of his fellow men."

TOXICOLOGICAL INVESTIGATION OF ACUTE ALCOHOLISM IN MAN.

In medico-legal practice it is of the utmost importance to determine the part played by alcoholism in the death of a person under suspicious circumstances. The result may change a charge of murder into one of homicide, or it may serve to place in their proper relation several factors found at necropsy any one of which might otherwise be held responsible. The application of Nicloux's method for the quantitative estimation of alcohol in organs and body fluids may prove to be of considerable value in this respect. Balthazard and Lambert¹ have established the fact that alcohol may be quantitatively estimated in the blood, urine, viscera, and muscles for several days after death, and that at least till the commencement of putrefaction the alcohol content does not appreciably diminish. A measured quantity of blood or urine, or a certain weight of solid tissue, is distilled and the amount of alcohol determined by the potassium bichromate method. From the amount found it is possible to calculate the amount of alcohol ingested before death. The experiments of Grélaud and Nicleux on animals, confirmed in man by Sweisheimer, showed that the amount of alcohol per 1,000 found in the blood corresponded exactly with the quantity of alcohol ingested per kilogram of body weight. Thus, if a quantity of alcohol represented by 1.57 c.cm. for each kilogram of body weight were taken by a non-alcoholic individual, after a lapse of two and a half hours the blood would give approximately 1.57 c.cm. of alcohol per litre. In the case of inveterate alcoholics, in whom the absorption and elimination of alcohol is said to be more rapid, the maximum alcoholic content of the blood is obtained in an hour and a half and it is relatively lower than in temperate individuals. Hence the quantity of alcohol estimated in the blood after death will represent the minimum ingested before death, and it has been shown that death in acute alcoholism generally occurs in the period of maximum alcoholic content of the blood. The urine gives figures practically identical with those of the blood. Amongst several important medico-legal cases of alcoholism the authors relate an example of the way in which the method may be employed: A habitual drunkard, weighing 51 kg., was found dead; the autopsy was made five days afterwards; the blood and the urine gave, in terms of absolute alcohol, 5.5 c.cm. per litre. Multiplying this by the weight in kilograms, we get 280.5 c.cm. of absolute alcohol ingested, a figure that corresponds to about 3 litres of wine or half a litre of brandy.

THE WHITE MAN IN WEST AFRICA.

THE Colonial Office has issued a set of returns giving the vital statistics of non-native officials in West Africa for the years 1915-1918. During this time the West African service was affected by war conditions, and it might have been supposed that the Colonial Office would have been at the pains to compose a report on so well-defined a period. This, however, has not been done, and we are presented with a series of reports for each year, from which it is laborious to extract any general conclusions. In 1915 the death rate among the European officers was greatly increased by the torpedoing of a ship by a German submarine, in consequence of which 27 officers were drowned. During this year the majority of the West African Frontier Force, and a large number of civil officers attached to it for military service, were engaged in war operations in

¹ *Comptes rendus de la Soc. de Biologie*, lxxiii, No. 7, 1920.

the Cameroons, where they were exposed to the risk of casualties and to greater risks of disease. Moreover, the consequent retention of officers beyond the time of their normal retirement, or their recall to duty, had an effect on the number of invalidings and deaths. Excluding deaths due to a state of war, the death rate was 13.5 per 1,000, an increase of only 0.8 on 1914. The main causes of death were blackwater fever and malaria, but there was one death from yellow fever. The invaliding rate in that year was less than in the previous year. The military campaign in the Cameroons was brought to an end in the early part of 1916, and many officers returned to their ordinary duties. The death rate declined to 11.8 (the same as in 1913); this rate included war casualties; if they be excluded the rate becomes 10.3 per 1,000. The death rate from disease was 8.5 per 1,000, as compared with 11.6 in 1915 and 10.5 in 1914. There was again one death from yellow fever. There were 5 deaths from blackwater fever, but only one from malaria. These good results were not maintained in 1917. The normal staff arrangements were disturbed by the dispatch of large forces from the West African colonies to East Africa, and among the officers of the force were many civil officials. The work thrown on the remaining staff, already greatly depleted, was therefore much increased and leave had to be stopped. The result of these conditions and the attendant restrictions, privations and discomforts, due to war, was shown in the death rate, which rose to 50.6 per 1,000; part of this high rate was accounted for by officers drowned through the act of enemy submarines, and others killed or dying on active service. The sinking of three vessels by enemy action involved the death of forty West African officials, and twenty-three were lost in another vessel, the foundering of which could not be traced definitely to enemy action; 26 officers were killed on active service, 2 died of wounds, and 4 from disease while with the force. Excluding these deaths directly due to the war, the rate is 14.4 per 1,000, a considerable increase on the rate for 1916. In this year there were 7 deaths due to blackwater fever, 6 to malarial fever, and 7 to yellow fever. The armistice came too late in 1918 materially to affect the adverse conditions. The death-rate from conditions other than those directly due to the war rose to 16.5 per 1,000, as against 14.4 in 1917. The rise is attributed entirely to the ravages of influenza and its complications. The epidemic which swept over the world in the last few months of 1918 did not spare West Africa; it caused 27 deaths out of a total of 41 excluding direct war losses, and thus in itself produced a death rate of 10.9 per 1,000. The rate, however, was much lower than in England and Wales for the corresponding period. On the whole, we gather that the writer of these reports is hopeful for the future.

PLANT RESPONSE.

SIR JAGADIS BOSE, C.I.E., C.S.I., F.R.S. (elect), gave a lecture on March 11th, at the Royal Society of Medicine, on plant and animal response, founded on researches carried out at the Bose Research Institute, Calcutta. The lecture was illustrated by a demonstration on the magnetic crescograph, and the lecturer mentioned that he had devised an apparatus to record the movements of a "praying palm" in Bengal, which was stated to prostrate itself at the hours of prayer; the tracing obtained showed that the effect was purely one of reaction to temperature and to light. Plants could perceive changes in environment to an unsuspected extent. Once in his laboratory the reaction of a plant to the customary stimulus became momentarily feeble, and he found that the cause was a small cloud passing across the sun. Automatic records led him to the conclusion that the vitality of a plant was lowered by the introduction of carbonic acid in its vicinity. One Indian plant, the *Desmodium gyrano*, had leaflets which went on beating like the cardiac muscle, and this

plant was made to record its pulsations. On the introduction of ether the pulsations were arrested; in fact, the reactions to drugs were exactly parallel to those in the human and animal heart. Coming to his experiments on growth, the lecturer said that his magnetic crescograph magnified ten million times, so that a rate of growth infinitesimally slow was represented on a lantern screen by a spot of light moving at a fair speed. He demonstrated such movements and their acceleration or retardation by drugs and chemical agents and also by the application of electricity. An electric spark caused the spot of light to stop in its passage and quickly retreat, showing that the first effect of the electricity was to induce retardation of growth. The effect of drugs or chemical agents depended entirely on the strength of the dose; a stimulating agent given in excess produced a great depression, while a depressant in very slight quantities provoked advance. The lecturer believed that nervous impulse in plants was not single but dual, and that the first effect, relaxation, was followed by contraction. He thought it possible that nervous impulse in animals presented the same dual picture, but that this duality had been obscured because the first phase was fleeting. He also said that plants gave responses to wireless signals. Professor Augustus Waller, F.R.S., in proposing a vote of thanks to the lecturer, said that ten million times magnification meant that a human blood corpuscle, magnified on the same scale, would have a diameter of 70 metres. It was movements of this order which Sir Jagadis Bose had shown, and, of course, errors would be magnified in the same proportion. The behaviour of the spot of light threw some doubt on the results. Application of electrical stimulus should have meant arrest and subsequent increase of growth; instead of that, the spot of light went violently backwards, showing that there was the reverse of growth. He would like the experiments to be repeated on non-living matter, for he believed that the same phenomenon might then be seen. The explanation of the contractility of plants—the phenomenon which Sir Jagadis Bose had announced—might be entirely the heating effects upon a tissue. He invited the lecturer to repeat the experiments under laboratory conditions here. Sir Jagadis Bose, in reply, said that these experiments had been tested under laboratory conditions by Professors Starling and Bayliss and other British physiologists.

AN UNRECOGNIZED FACTOR IN RELIEF VISION.

WHEN a group of objects occupies the whole of the visual field the contours of the objects situated at the periphery produce on the retina slightly distorted images, and the image of a straight line in these circumstances forms a segment of a hyperbola. We recall the chess-board experiment of von Helmholtz. The marginal distortion is due to the fact that the refractive media of the human eye do not constitute a perfectly rectilinear objective; if, nevertheless, the complete image of the visual field is sharp it is due to the structure of the fundus of the eye, the concave surface of the retina occupying almost exactly the focal volume of the refracting apparatus. If an object is gradually approaching the observer's eye it occupies a portion of the visual field all the greater as it comes closer, and the image formed on the retina similarly increases, but, at the same time, the distortion of the image will increase in inverse ratio to the distance of the object. Pech¹ holds that, owing to the progressive visual education we undergo from birth, this distortion of images is used by us to locate an object in space and that it constitutes a factor in relief vision not hitherto appreciated. He founds this opinion on the fact that a photographic image viewed with a certain distortion gives the impression of actual relief, and he cites two experiments to support this. A photograph examined by reflection in a concave mirror of 80 cm. to 1 metre

¹ C. R. de la Soc. Biologiste, lxxxiii, No. 7, 1920.

focals is seen in relief, and the eye of the observer does not notice that the peripheral portions are distorted. Again, when a photograph is projected on to a properly calculated concave screen, which can be prepared by stretching the cloth over a framework the sides of which are segments of hyperbolae instead of being rectilinear, we are able to appreciate the third dimension, a thing which is not possible with a flat screen. Further, in the previous experiment the observer is not conscious of the disturbing distortion. Pechl believes that these facts are sufficient to allow of the conclusion that the retinal distortion of images is a factor in relief vision. The sense of relief experienced in these experiments is a real relief, and it is not so evident as stereoscopic relief. The latter is particularly vivid because it surprises us, seeing that in ordinary life we are not accustomed to see a series of flat objects totally distinct from one another as the stereoscope shows us. With the stereoscope the appreciation of relief fails when the objects are not in the foremost planes, but this is not experienced in normal vision.

THE CAVELL MONUMENT.

THE memorial to Nurse Edith Cavell, looking down from the junction of Charing Cross Road and St. Martin's Lane on to Trafalgar Square, was unveiled by Queen Alexandra on Wednesday, March 17th. The monument which Sir George Frampton, R.A., has conceived and executed as a labour of love, is a very fine conception. On the top of a narrow pyramid in grey granite is a symbolic seated figure of Humanity resting on the cross and with a child on her lap. Projecting from the base on the southern side is a white marble statue of Miss Cavell in nurse's costume, with the inscription "Edith Cavell, Brussels, Dawn, October 12th, 1915." Above, at the foot of the statue of Humanity, are the words "For King and Country"; on the west side "Devotion"; on the north, which at the base bears a bas-relief of the lion of Belgium, "Fortitude"; and on the east, the word "Sacrifice." The monument is a distinct addition to the amenities of London, and Sir George Frampton in conceiving it has set an example to other sculptors. His own work harmonizes well with the surrounding buildings, with the spire of St. Martin's on the east, and the tower of the National Portrait Gallery on the west. Lord Burnham, addressing Queen Alexandra, said that the statue had been erected out of funds subscribed by all classes of the community. A large number of those who had sent the money were on active service in the navy or army, and certain sums also had come from across the Channel. One of the flags draping the statue had, he said, been presented by Queen Alexandra and the other by the Queen of the Belgians. Queen Alexandra handed a written reply to Lord Burnham in which she said: "The countless thousands who will pass this spot in our time and in future generations will think with sorrow of her cruel death, with pride of her splendid fortitude, and with affection of her unselfish and womanly character." The Bishop of London dedicated the statue to the glory of God and the immortal memory of Edith Cavell. "May it remind our countrymen and countrywomen of her splendid patriotism, and of her last words, that patriotism was not enough." Sir George Frampton handed the cord to the Queen, who unveiled the statue, and buglers sounded the "Last Post" and drummers the "Reveille."

PROFESSOR TUFFIER, whose appointment to be an Honorary Knight Commander of the Order of the British Empire we announced a few weeks ago, asks us to express his appreciation and thanks to members of the British medical profession who have congratulated him upon the high distinction His Majesty King George has conferred upon him, by which he feels greatly honoured.

Medical Notes in Parliament.

The Estimates.

THE papers giving the Navy Estimates and a Vote on Account for the Civil Service and Revenue Departments were issued on March 13th. In round numbers the Estimates for 1920-21 reach nearly £1,200,000,000. Of this amount the Military Forces (Army, Navy, and Air) account for £230,000,000, interest on the National Debt £400,000,000, and Civil Service and Revenue £57,000,000. The estimate for the Military Forces alone exceeds the total estimate submitted for all national services in the spring of 1914. The total vote for the Medical Services, R.N., is £692,000. Of this amount salaries and allowances account for £122,000 (a decrease of about £8,000), and hospital and infirmary provisions and stores, medicines and instruments, for £278,000. Details of the Army Estimates have not been published. We gave on February 28th, p. 312, an abstract of the War Secretary's statement with regard to the strength of the Medical Corps.

The estimate for the Ministry of Health (England and Wales) is 27½ millions, for the Scottish Board of Health nearly 4 millions.

Supplementary Civil Service estimates for the year ending March 31st, 1920, have also been issued; they show a total of 28½ millions. Included in this total is a sum of £148,500 for the Medical Research Fund, the original estimate was £60,000. The additional £88,500 is made up as follows: Additional grant to meet the cost of investigation in connexion with industrial fatigue, etc., £16,000; cost of radium to be taken over at a valuation from the Ministry of Munitions Disposal Board, £72,500; the radium will be used by the Medical Research Committee for research work. From April 1st the Committee will become the Medical Research Council, and will work under the direction of a ministerial committee of the Privy Council. The vote for next year may be expected to show a grant of larger amount to the new Council. There is also a supplementary estimate for the Ministry of Health, including an additional sum of £130,000 for child welfare, and of £650,000 for medical benefit in England and Wales. This sum is to meet the payment to insurance practitioners from January 1st of the capitation fee of 11s., the extra payment to practitioners in rural and semi-rural districts, and the payment to persons supplying drugs and appliances.

Training of the Blind.

THERE was a short debate on March 12th on the second reading of the Blind (Education, Employment, and Maintenance) Bill, which is identical with one introduced last session by Mr. Stephen Walsh, who for some time was Parliamentary Secretary to the Local Government Board, and was chairman of a committee which investigated the conditions of the blind. The second reading was now moved by Mr. Ben Tillett, who read the memorandum of the bill, which explained that its object was "to provide for the technical education of the blind by the establishment and equipment of technical schools where necessary, or by contributions to existing schools and institutions for the employment of the blind by the establishment and equipment of workshops where necessary; or by contributions to existing institutions providing work for the blind; for grants in respect of augmentation of wages earned by persons so employed; for the provision of the expenses of blind persons at institutions or hostels while under technical instruction; for the employment and maintenance of blind persons away from workshops, and for the maintenance of blind persons incapacitated from earning their livelihood."

Mr. Tillett said that of the 30,000 dependent blind persons in the United Kingdom 10,000 were supported by the Poor Law, 7,000 were more or less industrially employed, and 2,000 directly industrially employed. Their efficiency would be anything between 35 and 50 per cent. of the efficiency of the normal person. That efficiency depended not only on aptitude but on technical instruction. The Report of the Royal Commission on Venereal Diseases stated that maternal gonorrhoea not properly treated caused as much as 25 per cent. of blindness. The 30,000 necessitous persons represented only a part of the evil of defective sight. The bill did not interfere with any form of voluntary aid, but asked of those who accepted State assistance to recognize the controlling supervisory right of a National Advisory Committee.

Mr. Stephen Walsh, seconding the motion, said he was quite conscious there was at the Ministry of Health a very fine advisory committee, representing the blind in every capacity. In the course of the discussion Mr. T. Sgaden pointed out that the prenatal blindness and blindness at birth were not included in the scope of the bill, and expressed the hope that some facilities for dealing with these matters might be afforded in Committee. Sir Frederick Banbury objected to the definition of the word "blind" as too comprehensive. There was no provision for a certificate by a doctor and no appeal on behalf of the ratepayer.

Dr. Addison, in the course of his reply, said that 21 per cent. of the blind were blind within six months of birth, owing to venereal infection which was preventable. That was one justification for the vote the other night for better training of nurses, midwives, and others, to attend on the newly-born child. There were other preventable causes of blindness. Next in importance were those relating to industrial accidents, but the information available was insufficient. He would adopt Mr. Tillett's suggestion for a comprehensive inquiry of a scientific character into the causes and prevention of blindness. The Government desired that the bill should give power to require the registration of agencies appealing for support of a voluntary character for the blind, so as to make sure that the sympathies of the public were not exploited by agencies unworthy of support. It would not be necessary for every authority to set up a separate organization or workshop for the blind; authorities should combine for that purpose. After going into the matter carefully it appeared to him that blind persons after the age of 50 could not be taught anything. The Government proposed therefore to give a special form of relief at the age of 50 for those who were blind and not able to support themselves. The machinery of old age pensions would be used so that any blind person between the ages of 50 and 70, subject to the same disqualification as to income and so forth, should receive the same benefits and weekly allowances as old age pensioners got. That would meet the case of about 46 per cent. of the blind who were indigent and too old to be taught anything. On behalf of the Government he promised either to re-form this bill or to introduce another to give effect to the proposals of the Government.

The Future of Poor Law Infirmaries.—Lieut.-Colonel Fremantle asked, on March 10th, whether the legislation necessary before the Minister of Health could decide the future utilization of Poor Law infirmaries was to be expected this session; and, if not, whether he would give such definite advice to boards of guardians as would enable them to make the institutional provision urgently required for tuberculous persons without incurring expenditure on accommodation which might be unsuitable for its ultimate purpose. Dr. Addison said he was unable to say when the legislation referred to would be introduced. It was not the policy of the Government to encourage boards of guardians to make additional provision for tuberculous persons. He was pressing upon the public health authorities the need for providing further institutional accommodation for these cases with the aid of substantial financial assistance from the Exchequer. Lieut.-Colonel Fremantle inquired if this did not mean a large amount of institutional provision that might be superfluous when there were Poor Law institutions available and suitable. Dr. Addison replied that he did not think so; as a matter of fact, there were several thousand beds short.

Bovine Tuberculosis.—Sir A. Boscawen, Secretary to the Ministry of Agriculture, stated, in reply to Lieut.-Colonel Fremantle, on March 15th, that the Tuberculosis Order of 1913 as to herds would come into operation, either in its present form or slightly amended, at the same time as the Milk and Dairies Act. The proposal to employ whole-time veterinary surgeons was one which presented serious difficulties. The Ministries of Health and Agriculture were setting in close co-operation, and the possibility of introducing a system whereby herds might be guaranteed free from tuberculosis was under consideration.

Veneral Disease Treatment Records.—Dr. Addison, on March 10th, said, in answer to Mr. J. Davison, that arrangements had duly been made for the keeping of records regarding the treatment centres for venereal diseases, established partly or wholly at the public expense. The number of cases dealt with for the first time at these centres between January 1st, 1917, when the first treatment centres were opened, and December 31st, 1919, was approximately 175,000. The approximate expenditure of local authorities on these schemes during the years ended March 31st, 1917, 1918, and 1919, amounted to £18,000, £116,000, and £216,000 respectively. The estimated expenditure during the current financial year was £314,000. Of this expenditure, 75 per cent. was borne by national funds and 25 per cent. by local funds.

Rabies Muzzling Order.—Sir A. Boscawen informed Captain Under Rees that the last case of rabies in this country occurred in Surrey on February 18th. The Muzzling Orders were in force in six different parts of the country. Owing to the long incubation period sometimes observed in rabies it was not considered safe to free a muzzling area within a period of from six to eight months from the date of the confirmation of the last case.

Small-pox in Poplar.—In reply to a question by Mr. Will Thorne (Plaistow), on March 11th, Dr. Addison said that though the Poplar cleansing station was within the same grounds as the disinfecting station, children sent there entered by a different door, and all necessary precautions were observed. It was, he said, the case that a man employed as the driver of the disinfecting van, whose duties took him to the house of a person who had been removed suffering from small-pox, had developed that disease. The man had refused to be vaccinated. In reply to suggestions by Mr. Thorne and Mr. J. Jones (Silvertown), Dr. Addison said that he had no authority to direct the payment of compensation to the parents of children who might contract small-pox. He could not undertake to introduce legislation providing that any person contracting an infectious or contagious disease through the neglect of any individual, or any body of persons or any Government depart-

ment, should be entitled to compensation on similar lines to those which enabled the workman to receive compensation for contracting a disease in the course of his employment.

Criminal Law Amendment Bills.—A bill introduced in the House of Lords, on March 16th, by the Bishop of London, to amend the Criminal Law Acts was at the request of the Government read a second time and referred to a Joint Select Committee of both Houses, to which also will be submitted the Government Bill of 1918, shortly to be reintroduced, and Lord Beauchamp's bill. The Bishop of London proposed in his measure that the age of consent as a defence should be raised to 18, and there were in it several other provisions materially to strengthen the law.

The Restriction of Child Labour.—Major Baird (Under Secretary for the Home Office) stated, on March 10th, in answer to Mr. Short, that the International Labour Conference at Washington had adopted a draft convention to provide that children under 14 should not be employed in any industrial undertaking other than undertakings in which only members of the same family were employed. Special provisions were inserted in regard to the application of the convention to India and Japan.

Veterinary Surgeons Act Amendment Bill.—Sir Watson Cheyne, on March 11th, moved the second reading of a bill the main objects of which were to enable the Royal College of Veterinary Surgeons to charge diplomates an annual fee, and to give power to prohibit bodies of unqualified persons from forming themselves into a veterinary dispensary or hospital, a proceeding which was legal under the existing Act and lent colour to the idea that they were qualified. Another clause rendered it penal for any veterinary surgeon to employ an unregistered practitioner. The bill was opposed by Brigadier-General Colvin and Mr. Jodrell. It was supported by Sir Henry Craik and Lieut.-Colonel Raw. The closure was carried by 106 to 51 and the bill read a second time.

Pre-War Pensions and the Cost of Living.—The Prime Minister, on March 11th, dealt with several questions arising out of the motion passed on February 25th, on a private member's resolution, in favour of increasing police pensions in order to meet the increased cost of living. The proposal was that pensions granted before April 1st, 1919, when new rates were given, should be raised. It was vigorously opposed by the Home Secretary, who intimated that the Government was prepared to consider hard cases, but could not go further, as the whole pension system of the Civil Service was really involved. Mr. Lloyd George now said that the Government had again carefully considered the subject, and could not depart from the decision that it would be most unjust to the general taxpayer to raise the pre-war pensions in accordance with the present scale. They had, however, appointed a committee to consider whether any steps could be taken to relieve exceptional cases of hardship due, for example, to age and infirmity.

Sanatoriums for Uncertifiable Mental Cases.—Mr. Rendall asked, on March 12th, what steps the Minister of Health proposed to take in regard to the provision of sanatoriums for uncertifiable mental cases, and whether, for the encouragement of voluntary patients, such homes should be kept on a hospital footing—namely, free from detention and wholly unconnected with lunacy administration, so as to prevent their being regarded as halfway houses to asylums. Dr. Addison said that any scheme on the lines suggested (with which he was entirely in sympathy) would require legislation. The question was under consideration, but he was not in a position to say when the necessary legislation would be introduced.

England and Wales.

VENEREAL CLINICS IN LONDON.

At the meeting of the London County Council on March 16th it was reported that during 1919 the number of cases of venereal disease dealt with at the London hospitals under the scheme in which the Council is the chief participating authority was 27,364, and the total attendances at the clinics, 298,066.

The attendances represented an increase of 74 per cent. over the corresponding figures for 1918, which themselves showed an increase of 44 per cent. over the figures for 1917. The authorities participating in the scheme, in addition to the London County Council, were the councils of six adjacent counties and three adjacent county boroughs. It was estimated, however, that 75 per cent. of the cases came from the London area. The hospital authorities were making every effort to deal adequately with existing demands for treatment. The venereal clinic at St. Thomas's Hospital was the first to be opened in London daily and all day. The Royal Free Hospital was the first general hospital to make special provision for pregnant women suffering from venereal diseases. A medical home had been provided in Stockwell for the treatment and simultaneous education of children suffering from gonorrhoea. The Council was called upon to increase substantially the amount of grants for 1920-21. The grants to be made by all the participating authorities (London's share being 75 per cent. of the whole) would be £92,000 for treatment and pathological work at hospitals and £1,500 for hostels; the grants for the year just expiring amounted to £51,300. The reasons for the increase were; (1) the

large growth in the work of the clinics; (2) the increase in the cost of hospital maintenance; and (3) the probability that the increase in the work of the clinics would continue during the next twelve months at least, though not at the same rate as during the year 1919.

LEICESTER PUBLIC MEDICAL SERVICE.

The plan on which the Leicester Public Medical Service is conducted was described at the time of its foundation and its progress has been referred to in the *JOURNAL* on several occasions. The Board of Management in its report for 1919 records another successful year's work. The subscribers to the various sections of the service number upwards of 43,000, and in addition some 11,500 state insured members of friendly societies are paid for through the service. In consequence of changed conditions the Board felt obliged to revise the rates of contributions. The new scale came into force in July last, but special reduced rates are charged to subscribers in receipt of the old age pension and to those assisted by the guardians. The service undertakes free medical treatment to the uninsured blind of Leicester, and for this the committee of the Institution for the Welfare of the Blind has expressed its sincere gratitude. Free medical treatment is also provided for members of the Wycliffe Society for helping the blind and of the Cripples Guild. More than 189,000 prescriptions were dispensed during the year. By arrangement with the Education Committee the school clinic work is carried on at the central dispensary, where the Board is now equipping a pathological laboratory under Dr. T. C. Clare. At the annual meeting held recently a report was received also from the committee of the Leicester subdivision of the Union of Medical Practitioners, which made arrangements for giving medical attendance to patients of doctors absent on military service. A scheme for collective locumtenencies during the summer holidays was inaugurated last year and worked successfully; thirteen doctors took advantage of the facilities afforded by this scheme and twenty-six doctors attended patients for their absent colleagues. A scheme for collective locumtenencies during sickness or short absences was also arranged upon much the same lines.

MEDICAL WOMEN'S DINNER.

The past and present students and staff of the London (Royal Free Hospital) School of Medicine for Women held a reunion dinner, on March 12th, at the Abercorn Rooms, Liverpool Street, after an interval of six years. The chair was taken by Dr. May Thorne, in the absence of Miss Louisa Aldrich-Blake, M.S., Dean of the Medical School, who was laid up as the result of an accident. More than 300 were present, the guests including Sir Thomas and Lady Barlow, the Right Honourable F. D. Acland, M.P., Sir Cooper Perry, Sir Walter Fletcher, Dr. H. Morley Fletcher, Dr. Leonard Dudgeon, Professor F. G. Parsons, and Sir William Barrett. After the loyal toasts had been honoured, the Chairman expressed the regret of all the company at the absence of Miss Aldrich-Blake, and then in an admirable speech touched on the events of the past six years, paying a high tribute to the splendid work done in various theatres of war and at home by medical women trained at the Royal Free Hospital. The association of the hospital with the London School of Medicine for Women began in 1877. When no other hospital would look at women students the Royal Free placed its clinical resources at their disposal. Dr. May Thorne concluded by asking her hearers to support the new appeal fund. It is proposed to enlarge the hospital from the present 220 beds to 450, and to offer full facilities to women students for training, experience, and research. Of the beds 230 will be entirely free for the treatment of poor patients; the remainder it is proposed to set aside for persons of moderate means who can pay three guineas a week towards the expense of their maintenance whilst in hospital. The cost of the new buildings, equipment, and charges towards maintenance is estimated at £500,000. The land for the hospital extension and the nurses' and service quarters has already been given, and adjoins the present building. Land adjoining the present school in Hunter Street is available for the proposed school extension. The toast of the "Royal Free Hospital and London School of Medicine for Women," thus proposed by the chairman, was replied to in an amusing speech by Dr. Walter Carr, and by Miss S. T. Widdows, B.Sc., lecturer on chemistry, who described recent progress. Dr. Carr

told of the student of the school, who was found nursing her baby, smoking a cigarette, and studying a textbook on surgery at one and the same time; he thought this typical of the modern spirit. The toast of the guests was proposed by Lady Barrett, physician for diseases of women to the Hospital, and was responded to by Sir Walter Fletcher, secretary of the Medical Research Committee, who in the course of his speech mentioned the anxiety felt at the grave illness of Sir Robert Morant. The dinner was in every way a great success, and illustrated the strong feeling of loyalty felt by students and staff for their hospital and medical school.

A FREEMASONS' PAYING HOSPITAL.

During the war the Freemasons' war hospitals were maintained by the craft. The committee has now decided to continue one of the hospitals for the benefit primarily of freemasons of limited means and members of their families. It is intended to be conducted on nursing home lines, and the charges will be based on the estimated cost of maintaining a bed in a general hospital of the first rank, which is put at about £3 to £3 5s. a week. The actual cost will be substantially more, and the craft is raising an endowment fund for this purpose. The adult wards will be arranged in semi-cubicles curtained off. The nursing staff will consist of fully trained nurses, each member nursing her own patients throughout. It is intended that the patients shall pay something towards the surgical expenses, and the surgeons on the visiting staff will be asked, while looking at the institution in the same way as they would regard an ordinary hospital, to consent to take from the committee small nominal contributions towards the surgical expenses. The premises are those formerly occupied by the Chelsea Hospital for Women, Fulham Road, Chelsea; they will be opened at the beginning of May. The committee may, we do not doubt, count upon members of the profession to give the necessary medical and surgical treatment at nominal fees as an act of generosity towards the poorer members of the craft—at any rate, while the institution is in the early stage of its work; but the principle is unsound economically, and will, we anticipate, eventually be replaced by some plan under which the members of the craft will take upon themselves a full share of the whole cost of the hospital, and not place upon the medical profession a burden greater than is borne by other classes of the community.

Correspondence.

THE PHYSICAL BASIS OF MENTAL DISORDERS.

SIR,—At the present time the psychogenetic conception of mental disorders, or at all events that large section termed the psycho-neuroses, practically holds the field. Psychogenesis implies, I take it, the origin of mental disorders in the mind, the body only becoming affected secondarily, although I observe that Dr. Bernard Hart's definition in respect to the psycho-neuroses is that it implies merely predominance of psychical factors.

