In the course of the debate on going into Committee on the Army Estimates, on March 22nd, Lieut.-Colonel Fremantle delivered his maiden speech, drawing attention to army administration from a medical point of view. There was, he said, a waste of effort owing to the duplication of services and the overlapping by the Indian Medical Service and the medical service of the Colonial and Foreign Offices. He asked what steps had been taken to fulfil the promise of the Army Council to create an Imperial Medical Service after the war. The proposal was backed by the highest opinion of those who had experience of War Office administration. The services of medical men abroad usually came to a close when they were 45, and they should then be linked up with the services at home, under Pensions, Insurance, the Civil Department, and the proposed reform of the Poor Law. His second point concerned the way in which Territorial officers who had served their country before the war were penalized as compared with temporary medical officers. He liked the spirit of the young medical officer who told him in Gallipoli that he had left his private practice, his wife, and family, and was getting 14s. 6d. a day, because he had served in the Territorials before the war, whereas the man in practice beside him at home, with no pre-war sacrifices, had been taken on at 24s. a day. He did not want these things straightened simply from the point of view of payment, but he asked that it should be gone into on broader grounds. His third point concerned the position of the Director-General of the Army Medical Service. He was responsible only for the provision of doctors, nurses, drugs, instruments, and dressings. When a breakdown and consequent scandal occurred it was almost invariably in the provision of hospitals, or equipment, or in transport arrangements. The tragic breakdowns in the Crimean and South African wars were due to the difficulty of co-ordination. The result was the Hospitals Commission. When the Commission came home just before the end of the South African campaign the Secretary of State established a Departmental Committee, of which he was Assistant Secretary. On its report was based the reorganization of the Army Medical Service, but it included only one representative of the Royal Army Medical Corps. This was a lieutenant-colonel of most distinguished service, afterwards Surgeon-General Sir Alfred Keogh. One recommendation was that the Director-General should be on what was then—October, 1901—called the Army Board. On further rearrangement, after the report of Lord Esher's Committee in 1903, it was laid down that the Director-General—if necessary, associated with a civil representative of the Army Medical Service Advisory Board—should be summoned to the Army Council whenever his advice and special knowledge were required. That was the difficulty. Who knew when the advice of the specialist was required? Thus arose the difficulties foreshadowed by the British Medical Association when it represented this point of view to the Army Council; expeditions were undertaken without the Director-General of Army Medical Services having been consulted. He would like to know to what extent the Director-General was consulted before the original expedition sailed for Gallipoli. The report of the Dardanelles Commission showed that the errors were due largely to lack of co-operation and provision in thinking out the probabilities. Questions of sanitation went to the root of efficient strategy. Lord Esher's Committee recommended that the Director-General of Army Medical Services should come under the Adjutant-General, because sanitation was so much a question of discipline. It was, but hospitals depended on other things that came from the Quartermaster-General, from military intelligence, and from the Chief of the General Staff, and there was no real reason why hospitals or other branches of medical services should come under any one of those three officers. An officer was needed on the Army Council who would be responsible for all materials and supplies, and would have the power required to get hospitals efficient. He referred to the public recantation from Lord Esher, who, writing in 1917, said that September, 1914, had swept away his illusion, but the mischief had been done. He continued: "How much of the suffering undergone by our soldiers then and since was due to the short-sightedness of my committee (and notably of myself) will never be known. Certainly the control of the Adjutant-General's branch of the R.A.M.C. was and is responsible, not only for the early failure to grip the medical factors of this war, but for the hampering conditions under which Sir Alfred Keogh has worked. His triumphs and those of the R.A.M.C. have been achieved in spite of obstacles that the subordination of science to ignorance, of elasticity to military discipline,

explains but cannot justify. I would appeal to Lord Derby to strengthen the Army Council by placing upon it the Director-General of Medical Services, and to free from the control of a purely military officer (admirable as is Sir Nevil Macready in the sphere congenial to him) a body of men mostly volunteers from highly trained professions, and dealing with technical difficulties altogether outside the orbit of vision in which the soldier pure and simple habitually moved." In conclusion, Lieut.-Colonel Fremantle said that on the score of efficiency the Director-General should not only be given a seat on the Army Council, but should be given responsibility and what was more important—power to co-ordinate and organize the whole of the possibilities of medical and sanitary science for the comfort and the care of the sick and wounded in war, and for the better carrying out of strategy, whatever purpose was in view.

Captain Elliot supported the claim put forward by Lieut.-Colonel Fremantle that the Director-General should have a seat on the Army Council. Gigantic blunders were made because his advice was not available in that way. Many points in the malaria-haunted valley of the Struma were occupied and kept in the teeth of medical advice, where thousands of men were needlessly lost. Medical men had made contributions of the greatest value towards keeping an army in the field. Speaking as to the diet of the soldier, he said that it was impossible to give the young recruit too much to eat. The proof was that such a lad spent his own money in buying more food. In the first winter of demobilization the physiological experts warned the Army Council that men coming back needed an increase in rations. Of course the Army Council took no notice until Australia's troops mutinied, and then on threat of force they gave what was not conceded to reason. Immediately discontent began to fall away, but it was because the knowledge of experts was recognized. Troops sent to Egypt were brought into a district swarming with a parasitic disease known as bilharzia, which had been a scourge since the time of the Pharaohs. The Army Council were warned in time and they sent out experts. In a very few months the cause of bilharzia was discovered, and our troops were practically immune from this disease, which otherwise, but for the medical advice taken, would have invalidated many thousands, not only during the war, but when it was over. These cases showed that the voice of the medical man was of the greatest importance to keeping an army in the field. Therefore he asked that the Director-General should be given his proper place. Captain Elliot next referred to the grievances of army medical men in Mesopotamia. It was extraordinary that so many white doctors had been kept long after the time for demobilization. The medical profession was the only one to which conscription was applied up to the age of 56. There were many British doctors in Mesopotamia unrelieved because they were said to be indispensable, but Indian doctors were available to relieve them. A great injustice was that British medical officers were being paid less than Indian doctors. The discontent of the British officers was extending to the Indian Medical Service, which was in a state of seething unrest, and as soon as permission could be obtained to resign, many hundreds of commissions would be given up. After urging that dentistry should be made a divisional institution in the same way as the field ambulance, Captain Elliot referred to the attitude of the War Office towards women in the army. The salary of a nursing sister amounted to only £50 per annum, and it was disgraceful that they should ask a skilled woman to spend her life in serving the army for so small a sum. The war bonus allowances brought up the total to about £140, but there was great difficulty in getting the allowances, and if the sister went on holiday for a week or ten days they were stopped. A woman in the position of a nursing sister should rank as an officer.

Sir Arthur Williamson, Financial Secretary to the War Office, said that he recognized nurses were not paid as they ought to be, but their allowances brought the remuneration to the equivalent of £140, and the War Office could not go out of line with other Departments and civil institutions.

Mr. Churchill, in complimenting Lieut.-Colonel Fremantle on his "very interesting" speech, which showed "great fluency and knowledge," promised that what he had said should be carefully studied and examined by those in the War Office who were specially concerned with the subjects mentioned.

Diagnosis of Typhoid Fever.

Mr. Robert Young asked, on March 19th, whether a number of cases of illness in the army occurring in 1915 and 1916 in the Near East, and sent to Malta, Lemnos, and other places, were diagnosed by the clinical symptoms as

typhoid fever; whether the majority of these cases were subsequently returned as suffering from other diseases, the altered diagnosis being based on agglutination tests performed by bacteriologists sent out for the purpose; and whether it could be stated how the figures regarding typhoid fever in the late war, could be compared with those for other campaigns, in view of this alteration of method of diagnosis. Mr. Churchill replied that under active service conditions in the field it was often impossible to carry out careful and prolonged bacteriological and clinical examination of cases. In these circumstances a provisional diagnosis was returned. Such cases, on reaching the base hospital, as at Mudros, Malta, or Lemnos, were submitted to bacteriological and clinical examination as a routine measure by the pathologists and physicians attached to such hospitals. In many cases the provisional diagnosis was altered, but until the investigation of the records which was now proceeding was completed, it was not possible to give any estimate of the number of cases in which such alteration of diagnosis was necessary. Some of the cases provisionally diagnosed as enteric were subsequently returned as suffering from other diseases, and other cases provisionally diagnosed as dysentery or diarrhoea were finally diagnosed as typhoid or paratyphoid on the bacteriological evidence. The diagnosis of disease had undoubtedly been more accurate in the late war than in any previous campaign. Mr. Waterson asked whether the figures regarding typhoid fever contained in the recent White Paper were based on returns made by clinical diagnosis of the disease or on returns made by bacteriologists after agglutination tests had been made. Mr. Churchill replied that the figures were based on returns made both by clinical and bacteriological diagnosis. Bacteriological diagnosis was employed in every case so far as circumstances permitted.

National Insurance Amending Bill.—The second reading of the National Insurance Amending Bill was taken after eleven o'clock on March 22nd. Dr. Addison, in appealing to the generosity of the House to read the bill a second time without much discussion even at that late hour in order that it might be referred to Committee, briefly recapitulated the provisions which have already been given in the BRITISH MEDICAL JOURNAL. In the discussion Mr. Tom Myers, the Labour representative who defeated Sir John Simon and the Liberal Coalitionist candidate in the Spen Valley, rejoiced that the sanatoriums were being removed from the scope of the old Act, but expressed the opinion that as soon as a patient was certified as tuberculous, he should be taken out of the hands of the panel doctor and placed in an institution. The domiciliary visits in his opinion were waste. Sir Alfred Warren, speaking with an intimate knowledge of approved societies, also referred to the dissatisfaction that had been felt at the working of the panel system, and hoped that now it would be made really satisfactory. Mr. Ormesby Gore urged that before the bill left the House, members should be informed by the Minister of Health what he proposed to put in place of the sanatorium benefits scheme, which was being abolished. In his opinion it was essential for the smooth working of the panel system that the payment of doctors should be exclusive of drugs. He trusted that some arrangement would be made also which would prevent doctors and insured persons endeavouring to contract themselves out of the national scheme because they were not satisfied with its provisions. Captain Elliot deplored that a measure of such vast importance affecting fifteen and three-quarter million people was being hurried through the House of Commons in the small hours. It would assist matters very much if the Minister of Health were at that stage to indicate what his policy would be in connexion with the large number of health measures to be brought forward and would declare his intentions in regard to the variety of demands for the treatment of the tuberculous. Treatment should be based on attention by the general practitioners, who should be grouped into clinics, so that they could specialize to a certain extent. Thus the use of the doctor's waiting-room, which was most undesirable, could be avoided. Dr. Addison, in a short reply, promised that there would be no hiatus in the arrangements for consumptives. An appeal had been made to him that where wages were low, the contribution of health insurance should be divided between the State and employer. If the House showed a strong desire that this should be done he would be willing to accept an amendment in Committee. The second reading was then agreed to.

Tuberculous Ex-Service Men.—Mr. W. Graham asked, on March 17th, whether the attention of the Minister of Pensions had been drawn to the fact that many discharged men suffering from tuberculosis were being sent to ordinary medical boards for the reassessment of their pensions; whether these pensions were in many cases being reduced; and whether steps would be taken to ensure that an expert in tuberculosis should always be a member of a medical board dealing with such cases. Sir James Craig replied that whenever a specialist's opinion was required arrangements were made to secure either that the tuberculosis officer of the district should sit on the board or that the man should be referred to him for examination and report.

Remuneration of Medical Boards.—Major David Davies asked on March 17th, if medical men employed on medical boards had had their pay raised by 50 per cent., while medical men employed as assessors on sessional rates had had their pay raised by only 25 per cent. Sir James Craig, in reply, said that the conditions of work of the medical boards and the assessors were not the same. The members of the board were drawn from a panel; the assessors were continuously employed. It was not inequitable that the difference between occasional employment, which could not be counted upon from day to day, and regular employment should be marked by a difference in the rate of payment.

Loss of Both Legs.—In reply to Major Cohen, on March 16th, Sir James Craig said that Article (3) (1b) of the Royal Warrant embodied a special concession. Strictly interpreted, loss of both legs implied amputation of both legs to the thigh, but in practice the concession had been extended, with Treasury approval, to cases where there was loss of one foot, provided that the other amputation was above or through the knee. An amendment of the Warrant was not considered necessary.

Permanent Pensions Rate.—At the instance of Captain Loseby, Sir J. Craig, on March 18th, restated the position of soldiers wounded before 1914 as to reassessment of their pensions. Many men pensioned for disabilities incurred in former wars were now restored to health, or so much improved that a reassessment under present warrants would not advantage them. They, however, retained their rights under former warrants. Pensions could only be granted on the basis of the existing degree of incapacity. Captain Loseby put it that there was considerable dissatisfaction with the manner in which this particular class of pension had been assessed by the medical boards. Sir J. Craig demurred, but said that if particulars of any case in regard to which there appeared to be ground of complaint were stated he would give it attention.

Institution Accommodation for Tuberculosis.—Lieut.-Colonel Fremantle, on March 18th, again pressed on the Minister of Health the desirability of using for tuberculous cases any vacant accommodation in Poor Law infirmaries. Dr. Addison said that he was doing all that was possible, but the need for further provision could not wholly be met in that way. He did not think that the limited amount of new building required to provide additional sanatorium accommodation would seriously affect housing operations, but in any case the erection of new sanatoriums in some parts of the country was a matter of urgency.

Small-pox.—In reply to Mr. R. Young, on March 18th, Dr. Addison said that, in accordance with the usual modern practice, persons known to have been in recent contact with others who had since developed small-pox were offered free vaccination; they were bathed, their clothes disinfected, and they were kept under daily observation by the medical officers of the borough council for a period of sixteen days. He was advised that during the incubation period of the disease, which was usually twelve days, the infection was not spread; should any person under medical observation exhibit symptoms of illness, he would at once be isolated. Five of the contacts had since developed small-pox, but of these three had refused vaccination. The method of disinfection adopted in Poplar was considered satisfactory, and the local authority was doing everything in its power to prevent the spread of the disease. In reply to Mr. Bromfield, on March 18th, Dr. Addison promised to furnish a list of firms and bodies which manufactured or supplied vaccine lymph in this country. There was no government inspection of proprietary supplies.

Ministry of Health Nursing Services.—In reply to Captain Terrell, Dr. Addison said that, as the total membership of a Consultative Council for the Ministry of Health was restricted to twenty, he had not been able to include representatives of the Queen Victoria's Jubilee Institute for Nurses in the Council on medical and allied services. He hoped, however, to have the assistance of such representatives on any committee appointed by the Council to consider the future organization of nursing services.

Medical Officers in Mesopotamia.—Sir Watson Cheyne, on March 16th, asked what further arrangements were being made to relieve the medical officers of the Royal Army Medical Corps in Mesopotamia (Special Reserve and Territorial Force) who have been there for some years. He inquired whether the War Secretary was aware that at one centre, where five medical officers and five subordinates were stationed, it was stated that the medical work of each officer during the last six months had averaged ten minutes a day, and that for the last seven weeks, prior to January 24th, they had not received a single patient? Sir Archibald Williamson (Financial Secretary to the War Office) replied that the establishments were being reduced to the greatest possible extent, and regular Royal Army Medical Corps officers were being sent out as circumstances allowed. He was unaware of the particular cases mentioned, but would obtain a full report. He would point out, however, that in Mesopotamia and Persia isolated bodies of troops were stationed and required to be provided with medical personnel, as the distance precluded the dispatch of medical officers at short notice. Captain Elliot asked whether relief could not be given by native medical officers, who in many cases were being paid more than white officers. Sir A. Williamson said he was unable to answer without notice. At the instance of Sir Philip Magnus, the Minister said he would represent to the War Office the desire of the young officers to be recalled for the purposes of resuming their studies, and, on appeal by Mr. R. McFarquhar, he promised also to represent that three hot seasons were sufficient for residence in such a climate continuously.

England and Wales.

HOSPITALS IN LONDON.

The King's Fund.

•THE honorary secretaries of King Edward's Hospital Fund for London have issued a statement on the present position of the London voluntary hospitals, in which they indicate the scale of the problem by stating that the present system of collecting funds provided last year nearly £2,000,000 towards a total expenditure of less than £2,200,000. It is recognized, however, that the difference between expenditure and income may well be greater this year. In 1913 the Fund distributed £157,000; in 1918 it distributed £200,000; in 1919, partly in anticipation of the needs of the hospitals after the war, especially the necessity of carrying out deferred renewals and repairs, the sum distributed was £230,000. To find this amount the Fund had to draw on the reserves created during the war by exceptional legacies to the extent of £46,000. The Fund, it is stated, has before it particulars of extension schemes submitted by a large number of hospitals in London. The fact that since 1913 more than a thousand beds have been added may account for some of the deficit on current expenditure. The additional schemes proposed would add another 3,000 beds, and these, and certain plans for improvements not involving additional beds, would altogether involve the expenditure of a large sum for building and a large increase in maintenance charges. Towards the capital expenditure the King's Fund is about to allocate, in addition to a share in the ordinary distribution later on, the sum of £250,000 surplus Red Cross funds entrusted to it for this special purpose. This amount, it is said, will not go very far, and the Fund will examine very carefully the numerous schemes submitted, especially the larger ones, in order to ensure that only those financially practicable are undertaken and that the money available for building is expended only where it will produce the greatest benefit.

National Hospital, Queen Square.

At the annual meeting of the National Hospital for the Paralysed and Epileptic, Queen Square, the chairman, Sir Frederick Macmillan, gave details of the unsatisfactory financial position, owing to the great rise in the cost of maintenance. Last year it was considerably more than double what it was in 1913, having risen from £14,182 to £32,352. The cost of administration had declined from £1,750 to £1,323. The result was that the average weekly cost for each in-patient at the hospital was £3 3s. 11d., against £1 14s. 8½d. in 1913. The position, the chairman asserted, was not due to any want of prudence. Large sums had been spent in increasing the usefulness and the efficiency of the hospital, but nothing had been done to increase the cost of maintenance. When the jubilee of the hospital was celebrated in 1909 funds were obtained which made it possible to rebuild and rearrange the out-patient department and to rebuild and add to the nurses' quarters. The board of management had been driven to the opinion that only two alternatives were open—either a considerable sum of money must be immediately raised or the wards must be closed. If £10,000 could be obtained for a special maintenance fund this year, and £5,000 each for 1921 and 1922, it would be possible to carry on; if the appeal failed the wards must be closed, with the exception, possibly, of the surgical wing. The out-patient department, the convalescent home, and the pathological department would be carried on, as also the annexe, Bray Court, and Lonsdale House, which were either self-supporting or paid for by the Ministry of Pensions. The medical school was self-supporting; the school of massage, carried on in conjunction with University College Hospital, was also self-supporting, and indeed to a moderate extent a contributor to the hospital funds. Sir Frederick Macmillan claimed that the medical school, which has been reorganized, is doing work of immense scientific value amongst students and medical graduates coming from all parts of the British Empire and the United States, and this statement will be endorsed by everyone who is acquainted with the position of neurology in this country, which has been carried to its present command-

ing position largely by the efforts of the members of the staff of the National Hospital. The number of men and women graduates and students who attended the medical school last year was 355. The Chairman spoke hopefully of the prospect of obtaining the needed contributions for the special maintenance fund, and it is sincerely to be desired, in the interests not only of the patients of the hospital but of the progress of neurology in this country, that he may prove a true prophet.

Charing Cross Hospital.

At the annual meeting of Charing Cross Hospital the Chairman, Mr. Verity, said that he was not pessimistic with regard to the future of voluntary hospitals. Four years ago an appeal was made to clear the hospital from debt; it was entirely successful, the debt was wiped out, and funds were provided to open the closed wards and to improve the equipment. No extensions were in contemplation; the object would be to maintain the efficiency of the hospital. The expenditure last year amounted to £51,000, in place of £24,000 before the war. Great economies had been effected, but he hoped the expenditure might be brought down to £45,000 a year. Those who went to the hospital for treatment were mainly people who were receiving increased wages, while those who had supported the hospitals until now were not receiving any increase to their income, and therefore found it difficult to keep up subscriptions. It had been decided to put up notices that all patients would be expected to contribute to the upkeep of the hospital as far as their means allowed. Were the State to take over the hospitals it would be a blow to charity, would retard the advancement of medical science, and add enormously to the burden of compulsory taxation.

INQUESTS IN THE CITY OF LONDON AND SOUTHWARK.