The followers of the psychogenetic doctrines employ "psychotherapy" in some form or another as a curative agent—that is, they claim to cure mental disorders by mental means. No one would wish to dispute the good results obtained in the psycho-neuroses by these methods; but it is permissible to dispute their interpretation of its action. Equally good results are obtained by diametrically opposed "psychological" methods. One practises the repression of the painful ideas into the unconscious and substituting pleasant ideas; another the dragging of the painful impressions into the full light of consciousness and endeavouring to incorporate them in a modified or altered form into the conscious part of the ego.

Waller has recently shown that by speech one can influence the metabolism of the cells, and show graphically alterations in the electrical resistance of the body. Some speech leaves the subject unaffected, whilst that which evokes strong emotion produces marked effects. This is a biological phenomenon. In a similar way it may be that "psychotherapy" is really biological and not psychical. By this procedure certain sensory end organs, chiefly auditory, are stimulated, and nervous impulses from this centre react on the chief controlling station for the

endocrine glands. In this way it might be possible for an imperfect equilibrium between these organs, the result of shock or other cause, to be rectified. The effects of thyroid extract in certain cretinoid forms of insanity show the marvellous influence this internal secretory gland has on the mind. By its administration we can transform a mindless, repulsive, helpless child into an active, industrious, and fairly intelligent being; we have in fact by purely physical means put a mind into the child.

Some years ago, in the *Journal of Mental Science*, I gave an account of the pathological appearances found in the brain, kidneys, liver, and blood vessels of the insane. The results showed in what a large proportion changes, chiefly of a degenerative character, or evidence of lack of normal development occur in insane cases, even among the young and recently insane. It seems to me now, however, that it will be by a study of endocrinology that most promise of acquiring satisfactory evidence in support of the physical basis of insanity will be forthcoming.

Whether the psycho-neuroses are primarily psychical or physical in origin may seem merely of academic interest, but in my opinion there has been a tendency, especially among asylum medical officers, to study the psychological aspect of the question to the neglect of the biological. If I am correct in this, more than an academic interest is attached to the question if it may help to counteract this tendency.

Recently, however, the physical side of the question seems to have received more notice, even by the psychogenetic school, and Bernard Hart,¹ one of its ablest advocates, suggests that the causes now called psychical may ultimately be capable of expression in anatomical and physiological language. His attitude is "that in the present state of our knowledge we can express processes in psychological terms, and explain them by psychological laws, much more profitably than by the conceptions of anatomy and physiology."

The work of Pavlov on conditioned reflexes in the brain may open the door for a physical explanation of many phenomena now regarded as psychical.—I am, etc.,

JOHN TURNER.

The Mental Hospital, Brentwood, March 10th.

APPENDICECTOMY BY A NEW ROUTE.

SIR,—The title of Mr. Whitlocke's paper (February 14th, p. 211) aroused my curiosity, and I wondered what could be the "new route" that the ingenuity of the surgeon had devised for attacking the appendix. Great was my surprise, as I see the paper was read before the Surgical Section of the Royal Society of Medicine, to find that the new route was a slight—very slight—variation of the well known McBurney's operation.

Personally I fail to grasp wherein lies the claim that Mr. Whitlocke advances. The only difference I can detect is that the incision is placed perhaps half an inch higher on the abdominal wall, and perhaps half to one inch nearer to the anterior superior iliac spine. The structures divided and separated are precisely the same as in McBurney's operation, and I have no doubt that surgeons who have employed McBurney's method have on many occasions unwittingly performed the operation by the "new route," in that the incision has not been placed exactly in McBurney's line, but somewhat nearer the anterior iliac spine.

The essential feature of Mr. Whitlocke's operation, as of McBurney's, is the muscle splitting, and in this, as far as I can see, the two operations are exactly the same. As in McBurney's operation, it is necessary, in order to obtain enough room, to separate the internal oblique and transversalis muscles as far outwards as possible.

That the appendix can be removed without opening the general peritoneal cavity is doubtless true in rare instances, but it is also true that in the vast majority of cases, by whatever method of operation, the general peritoneal cavity is opened, and this is a strong argument in favour of the more surgical procedure of deliberately opening it before proceeding to search for the appendix, since, if any risk is entailed, it can be guarded against by packing, while if we delude ourselves with the notion that the general peritoneal cavity has not been encroached upon, the risk is obviously greater.—I am, etc.,

London, W., Feb. 23rd.

DOUGLAS DREW.

¹ BRITISH MEDICAL JOURNAL, February 14th, 1920.

THE TREATMENT OF UTERINE CANCER.

SIR,—The closing paragraphs of the leading article on tumours complicating pregnancy make one sad. It is to be hoped that they do not reflect the views of many gynaecologists. The writer, in calling attention to Dr. Herbert Spencer's statement that he had cured three cases of cancer of the cervix by high amputation, says that "these results must give us reason to pause and think." Surely no other conclusion can be drawn than that the operator was extremely lucky, and though it is but natural that a surgeon should attach undue importance to such fortuitous results, yet no one can guess what the effectiveness of the technique may be unless he knows the relative proportion of the successes to the failures. A very restricted operation is bound occasionally—but only by sheer luck—to remove the whole of the morbid process. The crucial test of any operative or other procedure in cancer must be: How many cases has the operator seen, and how many of these are alive and well, say, five years afterwards?

In the second place the article states that "throughout all gynaecological literature there is apparent a feeling almost of despair as to the powers of surgery in dealing with this particular form of cancer," and this is apparently the outcome of "the hopes based on the technique of Professor Wertheim." While Wertheim must be given a certain amount of credit in stimulating gynaecologists to improve the extent of their operative measures his technique was far from being the last word on the subject, and the way in which he went back on his original position showed that he never quite appreciated the lessons of the surgical pathology of cancer in general. There are gynaecological surgeons in this country to-day who do a much more thorough and scientific operation than ever Wertheim contemplated; they do not exclude so many cases, their operative mortality is lower, and their ultimate results are better.

Thirdly, "a note of fresh and confident hope" is detected in recent reports from America with regard to radium treatment. The same note may also be detected in recent French and other foreign journals, but it is altogether unconvincing. In this country we got over that rather hysterical "note" before the war. When the believers in the therapeutic marvels of radium in cancer can produce good pathological evidence of the malignant nature of the lesion before such treatment, and can produce the cured patient alive a few years afterwards, even in a minute proportion of cases, then those of us who are apt to allow our views of such cures to be biased by the results of our *post-mortem* examinations upon them will become more credulous.—I am, etc.,

ARCHIBALD LEITCH.

Pathological Laboratory,

The Cancer Hospital, S.W., March 18th.

EARLY DIAGNOSIS OF SYPHILIS.

SIR,—Dr. E. Harrison, in the course of an address to the members of the East Riding Division of the British Medical Association, stated (BRITISH MEDICAL JOURNAL, March 13th, p. 364) that "from his experience at the clinic [in Hull] chaneroid pure and simple was a rare condition; nearly always there was syphilis at the back of it."

Whilst admitting that it is never safe to exclude the possibility of syphilis in the case of a chaneroid, and that it is necessary to keep these cases under observation for at least three months, one is only prepared to accept the former statement providing the *S. pallida* has been found in the living state by dark-ground illumination. On the other hand, if Dr. Harrison's results are based on the detection of *S. pallida* by means of staining reagents, such as the Fontana method, an erroneous conclusion may be arrived at owing to the extreme difficulty in detecting the *S. pallida*, which has a notable lack of affinity for most staining reagents, and the ease by which other spirones resembling it are found.—I am, etc.,

A. BRYANS,

March 15th. Medical Officer, Middlesbrough Treatment Centre.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—It seems to me that when Dr. Baskett's theory is applied to the National Insurance Act it will not hold water.

Few will deny that prior to the passing of this Act there

were large numbers of persons who made no attempt, and not through inability, to put a little bit by in case of misfortune. They belonged to neither a friendly society, sick and draw club, nor other provident institution. Illness came, throwing the breadwinner on his back, and consequently there was nothing coming in.

The sick man and his dependants were saved from starvation by parish relief and charity. It was surely in part to mitigate the dismal results of such providence that the Insurance Act was evolved, forcing the spendthrift to make at any rate some slight provision for a rainy day, thereby lessening the degree of privation which not only he himself but also those relying on him for support might be called upon to bear in case of disability. As Britishers we inherently loathe and detest State interference and compulsion, and let us pray we may have no more of it than dire necessity compels.—I am, etc.,

H. W. FREER, M.R.C.S. Eng., L.R.C.P. Lond.

Colwyn Bay, March 14th.

SIR,—Dr. Davies agrees that poverty has been a chief factor in the past in tuberculous mortality, and that real wages have fallen since 1896—that is, that poverty has increased. He claims that many lives have been saved by paternalism; yet the death rate has risen. It follows that the seen good has been over-compensated by unseen harm.

That is my case. You can, we admit, shift a molehill by mining it with a ton of dynamite; what we say, and prove, is that you do not improve the level of your field. It is incumbent on his school to prove that poverty has other effects than it used to have. To talk of infection is to side-track; no more than poverty can it change its rôle; and while we knew nothing of infectivity the rate fell merrily. It is since we knew, and since we took precautions, that it has risen.

The individualist preaches self-reliance first, last, and all the time. Necessarily he approves of voluntary insurance; necessarily he disapproves of the Act, for it is hostile thereto. The principle is happily inveterate in England. It survived, with much scathing, the Compensation Act; it survives to-day. But the Act is doing its best to kill it.

There is a fallacy in his suggestion that voluntarism diminishes real wages. It diminishes a man's wages, doubtless, to pay out 6d. a week for insurance. But it does not diminish, it raises, the wage rate of a class which does so. A very simple test will demonstrate this fact. He will allow that the standard of living of a class is the ultimate standard of its wage rate. If the employee class decides to provide for itself, its standard of living is surely raised. If you force an employer to provide for his employee, whose standard is raised? Clearly not the employee's. You have forced the two classes into the position of the feudal baron and his retainer. Incidentally you have killed, by your compulsion, the kindly feeling of the one and the devotion of the other which were the redeeming feature of a degraded condition.

At first, at any rate (for in the long run compulsion must have its debasing influence), we may disregard the direct contribution. But the employers' and the State's contributions are a heavy burden on the persons to whom they are "given." If Dr. Davies marks the rise of large incomes up to 1914, by the side of the increased taxes and the fall of real wages, he will be driven to allow that, short of the point at which all are crushed, while taxation infallibly impoverishes the poor, it actually enriches the very rich. The plain fact is that heavy taxation must raise the rate of interest.

My views on government and its problems, for which he asks, are not relevant here: I have already urged that, especially in the matter of housing, paternalism has done great harm. This I may say to the point, that many educated men are weary of the incessant legislative tinkering, always involving rethinking, at these problems; they have so often had high hopes raised only to be baffled, and, as here, mocked, that their prayer has come to be "let us alone." Can Dr. Davies have already forgotten that only eight years ago the Insurance Act was to deal the *coup de grâce* to tubercle?

If he fails to see why a State scheme must necessarily be bad, after his own statements, I would urge him to read the scathing indictments of the German Act, published just before our own was passed, by its president and vice-president on their retirement.

It is odd that I who have spent so much time in trying to prove that the problem is too complex for a centralized agency should be reproached for treating the question as a simple one. My one desire is to define the function of the State therein. That is simple, as I believe. For fifty years it concentrated on national resistance and left treatment to individuals. That policy was a brilliant success. Later it has concentrated on treatment by a method which must lower national resistance, and left the question of resistance to individuals. As Dr. Davies has to acknowledge, the sequel is dismal.

Is the relation causal or coincidental? The question was important before; it is frightfully, tragically insistent now, with the awful prospect before us for at least a generation. If it is causal, then the man who spends more public money is an enemy to the public health. The principle underlying the Act is the principle of the thousand delirious schemes of "reconstruction." By insisting on an inquiry which shall exonerate, or establish the guilt of, the principle of the Act, medical men can do an untold service to their country.—I am, etc.,

Rayleigh, Essex, March 14th.

B. G. M. BASKETT.

THE TERRITORIAL FORCE.

SIR,—May I summarize six points (there are others) of inequality in the treatment of the medical officers of the Territorial Force during the recent war?

1. Pay was the same as for Regulars, but theirs is supposed to allow for a retiring (as against only a disablement) pension.

2. Pay even with allowances was less than that of temporary M.O.s.

3. Whereas a temporary M.O. could go on leave, or remain in hospital as a casualty for years, without the loss of a farthing, the unfortunate Territorial (and his family) had nothing but his bare pay (and 1s. 2d. food allowance on leave) on such occasions.

4. A temporary M.O. on a hospital ship had full pay and all found. A Territorial had pay and no allowances.

5. A temporary officer could invest or use his gratuity every year.

6. A temporary officer got "contract" leave, no matter what "strafe" might be on—and he got ordinary leave, too.

Compared with many I suffered little. I joined up through the T.F. as by a back door, being unable to pass the (1914) physical tests for temporary commissions. But I learned one lesson thoroughly: Believe nothing the War Office tell you, even if they give it you in writing, and wait till "an emergency arises." Neither the nation nor you will lose by it. The Regular R.A.M.C. are more than able to provide the inevitable red tape.—I am, etc.,

March 10th.

A TERRITORIAL MALGRÉ LUI.

SIR,—I have been much struck by the remarks of "Hard Hit" and others. Since 1907 I have given time, money, and energy towards qualifying myself to be of service to the country in an emergency. I was mobilized on August 4th while in camp—that is, without half an hour's notice—and served till the spring of 1919.

My honest advice with regard to the T.F. and S.R. is (1) if you are in either, get out as soon as you can; (2) if you are in neither, stop out; (3) when the next emergency arises, wait till you are forced into the service.

By following these simple rules one will achieve the following advantages: (a) increased leisure in peace time; (b) in war time, avoidance of being suddenly torn from practice; (c) more pay than the patriotic idiot; (d) probably higher rank, safer and more congenial work; (e) preferential recognition and earlier release from service.

I see that the Territorial Medal, a recognition of patriotism that would cost the Government 2s. 6d. but which would be valued much more, is not to be given with the 1914-1915 Stars—a regulation which bars 95 per cent. of those otherwise eligible.—I am, etc.,

"QUOTH THE RAVEN."

THE INDIAN MEDICAL SERVICE.

SIR,—In the letter by "I.M.S. Retired" (February 28th, p. 307) we have at last come to actual facts, and concrete examples of the financial position of members of the I.M.S. Your correspondent wisely strengthens his case by

deliberately under-estimating expenses in India. If those interested will refer the question to anyone with experience of the present cost of living in India they will find that 20 per cent. may fairly be added to "I.M.S. Retired's" estimate without exaggerating the case.

The comparative table given in the letter showing rates of pay of Indian Army, Supply and Transport, and I.M.S. is clear and decisive. I think that still more light can be thrown on the position of the I.M.S. officer by amplifying in the same way the comparison between the Education and Forest services and the I.M.S., and in the table I give the present rates of pay of these three services in each year of service from one to twenty years.

Comparative Rates of Pay (Monthly). Indian Education, Forest, and Medical Services.

Year of Service.	Education Service.	Forest Service.	I.M.S.
	Rupees.	Rupees.	Rupees.
1st	550	450	550
2nd	600	500	550
3rd	650	550	550
4th	700	600	700
5th	750	650	700
6th	800	700	750
7th	850	750	750
8th	900	800	800
9th	1,000	850	800
10th	1,050	1,000	800
11th	1,100	1,050	900
12th	1,150	1,100	900
13th	1,200	1,150	1,000
14th	1,250	1,200	1,000
15th	1,250	1,250	1,000
16th	1,300	1,300	1,150
17th	1,350	1,350	1,150
18th	1,400	1,400	1,150
19th	1,450	1,450	1,150
20th	1,500	1,500	1,150
	20,800	19,600	17,500
Total pay received in 20 years' service	249,600	235,200	210,000

The totals of each column prove that after twenty years' service the I.M.S. officer, who has had the longest and most expensive education, has received Rs. 39,600 less than the Education officer, and Rs. 25,200 less than the Forest officer.

The system of increase by annual increments is the most equitable, and might be applied with advantage to the I.M.S.—I am, etc.,

March 3rd.

INTERESTED.

CO-OPERATION BETWEEN HOSPITALS.

SIR,—The hospitals of the country require organizing properly. That may be a defect inherent in a voluntary individualistic system. Each is inclined to go its own way, and would probably resent any interference from others. Each hospital board has its own pet charity to administer to its own self-righteous way. The road to Heaven is paved with donations and annual subscriptions. At present there is reliance upon the Red Cross to stave off the nationalization of hospitals. It means an orgy of begging. It is possible that a great deal more can be done by co-operation between hospitals, both as to getting the money and, the importance of which is hardly realized, increasing their efficiency.

We have a Hospitals Association, but it is as if this country were governed only by the national Parliament, and there were no county, borough, or parish councils. There is a great need of decentralization. In Lancashire and Cheshire there are about 12 teaching hospitals, about 13 special and teaching hospitals, about 18 hospitals with between 100 and 200 beds, about 6 hospitals with between 50 and 100 beds, about 21 with under 50 beds.

Now, there is practically no co-operation between these hospitals. How much might be accomplished by co-operation between these hospitals, between their boards of management, and also between their medical and surgical staffs! The teaching hospitals are the great centres of efficiency, new ideas, and new knowledge. We need some means by which these may be rapidly brought to all the other hospitals in their sphere of influence. There is a lack of connecting links or liaison officers. If there was a provincial

council of representatives from the boards of management of the hospitals in Lancashire and Cheshire, it might deal with such questions as the raising of funds, private wards, payment of medical staffs, equipment, training and payment of nurses, and almoners or some other system to decide what patients should make part payments towards their treatment and keep, and what patients were fit subjects for free treatment.

Then there should be a council composed of representatives of the medical staffs, to consider new methods of treatment, for what cases they should receive remuneration, and how to make their hospitals as efficient as possible. It is possible that the liaison officers might be got from the consulting medical officers or that the assistant surgeons and physicians of the teaching hospitals might be attached as consultants to the other classes of hospitals. Co-operation of this kind would make post-graduate teaching easier, because the great need now is to bring the post-graduate to the doors of the busy general practitioners. Anyhow something on these lines has got to be done, and if it were well done 'twere well 'twere done quickly.—I am, etc.,

Wigan, March 8th.

FERDINAND REES, M.D.

PROPOSAL FOR A MEMORIAL TO SIR VICTOR HORSLEY.

SIR,—I am now not in the habit of seeing the JOURNAL, and it was therefore but yesterday that I became aware of a proposal for a memorial to my husband, Sir Victor Horsley, from the medical profession. I am very grateful for the thought which prompted the suggestion, and I cannot, of course, dictate to others as to their action in response to it. Yet I should be lacking in my duty to him if I failed to express on his behalf the strong feeling which I know would be his.

That there is no spontaneous or general desire in the profession is obvious, for my husband's death in Mesopotamia took place in 1916; nearly four years have passed since then. Without the support of such a strong general feeling such memorials seem to me not worthy of the effort to bring them into being; they lack conviction and sincerity and the underlying meaning which gives them all their value.

The times to-day are very hard for all of us, very hard for the medical profession, and above all for those scientific members of it who would be called upon to contribute, and who, from the multiplicity of such claims at this moment, must suffer serious inroads upon the altogether inadequate returns which the public and the State mete out to them in acknowledgement of their self-sacrifice in the cause of science.

I know, therefore, that it would give my husband no pleasure, but acute pain, if in any way through him the difficulties of the members of his profession were added to by one iota. I beg, Sir, to be allowed on his behalf to urge very earnestly that the work he did be suffered to remain his real and only public memorial.—I am, etc.,

London, W., March 14th.

ELDRED HORSLEY.

SCOTTISH BOARD OF HEALTH.

THE Consultative Councils set up, under the Scottish Board of Health Act have appointed the following Chairmen and Vice-Chairmen:

Medical and Allied Services.—Chairman: Sir Donald MacAlister, K.C.B., M.D. Vice-Chairman: Dr. Norman Walker.

National Health Insurance.—Chairman: Mr. William Thomson. Vice-Chairman: Mr. Thomas J. Addy.

Local Health Administration and General Health Questions.—Chairman: Sir Thomas Munro, K.B.E.

Highlands and Islands.—Chairman: Her Grace the Duchess of Atholl, D.B.E.

THE Ministry of Health has issued a standard specification for timber cottages. It can be obtained from the Stationery Office or through any bookseller, price 3d. net. The specification is to be adapted to local conditions by the architect, but every scheme for the construction of cottages in timber which has not yet gone to tender, or is not on the point of going to tender, must comply with this specification.

Obituary.

SIR ROBERT MORANT, K.C.B.

First Secretary of the Ministry of Health

THE death of Sir Robert Morant is a great loss to the country. These words are to be taken literally and not as a convention. He has been called a bureaucrat, but no man in public office ever was less. He was a man of wide sympathy, open to ideas, loving an enthusiast and ready to catch fire from him; but his business was to administer, and he was constantly impressed, often oppressed, by the difficulties of administration. The rebound from the first flush of comprehension of an idea to the realization of the obstacles in the way of its attainment was characteristic.

Robert Laurie Morant was born in Hampstead in 1863; from Winchester he went to New College, Oxford, and graduated B.A. in 1885. For the next quarter of a century he was concerned with education, first as a master at a preparatory school, then as private tutor to the Royal Family of Siam, and organizer of public education in that country, next with educational work in the east end of London, then in 1895 at the Board of Education, where the great ability he showed during the stormy times of the Education Act of 1902 led to his appointment to be Permanent Secretary to the Board in 1903. Thereafter began a gradual development of work and thought which finally brought Morant to have intimate concern with the affairs of the medical profession. To the reorganization of elementary education there succeeded investigation of the problems of secondary and of university education: both of immense consequence to the professions, the former perhaps to us the more important. After his translation to the chairmanship of the Insurance Commissioners—something, it may be, of a tumble upstairs—Morant retained to the full his zeal for education, and, without allowing his concern with the whole to be diminished, gave more and more attention to medical education and its continuance after graduation. He was greatly interested in the policy unfolded in the *Memorandum on Medical Education in England* presented to the Board of Education by Sir George Newman in 1918; the policy had been debated during his time at the Board of Education, and there is a passage in the *Memorandum* to which we have no doubt he heartily subscribed, for he was always an ardent advocate of width as well as depth in education. Sir George Newman, after speaking of the isolation too often to be observed between the various departments of a medical school, continued:

Yet biology, physics and chemistry are together the foundation of the intermediate subjects and pathology, even as they, in their turn, are the essential preparation for clinical understanding and training. The student is not sufficiently taught that the advanced subjects consist of biology, physics and chemistry applied to the life, form and function of the body in health and disease. The patient is a case of anatomy, of physiology, and of pathology to be interpreted and treated on grounds and by means which are in essence chemical, physical and therapeutic. The examples of this truth are manifold. Physiology, as we have seen, must be brought into touch with the elements of clinical study—the physiology of the mammal and of man, its application in the clinical laboratory and the ward, and above all the recognition of the immense part played by the organic regulation of structure and activity, which the wise physician and surgeon seek not to destroy or pervert, but to release, to aid and to supplement at the bedside. Any lack of co-ordination of subject and of method, and still more of scientific spirit, is not peculiar or confined to the United Kingdom, but it is harmful and mischievous.

As head of the National Insurance Department Morant sometimes had to act as leading counsel in presenting the case against the profession. It is the highest compliment to both sides to be able to say that those members of the medical profession who were brought into contact with him during the negotiations formed the highest opinion of his integrity, and conceived a strong liking for him as a man. It was evident that he was always trying to understand the reasons for the attitude of the other side; when it came to a tussle he was a clean fighter.

Sir GEORGE NEWMAN, K.C.B., M.D., F.R.C.P., Chief Medical Officer, Ministry of Health and Board of Education, writes:

I find it very difficult to respond to the invitation to say a few words about Sir Robert Morant. His departure

from amongst us has been so sudden and unexpected that some time must elapse before we are able to measure the magnitude of our loss, a loss which is not only personal but national; moreover, the moment of bereavement is not an occasion for considered judgements.

Morant and I began our friendship together in 1907, when Mr. McKenna first appointed me to the Board of Education. From that day to this the "combine"—or, as he sometimes preferred to call it, the "Siamese twin arrangement"—has lasted. For, though it is true that when he left the Board of Education I was no longer an official colleague, we saw much of each other, an association which became all the closer when we received official instructions in 1916 to begin to devise together the machinery of a Ministry of Health. As is well known, Sir Robert Morant was dreaming of a Ministry of Health as early as 1907. I am not transgressing any ministerial or official secrets if I say that in a particular measure and in a peculiar way the Ministry of Health, as now formed, is a product of Morant's mind, and his name will go down in our social history, not only in relation to the Education Act of 1902 and the administration of the Insurance Act since 1912, but also as the civil servant who above all others was the designer and builder of the Ministry of Health. To these great tasks he brought his exceptional natural faculties. Trained at Winchester and Oxford, with their inspiring traditions, he brought also a wide knowledge of men, and, above all, varied experience and human sympathy.

It has been said with much truth that Morant was a master of detail. I well remember when we were first designing the School Medical Service in 1907 how he drew a small cross in the middle of a sheet of foolscap, showing that the four arms of the cross were very close together and sprang from one centre. Then, with a stroke, he elongated each arm of the cross, showing that the final goal in each direction was pole-wide asunder from the others. To such a mind no detail is insignificant; it sees in the smallest particular far-reaching issues and in passing incidents and episodes illustrations of profound principles. Unless such a mind has a strong anchorage in principle, it will of course lose itself in a world of detail and triviality. This, however, was not Morant's habit. He was sometimes mysterious and sometimes inexplicable, sometimes provocative and apparently contrary, but he was never lost. Always for him there seemed to be, though unseen by others perhaps, a pillar of cloud by day and of fire by night.

Another characteristic closely related to his concentration upon detail was his tremendous power of analysis and destructive criticism. If he thought a proposition untenable, illogical, or in any way invalid, he could, with a quickness which was almost disconcerting, tear away the veil and ruthlessly expose what he considered to be the inherent fallacies of the argument. Indeed, one formed the opinion that his first great faculty was analytical, and so great was it that it overshadowed his constructive powers, in themselves of an exceptionally high order. The exercise of his analytical function often led him to appear to be suspicious, hostile, and even aggressively antagonistic, when what he really sought was the truth, and nothing but the truth. Persons, policies, predilections, prejudices—they were all swept away in his almost terrible powers of quest. It must be added that in the pursuit he was wary and rather slow to give or receive confidence, distrustful until secure. "I am like the heavy and clumsy elephant," he wrote the other day, "when he is going over softish ground, with his trunk endlessly feeling and testing and fussing." It was sometimes an exhausting process to all concerned; and, like the rest of us, he had the defects of his qualities.

There was a third thing, too, which became obvious to all of us who ever worked under him or with him, and that was his extraordinary devotion to duty. He embodied what is said to be a distinguishing principle of the English civil service—incorruptibility. He could not be bought, and he was not for sale. He bent his whole powers of body, mind, and soul to what he deemed to be his personal duty in the public interest. I am glad to have an opportunity of saying that I think Morant, all through the thirteen years that I have known him, proved himself to be over and over again a great and true friend to English medicine. We used to tease him that he had chosen the wrong vocation, and that he ought to have been a prophet or a physician. Everything connected with

medicine seemed to fascinate him. Every great advance in its science and art seemed to thrill him, and he believed that the primary asset of the nation is the health of the people. He was called "democratic" and even "socialistic" in his ideals; however that may be, he loved to give these ideals a medical setting. More than once I have seen him opposite a group of medical men combating and analysing the views which they expressed, the temperature of the whole party steadily rising as the conflict of opinion progressed; and I have said to myself, "Yet he is really loving them all the time." Medicine has been coming rapidly into its own kingdom in relation to the State during the last few years, and it has been my lot to watch Sir Robert Morant's hand often guiding the helm. In the old days at the Board of Education, all through the war, and at the Ministry of Health, through good report and ill he has steered disinterestedly, what to him was the right course for the advancement of our profession, the amelioration of its disabilities, and the provision of the full opportunity for its splendid purposes. If it is true that in some ways he has been the greatest Civil Servant of his generation, it is likewise true that in some ways he has been the greatest friend which Medicine has ever had in the counsels of Government.

There is one other trait on which I must try to say one or two words. Although his work often brought him into clash with persons and policies and so left along the road a series of men hurt or provoked, Morant had something of a genius for friendship. There are men and women in various walks of life and in various countries of the world who cannot think of him other than as an extraordinarily true and affectionate friend. His love seemed sometimes to surpass the love of women; and whilst to the enemy he could be formidable, for his friends he was able and willing to do the uttermost in loyalty, in affection, and in service. This great gift of friendship sprang from deep spiritual sources, where lay hidden his religious convictions. It is not for me to speak of these though we had often discussed them together. They did not conform to any orthodox creed that I know of, and were perhaps rather a catholic harmony of East and West, but they proved a mighty dynamic in his life, the inspiration of his sense of public duty and the motive power of that exhaustless self-sacrifice in which he laid down his life. As a prodigious worker his life was one of ceaseless labour, day and night, often seven days a week, and he has certainly died in the cause of the Ministry of Health. We begged him to spare himself, to take some rest, to give heed to the premonitions of overstrain, but it was all apparently disregarded, or, at least, of no avail. He was so great a person, so large hearted and keen minded, that his very dominance made it difficult to control him or to harness him, and now he has fallen a martyr to his spirit of devotion. He passes from our midst, though not from our hearts.

SIR WALTER FLETCHER, K.B.E., F.R.S., Secretary of the Medical Research Committee, writes:

Medical research and higher education in medicine in this country will remain always under a debt to Sir Robert Morant that is quite incalculable. A great public servant in a position like his can wield a power which must usually be decisive, and which is all the greater for good or evil in that it is unseen from outside. To him is greatly due the establishment of the Medical Research Fund under the National Health Insurance scheme of 1911, its unification for the four nations of the kingdom, and the constitution of the Medical Research Committee set up in 1913 to administer it. By its provisions—novel in many ways, and far-sighted in all—this constitution gave the best freedom and power to the scientific men charged with the responsibility of applying the Fund to the purposes of medical research. At every opportunity Morant brought all his forces to the service of medical science and research. Inspired by the highest ideals of intellectual truth and of human charity, he gave to these causes all his genius for organization, an unrelenting vigil against the dangers that beset them, whether from ill will or from ill-directed goodwill, and he gave them unstinted work whenever occasion arose among the other claims upon his tireless official industry.

An administrator in his position and with his power, but with less insight into the essentially new problems of government offered by the direct State endowment of free scien-

tific research work as such, might have strangled the new organization at its birth with the red tape of prescription. Morant responded instantly, however, to every right growth in the early life of the Committee towards freedom and flexibility, so long as the proper bonds of responsibility to Parliament and of financial efficiency were scrupulously preserved. More recently he laboured to secure on the right foundations the future work of the Committee, reconstituted as it will be from April 1st next as the Medical Research Council, working under the direction of a Ministerial Committee of the Privy Council. His interest in this plainly transcended any sectional views he might have taken if he had thought only as the chief officer of the Ministry of Health for England and Wales; he was concerned only with the realities of the problem and the best interests of the whole kingdom as these might be served by the advancement of medical science. He brought to this work—a fractional part only of the enormous tasks he bore at the time—not only the mind and experience of the professional administrator in education and in public health, but the warm-hearted zeal of a man keenly alive to the general interest and beauty of the scientific work being done in the universities or hospitals of the country.

His eager mind went out to all these things just as it responded to fine music, to literature, to good humour, and to all the fullness of life. It was, to my mind, his chief greatness that he had condemned himself for a long series of years to allow none of these to draw him aside from his intense application to official work. I have heard it said, even slightly, that the *technique* of administration was his passion. That I am sure was not so. His passion, the deep but true furnace of his energy, was a desire that others, that the whole country, should be raised to a fuller life, to a more abundant life of the mind through education, and to a better physical life through health. The test of this was given, I think, in his attitude to the technical methods and details of administration, whether in design or execution. These lost all interest for him when once their purpose was fulfilled. He pursued realities, and in gaining or securing these he was not intrigued by the mental sleight or the deft adjustments that had made the advance. He fought step by step with clear vision of the great objectives ahead, and not with any but passing zest for the smaller enjoyments of the sword play as such. After work that any man might have cast backward eyes upon with complacent interest in the performance, he would be found to have turned instantly to the next task at hand. Few men gave praise more generously to others, and no man's praise was better worth having. Yet when he praised, it was the effectiveness of workmanship that appealed to him, and not the effort or skill that might be shown. The work itself belonged to the curse of Adam; the result was to be hailed as a step, though it might be a very tiny one, towards Paradise. The trouble taken was to be deplored, but—as he would say—"You see, it was worth while."

His work for the National Insurance scheme must be debated by others; it must always be a curious speculation whether the scheme could have survived a year without him. It seems to have in it every element of tragedy that a man with his eager impulsion towards ideals of public health and with his fine sense of right organization should have been called upon to administer a national health scheme of which the financial basis was prematurely, perhaps fatally, developed before a sound structure of health services had been framed at all. What other man could have made scaffolding to hold together those disjointed elements until, after successive and almost heart-breaking delays, the fusion of the insurance with the local government activities allowed the building to begin from the foundations upwards and from the centre outwards? It is true, I think, that his interest in the medical research organization within the insurance scheme was warmed not only by his true instinct for the value of knowledge and its advance, but by the comfort he could also take in seeing that this at least brought no dislocation in the administrative structure, and that research, while it could make independent growth without strain on other parts, could never progress too fast in accumulating guidance for the future medical administration.

Now the sword has fallen from him—the sword that he would never have let sleep in his hand till the English race had gained the possibilities of health and happiness he dreamed of—and it has fallen in the moment when

he had joined battle at last upon his own ground and in his own way. We cannot measure this loss. It can hardly yet be the subject of thought. "His departure is taken for misery, and his going from us to be utter destruction." Yet those who knew him for himself can only have an abiding thankfulness for him and for the knowledge of what he was. That can never fade and his work can never die.

Sir JENNER VERRALL writes:

On behalf of the Central Medical War Committee I wish to add a few words of gratitude and respect in memory of Sir Robert Morant. Working in and with the Committee, he gave us from the first the full support of his advice, experience, and influence, and brought to our aid the resources of his department. In the early days of our work especially, when responsibility came heavily on us, and the machine was still far from perfect, this help was of the greatest value. The efficiency of his department he had always most at heart, but Morant recognized that, to estimate fairly the minimum needs of the Insurance Act service, you had also to consider the general need of the community for medical attendance of all kinds and by all practitioners. It was largely due to the intimate relations with the medical profession which this work in common provided that in his new sphere at the Ministry of Health he showed his desire to ascertain, and if possible to meet, the wishes of the profession on the many problems to be solved. We have much reason to regret the loss of a strong man who sought to agree when he safely could do so, and, when he could not, withstood with such courage and so fairly.

Dr. H. B. BRACKENBURY, Chairman of the Insurance Acts Committee, writes:

The death of Sir Robert Morant is a blow to the whole community, and to the profession in its relation with the Ministry of Health a real disaster. His great qualities have been shown abundantly since the formation of that Ministry, but to those who, like myself, have been intimate with him in his official capacity ever since he became Permanent Secretary to the Board of Education in 1903 they have been evident for long; and his loss is a personal as well as an administrative one which is so great as to be at present unrealizable. Through all the discussions of the last two years between representatives of the profession and the Insurance Commissioners and Ministry, his has been the dominating figure. He may truly be said to have seen many of the difficulties of the profession, and to have sympathized with them more than some members of the profession itself. While holding very firmly to the principles which he had adopted as right, he always seemed to be trying to understand and to help those who were not so clear-minded. He was a man with a vision of what ought to be, yet with a practical mind fertile in thinking out means for making his visions into realities. He can have had few equals in his skill in probing uncertainties, and in detecting and exposing slanders; and if the former process was sometimes painful and the latter on occasion merciless, they were both necessary and salutary. With great zeal and unsparing effort he was devoting himself to the upbuilding of a new and efficient health machinery and organization, and his death at this juncture leaves a gap which every member of the profession who has known anything of what he was and did must feel is almost impossible for any one man to fill. The public who care either for education or for health owe him an enormous debt; the medical profession owes him no less.

Sir JOHN LYNN-THOMAS (Cardiff, South Wales) writes:

The death of Sir Robert Morant is a calamity for the Ministry of Health from the administrative point of view. There is need and urgent call for a definite policy from the strictly medical point of view, irrespective of any other consideration. Medical ideals must be the bed-rock upon which the superstructure shall be built; how long it will take to build is not the immediate concern of the medical profession, which must not give the critics a loophole for attack. The ideal of the best for efficiency must prevail in the long run. The bogey of £ s. d. need not frighten the profession; it concerns the millions who cannot afford to pay when they use hospitals. Hospitals are now paid for by the few who are not entitled to enter them in the day of sudden and serious illness or accident to the human machinery in all its component parts—

mind, nerves, muscular and bony framework. In evolving a sound policy Morant's knowledge of affairs, his width of view, and his real sympathy with the aspirations of the profession would have been invaluable.

A memorial service held at the Church of St. Martin-in-the-Fields on March 17th was very largely attended. Among those present were Dr. Addison, Minister of Health, Sir George Newman, Chief Medical Officer of the Ministry, Sir Walter Fletcher, Secretary of the Medical Research Committee, Lord Dawson of Penn, Chairman of the Medical Consultative Council, Mr. Herbert Lewis (Parliamentary Secretary of the Board of Education), Sir L. A. Selby-Bigge (Permanent Secretary), and Sir Alfred T. Davies (Permanent Secretary of its Welsh Department), Viscount Sandhurst, Viscount Knutsford, Sir Francis Champneys, Sir Claud Schuster, Sir Almoth Wright, and Sir James Galloway. The British Medical Association was represented by Dr. T. W. H. Garstang, Chairman of Representative Meetings, Dr. G. E. Haslip, Treasurer, Dr. Brackenbury, Chairman of the Insurance Acts Committee, and the Medical Secretary, Dr. Alfred Cox, O.B.E. The BRITISH MEDICAL JOURNAL was represented by the Editor and Assistant Editor.

WILLIAM AUGUSTUS BONNEY, M.D. BRUX., F.R.C.S. ED.,
Chelsea.

We regret to record the death of Dr. W. A. Bonney, who died on February 29th. He was born at Brentford in September, 1840, and was consequently in his 80th year. His grandfather was John Bonney, solicitor, of Brentford, who with Horne Tooke (for some time vicar of Brentford) was imprisoned at the end of the eighteenth century for taking part in the so-called Horne Tooke Conspiracy. It was a very mild agitation when compared with our proceedings in the present day; in fact, Tooke and his friends merely desired to deal with the rank political abuses which disgraced their time. The trial is memorable because Tooke and his friend were the last political prisoners to be lodged in the Tower of London. His father was Dr. Francis Augustus Burdett Bonney, who practised at Brentford.

Dr. W. A. Bonney, after serving an apprenticeship to Dr. Clark of Twickenham, went to the Middlesex Hospital in 1863, and became M.R.C.S. in 1866. He was subsequently appointed resident obstetric officer to the hospital. In 1867 he went as assistant to Dr. Keen of Chelsea, and in 1869 started in practice there. He had lived in Chelsea upwards of sixty years, and witnessed many changes.

He was a man of great ability, whose life interest was in his profession, and he kept himself abreast of modern professional thought and practice. In 1880 he took the diplomas of L.R.C.P. and L.M. of Edinburgh, and in 1882 the M.D. degree at Brussels; finally, in 1895, when he was 54 years old, he became, by examination, a Fellow of the Royal College of Surgeons at Edinburgh, studying for the diploma at the Middlesex Hospital, where one of his sons was at that time a student. He had that natural power of storing up and profiting by experience which is the fortunate possession of some, and which, when combined with professional ardour and honour, produces the finest type of medical man.

He was a man of strong opinions, but in fortune and misfortune alike was upright, honourable, and resolute. He had a tenor voice of rare beauty, and this gift remained with him, weakened but still heautiful, up to the time of his last illness, a very unusual thing.

He died of influenza pneumonia, contracted in the course of his work, and he might have recovered had he given up directly he began to feel unwell. He had, however, an old patient he was determined to save, and on this account continued to struggle on until he himself was very ill. Thus he died, as he wished, in full harness, after a long and useful life—a fine record for any man.

He married in 1870 the daughter of Dr. Victor Poulain, and had three sons, two of whom are in the medical profession.

The death is reported of Sir T. ANDERSON STUART of Sydney. He was born at Dumfries in 1856, and received his medical education at the University of Edinburgh, where he graduated M.B., Ch.M. in 1880; he took the M.D. with the gold medal in 1882. He was president of the Royal Medical Society, Edinburgh, in 1832, and went to

Sydney in 1883 to assist in the foundation and planning of the medical school. In conjunction with Sir Alfred Roberts he threw himself heart and soul into the founding of the medical side of the university to make it worthy of the great nation which he foresaw would require its services. The result of his labours is a medical curriculum of the first order. On the retirement of Dr. Ashburton Thompson he threw his energies into the Public Health Department, and founded the offices and laboratories of the Board of Health there. His interest in public health matters continued, and he took a leading part in promoting the existing public health legislation of New South Wales. He also took part in the foundation of the Australian Institute of Tropical Medicine. He was Professor of Physiology in the University of Sydney, Dean of the Faculty of Medicine, and Fellow of the Senate since 1883; he was also chairman of the board of directors of the Royal Prince Alfred Hospital. He took great interest in the Industrial Blind Institution, of which he was president, in addition to being president of the Civil Ambulance Brigade, and the British Immigration League of Australia and other institutions. He organized the British Royal Society expedition to Funafuti, which bored coral reef, and proved the correctness of Darwin's theory of reef formation. He received the honour of knighthood in 1894.

Dr. ALEXANDER FERGUSON, professor of pathology in the School of Medicine, Cairo, since 1905, died on February 21st, after a long illness. He graduated M.B., C.M. Glasgow in 1892, and was afterwards for several years assistant to the Professor of Pathology in Glasgow, assistant pathologist to the Western Infirmary, and pathologist to the Hospital for Sick Children. In 1902 he graduated M.D. with honours, and received the Bellahouston gold medal for his thesis. During the war he was consulting bacteriologist to the troops in Egypt, with the rank of Major R.A.M.C. He took a particular interest in the pathological museum of Cairo, of which he published a descriptive catalogue in 1910.

The Services.

AFGHANISTAN DISPATCH.

IN his dispatch of November 1st, 1919, giving an account of the recent operations against Afghanistan, General Sir C. C. Monro makes several references to the Medical Services. The number of Regular R.A.M.C. and I.M.S. officers available in India was short of his requirements for complete mobilization:

The source of recruitment of these categories in India is small, and it had been found impossible to make good the deficiency from home. I was fortunate, however, in obtaining the services of 107 officers and 1,280 other ranks of the R.A.M.C. who happened to be in India *en route* from Mesopotamia to the United Kingdom.

The number of mobilized medical units employed during the campaign included 29 field ambulances, 12 casualty clearing stations, 15 sanitary sections, and 16,000 beds in general hospitals, with convalescent camp accommodation for 4,200. There were 11 ambulance trains, and a hundred specially fitted railway ambulance coaches for use with the ordinary passenger service. The Commander-in-Chief records that the two outstanding features of the campaign from the medical point of view were, first, an outbreak of cholera of unusual severity; and, secondly, the abnormal climatic conditions under which the troops were called upon to operate. The epidemic of cholera "for a time gave rise to grave anxiety; it was successfully stamped out by June 20th, an achievement for which the Medical Service deserves the greatest credit." Shortly after the outbreak of hostilities a heat wave of remarkable severity occurred over the whole of the Punjab and North-West Frontier Province, the daily temperature at Peshawar in May, June, and July being 5° to 7° F. above the daily average of the past twenty years. In spite of these trying conditions the incidence of sickness is described as not excessive. The daily admission rate was British 4.98, and Indian 2.97, in the period from May 5th to August 9th. This is compared with admission rates in Mesopotamia, which in 1917 were 5.04 and 2.11 respectively, and in 1918 3.48 and 2.27. The total forces, British and Indian, employed at this time seems to have numbered about 190,000. At a later period, the strength of the force employed on the other side of the Indus

amounted to 340,000 men. Notwithstanding the severe hardships imposed upon the troops, the Commander-in-Chief from personal inspection assures the Government of India that everything possible was done with the means at his disposal to alleviate the discomfort of the troops, and he records his high appreciation of the work of the administrative services and departments which contributed so largely to that end.

HONOURS.

K.B.E.

THE knighthood of the Order of the British Empire has been conferred on temporary and honorary Major Auguste Charles Valadier, C.M.G., Special List, in recognition of valuable services rendered in connexion with military operations in France and Flanders. Major Valadier contributed jointly a note on advances in the surgery of the jaw and face to the BRITISH MEDICAL JOURNAL of July 7th, 1917.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on March 12th the following medical degrees were conferred:

M.D.—R. R. Armitage, C. R. A. Thacker, H. A. Douglas.
M.B., B.Ch.—F. D. Marsh, F. H. Young.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on February 25th.

A letter was read from Lord Stamfordham intimating the King's approval of the suggestion that in future at dinners and other functions of the University of London His Majesty's health should be proposed as "Our Most Illustrious Doctor, His Majesty the King." The King when Prince of Wales accepted the honorary degree of Doctor of Laws of the University in 1933.

The following were recognized as teachers of the University in the subjects and at the medical schools indicated:—St. George's Hospital: Mr. Donald W. Roy (Midwifery and Diseases of Women). University College Hospital: Mr. T. W. P. Lawrence (Pathology). St. Mary's Hospital: Dr. W. S. Denham (Chemistry), Dr. A. H. Gosse (Clinical Medicine), Mr. K. A. Lees (Aural Surgery and Laryngology). Royal London Ophthalmic Hospital: Dr. G. M. Holmes (Ophthalmology-Medical).

The title of professor in the subjects indicated has been conferred upon the following teachers of the university:—St. Thomas's Hospital Medical School: Dr. Hugh MacLean (Biochemistry), Dr. J. Mellanby (Physiology). Middlesex Hospital Medical School: Dr. T. Yeates (Anatomy). London School of Tropical Medicine: Mr. A. W. Alcock (Medical Zoology).

It was reported that Dr. T. Lewis, to whom the Mickle Fellowship (value £200) was awarded for 1920, had intimated his intention of presenting half the money to the Graham Research Fund and half to the Cardiographic Laboratory at the University College Hospital Medical School. The chairman of the Graham Legacy Committee had communicated the thanks of that committee to Dr. Lewis.

In accordance with a request from the council of the Central Association for the Care of the Mentally Defective it was resolved to organize a course of lectures on mental deficiency for medical officers to local authorities and institutions and medical men engaged in work for defectives.

Presentation day will be held in the Royal Albert Hall on Wednesday, May 19th.

The University Medal in Branch IV (Midwifery and Diseases of Women) of the M.D. examination, July, 1919, has been awarded to M. H. Oldershaw, B.S., of University College Hospital.

UNIVERSITY OF ABERDEEN.

MR. WILLIAM G. CRAIB has been appointed Regius Professor of Botany in the room of the late Professor Trail. Professor Craib, who is M.A. Aberdeen, was for a time temporary superintendent of the Botanic Gardens in Calcutta, and was afterwards assistant at the Royal Gardens, Kew. He was appointed lecturer on forest botany and Indian forest trees at Edinburgh five years ago.

UNIVERSITY OF DUBLIN.

Honorary Degrees.

THE Senate on March 13th decided to confer a number of honorary degrees. Among them are the M.D. on Sir Archibald Garrod, K.C.M.G., M.D., F.R.S., Regius Professor of Medicine in the University of Oxford; the LL.D. on Sir Donald MacAlister, K.C.B., M.D., President of the General Medical Council, and Principal of the University of Glasgow; and the D.Sc. on Professor W. H. Bragg, F.R.S., whose investigations into radio-active elements have made his name so well known.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE diploma L.R.C.S. Edin. has been granted to S. K. Mukhopadhyaya.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS,
IRELAND.

The following candidates have passed the Conjoint examination for the diploma in Public Health:

Mabel C. Clark, W. E. Cooke, W. P. Cooney, C. E. H. Gater, J. A. Hamilton, W. P. Kelly, T. J. Lydon, J. F. Lyons, B. Murphy, W. O'Brien, G. W. Pope.

Medical News.

THE Prince of Wales, before his departure for Australia, signified his willingness to support the Oxford memorial to Sir William Osler, and sent a donation.

THE date for the receipt of signatures to the Automobile Association's petition to the Prime Minister on the cost of motor fuel has been extended to March 24th.

A DISCUSSION on the prevention and extermination of rats will be opened by Mr. T. J. Kenny, M.R.C.V.S., at a meeting of the Royal Sanitary Institute to be held in the Town Hall, St. Helens, on Friday, March 26th, at 7 p.m.

THE number of deaths from influenza in the ninety-six great towns of England and Wales during the weeks ending February 7th to March 13th inclusive have been 98, 109, 161, 178, 196, and 230. The number of deaths in London during the same period were 20, 25, 37, 38, 54, and 57.

THE Umberto I prize for the best orthopaedic work or invention is open to members of the medical profession in any country. Persons desiring to compete for the prize, which is of the value of 3,500 lire, should apply to the president of the Istituto Ortopedico Rizzoli, Bologna, Italy, who will supply full particulars. The competition will close on the last day of this year.

THE first reunion dinner of officers and nursing staff of No. 53 General Hospital (B.E.F.) will take place on March 25th, at the Hotel Great Central, at 7.30 for 7.45 p.m. Officers who have not already done so, and who wish to be present, should at once communicate with Lieut.-Colonel E. M. Callender, C.B.E., 73, Sussex Gardens, London, W.2; nurses with Miss M. S. Riddell, Principal Matron, T.F.N.S., 80, Pall Mall, S.W.1.

DR. NATHAN RAW, C.M.G., M.D., M.P., has been invited by the Minister of Health to assist him in the selection and organization of permanent village settlements for the treatment and training of persons suffering from tuberculosis. The Ministry proposes to provide nine settlements in Great Britain for tuberculous ex-soldiers and others.

THE Minister of Health has appointed an inter-departmental committee to consider the determination of a standard composition for condensed milk and other questions connected therewith. All communications on the subject should be addressed to the secretary, Mr. C. J. Bayley, Ministry of Health, Whitehall, S.W.1.

THE programme of the Child-Study Society, London, for the current year includes a lecture on March 25th, on adolescence and the continuation schools, by Mrs. Sloan Chesser, M.D., with Dr. F. C. Shruballs in the chair; and a lecture on April 29th, on biting insects and children (illustrated with lantern slides), by Dr. A. E. Shipley, F.R.S., with the Hon. Sir John Cockburn, K.C.M.G., M.D., in the chair. The lectures are given at 6 p.m., at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1.

THE Ministry of Pensions for some time past has supplied soldiers and pensioners who have suffered amputation of the leg with a provisional limb to supplement the permanent mechanical limbs that have been, and are being, supplied. The value of the provisional limb lies in its acting as a kind of "slipper" and as a reserve in case of accident to the mechanical limb. If a pensioner has not received a second mechanical limb he is entitled to apply to his local War Pensions Committee for a provisional limb, and arrangements to obtain one will be made with the nearest limb fitting hospital which works in connexion with a Red Cross provisional limbs dépôt established in its neighbourhood.

THE fourteenth French Medical Congress will be held in Brussels under the patronage of the King and Queen of Belgium from May 19th to 22nd. Three subjects have been selected for discussion: (1) Syphilis of the cardiovascular system, introduced by MM. Bayet (Brussels), Etienne and Spillmann (Nancy), Vaquez et Laubry (Paris). (2) Lipoid pathology, introduced by MM. Chauffard, Guy Laroche and Grigant (Paris), Linossier (Vichy), Zunz (Brussels). (3) The value of artificial pneumothorax in treatment, introduced by MM. Burnand (Leysin), Derscheid and Geeraerd (Brussels), Dumarest (Hauteville), Küss (Angicourt). The congress is organized by the

Association des Médecins de Langue Française; others desiring to attend the congress will pay a subscription of 40 francs (Belgian). The secretary of the congress, from whom further particulars can be obtained, is Professor René Verhoogen, 22, Rue Joseph II, Brussels. The treasurer is Dr. Godart-Danhioux, rue Montoyer, 9a, Brussels.

THE committee of the Lancaster Gate Medical Society decided, on March 1st, that the society in future should be known as the Psycho-Neurological Society, and that its object be "the study of psychological and neurological medicine." The officers for the year are: President, Dr. David Forsyth; Vice-President, Dr. W. A. Brend; Honorary Secretary, Dr. C. Worster-Drought; Honorary Treasurer, Dr. P. Bousfield. At a meeting on February 22nd Dr. Henry Head read the paper published in our issue this week, and a discussion followed. On March 15th Dr. R. Travers Smith raised a discussion on the simulation of valvular disease of the heart, and subsequent speakers deplored the fact that the psychological basis of cases of disordered action of the heart was so frequently overlooked.

THE National Association for the Prevention of Tuberculosis has issued an appeal for subscriptions to a fund to enable it to maintain and extend its educational work. Among the methods it employs is the organization of exhibitions at which are shown diagrams, models, and pictures illustrating the cause and prevention of tuberculosis. Lectures, illustrated with lantern slides and cinematograph films, are arranged, and caravans tour the country; in this way the association's organizers have visited every county and many county boroughs in England since peace was declared. The association is at present supplementing its main work, which is educational, by organizing a farm colony for discharged tuberculous soldiers and sailors. As evidence of the need for educational work it is pointed out that there was an increase throughout the country in the death rate from tuberculosis during the war; in 1917 deaths from tuberculosis in England and Wales numbered 55,934, and it is computed that the number suffering from the disease must amount to half a million. The increase is attributed not only to the hardships of living under war conditions, but to the impossibility of putting a sufficient preventive force into the field. The King is president of the association, the Chairman of Council is Sir Arthur Stanley, and the vice-chairman Sir Robert W. Philip of Edinburgh. The offices of the association are at 20, Hanover Square, London, W.1.

THE annual meeting of the Mental After-Care Association was held on March 10th at the Clothworkers' Hall, E.C., under the presidency of the Master of the Company, Mr. Walter Mews, who emphasized the importance of the task of finding suitable work for poor persons convalescent or recovered after treatment in institutions for the insane. The report, read by Dr. Percy Smith, showed a considerable increase in the number of persons assisted during the year; 1,074 had been guests for longer or shorter periods in the Association's Cottage Homes, where efforts were made to provide those capable of employment with situations within their scope under sympathetic employers; in many cases it was necessary to extend, sometimes for years, kindly supervision and advice with a view of preventing relapse. Unfortunately the balance-sheet showed some falling off in subscriptions, but the Guilds of Help had increased its contributions, so that the total amount raised in 1919 was £2,188 as compared with £2,276 in the preceding year. The working expenses had necessarily been affected by the general rise in prices, so that there was urgent need for increased support. Official recognition of the effective work of the association had been accorded both by the Board of Control and the London County Council Asylums Committee, with a prospect of monetary grants from special funds they administered. In moving the adoption of the report, Sir Marriott Cooke, K.B.E., vice-chairman of the Board of Control, testified, from official experience, to the excellent work accomplished by the association in the rehabilitation of discharged patients. Sir George Makins, G.C.M.G., President Royal College of Surgeons of England, in seconding, spoke of the desirability of judicious after-care in convalescence after physical disease, and emphasized its absolute necessity in the case of those who had suffered from mental disorders. Other speakers were Sir G. Wyatt Truscott, Bt., Sir Charles Wakefield, Bt., Sir George Savage, Sir R. Armstrong-Jones, and Mr. C. Gabain. Special reference was made to the invaluable and tactful work of the secretary, Miss E. D. Vickers, who is always glad to supply information as to the association from its offices, Church House, Deau's Yard, Westminster, S.W.1.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Antilogy, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

QUERIES AND ANSWERS.

DR. GWILYM R. PENNANT, of Leargaidh, Brithdir, Glamorgan, who has recently had under his care two cases of miners' nystagmus which developed double glaucoma, asks colliery surgeons to let him know whether they have had a similar experience.

INCOME TAX.

"C. P." states his probable income, exclusive of civil earnings, "for the financial year ending April, 1921," and inquires as to the appropriate personal and professional allowances.

* Assuming that the net income from the new work does not bring our correspondent's total income over the limit of £800, and that the present statutory rules remain in force for the year 1920-21, he would be entitled to regard the whole of his income as earned except that arising from the War Loan investments; to £50 allowance for his wife, and £65 for his two children; the earned rate of tax would be 3s. and the unearned 3s. 9d. in the £. With regard to the professional expenses, the rule is that they can be allowed in so far as they are incurred in carrying on the practice and not (a) in setting it up, or (b) in the ordinary way of private living. Applying this to the specific cases mentioned, "C. P." could deduct a reasonable proportion of the furnished rent—for example, 1½ guineas a week, cost of one servant's board and wages, cost of drugs, cost of running but not of purchasing motor car and bicycle. When either the car or cycle is sold, the cost of its replacement would be deducted, but the original car represents capital outlay in starting the practice.

INSOMNIA AGGRAVATED BY NOISE.

"G." asks to hear of a method of obstructing the auditory meatus in a case of insomnia aggravated by noises.

Dr. Dundas Grant informs us that though various forms of sound deadeners were used during the war with a view of diminishing the concussion without interfering with the hearing of orders, in civil life there is probably nothing better than a properly adjusted plug of cotton-wool, which may be lightly smeared with toilet lanoline or with spermaceti ointment. A pad of cotton-wool, fastened on with a light bandage, might be tried in the first instance.

LETTERS, NOTES, ETC.

CHAMELEON INFLUENZA.

DR. D. W. SAMWAYS writes from Mentone (March 7th) as follows: The variety of forms in which influenza may present itself has been well illustrated lately on the Riviera. The earlier cases in February were fairly normal, with frontal headache, moderate fever, pains, and rapid recovery. These were followed by a series in which nasal catarrh and sneezing were the predominant and most troublesome features. Then came a series with little fever, 0.5° to 1°, which resisted treatment of any sort for some days. With these there was great prostration, and, above all, inordinate depression. Finally, the tendency has been to concentrate on the digestive system, with abdominal pains, loss of all appetite, nausea, and a sickly slate-coloured tongue. I do not know whether in England similar kaleidoscopic changes have been taking place, nor have I previously observed such rapid transformations here.

SUBCUTANEOUS INJECTIONS OF CAMPHOR OIL.

IN extension of a reply on this subject published last week (p. 388) Messrs. Parke, Davis and Company (Beak Street, London, W.) ask us to state that they supply camphor dissolved in oil. The oil is sterilized and supplied in ampoules in two sizes. In the one 0.2 gram (3 grains) of camphor is contained in 1 c.c.m. (17 minims), in the other 2.35 grams (36 grains) in 10 c.c.m. (169 minims).

THYROID ADMINISTRATION IN HIBERNATING DORMICE.

DR. A. BERNHARD-SMITH (London, S.W.) writes: It may be of interest to place on record the effect of feeding thyroid extract to a pair of dormice (*Muscardinus arvenarius*) towards the end of the hibernating season. The amount ingested was 15 grains (Burroughs and Wellcome) over the space of six days. There were no symptoms after the first dose of 5 grains. I then withheld other food for twenty-four hours, and after the second dose a condition somewhat resembling normal torpidity was induced. The respiration became shallow, and the characteristic attitude appeared, but without rigidity. Indeed, after the third dose (although they have habitually become rigid during these cold nights), the new condition induced by the thyroid was such that the male on being given food rapidly recovered and, his appetite being now satisfied, conveyed a morsel to his helpmate, who was thereby awakened from her comatose state, and soon assisted in the consumption of a two-ounce carrot. Movements were somewhat sluggish for a few hours afterwards, but the pair are now none the worse for their experience.

CUTANEOUS MANIFESTATIONS IN A CASE OF CERVICAL FISTULA.

DR. MARTIN J. CHEVERS (Withington, Manchester) writes: The article appearing under this heading by Dr. Alfred Eddowes in the JOURNAL of March 6th, in which he states that he has passed the patient on to a surgeon's care, prompts me to call attention to an article by me in the BRITISH MEDICAL JOURNAL of April 28th, 1906, p. 974, entitled "The treatment of branchial fistula"; the treatment adopted was galvanism and the lady so treated—a relative of my own—has ever since remained perfectly cured and without the slightest trace of the fistula or mark in its course, except the slightest dimple the size of a pin head just above the clavicle. This tends to show that the use of the knife is not always necessary in such a case.

A PIN IN THE ALIMENTARY CANAL.