In the City of London, including H.M. prison at Holloway, inquests were held in the case of 158 deaths, as compared with 132 in 1918, and in the borough of Southwark in the case of 197 deaths, as compared with 177 in 1918. In addition, 79 investigations were made by the Coroner which rendered public inquest unnecessary. *Post-mortem* examinations were ordered in 85 per cent. of inquests held. Forty-four deaths were due to vehicles (19 in the City and 25 in Southwark). As suggested in former reports three chief means of prevention are recommended: more street refuges, especially in Southwark; more police at fixed crossings to assist foot passengers across congested streets; and side life-guards on all heavy commercial motors, similar to those in use on motor omnibuses. Inquests were held on the bodies of three infants, accidentally suffocated whilst in bed with their parents, as compared with seven such deaths investigated in 1918. There has been a marked decrease throughout England and Wales during the past few years in this class of death. The number in 1913 was 1,176; in 1917 it was 585. Dr. Waldo attributes this decrease chiefly to the greater use of cots and cradles and to the large and increasing number of necropsies ordered by coroners, by which means many of these deaths were proved to be natural. Drunk, he thinks, has little to do with these cases. Inquests were held in six cases (two in the City, and four in Southwark) in which sudden death was accelerated by the administration of anaesthetics for surgical operations. In five of these chloroform was the anaesthetic used; the sixth death was due to ethyl chloride. The Coroner adds:

It is a noteworthy fact that in nearly every instance of this class of case coming before me during the last eighteen and a half years death has been attributed either to chloroform or to a mixture containing chloroform. These deaths, however, have happily considerably diminished in frequency of late years, owing largely to the greater care and skill used in the administration, and discrimination exercised in the choice of the anaesthetic given.

Dr. Waldo recommends that a scientific inquiry into the whole question of anaesthetics and their administration be undertaken by the Medical Research Committee. In concluding his report Dr. Waldo expresses the view that the power in certain cases to hold coroners' inquests without a jury should be done away with, since in his opinion a fairly intelligent jury, assisted and directed by a coroner, is a far better tribunal for the elucidation of truth than a coroner unassisted by a jury.

Scotland.

HEALTH CONSULTATIVE COUNCILS.

IN an address to a combined meeting of the four Consultative Councils established by the Scottish Board of Health, the Secretary for Scotland said that the Board intended the Councils to have the fullest opportunity of forming and expressing free and independent judgements. As each would elect its own chairman and regulate its own procedure, subject to the very general regulations of the Order in Council, he considered that they would be masters in their own houses. The Board would place at the disposal of the Councils all the information in its possession, but would expect members to observe proper circumspection with regard to the information thus supplied. He invited the members to recollect that in their capacity as members of the Councils they were not representatives of any particular bodies or institutions, and any tendency towards adhesion to majority or minority views must be deprecated. The duty of the Board as expressed in the Act of Parliament was to take steps "to secure the effective carrying out and co-ordination of measures conducive to the health of the people." The members of the Councils were invited to be fellow-workers with the Board. Among the questions referred to the Council on Local Health Administration were (1) "the question of a reformed Local Authority for Health Administration, its area and constitution, and the powers and duties to be transferred to it"; and (2) the question of "applying to Scotland the principles of the Maclean Committee's report on the transfer of functions of Poor Law authorities in England and Wales." The Council on Medical and Allied Services was instructed to consider and make recommendations as to (a) the systematized provision of such forms of medical and allied services as should, in the opinion of the Council, be available for the community; and (b) medical research in Scotland. Further, each of the Councils had been instructed to consider, along with the Council on National Insurance, whether the present hospital service is adequate for the community, and to make recommendations for its improvement, or for the provision and maintenance of an adequate service. The establishment of the Board of Health was intended to prepare the way for a vigorous and co-ordinated campaign to raise the standard of the health of the people, but for success two things were necessary. One was that behind the Board there should be the solid opinion of the country; the other that there should be hearty co-operation between the Board and the Councils on the one hand, and the interests affected on the other. It would be the business of the Councils to keep in close, constant, and living touch with the opinions and feelings of the people outside. The four Councils afterwards held their preliminary meetings separately. The list of members of the Consultative Councils was printed in the *JOURNAL* of February 7th, p. 196. It was announced last week that the Medical Consultative Council has elected Sir Donald MacAlister to be its chairman and Dr. Norman Walker its vice-chairman.

LETHARGIC ENCEPHALITIS.

The Scottish Board of Health has supplemented a circular on acute lethargic encephalitis, poli-encephalitis, and poliomyelitis, issued to medical officers of health last June, by another circular dated March, 1920, with regard to lethargic encephalitis. The disease, it is stated, has so far been of rare occurrence in Scotland. In the new circular the importance of being on the look-out for its occurrence is insisted upon. As little is known regarding its essential nature or the channels by which it is spread, the means by which it may be prevented are not understood; the Board therefore considers it desirable that cases suspected to be of this nature or even remotely to resemble it should be intimated to the medical officer of health, who is directed to afford facilities for diagnosis and treatment and such isolation as may be necessary. It is asked also that he should receive information of the occurrence of ordinary acute poliomyelitis. The disease was made notifiable in England at the beginning of 1919. It is not quite clear why the Scottish Board of Health has not taken the same course. The cardinal symptoms of the disease are fever, somnolence, and diplopia, usually

followed by temporary paralysis of accommodation. An article was published last week (p. 409) on the pathology and diagnosis of the disease, and an earlier note will be found in our issue of February 7th, p. 193.

Correspondence.

THE TREATMENT OF UTERINE CANCER.

SIR,—Dr. Leitch, in the second paragraph of his letter (March 20th, p. 416) makes certain very definite, indeed dogmatic, statements.

Such statements are to be welcomed in that they raise the question out of a region of somewhat vague impressions to a plane where it can be examined in the light of scientific evidence.

Dr. Leitch is doubtless in possession of facts and figures with which to support his contentions. An opportunity of considering these facts and figures would be welcomed by me and doubtless by others.—I am, etc.,

Middlesbrough, March 21st.

W. S. DICKIE.

THE TREATMENT OF CANCER OF THE UTERUS COMPLICATING PREGNANCY AND THE PUERPERIUM.

SIR,—Dr. Archibald Leitch is saddened by reading your leading article on tumours complicating pregnancy. It had such a different effect on me that I feel I ought to do something to relieve his sadness. With that object in view I suggest that Dr. Leitch, having criticized my lecture on cancer complicating pregnancy, should now proceed to read it. He evidently has not done so, for he writes: "The crucial test of any operative or other procedure in cancer must be: How many cases has the operator seen, and how many of these are alive and well, say, five years afterwards?" and it is precisely that information which I gave in the lecture, and repeat here. Of ten cases seen four were cases of early pregnancy (one operable), all of these died, and six were cases of late pregnancy (three operable); the three inoperable patients died, and three patients, operated on by high amputation, remained well after 19, 22 and 25 years, and one of them, subsequently to the amputation, had a child delivered by Caesarean section who served as a soldier in the great war.—I am, etc.,

London, W., March 21st.

HERBERT R. SPENCER.

THE PHYSICAL BASIS OF MENTAL DISORDERS.

SIR,—Mind is ever embarrassed in the consideration of its own processes, normal or morbid, hence we may look for a divergence of opinion not met with in the more exact sciences on the genesis of psychoses and insane states.

Psychologists have fallen broadly into two classes—the biologist, subjecting the intellect to mechanistic forces, and the idealist, to whom the nervous system is but the instrument of spirit. Dr. John Turner, whose pathological researches in psychiatry are so well known, desires, as I judge by his recent letter (March 20th, p. 415), to place himself in the former group.

And yet, may I say how weak is his argument? He cites recent experiments of Professor Waller showing that certain speech produces metabolic changes in cells, whilst other does not, and that this is a biological phenomenon, but the very fact quoted by Dr. Turner—that the speech which stirs strong emotion alone creates those changes—would, one thinks, suggest that a mental phenomenon was here first in the order of sequence.

It is not the intensity of sounds projected along the neuronic path, but the ideation of the meaning of such sounds—in other words, the concept—which gives rise to a secondary perturbation in matter.

I have no doubt that Dr. Turner, analysing causative factors during these past few years, can find many cases of the acute insanities precipitated by purely mental stresses, which have exhibited symptoms indistinguishable from the manias and melancholias of clearly toxic or metabolic origin. The late Charles Mercier asserted that all mental disorders were occasioned by but two causes—heredity and stress. I agree with him, and assert that the latter may be of the cell or of the psyche.—I am, etc.,

FRANCIS H. EDWARDS.

Camberwell House, Peckham Road, S.E.

THE TREATMENT OF MALARIA.

SIR,—May I add a few remarks on the treatment of malaria to the valuable and interesting letters that have appeared in several of your recent issues?

The statements made by Major W. F. Law and Dr. J. Wallace Collett, in the *BRITISH MEDICAL JOURNAL* of February 21st, 1920, in general terms represent the form of treatment adopted in the Army in India. I believe all military medical officers there recognize the importance of preceding quinine treatment by an aperient, blue pill or calomel, followed by a saline. They are also alive to the urgent necessity of intravenous use of quinine in threatening or developed cerebral malaria. It is the only means of saving life in the vast majority of such cases. In the recent Afghan Campaign there were two exceptionally severe heat waves in June and July, 1919, associated with hundreds of cases of high temperature ranging from 106° F. to 111° F. amongst British troops. Roughly 15 per cent. of these were genuine heatstroke, having the usual classical symptoms and signs of that condition, 75 per cent. had pyrexial phenomena that military medical officers in India sixty years ago called "thermic" or "ardent fever," whilst about 10 per cent. were complicated with malaria, benign tertian infection being responsible in about 80 per cent. of these last mentioned cases. In India we have for many years been acquainted with the predisposition to the effects of the sun arising from infection with the plasmodium of subtertian malaria, but it is only in more recent years that we have attached due importance to the part played by the benign tertian parasite in this connexion. So far as I remember, it was Mannaberg in 1894 who put forward the view that cerebral malaria was a phenomenon of subtertian infection, explaining this singularity by the hypothetical increased agglutination of red cells infected by the subtertian plasmodium causing them to adhere to the walls of the cerebral capillaries. I am not prepared to refute this theory of enhanced adhesiveness of infected red cells in subtertian, but am quite confident that in India cerebral malaria is more commonly associated with benign tertian infection than with subtertian infection.

Medical officers who had the treatment of these cases of cerebral malaria combined with effects of the sun in Afghanistan and the Indian Frontier lately were unanimously of opinion that intravenous injections of quinine, promptly given, saved many lives. With this reference to heatstroke cases one might incidentally remark that in the last few years in India we have observed that if cases of genuine uncomplicated heatstroke are got under treatment early—that is, while the temperature is still rising—and ice and ice-cold water used on the surface with electric fans and thermantidotes working near the patients, the mortality is strikingly reduced and the severity and duration of the sequelae greatly lessened. The statistics of our heatstroke cases in the Army in India during the last two years show this. This, of course, means a high standard of medical organization in barracks, and in the field in camps, with ice for the purpose available everywhere, and a knowledge of first-aid treatment of heatstroke on the part of the comrades of the victims. We now have what are called *heatstroke stations* universally in barracks and in the field.

There are definite reasons why the military medical authorities in India were obliged to place certain restrictions on the use of quinine intravenously and intramuscularly, and to forbid its use hypodermically. At one period there was a run of tetanus cases following the latter use of the drug. It was generally considered that the *Bacillus tetani* was introduced with the injection, although some bacteriologists thought that the spores of this micro-organism, already in the bowels, developed and found its way to the seat of the injection. The restrictions have to a large extent been removed, but the hypodermic use of quinine is, I believe, still prohibited, and I consider rightly so. It would be most injudicious to allow young sub-assistant surgeons to use the drug in this way without supervision.

Whilst the prompt use of quinine intravenously or otherwise is necessary in cases of hyperpyrexia due to malarial infection, it is necessary to be quite sure that it is malaria we are dealing with, and not give quinine on the off-chance that the high temperature is malarial in origin as is sometimes done. In July, 1917, at the end of our penultimate Mahsud Campaign, I got a sudden rise of temperature to

105.2° F., with intense headache, etc., following a prolonged shivering fit. Sandfly fever was epidemic at the time. A blood smear was made, but for some reason not examined for three days. Nevertheless I was given 45 grains of quinine daily for two days without any effect; I have seldom suffered so much as on the evening of the second day, when a dose of trioval put me to sleep, and I woke up next morning free from fever, and feeling quite well except being rather feeble. The blood smear when examined was found to be negative as regards malarial parasites. The diagnosis was wrong.

Most medical officers doing duty with troops in India consider that in cases of malaria of any duration, even with very slight enlargement of the spleen and but little anaemia, a course of arsenic and iron is a valuable adjunct to the treatment; this is certainly the case where there has been a noteworthy destruction of erythrocytes.

I do not agree with a correspondent who states that medical officers infected with malaria do not take the prolonged course of quinine they recommend to their patients after malarial infection. I am quite certain that most medical officers from India serving in Mesopotamia up to the end of 1915 who got infected took quinine continuously for months. Without such a course they were almost certain to be invalidated owing to relapses. Personally I acquired a heavy benign tertian infection at Kurna (on the rivers Tigris and Euphrates, north of Basra) on February 25th, 1915. I took 30 grains daily for a week, 20 grains daily for two weeks, and then 10 grains daily. During the last named period I had what appeared to be a relapse; I began the intensive treatment again, continued it for three weeks, and then kept up the quinine in gradually decreasing doses for five months without any recurrence up to date.—I am, etc.,

P. HEHR,

London, W., March 1st.

Major-General I.M.S.

SIR,—Disregarding the few who exhibit nothing more than the general debility and anaemia of post-malarial intoxication, by far the larger proportion of cases of malaria that come under the observation of the general practitioner in this country, during present times, consists of those in which the infection has become more or less long standing; where the earlier and severer attacks of fever have given place to milder relapses at longer intervals; and cases of "latent malaria" presenting few or none of the clinical and physical signs of the disease.

In most of these cases of "active malaria" of benign tertian type (the type usually met with) the routine treatment previously advised in these columns is sufficient. This resolves itself into the administration of a quinine salt in quantities of about 20 grains in twenty-four hours during the acute symptoms, and its gradual reduction to about 10 grains daily afterwards, the whole course being spread over a period varying with the severity of the illness from about six weeks to three months. This routine is substantially the same as that described in your issue of March 13th, excepting that I think there is no advantage in giving quinine in larger single doses than 5 grains; otherwise the unpleasant symptoms of quininism are apt to supervene. The secret of success lies in the fact of the continuous and regular dosage for a necessary period of time. In subtertian malaria more vigorous treatment is, as a rule, indicated.

When, however, the parasites of malaria have become pathologically quiescent within the spleen and other organs—that is to say, in latent malaria—treatment by quinine alone is very disappointing. Quinine acts quickest and best upon the parasites when they are in the blood. For this reason they must be routed out of their lair within the organ cells into the circulation before quinine is given. Strychnine and iron are drugs which provoke the parasite to reappear in the blood stream, and the successful treatment of "chronic malaria" should always include a preliminary course of these and similar medicines.

With reference to the inadvisability and the uselessness of intramuscular injections of quinine, the value of this method in those cases (which do occur) where nothing can be retained by the stomach for the first few days of fever cannot be doubted; nor has its use in my practice ever been followed by extensive necrosis of muscle. I have never injected quinine hypodermically—that is to say, in the same subcutaneous manner as morphine is given for

example. I have always inserted the whole needle deeply into the tissues, and, with ordinary care to secure asepsis, nothing worse than a little pain and tenderness for a few days, together with some discoloration in the region of the puncture point, has been my experience with patients, as with myself personally.

In a tropical climate, and under the conditions of active service in the field, it is not difficult to imagine that the necessary cleanliness and care are not easily possible; and this fact may explain the advisability of administration by the mouth and the untoward results complained of.—I am, etc.,

Guernsey, March 15th.

J. WALLACE COLLETT.

MODE OF QUININE ADMINISTRATION.

SIR,—During the war I was stationed for nearly three years at Wynberg Hospital, where we had a very large number of patients suffering from malarial fever contracted in German East Africa, and amongst them cases of phlegmon and paralysis due to intramuscular injections of quinine. These cases are very serious, not only because of the long time required for convalescence, but in the permanent deformities often left, due to sloughing of a large amount of muscle and paralysis. These complications are not due to sepsis or faulty technique, but to the escharotic action of quinine in susceptible subjects. The result is that men hesitate to give injections unless the patient is gravely ill. Hearing that an officer was giving quinine subcutaneously with the same therapeutic result as obtained by the deep method, I started giving quinine under the skin to all acute cases, and did so for the last year I was attached to the hospital. The results, dosage, etc., are recorded in a paper read before the British Medical Association (Cape Town Branch), printed in the *Medical Record*, July, 1918, and reprinted in the *Epitome of Tropical Medicine*, November, 1918, entitled "A plea for the routine treatment of acute malaria by subcutaneous injections of quinine." Briefly I think I proved my thesis that injections of quinine act quicker, and can be given during the fever when the parasites are free in the blood—a great advantage, especially as the majority of cases vomit during the paroxysm, so that quinine by mouth cannot be given. There is no anxiety regarding complications; hundreds of injections were given in my wards; in six cases small collections of necrotic pus were evacuated; within ten days the arms were well, and in the meantime there was no inconvenience to movement of limbs. If this method is given a trial much suffering to the patient will be avoided, and the doctor will have his acute cases free from fever in from twenty-four to fifty-six hours, two to six injections being required either in benign or malignant malaria.—I am, etc.,

H. KNIGHTS RAYSON, M.D. BRUX.,

Kirkwood, South Africa,
February 24th.M.R.C.S., L.R.C.P.,
Late Captain S.A.M.C.

CARCINOMA OF THE THYROID.

SIR,—The case of papilliferous carcinoma of the thyroid in a girl of 13 (reported by Mr. Basil Hughes March 13th, p. 362) is interesting, not only on account of the nature of the growth, but also on account of the age of the patient.

In my experience ordinary adeno-carcinoma of the thyroid is also rare, and a correct diagnosis is not usually made until the growth has spread through the capsule of the thyroid and the chance of a cure by operation is remote. I should like to know if this tallies with Mr. Hughes's experience.

Last September I excised the left lobe of the thyroid from a woman aged 25. The lobe was slightly nodular, but appeared clinically to be an ordinary parenchymatous enlargement, causing dyspnoea. The lobe was not adherent to the surrounding structures; a portion was burrowing between the trachea and oesophagus, but there was no difficulty in the operation. On cutting into it afterwards it was seen to be the seat of a greyish-white soft tumour the size of a golf ball, which on microscopical examination proved to be an adeno-carcinoma. There was no sign of glandular infection, and up to the present there is no sign of recurrence. Apart from her age and the unexpected finding of the tumour, an interesting point about this case is that I had removed her right lobe for parenchymatous enlargement six years previously. (A microscopical section from this lobe proved it to be an ordinary parenchymatous

goitre.) She still has a small portion of the isthmus, but is taking thyroid extract gr. j daily.—I am, etc.,

Norwich, March 22nd.

A. J. BLANLAND.

SENIOR SURGEON COMMANDERS, R.N.

SIR,—The Admiralty evidently realize they have a very bad case when defending their treatment of senior surgeon commanders. Mr. Long's reply (*BRITISH MEDICAL JOURNAL*, March 13th, p. 378) is misleading, and made up mainly of garnishing and red herrings.

He speaks of having put the various branches on the same basis as far as possible. This is exactly what he has not done to senior surgeon commanders except when it was to their disadvantage. Thus: (1) We have been retired earlier than the regulations showed when we joined; (2) we got no acting rank scarcely during the war; (3) we get no increase of retired pay, varying from 40 to 100 per cent., that all other branches, ranks, and ratings get; (4) worst of all, promotion to captain was not put on the same basis as in the executive line by a huge amount. For instance, three senior surgeon commanders were placed on the retired list last January 1st at the age of over 54 without even having come within the zone for consideration for promotion. At the same time, commanders (executive) come within the zone at about 38 years of age.

These three unfortunate surgeon commanders find themselves prematurely retired on a pension approximately only 9 per cent. more than the rates fixed forty years ago. They are not getting an increase sufficient to pay increased income tax, much less provide for their families. Have we no friends except the British Medical Association?—I am, etc.,

March 17th.

SURGEON CAPTAIN RETIRED.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—I regret to have to trouble you once more, but I must again remind Dr. Baskett that it was not comparative poverty *per se* that caused tuberculosis but the destitution that accompanied it, and that that destitution very largely vanished under paternal legislation, as well as did earlier so much of the infection of which destitution formed the favourable soil.—I am, etc.,

March 22nd.

SIDNEY DAVIES.

Medico-Legal.

A PANEL PRACTITIONER'S ACTION FOR SLANDER.

THE Lord Justice Clerk and Lords Dundas and Salvesen recently heard an appeal in an action raised in the Glasgow Sheriff Court by Dr. James Wylie, who sued the general secretary of a friendly society for damages for slander. Dr. Wylie had among his panel patients a woman member of that society. On January 20th, 1917, after a few days' absence in the country, she returned to Glasgow, called on Dr. Wylie, who examined her, and gave her a certificate of incapacity for work, which she forwarded later to the secretary. The latter, misunderstanding the remark of a health inspector as to the date of the patient's return, wrote to the secretary of the Glasgow Insurance Committee stating that the certificate had been granted by Dr. Wylie without seeing the patient, and that in his opinion the doctor had committed a breach of the Medical Benefit Regulations. The Sheriff-Substitute, who first heard the case, found that the letter was defamatory and malicious, and awarded Dr. Wylie £10 damages. The Sheriff, on appeal, acquitted the defender on the ground that the letter was privileged, and that malice had not been proved. Their lordships reversed the latter judgement, and reverted to that of the Sheriff-Substitute, with expenses, holding that the letter had been sent without due inquiry, and that the defender's recklessness in making the charge without regard to its serious nature and to the want of information on which it was founded amounted in law to malice, debarring the plea of privilege. Dr. Wylie was represented by counsel instructed by the Medical and Dental Defence Union of Scotland, Ltd.

THE Linnean Society is taking steps to increase the annual subscription from £3 to £4, mainly on the ground of the increase in the cost of the production of its *Transactions and Journal*, but also owing to the tendency of all establishment charges to rise. If the difficulties were temporary, some of the small investment funds might have been used, but as there is no prospect of a return to former conditions an increased income is regarded as absolutely essential. *Nature*, in commenting on the announcement, states that all the learned societies are at present faced with similar problems.

SIR ROBERT MORANT.

BY

The Right Hon. CHRISTOPHER ADDISON, M.D., M.P.,
MINISTER OF HEALTH.

SIR ROBERT MORANT was more than a great public servant; he was a great patriot, a man of tireless self-sacrifice and deep enthusiasm. He was perhaps better known than many leading civil servants, but, in common with them, the full variety and the greatness of his work could only be fully known to those who worked with him.

My first close personal association with him was during the fierce political controversies which arose over the introduction of the National Health Insurance Act. He grasped at once the immensity of the task and the character and the extent of the organization necessary to cope with the enormous mass of detail involved. Often in the struggle against time, as the day drew near for bringing the different services into operation, he would say in his nervous, masterly way that this or that could not be done, yet it was done. It was done because a man was in charge who had an indomitable spirit, an infectious energy, and a singular capacity for gathering around him a team of younger men whose standard was efficiency. He tolerated no inefficiency, and was impatient of failure to act according to principles laid down; at the same time he was peculiarly sympathetic, often tender, to lowly members of his staff, and I have never known him fail to spare others rather than spare himself. Had his consuming conscientious energy been less active he might perhaps be with us still.

Many a time in those days we tried to forecast the order of development and the nature of a system of organized health services which the nation so sorely needed. None was more conscious than he was of the difficulties in the way and of the time that would be required in overcoming them. Yet he was not dismayed when he realized that it would be necessary to deal with a medley of interests and authorities, an antiquated and cumbersome system of the Poor Law, a lack of trained personnel in all directions, a mass of vehement, deep-rooted prejudices, and, above all, with the common habit of thought that national health services were solely associated with physic and doctoring.

He loved to talk of these things and longed to have a hand in the working. Often enough he would speak despairingly when he thought of the vicissitudes of political life, of the slowness of things, and of the lack and accidents of opportunity. When he fretted thus it was only because his eager spirit was anxious to be at work.

Among the many facts which the war made manifest was the urgent need of an organized system of health services, and I believe that he achieved one of the chief ambitions of his life on the day when it was my high privilege to ask him to become the First Secretary of the first Ministry of Health. He saw before him an opportunity for years of useful work in the things he loved, and as a great practical idealist he rejoiced in the prospect.

He never got lost in the thicket of details, of arrangements, rearrangements, adjustments, conferences, discussions, delays, and difficulties which attend the development of a progressive policy. All the time he knew where he was going, and his smallest actions were purposeful, and designed to help things forward. He had the priceless gift of a wide view whilst retaining command over near and detailed work.

The tragedy of his loss would appal us all were it not for the unforgettable example of his dauntless courage. Those who really knew him loved him even for his foibles. There was nothing petty about him. When a course of action had been decided upon he pursued it; the doubts and questionings that had preceded its decision having been carefully examined and estimated were cast behind him; whether he agreed in all respects or not he went straight on when the course was decided, and that annoying habit of lesser men of bringing up again and again all sorts of pointless questionings was never his. A great reasoner himself, he respected reasoning in others, and his masterful manner did not arise from any love of domination for its own sake, but from what he felt to be the necessities of the case. He was ready enough to subordinate himself and modify his views, and he looked for a similar practice

in others. The cause was the only thing that mattered to him.

He was an inspirer of others, a magnificent chief of staff, greedy for labour in a worthy cause, a despiser of trifles and an affectionate and loyal friend, a tower of strength to whatever he supported, a devoted and splendid citizen. We are made poorer as a people by his loss. We are shocked by the tragedy of his death at the moment when he seemed to have the fullness of his power and opportunity. In our sorrow we can but reverence his memory and pay the tribute that he would value most in striving with all our might to imitate his great example.

Obituary.

PROFESSOR WERTHEIM,
Vienna.

PROFESSOR ERNST WERTHEIM, of Vienna, died from pneumonia on February 15th. About ten years ago he succeeded Chrobak as chief of the second Gynaecological University Hospital in Vienna. For some time he was a pupil of Schauta, with whom he subsequently carried on many discussions, especially with regard to the abdominal and vaginal routes for operating on cancer of the uterus. Wertheim, at a comparatively early stage in his career, elaborated a method for cultivating gonococci which was in common use for many years. He will, however, be best known for his work on cancer of the uterus and for his operation for prolapse. In the nineties he was appointed to the Cancer Hospital established by one of the Rothschilds in memory of his wife who had died of cancer of the breast. This hospital, which was devoted to gynaecological cases, patients with cancer being given preference, was equipped with large laboratories, and was a model of its kind. Here Wertheim evolved the operations on the uterus which have become associated with his name. He was a first-rate teacher and a generous host, freely giving of his best.

Dr. HERBERT SPENCER writes: It was with sorrow that I heard of the death of Professor Wertheim, one of the great heroes of gynaecology, whose name will always be associated with the abdominal operation for cancer of the uterus. It was from reading his early work on that subject, and from finding in 1904 that an extensive growth which could not be removed in a surgical manner by the vagina could be removed by his method, that, as President of the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association at Leicester in 1905, I asked him to come as my guest and read a paper. The paper, written in German, was translated under my supervision in the office of the JOURNAL; it was published with illustrations in the BRITISH MEDICAL JOURNAL, September 23rd, 1905, and has had a great effect in extending this method of his operation. In discussing the paper at the time, I said that I "considered this paper of Professor Wertheim's the greatest which had been published on the operative treatment of cancer of the uterus, and indeed of cancer of any other organ," an opinion which I have seen no reason to alter. It had since been surpassed by his monumental work on *Die erweiterte abdominale Operation bei Carcinoma colli uteri* (500 cases), 1911. The enormous labour involved in operating, recording, and following up a series of 500 cases of cancer arouse our admiration and gratitude. During the week of his stay with me I was impressed by the zeal and enthusiasm with which he devoted himself to the study of the relief of women from this scourge, and by the pain which the high mortality of his early operations caused him. On the surface Wertheim sometimes seemed a hard man; he was "ever a fighter," but a fighter for the truth. Patients who had been under his care spoke warmly of his kindness, and the apparent harshness of some of his remarks in discussions was due to his sincere belief in the truth of his views, and to his annoyance at criticism based on small experience. Several of my assistants who have visited his clinic have received many acts of kindness and much instruction from him. Wertheim used to seek relaxation in the vacation by deer stalking. I last saw him in Berlin in 1912 at the Obstetrical and Gynaecological Congress,

where he upheld his practice of closing the vagina by clamps and leaving it open for drainage, instead of opening the vagina unclamped and closing the peritonium over the raw surface as Bumm had done, thus reducing his rate of mortality. Wertheim did much other work in gynaecology, and at the time of his death was, with Bumm, editor of the *Archiv*, but his name will be forever associated with his *magnum opus* on cancer. All British gynaecologists will agree that though the author is no more amongst us his work will live.

A CRIMEAN V.C.

ASSISTANT SURGEON HENRY THOMAS SYLVESTER, V.C., R.A.M.C. (retired), died at Paignton, Devon, on March 13th, aged 89. He was born at Devizes on April 16th, 1831, and educated at Marischal College, Aberdeen, where he graduated M.B. in 1853 and M.D. in 1855, also taking the L.R.C.S. Edin. in 1853 and the L.S.A. in 1869. He entered the army as assistant surgeon in March, 1854, served in the 23rd Foot, the Royal Welsh Fusiliers, and retired on half pay on November 15th, 1861—nearly sixty years ago. He served with the 23rd in the Crimea, when he took part in the siege and capture of Sebastopol, was mentioned in dispatches, received the medal and clasp, and also gained the Victoria Cross, as well as the Legion of Honour, which was bestowed on him in 1856. With his regiment he went on from the Crimea to India, where he served in the Mutiny, and took part in the relief of Lucknow, receiving the medal with a clasp. The services for which he received the V.C. were given in the *London Gazette* of November 20th, 1857: "For going out under a heavy fire, close to the Redan, to dress the wounds of Lieutenant Dyneley, who lay there mortally wounded. He was again mentioned in General Simpson's dispatch for similar courage, also under heavy fire, during our disastrous assault." This was one of the first Crosses given; the dates referred to in the dispatch were September 8th and 18th, 1855. Before joining the army he filled the post of resident medical officer of Swansea Hospital, and, after he left it, was for many years in practice at Westminster till he retired from work some years ago.

With great regret we report the death from pneumonia of Dr. GEORGE V. PEREZ of Santa Ursula, Teneriffe, on February 29th. Dr. Perez was descended from a medical ancestry. He received his medical training at University College Hospital, and filled the post of resident clinical assistant at the Brompton Hospital for Consumption. He took the diploma of M.R.C.S. in 1882, and graduated M.B. Lond. in 1883. He married Miss Carnochan of Harrogate before returning to Teneriffe, where he was for many years the leading physician in Orotava. Dr. William Ewart, Consulting Physician to St. George's Hospital, writes: Dr. Perez was best known to the medical world through his discovery of the characteristic sounds often yielded by fibrous mediastinitis—Perez's sign. He combined with great accuracy of observation special keenness for therapeutics. If not, perhaps, the first, he was an early and original advocate of the administration of tincture of iodine in typhoid fever. He held a strong belief in the healing virtues of raw garlic for pulmonary and other affections. His most recent therapeutical inquiry related to the beneficial action of eucalyptus in glycosuria and diabetes. After undergoing a severe abdominal operation in London some years ago he did not completely recover his strength; and afterwards retired from practice. But his active mind never rested from the attempt to elucidate the pathological problems suggested by his own unusual case. To the last it was his great wish that his sufferings might serve some good purpose for the furtherance of medical knowledge. The profession loses in him an untiring student, and many friends will mourn the loss of one so kind and true.

MAJOR HUGH GODWIN SHERRIN, R.A.M.C., died during the last week of February at Constantinople, of typhus fever contracted while attending Russian refugees, and was buried with full military honours on March 1st in the British Crimean cemetery at Haidar Pasha. He was educated at the London Hospital, took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1905, and entered the

R.A.M.C. as lieutenant in 1905, becoming captain on January 31st, 1909, major on October 15th, 1915, and acting lieutenant-colonel on June 24th, 1918. He also took the D.P.H. of the London Colleges in 1913.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Diploma in Radiology and Electrology.

In connexion with the courses now in progress in London at University College and at the Royal Society of Medicine the Committee for the Diploma propose to announce to the Senate the following dates for the next examination, which will be held at Cambridge: Part I (a and b), Tuesday, July 27th, 1920; with practical work and viva voce examination on July 28th; and Part II (a and b), Thursday, July 29th, with practical work on July 30th.

Candidates desiring to take the diploma by thesis next term under Regulation 13 should apply to the Secretary, Dr. Shillington Scales, Medical Schools, Cambridge, without delay for the necessary certificate forms.

The Committee propose to hold courses of lectures and practical work in Physics and in Electrology during the ensuing Long Vacation in Cambridge, beginning June 22nd and finishing about the middle of August; and in Radiography in the next Michaelmas term, beginning October 12th and finishing in time for the examination at Christmas. The necessary clinical work can be carried out at Addenbrooke's Hospital, Cambridge. The Physics course will be given by Dr. Crowther, by arrangement with Professor Sir Ernest Rutherford; the course in Radiology and Electrology by approximately the same lecturers, all leading workers in these subjects, who have given the courses now running in London. The holding of these courses in Cambridge will, however, be dependent on a sufficient number of students entering for them, and for this reason early application should be made to Dr. Shillington Scales. It is hoped in future to hold courses and examinations twice a year, the courses in Cambridge alternating with those in London, so that candidates from overseas may have an opportunity of taking the diploma.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B. AND CH.B.—Part I (*Pathology*): F. H. Alexander, G. P. F. Allen, Eleanor E. Briant, G. L. Gately, H. T. Hughes, Isobel K. Johnstone, J. G. L. Jones, R. J. Jones, H. R. Madan, J. B. Oldham, T. R. Robertson, C. F. H. Sergeant, F. C. H. Sergeant, S. S. Shrikanth, C. C. L. Spurring, P. A. Williams. Part II (*Forensic Medicine and Toxicology and Public Health*): J. F. C. McColl, J. C. Twomey, S. A. Walker. Part III (*Medicine, Surgery, Midwifery*): W. H. Butler, Mary S. Share-Jones.

M.B. AND CH.B. WITH HONOURS.—(Second Class): *Isabel M. Collier, *W. H. Evans, H. Reid.

D.P.H.—A. E. Sanderson, W. F. Young.

* With distinction in Medicine.
† With distinction in Surgery.

UNIVERSITY OF EDINBURGH.

Honorary Degrees.

THE Senate has resolved to confer a number of honorary degrees on the occasion of the conclusion of peace. Among those who receive the honorary degree of LL.D. are Viscount Allenby, the Right Honourable G. N. Barnes, M.P., Professor Emeritus Francis M. Caird, F.R.C.S. Edin., Lord Robert Cecil, Sir Richard T. Glazebrook, C.B., F.R.S., until recently Director of the National Physical Laboratory, Mr. John Horne, F.R.S., formerly of the Geographical Survey of Scotland, and President of the Royal Society of Edinburgh, Mr. Rudyard Kipling, Professor Emeritus William Russell, M.D., and Professor Emeritus George Saintsbury. Mrs. Humphry Ward has not lived to receive the honorary degree.

Spring Term Examinations.

At the recent examinations in two subjects of the First Professional Examination the number of candidates was in each over 300. Altogether the number of persons, including those sitting for the preliminary examination, who were being examined in the University on March 20th, was over 1,500. The number of candidates at the preliminary examination was about normal.

UNIVERSITY OF GLASGOW.

AT the last meeting of the University Court of Glasgow Professor Bryce said that it had not been possible to find accommodation for 76 applicants for admission as medical students. All the service men and women had been placed in a separate category and were admitted first; the remaining applicants were taken in the order of the standard of their preliminary examination. The number admitted was 116, of whom 36 were women. Similar excess of applicants was stated to exist in respect of first-year classes for the B.Sc. degree in engineering. The Principal said that it would be necessary to build, but the building could not be commenced before October, and all that could be done at present was to intimate to students the necessity for making early application for admission.

The Services.

NAVAL MEDICAL MEMORIAL FUND.

SIR,—May I bring the following to the notice of any of your readers who may be interested?

It is proposed to perpetuate, by a suitable memorial, the memory of the medical officers, nursing sisters, and men of the Sick Berth Staff who were killed or died on service during the war. The memorial will be dedicated to permanent reserve and temporary officers, R.N., and R.N.V.R., and permanent and reserve nursing sisters and Sick Berth Staff.

The final decision as to what shape the memorial will take will be in strict accordance with the wishes of the majority of the subscribers to the memorial fund, provided that the amount received will be sufficient for the purpose.

Those of your readers who have not already received a letter on this subject and who may wish to subscribe are invited to write to the Honorary Secretary, Naval Medical Memorial Fund, Medical Department, Admiralty, who will forward a copy of the original letter that has been circulated amongst those whose addresses are still on record at the Admiralty.—I am, etc.,

C. K. BUSHE,
Surgeon Commander R.N.,
Honorary Secretary.

Admiralty Medical Department,
1, Lake Buildings, St. James's Park, S.W.1.
March, 1920.

HONOURS.

TERRITORIAL DECORATION.

The Territorial Decoration has been conferred upon the following medical officers for the terms of the Royal Warrant dated August 17th, 1908, as modified by the Royal Warrant dated November 11th, 1918:

Colonels Alfred Bertram Soltan, C.M.G., C.B.E., Sir William R. Smith, V.D. (Sanitary Service); Lieut.-Colonels Alexander B. S. Stewart, O.B.E. (1st London General Hospital), John Kyffin (5th Southern General Hospital); Major (brevet Lieut.-Colonel—acting Colonel) Henry A. Leebody (attached to Head Quarters Staff, Scottish Command); Majors Harry G. Parsons (2nd Wessex Field Ambulance), Charles B. Baxter, O.B.E. (attached South Midland Clearing Station), Francis W. Squair (attached to 3rd Highland Howitzer Brigade, R.F.A.), Henry Halton (attached Western Signal Company, R.E.), John R. Williams, retired (attached 6th Battalion, Royal Welsh Fusiliers), Thomas A. Sellar (attached 6th Battalion, Gordon Highlanders), Surgeon Major Gardiner W. Trouton (West Kent Yeomanry).

FOREIGN DECORATIONS.

The following decorations have been conferred by the President of the French Republic for distinguished services rendered during the course of the campaign:

Légion d'Honneur.—*Officier*: Major David Leonard Fisher, D.S.O., R.A.M.C.(T.F.).

Croix de Guerre.—Captain William Donald, M.C., R.A.M.C.(S.R.), Lieutenant (acting Major) Henry Goff Kilner, 5th Battalion, Suffolk Regiment, T.F. (attached R.A.M.C.), temporary Captain Henry Leslie Messenger, M.C., R.A.M.C.

Ordre de l'Étoile Noire.—*Officier*: Major John Humphrey Barbour, R.A.M.C.

Médaille d'Honneur avec Glaives (en Vermeil).—Captain William Victor Corbett, R.A.M.C.

Médaille des Epidémies (en Vermeil).—Captain John Robert Crollis, R.A.M.C.(S.R.).

Médaille des Epidémies (en Argent).—Captain and Brevet Major Robert Ernest Kelly, C.B., and Captain John Francis Roberts, (R.A.M.C.T.F.).

Medical News.

WE are informed that the printing of the volumes that were to have been presented to the late Sir William Osler on the occasion of his 70th birthday last July is at length completed. Copies have been dispatched from America and their arrival may be expected in a few weeks. The long delay in their appearance has been due to strikes and other disturbances in the printing and publishing trades.

To exercise his powers as President of King Edward's Hospital Fund for London during his absence from the United Kingdom the Prince of Wales has appointed a committee, consisting of the Earl of Donoughmore, K.P., Viscount Finlay, G.C.M.G., and the Governor of the Bank of England.

The Bordeaux Society of Medicine and Surgery has appointed a commission composed of Drs. Anglade, Henri Verger, René Cruchet, Ginestons, Galtier, and de Teyssieu to study epidemic encephalitis and to draw up a report.

THE late Professor Alexander MacAlister left estate valued at £12,140, with net personality £11,864.

THE well-known neurological journal *L'Encéphale* and its supplement *L'Informateur des aliénistes et des neurologistes* has resumed publication.

THE number of wounded and sick demobilized French soldiers under treatment in military hospitals on January 15th, 1920, was 7,133.

LIEUT.-COLONEL F. E. FREMANTLE, M.B., M.P., has been elected chairman of the Housing Committee of the London County Council.

THE Berrante prize of the Académie de Médecine for research in cancer has been awarded to Dr. Alexander Paine, director of the Cancer Hospital Research Institute, and Dr. Albert Peyron, director of the Military Laboratory for Cancer at the Hotel Dieu, for their joint investigations on the subject.

THE Friday evening discourses of the Royal Institution of Great Britain are now again given at 9 p.m. On April 23rd Professor H. Maxwell Lefroy will speak on the menace of man's dispersal of insect pests, and on May 14th Professor Karl Pearson will deal with sidelights on the evolution of man. Among the lectures to be given at 3 p.m. during April, May, and June are four on the ethnology of the invaders of England, by Professor Arthur Keith, F.R.S., and two on dreams with special reference to psycho-analysis by the dramatic critic, Mr. William Archer, M.A.

THE last quarterly return of the Registrar-General for England and Wales states that the births registered in the fourth quarter of 1919 were 48,202 more than in the preceding quarter and 61,794 more than in the fourth quarter of 1918; it was the highest recorded in any fourth quarter since 1906. Of the 223,569 births registered during the quarter 115,419 were males and 108,150 females.

A WHITE PAPER just issued shows that the number of persons injured by street accidents in England and Wales in 1919 was 45,544, as against 33,456 in 1918. The number of deaths was 2,239, as compared with 1,852 in the previous year. Mechanically propelled vehicles were responsible for 1,741 of the fatal accidents, as compared with 1,365 in 1918. Pedal cycles caused 142 deaths, as against 105 in 1918. The number of fatal accidents in the metropolitan area was 700, and 13 of them occurred in the City of London.