DR. A. B. ROBERTS (Shepherd's Bush) writes: The case mentioned by Dr. H. B. Pope (February 14th, p. 242) reminds me that about three years before the war a young man about 22 years old, a dancing and deportment teacher, came to me suffering from spasmodic pain and discomfort referred to the anus, especially during evacuation of the bowels. These symptoms had been present about three days. On examination with the rectal speculum a blackened, rusty pin was easily removed by long artery forceps. The patient's only explanation was that he had swallowed the pin without knowing it at the time. As the pin was somewhat bent it lodged near the inner sphincter.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 48, 49, 50, 51, 52 and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 46, 47, and 48.

THE following vacant appointments of certifying factory surgeons are announced: Castle Acre (Norfolk), Consett (Durham).

THE post of specialist medical referee under the Workmen's Compensation Act, 1906, for ophthalmic cases in County Court Circuits Nos. 12 and 14, is vacant. Applications to the Private Secretary, Home Office, by April 3rd.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

THE charges for advertisements in the BRITISH MEDICAL JOURNAL will be increased at the end of March. The new charges will apply to all advertisements for insertion in the JOURNAL of April 3rd and subsequently. The rates will be as follows:

Six lines and under	7s. 6d.
Each additional line	1s. 3d.
Whole single column	46 0s. 0d.
Whole page	416 0s. 0d.

An average line contains six words.

From the issue of April 3rd the charge for announcements of births, marriages, and deaths will at the same time be increased to 7s. 6d.

Present Scale.

Six lines and under	£ 5. 0.
Each additional line	0 6 0
Whole single column	0 0 9
Whole page	4 0 0
	12 0 0

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

ABDOMINAL EMERGENCIES.

THE SUBSTANCE OF TWO LECTURES OF THE POST-GRADUATE COURSE, NEWCASTLE-ON-TYNE.

BY

RUTHERFORD MORISON,

PROFESSOR OF SURGERY, UNIVERSITY OF DURHAM (NEWCASTLE).

SEVENTEEN years ago, in an address on abdominal emergencies given to the Middlesbrough Medical Society (*Surgical Contributions*, p. 480), I said:

Future progress in abdominal emergencies is to be sought for in prompt treatment, and the most important advances depend upon your care and skill; they are not to be expected from the ingenuity and daring of mere operators but from more prompt diagnosis and more vigorous action on the part of the general practitioner.

Here is a list of the twenty-six cases in the Royal Victoria Infirmary to-day:

Acute appendicitis	8
Appendix abscess	7
Gall stones, acute	3
Ruptured duodenal ulcer	5
Intestinal obstruction, acute	3
Total	26

Of these, one, a case of duodenal ulcer, died from septic peritonitis of fifty-three hours' duration. He was moribund when admitted.

Sixteen doctors answered, by letters, questions concerning these patients, and I am indebted to them for much valuable information given on short notice.

THE ABDOMINAL FACIES.

In every case you will be sent for because the patient has abdominal pain. The first question to be answered is whether this is due to some serious cause or not, and that can often be decided if the patient is seen in the early stage after a single look. Doctors are students of the expression of the emotions, and, if they are wise, cultivate the faculty of careful observation of every detail. It is only because observation of the expression and conduct of patients is so commonplace that this has not received the attention due to it, though it is only fair to note that the "abdominal facies" is emphasized in some recent surgical literature.

One of the sayings of the late Dr. Murphy of Sunderland was that when he entered a woman's room after an abdominal operation and saw her hand leaving her hair he knew that there was nothing very serious the matter with her, however loud her complaints. Such an observation is based upon a knowledge of human nature. A desperately ill patient is careless of the ordinary small refinements of life, and looks like it.

INITIAL SHOCK.

The second point helpful in arriving at an opinion is a history of the illness. At the commencement of every serious abdominal emergency there is "shock," and this produces effects so obvious as to alarm the patient's friends. They "noticed the change and they thought something serious had happened." It is well to listen to their story, because in some cases "shock" very quickly disappears and a stage of reaction follows, when recovery may appear to be so complete as to deceive the most wary. This occurs even in such serious and hopeless conditions as lacerations of the hollow viscera by injury and perforations of gastro-intestinal ulcers.¹ To impress this upon students I used to relate to them the story told at a coroner's inquest on a famous footballer. During the game on a Saturday he was forcibly struck in the abdomen by the bent knee of an opponent, fell down at once looking very bad, and was carried to the club-house "winded." He was immediately seen by a doctor, but in two hours had so far recovered that he was able to be taken home, and everyone thought he was little the worse. On Tuesday he was very ill with "inflammation of the bowels," and was sent to the cottage hospital, where he died on Thursday. *Post-mortem* examination showed that the small bowel had been torn across and had leaked, and that death was due to peritonitis. Think of it, and remember that similar cases are still occurring every week. A kick from a horse, a blow from a cart shaft, some localized force suddenly applied to the abdominal wall, ruptures the intestine. Operation within six hours

would save 90 per cent. of these patients; the policy of "wait and see" allows 90 per cent. of them to die. The reason why they do not all die was made the subject of experiment by Hamilton Drummond in France. He cut the intestine of animals and replaced them open. For many hours the intestine lay where it was placed and expelled none of its contents. Natural repair followed and the animals recovered—because their intestine was paralysed from the injury. In soldiers shot through the abdomen he found a similar paralytic condition of the intestine, with little extravasation of its contents.

In the reactive, or second, stage the patient may look and feel so much better that it seems almost impossible that there are serious results to follow. Now is the time when diagnosis is most difficult, and often most important, and it may be impossible to answer the first question we have to ask ourselves—namely, Whether is the condition a serious one or not? (Case 1.)

HISTORY AS TO PAIN.

The third clue is to be found in a study of the history of that pain which was the cause of your attendance. How did it commence? How did it progress? Was it preceded by any warning? Have similar attacks occurred before?

The causes of abdominal pain are special to the abdomen. All the viscera are insensitive to ordinary pain stimuli. They can be cut or burned or sutured and no sensation results. On the other hand, the parietal peritoneum is exquisitely sensitive, and stimulation of it produces the first type of pain; the hollow viscera respond strongly to intravisceral irritation, especially such as is produced by foreign bodies *plus* infection, and to tension, and this is the second cause of pain; the mesentery and attachments of the viscera are painful when dragged upon, and this is the cause of a third type of pain.

Irritation of the Peritoneum.

A countryman was going home at the end of a day's work, and when within a hundred yards of his cottage jumped over a low railing. In the act of jumping he was suddenly seized with a pain in his stomach so severe that he fell, and thought he was going to die. For an hour he lay where he fell, entirely conscious but feeling that he had to lie still, and that he dare not make even the effort to shout for help. He was carried home, seen by a doctor (who found him cold and collapsed), and sent to the infirmary on a stretcher in a guard's van. On arriving there he appeared to be very well, but there was some evidence from physical signs that he was not. His previous health had been good except that he had had periodic attacks of "indigestion," but never serious pain before. Operation showed a perforated duodenal ulcer. Such a sudden serious pain suggests perforation of a hollow viscus, and the cause is irritation of the peritoneum by escaping visceral contents.

Forcible Contraction of Unstriated Muscle.

A young man got up at 5.30 in the morning to go to work, and felt some pain in his inside. He took a "good dose" of castor oil before going out. He went to his work on a tram car. The pain grew worse, and he vomited twice before reaching his destination, and was able, but doubled up and with difficulty, to walk to a signal cabin on the railway, where he sat down. During an hour there he vomited four times, and the pain was so bad that he could not help shouting and rolling about on the floor. On admission to hospital three hours later, he had frequent paroxysms of pain during which he shouted out like a woman in labour, and tossed about in bed. Previously he had had similar attacks, but none so severe, and a dose of castor oil had always put him right before. Operation showed a loop of gut strangulated by an adherent Meckel's diverticulum. Such a pain, paroxysmal in character and severe enough to make the patient shout and roll about, suggests the forcible contraction of unstriated muscle, caused by increased intravisceral tension. Gall stones, stones in the pelvis of the kidney or ureter, and obstruction of the intestine are the most familiar examples of this variety of pain.

Dragging on the Mesentery (Torsion).

A young man was awakened by severe pain in his lower abdomen and right testicle which was partly undescended

He felt faint, broke into a cold sweat, slept no more and vomited twice. In a few hours his testicle had swelled to the size of an orange, and pain continued till operation, seventy-two hours later. There was complete torsion of the spermatic cord and gangrene of the testicle. A similar condition is more common in women, when ovarian cysts twist their pedicles. In all of them, men and women, the final half twist has been preceded by others less severe, and this story also holds true of the similar condition called volvulus of the intestine. In all the pain is mainly due to forcible dragging on the mesentery.

The severity of pain, its method of onset, its character, its precedents and progress may tell a story sufficiently clear to aid in diagnosis.

RIGIDITY OF ABDOMINAL WALL.

There is only one more point to which I need specially refer, and as it concerns a physical sign it is of great importance.

What is the condition of the abdominal wall? Look at it. Does it move freely, or does it move at all with respiration? If it moves freely, the abdominal condition is unlikely to be serious; if it does not move at all, peritonitis due to a ruptured viscus is suggested.

The joints and the abdomen present features in common. The same nerves supplying a joint innervate the muscles which move it, so that pain in a joint results in a protective contraction of the muscles which activate it. Visceral nerves are similarly related to the nerves supplying muscles which move the abdominal wall, and abdominal pain is accompanied by protective rigidity of the muscles overlying an intraperitoneal lesion.

Now feel the abdominal wall. If there is no tenderness, no rigidity, and no underlying lump, a colic (forcible contraction of unstriated muscle) is the cause; a tender tumour, without considerable rigidity over it, is a localized lesion connected with one of the intra-abdominal viscera; definite rigidity and tenderness point to inflammation of the peritoneum, and the more diffuse these are the more serious the condition probably is.

INTRA-ABDOMINAL HAEMORRHAGE.

Another of the serious abdominal emergencies is due to intra-abdominal haemorrhage.

Blood is an irritant to the peritoneum, not so vicious as extravasated contents of the hollow viscera, but sufficient to cause pain, so that pain is usually the first symptom of intra-abdominal haemorrhage, whether it be caused by injury or not. The same shock, followed by reaction, is present as in the conditions considered previously, but instead of developing symptoms of peritonitis, the third stage in intra-abdominal haemorrhage is the result of loss of blood. Symptoms occur in the following sequence:

(1) A feeling of anxiety and weakness; (2) pallor of the visible mucous membranes and face; (3) thirst; (4) quickening and enfeeblement of the pulse; (5) a craving for more air; (6) a cold, clammy skin, earliest appreciable on the forehead; (7) sighing, yawning, restlessness; (8) noises in the head and dimness of vision; (9) dilated pupils and syncope; (10) diminished percentage of haemoglobin in the blood.

These symptoms occurring after an abdominal injury suggest rupture of one of the solid viscera—liver, kidney, spleen; after operation, slipping of a ligature; without injury, and in a woman a ruptured ectopic gestation.

Operation, if done early enough and followed or preceded by blood transfusion, in the worst cases will save the majority from death.

TREATMENT.

Relief of his pain is what the patient demands, and so would any one of us; but before giving either a hypodermic injection of morphine or any purgative it is essential to answer the question, Is the case serious or not? If no satisfactory answer can be found, no morphine or aperient must be given till the problem has been solved. Before leaving the patient count and note his pulse rate, and later count it again. A rise in the pulse rate is the most important sign of progressive mischief, and in doubtful cases the pulse rate should be noted at least every hour.

Pathology teaches us that operation offers the only reasonable chance in an overwhelming majority of serious cases, and its chief objects, in the abdomen as everywhere

else, are: (1) To arrest haemorrhage, (2) to remove or exclude a focus of disease, and (3) to deal with mechanical obstacles.

To prevent septic peritonitis, which can only be accomplished by removing or excluding the focus of infection before widespread mischief has arisen, is the chief object of abdominal operation. It is possible in early cases of peritonitis to arrest further infection, but it must be recognized that recovery has been brought about by giving nature a chance. General peritonitis is the same deadly infection it always has been, and when fully developed, or when the cause of it cannot be dealt with, surgical operation has always done more harm than good. Surgeons are now beginning to realize that peritonitis resulting from acute gonococcal, pneumococcal, and pancreatic infections—conditions for which no satisfactory means of dealing with the focus of infection exist—may be made worse by operative interference, and that the best chance for these patients is to wait for localization, prepared to deal with an abscess if life should be prolonged for a sufficient time to allow of its development.

The moral of this knowledge is obvious, and I have preached the application of it in season, and perhaps out of it, for at least twenty-five years. As it is not yet universally applied, let me reiterate.

Every patient with a more than ordinary pain in the abdomen ought to be sent for observation, and, if needful, operation, to a properly equipped hospital without delay. A note as to the condition of the patient when first seen, and stating whether morphine has been given or withheld, should accompany him. It has been the custom with some medical men in this district to do this for years, and many of them can now boast that no patient of theirs has died as a result of an abdominal emergency.

The first portion of the time at our disposal has been occupied in discussing the most important problem to be solved—namely, Is the condition serious, or is it not? On the next occasion I shall deal with the differential diagnosis of cases.

DIFFERENTIAL DIAGNOSIS.

It has always to be remembered that abdominal pain may depend upon conditions not strictly surgical, and the advantage of a physician's co-operation should not be lost sight of.

The following is a list of the possibilities of which I have personal—and sometimes unfortunate—knowledge. They can be grouped into three classes:

1. *Irritation of the lower six intercostal nerves*, resulting from pneumonia, pleurisy (purulent or otherwise), pericarditis, herpes zoster, growths or caries of the vertebrae, locomotor ataxia, and hysteria, may produce abdominal pain and rigidity of the muscles. Acute inflammations in the chest, which are occasionally, in the early stages, accompanied by vomiting and pain referred to the abdomen, are specially difficult to distinguish from the abdominal emergencies, and should not be forgotten.

2. *General toxic conditions*, such as arise from chronic kidney disease, diabetes, Addison's disease, Henoch's purpura, ptomaine poisoning, lead poisoning, typhoid fever, may each be introduced to your notice because of acute abdominal pain.

3. *Abdominal conditions*, such as pyelitis, kidney and ureter stones, tuberculous lymphatic glands, and especially acute dilatation of the stomach, may produce symptoms simulating those of peritonitis, and in women dysmenorrhoea may be mistaken for something worse.

So much has been made of the difficulties of diagnosis that it has become a fashion to teach, "Open the abdomen and see"; but this is a pernicious doctrine fatal to all progress, and sometimes to the patient. There are still doubts which can only be cleared up by operation, but they have become a steadily diminishing quantity as the result of more careful study of the problems to be solved. If a note be kept in every case of the pre-operative diagnosis, and later compared with the findings at the operation, an efficient stimulus to better work will be provided.

The most common cause of an abdominal emergency is appendicitis, and it is a good rule in diagnosis to consider the most likely thing first.

APPENDICITIS.

As usual your attendance has been asked for on account of abdominal pain.

When the vermiform appendix is in its normal position, on the inner side of the caecum and pointing upwards to the spleen, and is acutely inflamed, the symptoms and signs are so definite that mistakes are now seldom made.

In the early stage a variable amount of shock is present, and the patient looks ill, but seldom dangerously so. A history of previous attacks is frequently obtainable. The shock stage is quickly followed by reaction. The pain has often wakened the patient from sleep, and generally prevents any further rest on that same night. It is at first diffuse, and referred to the epigastrium or umbilicus, a few hours later settling to the right iliac fossa. Though often coming on quickly and very acute, it is never so sudden in onset or so severe as that produced by the rupture of a duodenal ulcer. In the early stages it may have periods of intermission and exacerbation, due to the efforts of the inflamed appendix to empty itself of its contents (appendicular colic). The pain, like nearly all surgical pain, is due to tension, and the greater this is the more severe the pain. If the appendix cannot empty, tension gangrene of it quickly supervenes, and, as dead nerves convey no impulses, the acute pain disappears.

An acutely inflamed appendix which is draining into the caecum will produce little pain until peritonitis develops.

Soon after the pain appears, vomiting commences, and then follows a rise in temperature. Great stress has been attached to this sequence by Dr. Murphy of Chicago, as the most valuable part of the history in arriving at a diagnosis.

The *Physical Signs* are: (1) Rigidity of the muscles covering (2) a tender spot in the right iliac fossa.

The most dangerous and acute cases, if not seen in the early stages, are often during the reaction stage most deceptive. The urgent early pain having disappeared, those who know no better are relieved of their anxiety till the gangrenous appendix, distended by highly infectious contents, ruptures into the peritoneum. During the gangrenous stage in these serious cases the only definite clues to diagnosis may be right iliac rigidity and tenderness, which do not disappear with the pain.

You may remember that of the fifteen cases of acute appendicitis in the infirmary on the day we last met seven were abscess cases. The explanation of this is generally to be found in the anatomical position of the appendix. If it is not in its normal position but in the subcaecal pouch, or the pelvis, or lying in the gutter on the outer side of the caecum and ascending colon, the symptoms and signs are less definite, and require more careful looking for. They can and ought to be found, because an appendix which has leaked reflects discredit upon someone, as the leak adds to the danger of an operation, and is followed by more severe complications and longer convalescence after it. Careful palpation of the abdomen or through the rectum will seldom fail to discover a specially tender area overlying the inflamed appendix.

The symptoms of inflammation everywhere are—(1) general, and (2) local. The general symptom is fever; the local: pain, redness, heat, swelling, and loss of function, but the last four are not perceptible in appendicitis till the appendix has been exposed.

Consequently, in the most difficult cases sudden abdominal pain and a rise in temperature or a leucocytosis may be the only symptoms, and it is seldom wrong to make a diagnosis of appendicitis when these are found together. The most frequent mistake made now is to think of a *B. coli* pyelitis as appendicitis, but the discovery of pus in the urine will help to clear this up.

The most serious cases are often attended at their commencement by a rigor; severe pain, repeated vomiting, and diarrhoea are always danger signals.

[Two coloured drawings were shown to illustrate the shock stage with a red, tense, swollen appendix, and the stage of reaction, with complete gangrene of the appendix.]

CASE I.—Complete Gangrene of the Appendix.

This man, aged 39, admitted January 14th, 1920, had been awakened at 2 o'clock in the morning of Tuesday, January 13th, with pain all across the abdomen above the navel. He slept no more that night, and was so bad he "felt his end was up." At 10 a.m. on Tuesday vomiting commenced, and he vomited at least twelve times before Tuesday night, when the vomiting ceased. On Tuesday afternoon he began to feel feverish, and slept none, or very little, during Tuesday night. On Wednesday morning he was purged three to four times. After the purging the pain left his stomach and settled in his right side, but more as a feeling of soreness than of pain, and he was otherwise

quite comfortable. When the doctor examined him he only felt tender on the right side.

The doctor saw him at 12.30 p.m. on Wednesday, and told him he had appendicitis and should go to the infirmary at once for an operation. When he was told this he got up, put his clothes on without help, and walked about the kitchen till the taxi came to drive him to the infirmary, a distance of 50 miles. He had no trouble on the journey, and wondered when he felt so well whether the doctor was right in saying he had appendicitis. He walked from the cab, got a ticket at the infirmary office, and proceeded into the ward without difficulty or pain; indeed, he "felt as if he could walk for miles." He had never had any abdominal trouble before.

On admission his pulse was 98, temperature 100°. There was some muscular rigidity in the right iliac fossa, and he was very tender over McBurney's point.

Operation was performed on Wednesday, January 14th, 1920, at 8 p.m. The vermiform appendix was gangrenous throughout, and so rotten that it ruptured during its extraction.

ACUTE INTESTINAL OBSTRUCTION.

The causes of intestinal obstruction are similar to those which cause obstruction in all the tubular structures of the body. It may be produced by obstacles (1) outside the tube, (2) in its wall, (3) in its lumen, (4) by displacements of the tube itself.

The diagnosis of intestinal obstruction is based upon a trinity of signs: (1) Severe spasmodic pain, (2) evidence (visible, audible, or palpable) of increased peristalsis, (3) inability to pass flatus per anum. In acute cases persistent and frequent vomiting is valuable additional evidence.

When these symptoms are present the first thing to do is to examine the hernial sites with the greatest care, because a strangulated hernia is the most common cause of intestinal obstruction. It is one still too often neglected, if the patient has overlooked the presence of a hernia, or has attached no importance to the swelling.

In the early stage shock is most pronounced when a considerable loop of gut has become acutely strangulated by a tight band or collar, and may continue till gangrene develops, when the reaction stage commences. It is not yet realized how deceptive the appearance of recovery of patients with gangrenous intestine may be.

The treatment of intestinal obstruction is still one of the black spots in our work, because delay follows on diagnostic difficulties, and dangerous changes occur with such serious rapidity as to make prompt action essential to success.

The differential diagnosis of cases of intestinal obstruction may be as difficult as that of other abdominal lesions. It is occasionally helpful to remember that in children intussusception is the most common cause; in adults, bands from adhesions due to healed tubercle, or the results of appendicitis, or past operation, or remnants of Meckel's diverticulum; and in elderly patients malignant strictures, especially of the colon. In addition to examination of the hernial sites, an examination of the rectum should never be omitted if humiliating mistakes are to be avoided.

[A coloured drawing showing the serious condition of bowel six hours after acute strangulation was exhibited.]

CASE II.—Acute Intestinal Obstruction due to Adhesion to old Tuberculous Mesenteric Gland.

This man, aged 22, admitted January 13th, 1920, had had a pain in his abdomen on Sunday evening (January 11th, 1920). It doubled him up all night, but he got some relief from hot fomentations and pressing his hands into his belly. Two hours after the pain vomiting came on, and it never ceased till his admission on the following Tuesday evening at 7 o'clock. After the pain commenced he had passed no wind or motion, but on Monday morning heard rumbling, and could feel something rolling in his belly. He was seen by a doctor on Monday and got some medicine, but vomited it all. He says he told the doctor then about the rumbling and his guts rolling round. The doctor saw him again on Tuesday afternoon and ordered him to go to the infirmary at once. On admission he was in a condition of shock. Pulse 112, temperature 95°, respirations 36. He vomited yellow faecal-smelling fluid. His abdomen was somewhat distended, rigid and tender in the centre. A peristaltic wave could be seen and felt in a line above the umbilicus and passing to the left.

A diagnosis of acute intestinal obstruction due to old tubercle was made by Mr. Willan.

Operation showed acute distension of the upper four feet of jejunum and an obstruction due to adhesion of intestine to an old tuberculous gland in the mesentery. A lateral anastomosis of distended gut above and contracted below was made.

He could not say whether he had any abdominal illness as a child. Two years ago he had a pain similar to this one, but it only lasted six hours.

PERFORATION OF THE STOMACH AND DUODENUM.

There is abundant evidence for the view that these serious lesions may undergo a natural cure, but this must not be offered as an excuse for delay in their treatment, because they still rank as the most dangerous of the abdominal emergencies.

Simple ulcer of the stomach or duodenum is the recognized cause of the great majority of perforations, and if they can be satisfactorily closed before the leaking contents have widely infected the peritoneum, recovery is almost a certainty.

A history of previous "indigestion" is obtainable in the great majority; then comes a sudden overwhelming pain. In duodenal cases the intestinal contents, leaking into the subhepatic pouch, escape down the gutter on the outer side of the ascending colon and caecum into the pelvis, and may cause the chief pain, tenderness, and rigidity to be referred to the right iliac fossa. This accounts for the frequency with which such cases are sent with a diagnosis of appendicitis. Mistakes will be less frequent if a history typical of duodenal ulcer is available, and if the sudden overwhelming onset receives due consideration.

[Photographs of specimens of ruptured gastric and duodenal ulcers were shown.]

CASE III.—Ruptured Gastric Ulcer.

This youth, aged 17 years, was admitted January 3th, 1920. He brought with him the following note from his doctor:

Dear Sir,

I hope that you will admit F. C., aged 17 years. Diagnosis is—Ruptured gastric ulcer.

History.—The patient has been troubled with slight dyspepsia (he describes it as a sickly pain, though he never vomited, coming on about two hours after food) for the last three weeks. At 6.50 this evening, when at work, he was suddenly seized with severe abdominal pain. He attempted to walk home, but when he got half way was found by a lady standing leaning against a pole and groaning with pain. The lady helped him home, and got him there with difficulty. He has vomited twice since getting home.

I saw the patient at 8 p.m. He was lying on his back groaning with pain. He was very pale, cold, and collapsed. Pulse 112, and very faint; temperature 95.6°. His abdomen was as hard as a board on examination and very tender. Liver dullness present. Breathing was thoracic in character.

Yours truly,

The patient was driven to the infirmary, well packed with blankets and hot-water bottles, in an ambulance, for six miles.

On admission he was in good condition. Skin warm, pulse 75, of good volume. There was board-like rigidity of the whole abdomen.

Operat (five hours after perforation) showed a leaking ulcer on the gastric side of the pylorus. This was closed by pyloroplasty through the ulcer.

GALL STONES AND CHOLECYSTITIS.

It is not sufficiently recognized that if a gall stone suddenly blocks the neck of an infected gall bladder, conditions of great danger may quickly develop. A distended inflamed gall bladder in the course of twenty-four hours may become gangrenous, and the patient seriously ill. Unless quickly relieved by operation, rupture of the gall bladder allows of the discharge of its infected contents into the peritoneum, and peritonitis, likely to be fatal, results. Diagnosis is based upon the previous history of gall-stone attacks, but chiefly on the discovery of a hard, tender rounded lump in the position of the gall bladder under the right costal margin. [A coloured drawing of a gangrenous gall bladder with stone impacted in its neck was shown.]

OVARIAN CYST WITH TWISTED PEDICLE.

In women this is a common cause of an abdominal emergency. If the tumour has been previously recognized, or is evident on examination, and a sudden attack of abdominal pain has developed with tenderness and enlargement of the lump, it is probably due to torsion of the pedicle of an ovarian cyst. In the majority of instances a serious attack has been preceded by one or more minor seizures—which have left the patient apparently little the worse. In serious attacks the vascular supply of the tumour is interfered with, and gangrene of the tumour and peritonitis are the terminal results. [A drawing of an ovarian cyst with twisted pedicle was exhibited.]

ECTOPIC GESTATION.

Another serious abdominal emergency peculiar to women is caused by intra-abdominal haemorrhage, due to rupture of an ectopic gestation.

In the most dangerous variety of this lesion diagnosis has to be made chiefly upon the signs of internal haemorrhage. An early impregnated ovum has eroded through the Fallopian tube, usually close to the uterus, and such furious haemorrhage follows that life can only be saved by operation.

In the more common variety one or two periods have been missed and the patient suspects that she is pregnant. The first warning that all is not right arises from a sudden attack of pain, which may be repeated once or more before the final rupture (Case IV). This pain is probably due to colic of the tube in its endeavour to expel the impregnated ovum. At this stage vaginal and bimanual examination can discover the distended tube at one side of or behind a uterus which offers evidences of pregnancy, and examination of the breasts may support this suggestion. If left alone the patient is suddenly overwhelmed by pain, and the symptoms of internal haemorrhage more or less quickly develop. In many the loss of blood has been so great as to allow of an additional sign—shifting dullness in the flanks—to be discoverable before operation.

Some of the most wonderful resurrections due to surgery have been obtained by operation in these cases, and death following it has been rare, except when the patient was already moribund before the abdomen was opened.

CASE IV.—Ruptured Fallopian Pregnancy.

This married woman, aged 29, was admitted January 14th, 1920. Four days before she was suddenly seized with pain in the lower part of the belly, "worse than labour pain." She felt at once very ill, the pain "went up to her heart," and made her feel as if she would die. She vomited several times.

On admission she was very ill, pale and anaemic, with dirty tongue, and was complaining chiefly of rectal tenesmus. (This is a common symptom in ectopic gestation.) There was a tender lump in the right iliac region with some rigidity.

Previous History.—Two children, elder 10, younger 8 years. Never well after last labour. Menstruation irregular, seldom a week without haemorrhage till four months ago. Then haemorrhage ceased for five weeks. Two months ago she thought she must be pregnant because her breasts swelled and milk came from them. A month before admission she had an attack of pain which lasted for two or three hours and made her feel faint. The pain was accompanied by free haemorrhage and the discharge of a "skin." This pain had been repeated several times before the final attack (examination then would have discovered a tubal swelling). She had consulted three doctors, but was not examined till her final seizure, when the condition was correctly interpreted.

On opening the abdomen, it was found to be distended with blood and clot, and there was a pregnancy in the right Fallopian tube.

REMARKS ON THE ASSOCIATION OF AORTIC ENDOCARDITIS AND AORTITIS.

BY

J. E. MACILWAINE, M.D., B.Sc., D.P.H.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS, ROYAL VICTORIA HOSPITAL, BELFAST.

In bringing forward this subject my object is to allow the members of the Branch to see two morbid specimens which we have been recently fortunate enough to secure. I would like to acknowledge my indebtedness to Dr. Boyd Campbell who has been associated with me in studying these cases, and who has taken the notes and made all the blood examinations.

For a considerable period it has been my experience to see a number of genuine endocarditic lesions of the aortic valve where clinical evidence seemed to point to the fact that the myocardium was not the important consideration in prognosis and treatment. I have had the advantage of making an electro-cardiographic examination in practically all the cardiac patients I examined, and this method added in some cases a considerable weight of evidence for the conviction that myocardial change was not in itself at all sufficient to endorse the grave prognosis which evidently the general condition of the patient demanded.

After reading Sir Clifford Allbutt's wonderful contribution to cardiac literature in his work on arterial disease,¹ it

¹ Read before the Belfast Branch of the British Medical Association on February 12th, 1920.

was borne in upon me that in all cases of aortic endocarditis we must think primarily of what is the condition of the aorta itself.

To speak broadly, aortic endocarditis can be divided into two etiological groups—namely, the syphilitic and the rheumatic. In a very exhaustive examination of men entering military service some observers came definitely to the conclusion that the commonest cause of the endocarditis in these recruits was the rheumatic virus.² On the other hand, experience of a considerable amount of work amongst the pensioners leads to the conclusion that the syphilitic virus is the principal etiological factor. This is a matter of the very greatest practical importance, and, fortunately, to-day we are in a position to consider it fully, and are able to arrive at a perfectly fair decision as to the etiology of most cases of aortic endocarditis.

I show specimens from two men who both exhibited the classical clinical appearance of aortic regurgitation. The first man died through the rupture of an acute aortic ulcer into the trachea, while the second died after a period of cardiac incompetence which lasted for a considerable time. These two cases have occurred in a series of twelve pensioners in hospital who suffered from aortic endocarditis with aortic reflux.

CASE I.

In the first man the cardiac condition was not in itself at all alarming, but the man's symptoms were persistent and severe. So much was this the case that the question of syphilitic aortitis was discussed, and a Wassermann reaction, which proved to be strongly positive, was obtained. This patient was in hospital for some months and underwent a course of mercurial inunction, with potassium iodide internally. He seemed improved, and had been able quietly to go about while in hospital; he was discharged as unfit for work. The symptoms persisted, and he was readmitted to hospital with hæmoptysis and dyspnoea, with severe constant pain behind the manubrium sterni and between the shoulders. He died suddenly, after a couple of days in hospital, coughing up a huge amount of blood. The necropsy showed the usual syphilitic aortitis with a considerable amount of inflammatory adhesion around the aorta, which was definitely dilated and closely bound down to the trachea. A large atheromatous ulcer had eaten its way through, with a considerable amount of calcification round it, into the trachea. Unfortunately, no x-ray plate of this man's chest was taken before he left hospital, but an ordinary careful clinical examination had not led us to suspect aneurysm, nor, indeed, was the *post-mortem* finding more than a dilatation of the aorta in its ascending and transverse portions. With the experience of this case we began, as a routine, to have a Wassermann reaction taken in all aortic cases, and so far, I think, there has only been one which gave a negative result.

CASE II.

The second case, in which we were enabled to obtain a *post-mortem* examination, was a pensioner, aged 40, who gave a definite history of specific infection twenty years previously. Clinically he presented symptoms very suggestive of acute aortic inflammation. There was well-marked aortic reflux with apparent mitral incompetence, and the general appearance of the patient was rather like septico endocarditis or general septic intoxication. The main symptoms complained of were increasing dyspnoea, pain upon effort behind the manubrium sterni; associated with this was an oedema of the lower extremities. The condition of the patient was evidently very grave, and we suspected, on account of the pain, and dyspnoea even at rest in bed, that there was some involvement of the aorta, as the Wassermann reaction was definitely positive. When we endeavoured to get an x-ray picture of the arch of the aorta it was discovered that the patient had a German machine gun bullet in the thorax above the level of the arch of the aorta, between the oesophagus and the trachea. This bullet had nothing whatever to do with the man's general condition, as *post-mortem*, it was found not to be surrounded by any marked inflammatory reaction. Its presence there, however, when it became known to the patient, had a most disquieting effect. In fact, Dr. Robb, who was in charge of the patient, said "He never looked up after that bullet was discovered." Unfortunately, the patient's cardio-vascular condition was such that there was not much hope of improvement from the start. To this patient we gave small doses of novarsenobillon, and at first there appeared to be definite evidence of improvement. However, the patient died before he had had a lengthy course—died rather suddenly of, apparently, complete failure of compensation. The necropsy in this case showed, in the first place, general evidence of old-standing syphilitic infection, and, in the heart, marked fatty degeneration; the aorta presented the picture of syphilitic aortitis, a type in which we have an acute inflammatory condition of the great vessel. The aortic valve shows chronic syphilitic endocarditis without any recent change. The inflammation, which is hæmorrhagic in parts, is most marked in the ascending portion of the vessel, and this is a usual occurrence. This patient was, unfortunately, too ill to be taken to the Royal Victoria Hospital for cardiographic examination.

It is a common experience to see heart patients who have previously had a syphilitic infection, and who have usually come in consultation on account of pain—either true anginal attacks, or pain which occurs on effort behind the manubrium sterni, and which may be referred from there into the back, between the shoulders, or into one special shoulder, or sometimes up into the neck, sometimes into the arms, etc. It is extremely difficult in some of these cases to say whether true angina pectoris should be considered to be present, or, where the pain is not of the classical description of "breast pang," some other place in the classification must be sought for it. Some of these patients present definite myocardial change, as evidenced by clinical examination by the electro-cardiograph. Many, of course, present the ordinary clinical features of aortic reflux with occasional associated stenosis, but the one common ground is the symptomatology of retrosternal pain and dyspnoea upon effort. I have one patient before my mind in whom these attacks of pain were so frequent that in walking a distance of half a mile on the level he would have to stop as many as half a dozen times. In this patient no cardio-vascular change of any description could be detected on physical examination, nor was the mechanism of the beat in any way altered in the electro-cardiogram. The blood pressure was not excessively high—about 160. In this patient, on blood examination, the Wassermann reaction was positive. There was no question as to the genuine history of this retrosternal pain, and the strange fact was that this patient, once he got started on a Peace Day celebration march, was able to do the whole march of about five miles on an excessively hot day. I have no doubt his pain is due to aortitis on a syphilitic basis.

The diagnosis of aortitis must in the main depend upon the symptoms. It is possible, by means of x-ray examination, in most cases to show a general enlargement of the aorta. It is occasionally possible to hazard the opinion that in these patients there is more dullness behind the manubrium sterni than is normal. Well-marked pulsation in the episternal notch, tracheal tugging, and an occasional alteration in voice should be sought for. I would urge, however, as a matter of deduction, that if a patient with the signs of aortic endocarditis develops definite symptoms of pain, and dyspnoea, we may conclude that the aorta is often more to blame in the circulatory decompensation which results than the actual myocardium. It is well known to every clinical observer that the vast majority of patients who suffer from aortic regurgitation are free from pain for years. Therefore we might argue that it is only when the aortitis becomes marked that its pain becomes prominent.

The pathology of aortitis is of a chronic inflammatory type—that is to say, the aorta loses its resiliency. It requires but little consideration to appreciate fully the fact that, while the first *vis a tergo* in the circulation is the contraction of the heart muscle, the second *vis a tergo*—if one might so term it—is due to the resiliency of the aorta, which takes up the shock of the force of impact the cardiac muscle gives to the blood, and returns this force in the form of the pulse wave transmitted over the arterial system. This mechanical necessity for the resiliency of the aorta has only to be considered in order that we may realize what a chronic inflammation of this thick elastic tube must mean. The source of this retrosternal pain would seem to be undeniably the aorta, and the cause the chronic inflammation that is present in it.

The prognosis in these cases of aortitis seems to me to be uniformly unfavourable. Certainly our experience, since we began regularly to do the Wassermann reaction, would point to the fact that the old clinical rule stands, that "Where symptoms begin to develop in an aortic lesion there is usually rapid decline of the circulatory efficiency." As already stated in the opening part of this paper, the myocardial condition does not seem to be a very great element in actual prognosis. In the first case cited, we were definitely certain, from the clinical side, that the myocardium was efficient, with a small aortic lesion, and this was borne out by *post-mortem* examination. The prognosis in the second case depended entirely upon the symptoms of the persistent severe pain and dyspnoea, with the fact that the general appearance of the patient was septic, and he had a positive Wassermann reaction.

With regard to treatment, in the first few cases we adopted mercurial inunction and large doses of potassium iodide, but for the past six months, in all the cardiac cases

with a positive Wassermann reaction we have endeavoured to improve the condition by intravenous injection of small doses of novarsenobillon. It would appear that there is some improvement possible, but unfortunately the Wassermann reaction persists in spite of this treatment. It is too early for us to state definitely whether we shall be inclined, as the result of this treatment, to alter the very unfavourable prognosis that we are inclined to form in aortitis.

TREATMENT OF CEREBRO-SPINAL FEVER BY MONOTYPICAL SERUM.

BY

W. T. MUNRO, M.D., Ch.B., D.P.H.,
 DISTRICT LABORATORY, COLCHESTER.

I VENTURE to bring to notice a digest of twelve consecutive cases of cerebro-spinal fever which have come to my notice, and to point out in particular that no case has died where it was possible to treat by monotypical serum.

The work of Dr. M. H. Gordon, C.M.G., who was in charge of the Central Cerebro-spinal Fever Laboratory, has demonstrated that 98 per cent. of cases of cerebro-spinal meningitis serologically fall into one of four types.

Those of us who were engaged in the work at out stations were supplied with agglutinating serums to the four types. It was a relatively easy matter to determine the type.

A growth on tryptagar was obtained from the cerebro-spinal fluid, emulsified, heated to 65° C. to destroy the autolysin, and tested against the four types of agglutinating serums in dilutions of 1 in 50, 1 in 100, and 1 in 200; 0.5 c.cm. serum was mixed with 0.5 c.cm. emulsion of cocci, and the final dilutions then were 1 in 100, 1 in 200, and 1 in 400. Clear and absolute agglutination could usually be readily seen at the end of eighteen hours, and thus the case was typed. For treatment pooled serum containing 50 per cent. of antibodies to Type 1, and 50 per cent. of antibodies to Type 2 was issued, and in addition monotypical serum to be used after the type was determined.

It might be argued that pooled serum ought to contain antibodies to all the types, but typing of the cases as they came showed something like 40 per cent. to be Type 1, 42 per cent. to be Type 2, 16 per cent. to be Type 3, and 2 per cent. to be Type 4.

It will be at once seen that to add antibodies of Type 3 and Type 4 to such a pooled serum would reduce its value by 50 per cent. to 82 per cent. of the total cases. These serums were prepared under the direction of Dr. Gordon, and were tested both as regards their antimicrobial potency and their anti-endotoxigenic values.

Of the 12 cases which came to my notice, 8 recovered, and 4 died. The deaths all occurred in soldiers; two of them were dead before they were seen by me, and the other two exanimate.

On July 11th, 1918, I was called to a military hospital to see a man who had been newly admitted. I saw him at once, but he had just died. The striking feature was a deep plum-coloured rash over the thighs, legs, arms, neck, cheeks, and even to the tip of the nose. The deep mottled colour and confluent nature of this rash marked it out for special notice. Lumbar puncture after death yielded a turbid fluid full of polymorphs and Gram-negative diplococci, and most of the diplococci were extracellular. The growth which was obtained proved to be Type 2.

The second case seen after death was from the same unit. A medical officer who came to see me later on the same day said that a man had been admitted to the same military hospital at 4 p.m. the day before, and had died at 4 o'clock that morning. I saw the body in the mortuary at 11.30 a.m. There was here, too, a deep plum-coloured rash, and puncture seven and a half hours after death yielded a growth which proved to be meningococcus Type 2. The fluid was turbid and full of polymorphs, and contained many Gram-negative diplococci, mainly extracellular.

I was not able to get any good histories of the illnesses of these two unfortunate cases. They were no doubt missed as cerebro-spinal fever cases owing to the number of men being dealt with in the July epidemic of influenza.

One of them had been ill from July 2nd to 5th with influenza, and one returning from leave had made a long railway journey on July 7th. These two men were

stationed at a brigade training school. There were 56 other men there, and 6 of them were found to have meningococci in the posterior nasopharynx. With the two fatal cases this gives a carrier rate of 14 per cent. (8 out of 58). All the carriers proved to be Type 2.

The third death occurred in a man sent a thirty mile motor journey to a military hospital as "mental." He was seen just before death, when there was a deep mottled rash over arms and legs. Lumbar puncture at noon yielded a very turbid fluid full of polymorphs and Gram-negative diplococci. Pooled serum was given at the puncture, but he never rallied, and died a few hours later.

The fourth case was similar. He died three hours after being first seen. Both of these cases yielded Type 2 growths.

The feature common to them all was a deep mottled rash, and indeed I had begun to look on these rashes as being Type 2 cases, and I risked the type in the last case and gave Type 2 serum on the first and only puncture, and not a pooled serum. The second feature was the very great number of extracellular diplococci in the fluid.

In Case III no contacts were examined by me, and in Case iv, among 24 contacts 4 were positive, so that with the case there were 5 carriers among 25 men, giving the carrier rate of 20 per cent. Necropsies were not obtained.

Reviewing these cases, all were Type 2. Two were dead before any specific treatment was asked for, the second two were moribund when first seen, and died within four hours of lumbar puncture—that is, they were dead before the type could be determined. The age of three of the cases was 18 years, and one (Case III) was 37 years of age.

All the cases showed the usual signs and symptoms of the disease. There were eight recoveries. One was a woman aged 49, and one a boy aged 11. The others were soldiers, four of whom were 18 or 19 years of age, one was 24 years, and the last, a discharged soldier, 34 years of age. In all the cerebro-spinal fluid was turbid, with polymorphs and Gram-negative diplococci, mainly intracellular, but in one patient, whose condition was very critical for some days, the fluid showed many extracellular diplococci.

Seven of the cases showed slight rashes, mainly petechial, and only at points of pressure. Five of the cases gave growths which proved to be Type 1, two proved to be Type 2, one of these showed many extracellular organisms, and one case (the boy) was Type 3.

Causation.

Of the eight patients that recovered, three had suffered from influenza and were recovering when they took ill. Three had had long railway journeys before becoming ill. Of these, one left Aldershot on March 6th, 1919, and became ill on March 8th, 1919; a second, who left Portsmouth on February 12th, 1919, became ill February 15th, 1919; a third left France May 11th, 1919, and became ill three days after reaching home. This is to be compared with Case II among the deaths, who left his home, London district, July 7th, 1918, and became ill on July 10th, 1918.

No depressing factors such as T.A.B. inoculation or vaccination could be traced as having any connexion with the onset of the illness. Four only of the cases had less than six months' service and two of these were the two deaths first recorded. There was no overcrowding.

Examination of Contacts.

In two of the cases no contacts were examined by me. In the case of the woman who recovered, all the contacts examined proved negative with one exception. The patient was Type 1, and the contact was Type 2, but it was subsequently ascertained that this carrier had nursed a patient of Type 2 who died at Ipswich.

This patient could have hardly infected others, as she occupied a room to herself in a good-sized house, but it is noteworthy that a pure growth of Type 1 coccus was obtained from her nasopharynx. Of the five remaining cases, one slept in a six-roomed empty house with thirty other men. There were six carriers besides himself, all Type 1, a carrier rate of 23 per cent. A second, who occupied a billet with two other men, showed one carrier, that is, two out of three men were carriers. No others were found in the company. In the case of the third, the patient who took ill after coming from Aldershot, two out of the sixteen men examined were carriers, but they were Type 1 and the case was Type 2. This could scarcely have infected the unit in two days; and two carriers were accidental discoveries. The fourth lived in barracks with thirty other men; four carriers found, three of whom corresponded in type with the patient coccus; therefore there were four serologically similar 1

among thirty-one men, a carrier rate of 13 per cent. In the fifth case twenty-nine contacts showed five carriers, and with the positive cases gives 20 per cent. carrier rate, all Type 1.

Treatment.

As soon as a likely case of meningitis was seen a lumbar puncture was made, and if the fluid was turbid and middle-disease excluded, pooled serum equal to two-thirds of the volume of cerebro-spinal fluid withdrawn was given intrathecally. The serum was given at body temperature and allowed to run in by gravitation, thus ensuring a slow and even flow. Generally 60 to 70 c.c.m. of turbid fluid was withdrawn, and 40 to 50 c.c.m. of pooled serum allowed to run in.

The fluid was at once examined for diplococci, and plated on at least four tryptic agar plates. By next morning there was always sufficient growth to enable one to determine the type. It is a matter of urgent importance to determine the type with the least possible delay in the manner described above. Agglutination is more rapid at 55° C. than at 37° C.; Tulloch has shown that this is due to the more rapid convection currents. Browning¹ in his work on the agglutination of the enterica group, points out that agglutination can be hastened by alternate heating and cooling. After the rack has been in the incubator at 55° C. it should be removed and left at room temperature for ten minutes and then returned. He shows that agglutination will sometimes occur suddenly in the cold. This principle applies to the meningococcus. A long narrow tube which exposes a greater surface to variations of temperature gives more rapid convection currents.

I always set up my agglutinations in a Wassermann tray. I use a hot-air incubator at 55° C. and remove the tray at the end of thirty minutes, allow it to stand for five minutes in the cold, and then return it. I can generally see agglutination beginning in three hours, and it is thus quite possible to give the patient his own type serum on the second day. I see the patient on the morning of the second day, and if he does not seem too distressed I wait for the type, and do the second lumbar puncture on the afternoon of the second day.

In the eight recoveries this procedure was adopted. Five of the cases were Type 1. One required fourteen injections of Type 1 serum before he finally recovered. A second required four injections; and the three others had each three injections of monotypical serum.

The first patient, who required fourteen injections, had to all appearance recovered after two monotypical injections, but relapsed three days later; he finally recovered with the use of serum and an autogenous vaccine. The injections were given daily, and every Type 1 case made a long stride towards recovery after the first injection of monotypical serum. Two cases of Type 2 were punctured morning and evening, one for three days and the other for five days. A monograph issued by Major Hine, of the Central Cerebro-spinal Fever Laboratory, pointed out that Type 2 serum was not so rich in anti-endotoxin as Type 1 serum, and he suggested puncture twice a day, a procedure which was followed here with excellent result.

The only case of Type 3 was the boy of 11 years. He had been ill for five days before he was seen. He only showed any change after the type was determined, and he was given Type 3 serum. He recovered after four injections. He was the only case to show any permanent defect as a result of the disease. He was deaf, and this nerve deafness was probably present before treatment was begun. As above mentioned, the one case that relapsed was also treated with an autogenous vaccine. If a vaccine is to be of any use it must be combined with lumbar puncture. In the ordinary case the intracerebral pressure is high, and until this pressure is reduced by puncture no antibodies can reach the seat of infection. The use of vaccine does raise the resistance, and combined with lumbar puncture the immunizing response can be carried to the centres of infection.

Since this paper was prepared for publication a thirteenth case came to my notice. The patient, a girl aged 14 years, was treated by Dr. W. F. Corfield, Medical Officer of Health, Colchester, at Myland Infectious Hospital. I ascertained that the infection was Type 3; she recovered after four daily injections of Type 3 serum. This case was complicated by unilateral iridocyclitis, no doubt of meningococcal origin. She had been ill for four days before admission, and the right iris was then seen to be fixed in semi-dilatation; the cornea was dull, and there was pericorneal injection. The eye was treated energetically with atropin ointment and hot fomentations; undoubted optic neuritis is present, and there is some injection which is regressive; the patient can see and count fingers. It

seemed at one time that panophthalmitis would develop. This complication is not uncommon,² and is stated to have been present in 3 to 6 per cent. in a Paris epidemic. It is worthy of note that the only two cases to have after-effects belonged to Type 3; I would not attribute any special virulence to Type 3, but believe that the complications were due to the cases coming under treatment late. In this connexion the constant warning of military medical officers to be on guard for any possible case of meningitis allowed of an early diagnosis. The boy of 11 years with deafness first received treatment on the fifth day of his illness, and this last case on the fourth day.

Summary.

1. Early treatment affords every prospect of success.
2. Type 2 is the most virulent.
3. A deep confluent rash is of grave significance, and many extracellular diplococci mean a severe case.
4. To ascertain the type early, and then use monotypical serum, affords the best chance of recovery.
5. Of ten cases that had serum eight recovered.
6. No case that lived long enough for the type to be determined died.
7. Vaccine treatment may help in a relapse when improvement is slow.

Nine of the ten cases who had serum were treated at Myland Infectious Hospital, Colchester. To the staff there, for careful nursing, and to my laboratory assistant, Miss Carder, grateful thanks are due.

THE ASSOCIATION OF LETHARGY WITH THE INFLUENZA BACILLUS.

BY

W. M. CROFTON, M.D.,

LECTURER IN SPECIAL PATHOLOGY, UNIVERSITY COLLEGE, DUBLIN;
PATHOLOGIST STEEVENS'S HOSPITAL.

In a paper published in the *BRITISH MEDICAL JOURNAL* for March 1st, 1919, I gave my reasons for considering that *B. influenzae* was the cause of influenza. They may be briefly recapitulated:

1. The bacillus can be isolated from the large majority of cases of influenza, 80 to 90 per cent.; between the epidemics from only an occasional case that must be considered a carrier.
2. A pure influenza antigen protects when used prophylactically. It is interesting to note the close correspondence of my figures using a pure antigen with Sir W. Leishman's figures for the army using a mixed antigen, approximately an 86 per cent. protection in both cases.
3. A pure influenza antigen rapidly aborts the disease in uncomplicated cases.
4. A pure influenza antigen during a reaction can produce transitory typical symptoms of the disease.
5. The serum of influenza patients agglutinates the influenza bacillus sometimes in a dilution as high as 1 in 1,000.

It is, in my opinion, a great pity that pure antigens are not being used for prophylactic purposes on a large scale. No conclusion can be come to by the use of mixed antigens.

If the connexion of influenza with the influenza bacillus is not generally accepted, still less is the connexion of it with encephalitis lethargica. This disease is vaguely thought to have some epidemiological connexion with the influenza epidemic. The following brief accounts of four patients treated with pure influenza antigen may encourage others to try the method and help to clear up the etiology of a dangerous condition.

CASE I.

A medical student had had for some days a temperature ranging from 100° to 102° before taking to his bed. He complained of seeing double. He became increasingly sleepy, was delirious, and had hallucinations; when spoken to he could be roused up, and talk fairly sensibly. His conjunctivae were congested; he was badly constipated, and passed urine under him. He had, in fact, symptoms suggestive of lethargic encephalitis. On the chance that the infection might be caused by the influenza bacillus (the case occurred during the epidemic) I gave him subcutaneously 2½ million pure influenza antigen. The improvement was marked at the end of twelve hours. Thirty-six hours later I gave him 5 million, and forty-eight hours later 7½ million. After this he had complete control of his functions and he was no longer lethargic, although his memory was still defective. He still had difficulty in reading, and his temperature was not quite normal—99° F. I then gave him 10 million in the morning, forty-eight hours after the last dose; that evening his lethargic symptoms returned in full

intensity, although there was no further rise in temperature. His mind did not become normal again for two days. He made a rapid convalescence, but could not read for any length of time or study for some months. The focal reaction after the last dose makes it, to my mind, certain that the influenza bacillus was infecting his brain.

CASE II.

An elderly gentleman when first seen by me had been ill for a week with lethargy and bronchopneumonia. *Micrococcus flarus*, streptococci, and influenza bacilli were isolated from his sputum. He was exceedingly ill. The temperature was 102°, the pulse 90 to 100. He was given at once a mixed antigen containing the above microbes pending the making of an auto-genous antigen. The first dose was ½ million of each. There was a distinct improvement in twenty-four hours. Forty-eight hours after the first dose he was given 2½ million of each. The next dose of his own antigens contained the same amount, and was given at a similar interval. The doses were continued up to 20 million of each. All his symptoms and physical signs rapidly cleared up so that at the end of ten days he was convalescent. He had no recognizable reactions after any dose, and made an uninterrupted recovery.

CASE III.

A woman, aged 22, became ill on December 25th, 1919. She felt very exhausted and sleepy, and in her sleep talked continuously, was very restless, and had jerking movements of the limbs. She had been overworking, and had had two falls the week previously; she had had a previous nervous breakdown at the age of 16, when she suffered from undue sleepiness; for some time I thought her symptoms could be similarly accounted for. When awakened from sleep she roused with a start, and told me she was very well; after a few minutes her eyes became fixed, the eyelids closed, and she was asleep again, resuming the muttering and restless movements. She roused occasionally, and took food well. She was very constipated, but got out of bed to urinate. At first she used to get up to sit by the fire, but always went to sleep in her chair.

After a time, since the sleepiness was getting worse rather than better and her memory for my previous day's visit was a complete blank, I determined to give her a dose of 2½ million pure influenza antigen. It was given at 10.30 a.m. on January 13th. She was asleep within five minutes of getting it. Two hours after she woke up very excited, nervous, and shivering, and was given 10 grams of aspirin. The unpleasant symptoms passed off in an hour or two, and that evening she was much better, was able to talk rationally, and had no symptoms of lethargy. She slept much more normally that night and was much less restless in her sleep. When I saw her next morning she laughed and talked to me quite naturally. She improved steadily for some days, then began to get sleepy again and the other symptoms returned. On January 20th I gave her 2½ million, and she had the same symptoms as before but to a less extent, and next day was awake smiling and talking to me normally. Three days later, on January 23rd, I gave her 3½ million; she went to sleep after it, and remained lethargic that and the whole of the next day, being roused up to take food and then going to sleep again. Forty-eight hours after she was herself again. Since then she has been given 5 million on February 2nd and 5 million on February 13th; this dose was delayed by three rather severe attacks of palpitation and then an attack of colitis. On February 16th she was given 7½ million and on February 20th 10 million. On February 23rd she was quite convalescent. I shall continue her doses up to 20 million so as to leave a margin of safety. The temperature was normal throughout.

CASE IV.

This was a minor case. The patient, a bank clerk aged 20, had to leave her work early in December on account of feeling ill, having a severe headache and backache, feeling very drowsy and seeing double. When the acute symptoms had disappeared she went back to work, but could not do her work on account of not being able to focus. I saw her on December 22nd; she was then fairly well, with the exception of the diplopia and being very easily tired. I assumed from her history that she was a case of influenza. I gave her three doses of pure influenza antigen, namely, 5 million, 7½ million, and 10 million, at weekly intervals. She had marked general and focal reactions, beginning a few hours after the first two inoculations, becoming so drowsy that she had to go to bed, and slept without stirring. The diplopia was intensified the next day, but then gradually improved until the reaction after the second injection; she had much less reaction after the third, and then improved so rapidly that I found it unnecessary to continue treatment.

I have found that pure influenza antigen rapidly relieves other cases of post-influenzal debility.

No doubt those who do not believe in the specificity of antigen-therapy will question the diagnostic conclusions I have drawn from these cases, and also my belief in the specific therapeutic results obtained. I believe that such results can only be obtained with a specific antigen or antigens, and think the test is just as specific and significant as the subcutaneous tuberculin test.

APPENDICITIS WITHOUT PROTECTIVE
STIFFENING OF THE ABDOMINAL
WALL.

By JOHN D. MALCOLM, F.R.C.S. EDIN.,

CONSULTING SURGEON, SAMARITAN FREE HOSPITAL, LONDON.

PROTECTIVE contraction of the abdominal wall over the caecal region is a well known indication of appendicitis, but its importance is sometimes exaggerated. Twice recently it has been suggested to me that appendicitis could not exist because of the absence of this sign. The following case is to the point:

On January 24th a lady, aged 23, being apparently quite well, was seized with intense abdominal pain about 3 p.m. At 5 p.m. Dr. J. A. MacLaren found a round swelling in the appendix region. It was very tender, but the fingers could be pushed deeply into the tissues all round and close to it without causing pain or muscular resistance. The temperature was 102° F., the pulse 100. A dose of castor oil was given, and two days later all swelling, pain and fever had gone. On January 30th I detected only the slightest tenderness at one spot deep in the caecal region. There was no resistance to palpation.

At the age of 3 months and again at 12 years this patient had severe illnesses affecting the abdomen. Occasional stitches in the side and indigestion, characterized chiefly by breathlessness, had been increasingly troublesome within the last half-year. Stone in the ureter was excluded by x-ray examination, and appendicitis of old standing was diagnosed.

When the abdomen was opened, the appendix, except about half an inch at its base, was firmly adherent in a peritoneal pouch behind the caecum. It measured 4½ in. by ½ in. throughout its length, and it was of firm consistence, all its coats being thickened and its canal containing a little soft faeces. It was removed and recovery was uncomplicated.

There is little doubt that this patient had her first attack of appendicitis in childhood. The absence of protective contraction of the muscles was due to the position of the appendix and to the fact that a spreading peritonitis was prevented by the adhesions, which had long existed. In such circumstances the danger is not so great as when the appendix lies free amongst the coils of small intestine. But in this case it would have been a serious mistake to have delayed surgical treatment. The operation was not easy, and it would have been much more difficult and dangerous had it become necessary during an acute inflammatory attack.

A dose of castor oil is sometimes the best treatment for an appendicitis, always provided that an immediate operation can be arranged if this method is not successful, and that the rapid and apparently complete cure which may be effected does not mislead the medical adviser.

A NOTE ON ARTIFICIAL PNEUMOTHORAX.

WITH DESCRIPTION OF A NEW NEEDLE.

BY

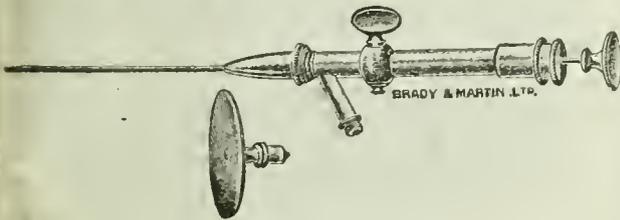

FREDERIC C. COLEY, M.D.,

PHYSICIAN TO THE NORTHERN COUNTIES HOSPITAL FOR DISEASES OF
THE CHEST, AND TO THE BARRASFORD SANATORIUM.

I HAVE been using for many months a pneumothorax needle which has, I believe, several important practical advantages. The ordinary Saugman's needle with which I began to work has an obvious defect. It has no provision for excluding communication with the external air when the stopcock is opened to admit the stylet. This is the more objectionable because the stylet is required just when such communication might be most dangerous, namely, when oscillations of the manometer are absent or imperfect. If the stylet has been successful in clearing the needle and establishing free oscillations, it will be practically impossible to prevent some air from being sucked into the pleura while the stylet is being withdrawn, before the stopcock can be closed, and that air will not be aseptic. Dr. Clive Riviere obviates this difficulty by tying a piece of sheet india-rubber over the open end of the instrument. I believe he uses this either with his own trocar and cannula in primary operations, or for an ordinary needle in doing "refills." I have secured the same object, I believe more effectually and simply, by attaching to the mount of the needle a little stuffing-box like that of a Potain's aspirator. But in Potain's instrument the stuffing-box simply plugs into the mount of the needle. This

makes a joint which is apt to be leaky; and moreover, as we have experienced, it is quite possible for the stuffing-box with the stylet to tumble off from the mount of the needle at some extremely inopportune moment. In my instrument the stuffing-box is screwed into the mount, and a washer secures perfect air-tightness. In Potain's trocar and cannula, as usually supplied by the instrument makers, the stuffing-box has a leather packing. I prefer to pack it with cotton-wool which is effectually sterilized when the instrument is boiled. From the stopcock of the needle to the stuffing-box is 4.5 cm. This affords sufficient space to make it quite easy to withdraw the stylet so as to permit closure of the stopcock without risk of bringing the stylet right out of the stuffing-box and so opening communication with the external air.