POST-GRADUATE classes in surgical tuberculosis are given at the Lord Mayor Treloar Cripples' Hospital, Alton, Hants, under the direction of Sir Henry Gauvain, Medical Superintendent. The next course will begin on Monday, March 29th. There will be daily demonstrations in the wards, and practical work will be performed in the plaster room, theatre, and x-ray room. Lectures will be delivered on choice of site, organization and administration of a special hospital for the treatment of surgical tuberculosis; conservative treatment of tuberculous abscesses of bony origin; diagnosis and treatment of tuberculous disease of the spine, hip, knee and other tuberculous bone and joint lesions; tuberculosis and peritonitis; adjuvant measures of treatment (x rays, etc.); heliotherapy, chemotherapy, vaccine therapy, and balneotherapy. These courses are informal and intensive; no fees are charged; lunch and tea are provided. Only a limited number of students are accepted for any given course.

THE Lord Mayor of London, who presided at the annual meeting of the Royal Medical Benevolent Fund Guild at the Mansion House on March 19th, made a strong appeal for increased support to the Guild, which exists to assist distressed members of the medical profession, their wives, widows, and families. Mrs. Scharlieb, M.D., who presented the financial report, said that part of the annual expenditure was met by the interest on investments, but the Guild had to live on a precarious margin. The contributions from different parts of the country showed great variations. A cordial vote of thanks was given to Lady Tweedy, chairman of council, who had been succeeded in the chairmanship of the General Purposes Committee by Lady Frigg. Lady Barrett, O.B.E., said that the closure of St. Anne's School for girls had been a misfortune to the Guild; it was hoped to make arrangements with other schools, but the task was not easy. Miss Lilian Braithwaite, speaking for the theatrical profession, which, she said, always responded liberally to appeals, asked for contributions for the erection of a Guild hostel for persons requiring rest and treatment. A vote of thanks to the press, moved by Sir Alfred Frigg, for its share in making known the objects of the Guild, was carried, as was a vote of thanks to the Lord Mayor for presiding.

THE Achilleion palace at Corfu, formerly the possession of the ex-Emperor of Germany, was converted into a hospital by the French after the Serbian retreat, and is now known as the Tribondeau hospital, after the naval medical officer and bacteriologist who died of influenza in the epidemic of September, 1918.

THE annual report of the Seamen's Hospital Society for the year 1919 shows that the Dreadnought Seamen's Hospital at Greenwich, which has 250 beds, received 2,669 in-patients, and the Albert Dock Hospital, with 50 beds, 760 in-patients; 401 patients were treated in the Augas Convalescent Home, Cudham, Kent, which has 30 beds, and it is announced that a site has been acquired at Bramshott in Hampshire for a tuberculosis sanatorium. The most memorable event of the year was the acquisition of the premises in Endsleigh Gardens, used during the war as an officers' hospital, for a central hospital for tropical disorders. A gift of £100,000 from the Joint Committee of the British Red Cross and the Order of St. John rendered it possible to purchase the building, and another gift from the Mesopotamia Comforts Fund in memory of Lieut.-General Sir Stanley Maude has been devoted to the endowment of a ward which will bear his name. The building is large enough to provide accommodation also for the London School of Tropical Medicine. The report makes special reference to the death of Dr. Guthrie Rankin, consulting physician to the hospital, and mentions that he bequeathed £1,000 to its Samaritan Fund.

Letters, Notes, and Answers.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

QUERIES AND ANSWERS.

"T." asks for suggestions in the treatment of a child, aged 4 years, who suffers from enlarged tonsils with adenoids, complicated by purulent otitis media, and in whom operation is contraindicated owing to the fact that he is a haemophilic.

HAY FEVER.

"R. A. J." asks for advice in the treatment of a lady, a professional singer, who has hay fever every April or May. He has tried vaccine and the patient has had the turbinates cauterized.

GRANULOMA OF THE EYELID.

A. C. R." suffers from a chronic condition of the upper lid, consisting of three flattened nodular masses of granulomatous tissue, not definitely cystic; five operations have been undertaken since 1916. At times nodules become inflamed, and fresh ones are apt to form. Further operative interference is considered risky from fear of cicatricial contraction. Astigmatism and monocular diplopia are now present from pressure on the eyeball. Section of a portion removed shows solid mass of granulomatous cells. Yellow oxide and massage have been tried without avail. Would induction of a general leucocytosis and local application of heat be likely to promote absorption? If so, what will be the best agent to employ?

INCOME TAX.

"J. G. S." inquires whether officers' pensions are subject to income tax.

* * * Would pensions granted to members of the naval, military, or air forces be exempt from income tax under Sec. 16 of the Finance Act, 1919. If the pension does not fall within that category it is apparently liable to income tax and should be separately shown in the annual return.

LETTERS, NOTES, ETC.

THE ROMAN NETTING NEEDLE FOR WINDING A SURGICAL THREAD.

DR. S. HOLT (Christiania, Norway) writes: Thanking you for your kind mention on p. 263 of my account of "Graeco-Roman and Arabic Bronze Instruments and their Medico-Surgical Use," I beg you to correct a small error appearing at the end of your note—namely, "The Roman netting needle was

employed for surgical suturing." I only put forth the thought that the surgeons of antiquity found the netting needle handy to wind up the suturing thread, exactly as the fishermen did with the net-binding thread. In literature there is no evidence for my suggestion, because Celsus, Galen, and Paulus Aegineta do not mention any way of how to carry the suture thread. I have no other support for my suggestion than that three netting needles are among John Stewart Milne's and Baron Ustinov's collections of Graeco-Roman surgical instruments. The netting needle I mentioned in the museum of Saint-Germain-en-Laye did not belong to the Gallo-Roman oculist Gaius Firmius Severus in Rheims, but came from the neighbourhood of Compiègne. This last information is due to the kindness of Monsieur Salomon Reuach, the director of the museum.

THE BROTHERS MICHELIN.

WE have received a well illustrated pamphlet on the brothers Michelin, originally written by William Serieux for the French magazine, *Je Sais Tout*. It gives the history of the origin of the famous tire works at Clermont. The grandfather of the Michelins, M. Barbier, joined his cousin, Captain Daubrée, in founding a sugar factory on the banks of the Allier. Daubrée had married a niece of the Scottish chemist, Mackintosh, whose name, through his discovery of the solubility of rubber in benzine, has become associated with waterproof garments. Mackintosh and his niece had amused themselves by making rubber balls, and Madame Daubrée resumed with success and profit the manufacture of these playthings in a corner of her husband's factory. When the sugar factory was washed away by floods M. Barbier and Captain Daubrée started a rubber factory at Clermont, which has since become the Michelin factory for tires.

In their early days neither of the brothers Michelin had much to do with the factory; one brother studied painting, while the other was interested in the manufacture of iron, but finding in 1883 that the factory was about to break up, they decided to try to re-establish its former prosperity. In 1891 the first attempt was made to produce a pneumatic bicycle tire which should be easily detachable, in order to allow of immediate repair in case of puncture; and in September of that year the cycle race from Paris to Brest was won on detachable tires manufactured at the Michelin works.

In 1896 a cab appeared in Paris on pneumatic tires. In the meantime the Michelins had set to work to devise pneumatic tires for motor cars, and in 1895 a car mounted on such tires was entered for the Paris-Bordeaux race. This car proved to be so dangerous to drive that a few days before the race the driver refused to undertake it. Consequently the Michelin brothers had to do so themselves. Punctures were numerous, so that the wits of the day said, "The pneumatic tires absorb all obstacles—and die of them." However, the car reached Bordeaux—ninth and last!

After the description of the Michelin works and the Michelin tire, the pamphlet gives other instances of the initiative, enterprise, and imagination of the brothers Michelin. To them was due the Prix du Puy de Dôme for flying. They instituted also the Prix de l'Aéro Cible for bombing aviation. They have established scholarships to enable students to travel abroad and study working organizations; and they have developed clubs, cottages, societies, and pensions in connexion with their works. It would seem that the Michelin factory is one of which France may well be proud.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 43, 44, 45, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 41, 42, and 43.

THE appointment of certifying surgeon at Tipperary (Tipperary) is vacant.

CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

NEW SCALE.

THE charges for advertisements in the BRITISH MEDICAL JOURNAL will in future be as follows:

	£	s.	d.
Six lines and under ...	0	7	6
Each additional line ...	0	1	3
Whole single column ...	5	0	0
Whole page ...	16	0	0

An average line contains six words.

The charge for announcements of births, marriages, and deaths will be 10s. 6d.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

The Schorstein Lecture

ON

THE DIAGNOSIS OF DISEASE OF THE PANCREAS.

DELIVERED AT THE LONDON HOSPITAL MEDICAL COLLEGE ON FEBRUARY 20TH, 1920.

BY

SIR ARCHIBALD E. GARROD, K.C.M.G., M.D., LL.D., F.R.S.,

PHYSICIAN TO AND DIRECTOR OF MEDICAL CLINIC AT ST. BARTHOLOMEW'S HOSPITAL; REGIUS PROFESSOR OF MEDICINE DESIGNATE, UNIVERSITY OF OXFORD.

He who is commemorated in a memorial lecture is often but a dim figure of the past, for whom and for whose work the lecturer can feel only a platonic admiration; but it is a very different matter when one does homage to a man whom he has known and liked, a member of his own university, and a dweller in the next street. Such was Gustave Schorstein, whose too early death left, for all who knew and valued him, a gap not easily filled, a sense of loss of a talented and attractive personality. I esteem it a great privilege to be permitted to pay this tribute to his memory.

This lecture should have been delivered five years ago, but the war and its duties intervened. Now that we are at peace once more, and are trying to make up the time lost during "the years that the locust hath eaten," the invitation has been renewed, and for that honour it is my pleasant duty to return my thanks.

In point of diagnostic display the liver and the pancreas, both glands of many vital functions, may be compared to a shop window and an office door. Derangement of the work of the shop may be obvious to the passer-by in the street, whereas what goes on behind the ground glass of the office door is hidden from public view, and is only manifested in the indirect effects of disorder of the activities within. If only the pancreas produced such a coloured secretion as the bile, how much easier would be the diagnosis of many of its lesions!

As it is the position of the pancreas, sufficiently remote to shield it from examination but not from injury, and the fact that its secretion is poured into so inaccessible a region of the alimentary canal, enabled it for a long time to puzzle the physiologist and to baffle the physician.

In the middle of the last century Sir Thomas Watson,¹ in one of those delightful lectures of his which, in lucidity and literary style, rank with those of Trousseau, spoke as follows: "It may seem a slight to the pancreas to pass it over without noticing the diseases to which it is subject. But really these diseases appear to be but few; and they do not signify their existence by any plain or intelligible signs." Somewhat later Bristowe,² in his well known textbook of medicine, expressed his belief that in the great majority of cases pancreatic disease will doubtless remain undetected during life. But some other writers of that period struck a more hopeful note, and among them Wardell,³ who, in 1871, wrote: "No symptoms are pathognomonic of pancreatic disease; an assemblage of symptoms indicates the probability of its lesion." These words still held true to-day, and they embody the thesis of this lecture.

It is true that we have learnt to recognize in fat necrosis a sign pathognomonic of certain lesions of the gland; but since this is only made manifest by opening the abdomen it lends us no help at the bedside. One other sign has been claimed as distinctive—namely, true steatorrhoea, which was recognized by Kunzmann⁴ as early as 1824, and independently by Richard Bright⁵ in 1832, as indicative of pancreatic disease.

Even nowadays pancreatic lesions often escape diagnosis, and Paul Carnot⁶ puts his finger upon the cause of many such failures in the following passage: "Le plus difficile est, souvent alors, de songer au pancréas, étant donné la rareté apparente des affections de cette glande." The more constantly we bear the pancreas in mind as a possible seat of origin of obscure abdominal troubles, the less likely shall we be to overlook its lesions. The diagnostic indications at our disposal fall into three main groups. In the first are the clinical signs and symptoms, such as tumour, pain, tenderness, vomiting, cyanosis, and

the like, and the signs of pressure upon neighbouring structures. Secondly, we may detect signs of failure of external secretion, defective digestion of proteins, fats, and carbohydrates. Thirdly, indications of failure of internal secretion, of which glycosuria is at the same time the most important and the best known.

TABLE I.—Pancreatic Signs and Tests.

Physical Signs and Symptoms.	Defects of External Secretion.	Defects of Internal Secretion.
Aspect	Steatorrhoea	Glycosuria
Tumour	Fatty stools	Lowered sugar tolerance
Pain	Creatorrhoea	Cammidge's tests
Tenderness	Impaired casein digestion	
Cyanosis		
Vomiting	Drudinal sound	
Constipation	Einhorn's method	
Diarrhoea	Oil breakfast	
Jaundice		
Sympathetic signs	Sabli's capsules	
Ocular	Schmidt's test	
Loewi's test	Kashiwado's nucleartest	
	Sajodin test	
	Diastase test, in urine and faeces.	

Lastly, there are certain syndromes which clinical and pathological experience has taught us to associate with lesions of the pancreas. Thus the diagnosis of carcinoma of the head of the gland is often correctly made upon purely clinical evidence, and in cases of bronzed diabetes, with enlarged cirrhotic liver and peculiar pigmentation of the skin, the pancreas is always implicated.

Many ingenious tests of pancreatic efficiency have been devised, and each test has its adherents, and each its critics who question its utility. But surely we are wont to ask too much from such tests. We cannot look to any test for a penny-in-the-slot diagnosis, especially of such widely diverse lesions as those to which the pancreas is liable. At best we cannot hope to gain more than an item of circumstantial evidence which, taken in conjunction with other items, may contribute to a diagnosis of probability, or even of certainty. Taken alone each test may fail or may actually mislead. In some instances a negative, and in others a positive, response carries little weight, and one needs to get to know a test well before he can estimate the significance of its answers.

It is not my intention, nor would it be possible in a single lecture, to describe the many pancreatic tests. In my wards we have employed most of them in turn, and in cases of special difficulty have resorted to many. For some years before the war we were interested in this subject, and it is to the help of a group of active fellow workers that I owe most of such knowledge of it as I possess. I would specially mention my indebtedness to my former house-physician, Dr. Sladden, who has embodied his conclusions in two valuable papers,⁷ and to Dr. Mackenzie Wallis, whose M.D. thesis on this subject I have been permitted to read, and who has forgiven me beforehand if I should encroach upon his ground in advance. To Dr. Hurtle, to my assistant Dr. G. Graham, and to Dr. Geoffrey Evans also, I am grateful for much valuable help.

Where there is so great a choice of tests, workers tend naturally to concentrate upon some few which have seemed to them especially useful and easy of application. Each one develops his own routine, and different workers make different choices. The tests upon which one man relies do not necessarily serve another best.

The physical signs and symptoms of disease of the pancreas are best seen in cases of acute pancreatitis, although the large cysts which sometimes spring from the gland produce far more conspicuous swellings, and it is with carcinomata that the pressure signs are most clearly manifested. Nevertheless, the diagnosis of acute pancreatitis is by no means easy in many cases, and the most common false diagnosis is one of acute intestinal obstruction.

A grossly enlarged pancreas forms a tumour in the upper part of the abdomen, lying between the xiphoid cartilage and the umbilicus. It does not move with respiration, and has often but an ill-defined outline. The natural dullness on percussion is obscured by the overlapping of the stomach and intestine. In favourable

cases, in thin subjects, and especially under an anaesthetic, it is even possible to feel a pancreas which is only slightly enlarged, and some have claimed to have felt the normal pancreas. By percussion over the back Dr. Ewart maintains that the size of the gland may be mapped out with considerable accuracy.

The pain of pancreatic disease may be continuous or paroxysmal; it is felt in the abdomen, and is liable to be confused with other acute abdominal pains. My own experience and that of my colleague Mr. Waring, which is considerably greater, leads us to attach much more importance to pain across the back than do most of those who have written upon the subject, and in cases of carcinoma of the pancreas also such pain is often a prominent symptom.

In acute pancreatitis vomiting is usually severe, obstinate constipation tends to strengthen the suspicion of intestinal obstruction, and a feature which has some diagnostic value is a slight degree of cyanosis. The abdomen is usually distended, but, as a rule, there is less rigidity of the muscles than in other acute inflammatory lesions within it.

Of pressure symptoms referable to the diseased pancreas jaundice is by far the most conspicuous, and, in view of the anatomical relations of the gland to the common bile duct, this is in no way surprising. In cases of carcinoma of the head of the gland the jaundice is of extreme degree, and the complete absence of urobilin from the stools shows that the bile duct is completely occluded. Oser⁷ suggests, and Sir Mayo Robson⁸ also holds, that the so-called catarrhal jaundice may often have its origin in a swelling of the pancreas. We have as yet little knowledge of the slighter inflammatory affections of the gland, but there is one variety the clinical features of which are fairly well known—namely, that which occurs as a metastasis of mumps. Some years ago Dr. Cammidge told me that of eight cases of mumps with abdominal symptoms he had found his test positive in four, and in one of these it was no longer obtained after an interval of a month. Glycosuria was present in one case. Barbieri⁹ has recorded a case of temporary glycosuria with this affection, and Finizio¹⁰ one with transitory steatorrhoea, with as much as 60 per cent. of neutral fat in the stools. I have been able to find only a single record of an autopsy in such a case, and in that case alone was jaundice one of the symptoms. Lemoine and Lapasset,¹¹ who described it, found the pancreas swollen, oedematous, congested, and of a reddish-grey tint.

The absence of jaundice in almost all cases of the pancreatitis of mumps seems to me to afford a strong argument against the connexion of catarrhal jaundice with a catarrhal pancreatitis, and it is certainly no common feature of cases of grave pancreatitis, haemorrhagic or other.

On the other hand, there is, as Mayo Robson has shown, a close connexion between gall-stone troubles and interstitial pancreatitis, and from the anatomical relations of the biliary and pancreatic ducts an infection of the one is likely to spread to the other. So jaundice with pancreas lesions may have other origin than in compression of the bile duct. A tumour of the pancreas may cause considerable obstruction of the duodenum also. Watson mentions this in his lecture already referred to, and actual obstruction may occur in those rare instances in which the head of the gland encircles the duodenum completely. Again, there may be signs of pressure upon the portal vein and vena cava.

In a short paper, published in 1912, Cohn and Peiser¹² called attention to the presence in some cases of pancreatitis of the ocular symptoms which we associate with undue activity of the thyroid gland. Of a series of five cases, three of haemorrhagic, one of suppurative, and one of chronic interstitial pancreatitis, they found some exophthalmos in four, von Graefe's sign in four, Moebius and Stellwag's signs in all five, and also tremor and dermatography in all. However, they wisely decline to draw any sweeping conclusions from so small a number of cases.

Shortly after reading their paper I was able to confirm their observations in a case of which I shall speak later. The association clearly calls for further study, and has very interesting bearings upon the wider subject of the interaction of the thyroid gland and pancreas, of which I hope to treat at greater length on some future occasion.

The experience of many of us who have been engaged

on military duties in recent years has taught us to look for signs of hyperthyroidism in conditions which we did not formerly connect with the thyroid gland, and to recognize that the characteristic case of Graves's disease is merely the culminating point of a series of intermediate grades which bridge the gap between it and normality. Moreover, we have witnessed a dissociation of the thyroid symptoms, one patient showing the ocular signs alone, and another tachycardia with tremor. Indeed, it would seem that there are several thyroidal hormones, and that excess of one does not necessarily carry with it excess of another.

Of such conceptions we have long had glimmerings, as witness the use of the term "larval Graves's disease."

As a rule, when thyroidal and pancreatic symptoms are seen in association, the thyroid appears to be the organ primarily at fault, and the observations of Cohn and Peiser, for which the converse holds good, are of all the greater interest on that account.

But if in pancreatitis the eye symptoms referred to are due to excessive thyroid secretion, it is really the sympathetic nervous system which is stimulating the gland to over-activity, and it is not wonderful that the sympathetic should be disturbed when the pancreas is the seat of disease, seeing how near a neighbour it is of the great abdominal ganglia and plexuses. Indeed, many of the symptoms of acute pancreatitis, the severe and often paroxysmal pains, the vomiting and collapse, are, by many, attributed to this proximity. There is evidence, too, of a restraining effect of the pancreas upon the excitability of the sympathetic, an influence which is withdrawn when the pancreas becomes the seat of disease.

It was to test the existence of such a soft-pedal influence that O. Loewi¹³ applied his adrenalin mydriasis test to depancreatized cats and dogs. The extension of his observations to human subjects led to the introduction of one of the most interesting, although not one of the most conclusive, of the tests of pancreatic efficiency.

Two or three drops of a 1 in 1,000 solution of adrenalin, freshly prepared, are dropped into the conjunctival sac, and the process is repeated after an interval of five minutes. In the great majority of instances no dilatation of the pupil occurs, but in a few cases there is conspicuous dilatation in the course of half an hour or an hour. The dilated pupil is usually excentric in position, and often conspicuously oval in form. When Loewi first tried the test upon normal people, and upon a series of patients in the Vienna clinics, mydriasis was seen only in 1 of 3 cases of exophthalmic goitre and in 10 out of 18 diabetics. Apparently there were no cases of gross pancreatic disease in the series. Loewi regarded the positive results in some cases of diabetes as indicative of a pancreatic origin, but attributed the mydriasis in the case of exophthalmic goitre to the irritability of the sympathetic in that disease.