The form of the end of the needle is very important. The end of an exploratory or aspirator needle is ground upon a wheel, which makes it slightly concave on the surface that is ground, and causes it to end in a sharp point. This is, of course, desirable in instruments of that kind. But it is quite inadmissible in a needle for the induction of artificial pneumothorax. We want an instrument which will pierce the parietal pleura but push the visceral pleura before it unwounded. Obviously no instrument can do this when the puncture happens to be made at the site of an adhesion. But even where there are no adhesions a needle with a fine point will probably wound the lung. What is wanted is a needle with a round cutting edge, rather than a sharp point. This is produced by grinding the end of the needle on a flat hone, instead of a wheel, the result being naturally a perfect oval, which is just the form which is required. As the result of experiment, I have found that an angle of about 22.5 degrees with the axis of the needle (a quarter of a right angle) is best. If it is more acute than that there will be more danger of wounding the lung. An angle of 45 degrees is too blunt. It is apt to push the parietal pleura before it, as I have found to my sorrow.

Needle and Holder.

I have contrived an appendage to the needle, which I have found extremely useful and convenient. I call it the "holder," for want of a better name. The needle passes through it, and is fixed by a nut, which works on a conical screw, like the chuck which fixes a point in a small drill. This part of the holder is attached to the centre of an oval plate, 3.5 by 2 cm. This plate is slightly convex on the side which lies against the patient's chest. In use the holder is slipped on to the needle and adjusted so that the length of needle projecting through the cover-plate corresponds with the estimated thickness of the chest wall. But it is not screwed up so tightly as to preclude the possibility of readjustment *in situ* if that should be found necessary. As soon as satisfactory oscillations occur I give the needle into the charge of my assistant, who is instructed to hold it only by the "holder," which is to be pressed closely to the chest wall. There is then no fear of the needle being inadvertently thrust more deeply in, or partially withdrawn, which is very apt indeed to happen, especially with an inexperienced assistant, or one to whom the process of inducing an artificial pneumothorax is an interesting novelty. Having usually to work with such assistants, I have found the "holder" extremely useful.

The stylet should be long enough to project about a centimetre beyond the point of the needle. It is then sometimes useful as a probe to help us to judge whether we have reached the pleural cavity. In order to be used in this way it must not fit the needle too tightly to move freely in it. For the same reason great care must be taken to keep the stylet perfectly straight. The end of it should be ground perfectly flat so as to make it as fit as possible to push the visceral pleura before it without

inflicting a puncture; but of course the greatest possible gentleness must be used, the stylet being necessarily very thin.

This needle is made in accordance with my suggestion by Messrs. Brady and Martin of Newcastle-upon-Tyne.

DERMATITIS ARTEFACTA IN THE ARMY.

BY

HALDIN DAVIS, M.B. OXON., F.R.C.S.,
DERMATOLOGIST TO THE ROYAL FREE HOSPITAL.

Not much has been written in this country about dermatitis artefacta in connexion with the army. A single case was shown to the Dermatological Section of the Royal Society of Medicine by Dr. Sibley in April, 1918. The patient was a Russian suffering from an extensive pustular eruption, or folliculitis, which the members present generally agreed was an artefact produced for the purpose of evading military service, and it was stated that this case was typical of many others which had been met with at medical boards. In the army itself, however, apparently not much was seen of these cases, although several medical officers reported that a good many men suffering from impetigo and scabies made the most of their troubles, and did what they could to prevent themselves from getting well too quickly. But there were not very many cases reported of men who were found to be suffering from purely artificial lesions. Dr. MacCormac in his excellent paper on Skin Diseases under War Conditions (May, 1917) mentions a "linear" type of impetigo, of which he gives illustrations, and suggests, as indeed do the illustrations published, that this may be an artefact. During six months in which I had charge of the dermatological cases in Alexandria I saw only one case of dermatitis artefacta, but a large portion of this period was after the armistice, when there was no temptation to produce skin lesions. The one patient I saw suffering from this condition was a simple and typical case. He had numerous lesions on the forearms (both right and left) and also on the shins and the dorsum of the feet, especially on the right. He had been in hospital for some considerable time before he came under my care, and on my giving a very strong hint that I understood the real nature of his disease he permitted the lesions on his arms to heal up quite promptly, but other lesions continued to appear on the right ankle. I had the satisfaction one morning of catching him *in flagrante delicto*. He occupied a tent pitched on sand, and consequently was unable to hear footsteps outside. I approached the tent one morning in the course of my ordinary round, really without any thought of catching him, and I actually surprised him lying curled up on his bed in the act of scratching his ankle gently with the forefinger of his right hand. The lesions were all of characteristic oval shape, obviously scratch marks, with the long axis parallel with the long axis of the limb.

Cases of dermatitis artefacta cannot have been particularly numerous among the British forces. There were certainly more in other armies, and in some instances considerable ingenuity was exercised in the production of the lesions. One of the most interesting papers is by Professor Dubreuilh of Bordeaux. Another is by Burnier, who gives a list of diseases imitated. The list includes the following:

Scabies, imitated by pricking the skin with a needle and rubbing in brine.

Pustular dermatitis by rubbing in croton oil or thapsia.
Eczematiform dermatitis in various ways; sometimes substances are employed, such as iodoform or mercury, which act by a special idiosyncrasy well known to the malingerer. Other men, not provided with a special idiosyncrasy to some drug, employed ordinary well known irritants, such as turpentine, petrol, sodium sulphide, etc.

Bullous dermatitis was often produced by the use of blistering plants, found especially among the Ranunculaceae and Cruciferae. Chemicals were also sometimes employed.

Abscesses were produced by the insertion of thread, horsehair, or splinters into the skin and the hypodermic injection of turpentine or petrol. The favourite site of injection was the back of the left hand.

Oedema was produced by the use of a ligature, usually a broad tape, because it was less painful than a narrow one.

Bruises were often produced by repeated tapping with a hard object upon the same place.

Dubreuilh records still quaint examples of misplaced ingenuity. In treating cases of artificially produced ulcers

on the legs he found that it was by no means sufficient to use an occlusive dressing, which was only removed or touched by an attendant. The patients circumvented this difficulty by obtaining a hypodermic syringe and injecting croton oil through the bandage. He found it necessary to use what he calls an "inviolable dressing." This consisted of a very thin zinc plate interposed between the bandage and the ulcer. This prevented the injection of croton oil on to the ulcer, and in some cases the mark of the needle was found on the zinc when an attempt had been made. In other cases fresh lesions appeared round the edge of the plate. Another ingenious method employed to produce lesions under a bandage was the introduction of a rough iron wire or a twig between the bandage and the skin. The most difficult cases to deal with were those of croton oil syccosis, because these could not be completely covered up all day, and hence were always occasionally accessible to the malingerer.

Under ordinary circumstances artefacts, as is well known, are rare amongst men, but the temptations which led to their production in military life are to some extent continued among pensioners. The inducement to obtain a pension of several shillings a week by the cultivation of a few not very painful ulcers on the shins is in some cases too great for the moral strength, and there are a fair number of such individuals scattered over the United Kingdom. Two of them have recently come under my own care, and I have seen others. My own two cases greatly resembled one another. Each said he had suffered from ulcers on the legs since 1915. In both they had succeeded a shrapnel wound of the calf which, of course, had become septic. They both gave a history of treatment in many hospitals, sometimes getting better for a time but always breaking out afresh. Both had had the advantage of the most elaborate pathological investigations and many vaccines, and much electro-therapy. In both the lesions were situated on the shins, in one case exclusively upon the right side and on the outer side of the leg; in the other case they were principally on the right, but there were also a few on the left. In appearance, when the patients were first seen, there was nothing to distinguish the lesions from ordinary simple ulcers doing their best to heal.

It is the habit of such patients to flatter in turn each new hospital which they attend by allowing the ulcers nearly to get well during the first few weeks of the treatment, and in one case I ventured to prophesy to the students that such would be the course of events in this case—and so it was; but after about three weeks the patient arrived announcing that the ulcers had suddenly got much worse again, which was indeed the case. They were much deeper, more inflamed, and (a very important point) the edges presented a white and sodden appearance. The significance of this appearance was of course that it strongly suggested that carbolic acid, probably applied with a match, had been used to produce the lesions. Both my patients were engaged in clerical occupations, in which a few ulcers on the shins would scarcely at all detract from their earning powers, and it can easily be understood that such a position for the ulcers would be far more convenient than the left forearm or hand (usually the site of election for dermatitis artefacta) where they would seriously interfere with their work.

TREATMENT OF GONORRHOEA IN WOMEN.

BY

R. STAFFORD FOSS, M.B., B.S. LOND.,
M.R.C.S., L.R.C.P.,

LATE CLINICAL ASSISTANT, VENEREAL DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE multiplicity of solutions recommended for local application both in acute and chronic cases of gonorrhoea in women is a proof that we have not yet found an ideal formula. The comparative failure of most reagents is due to the inaccessibility of the gonococcus.

The majority of cases seen in the clinic have reached the chronic stage; in nearly 50 per cent. of the cases the cervix uteri is the only part involved. The cervical canal is lined by ciliated columnar epithelium richly supplied with glands of the compound racemose type; in these glands

the gonococcus finds its ideal nidus, and is untouched by the ordinary methods of irrigation with antiseptic agents.

Though it is difficult if not impossible to ensure the penetration of an antiseptic, it seems rational to suppose that a greatly increased secretion from the glands will produce a flushing out which will bring the gonococcus within reach of the antiseptic. Glycerin acting on a mucous surface produces a large secretion, varying directly with the concentration. It is possible to use it pure, but a high concentration tends to produce discomfort, which in some patients amounts to actual pain. I found that 25 per cent. glycerin was the most satisfactory strength. As a bactericidal agent I chose methylene blue, partly for its great affinity for the gonococcus and partly because the anilins are absorbed by mucous membranes and even by squamous epithelium:

Methylene blue	1 gram.
Glycerin	25 c.cm.
Aq.	ad 100 c.cm.

In acute and chronic cases it was applied as follows: The cervix was exposed with a Fergusson's speculum and swabbed with a saturated solution of sodium bicarbonate in order to remove mucus and discharge. A gauze plug 12 in. by 2 in. was dipped for half its length in the solution; this end was packed tightly against the cervix, the rest lightly in the vagina. The speculum was then withdrawn. The plug was removed after twenty-four hours. This was carried out for five days and then for two days dry plugs were used. This rotation was continued as long as the discharge occurred.

There are two contraindications for the use of this method:—(1) Pregnancy. Plugging the vagina is inadvisable owing to the increased liability to abortion in these patients, in whom the endometrium is generally diseased. (2) The puerperal state. The vascular engorgement of the uterus persists for some weeks *post partum*; the glycerin acts so powerfully that an undesirable amount of secretion is produced attended by severe pain.

General treatment is carried out on the usual lines. Urinary antiseptics and gonococcal vaccine are given as indicated. In addition to cases of true arthritis a large number of patients complain of indefinite wandering pains (arthralgia). These are benefited by a graduated course of vaccine—a course of six injections given weekly, commencing at 5 million and working up to 150 million.

At present it is impossible to give a satisfactory standard of cure in women. It is on the clinical symptoms alone that we can judge. When the general symptoms have gone and the discharge has remained absent when treatment is suspended, then we can hope that a cure has been effected. Smears and cultures from the cervix have proved deceptive and generally useless, and complement fixation, recommended by Gilbert Smith, has so far proved disappointing.

The advantages of the solution are:

1. Erosions of the cervix respond very rapidly to the treatment, and healing occurs with a disappearance of oedema and a return to normal size.
2. An acute, and especially a chronic, discharge is stopped in a short time.
3. It is a painless and effective method of dealing with the deep-seated gonococcus.

I am indebted to the courtesy of Dr. T. Anwyl Davies for permission to give full trial to the treatment in the department.

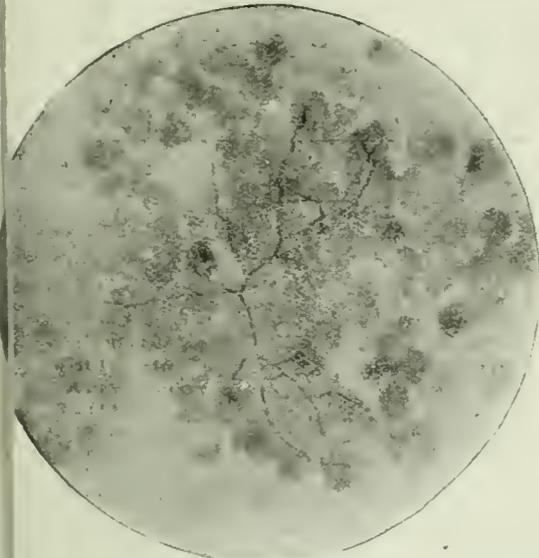

THE scheme for the supply of ambulances for civil work in the United Kingdom, which was brought into force by the Home Service Ambulance Committee of the British Red Cross Society and the Order of St. John, continues to make progress. At the end of last year 238 ambulances were in use; the number has since risen to 252, and 54 others will be supplied as soon as the Ford chassis ordered last autumn can be obtained. The total number of cases carried since the inception of the service last summer is 5,227, and the mileage run is over 68,000 miles. The rise in the cost of petrol has caused anxiety to local committees, and the central committee has supported the petition to the Prime Minister against the increased charges for petrol.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A SIMPLE METHOD OF CULTIVATING THE MICRO-ORGANISM OF ACTINOMYCOSIS.

The object of this brief note is to draw attention to two points with regard to cases of actinomycosis. The first is the fact that instances of this disease are apt to be overlooked unless film preparations are invariably made from purulent material submitted for bacteriological examination. The writer has had experience of two tragic cases in which, apparently from this omission, the true nature of the disease was only diagnosed shortly before death. One of these cases was a young woman who had suffered for some months from metastatic abscesses; a number of consultants had been called in, but as blood cultures were negative and cultures from the pus had only yielded staphylococcus, the condition was thought to be due to the micro-organism. The writer saw the patient for the first time a few hours before her death. A film of pus discharging from a sinus in the wall of the abdomen when stained by Gram revealed the typical actinomycotic mycelium seen in the accompanying microphotograph taken by Dr. Albert Normau from the preparation in

Pus showing mycelium of actinomycetes. $\times 700$.

question. The other case was an empyema of some standing which had been attributed to the pneumococcus. Here the detection of actinomycetes, which was present in abundance, was effected too late for treatment either by codic or vaccine to be of avail.

The second point to which I wish to draw attention is that the actinomycetes fungus can readily be cultivated in ordinary nutrient broth to which a few drops of fresh human blood have been added. It is advisable to sow the material in two blood broths, one of which is covered by a layer of oil 1 cm. deep. After incubation for a few days at 37 C., the actinomycetes fungus can be seen growing at the bottom of the tube in small white masses—like little mounds. As a rule, growth occurs first in the broth covered with oil, but when other bacteria are present the actinomycetes may come up first in the aerobic tube. Before using this method the writer could never get a satisfactory primary growth of actinomycetes, but since employing it he has succeeded in doing so with ease in all of seven cases. The practical advantage of getting a growth is that a vaccine can then be prepared. In two cases in which a vaccine of homologous organism was employed improvement followed. In the majority of the cases, however, vaccine treatment was not attempted, as secondary infections were frequent and the disease was too far advanced. Vaccination with stock actinomycetes vaccine is, in the writer's experience, useless; it seems essential to employ the actual infecting the patient. In the case of patients whose discharges clear up under vaccine treatment, it is wise to

preserve a phenolated suspension of the vaccine in a sealed glass tube, so that it may be available in case of recurrence. In one case recurrence took place after an interval of nearly two years.

Bacteriologist to St. Bartholomew's Hospital.

MALIGNANT ENDOCARDITIS IN A WAR PENSIONER.

THE following fatal case of malignant endocarditis seems worth recording for the information and guidance of medical officers who have to deal with pensions claims. This is probably not a unique instance, and may throw light on other difficult and unexpected cases of disability attributable to war service.

A. B. C., aged 31, was a painter before the war, and had one attack of colic in 1913. He served with the infantry of the 48th Division for three years overseas, and kept in very good health. His only sickness on service was a mild attack of P. U. O. in 1916 on the Somme, for which he went to a divisional rest station for about ten days. He was demobilized from Italy in January, 1919, feeling in perfect health and being passed, in his own words, "as A1 by the doctor." In August, 1919, he was compelled to give up work on account of cardiac symptoms. In February, 1920, he died of heart failure in the Bristol Royal Infirmary.

A post-mortem examination showed extensive vegetations on the aortic valves; one tag of vegetations was over an inch long. At the point on the mitral valve where the regurgitant stream from the aorta would impinge there was an exuberant mass of vegetations covering an area about the size of a shilling, which had almost perforated the cusp. There were many septic emboli in the lungs and kidneys. There were recent and old infarcts in the spleen. Dr. J. R. Kay-Mouat (pathologist to the Royal Infirmary) in his report stated that some of the infarcts in the spleen were converted into completely contracted fibrous tissue, which had lost its cicatricial density, and could not therefore be less than a year old.

The importance of the case is evident. The age of the splenic infarcts shows that the disease existed at the time of the man's discharge from the army. Yet neither he nor his medical officer had any reason to suspect this.

J. A. NIXON, C.M.G., M.D., F.R.C.P.,
Physician to the Bristol Royal Infirmary;
formerly Consulting Physician to the
British Armies in France and on the
Rhine.

ACUTE OEDEMA OF THE LUNGS.

I ENTIRELY agree with Dr. Stewart McNaughton that the cases which have been recently described as "acute suffocative catarrh" are identical with the disease known as "acute oedema of the lungs."

Very little notice has been taken in English textbooks of medicine of this rare and extremely interesting condition, although I believe it has been described in French textbooks for a good many years.

It is associated generally with high arterial tension and valvular disease of the heart, and though often fatal is by no means necessarily so.

Some years ago I was called at 3 a.m. to see a domestic servant who had been suddenly seized by this alarming complaint. She was a woman of about 50 who had a mitral systolic murmur, but no symptoms of cardiac insufficiency.

She had gone to bed in her usual health, and woke about 2.30 a.m. with extreme dyspnoea and distress. When I saw her she was pallid and cyanotic with a very feeble pulse and an incessant cough; she was expectorating continually pink froth. There were moist crepitant râles all over the lungs, and she appeared to be practically moribund.

I gave a hypodermic injection of strychnine, and in the course of an hour she gradually began to improve, and within another hour the symptoms subsided and she was able to rest.

The next morning the lung was normal, and she was practically well. All the crepitant moist râles had gone. She had expectorated about a pint of clear pink fluid.

I have not heard of this patient having had any subsequent attack, and do not know whether she is still living.

The condition appeared to me to be allied to angioneurotic oedema, but I think it might be explained by a sudden and temporary dilatation of the left ventricle including the auriculo-ventricular orifice (there was already some incompetence of the mitral valve), and consequent acute regurgitation and engorgement of the pulmonary capillaries.

I remember seeing precisely similar pink frothy expectoration in a patient in whom the chordae tendineae of the

mitral valve had suddenly given way; it continued until he died about twelve hours after the rupture.

HERBERT H. BROWN, M.D.Lond., F.R.C.S.,
Surgeon to the East Suffolk Hospital.

THE COMBINED USE OF NOVARSENOBILLON AND MERCURY INTRAVENOUSLY.

A FEW weeks ago a note describing the combined use of neo-salvarsan and mercury intravenously was published in the BRITISH MEDICAL JOURNAL (December 6th, 1919, *Epitome*, para. 232). Since reading the note I have given several hundred injections of a mixture of 0.45 gram N.A.B. and 2 c.cm. of a 1 per cent. solution of mercury perchloride, with excellent results. The method employed is as follows:

A porcelain gallipot capable of holding 200 c.cm. of water is used as a mixing pot. The gallipot is thoroughly washed and flamed by means of a little methylated spirit, washed again in doubly distilled water, and placed on a sterilized piece of lint. The requisite amount of mercury perchloride is dissolved in doubly distilled water to make a 1 per cent. solution. This solution is kept in a sterilized glass-stoppered bottle. Four and a half cubic centimetres of distilled water are poured into the gallipot from a sterilized measuring glass; 2 c.cm. of the 1 per cent. mercury perchloride solution are added, and a short sterilized glass rod is placed in the solution, which now contains 4.5 c.cm. of distilled water and 2 c.cm. of the 1 per cent. solution of mercury perchloride in the gallipot, and it remains to add the 0.45 gram of N.A.B. Immediately this is added the solution, which was colourless, becomes first yellow-brown, and then dark grey-green. The glass rod is used to stir the mixture thoroughly. A sterilized 10 c.cm. eccentric nozzle Record syringe is used to administer the solution. The solution is sucked up into the syringe, and a platinum and iridium needle is well flamed and then fixed to the syringe. A little fluid is expressed to cool the needle and to obviate air bubbles. The solution is injected into the vein in the usual way. Ten doses can be mixed at the same time, and with a thorough stirring of the mixture before each injection there is a complete combination of the two solutions.

There are several advantages in the combined use of "914" and mercury given intravenously.

1. The mercury certainly gets into the circulation; sometimes after an intramuscular injection the mercury becomes encapsulated, and remains as a hard lump. Again, there is no fear of an abscess in the intravenous method. There is no pain, no limping, and patients will come back for treatment that is painless.

2. The method is quick and time-saving, as both drugs are given at the same time.

3. Lesions clear up more rapidly than when using the drugs separately—that is, intravenously and intramuscularly.

4. Stomatitis has not occurred in a hundred cases I have treated. These cases have all had seven injections, with an eight-day interval between each injection.

5. In the hundred cases I have only had two instances of reaction, and in each it was of the Jarisch-Herxheimer type.

6. At the completion of the course the blood was negative in 95 per cent. of the cases.

Compared with a hundred cases treated in the usual way this is an improvement, as the percentage of negative results was 85.

In these series old tertiary cases are not counted.

REGINALD JOHNSON, M.D.,
M.O. i/c V.D. Wards, Bermondsey Military Hospital.

ILLEGITIMATE BIRTHS AND OPHTHALMIA NEONATORUM.

It has been asked whether the number of cases of ophthalmia neonatorum has increased *pari passu* with the increase in the number of illegitimate births. Ophthalmia neonatorum has been notifiable since April, 1914. Statistics are here given for the six years 1914 to 1919 inclusive in respect of four boroughs—one in Scotland, one in the north of England, and two in the south of England; the averages of the first three years and of the second three years are given. In each of the four boroughs there was a fall in the total number of births, but an increase in the number of illegitimate births, not only in actual figures but in proportion to the total number of births. In the first and second boroughs the increase in cases of notified ophthalmia neonatorum is very marked. In the third and fourth boroughs, though there is an actual increase in the number of cases, the proportion of

cases to the number of illegitimate births is not raised in comparison with the first three years. The fourth column represents the calculated number of cases of ophthalmia neonatorum had they been in the same proportion as for the first three years. It is possible and probable that the Registrar's figures in respect of number of illegitimate children is understated, inasmuch as a married woman will register her illegitimate child under her married name and her husband's name when at all possible.

Table showing Number of Births and of Cases of Ophthalmia Neonatorum in respect of Four Boroughs for Two Periods of Three Years each.

Borough and Period.	Average No. of Total Births.	Average No. of Illegitimate Births.	Average No. of Notified Cases of Ophthalmia.	Average No. of Calculated Cases of Ophthalmia for Second Period.
1. Borough in South of England (seaside resort). Pop. 30,000.				
1914-16	515.3	24.3	2.3	—
1917-19	495.6	31.0	7.0	2.9
2. Borough in Scotland (port). Pop. 90,000.				
1914-16	1979.6	99.6	8.3	—
1917-19	1725.6	111.6	14.5	9.3
3. Borough in South of England (residential). Pop. 90,000.				
1914-16	1497.0	32.6	6.6	—
1917-19	1125.0	41.0	7.3	8.9
4. Borough in North of England (industrial). Pop. 130,000.				
1914-16	3748.6	145.6	31.3	—
1917-19	3306.0	170.0	36.3	36.5

GRACE H. GIFFEN DUNDAS,
Medical Officer to Maternity and Child Welfare, Middlesbrough.

CIRCUMCISION—A BARBAROUS AND UNNECESSARY MUTILATION.

As it appears that the foreskin is intended to serve a useful, even necessary, purpose, I desire to urge serious reconsideration as to the wisdom of persisting in our reverence for the cult of this body mutilation, one amongst many others—for example, removal of the tonsil. If the prepuce be intended as a protector for the delicate glans penis, it must be foolish to remove such a shield. The arguments in favour of the time-honoured mutilation of circumcision are (1) as a preventive of masturbation and sexual excitement, due to irritation of retained secretions; (2) as a measure of cleanliness; (3) as a prophylactic against the contraction of venereal diseases, etc.

Now all the alleged advantages (with none of the disadvantages) to be gained from circumcision can be attained by retaining the prepuce and so dilating its orifice that it slides freely backwards and forwards over the glans. This should be done in infancy, and it can always be effected by dilatation, even when at first sight such appears unlikely. Trial will show that the difficulties are imaginary, not real. One dilatation nearly always suffices, but if not, a second can be carried out. Very little time (a minute or two) is required, and no cutting or mutilation. The small size of the preputial opening in an infant is less than appears while prepuce adheres to glans; it is, in fact, due to the adherence, and if separation be effected by a sinus forceps or probe, it will be found that a blunt dilator will readily stretch the foreskin, so that it can be freely drawn backwards over the glans. The parts are then lubricated with vaseline and the prepuce kept in reposition by wrapping a strand of wool layered with vaseline round the part.

Secretions can only collect under the foreskin when its orifice is too small to allow of free retraction. Complete dilatation obviates this. Hence the objections to the prepuce on the ground of hygiene and irritation fall to the ground: they only apply to an unretractable prepuce.

Regarding venereal diseases the same argument applies, as discharges are not retained under a foreskin that is

dilated and freely movable, and therefore fully retractable, and which also for the same reason can be kept clean. But this argument as to venereal disease, assuming its validity, is not an argument in favour of circumcision, but for the abolition of venereal diseases.

At one time, when I accepted what "authorities" and books told me, I was such a believer in the orthodox cult of circumcision that I performed the operation on myself; but increasing experience has convinced me of the unsoundness of this operation, and I never perform it now as a routine procedure—always dilatation, with most excellent results. I would strongly urge that this amongst many other unnecessary and evil mutilations be relegated to limbo. This injurious procedure, like that of keeping women in bed after childbirth, we owe to the Jews, and we have nothing to thank them for as regards these two of their religious rituals.

Sydney, N.S.W.

G. S. THOMPSON, F.R.C.S.

AN ECTOPIC OVARIAN CYST.

Mrs. R., aged 60, was admitted to hospital on December 12th, 1919. Thirteen years previously an ovarian tumour had been removed, and seven years later a further operation was performed for a similar condition. The abdomen was fat and pendulous. There were two subumbilical scars, one in the middle line, the other right paramedial. For several months there had been continuous discomfort in the abdomen with occasional attacks of severe pain, but just before admission there was a very violent attack of abdominal pain and vomiting.

When the patient was anaesthetized a tumour was readily palpated at the level of the umbilicus. It was freely movable laterally and in an upward direction, but only slightly downwards. A subtotal hysterectomy had been performed with removal of the ovaries. Suspended from the lower border of the omentum was a rounded tumour, 6 in. in diameter, containing sanguinous fluid. Its inner surface was studded with numerous papillary outgrowths of varying sizes. There were no attachments except to the omentum.

Macroscopically and microscopically this was a papillary ovarian cyst.

Wakefield.

J. W. THOMSON, M.B., C.M. Aberd.

Reports of Societies.

ACCIDENTAL HAEMORRHAGE.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, held on March 4th, with the President, Mr. J. D. MALCOLM, in the chair, Dr. GORDON LEY read a clinical paper on fifty consecutive cases of utero-placental apoplexy (accidental haemorrhage). He dealt first with the causative factor, which, he was of opinion, was the toxæmia of pregnancy; 84 per cent. of his cases had considerable albuminuria and 32 per cent. had other manifestations of toxæmia. He suggested the following theory:

(1) Fetal necrosis with haemorrhage in the uterine musculature and decidua. (2) Resulting separation of an area of the placenta opening up uterine sinuses. (3) Extensive retro-placental haemorrhage therefrom.

From a clinical point of view he grouped his cases under three headings: External cases, internal cases, and combined external and internal cases. The external cases were the most mild, the haemorrhage as a rule being not very severe. The mildest cases were amenable to rest. The more severe cases were best treated by rupture of the membranes, the application of a tight binder, and the hypodermic injection of pituitrin. For the internal cases, which he considered were entirely due to uterine paralysis, the result of the sudden forcible distension of the uterus by blood, he advocated rest with careful watching of the pulse, general condition of the patient, and the outline of the uterus. If the patient improved she should be left alone until contractions started. These would be evidenced by the appearance of blood from the vagina even before they were recognizable to the patient, or by palpation. On the advent of pains he advocated treatment as for external haemorrhage. If the patient's condition became worse, as

evidenced by rising pulse rate or enlargement of the uterus, he advocated Caesarean section, followed, if necessary, by hysterectomy. For the combined cases he advocated treatment of the condition present at the time when the patient was seen—that is, treatment for external cases if bleeding were present; treatment for internal cases if bleeding had been present, but had ceased, and the patient's condition had become worse. His results had been as follows:

The external cases had all recovered. Of 11 internal cases, 9 had recovered; 2 in which hysterectomy had become necessary had died. Of 25 combined cases, 23 had recovered and 2 died, one of uterine rupture and the other of post-partum haemorrhage.

Dr. EARDLEY HOLLAND considered the paper an important contribution, because accidental haemorrhage was a subject needing all the knowledge that could be got. With regard to treatment, he was in complete agreement with Dr. Ley in all essential details. He was not convinced, however, of the efficiency of plugging in the arrest of haemorrhage. He thought it quite likely that the patients recovered in spite of, just as much as because of, the plugging. He doubted whether the plug ever compressed the uterine arteries, and even if it did it failed to control the ovarian arteries. He doubted also whether the plugging and the binder increased the uterine pressure, because the uterus was a plastic hollow organ, and if its capability of expansion were limited in one direction it could still expand in others. The question, however, as to the value of plugging could only be settled by an analysis of a large number of cases treated by different methods. Caesarean hysterectomy, he believed, was never necessary. From his own experience he was convinced that the uterine could always be made to contract if time were given it. He would not hesitate to wait even fifteen or twenty minutes for this to occur, controlling the haemorrhage in the meantime by compression of the uterus by hot towels without and hot gauze pads within. Another reason given for hysterectomy was the infiltration of the uterine wall with blood. This, however, was no indication for its removal. He criticized the title of Dr. Ley's paper. The word apoplexy meant a knock-down blow, and it was quite inapplicable to uterine haemorrhage; but if employed it should be limited to cases of severe concealed accidental haemorrhage associated with interstitial haemorrhages in the uterine wall. In spite of these and other criticisms he was deeply grateful to Dr. Ley for his statement of facts; if every hospital would display and analyse its cases as he had done, knowledge would advance more quickly.