Of recent years we have employed Loewi's test widely in my wards, and in my opinion it is of undoubted value in the diagnosis of pancreatic lesions, provided always that its ways have been studied and that its limitations are fully recognized.

The dilatation of the pupil is a decidedly uncommon phenomenon. Unlike Loewi, I have seen it in very few cases of diabetes in which there was no other evidence of lesions of the pancreas, and I have obtained it only once in exophthalmic goitre. We have failed repeatedly to obtain dilatation when the test was repeated, within a day or two, upon an eye which had previously dilated, whereas the mydriasis was again brought about after a longer interval.

The pupils need to be carefully examined before the adrenalin is applied, not only as to their equality, but also to make sure that the iris of the eye tested is mobile. We have been deceived in one case by trying to dilate a pupil fixed by synechiae, and the dilatation is inhibited for a time by the administration of morphine.

The test may fail, at a later stage, in a case in which dilatation had occurred at an earlier period. It may fail in a case in which there is definite disease of the pancreas, and may succeed in another in which there is no gross lesion of the gland. All this sounds very discouraging, but the experience gained in a large number of cases has taught me to regard adrenergic mydriasis as strongly suggestive of a pancreatic lesion, and to look upon it as a valuable link in a chain of evidence pointing to such a lesion.

On the other hand, I would *never* venture such a diagnosis upon this reaction alone, nor should I conclude from the absence of any dilatation that the pancreas was intact. Of few of the tests of pancreatic efficiency can more be said.

One of the drawbacks of Loewi's test is that it is, if anything, too delicate, and is wont to give a positive response to a lesion which merely worries the pancreas without involving it to any noteworthy extent. Against this may be set the advantage that the dilatation of the pupil is apt to be most marked at a stage when the excretory functions of the gland are not as yet seriously impaired.

The indications of abeyance of the external secretion of the pancreas, which now claim our attention, are the most valuable aids to diagnosis that we possess, and upon such evidence alone a secure diagnosis may in some cases be based. We may look for failure of the digestion of proteins, fats, and carbohydrates alike, for, unlike any other digestive gland, the pancreas takes an important part in the digestion of all three classes of foodstuffs. But, in my opinion, the signs of failure of digestion of fats are the most significant of all.

If there be any single sign which, standing alone, may be regarded as pathognomonic of disease of the pancreas it is true steatorrhoea. By this is meant the passage with the faeces of liquid fat which solidifies on cooling.

Salomon¹¹ speaks of it as a sign observed only with pancreatic disease, and for my own part I should not hesitate to share his view but for a case which Dr. Hurlley and I investigated some years ago.¹⁵ The patient, a boy then 7 years old, had passed oil with his motions from birth. A younger brother who died of measles at 11 months had exhibited the same anomaly, whereas the three other children had not. The parents are first cousins. The boy was otherwise in good health, well grown, and with no trace of infantilism. Last month I saw him again after an interval of six years, and found that the same still holds good. Although many tests were applied no other sign of lesion of the pancreas could be found, and, in spite of the defect of fat utilization, the digestion of proteins was not impaired, and the stools contained no undigested meat fibres. Apparently this boy is the subject of an inborn error of metabolism, probably due to the absence of a normal enzyme, presumably a pancreatic enzyme. It is difficult to believe that there is any real disease of his pancreas.

There are grounds for the belief that both the external and internal secretions of the pancreas take part in the utilization of fats, the lipase being concerned with the splitting of fats, the internal secretion with their absorption. The gross failure of fat-splitting, which Friedrich Müller¹⁶ described as so characteristic of lesions of the pancreas, may be lacking in cases in which there is conspicuous excess of faecal fat in association with such lesions, and experience teaches us that the total fat content of the stools, made up of fats, fatty acids, and soaps, affords a safer guide. Better still is the information supplied by the far more laborious estimation of the proportion of the fat taken in the food which is lost in the faeces. When, in addition, there is a conspicuous failure to *split* fats the evidence of a lesion of the pancreas is so much the more cogent. In the stools of a healthy man some 75 per cent. of the fat is in the split form, whereas some patients with pancreatic disease pass as little as 20 per cent. in the forms of fatty acids and soaps. The great diagnostic significance of true steatorrhoea arises from the fact that it indicates not only an excess of fats in the stools, but also an undue proportion of neutral fat.

In cases with no gross steatorrhoea the microscope may show abundant fat globules and many acicular crystals of fatty acids. Moreover, the large bulk of the fatty stools may arrest attention, and in some cases they are justly described as elephantine.

The jaundice which is so often associated with obstruction of the pancreatic duct obscures to some extent the indications afforded by the estimation of the faecal fats, for the mere absence of bile from the intestine causes a great impairment of fat absorption; but even when the pancreatic duct alone is blocked widely divergent results are obtained in different cases. Moreover, in the majority of cases of disease of the pancreas there is no blockage of the duct, and the impairment of secretion results from

damage to the glandular tissue and is less in degree. A patient with grave disease of the pancreas may pass stools with normal fat-content, and this is true even of some cases in which the duct is obstructed, probably because the duct of Santorini remains patent and provides an emergency outlet.

Even when jaundice is present a proportion of fats in the dried faeces exceeding 40 or 50 per cent. is strongly suggestive of a pancreas lesion, and in some cases there is a percentage of 80 or more.

L. Zoja¹⁷ lays stress upon an unduly low proportion of soaps as indicative of pancreatic disease, presumably from a deficient supply of alkali in the intestine, but our own experience, and that of others, leads us to attach little importance to this sign.

Oskar Gross,¹⁸ who made a very complete study of the fat excretion of two patients with indubitable disease of the pancreas, found that in one case the percentage of the food fat lost in the faeces remained constant, in spite of wide variations in the amounts in the diet, and Hurlley and I found the same to be true for our case of congenital steatorrhoea; but in Gross's second case, and in that investigated by Spriggs and Leigh,¹⁹ the loss of fat became much greater when the fat in the diet was increased. The last named observers suggest that the constant percentage loss may only hold good for cases in which the patient's nutrition remains good. It is a remarkable phenomenon, and one not easily explained, but upon which future work may throw light.

It will be seen, from what has gone before, that a patient whose pancreas is diseased may pass excess of neutral fats in his motions, or a great excess of fats, fatty acids and soaps, without any undue proportion of neutral fat. Lastly, a lesion of the pancreas can by no means be excluded on the ground that the stools contain no excess of fatty substances.

Winternitz has introduced a test of the efficiency of the pancreas in dealing with fats. Half a gram of iodo-belenic acid, or the drug sajodin, which is its calcium salt, is given by the mouth, and iodide is looked for in the urine. The sajodin is only broken up when it comes under the influence of the pancreatic juice, and by it *only* in presence of bile. On this account the test is not applicable when the bile duct is completely obstructed. When there is no jaundice, failure to find iodine in the urine suggests that the lipolytic action of the pancreas is in abeyance.

When in addition to impaired splitting or utilization of fats there is obvious failure of protein digestion, the evidence of a pancreatic lesion is wellnigh conclusive. There are many ways in which such failure may be detected, but the simplest of all is at the same time the most convincing. A patient with severe pancreatic disease will, as a rule, pass in his faeces large numbers of muscle fibres, derived from the meat which he eats, undigested and with their striae clearly visible under the microscope. He may also pass particles of undigested tissue, and Albu²⁰ recommends calf's thymus as an article of diet the structure of which is easily recognized in the stools. For this phenomenon Ehrmann suggested the name "creatorrhoea," by which it is generally called; and although the term invites criticism it is not easy to invent a better.

Creatorrhoea, although it may accompany profuse diarrhoea from any cause, is hardly inferior to fatty stools in diagnostic value, and it has the advantage that it is not affected by blocking of the bile duct. In a case with jaundice in which the indications afforded by the faecal fat are not unequivocal, the discovery of undigested striped muscle fibres in the stools may help materially to clinch an otherwise doubtful diagnosis.

Cases are met with in which the syndrome steatorrhoea-creatorrhoea persists for years, in a patient who otherwise enjoys moderately good health, who leads an active life and exhibits no other gross sign of disease. Some such patients have been found to have the duct blocked with calculi, and the structure of the gland destroyed, and yet may never have exhibited glycosuria. In these cases the more elaborate tests will, as a rule, afford additional evidence of disease of the pancreas.

Excessive excretion of nitrogen in the stools, and a consequent inordinate loss of nitrogen as determined by metabolism investigations, affords additional evidence of impairment of protein utilization, but other ferments

besides trypsin take part in this work, and azotorrhoea, so called, is far less distinctive than the escape of striped muscle fibres and nuclei. Moreover, the fatty stools of a patient with pancreatic disease offer a far from ideal material for Kjeldahl estimations.

The majority of the pancreatic tests are concerned with the failure of tryptic digestion. They fall into three main groups of procedures: Some of them aim at obtaining a sample of duodenal contents for examination; others rely upon the dispatch of messengers along the alimentary canal, and the examination of the stools or other secretæ for evidence as to what has happened to them in their transit; and yet others upon estimation of the tryptic action of the faeces.

The oil-breakfast test relies upon the fact that, under its influence, some of the contents of the duodenum are regurgitated into the stomach, and may be found in the test meal when it is siphoned off. The technique of the test is comparatively simple, and its results are, as a rule, instructive, but the swallowing of a large dose of olive oil, 2 oz., with a test meal, upon an empty stomach, and its subsequent withdrawal, is a proceeding which has little attraction for the British patient. It has been clearly shown that it is possible to obtain a sample of the secretion in the duodenum, either by means of a suitably constructed duodenal sound, or, better still, by Einhorn's ingenious device of a small metal capsule cased in gelatin and attached to a string or to an india-rubber tube. The capsule is swallowed and is passed on into the duodenum by gastric peristalsis. It is well to check its progress by *x*-ray examination. By this means as much as 5 to 10 c.cm. of duodenal juice may be obtained in favourable cases, and its tryptic activity tested. I have no experience of these methods, and therefore am not in a position to judge of the value of the indications which they afford, nor of the degree of discomfort to the patient which their application may entail. It is obvious that there are possibilities of fallacy, and that, whereas the finding of trypsin in the juice affords positive evidence that pancreatic secretion is entering the duodenum, the failure to find it in the fluid obtained is far less conclusive as evidence of inefficiency of the gland.

Of methods which test the tryptic power of the faeces that of Oskar Gross is most often employed. It is based upon the digestion of casein by an alkaline extract of the faecal material. Failure to digest casein offers strong evidence of pancreatic inefficiency, but, seeing that other ferments in faeces can act like trypsin, a positive outcome of the test, unless very pronounced, has less value.

What may be called the messenger tests are of several kinds. Thus Sahli administered capsules of gelatin hardened by formalin, and enclosing a drug easily detected in the urine or saliva. Provided that the capsule is well made, it is only amenable to tryptic digestion, and escape of the drug is taken to indicate tryptic activity; but a negative finding is far from conclusive. The capsule may resist tryptic digestion, especially if its journey along the alimentary canal be unduly rapid. It is only necessary to mention Schmidt's beef-cube test, and Kashiwado's in which stained nuclei from the calf's thymus are swallowed, mixed with lycopodium granules, the latter to serve as indicators of the part of the faeces to be searched. Sladden, who tried this test on several of my patients, obtained no very encouraging results, and compares the search in the bulky faeces of a patient with pancreatic disease to the proverbial hunt for a needle in a haystack.

It seems to me preferable to rely rather upon such gross phenomena as creatorrhoea and steatorrhoea as indicators of inefficiency of the pancreas, than upon the somewhat uncertain responses of these messenger tests.

To pass on to the consideration of carbohydrate digestion. It was shown by Wohlgenuth, whose observations have been abundantly confirmed, that a diminished output of diastase in the stools, and an increase of that enzyme in the blood and urine, are common phenomena in cases of lesion of the pancreas, and it would seem that we are here dealing with a sort of colourless jaundice, due to an obstructed flow of the pancreatic juice into the intestine, or else to a direct escape of diastase into the blood, comparable to that of lipase which brings about fat necrosis. But there are indications that the explanation of neither of these events may be so simple. However this may be, the estimation of diastase in the urine affords one of the best and most useful tests of the integrity of the pancreas,

and at the same time one of those most easily and rapidly carried out. This last is an important matter when we are dealing with acute conditions, in which delay of surgical interference may greatly lessen the prospect of its success. The diastase and adrenalin mydriasis tests may be carried out within an hour, whilst the patient and the theatre are being prepared for an operation. But the diastase test shares the uncertainty which pertains to pancreas tests in general. Instead of the normal ten to twenty, or even thirty, units, to use the accepted measures of the test, a patient with pancreatic disease may excrete in his urine fifty, a hundred, or even two hundred units. On the other hand, another patient similarly affected may show a normal diastase excretion. Mackenzie Wallis emphasizes the fact that the diastase increase is a temporary incident, most conspicuous in the earlier stages of a case. Repeated examinations at intervals may reveal a quicker or slower decline of the diastase output until normal, or even subnormal, figures are reached. Thus it comes about that whereas a conspicuous excess of diastase in the urine is strongly suggestive of disease of the pancreas, a normal excretion, such as was found by Spriggs and Leigh in their case, in no way excludes even advanced disease of that gland.

Nor must it be forgotten that in many cases of renal disease the power of the kidney to excrete diastase is so seriously impaired that its estimation in the urine is utilized as a test of renal efficiency. This deprives the indications of most of their value, for our purpose, in cases with albuminuria. Again, like Lœwi's reaction, the diastase test errs on the side of excessive delicacy. Both tests may give positive answers when, so to speak, the pancreas is merely worried by adjacent disease. Thus, when both these tests yield positive findings, strong evidence, stronger by far than either alone supplies, is afforded that the pancreas is at least concerned in the malady; but apart from other indications they are in no way conclusive. Of the two, I attach greater importance to the diastase findings. Undoubtedly the failure of both tests in no way excludes serious pancreatic mischief.

There remains to be considered the evidence of failure of *internal* secretion of the gland. Since the classical researches of von Mehring and Minkowski, glycosuria has occupied a foremost place among the signs of pancreatic lesions, but, from the clinical standpoint, it is far from fulfilling the promise held out by physiological experiments. Whereas it is highly probable that the pancreas is concerned in all cases of glycosuria, save, perhaps, those in which the proportion of sugar in the blood is below the normal, it may well be that in most cases of diabetes the hyperglycaemia and glycosuria result from a disturbance of the normal balance between the pancreas and other endocrine glands, with the result that its internal secretion is inhibited or overpowered. We know that an excess of thyroid secretion may cause glycosuria although the pancreas be intact, and the same holds true for pituitary secretion and adrenalin.

On the other hand, experiments show that a small residue of pancreatic tissue may avert glycosuria, and it is a matter of common knowledge that the gland may be gravely damaged, and even to all appearance destroyed, by disease, and yet the patient may excrete no sugar in his urine. Indeed, it may be said that, except in cases of chronic pancreatitis, glycosuria is an uncommon symptom of pancreatic disease. I am inclined to think that daily observations throughout the illness would reveal the presence of sugar in the urine at times in many more cases than appears at present. In an acute case I have met with it in one single specimen and never afterwards. In cases of carcinoma of the head of the pancreas glycosuria is less rare than might be expected, seeing how large a part of the gland usually escapes invasion, and how little time is afforded for the development of secondary changes. Miraillet²¹ found it in 13 out of 50, and Guillon²² in 20 out of 71 cases.

Speaking generally, the absence of glycosuria affords no argument against the presence of disease of the pancreas, but in not a few cases its presence supplies the crowning evidence in support of a diagnosis based upon other findings. Lastly, even those who attribute all diabetes to disease of this gland will hardly maintain that the presence of glucose in the urine is in itself sufficient evidence of

such disease. Even in chronic interstitial pancreatitis glycosuria is by no means always present, and Opie²³ attributes the difference in this respect to differences in the incidence of the lesion, which in some cases involves, and in others spares, the islands of Langerhans.

Short of actual glycosuria, the patient's tolerance for glucose may be so far below that quantities of that sugar far smaller than are required to induce glycosuria in a healthy subject, cause glucose to appear in the urine. Thus tests of sugar tolerance are among the diagnostic means at our disposal; but it must be remembered that almost any disturbance of the balance of the internal secretions leads to an alteration, either a raising or a lowering, of glucose tolerance.

Cambridge's reaction, which may be fitly referred to in this place, is a phenomenon of much interest, the further investigation of which may throw light upon important metabolic events. It is undoubtedly connected with pancreatic derangements, and when observed supplies a contribution to the building up of a diagnosis. But it shares the uncertainty of other pancreatic tests, and may fail us in cases of severe disease of the gland, especially when the disease has reached an advanced stage. So it is natural that many prefer to employ methods which are less time-absorbing, and less at the mercy of small errors of technique. This test has suffered from the fact that too much has been expected from it, perhaps that too much has been claimed for it; and because it has not proved so decisive as was hoped its utility has not received the credit which it deserves. Of Cambridge's iodine coefficient method, which is a development of his original test, I have had no experience.

In this survey of the methods at our disposal for the diagnosis of lesions of the pancreas I have presented to you the separate pieces of a jig-saw puzzle. Only when the several pieces have been fitted together can we form a distinct clinical picture of pancreatic disease. Nor must we forget that when we have determined the seat of a lesion we have attained to only half of a diagnosis. We need to diagnose the nature of the lesion also. As it happens this is, in the conditions under discussion, the less difficult problem of the two.

In the endeavour to diagnose the nature of the more common diseases of the pancreas, such as acute pancreatitis, carcinoma, cysts, and chronic interstitial pancreatitis, we rely mainly upon the evidence afforded by physical signs and symptoms. Here clinical experience, when fortified by the experience gained in the *post-mortem* room, is our best guide, although we may derive no little help from the grouping of the responses of the various tests. Even pancreatic calculi have been diagnosed and removed with success; but it is probable that there will long remain a residuum of cases in which we have reason to believe that the pancreas has been damaged by disease, but in which the nature of the lesion cannot be determined with any degree of accuracy.

In order to illustrate some of these aspects of my subject it will be necessary to place before you brief records of a few characteristic cases, and to indicate the steps by which a diagnosis was arrived at in each instance. The examples chosen were wholly unlike in their general features, and had little in common beyond the fact that in all but one of them the pancreas was or is undoubtedly implicated in disease. Each one illustrates some special diagnostic points.

Case 1.

A man, aged 50 years, a street salesman, was admitted to hospital complaining of abdominal pain. Seven weeks previously he had been thrown from a van, struck his head and abdomen, and was rendered unconscious for a short time. After the accident he suffered from severe pain in his back and vomited each morning. Three days later he returned to work, although he felt very unwell and the vomiting continued. A fortnight before his admission he noticed swelling of the upper part of the abdomen, and was obliged to loosen his belt. Five days later he was seized with a violent pain, of sudden onset, with sweating and collapse. The pain was relieved by hot fomentations. From that date the abdominal swelling increased, the vomiting persisted, his bowels were confined, and he suffered much from thirst. He was

brought to the hospital after a second attack of severe abdominal pain.

The man's appearance was suggestive of grave illness; his expression was anxious, his skin moist, and there was a slight degree of cyanosis. His temperature was only 99°, his pulse 110, and respirations 24 in the minute.

Situated in the upper part of the abdomen, midway between the xiphoid cartilage and the umbilicus, was an ill-defined elongated mass, overlapped in part by the gastric resonance. A band of resonance, 1½ inches wide, separated the mass from the hepatic dullness. The tumour did not move with respiration, and no fluctuation could be made out. The abdomen was somewhat distended, but the muscles were not rigid. There was no free fluid in the abdominal cavity. The patient complained of severe pain in the back, across the lumbar region. The mass was very tender, but the greatest tenderness was over the left flank.

It is worthy of note that there was exophthalmos of slight degree; von Graefe's sign was pronounced, and he wrinkled his forehead very little when he looked upwards. A well marked tache could be elicited, but there was no tremor of the hands.

The physical signs and symptoms pointed to a subacute pancreatitis following the injury to the abdomen, and when a specimen of urine was obtained and found to contain sugar, little doubt remained as to the correctness of the diagnosis. My colleague, Mr. Waring, saw the patient with me and concurred, and an operation was decided upon. Meanwhile Dr. Graham estimated the sugar in the blood at 0.21 per cent.; Loewi's reaction was positive but not of an extreme degree, and Dr. Mackenzie Wallis found 50 units of diastase in the urine. At the operation the diagnosis was confirmed. The pancreas was explored and drained.

The man lived six weeks after the operation. On the third day Moehius's sign was present, and von Graefe's persisted, but all the eye signs disappeared before the end. A second specimen of urine obtained before the operation contained no sugar, and none was found at any subsequent examination.

Case 2.

In March, 1919, a carman, aged 59, was admitted to my wards deeply jaundiced, and with a history of three months' illness. On examination his liver was found to be greatly enlarged and of smooth surface; the gall bladder was not palpable. Some enlarged glands were felt in the abdomen. Occult blood was found in the stools, but urobilin was wholly absent—signs which suggested that a malignant growth had occluded the bile duct. Although the clinical features were so unlike those of a classical case of carcinoma of the head of the pancreas, so well described by Bard and Pic,²⁴ in that the liver was so large, the gall bladder was not palpable, and the patient was neither emaciated nor unduly feeble, the possibility of such a growth was considered, as also that of a malignant growth originating in the bile ducts. It soon became evident that wherever the growth started the pancreas was implicated, and for the following reasons:

Adrenalin caused a conspicuous mydriasis on several occasions; the urinary diastase amounted to 125 units; the total fats of the faeces constituted no less than 70 per cent. of the dried material, and many undigested striped muscle fibres were seen in the faeces.

A week after his admission sugar appeared in the patient's urine for the first time, and the glycosuria persisted until his death. The average daily output of glucose was about 35 grams.

The fat content of the faeces, which was far greater than the jaundice could explain, increased as time went on, whereas the urinary diastase fell gradually from 125 to 60, 25, and 30 units, figures scarcely above the normal.

The patient died after he had been in hospital two and a half months. At the autopsy carcinoma of the head of the pancreas was found; there were no secondary growths in the greatly enlarged liver which had completely hidden the gall bladder which latter, although greatly distended with bile, had never been palpable during life.

Case 3.

The next case to which I shall refer could not be subjected to any systematic investigation. A man,

aged 53, was first seen by me in October, 1910, at the request of his medical attendant, Dr. Robbs. His complaint was that for six months past he had passed oil with his stools, which became solid fat on cooling. In twelve months he had lost a stone of weight. He suffered no pain of any kind. Nothing abnormal could be found on examination of his abdomen; his liver was just palpable; there was neither fullness nor tenderness in the region of the pancreas and there was no jaundice. His urine contained neither sugar nor albumin.

When I saw the patient again, in June, 1913, he had lost another stone, but had developed no fresh symptoms, and his urine was still free of sugar. He was still able to lead an active life. Loewi's test gave no mydriasis, and the urinary diastase did not exceed the normal.

Dr. Cammidge examined his urine and faeces, in January, 1914, and obtained a positive reaction with his test. The total fat in the dried faeces amounted to 51.2 per cent., and of this only 4 per cent. was in the form of soaps. There was obvious creatorrhoea with many undigested muscle fibres in the stools, and by means of Gross's test casein digestion by faecal material was found to be very incomplete.

Dr. Robbs tells me that now, in 1920, the patient's health is better than for some time past, and he has gained seven pounds of weight during the past six months.

Case 1.

The last case is that of a Belgian refugee, aged 32, who was admitted to my wards in January, 1915. For three years he had been liable to paroxysmal attacks of pain, referred to the region between the xiphoid cartilage and the umbilicus. During the attacks, which were obviously very severe, the patient assumed a position of opisthotonos, but he never vomited. It was suspected that he might have a pancreatic calculus, but the x rays showed no shadow in that region. Loewi's reaction was conspicuously positive, and the urinary diastase was at first 100 and afterwards 50 units. There was no excess of fat in the stools, no glycosuria, and only 0.12 per cent. of sugar in the blood. Thus the only indications of pancreatic disease were the position of the paroxysmal pain, the excess of diastase in the urine and the adrenal mydriasis. Our investigation of his symptoms was much hampered by the fact that he spoke only Flemish, and a very few words of English.

A month after his admission he passed a large tarry motion. A few days later Mr. Waring performed gastrojejunostomy. A few days after the operation the patient developed bronchopneumonia, with maniacal delirium, of which he died. At the autopsy a chronic ulcer was found in the second part of the duodenum, three-quarters of an inch in diameter and adherent to the pancreas and adjacent structures. The note describes the pancreas as normal to the naked eye.

If we review these four cases we notice how widely different were the clinical pictures which they presented. In the first case the diagnosis rested mainly upon the clinical signs and symptoms, but several tests of pancreatic efficiency supported the clinical diagnosis. In the second case, that of carcinoma, the evidence of a lesion of the pancreas rested largely upon disturbances of the external and internal secretion of the gland, but was quite conclusive. The only point in doubt was the primary seat of the growth. Except the intense jaundice the clinical signs did not afford much help.

In the third case the associated steatorrhoea and creatorrhoea leave no doubt that the patient is suffering from a severe pancreatic lesion, and Cammidge's test gives further support to this view. Presumably the duct is obstructed, and the pancreas is the seat of interstitial changes. The absence of pain does not exclude the presence of calculi. The failure of the adrenalin and diastase tests in no way invalidates the diagnosis. The case resembles one described by T. J. Walker²⁶ of a patient whose steatorrhoea persisted from the age of 62 until his death at the age of 90, and whose pancreas was found to be completely obsolete and replaced by fat, and the duct was studded with calculi. In cases in which a like syndrome is presented with glycosuria in addition the patient's health is much more seriously impaired, and the prognosis is far more unfavourable

In the last case, that of the Belgian, we can hardly escape the conclusion that the disturbance of the pancreas by the adjacent ulcer was the cause of the increase of urinary diastase and of the adrenalin mydriasis.

In a case of bronzed diabetes which has been described at length elsewhere²⁶ we employed several pancreatic tests. Of these Loewi's test, Schmidt's beef-cube test, and the glycosuria pointed to implication of the pancreas, whereas Cammidge's test, the estimation of fat in the faeces, and the determination of the tryptic and diastatic activity of the stools gave no indication of damage to that gland. After death the pancreas was found to be fibrotic, and loaded with iron-containing pigment.

In the case of congenital steatorrhoea, on the other hand, there was no creatorrhoea, the faeces digested casein; Sahli's capsule test and that of Schmidt, a normal diastase content of the urine, and the absence of adrenalin mydriasis, all tended to acquit the pancreas. Cammidge's test alone, kindly carried out by its author, was found to give a "slightly positive result."

TABLE II.

Case.		Loewi's Test.	Fatty Stools.	Creatorrhoea.	Casein Digestion Test.	Sahli's Test.	Schmidt's Test.	Urinary Diastase	Glycosuria.	Jaundice.	Cammidge's Test.
1	Subacute pancreatitis ...	+	-	-	-	-	-	+	+	0	-
2	Carcinoma of head of pancreas	+	+	+	-	-	-	+	+	+	-
3	Blocked duct, chronic pancreatitis	0	++	+	+	-	-	0	0	0	+
4	Duodenal ulcer adherent to head of pancreas	+	0	0	-	-	-	+	0	0	-
5	Bronzed diabetes, chronic pancreatitis	+	0	?	0	-	+	-	+	0	0
6	Congenital steatorrhoea	0	++	0	0	0	0	0	0	0	?

+ Signifies positive; ++ true steatorrhoea; 0, negative; -- not tried.

It will be evident from all that has gone before that practically every sign, symptom, or test may fail us at times, and that in each individual case we need to balance the quantity and quality of the evidence for and against a lesion of the pancreas. In a word, we come back to Wardell's statement of 1871. It is still true that "no symptoms are pathognomonic of pancreatic disease; an assemblage of symptoms points to the probability of its lesion." But we have at our disposal a far greater assemblage of symptoms than Wardell had, and in not a few cases the degree of probability is not to be distinguished from certainty.

That is as much as can be expected when we are dealing with a problem the solution of which rests so largely upon circumstantial rather than direct evidence. If we cannot claim for the diagnosis of pancreatic disease the clear-cut, direct answers obtained in some other regions of clinical medicine and surgery, we may none the less regard with complacency what has so far been accomplished in this field by the application of physiological discovery at the bedside, by the co-operation of the laboratory and the ward.

INFLUENZA AMONGST THE LAPPS.

BY

A. H. MACKLIN, M.C., M.B., CH.B. VICT.,

LATE ACTING MAJOR R.A.M.C.,

LATE SURGEON, IMPERIAL TRANS-ANTARCTIC EXPEDITION.

DURING the winter of 1918-19 reindeer transport was extensively used by the Syren Force in North Russia. The drivers were all Lapps. As they are nomadic and live widely scattered over a huge area, the officer in charge of reindeer transport spent a great deal of time and had considerable difficulty in maintaining a sufficient supply of drivers. In December, 1918, he reported that "a terrible sickness carrying death wherever it went" had broken out amongst them, making it difficult for him to maintain a sufficient supply for army requirements. He asked that a medical officer should be sent to investigate the cause, and if possible limit its spread.

The A.D.M.S. Syren, anxious that no form of infectious disease should reach British or Allied troops from this source, ordered me to proceed into Lapland, make full investigation, and report as soon as possible.

A start was made at once. I was successful in securing the assistance of Captain Hussey and Lieutenant Stenhouse, R.N., both of them experienced explorers, and the services of an interpreter. We proceeded by train to Kola, where we obtained a Lapp driver and sufficient reindeer and sledges.

Our equipment consisted of a "medical companion" of the usual army pattern, a sleeping bag each, and rations for ten days. The Lapp driver occupied the leading sledge, to which were harnessed three reindeer, each by a single trace, but of unequal length, and with their horns cut so as to fit into the narrowest space possible. Their sledge was flat and built on high runners. The other sledges, which we occupied, were shaped like little boats, with rounded bottoms, drawn by one reindeer each, each reindeer secured by a thong to the sledge in front, and the whole proceeding as a linked-up convoy in single file.

We proceeded into Lapland in this way for a distance of sixty miles, sleeping at night in the open in front of huge fires built by the Lapp driver, or in small huts scattered about the country, the locality of which seemed to be known to our guide. The route followed was first in a south-westerly direction up the frozen surface of the Tuloma River, and then passed over a divide to another frozen river, a process repeated many times, using always the comparatively easy going of the river surfaces. Our track led us through thick, heavily timbered forest, with occasional open glades, the trees heavily covered with rime and very beautiful.

We passed from settlement to settlement, widely scattered, often two to three days' journey apart. Medical notes were made en route. The disease which had broken out proved to be influenza of a very acute type.

The usual course of uncomplicated cases was as follows: Acute onset with rapid rise of temperature, varying from 100° to 103.5°, with heavily-furred tongue, offensive breath, complete loss of appetite, intense headache and great restlessness. The fever lasted from two to four days, ending with sudden resolution of temperature and apparent almost complete recovery. Two good instances of this were a man and a woman, who were seen on the outward stage of our journey on the second day of their illness, and three days later on the return journey, were going about their ordinary duties, apparently little the worse for their illness, complaining of no weakness, and with enormous appetites fully restored.

I had no chance of observing the course of the disease in its continuity, but it appeared that cases which did not recover within four to five days did not recover at all. The chief complication appeared to be bronchopneumonia, from which I gathered there were practically no recoveries. From information, I estimated that about 50 per cent. of all cases died; at any rate the percentage was high.

The Laplanders had a very thorough if unsympathetic way of dealing with their cases. The settlements were composed of wooden huts, small but generally well made and warm. A common type consisted of but one room.

used by the family for all purposes. Better class Lapps had better huts, with two or three rooms. In each settlement one of the single room huts had been set apart, and into this each case of sickness as it arose was unceremoniously pushed; and none were permitted to return to their own huts until completely recovered. Whilst there they received practically no attention, and no healthy person ever entered to attend to their wants. Occasionally a bowl of water or reindeer milk was hastily passed in at the door, or a huge chunk of reindeer meat thrown in, uncooked and uncarved.

We visited every settlement within our reach and entered these huts. The stench on opening the door met one like a poison blast, and the rooms were nearly always ill lighted and dark. The patients lay littered about the floor in a crowded mass, fully dressed in clothes and boots (most of them had no socks), and with no other cover but an occasional greasy rug. Although the outside air was cold and the ground snow-covered, the temperature inside, maintained by the combined mass of bodies, was generally sufficiently high. The patients in these huts included both sexes and all ages; some when we entered sat up, and with flushed faces and dull, uncomprehending eyes, watched us listlessly. Others lay restlessly twisting about, quite incapable of taking any interest or of answering any questions. In these circumstances a thorough examination was difficult, and the difficulty was increased when none of the inmates could speak Russian, for our interpreter did not understand their language, and though many of the Lapps spoke Russian a double interpretation was often required.

Constipation was a constant factor, and many cases had not had their bowels opened since the onset of their illness—in some cases seven to ten days. Others had voided urine and faeces just as they lay. In some huts those of the patients who had passed the worst stages of their illness assisted and looked after those more acutely ill.

There was little I could do with my very limited equipment to improve their lot, and the methods adopted by the Lapps, at first sight so callous and neglectful, appeared to be essential for the preservation of their race. My companions, neither of them medical men but smitten with commiseration for these poor wretches, insisted always on entering the huts, and unused though they were to such conditions, and driven frequently to seek the open air, did their best to straighten things out and make the lot of the inmates a little less hard. I instructed the Lapps to increase the supply of water and milk—both were eagerly drunk—and to substitute reindeer soup for the huge chunks of meat which were always untouched; this they promised to do. We were able to leave them some oxo, and a little tea and sugar, carefully doled out.

On the way back I pondered over the question of what could be done, and what ought to be done to cut short this disease, and improve the conditions of those affected. The parts visited formed but a fringe of the vast area of Lapland, the nomadic tendencies of the inhabitants, whilst making them difficult to find would probably prove beneficial in leaving behind sources of infection. Any organization, to deal adequately with the situation, would, of necessity, be costly, take considerable time to materialize, and be on a vast scale. The Lapps, owing to their poorness in the world's goods, were quite unable to deal efficiently with their sick, and they had no doctors.

Finally, I felt convinced that for them the only possible thing was to do everything possible to stamp out the disease. Methods in civilized countries had had little effect in this way. I decided that their own methods, drastic and unsympathetic though they were, were best, and that the chief care should be directed to preventing spread to our own lines.

Arrangements were made, however, for a supply of quinine (which owing to its bitter taste had a great suggestive value) and of medical comforts, tea, sugar, milk, and oxo, to be sent to those areas supplying drivers and reindeer for the allied armies.

The wave of infection passed rapidly over, and on inquiry four weeks later no cases were reported. I could obtain no statistics of the number of cases in relation to the population, or of the mortality, but consider that the latter must have been high.

Two points particularly interested me :

1. The number of bugs in these pest houses. Their number and size were amazing. I saw no other type of body parasite in Lapland.

2. For less acute diseases the Lapps did not adopt the same drastic attitude. I saw many cases of tuberculosis, including one bed-ridden case of advanced pulmonary tuberculosis. They lived with the rest of the family, and appeared to be well looked after and kindly treated.

CLINICAL ANALYSIS OF 100 CASES OF EARLY BERI-BERI.

BY

H. H. HEPBURN, M.D., C.M.McGILL,
F.R.C.S. EDIN.

The incidence of scurvy and beri-beri among British troops in the East having been recently reported on by Colonel W. H. Willeox, C.B., C.M.G., A.M.S., the following observations may be of general interest:

During 1913 and 1914 I had occasion to investigate a series of cases of early beri-beri at the Police Hospital in Bangkok, Siam, under the direction of Dr. Highet, the P.M.O. While Drs. Morden, Carthiew, and A. C. Rankin were concerned with the problem of etiology, I undertook to analyse the early manifestations of beri-beri, with a view to establishing the correct chronological order of the early signs and symptoms. The completion of my work was interrupted by the war, hence the delay in publication.

The data to follow are compiled from over 300 examinations of 100 cases. All patients were adult Siamese males, and each case was thoroughly examined at least twice.

The first symptom or sign to be noted by the patient was invariably one of the three following: (a) Oedema of feet and legs (50 per cent.); (b) numbness or anaesthesia of feet (43 per cent.); and (c) epigastric fullness and distress (7 per cent.)

TABLE I.—Early Signs and Symptoms.

Sign or Symptom.	First Complaint.	Later Complaints.	Not Observed by Patient.
	Cases.	Cases.	Cases.
Oedema of feet...	50	39	11
Anaesthesia of feet ...	43	57	0
Epigastric distress ...	7	70	23

In every case the oedema appeared first in the feet, then the legs, and then in the hands. Appreciable swelling of the hands was seldom seen in these early cases. Practically all patients complained of more or less general weakness. Several patients stated that swelling of the feet had come and gone before the onset of anaesthesia. Nine patients complained of early pains in the legs. One developed effusion into both knee-joints, but had a previous rheumatic history. In eighty-two cases the action of the bowels was considered normal. Seventeen were constipated, and one complained of diarrhoea at the date of first examination.

Cardiac enlargement was found at the first examination in only 15 per cent. of cases. Subsequent enlargement

TABLE II.—Pulse Rate.

In Erect Posture after Walking Ten Yards.	After Sitting for Five Minutes.		
	Cases.	Cases.	
80 to 90 per minute ...	14	70 to 80 per minute ... 23	
90 to 100 ..	19	80 to 90 ..	27
100 to 110 ..	30	90 to 100 ..	18
110 to 120 ..	20	100 to 110 ..	23
120 to 130 ..	10	110 to 120 ..	5
130 to 140 ..	5	120 to 130 ..	1
140 to 150 ..	2	130 to 140 ..	2

occurred in four additional cases in spite of treatment. The treatment adopted was physical rest, with a diet rich in anti-beri-beri vitamins, polished rice being rigidly excluded. Further treatment was largely symptomatic. A soft mitral systolic murmur was heard at the first examination in twenty cases. Cardiac arrhythmia was noted in five of these early cases. The pulse rate per minute is shown in Table II.

The arterial tension as recorded by the "Tycoos" sphygmomanometer at the first examination is shown in Table No. III, the normal in healthy adult natives falling between 90 and 100:

TABLE III.—Arterial Tension ("Tycoos").

80 to 90 ...	24 cases	100 to 110 ...	22 cases
90 to 100 ...	17 ..	110 to 120 ...	15 ..
100 exactly ...	21 ..	120 to 130 ...	1 case

Of 41 cases with a tension below 100, after a few days of treatment 23 were raised to between 95 and 100, whereas of the 38 cases with a tension of over 100, 21 were reduced in a few days to 100.

The knee-jerk is involved early. An increased reaction was observed in a few cases to be followed by diminution or abolition of the reflex. Table No. IV shows the conditions found:

TABLE IV.—State of the Knee-jerk.

	Increased.	Normal.	Diminished.	Abolished.
First examination ...	6	23	22	49
Later examination:				
Increased ...	0	1	0	0
Normal ...	4	10	7	2
Diminished ...	1	12	12	9
Abolished ...	1	0	3	38

The plantar reflex was found to vary in inverse proportion to the anaesthesia. Steppage gait in walking increased with the anaesthesia, and in severe cases amounted to ataxia, with a positive Romberg sign. A positive knee-jerk and abdominal reflex was sometimes obtainable in a patient who was anaesthetic to pain of a pin-prick up to the costal margin.

Sensation to pain of a pin-prick always disappeared before the sensations of superficial touch, deep pressure, and posture.

The degree and extent of anaesthesia, and the condition of the reflexes may fluctuate widely from day to day, recovery frequently being effected with amazing rapidity. For example, deep anaesthesia to pain up to the knees has disappeared in five days. Another case (No. 68) is worthy of special mention. On admission to hospital this patient was anaesthetic to pin-prick up to the umbilicus, with hyperaesthesia shading gradually up to the level of the clavicle. After five days the anaesthesia did not extend beyond the knees. Table V shows the extent of anaesthesia to pin-prick at the first examination. I might add that it is not unusual for a patient to be walking about with anaesthesia to pain of pin-prick up to the level of the umbilicus, or even the clavicle.

A LESSON OF THE WAR: SUPPURATIVE MIDDLE-EAR DISEASE.

A PLEA FOR TREATMENT IN ITS EARLIEST STAGES.

BY

H. SMURTHWAITE, M.D.,

SURGEON, THROAT, NOSE, AND EAR DEPARTMENT, ROYAL INFIRMARY, GLOUCESTER.

OUT of 5,000 odd cases under my care at the Throat, Nose, and Ear Department of the Military Hospital, Tidworth, during the year ending October 31st, 1917, no fewer than 890 were suffering from chronic suppurative ear disease—practically a battalion; the period of their disability ranged from a few months to many years, or in the patient's words, "as long as I can remember." A large majority of these cases were only fit for Category C, as it was at that time, whatever some people might say to the contrary. They all suffered from deafness, more or less, and were not fit for the firing line; most of them were in very indifferent health, were anaemic from prolonged suppuration, and consequently a fitting soil for every microbic disease.

A large number were most of their time in the medical officer's hands for treatment, a treatment of syringing and drops, which was only marking time, for little short of a mastoid operation would cure such cases, and space and time would not permit this.

The greatest number of those cases, if not all, would have been "A" men, as far as their ears were concerned, had systematic and energetic treatment been carried out in the earliest days of the onset of the disease. Chronic suppurative ear cases could be enormously reduced if we adopted systematic prophylactic methods and did not wait until the disease was far advanced.

Every fever hospital should have an otologist attached, or at least a medical officer in charge who has a fair knowledge of ear diseases, and who would always be on the alert for its early onset, for these institutions are a fruitful source of suppurating ears, and what is more, these cases can act as carriers of a specific fever, thus becoming a danger to others coming in contact with them. As bearing on this the following will suffice:

A patient was admitted to a ward in a military hospital of which I had charge in 1915, suffering from slight fever and a profuse discharge from the left ear. Though at the time of admission he had no throat trouble, there was a history of such some three weeks previously. The discharge being profuse and not abated by treatment, a swab from the ear was examined and Klebs-Loeffer bacilli were found in large numbers. The case was promptly isolated. Two days later the patients in the beds on either side of this case developed diphtheria. A day later I myself was a victim to the same disease. No doubt the throat trouble which the ear case had had three weeks before admission had been diphtheria, but probably on account of slight physical local signs had been overlooked, and the disease had in the meantime spread to the ear.