Dr. RUSSELL ANDREWS congratulated Dr. Gordon Ley on the excellent use he had made of his extraordinary collection of cases of ante-partum haemorrhage. He did not agree that shortness of the cord was never a cause of separation of the placenta. Shortness of the cord undoubtedly caused inversion, and if it caused inversion it also caused separation of the placenta. The explanation of concealed accidental haemorrhage as due to paralysis of the uterus had been generally held for a long time.

The paper was discussed also by Dr. A. M. ROSS, Dr. STEVENS, and Dr. LACK, and Dr. GORDON LEY replied.

VACCINES IN GYNAECOLOGY AND OBSTETRICS.

At a meeting of the Edinburgh Obstetrical Society held on March 10th, with Dr. WILLIAM FORDYCE, President, in the chair, Dr. ROBERT ROBERTSON read a paper on the value of vaccine treatment in gynaecological and obstetrical practice. He recorded a number of illustrative cases. The first was a case of menorrhagia and frequency of micturition. An anaerobic diphtheroid bacillus was recovered from the urine. Vaccine was prepared, and its administration produced as a reaction haemorrhage from the uterus. It resulted in cure. The second case was one of uterine fibroid, the anterior surface of the uterus pressing on the bladder. There was frequency of micturition and clinical symptoms of *Bacillus coli* infection. An autogenous vaccine was prepared from the urine, which led to complete relief of the symptoms. The fibroid was not removed. Two cases of rheumatoid arthritis were reported where the uterus was the septic focus. The first was treated by curettage and stock

rheumatoid arthritis vaccine. Very great improvement took place in the rheumatoid condition. In the second case an anaerobic diphtheroid was isolated from the uterus in an unmarried lady. Characteristic reactions were obtained after the use of this, with a great amelioration of the rheumatoid condition. The use of *Bacillus coli* vaccine in menorrhagia in young girls was favourably commented on. Another case reported was one of parametritis complicated with cystitis. The patient was seriously ill. She was treated with autogenous *Bacillus coli* vaccine. The cystitis cleared up and the swelling in the broad ligament gave no further trouble. Chorea was treated with considerable success with stock vaccine obtained from cases of rheumatism. One case of chorea in pregnancy was cured after three such inoculations. The patient had had a second child with no recurrence of the chorea. In puerperal septicaemia the desirability of taking a swab from the uterus, preparation of autogenous vaccine as soon as possible, and in the interval the early use of a combined staphylococcus and streptococcus vaccine, was emphasized. It was very important that this should be used early before there was a great circulation of toxins in the blood. Several cases of phlebitis and phlegmasia were reported which were satisfactorily treated with *Bacillus coli* vaccine.

Colour in Pregnancy.

Drs. J. W. BALLANTYNE and F. J. BROWNE read a paper on 'the colour scheme in pregnancy, based on the study of 200 consecutive cases of pregnancy at the antenatal clinic in the Edinburgh Royal Maternity Hospital. The dependence which, according to the textbooks, was supposed to exist between the complexion of a woman and the pigmentary changes of pregnancy was shown to have many exceptions. The record was based on the examination of the relationship existing between the hair and eyes and the linea nigra and the mammary areolae. It was pointed out that no definite relationship existed between the intensity of the linea and the areolae. As often as not, also, the pigmentation of the linea or the areola was just as marked in the blonde as in the brunette. The facts showed that there was as the underlying factor something other than the complexion; and it was suggested that the pigmentary phenomena of pregnancy might be bound up with the activity of the endocrine glands. This was a point for future research to determine.

The paper was commented on favourably by the PRESIDENT and Dr. HAIG FERGUSON. In reply to a question from Dr. LACKIE, Dr. BALLANTYNE said that so far they had not investigated the relation between the degree of pigmentation and the toxæmias but that this matter was being gone into.

BORDERLAND CASES.

A MEETING of the London Association of the Medical Women's Federation was held on March 16th, at 11, Chandos Street, W., with the President, Mrs. FLEMMING, M.D., in the chair. Dr. HELEN BOYLE read a paper on early nervous and borderland conditions. She said that it was important to abolish the artificial division of these cases into neurological and insane; that no one should attempt to diagnose and treat the psycho-neuroses without studying insanity in all its forms, and no one should have care of the insane without being conversant with work on the psycho-neuroses. The war had caused an upheaval of interest in mental and nervous work, and had shown the nations the causation, initial symptoms, development, course and end of innumerable cases of psycho-neurotic disorders. Psycho-analysis had attracted the greatest attention and criticism, and there were many modifications of the system. She said that some claimed that cure was due to the abolition of the amnesia and the unting of the forgotten facts with the general consciousness. Others claimed that cure was due to the subsequent readjustment of the patient's attitude towards the revived incidents. Still others claimed that suppressed emotion acted as an irritant and that repair of amnesia was useless without letting this out. Dr. Boyle urged that all forms of treatment, mental, physical and spiritual, had their uses in the cure of early nervous and borderland conditions. She said that amnesias and repressions are found in healthy and normal people, and are probably part of nature's method of adapting the individual to the environment, and that they are therefore reparative in intention and only need interference when they go beyond this.

The best method in medical treatment has ever been that which helps nature to help herself. Dr. Boyle then described some cases successfully treated through the body alone, and emphasized the importance of the blood pressure and the endocrine glands. An "adaptation" often helped patients—for example, religion was often one of the greatest adaptations. Dr. Boyle ended with a word of warning as to the danger of breaking down resistances which the patient's mind offered to investigation. She said that repression of ideas, considered to be inappropriate and unworthy, was often a natural and wholesome tendency, and that success may sometimes be attained by contemplation of the ideal.

A discussion followed in which Dr. CONSTANCE LONG, Dr. JOHNSTONE, Dr. BERTINE (New York), Dr. M. C. BELLI, Dr. MADGSTON and others took part.

A MEETING of the Hampstead Division of the British Medical Association was held at the Hampstead General Hospital on March 11th, the President, Dr. COLLINGWOOD ANDREWS, being in the chair. The following cases were shown and discussed:—By Dr. STANLEY GEORGE: A case of aneurysm of the ascending aorta with aortic incompetence. By Mr. SIDNEY BOYD: (1) A case of endothelioma of the stomach treated by gastrectomy in May, 1919; the patient was well, and had gained 3½ st. in weight. (2) A case of extensive epithelioma of the upper jaw treated by excision in 1909; the man was still well and free from recurrence. (3) A case of congenital dislocation of the hip treated by Lorenz's method in 1914; the child is now 11 years of age and walks quite normally. (4) A case of temporo-sphenoidal abscess operated on in December 1919. (5) A case of tuberculous disease of the shoulder (arthritis sicca) in a boy, aged 8. Mr. Boyd also showed specimens of (1) a Meckel's diverticulum which had produced strangulation of a coil of small intestine and perforative peritonitis; the patient was a child of 2 who made a good recovery after operation; (2) a very large appendix the seat of acute inflammatory changes; (3) a horse-shoe kidney.

AT a meeting of the Cardiff Medical Society, held on March 10th, Dr. HERBERT EVANS read a paper on the urinary system and the *Bacillus coli communis*. After a brief survey of the history of the subject, together with a short account of the bacteriology and pathology, notes of cases illustrating the various lesions were read, and particular reference was made to certain complications which masked the urinary trouble. These were (a) anaemia of the secondary type with enlarged liver and spleen in two cases and enlarged spleen in a third case; (b) iritis, of which four cases were quoted, all occurring amongst women (c) *petit mal*: one case in a child showed attacks similar to *petit mal*, which cleared up on treatment of the urinary condition. In this case no symptoms were reported suggesting the condition, which was recognized only by bacteriological examination. The various forms of treatment were outlined—alkalis were advocated in cases occurring amongst young children, and in the case of adults a combined treatment varying somewhat with the case and condition of the urine. Satisfactory results were reported from the use of vaccines.

THE Council of the Royal Society of Medicine has appointed representatives to the Federation of Medical and Allied Societies.

THE proposal to establish an Institute of Research in animal nutrition at Aberdeen, at a cost of £25,000, has been brought nearer realization by the gift of £10,000 made by Mr. J. Q. Rowett.

THE Dutch Congress for Public Health will hold its twenty-fifth annual meeting next September at the Hague under the presidency of Dr. W. P. Ruijsen. The campaign against venereal disease and the organization of public health services will be the chief matters discussed.

THE thirty-first congress of the Royal Sanitary Institute will be held this year at Birmingham under the presidency of Viscount Astor, Parliamentary Secretary to the Ministry of Health. It is intended to have five sections and to hold seven conferences. The lectures to the congress will be given by Sir Frederick Mott, on "Body and mind." The popular lecture, on "Links with the tropics," will be given by Dr. Andrew Balfour. The congress will begin on July 19th. Arrangements are being made locally by a committee under the chairmanship of the Lord Mayor of Birmingham. Full particulars can be obtained from the Secretary of the Institute, 90, Buckingham Palace Road, London, S.W.1.

Rebivus.

SIR WILLIAM TURNER.

WE do not know of any medical biography which is so likely to hearten a struggling and ambitious medical student of to-day as this life of Sir William Turner,¹ by his son, Dr. A. LOGAN TURNER, unless it be the life of Turner's master, Sir James Paget. It is said, but we sincerely trust the statement is not true, that biography is at a discount amongst modern medical students, for we know of no draught so likely to give fresh courage to students striving against adversity and the oppressive prices of these times as a perusal of the hardships which Paget and Turner had to pass through before success began to crown their industry. To those who only knew Turner as the august but lucid professor of anatomy, the dignified Principal and Vice-Chancellor of Edinburgh University, the sagacious President of the Medical Council, William Turner, the surgeon's apprentice from Lancaster, the unobtrusive, ingenious, observant, and economical student at "Bart's," will come as a surprise, for he proves himself to be one of the most engaging youths in medical history. Let this letter to his widowed mother, dated July 1st, 1853, when, after three years of study, he had obtained his diploma as member of the Royal College of Surgeons, speak for itself:

It may not be uninteresting now, at the close of my third summer's attendance at the hospital, to take a review of what I have effected during my three years here, and also to estimate what I have paid in fees, books, instruments, and personal expense during my residence in London. The money I have received from home and my half-year's scholarship amount to £312 5s. Of this I have now in hand 88. This gives an expenditure of £304 5s. The outlay is as follows: Fees: St. Bartholomew's, £108 8s.; London University, including cap and gown, £6 4s.; Royal College of Surgeons, £22; books, apparatus, instruments, and dissection expenses, £20 18s. Personal expenses, £146 14s. 6d. I think, on looking at the personal expenditure, that no one can accuse me of extravagance.

Mark this fact, O reader! A widowed lady of Lancaster and her two spinster sisters spend £304 5s. in giving Britain the leading anatomist of his day and Edinburgh the best principal she ever had. The future principal had to qualify for office by learning to feed and clothe his body at an expenditure of £48 per annum; St. Bartholomew's hospital laid the basis of his lore for £108 8s., and Paget gave him a priceless example for nothing. It was not an easy task which Turner had set himself from his 18th to

his 21st years, as we learn from another letter to his mother.

I am again in want of money, the supply you sent me being only sufficient for another week. The amount required for the summer fees will be eight guineas. I shall also be compelled to get a new coat, and, in addition, I want one or two other little things, such as a pair of gloves and a new tie, all of which I shall get in town. I have given you a pretty long list of my wants. I always endeavour to make my clothes last as long as possible, but they will become shabby in spite of the greatest care.

Oh, these habits of hard-up student days! How deeply they become ingrained! In later and prosperous days Lady Turner had to exercise her gentlest wiles to separate him from garments to which he had become attached. In another letter he informs his younger brother that he had given up the reading of fiction, but we suspect from this extract from another letter that he was not unfamiliar with *Sartor Resartus*; at least he utters a note which his modern successors will echo:

Oh! would some enterprising individual arise who could manufacture garments that would wear to eternity if required. If such a man did appear, great would be the rejoicing amongst such ever-seedily, ever-threadbare persons as myself.

These extracts show that the full rounded periods in which Sir William Turner expounded the structure of the human body to thirty-seven generations of Edinburgh medical students was an acquisition of his youth. We have only to turn to the letter he wrote on reaching London, September 30th, 1850, to commence his medical studies, to see that he was master of a style before he had listened to the finished speech of Paget:

About two miles from London I could perceive the twinkling of the lamps stretching a long way on each side of the line. At the Enston Station the porters grumbled about my luggage (luggage was always a source of care for Turner), and said I should have it weighed; but, after a little difficulty, I got it free.

After reaching my lodgings in Queen Street, Lincoln's Inn, at the rooms of his cousin James McNaught, we had tea, and, feeling myself much refreshed, James took me out for a little walk. We first went to Oxford Street, and walked halfway along it, and, as far as the eye could reach, there stretched on each side of us a long row of lamps, glimmering and twinkling far away into the darkness. It was a beautiful evening, the stars shone brightly in the dark sky. . . .

This surgeon's apprentice from Lancaster, aged 18, was already a master of description—not of his subjective feelings but of the events which fell upon his senses; the measured phrases with which generations of Edinburgh students became familiar were gifts he brought with him from his home. Next day he "saw Mr. Paget, the warden," and paid him "fees to the amount of £45." Dr. Kirkes spoke very kindly to him, and said he "would be always ready to give me any information I required." This is an example of how a great medical school should be built up.

Then came August, 1854, which made him an M.B. of London University at the age of 22. His original aim was

SIR WILLIAM TURNER.

From a pen and ink sketch made about 1886 by the late William Hole, A.R.S.A. (By kind permission of Dr. A. Logan Turner.)

¹ Sir William Turner, K.C.B., F.R.S., Professor of Anatomy and Principal and Vice-Chancellor of the University of Edinburgh. Chapter in Medical History. By A. Logan Turner, M.D. Edinburgh and London: Wm. Blackwood and Sons, 1919. (Demy 8vo, p. xv + 514. 18s. net.)

general practice in the country, but scholastic successes and encouragement from members of his hospital staff made him weigh the pros and cons of a physician's life in London; such a choice offered him, he perceived very clearly, a fair prospect of penury. His difficulties were solved by the famous Goodsir of Edinburgh coming to London in search of demonstrators of anatomy. On Paget's recommendation Professor Goodsir appointed Turner as his senior demonstrator at a salary of £200 per annum, and asked him to dine at his hotel, Anderton's, in Fleet Street, in order to settle the bargain.

I recollect very well the dining-room, divided into compartments, seated with hard wooden benches and with a sanded door, and there I had my first dinner with Goodsir. After we had satisfied our respective appetites, he said to me, "Mr. Turner, you will have to meet a class of 200 students and demonstrate to them. Now let me hear how you describe the sartorius muscle." And so I described the sartorius muscle, and he said, "Very good, Mr. Turner, that will do." That was the beginning of my career as a teacher of anatomy.

Thus it came about that two of the chief links in the chain of British anatomists were interlocked over an evening meal in the dim light of a Fleet Street inn.

In the early hours of a chill October morning Turner made his first acquaintance with Edinburgh as he wandered friendless to his lodgings in Lauriston Place. He has left us a record of his impressions:

What a revelation to me for the first time, the old and the new towns perched on the sides and summits of eminences, about midway between the adjacent hills and the Forth, commanding a varied and glorious prospect of mountain and sea, of wooded heights and fruitful fields. The city with its traditions and history, its monuments and its public buildings, the castle surmounting a precipitous rock, the church of the Holy Rood with its Royal Palace, the ancient streets and modern squares associated with Nobles, Divines, Philosophers, Men of Letters and of Science, took firm possession of my imagination. No one with a feeling for the past but must become inspired by such an environment and be impelled to labour for his generation and for the future.

At one glance, as it were, Edinburgh had wooed and won William Turner, the Lancastrian lad, whom Bart's had bred to medicine. In the spring of the same year—1854—she had captured Joseph Lister.

Dr. Logan Turner has given this biography the subtitle "A Chapter in Medical History." Sir William Turner's life was so intimately interwoven with the medical events of his time that his biography could not be other than a chapter in medical history. No doubt those who have taken part in these events, and those who seek to know how present conditions of medical practice have come about, will be grateful to the biographer for those sections of his book which deal with Sir William Turner's public life, but for us the fascinating parts of the book are those which reveal the intense humanity of a man built on big lines—the Samuel Johnson of anatomists. We must again quote a passage—one from the letter written by Turner to his mother on November 16th, 1862, telling her that he had become engaged to be married. He was then in his thirty-first year, having been eight years in Edinburgh—

As I am now in receipt of £400 per annum I have determined to carry into effect a plan of which I have been for some time thinking, and to take unto myself a wife. I am quite tired of leading a bachelor life, and I have arrived at an age at which one is fairly entitled to marry without being charged with impudence or haste. . . . The young lady who has consented to share my lot is the eldest daughter of Mr. Logan, a gentleman living in the South of Scotland. I have been acquainted with her and with her family for some time. . . .

Even in this emotional crisis of his life the fullness and formality of his style suffers no curtailment. The one thing he could not do was to gush. Wiseacres may shake their heads over the formality of this note, but it proved to be the announcement of a contract which gave its participants forty-six years of such happiness as falls not often to human mortals.

Thomas Annandale was his groomsman, and his students made him a present. In his speech thanking them for their gift he gave a glimpse of the secret of his success in handling young men. He spoke of "the influence of that mysterious sympathy which binds together a lecturer and an attentive audience." The power to rouse that "mysterious sympathy" was Turner's gift by birth, but he maintained it by an honesty of purpose and a will to serve which have rarely been matched in the occupant of a professorial chair. How strong was his personal

influence as a teacher of anatomy may be seen from a list of chairs of anatomy which were filled by his pupils:

Owens College, Manchester, Morrison Watson and Alfred Young; Otago University, John Halliday Scott; Trinity College, Dublin, Daniel John Cunningham, Turner's greatest pupil and afterwards (1903, his successor in Edinburgh; Queen's University, Belfast, Johnson Symington; University of Tokio, F. Dyce Fraser; University of Oxford, Arthur Thomson; University of Sydney, J. T. Wilson; King's College, London, Arthur Robinson, Cunningham's successor in Edinburgh; University of Liverpool, A. M. Paterson; University of Durham, Robert Howden; Lahore College and subsequently of University College, Dundee, J. C. Lamont; University of Toronto, Alexander Primrose; University of St. Andrews, James Musgrove, succeeded by David Waterston; University of Bristol, Edward Fawcett; University of Glasgow, Thomas H. Bryce; University College, Cardiff, David Hepburn; Melbourne University, R. J. A. Berry; University of Leeds, J. K. Jamieson; McGill University, Montreal, A. C. Geddes—now the Right Hon. Sir Auckland Geddes, Ambassador to the United States; University of Cape Town, T. B. Johnston.

Here is a record which has never been approached, much less equalled, by any other Master of Anatomy.

A. K.

BODILY CHANGES IN THE EMOTIONS.

THE interrelations of the ductless glands on the one hand and the nervous system and the emotions on the other have recently attracted much attention, especially as the result of the problems raised by the war, and our knowledge has been much expanded, particularly by Professor W. B. Cannon² of Boston, whose book on *Bodily Changes in Pain, Hunger, Fear, and Rage* summarizes some of the most important research work on this subject carried out in the physiological department at Harvard.

The functions of the three parts—the cranial, the thoracic-lumbar or sympathetic, and the sacral—of the autonomic system are considered in an attractive manner; the cranial portion is occupied in building up the reserves (adrenin, sugar) and fortifying the body against times of stress; the middle division is concerned with the manifestations of intense emotions—fear, anger, and pain—and is concerned with the preservation of the individual; and the sacral autonomic looks after the sexual activities, and so the racial continuity. When the neurones of the middle division meet in any organ the neurones of either of the other divisions, the influence of the two sets is antagonistic, the reciprocal innervation of the antagonistic divisions being comparable to the reciprocal innervation of antagonistic skeletal muscles. The increased secretion of adrenin, as the result of impulses travelling by the splanchnics, during pain and the dominant emotions of anger and fear, is held to constitute a reflex mechanism for the preservation of the individual; thus the blood pressure is raised; the amount of sugar in the blood, and so the source of muscular energy, is increased; the blood is driven from the splanchnic area to the nervous system, lungs, heart, and muscles; muscular fatigue is rapidly abolished; and the coagulation time of the blood is shortened. These visceral and other changes are directly serviceable in making the organism more effective in the violent display of energy which fear, rage, or pain may involve.

Hunger, which is on the same plane as pain and the dominant emotions of fear and rage as agencies determining the actions of the organism, is fully considered, and as the result of experiments it is shown that the immediate cause of the sensation of hunger is the contraction of the stomach. In fever the absence of hunger is correlated with the observation that infection with systemic involvement is accompanied by total cessation of all the movements of the alimentary canal.

In the last chapter of this extremely interesting monograph Professor Cannon considers alternative means of satisfying the fighting emotions, and while admitting that his researches confirm the militarist contention that the fighting instinct is firmly fixed in human nature, he advocates international games as a substitute for military discipline.

² *Bodily Changes in Pain, Hunger, Fear, and Rage. An Account of Recent Researches into the Function of Emotional Excitement.* By Walter B. Cannon, M.D., C.R., George Higginson Professor of Physiology in Harvard University, New York and London. D. Appleton and Co. 1920. (Post 8vo, pp. xiii + 311; 39 figures. 15s. net.)

NOTES ON BOOKS.

THE merits of LUY'S *Textbook on Gonorrhoea and Its Complications*³ have received such wide recognition that a second edition of the translation by FOERSTER is sure of a welcome. Few changes have been made because, as the preface to the new edition explains, both author and translator have been away from home, and collaboration during the busy years of the war has been impossible. No great advances in the treatment of gonorrhoea have been made during the last few years, and the work can therefore still be regarded as up to date. A note appears in the new edition on the electrical treatment of gonorrhoea. The experiences of the translator, Dr. Foerster, with regard to electrolysis would appear to be in agreement with those of the majority of English observers. Electrolysis has a limited use in the treatment of urethritis, but its indiscriminate employment is often productive of harm. No alteration has been made in the illustrations, beyond an attempt to replace German instruments by those of other countries. The coloured plates are the same as those in the previous edition.

Eyes Right,⁴ by Dr. JAMES MACPHAIL, consists of a series of papers published originally in *Indian Education*, designed primarily for the use of teachers and parents and devoted to hygiene and treatment of the eye. From the fact that the work has run into its second edition, we may conclude that those for whom it is written find it useful. The author has attempted to get a great deal into his book, and many of his descriptions are too sketchy to be of real service to anyone; we doubt, for instance, whether a description of such a condition as arcus senilis is of any use either to the teacher or the parent. The author has a good deal to say on the subject of paper and print of a school book, which is valuable; we must therefore regret that both paper and print, particularly the latter, of his own work fall short of what is desirable.

³ *A Textbook on Gonorrhoea and Its Complications*. By Dr. Georges Luy's, late Assistant to the Urological Clinique, Hôpital Lariboisière, Paris, etc. Translated and edited by Arthur Foerster, M.R.C.S., L.R.C.P. Lond. Second revised edition. London: Paillière, Tindall, and Cox. 1917. (Roy. 8vo, pp. xxi + 386; 201 figures, 3 coloured plates. 21s. net.)

⁴ *Eyes Right*. Papers for Teachers and Parents on the Hygiene and Treatment of the Eye. By James M. Macphail, M.A., M.D. Second edition. Calcutta and London: Butterworth and Co. 1919. (Fcap. 8vo, pp. 75. Re. 1 net.)

INCOME TAX RECONSTRUCTION.

WE make no apology for returning to the subject of income tax; the recent report of the Royal Commission marks the commencement of a determined attempt to simplify the present highly complex system and at the same time to redress those grievances which the rapid rise in the rates of tax has rendered so acute. Any reconstruction of so heavy and so widespread a tax as the present income tax is a matter that demands the earnest and immediate consideration of all.

Evidence on behalf of the British Medical Association was given by the Treasurer, Dr. G. E. Haslip, last October, and it is proposed to deal first with the report of the Commissioners as it affects the points raised by Dr. Haslip's evidence.

The "Three Years' Average."

It was suggested that a preferable basis of charge would be the "income of the previous year," partly because the complications introduced by a three years' average would thereby be avoided, and partly because "the year following a year when profits were high is more favourable for the payment of a large income tax, and vice versa." The report notes that the change seems to be almost universally desired, and states that the Commissioners "have no hesitation in recommending that the change be made"; it is suggested that when losses are incurred the amount of loss might be carried forward and deducted from future profits, subject to a time limitation of six years.

The Commissioners point out that the Revenue is likely to benefit by the change during a period of rising incomes, such as the present time, but state that that consideration has not influenced their decision. It is of course equally clear that, on the other hand, any future fall in the general level of earnings will be reflected more quickly in a reduced yield of tax.

Depreciation of Plant and Machinery.

The evidence put forward on behalf of the Association called attention to the fact that the restriction of the depreciation allowance to traders as distinct from professional men constituted a substantial and obvious grievance that needed an early remedy. This is admitted in the report with complete candour. The Commissioners say: "A business man is allowed a deduction for the depreciation of a motor car employed in his business, but a doctor whose practice may equally necessitate the use of a car is not entitled in law to any such deduction. We recommend that the allowance should no longer be restricted to traders."

Depreciation of Wasting Assets.

The particular example put before the Commission was the case of the purchase of a lease of premises for professional purposes. The report lays down certain principles the result of which, stated briefly, would be to give an allowance for "inherently wasting material assets" where the anticipated life of the asset does not exceed thirty-five years, but would not extend the allowance to the case of the purchase of a lease where the wasting applies not to the material asset but to the period for which the holder is entitled to enjoy it. Considerations of space forbid a more complete examination of the arguments on this point, which is after all less important from the point of view of the average medical practitioner than those mentioned above.

The Joint Assessment of Partnerships.

Dr. Haslip's evidence pointed out that there were many objections to the present method of joint assessment, one consequence of which was that a formal notice was sent to the precedent partner which often indicated under the system of allowances particulars of the other partner's private income. The report states that the Commissioners consider that the profits of the partnership as a whole should still be returned in one sum by the precedent acting partner, and that he should be responsible for showing how that profit is divisible among the partners, but they recommend that it should be open to any partner to claim that his share of the partnership profits should be separately assessed, so that his private concerns may no longer be made known to his fellow partners, and they add that such separate assessment should be subject to the ultimate right of the Crown to recover from a firm tax due from an individual partner on his share of the firm's profits. It will be seen that the Association's objection is met in substance, subject to conditions which are likely to have only very rare application in actual practice.

Deduction for Rent.

Dr. Haslip called attention to the fact that a good deal of variation was noticeable as between different bodies of local Commissioners on the question as to how far the allowance for rent or annual value should be granted up to the maximum of two-thirds allowed by the Income Tax Acts. In cross-examination, he expressed the opinion that a universal allowance of two-thirds might create unfairness in certain cases—for example, that a higher proportion should in fairness be taken in dealing with a practice in Harley Street than in the case of one in a provincial town. On this point the report states "the general limitation to a sum not exceeding two-thirds of the annual value or rent should be retained, but the Commissioners should be empowered to grant a larger allowance in special circumstances where the application of the general rule would result in hardship." The adoption of this recommendation would not materially affect the present position in most cases, but the admission that the hard and fast insistence on the maximum of two-thirds creates hardship in some cases will be welcomed by those concerned as an indication of relief to come.

Relief in Respect of Children.

The Commission was urged that the relief should be extended, first, as regards the quantum of the allowance per child, and secondly, as regards the class of parent relieved, a class which to-day is restricted by the condition that the total income shall not exceed £800. On this question the report suggests several alterations:

1. The allowance should be £40 for the first and £30 for each subsequent child, instead of £40 and £25 respectively, as now.
2. The income limit should be swept away, so that the allowance may be universally applied.
3. The allowance should be treated as a deduction from the gross income in such a way as to reduce that income for all purposes, so that the rate of tax should be determined by reference to the amount of income left after these allowances have been made, and
4. The allowance should be withheld when the income of the child in its own right exceeds the amount of the allowance.

This was the last of the specific points put to the Commission by the Association, and, as will be seen, it met with favourable consideration on the whole. There is a great deal to be said for the contention that a parent should be allowed to deduct the annual cost of education and maintenance (or at least some proportion of that cost) in lieu of the "flat" allowance which is given now whether the parental obligation is small or large and whether it is met fully or only partially. The Commissioners have taken the view that the family allowances are to be regarded as extensions of the exemption limit, which of course raises entirely different considerations. Their recommendations will at least carry the relief to ranges of income to which it is at present denied; in fiscal matters gratitude for small mercies is a virtue for which there is only too little scope, and it would perhaps be ungracious to forego its exercise on this occasion.

Leaving the Association's evidence and its results, it may be worth while to deal somewhat more fully with these general questions which were touched on in our last issue:

Allowances.

The substitution of the fixed allowances of £150 in the case of single and £250 in the case of married taxpayers for the sliding scale of abatements plus the wife allowance of £50, simplifies the calculation of the tax in the majority of cases. The new allowances are to apply irrespective of the amount of total income, and, as has been mentioned above, operate to reduce the total income to the "taxable income." By this means the "jumps" which the tax makes at the various points where the present allowances are restricted or swept away are avoided, and a frequent source of irritation is thereby removed.

Graduation.

At the same time the deduction of these allowances on a fixed and not on a proportional basis produces a certain amount of graduation, but not enough to bring the system into a comparable condition with the present system of allowances plus varying rates of tax. The Commissioners accordingly addressed themselves to the task of finding some method whereby the effective rate of tax would increase with the increase in total income without the introduction, as at present, of numerous rates of tax and consequent "jumps" at the income limits at which the rates of tax increase. The scheme which they recommend is certainly ingenious. It may be formulated as follows: From the assessable income deduct the allowances to arrive at the "taxable income"; if that does not exceed £225, it should be charged at half the standard rate of tax, otherwise the first £225 should be charged at half the standard and the remainder at the standard rate of tax.

The report suggests that this graduation should be steepened by applying the existing super-tax to all incomes exceeding £2,000. At present super-tax is chargeable on the excess of the total income over £2,000 only when that total exceeds £2,500, so that a person with an income of, say, £2,600 pays super-tax on £600, but another with an income of £2,400 is exempt from that duty. The Commissioners are of opinion that super-tax should be increased and should apply to all excesses over £2,000, and that this alteration would bring an additional 30,000 persons within the scope of the tax; they further suggest that one consequence of such an extension would be to make it desirable that the work of assessment should be done in the local offices of the inspectors of taxes, unless the taxpayer should express a preference for assessment by the central authority.

Differentiation in Favour of Earned Income.

On this aspect of the income tax the Commissioners have made rather drastic recommendations. The present

scales of tax give an advantage of 9d. in the £ in each range of income, the proportion of relief varying from 25 per cent. for the lowest to 12½ per cent. at the highest range to which the earned rate applies—that is, to total incomes between £2,000 and £2,500—and ceasing altogether at a limit of total income of £2,500. The report suggests that "the present differentiation against small unearned incomes is too great, and should be materially diminished." On this we offer two comments—first, that the differentiation of 25 per cent. might with equal truth be said to be "in favour of small earned incomes," and second that 25 per cent. was the original proportion when differentiation was first introduced in 1907 to reduce the standard 1s. rate to 9d. for earned incomes. The Commissioners refer to the increased estate and succession duties as falling on the recipient of "investment income," and thereby introducing indirectly an increased differentiation in favour of the recipients of earned income, and suggest that for all persons there should be an allowance of 10 per cent. instead of the present allowance, which varies from 25 per cent. to *nil*. The administrative simplicity of such a scheme is attractive, but its equity seems to depend very largely on the indirect effect of the death duties. As Dr. Haslip pointed out in his evidence on behalf of the British Medical Association, every trader employs capital in his business, and often to a very large extent, and no attempt is made to separate the concealed interest on business capital from the total profit, which is assessed at the earned rate. Broadly speaking, the greater the profit the greater the capital, and therefore the greater that element of profit which is taxed as earned but is really the result of investment in the business, and on this ground a 10 per cent. differentiation seems difficult to justify, unless it is accompanied by the taxation at the investment rate of the interest on business capital. The isolation of this element in the total profit for taxation as investment income should not be beyond administrative skill.

Effects Illustrated.

The report contains a number of clearly framed tabular statements and graphic representations showing the effect of the proposed changes. While they cannot be dealt with here in detail some general comment may be useful. For this purpose taxpayers as a whole may be divided into the usual three classes—wealthy, middle, and lower—taking the first mentioned to coincide with the supertax class and the second to include persons whose total incomes are between £500 and £2,500. On the basis of this rough division it may be said that the general effect of the Commissioners' recommendations would be to relieve the lower at the expense of the wealthy classes and the married man at the expense of the single. Among the earning classes the wealthy tend to gain relatively and the middle class to lose. The following tabular statement will serve to indicate the general effect of the proposals as affecting the majority of practitioners, it being borne in mind that the

Married Couple with Three Children.

Incomes of £250 and under, *nil*.

family allowance has hitherto been given only where the total income does not exceed £800, and that in consequence the increase of the "postulated charge" is correspondingly greater in the case of the single man or the married man with no claim to relief in respect of children.

A good deal of criticism will be addressed to that portion of the report which proposes changes in the administration. Most of the recommendations on this question are directed to transferring the legal functions of the independent local commissioners and the assessors appointed by them to the inspectors of taxes who are members of the co-ordinating State Department. The underlying principle on which this portion of the report proceeds seems to be that the legitimate interests of the taxpayer will be sufficiently safeguarded if the judicial functions of the local commissioners are preserved in their appeal courts, even though their other functions are transferred to the Revenue authorities. This country's dislike of a bureaucracy has in no way been diminished by the experiences of the past five years, and the case for this proposed transfer of functions must be very clearly established if it is to command any general support. The report sets out the facts in some detail, and states that in practice many of these functions—for instance, the preparation of the assessment before its notification to the person assessed—are already performed by the inspector, and in some cases could not possibly be performed in present conditions by an unpaid local committee. The Commissioners say "many of the recommendations we have to make with regard to administration are directed towards recognizing and giving legal sanction to those practical developments in the working of the tax which have so largely contributed to its success." It is inevitable that the changes in social and industrial conditions which have taken place during the past century should have rendered obsolete and cumbersome many of those safeguards which were essential when Pitt and Peel devised the system that has stood for so long and, on the whole, has served its purpose so well.

The Commissioners' report carries great weight, and on some points is entirely convincing, but a plea for caution is not out of place where a question of principle is concerned. If the taxpayer's safeguard against unnecessary requests for information or evidence of various kinds is to be restricted to the exercise of his right of personal appeal, steps should be taken to render more easily accessible the right of appeal to the Special Commissioners who at present go to various parts of the country only at infrequent intervals, and the Board of Inland Revenue should recognize that a greater demand for tact and discretion will be thrown on their own staff.

The report is a lengthy document and bears evidence of much spade work as well as acute reasoning and criticism. It cannot please everybody, for from the very nature of the subject matter with which it deals income tax cannot be made either light or simple or agreeable, but it is clear that a long step has been taken in the right direction. We say has been taken advisedly, because, though parliamentary sanction is needed to clothe the recommendations with the statutory force necessary to give them operation, we may safely assume that so exhaustive a report will by its practical unanimity possess sufficient authority to achieve fruition in substance if not in detail.

THE COST OF LIVING.

THE statistics issued by the Ministry of Labour in the *Labour Gazette* show a slight decrease in the retail price of food on March 1st as compared with February 2nd. The price in March was 133 above the estimate for July, 1914; it was 135 in February. These percentages are based on the assumption that the standard of living among the working classes is the same now as before the war, but the average increase in expenditure on food is believed to be less; the increase of such expenditure on March 1st is estimated to be 107. Owing to the shortage of certain articles—for example, sugar and butter—it is not in fact possible to obtain every article in the same quantity as before the war. The foods included in the statistics are beef, mutton, bacon, fish, flour, bread, potatoes, tea, sugar, milk, butter, margarine, cheese, and eggs, which together normally account for over three-fourths of the total family expenditure on food. The most important

omission is that of fruit and vegetables (other than potatoes), which are not included owing to the wide variations in quality and the seasonal variations in supplies.

The statistics are founded on information as to the predominant retail prices of these articles of food obtained from labour exchanges and retailers, including co-operative societies, multiple firms, and private shopkeepers conducting a working-class trade, to the number of 5,500. It is collected in 90 towns with a population exceeding 50,000 and from 540 smaller towns and villages. The figures are tabulated for large towns (over 50,000) and for smaller places, and allowance is made for differences in the importance of each item in the budget. Expenditure on rent is regulated by the Rent Restriction Acts, which provide that rents of working-class dwellings may not be raised by more than the equivalent of the increase in rates. The statistics with regard to clothing, fuel, light, and other items are more conjectural, but it is estimated that if the total working-class expenditure be taken at 12.5, food accounts for 7.5, rent for 2.0, clothing for 1.5, fuel and light for 1.0, and other items, such as soap, domestic appliances, tobacco, travelling, and newspapers, for 0.5. An attempt is made to compare the percentage increase in retail food prices since July, 1914, in various countries, with the following result:

Percentage Increase in Retail Prices of Food since July, 1914.

* Signifies decrease.

The average increase in all the items of the budget of the industrial classes indicated above, including that is, in addition to food, rent, clothing, fuel, light, and minor articles of consumption and domestic use, is 130 per cent. for the United Kingdom, as compared with July, 1914. Perhaps the most important outcome from the medical point of view is the statement as to the changes in dietaries, which, it is said, are founded on figures supplied by the Ministry of Food. Had the diet been maintained at the pre-war level the increase in expenditure would have been 133 per cent., whereas it is only 107, so that, if these figures can be accepted, the industrial classes—although the percentage has increased from 97 in November, 1918, to 107 to-day—are still spending less, in proportion, on food than they did.

THERE has recently been a remarkable increase at Zurich in the number of non-alcoholic restaurants, where it is stated that 20,000 of the 200,000 inhabitants take their meals daily; only bottles of water are seen upon the tables.

British Medical Journal.

SATURDAY, MARCH 27TH, 1920.

THE EPIDEMIOLOGY OF PHTHISIS.

I.

DR. JOHN BROWNLEE'S inquiry into the epidemiology of phthisis is a statistical research of first-rate importance. In the earlier parts of his elaborate memoir on the subject Dr. Brownlee submitted reasons for regarding phthisis as, from the epidemiological point of view, a complex, resolvable into three diseases—the phthisis of early, of middle, and of late life, each responding differently to environmental factors and perhaps etiologically distinct. In a third part of the memoir, published recently by the Medical Research Committee,¹ this thesis is developed. We propose now to deal only with the earlier sections of this new instalment and to recur to the matter in an early issue.

In his preliminary remarks Dr. Brownlee takes note of the facile assumptions which tend to characterize statements about infectious disease—for instance, the assumption that because a disease is infectious it must needs be more prevalent and also more fatal in crowded districts. He thinks there is no evidence that diphtheria is either more prevalent or more fatal in poor and unhealthy than in rich and otherwise healthy urban districts. He even doubts whether scarlet fever is more prevalent in poor districts, the London notification rate for the years 1907–11 being negatively correlated with the standard death rate. It may be remarked in this connexion that Ewart,² who analysed sixty-four rural districts in the Eastern Counties, using the notifications of 1911–13, found a considerable positive correlation between the attack rate of scarlet fever and the percentage of population living more than two to a room, and that this was increased when the partial correlation was determined, mean size of family, proportion under 10, and acres per family being made constant.

Dr. Brownlee next considers the value of a standardized death rate as a measure of mortality and shows that, despite its necessary inferiority to a complete life table, for this purpose it is sufficiently exact. The following section is devoted to a discussion of the effects upon the phthisis death rate of an elimination of susceptible units by the operation of a selective fertility rate. The problem to be solved is this: given that a predisposition to phthisis is heritable and that, dying early, the phthisical are unable to contribute their full quota to the following generation, how will this affect the secular trend of the death rate? The answer must depend, among other things, upon the way in which the selection operates—whether, for instance, it cuts off all having more than an assigned measure of susceptibility or merely removes a proportion the magnitude of which is correlated with the grade of susceptibility (a more probable hypothesis). The distinction between these cases was clearly drawn by Greenwood and Yule in their discussion of inoculation statistics,³ and Dr. Brownlee gives several numerical illustrations. They

are based upon a theory of the statistical frequency of units of resistance which may not be correct; its correctness does not, however, affect the general argument that the secular reduction of a death rate consequent upon elimination of susceptible units would become slower the longer the selection had operated. The fact that the phthisis death rate declined faster in the later years of the period studied is used by Dr. Brownlee as evidence that the decline has not been chiefly due to selection. It is implicit in this argument that the force of selection has been constant, that it was acting with its maximum intensity at the beginning of the period considered—an assumption not obviously true. It must, of course, be granted that the various agencies which, in the opinion of pessimistic eugenicists, also perhaps in the opinion of those who are not propagandists, favour the multiplication of the “unfit,” have acted with greater intensity in the last generation than forty years ago. On the other hand, the institutional treatment of the tuberculous and the resulting diminution of effective fertility, as well as emigration of the weak-chested, might have favoured the selective process in our generation. We must also notice that in the decennium 1901–10, the results for which were not available when Dr. Brownlee wrote, a slackening of the rate of decline in phthisis mortality has occurred. The problem is, indeed, far too complex to admit of summary solution, nor does Dr. Brownlee claim to have solved it.

In the next two sections Dr. Brownlee discusses adjustments of the coefficient of correlation and of the lines of regression desirable when the quantities correlated are not direct measurements but morbidity or mortality rates derived from samples. This point was first taken by Mr. J. A. Cobb, and has been discussed by Greenwood and Yule in the paper referred to above. It is sufficient to remark that factors of correction are themselves subject to errors of sampling, and that the adjustments, even when absolutely large, are not infrequently within the ambit of the sampling errors of the crude correlations. The point is, in fact, of rather minor interest in the present connexion, since Dr. Brownlee properly bases his conclusions upon coefficients which, with or without correction, are large.

In the next place Dr. Brownlee shows that in London the correlation between the standard death rate (males) at ages 15 to 65, either from all causes or from all causes less phthisis, and the death rate from phthisis is very large, and that such changes as have occurred in London since 1851 are consistent with the hypothesis that general hygienic improvements (of which the standard death rate is taken to be a measure) are responsible. In North Wales, South Wales, and Cornwall, on the other hand, there is little if any correlation between the death rates from phthisis and from other causes. We think that the interrelations of the phthisis death rate and other variables in London are more conveniently studied by a separate evaluation of the constants for age groups than by using a standardized rate. Unpublished work we have seen brings out a sharp contrast between the age groups 15 to 25, 25 to 45, and 45 to 65. In the first group the death rate from tuberculosis is not positively correlated in either sex with domestic overcrowding, while at ages 25 to 45 there is a very high partial correlation between the measure of overcrowding and the male tuberculosis death rate but no correlation between it and the female tuberculosis rate.

The London correlations in this analysis are quite different from those derived from a sample of county

³ *Proceedings*, Section of Epidemiology and State Medicine, Royal Society of Medicine, 1915.

boroughs, a finding in complete accord with Dr. Brownlee's hypothesis. The great difference, however, between males and females and between adolescents and adults is, we believe, best explained by reference to industrial conditions. The seeming paradox that the phthisis death rate in the London boroughs at ages 15 to 25 is not positively correlated with overcrowding is, we suggest, due to the fact that the relative earning capacity of adolescents is much higher at younger ages amongst the families of the unskilled operatives, because their children tend to enter the blind-alley grades which bring an immediate accession of family income at the cost of subsequent unemployment or casual employment. This temporary prosperity may for a time mask the effects of bad home environment, since it may improve the nutrition of the adolescents. Such an explanation is concordant with Dr. Brownlee's remarks upon young adult phthisis, to which we shall presently refer. The explanation of the difference between males and females at ages 25 to 45 is, we believe, to be found in the great difference of the proportions of the sexes industrially employed in this age group, but its discussion would carry us too far from the subject of Dr. Brownlee's researches to be pursued here.

MILITARY SERVICE AND MEDICAL GRADUATION.

RATHER more than a year ago, when medical demobilization was making but slow progress, we discussed some of the difficulties in the way of releasing at that time the younger men in order to remedy the shortage of resident medical officers in civil hospitals. We pointed out that the hospital resident is of value to the community in two ways: he attends to the immediate medical needs of a large number of people; and in performing this duty he increases his own efficiency and therefore the value of his future services to the community in a manner almost impossible under other conditions. It seemed only just and reasonable that everything possible should be done for the younger men, who, owing to their service in the navy and army, had not been able to round off their clinical and scientific training by the experience which a resident hospital appointment affords. Apart from the demand of the hospitals for proper treatment of the sick, and apart from the public need for well trained doctors, we maintained that the position of the young doctor in regard to his own future ought to be considered. The Australian Government had already given a lead by sanctioning a scheme designed to afford opportunities for a number of officers of the A.A.M.C. to obtain post-graduate instruction before returning to Australia. This scheme provided that during his period of study or service in hospital the medical officer should receive full pay and allowances, together with 5s. a day subsistence allowance and approved tuition fees, besides retaining the emoluments of any post he might hold. We commended this statesmanlike and far-seeing policy of the Commonwealth Government, and held it up as an example worthy to be followed by the other country.

But, while grants from Government funds have been made to many demobilized medical students to enable them over their last years of professional study, nothing has been done by the State for the young doctors who, by reason of their military or naval service, have held no hospital posts and have thereby fallen behind in the race. It has been ruled that a student may be helped to qualify, but that a qualified one cannot be assisted to obtain a higher degree or

diploma. Public attention has been drawn to this hardship by Sir Wilmot Herringham in a recent letter to *The Times*. A considerable number of civilian medical officers, he says, are still compulsorily retained in the R.A.M.C., both in Europe and in the East, because reliefs cannot be found for them. Some of them are young men who were on their way to a university degree in medicine, and had already passed their earlier examinations, but were commissioned immediately on taking the Conjoint diploma and thereby prevented from completing their university course and going up for the M.B. examination. Many such cases have been brought to our notice during the past year or so.

"Three years in the army," Sir Wilmot Herringham says—and having served on the Head Quarters Staff of the British Armies in France throughout the war he has had exceptional opportunities for forming a judgement on the matter—"means that a man has forgotten a large part of the knowledge necessary to pass the M.B., and will require at least six months' hard work, and perhaps even longer, to bring himself again up to the standard. The expense of so long a period of living without earning is too great for some of these men, and they are writing to me that they fear they will have to sacrifice their degree. This would be a severe hardship, for a degree means a great deal to a doctor." The case could not be put more clearly and temperately. These young men have deserved well of their country; among them there are doubtless some who in happier circumstances would by now have begun to make a name for themselves in civil practice or in research. Something ought to be done for them, and Sir Wilmot Herringham makes the timely suggestion that on demobilization they should receive a grant towards the expense of finishing their medical education.

It will be seen from our Parliamentary Notes that the Financial Secretary to the War Office undertook last week in the House of Commons to represent to the War Office the desire of young medical officers detained in the East to be recalled for the purpose of resuming their studies. We submit that this does not go far enough, and that steps should also be taken to provide material assistance to those in need of it.

ASSOCIATION OF SURGEONS OF GREAT BRITAIN AND IRELAND.

THE first annual meeting of the Association of Surgeons of Great Britain and Ireland, the foundation and constitution of which were described in our issue of January 17th, p. 90, will be held in London at the end of the second week of May. The association exists for the "advancement of the science and art of surgery, and the promotion of intercourse and friendship among the surgeons of the United Kingdom." The number of fellows is not to exceed 250, and all must be engaged in purely surgical practice, in the teaching of surgery, or in surgical research. A fellow on ceasing to be a member of the active staff of his hospital will become a senior fellow, and will retain the privilege of attending the meetings. A general meeting will be held once a year, in May, in some town in the United Kingdom which possesses a university or medical school. It was arranged that the first meeting, and subsequently at least every third meeting, should be held in London. Fellows will be required to speak, not read their communications, and will be allowed not more than fifteen minutes. No reporters are to be present, and no reports of the meetings are to be sent to the journals or newspapers. The first general meeting will begin on Thursday, May 13th, at the house of the Royal College of Surgeons of England, Lincoln's Inn Fields, when the

President, Sir John Bland-Sutton, will deliver an address at 5 p.m. On Friday morning there will be a discussion on "The ritual of the surgical operation." On Saturday morning the specimens in the War Collection in the Museum of the Royal College of Surgeons will be exhibited; Professor Keith will relate the history of the collection; Sir George Makins will speak on selected specimens of wounds of vessels, and Sir Cuthbert Wallace on gunshot injuries of the abdomen. The afternoons of Friday and Saturday will be spent at various London hospitals, where cases will be shown and operations witnessed. Further particulars will be supplied later to each fellow.

THE UNIVERSITY OF LIVERPOOL.

AN appeal has been launched by the University of Liverpool for contributions to a fund to enable it to respond to the increasing calls upon it. It is signed by the Chancellor, Lord Derby; the Vice-Chancellor, Dr. George Adams, F.R.S.; and the President of the Council, Mr. Hugh R. Rathbone. The appeal is rendered necessary partly by the increase in the number of students; last year they numbered 1,522, this year 2,545. Every available scrap of space is overcrowded; wooden huts have been erected in the quadrangle and grounds, and equipped as laboratories, until there is no room for more. Open courts have been roofed over and private dwelling houses pressed into service for important departments, but the accommodation is so wholly inadequate for practical work that the course in the physical laboratory for the first year is being repeated eleven times; this is, of course, a terrible tax on the lecturers and demonstrators, and must have a deadening effect. The University requires at once new laboratories for chemistry and for electrical engineering, and new buildings for the education department, for the veterinary college, and for the school of architecture. It also wants a physical drill hall, a university hall and hostels for students, and extensions of the library, engineering laboratories, students' union, and club rooms. To meet all these requirements, which are described as the minimum immediately necessary, a very large sum of money is needed. It is claimed for the University that it provides as good teaching as can be given in arts, science, medicine, law, and engineering, and that it gives particular attention to those subjects essential to success in commercial life. The University of Liverpool was incorporated in July, 1903, and from the beginning it had faculties of arts, science, medicine, law, and engineering. It had been preceded by University College, Liverpool, which was one of the colleges of the Victoria University, and the separation was formally brought about by an Act of Parliament in 1904. Since then the University has advanced both in efficiency and in numbers, and its undergraduates are now drawn not only from Great Britain and Ireland, but also from British colonies and dependencies, as well as some foreign countries. All its faculties are maintained at a high level and it is remarkable for possessing a department of oceanography, and a flourishing department of tropical medicine whose staff are in the forefront of this new and rapidly advancing department of medicine. A special office for the appeal has been opened at 4, Moorfields, Liverpool.

COCOA BUTTER.

DURING that period of the war when butter and the animal fats commonly used in cooking were hard to come by, cocoa butter appeared in the shops, generally in the form of large hard, brittle slabs, of a white or slightly yellow colour. Many people experimented with it, but it was not altogether a success. Some found it just tolerable, others disliked it, and some asserted that it gave them indigestion. Their opinion found some support from experiments made by Langworthy and Holmes in America. The cocoa nib contains about 50 per cent. of fat, but

during the process of manufacture this is reduced in cocoa for drinking and in many chocolates for eating to about 30 per cent. Its melting point is about the same as butter, so that on that ground there was no reason why it should not replace butter. But there was some doubt as to whether it was utilized as completely in the body. The Food (War) Committee of the Royal Society therefore induced J. A. Gardner and F. W. Fox¹ to carry out an investigation at the Physiological Laboratory of the University of London. The standard diet used for control was that employed by the subcommittee of the Royal Society in experiments on the digestibility of breads. This diet contained 50 grams of butter a day, and in the investigation it was replaced by the same quantity of cocoa butter. The subjects upon whom quantitative experiments were made found cocoa butter palatable and suffered no appreciable change in weight; the excreta were normal in appearance, no apparent digestive trouble was noted, and their health was normal throughout the experiment. The average percentage utilization of fat on the cocoa butter diet was found to be rather lower than the average values on butter diets, but the difference was not great, and came within the limits of variation of butter diets. The utilization of cocoa butter must, from this point of view, be regarded as satisfactory. Four persons were induced to promise to take excessive quantities of cocoa butter (3 oz. or 4 oz. a day) with ordinary diet; three of the four became accustomed to it, but it gave the fourth indigestion. In a few of those who consumed large quantities a slight laxative action was observed. It had been alleged that cocoa butter was "a slow poison," but no evidence of any such action was obtained. The conclusion is that it could be used to supplement the fat need of the population with safety. This conclusion, it is added, is in agreement with general experience, since large quantities of cocoa fat must be consumed daily with impunity in the various chocolate preparations on the market, which may contain as much as 20 per cent. of fat.

HOURS OF LABOUR.

DURING the discussion on the second reading of the Shops (Early Closing) Bill in the House of Commons on March 19th, Dr. A. C. Farquharson recurred to a point to which he had previously called attention. He urged that an effort should be made, when the limitation of hours of labour was under consideration, to arrive at a sound method for deciding the number that should be worked. He contended that a decision should be made not at the request or demand of any group of political parties, for it was in essence a scientific question to be answered by the result of scientific investigation. During the war such investigations had revealed the relation of meals and periods of rest to production. It was unscientific to limit the number of hours of labour of a healthy vigorous man by some arbitrary, unreasoning, unscientific rule. Work was a source of joy to many people, and the value of leisure depended on the way it was spent. We believe that Dr. Farquharson is on the right track. The long hours of labour that used to be worked must be condemned, and he condemned them during the course of his speech; but there must be a limit to the reduction necessary in the interests of health, and the limit no doubt varies at different ages, in different occupations, and in varying states of health. These variations render the scientific problem more difficult of solution, but do not make it insoluble; the class of worker is already self-limited to a very considerable extent by the worker, who usually chooses the kind of occupation to which he feels himself best adapted. Valuable investigations on industrial fatigue were made during the war by the Health of Munition Workers Committee and the Medical Research Committee; the latter, we observe, is

¹ *The Biochemical Journal*, vol. xiii, No. 4, p. 368

continuing this work. In the supplementary estimates is a sum of £16,000 to meet the cost of certain investigations conducted by the Committee, among which those connexion with industrial fatigue are specified.

COMPLIMENTARY DINNER TO SIR JOHN MACALISTER.

COMPLIMENTARY dinner, to congratulate him on the eightieth recently conferred upon him, was given to Sir John MacAlister, Secretary of the Royal Society of Medicine, in the Connaught Rooms, London, on March 18th. The large attendance (about 300) was striking evidence of the esteem in which he is held. Sir Humphry Rolleston, President of the Society, who was in the chair, said that the guest was so young in mind that it was difficult to believe that thirty-three years had passed since he became an officer of the Royal Medical and Chirurgical Society. Sir William Church, the first speaker to the toast of the guest's health, referred to early days. He said that the acquisition of the property in Hanover Square was due most of all to Sir John MacAlister's imagination, initiative, persuasiveness, and willingness to accept responsibility. Sir Rickman Godlee, who was honorary librarian while the Society was at Hanover Square, said that it was through Sir John MacAlister that the amalgamation of many London societies into the Royal Society of Medicine was brought about. Sir Francis Champneys, speaking as the treasurer, and afterwards President of the Society after the amalgamation, referred to the many activities of the Secretary, especially in connexion with the social evenings, attended by over 4,000 guests unconnected with the Society and resulting in the accession of nearly 600 Fellows and members. He referred to the establishment of the Section of Medical History in 1912, and of the first subsection, that of Proctology, in the following year. The financial situation had been eased by the issue of subscription bonds to Fellows, and by the extension, through the Secretary's exertions, of the lease of the house in Wimpole Street from 99 years to 999, subject to a ground rent. In all these matters Sir John MacAlister had shown himself a man of ideas and resource. Sir Arbuthnot Lane, who followed, said that in 1887 the Society's assets amounted to £3,040, whereas at the last audit they were £72,000, apart from the appreciation of the house property, which was well worth £100,000. In acknowledging the toast, with which the name of Lady MacAlister was coupled, Sir John mentioned that on the site of the Connaught Rooms the Royal Medical and Chirurgical Society had been founded on May 22nd, 1805, when Abernethy, Matthew Baillie, and the best men in medicine that day were present. Speaking of the amalgamation of societies in London, he said that though it must have come about sooner or later, that it came when it did was due to Sir William Church, who had taken up the negotiations at the point at which they were left on the sudden death of Sir Andrew Clark. The enthusiasm of Dr. Arthur Hatham and Mr. Herbert Pendlebury, the first two honorary Secretaries of the amalgamated society, had much to do with its success, and Sir Henry Morris, who followed Sir William Church, might be described as the architect of the amalgamation. In closing, he said he looked forward to a time when the libraries of the Royal College of Physicians, the Royal College of Surgeons, and the Royal Society of Medicine would be under one dome. Could this amalgamation be brought about there would be a great economy of expenditure and effort; there would be one domestic service, one clerical department, one common library, with a paid staff of searchers at the disposal of Fellows all over the world for the making of translations and abstracts; one central set of rooms open until midnight on weekdays and on Sundays; and finally a volume of *Transactions* which would be the greatest medical publication in the world.

THE MEDICAL SOCIETY OF LONDON.

THE 147th anniversary dinner of the Medical Society of London was held in the Wharfedale Rooms, on March 17th, with the President, Mr. V. Warren Low, C.B., F.R.C.S., in the chair. There was a large gathering, and in the after-dinner speeches every speaker scored a success. The President, proposing "Prosperity to the Medical Society of London," spoke with pride of its long and distinguished history since its foundation in 1773, by John Lettsom. He then handed to Dr. Henry Head, F.R.S., the Fothergillian gold medal, awarded to him in recognition of his monumental investigations in neurological science. Dr. Head, in returning thanks for the great honour paid him by the society, confessed that he had never been docile—indeed, the docile child was never the one who received the Fothergillian medal. He knew, too, that his researches had added to the labours of medical students, whom he had vexed more even than did "Timothy" of the old mnemonic. The toast of "The Army and Navy" was proposed by Sir George Makins, G.C.M.G., President of the Royal College of Surgeons, who said that the medical profession was never so closely related with the services and with the Dominions as it had been during the past five years. The medical branch did as much as any, and more than most, in gaining the victory; it entered the war prepared, and tackled each new problem as it arose; the victories in medical science and practice were among the greatest achievements of the war. Surgeon Rear Admiral Sir Robert Hill, K.C.M.G., Medical Director-General, R.N., in his reply, said that no one knew better than the navy that the war was won by the nation as a whole. When he was principal medical officer of the Grand Fleet—now dispersed throughout the world, policing the seven seas—one of his best helpmates was Sir Humphry Rolleston, who visited them punctually once a month, when the moon was full and the fleet likely to be in harbour. Lieut.-General Sir John Goodwin, K.C.B., Director-General A.M.S., replying on behalf of the army, added his praise for the work of the civil profession during the war. Taking up an allusion by the President to the Quakers who have added lustre to the medical profession—for instance, Lettsom, John Fothergill, Lister, Marcus Beck, and George Newman—he recalled the heroic work of the French ambulance unit of the Society of Friends, during the dark days east of Ypres, at the end of 1914. The toast of the visitors gave an opportunity for an exchange of entertaining personalities between Dr. Leonard Williams, the proposer, and Viscount Knutsford, the responder. Sir Humphry Rolleston, K.C.B., President of the Royal Society of Medicine, who replied on behalf of the kindred societies, made graceful reference to his old teacher, Sir Norman Moore, President of the Royal College of Physicians, who was prevented from attending. A very enjoyable evening closed with the toast of the President, proposed by the Lettsomian Lecturer, Dr. Herbert R. Spencer, and briefly acknowledged by Mr. Warren Low.

MEDICAL RESEARCH COUNCIL.

THE connexion between the Medical Research Committee and the National Insurance system will cease at the end of this month. The Committee will come to life again as the Medical Research Council and will act under the direction of a Committee of the Privy Council, consisting of the Lord President of the Council, the Minister of Health, the Secretary for Scotland, and the Chief Secretary for Ireland. A charter of incorporation has been granted to the Medical Research Council, which will receive its funds through the Committee of the Privy Council out of moneys provided by Parliament. The Committee will make an annual report to Parliament. This change in the status of the Medical Research Committee was decided during the debates on the Ministry of Health bill last year. The practical effect will be to establish the Medical Research Council as an independent department and in this way tend to increase its opportunities of usefulness.

The Army Medical Services.