It is in the earliest stages of any disease we have the best chance of obtaining permanent cure; I have invariably admitted to hospital every case of acute otitis media, and every case of suppurating ear when the disease had lasted less than two months, with the certainty of effecting a cure by careful and energetic treatment. Speaking generally, cases beyond this period cannot be so favourably regarded; also they are too numerous to be treated as in-patients, and in the majority permanent damage, more or less, has already been done to the structures in the middle ear, with consequent loss in the hearing power.

During the period mentioned there were 54 cases of acute or subacute otitis media, all of whom left hospital with the discharge ceased, the rent in the drumhead healed, and the hearing restored. Our object must be to gain at once the upper hand in the early stage, and to restore the middle ear to a healthy state before serious changes take place, such as involvement of the antrum and mastoid cells, lateral sinus, or meninges. Even should the patient escape these, there is always, if the suppuration continue for an extended time and finally dry up with the perforation in the drum healed, marked fibrous change in the lining membrane of the middle ear, which must impair the hearing, varying from absolute deafness to loss of the acuteness of hearing.

The pathology of acute middle-ear disease is similar to that of disease of other mucous membranes: dilatation of the vessels, with swelling and lessening the lumen of the

cavity. The starting point is invariably the posterior nares, and oftener than not follows the acute febrile diseases—scarlet fever, measles, mumps, influenza, etc. Among the predisposing causes the most important are adenoids, enlarged tonsils, and nasal disease. Inflammation or catarrh in the neighbourhood of the Eustachian tube easily spreads up the tube to the middle ear, and, should its lining membrane become thickened by inflammation, its walls soon come together and block the lumen. The middle ear then becomes an enclosed cavity, with no outlet for the serous fluid thrown out by the engorged vessels, and the patient then experiences fullness in the ear and deafness. The drum membrane has lost its lustre, and in all probability is indrawn, for part of the air in the middle ear has been absorbed, and the external air pressure is greater than that within. If there is much fluid in the middle ear there will be bulging in the posterior quadrant of the drum, and should the dam in the Eustachian tube be allowed to continue many things may happen: the inflammation may slowly resolve, but often it does not, and unless a knife is put into the bulging membrane and politizerization carried out the serous exudation in the middle ear becomes septic, and an abscess forms. The drum becomes intensely red and bulging, and the patient is in great pain until relieved by the abscess bursting into the external auditory canal, leaving a small jagged opening in the membrane. In some cases following the acute infectious diseases, such as scarlet fever, the inflammation spreads so rapidly that the antrum and mastoid cells are acutely attacked before the abscess can burrow through the drum, and an acute mastoid abscess develops, or the inflammation may spread to the meninges or lateral sinus, with, naturally, very grave consequences. It is therefore advisable in all these cases to incise the bulging drum early and so establish drainage as soon as it is certain that the fluid in the middle ear is not subsiding.

Every case of acute middle-ear inflammation should be put to bed and given a brisk calomel purge. If there is any nose or throat trouble this should have appropriate attention. Should the drum membrane be bulging, the external auditory canal should be thoroughly disinfected by swabbing with 1 in 4,000 flavine or 1 in 20 carbolic, and the membrane freely incised under general anaesthesia; the incision should be made in the posterior quadrant just behind the handle of the malleus and running crescentically down to below the tip. Gentle use of the Politzer bag will open the Eustachian tube and force the fluid out of the middle ear. This fluid is then mopped out of the canal; a pledget of cotton-wool soaked in flavine is placed close up to the drum, but must cause no pressure. It should be changed every few hours. I have sometimes plugged the canal lightly with wool soaked in 50 per cent. rectified spirit, which can be increased in strength if it causes no excoriation. At each dressing politizerization should be carried out or the fluid extracted from the middle ear by gentle suction.

For the pain, which is sometimes very acute, glycerin of carbolic, 10 grains to 1 oz., is useful; a few drops warmed in a teaspoon and instilled into the ear, or a few drops of chloroform, will give relief; hot fomentation over the mastoid and auricle is always very soothing to the patient. There is always some post-nasal catarrh, and a warm inhalation of compound tincture of benzoin every two hours will relieve the congestion of the lining of the mouth of the Eustachian tube and help the necessary drainage.

Pain in the ear should never be passed over. It may only have its origin in a carious molar tooth or hard cerumen in the external auditory canal, but it is Nature's danger signal, and should ever be regarded.

The object of this paper is to draw attention to the large number of cases of chronic suppurative ear in England to-day, and to urge that everything in our power should be done to lessen it. A man with ear disease loses from 10 to 70 per cent. value in the labour world.

A large and increasing number of cases is now coming under my notice originating in rupture of the drum by high explosives and secondary infection of the middle ear, which, for lack of continuous and expert treatment, have become chronic. The drum is torn by the terrific concussions of high explosives, and though the man may escape all other injury he is so dazed that he does not notice he is deaf, and possibly has some slight bleeding from one or other ear. A day or so later there is pain in the ear and

a slight mucopurulent discharge. In other cases there was no pain in the ear and only a slight discharge, and the men, thinking it only trivial, did not complain until it became profuse and was accompanied by marked deafness.

During the last twelve months I have examined some hundreds of cases of deafness in varying degree for pension purposes, and I now, as never before, realize at what a disadvantage a man with even a partial loss of hearing is. There are many trades in which good hearing is indispensable. The miner has again and again told me he can no longer get work down the pit on account of his loss of hearing, because he may fail to hear sounds in the pit which portend disaster or death to himself or his comrades. The same applies to many other trades, and the man has to seek other work, each succeeding class of work is more precarious for him, and he is finally driven to casual labour. The poorer classes take but casual notice of the condition of the ear, and this applies especially to suppurative otitis media. Pain is not a frequent concomitant, otherwise they would oftener seek advice. I cannot do better than quote Dr. Mygind of Copenhagen in his book on deaf-mutism. He writes: "It is to be hoped that the recognition which is by degrees, though slowly, being yielded to otology by the medical profession, will make itself felt in the prevention of deaf-mutism, by opening the eyes of the practitioner to the importance of ear diseases and their treatment, and also that the general public may be led to form other opinions upon the subject than those now prevalent."

If by propaganda the poor and so-called working classes could be taught to look upon their hearing as precious, and realize that a "running ear" may lead to the loss of that power and calls at the earliest onset for advice, the efficiency of the nation in general would be increased.

STRANGULATED UMBILICAL HERNIA:

RESECTION OF GANGRENOUS ILEUM AT THE AGE OF 69.

BY

C. M. KENNEDY, M.B.E., F.R.C.S. ENG.,

LATE MAJOR R.A.M.C.(T.C.).

ASSISTANT SURGEON SOUTH DEVON AND EAST CORNWALL HOSPITAL.

Successful resection of gangrenous gut in inguinal and femoral herniae are by no means rare, but in umbilical herniae successful resection is less common. The following case is thought to be of interest because success was attained in spite of the patient's age.

M. P., a widow aged 69, was admitted to the South Devon and East Cornwall Hospital on the afternoon of January 21st, 1920, complaining of severe abdominal pain and vomiting.

Her history was difficult to elicit, and was probably inaccurate. So far as could be discovered she had had an umbilical hernia for many years. She stated that she had had pain in the hernia for more than a week, associated with vomiting. During this time the bowels had been very slightly opened after aperients, and for three or four days had not moved at all. She did not call a doctor in until the day of admission, and he at once sent her to hospital.

On admission she looked ill, and senile beyond her years. The pulse was 94 but weak, the temperature 98°. At the umbilicus was a tense tender red—almost purple—swelling about the size of a cricket ball. There was no impulse on coughing. The rest of the abdomen was somewhat distended, but not tender. The vomit was bile-stained and foul, but hardly "faecal."

Under a chloroform and ether mixture the hernia was surrounded by a transverse elliptical incision, which was deepened to the rectus sheath. The hernia was then lifted off the rectus sheath until the neck was exposed all round. The abdomen was then opened just clear of the neck of the hernia. The hernia was then isolated by extending this incision completely round, but just clear of, the neck. The abdomen was then packed off, and the sac opened by splitting up the neck from what had been its peritoneal aspect. The sac contained a quantity of very foul, almost black, purulent fluid, a mass of adherent and gangrenous omentum, which was ligatured off and removed with the sac, and about four inches of gangrenous ileum. The centre of this length of small gut was of very doubtful viability, but at either end, where it had been nipped, it was reduced to little more than a slough. In order to leave a good margin on either side of the damaged gut about eight or nine inches of gut was resected. Continuity was restored by end-to-end anastomosis, the collapsed distal portion of the gut being split along its anti-mesenteric border so as to give a sufficient lumen for an anastomosis to the proximal distended gut.

The abdomen was closed in layers by mattress sutures placed transversely (modified Mayo's method). A rubber drain was placed at either angle of the wound, as the subcutaneous fat was considered likely to be infected.

On the day following operation the temperature was 97.4°, the pulse 80, and respirations 22. There was considerable flatulence. The bowels were opened by a turpentine enema on the following day. Thereafter convalescence was smooth but for trifling superficial sepsis necessitating removal of a couple of skin sutures.

The patient left hospital for a convalescent home on February 24th, 1920. She was then in her normal state of health.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SHINGLES AND CHICKEN-POX.

ALMOST immediately after reading Dr. Taylor's neurological jottings in your issue of February 28th, a girl of 16 came to my surgery for some medicine for her father, who had developed shingles about a fortnight before. She asked me about a "rash" which had appeared on her body on the previous day. I found that she was in an early stage of chicken-pox, which subsequently developed, with a temperature of 102°, into a good crop of vesicles. There is no other case of chicken-pox in the neighbourhood. Her father is an instructor in gardening at a boys' home, but there have been no cases amongst the boys, probably because of the work being entirely in the open air.

Chobham, Surrey.

A. INGRAM COOKE, M.D.

ACUTE OEDEMA OF THE LUNGS.

I HAVE been much interested in the correspondence on this subject, as, with Dr. Stewart McNaughton (February 28th, p. 293) I believe that the disease is more common than is usually thought. In the autumn of 1897 I reported a case of dramatic severity in the *Lancet*.

The victim was a man aged about 50, who was seized with respiratory distress after a bicycle ride against a cold head wind. He died within an hour of his first symptoms, and for the last few minutes of his life poured out pints of bright pink foam. Auscultation revealed the presence of fine crepitant râles, commencing at the bases and very rapidly spreading upwards. There was a history of some previous renal mischief.

Within a few months I saw a woman of much the same age who fell ill suddenly after cleaning out a flooded basement. Her condition was less acute. The expectoration was aerated, bright pink, but not so great in quantity, nor so frothy. She lived a few hours.

Again, a man of 60 was placed under my care with a story of recurring suffocative attacks at night. He had aortic regurgitation. The urine was of low gravity, and contained a trace of albumin. During a period of perhaps two months he called me some half-dozen times, always a little before midnight. He was invariably in great distress, standing with both hands grasping the bed rail. The sputum was more or less frothy and coloured red. A hypodermic injection of atropine would relieve him at once, allow him to go back to bed, and in the morning he would be quite recovered. The fine râle was very evident in this case, and the rapidity of the upward extension remarkable. His last attack was more severe and I was longer in reaching him. This time atropine failed to check the secretion, and he died expelling much frothy sputum.

Two other cases of recurrent oedema occur to me. One in a woman of over 70, suffering from mitral regurgitation; the other in a woman of 60, suffering from myocardial degeneration. In each instance the crises were spread over a period of two or three years at varying intervals of months. In each there was the great distress, the rapidly ascending râle, and the tinged aerated sputum. Atropine acted well in both and promptly relieved the condition.

The older patient eventually, after her cardiac condition had badly deteriorated, died in an attack, in spite of the usual dose. The other died of gradual heart failure and generalized oedema. The last time I saw the condition was in the following case:

A man of 46. He suffered from extreme arterial high tension, and gave a history of a former but milder bout.

I was called in the night to find him intensely dyspnoeic, unable to move or lie down. There was the usual type of sputum; but for the first time in my experience the râles were the most abundant at the upper part of the lungs. A dose of atropine relieved at once and allowed him to return to bed. In the morning he was quite well.

There are differences in all these cases, but they clearly belong to one group. It is noticeable that where a history

is available all suffered from renal or cardio-vascular changes.

The first case to receive atropine dates back twenty years. I gave it after thinking over the first two, who died quite unrelieved by such treatment as I could then devise.

The disease appears to be due to acute hyperaemia of the small bronchioles, and atropine acts presumably by stopping their secretion. All these patients lived close at hand, and had it been otherwise would probably have died without recognition of the real mode of death.

CECIL MUSGRAVE, M.D. Lond.

THE PATH OF THE ECLAMPTIC TOXIN.

It is taught that eclampsia is due to a toxin, but what that toxin is has not yet been proved. No attempt will be made to do this here, but a suggestion as to how the toxin acts may be of some value in deciding what is the most rational method of treatment. Needless to say the ideas arose after reading McCarrison's work on the thyroid.

Spinal anaesthesia is produced by injecting a local anaesthetic, such as stovaine, into the spinal canal—by, that is to say, bringing a paralyzing substance into contact with the spinal cord. If instead of a paralyzing substance an irritant, like the toxin of eclampsia, is mingled with the cerebro-spinal fluid, we would expect the results of irritation—namely, convulsions, as in eclampsia.

If it be true that the eclamptic toxin is to be found in the cerebro-spinal fluid, it must get there through the choroid plexus, which normally secretes the fluid. The choroid plexus is a true secreting gland, and in health has a selective action which prevents toxic bodies passing from the blood to the cerebro-spinal fluid. If from disturbed function this selective action is lost, toxins will pass through the gland to the spinal canal, and those toxins may be the toxins of eclampsia.

The choroid plexus, which is an internally secreting gland, is controlled by hormones produced by the thyroid gland (or more probably the parathyroid) according to my interpretation of McCarrison's teaching. Hence a deranged thyroid entails a deranged choroid plexus from hormone starvation.

McCarrison mentions two classes of toxins: (1) Those resulting from endogenous metabolism, and (2) toxins of bacterial action.

Possibly the first class, by their presence in the cerebro-spinal fluid, are responsible for the symptoms of eclampsia. Normally the kidneys would excrete these toxins. In pregnancy they are much increased in quantity.

From McCarrison's work it seems reasonable that the bacterial toxins bring about the disordered condition of the thyroid, and that they are elaborated in the alimentary canal. He points out the frequent enlargement of the thyroid in pregnancy. On account of the presence of the fetus the thyroid must increase its activity, and since it is acting under greater pressure is more easily disturbed. Most obstetricians believe that the toxin of eclampsia is elaborated in the alimentary canal of the mother. This is compatible with the above suggestions.

To sum up: bacterial toxins elaborated in the alimentary canal are absorbed into the blood and carried to the thyroid apparatus, upon which they act injuriously and cause insufficient hormone production. This leads to choroid plexus insufficiency with loss of selective action, which permits (toxic) endogenous products of metabolism to enter the cerebro-spinal fluid, where they act upon the central nervous system and produce the condition of eclampsia.

If this view be correct, the rational treatment would be:

1. To remove the organisms which form the toxins from the alimentary canal.
2. To remove toxins, both bacterial and metabolic, from the blood.
3. To remove toxins from the spinal canal.
4. To supply hormones to activate the choroid plexus.
5. To treat symptoms as they arise.

To meet the first point, the stomach and bowel are washed out and purgatives given; the second is met by venesection, saline purgatives, counter-irritation of the kidneys, and transfusion; toxins are removed from the spinal canal by lumbar puncture, and hormones supplied by giving thyroid extract. Symptoms must be treated as they arise (for example, fits controlled with morphine or

chloral), since the toxins cannot be removed completely or immediately from the system. A local anaesthetic might, perhaps, be injected into the spinal canal with benefit after lumbar puncture.

Reports of Societies.

VENEREAL DISEASE.

A MEETING of the Bradford Medico-Chirurgical Society held at the Royal Infirmary on Tuesday, March 16th, was devoted to venereal diseases. Dr. H. H. WHITE read a paper entitled "A brief review of venereal diseases with special reference to modern methods of treatment, some points in diagnosis and some complications." He pointed out that gonorrhoea was a most difficult disease to treat and cure. Patients rarely came early enough for it to be possible to abort it, though he had recently aborted one case with 15 per cent. argyrol twice a day for three days, followed by irrigation with potassium permanganate, and had seen other cases aborted with acriflavine. In the acute stage the best results were obtained by irrigation with potassium permanganate and sodium carbonate, prescribing an alkaline mixture, and rest in bed. When the posterior urethra was affected the case was much more difficult to cure, and the prostate should then always be examined. The complications of gonorrhoea were legion, and he described them and their treatment. He dealt also with gonorrhoea in women, and the difficulty of diagnosing it clinically; he described its treatment, and pointed out that the urethra in women was a common hiding-place for the gonococcus, and that this was the chief source of conveying the disease to others. He then dealt with syphilis, and said that as soon as dark-ground illumination showed the spirochaete, treatment with 606 or 914 should be given forthwith. He showed the importance of not accepting an early negative report as proof that the disease did not exist, and described the untoward results following injection of 606 and 914.

Dr. W. CAMPBELL read a paper on "Matters relating to the diagnosis of syphilis and to the serological methods used in the control of treatment." He indicated the various sources of error in the Wassermann reaction, and showed serums illustrating these errors. He demonstrated the necessity of titrating antigen so as just to exclude a non-specific reaction in cases of psoriasis, and pointed out the importance of examining the blood as soon as possible after its removal from the patient to prevent the serum becoming anti-complementary. The Wassermann reaction of the cerebro-spinal fluid was also dealt with. The discussion was continued by Drs. MARGARET SHARP, MARTIN, HAMBLEY ROWE, BUCHAN, and others.

Reviews.

A MANUAL OF WAR SURGERY.

A Manual of War Surgery,¹ edited by Colonel SEYMOUR BARLING and Major J. T. MORRISON, contains sixteen chapters to which some seventeen independent authors contribute. Its scope is restricted to the surgical methods employed in the large military hospitals at the various bases in France. As Sir George Makins remarks in an introduction he has written to the volume, "few men are in a position to write with confidence and authority on the progress and treatment of gunshot injuries from the time of reception of the wound to the period of actual recovery and cure." Yet the picture can be reconstructed, and the important intermediate stage, comprising the patient's time in the base hospital in France, is well covered by this book. Here, to quote again from the introduction, "came not only the successes of the clearing station line, but also some of the failures"; and few who have not had experience of this type of work realize what a tax they made on the resources and surgical judgement of the base hospital staffs.

Had the book appeared at the time the editors intended—the autumn of 1918—it would undoubtedly have had a wide popularity. All the sections are ably dealt with;

¹ *A Manual of War Surgery*. By Colonel Seymour Barling, A.M.S., and Major J. T. Morrison, O.B.E., M.B., F.R.C.S. With an introduction by Major-General Sir George H. Makins, G.C.M.G., C.B., P.R.C.S. London: Henry Frowde, and Hodder and Stoughton. 1919. (Demy 8vo, pp. xvi + 479; 149 figures. 2s. net.)

they are the work, in the main, of young men, and are all the better for that. The section on general wound treatment by J. T. Morrison is excellent, and his conclusions as to the relative value of the various methods of treatment of infected wounds will be endorsed by the majority. He gives some interesting charts and tables of the results of the various methods. A. J. Hutton's section on injuries of the head and spine bears deeply the imprint of Harvey Cushing—as it should. The brief chapter on spinal injuries shows up baldly the poverty of the work that was attempted on these important lesions. This remark casts no aspersions on those who did contribute to the subject, but when one thinks of the monographs and papers which might have been written but were not, it is a sad business. These cases should have been segregated and studied intensively in France on a far larger scale.

It is impossible adequately to outline the scope and value of the various sections. Forbes Fraser's account of the wounds of joints, Barling and Sevestre on wounds of the chest, Burrow's article on tetanus, Hartley and Shore on wounds of bones, are all good; H. C. Bazett writes a synopsis on shock which is much too short.

We can recommend this book to our readers, for whilst no observer of startling brilliance is revealed, it is very sound, and a very fair and reasonable exposition of the type of surgery which it sets out to describe.

MODERN UROLOGY.

THE claims of urology to rank as a specialty have been more fully recognized in America than in England. The treatise in two volumes on *Modern Urology*,² under the editorship of Dr. HUGH CABOT, is the outcome of this recognition. It is a composite work to which the most eminent of America's urologists have contributed. Although a similar treatise was compiled in the past by Dr. Prince Morrow, it was not written by genito-urinary surgeons, but by general surgeons interested in genito-urinary work. Cabot's book is therefore the first articulate expression of the school of American urology, and as such is a publication of considerable importance.

The task of reviewing a composite work to which many different writers have contributed is in some respects difficult, for although the clinical ability of all of the contributors to the volume be beyond question their success as writers varies. This is a weakness inherent in all such composite works. It is, however, a fault that is not conspicuous in the volume before us. Moreover, the advantages that are derived from the fact that each section has been written by an expert on that particular subject outweigh all other considerations. *Modern Urology* is primarily a book of reference. It is a work to which the genito-urinary surgeon rather than the student will turn. The bibliography scattered throughout its pages will be of great value to him, for it has the merit of being remarkably complete. Completeness is, indeed, the word which best describes the work as a whole. Although America now possesses a school of urology of her own, the American compilers of this book cannot be accused of neglecting work done elsewhere. It should be as well received in Europe as in America.

The book is clearly written and the arrangement good. It is well illustrated and contains a sprinkling of coloured plates. The editor has wisely limited it to urology pure and simple, and has only dealt with syphilis in so far as it affects the genito-urinary system.

THE MAKING OF NECROPSIES.

WE are glad to note the appearance of a second edition of Dr. Box's *Post-mortem Manual*.³ It is intended as a guide to students and practitioners in the performance of *post-mortem* examinations, and within its small compass is information enough to convert the tiro into a skilled morbid anatomist. To the more experienced it presents a systematic and practical epitome of the subject. After

² *Modern Urology*. Edited by Hugh Cabot, M.D., F.A.C.S., Chief of the Genito-Urinary Department of the Massachusetts General Hospital. Two volumes. Philadelphia and New York: Lea and Febiger, 1918. (Roy. 8vo.; Vol. I, pp. 749, 368 figures, 7 plates; Vol. II, pp. 708, 261 figures, 10 plates. 14.00 dollars.)

³ *Post-mortem Manual*. A Handbook of Morbid Anatomy and Post-mortem Technique. By Charles R. Box, M.D., B.S., J.Sc.Lond., F.R.C.P.Lond., F.R.C.S.Eng. Second edition. London: J. and A. Churchill, 1919. (Cr. 8vo., pp. xi + 372; 22 figures. 8s. 6d. net.)

some preliminary remarks on instruments and appliances, in which no necessary instrument is omitted and nothing superfluous added, the author proceeds to a minute examination of the external appearances of the body. This is followed by instructions for the removal of the viscera with indications of the morbid conditions which must be looked for while doing so. Each organ is studied in turn and the pathological appearances are carefully described. The whole body is dealt with in this manner. Morbid histology and bacteriology are outside the scope of the volume, nevertheless useful instructions are given for the collection of material for such investigations. The chapter on *post-mortem* examination of the newly born will prove of the greatest assistance to the practitioner confronted with the necessity of ascertaining the cause of death in an infant, especially where access to larger medico-legal works cannot be had. An excellent summary of the causes of sudden death is also given. A section on embalming and on the restitution of the body completes the volume. The work is marked throughout by thoroughness and attention to practical details. Omissions are hard to find. Indeed, only two examples occur to us. We can find no mention of tuberculous ulcers in the colon, although they are described in the small intestine and caecum; and, under syphilis of the spleen, there is no reference to the splenomegaly which is sometimes present in the tertiary stage of the disease. In matters of technique we think it a pity that the author has followed the common practice of dividing the skin just below the symphysis mentis. With a little care it is quite easy in most cases to remove the tongue and fauces without going higher than the upper border of the thyroid. The deceased's friends can then view the clothed body with no risk that they will be offended by the site of an incision. These are minor points, however, and do not detract from the value of the book. Excellent diagrams and illustrations are given throughout the text. The volume may be thoroughly recommended.

PSYCHOLOGY AND MENTAL DEFICIENCY.

DR. GODDARD, the author of *Psychology of the Normal and Subnormal*,⁴ is especially interested in the subject of the feeble-minded, and he is well known as the writer of *The Kallikak Family*, an interesting study in heredity. The present volume is concerned with psychology in its relation to mental deficiency, and though it is written on popular lines it will be found of interest and value to the medical as well as to the lay reader interested in the care and treatment of the feeble minded. The book is written in a clear and simple style, and in dealing with psychology the writer always keeps in the foreground the practical applications of his subject. Emphasis is throughout laid on the psycho-physical standpoint in describing mental states. There is a certain cheerfulness and vigour about the book which will be found stimulating by those who are working in a sphere which is often difficult and discouraging. This may be indicated by the concluding sentences, which aptly sum up the question of discipline in relation to the feeble-minded: "Treat them as children according to their mental age, constantly encourage and praise, never discourage or scold, and *keep them happy*." In concluding this notice we must confess that, even with the best will in the world, we cannot read such spelling as "thot" for thought without some degree of discomfort; nevertheless this book may be thoroughly recommended to those for whom it is intended.

THE NUTRITION OF THE FOETUS.

WE are pleased to see that Dr. MORRIS SLEMONS has published as a little book the oration which he delivered to the Ontario Medical Association last May upon *The Nutrition of the Foetus*.⁵ A brief abstract of his lecture appeared in our Epitome of Current Literature last autumn, but his work deserves the fullest publicity. The subject is one of very real importance, and of interest not

⁴ *Psychology of the Normal and Subnormal*. By Henry Herbert Goddard, A.M., Ph.D., Director Ohio Bureau of Juvenile Research. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1919. (Demy 8vo., pp. xxiv + 349; 18 figures. 25s. net.)

⁵ *The Nutrition of the Foetus*. By J. Morris Slemons, M.D. New Haven: Yale University Press. London: Humphry Milford. 1919. (Cr. 8vo., pp. 49. 3s. 6d. net.)

only to the medical profession, but also to all those who, either in an official or in a philanthropic capacity, are connected with the welfare of the future generations.

In view of the abstract mentioned it is unnecessary here to discuss Dr. Slemmons's investigations or conclusions, but it is a pleasure to pay a tribute to the simplicity of his writing, which makes his book agreeable to read, and renders a complex subject as clear as crystal. Dr. Slemmons's work is the most important contribution to our knowledge of the physiology of the placenta that has appeared for some time, and we earnestly commend it to the attention of the many who are or ought to be interested.

CONSERVANCY IN INDIA.

A Manual of Conservancy,⁶ by JAHAR LAL DAS, of Calcutta University, is addressed to those in India who are training to become sanitary officers, and for this purpose it is most excellent. The fact that the book is written by an Indian worker is of the first importance, and amply justifies Dr. BENTLEY's able introduction, in which he reminds us that our own country was in a bad state from a sanitary point of view only a few decades ago. Dr. Bentley further likens the movement of the Indian people towards improved methods of living to a similar period in our own development.

The author divides his book into four parts. The first deals with scavenging, the second with conservancy proper, and the third with the management of cattle; the fourth part contains a number of appendices. The local hints are invaluable, and the description found in Part III of a good bull is entertaining and possibly reminiscent.

Unfortunately the illustrations are poor, and should further editions be called for the author will do well to replace the present collection.

NURSES' TEXTBOOK OF OPERATIONS.

MR. HEY GROVES is to be congratulated upon his *Surgical Operations: A Textbook for Nurses*.⁷ In it we have a book worthy of the nursing profession, a book which credits nurses with intelligence and will satisfy their usually insatiable curiosity. With the generous help of the publishers of the Oxford Medical Publications, of which excellent series this book is one, the author has rendered nurses a real service. The volume is a pleasant size to handle, clearly printed, and extremely well illustrated with large sized figures. The operations described are systematically arranged, and are typical of those performed daily in general hospitals. Operations on the head, neck, breast, thorax, abdomen, and pelvis, as well as amputations, are adequately described. The eye, ear, and nose receive brief attention, the operations for removal of cataract, nasal polyp, tonsils, and adenoids are described as well as the typical mastoid operation and those on the nostril of Highmore and nasal septum. Each section is followed by a note upon the special post-operative care required in each instance. Obviously, in a work of this size, a work which requires above all to be freely illustrated, it is not possible to describe a variety of operations for individual diseases. Thus the "gridiron" incision alone is described for appendicitis, Witzel and Frank's gastrostomies are given preference to Senn's, and so forth. There is a serious omission in the "typical laparotomy set" on p. 16. No mention is there made of intestinal clamps. In this same appendix to Chapter I xylol is referred to as an oil. Further, in the section on "Methods of Sterilization," with reference to the preparation of the hands for operations, there is no mention of the arms. Sleeves are omitted from the routine operation dress, although leggings are included. Those worried by split infinitives will have their sensibilities wounded in this first chapter. Such slips as those mentioned are easily remedied, and in no way detract from the general merits of the book. At the end will be found a most helpful appendix of thirty-six pages where all the ordinary instruments are separately figured and named. There is a satisfactory index.

⁶ *A Manual of Conservancy*. By J. L. Das, L.M.S.Cal. Univ. London and India: Butterworth and Co. 1919. (Demy 8vo, pp. xix+189; 44 figures. Rs.5/10.)

⁷ *Surgical Operations: A Textbook for Nurses*. By E. W. Hey Groves, M.D., B.Sc., M.S., F.R.C.S. London: Henry Frowde, and Hodder and Stoughton. 1919. (Roy. 3vo, pp. viii+255; 191 figs. 2s. net.)

NOTES ON BOOKS.

THE ninth edition of Professor CHURCH and Dr. PETERSON'S *Nervous and Mental Diseases*⁸ appears only twenty years after the first; it is designed for medical students and general practitioners, is written in a simple and straightforward style, and is not overweighted with novelties of theory or the fancies of the Vienna school. The first section by Professor Church deals with nervous disorders and covers over 680 pages; each disease is described with clearness and on the lines commonly followed by writers on neurology. The second section contains an account of mental diseases by Dr. Peterson, and gives an excellent description of the subject, practical and sensible. The book is well printed and turned out.

Lieut.-Colonel O'MEARA'S *Medical Guide for India and Book of Prescriptions*⁹ contains a great deal of assorted information on all the many questions that may arise in the daily work of practitioners and medical students in India. The first three hundred pages are given to drugs, prescriptions, and special methods of employing certain remedies: a few pages are devoted to the use of indigenous drugs such as those employed in the Yunani and Ayurvedic methods of treatment, that are said by the author sometimes to be of great use in the hands of Indian physicians. He gives, indeed, an indigenous prescription for impotence that demands the boiling of equal parts of earthworms and half a dozen presumably vegetable drugs in sweet oil, the resultant extract being for local application. The rest of the volume contains a great deal of heterogeneous but serviceable information; foods and feeding, antiseptics, blood pressure, anaphylaxis, pelvic measurements, drug eruptions, microscopic stains, insects, vaccination, lists of asylums, laboratories, vaccine depôts, and medical colleges, and fifty others of the things a medical man may want to know about suddenly will here be found set forth. Regarded as the practitioner's "Where's What" it should be of service to medical practitioners in India.

The fact that HARDWICKE'S *Sight Testing made Easy*¹⁰ has reached its fourth edition shows that it meets a demand. The groundwork of the book is subjective testing, and we find in consequence much about the astigmatic fan, the pinhole, and the slit; students nowadays begin their work in the eye department with retinoscopy, and it might be no bad practice for them occasionally to revert to the older methods. Some of the statements in the book are too sweeping; for instance, it is not correct to say that glaucoma is hardly ever met with in the myope, for quite a definite proportion of the cases of glaucoma seen occur in myopes. One or two misprints need correcting, such as "axles" for "axes" on p. 33; while in the first formula on p. 56 the cylinder has been printed *plus* instead of *minus*; the sentence on p. 47 about the liability of a cycloplegic to glaucoma should be rewritten.

Oscar Montague, Paranoiac,¹¹ by Dr. G. L. WALTON, is a somewhat disappointing attempt to depict in a novel the development of a morbid temperament. The story, which only succeeds in being interesting at intervals, is concerned with the troubles of a family consisting of an alcoholic and scheming father, a psychasthenic mother, Oscar the paranoiac son, and the daughter. We thoroughly sympathize with the dilemma of this bright young lady in regard to the question of heredity when she falls in love, and we are glad that Dr. Reynolds, whom she consulted, gave her such sensible advice. Singularly enough, in view of the title, Oscar is only a secondary character, and it is the trouble he causes others, rather than the study of his mental development, that furnishes most of the material for the story. Many of the characters are unimportant, but the personality of the doctor is attractive; and from the advice he gives to his patients we suspect him of being able to write excellent popular medical books for nervous invalids of the same kind as "Why Worry" and "Those Nerves." Dr. Walton has already earned a reputation as the author of these books, but this novel suggests that he is not equally at home in the domain of fiction.

⁸ *Nervous and Mental Diseases*. By Archibald Church, M.D., and Frederick Peterson, M.D. Ninth edition, thoroughly revised. Philadelphia and London: W. B. Saunders Co. 1919. (Roy. 8vo, pp. 949; 350 figures. 30s. net.)

⁹ *Medical Guide for India and Book of Prescriptions*. By Lieut.-Colonel E. J. O'Meara, O.B.E., F.R.C.S. Eng., D.P.H. Camb., Civil Surgeon and Principal of the Medical School, Agra. Calcutta: Butterworth and Co. (India), Ltd. London: Butterworth and Co. 1920. (Demy 8vo, pp. vii+717. Rs. 12 net.)

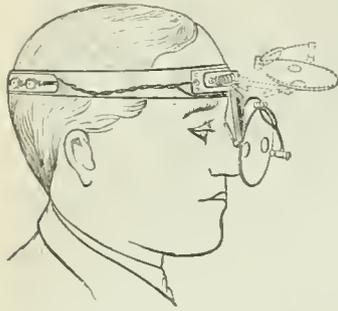

¹⁰ *Sight Testing made Easy*. By W. Wright Hardwicke, M.D. Fourth edition. London: J. and A. Churchill. 1920. (Cr. 8vo, pp. viii+79; 12 figures. 5s. net.)

¹¹ *Oscar Montague, Paranoiac*. By George Lincoln Walton. Philadelphia and London: J. B. Lippincott Co. 1919. (Post 8vo, pp. 304; frontispiece. 6s. net.)

APPLIANCES AND PREPARATIONS.

A Head Lamp.

MR. GILBERT CHUBB, F.R.C.S. Eng., Assistant Surgeon Throat Hospital, Golden Square, has devised a head lamp on the well known Klar principle, but with a reflector of speculum metal, so that it cannot break, and of sufficiently small size to allow of very useful peripheral vision when in place. The eyeholes are very large and placed on the converging lines for near binocular vision. The reflector is attached to a rigid headband by an arm with an adjustable hinge at either end, permitting of movement only in the sagittal

plane. The lamp can thus be adjusted before washing up, and then brought down into place, or pushed away from the face, with a mop. An automatic switch cuts off the current when the reflector is out of use, thus enabling it to be used off a pocket battery without waste. The front part of the head-band is sloped back through 15 degrees, so that it lies flat on the forehead, and permits of the lamp being worn for long periods without discomfort. Mr. Chubb has found the lamp useful not only for ear, nose, and throat work, but also for many operations in general surgery where the general illumination available was insufficient. The lamp is made by Messrs. Mayer and Phelps.

A Tonsil Bayonet.

Mr. A. SCOTT GILLET, F.R.C.S. Edin. (London, W.), writes: In opening peritonsillar abscesses it is usual to employ either a small scalpel guarded with strapping, or unguarded forceps. When employing the former method it is difficult to sterilize the strapping; in the latter it is

easy to go too far in searching for deep pus. With the idea of overcoming these two disadvantages Messrs. Allen and Hanburys have made for me the instrument here figured. The following advantages are claimed: (1) Ease of sterilization; (2) the presence of a collar, which prevents the operator stabbing too deeply; (3) the double-edged bayonet which facilitates the conversion of the stab into an incision in either an upward or downward direction. The operation can then be completed with blunt forceps quite safely. Messrs. Allen and Hanburys are the makers of the instrument.

Anti-Vermin Paste.

We have received from Captain C. G. MOOR, R.A.M.C.T., of the 1st London Sanitary Company, a sample of the anti-vermin paste which he devised in France towards the close of the war. Captain Moor is part author of an excellent little handbook on *Field Sanitation*, reviewed in our issue of February 9th, 1918, p. 177. His preparation was tested privately among their men by various medical officers, who reported very favourably on its effect both in destroying lice and preventing their approach. The novelty of this preparation lies in the fact that the active ingredient, naphthaline, is combined with the ointment, so that the user is constantly clothed in the vapour of naphthaline. In theory, at least, the British army is now free from body vermin, but in the terrible conditions of Eastern Europe louse-borne diseases (typhus and relapsing fever in particular) are rife, and there is therefore still a large field for anti-vermin measures. This paste is manufactured commercially by the Sanitas Company, Ltd., Locksley Street, Limehouse, E. It is sold in tins at 9d.

THE Faculty of Medicine of Liège University has arranged a vacation course in various branches of medicine, surgery, and obstetrics, from March 29th to April 10th.

THE activities of the Italian Section of the International Association "Pneumothorax artificialis," suspended during the war, have been resumed. It is now inviting the enrolment of new members, who should communicate with Professor U. Carpi of Lugano. The Association proposes to revive the international review, *Pneumothorax Therapeutique*, which, under the direction of Carlo Fortunini, contained a collection of the world's literature on artificial pneumothorax.

THE MENTALLY DEFECTIVE AND THE
UNSTABLE BROUGHT BEFORE
THE COURTS:

THE BIRMINGHAM SCHEME.*

BY

W. A. POTTS, M.A., M.D.,

MEDICAL OFFICER TO THE BIRMINGHAM COMMITTEE FOR THE CARE
OF THE MENTALLY DEFECTIVE; PSYCHOLOGICAL EXPERT TO
THE BIRMINGHAM JUSTICES.

In considering this problem it is necessary to mention two outstanding facts of criminology. The first is that in England it was found recently that out of 168,260 convictions, 104,171, or 62 per cent., of the persons convicted had received at least one previous conviction, while 12,133, or over 7 per cent., had been convicted about twenty times previously; of the 11,000 odd convictions for more serious offences tried at the assizes and quarter sessions, 70 per cent. had been previously convicted. The other fundamental fact is that "practically all confirmed criminals begin their careers in childhood or early life." The late Dr. Goring proved that between 15 and 20 is the age for recruiting into the criminal classes.

These facts show that prison is not a remedy for this social disease. It can scarcely be expected that imprisonment would do much good, because, at the best, prison means discipline without training, and takes no account of the initial cause of wrong-doing. If by chance the cause is discovered, no steps are taken as a rule to deal with it; for justice, as we call it, can only deal with the offence for which the prisoner is charged, and therefore does not punish him for his initial fault, which is frequently something quite different from the charge the court is considering. For instance, women who are charged with petty thefts are often inebriates; to punish them for stealing does no good; in fact, it makes them worse. Dealing with them satisfactorily as inebriates would cure their drinking habits, and their thieving propensities would then right themselves. Some people steal because they are lazy and play truant from work, but stealing is not the fundamental fault. Punishment for stealing, therefore, only makes them more degenerate, especially as it develops an anti-social grudge. Dealing with the laziness by medical treatment, if it is due to constitutional disease or weakness, or by a labour colony and training in high ideals if it is a moral weakness, might effect some good. Frequently lying is the fundamental cause of going wrong, and is the fault that should be punished, or rather dealt with.

The investigations of the Royal Commission on the Care and Control of the Feeble-minded, and many other investigations, have shown that a considerable proportion of prisoners—a percentage varying from 10 to 30—are mentally defective, and should be dealt with as such, and not as criminals. Careful examination will show that physical illness and incapacity are the cause in another large percentage of cases. In addition to this there are, as frequent causes, wrong occupations, want of training for any occupation, bad homes, and alcoholism. It might be objected that alcoholism has no place in the production of criminals, as most are developed at 16 or 18 years of age; hereditary weakness, however, is often seen in children of alcoholic parents, while bad homes are more often due to drink than any other single cause. Venereal disease is important. Sometimes it poisons the mentality, and is a cause of crime, or at least a contributory factor. Whether it is the cause of crime or not, many prisoners will be found to be infected; their disease should be treated. This is not always done, sometimes because the disease is not diagnosed, but more often because the term in prison is too short for effective treatment. Often the presence of such disease untreated is only another sign of mental defect. The National Council for Combating Venereal Disease finds mental defectives one of its great difficulties; such persons often spread disease broadcast. In them untreated venereal disease should be accepted as a proof of "neglect," thereby bringing them under the Mental Deficiency Act (1913). There would seem to be no reason

* Being a paper read at a Conference on the Administration of the Mental Deficiency Act, 1913, in the Church House, Westminster, in November, 1919.

why this should not be done, but it would be well to amend the Act to this effect.

Some of the disabilities I have described are dealt with by the Borstal system, the Probation of Offenders Act, and the Children's Court, but all these will fail time after time if there is no scientific investigation into the real cause of the crime. This has been recognized for several years by the Birmingham justices, who have realized that many mental defectives must have passed unnoticed through the courts. More recently these justices became concerned at the prospect of the discharge of a number of soldiers suffering from shell shock, and the probable effect of alcohol on them and other weaklings when released from the strict discipline of the army. The Birmingham justices decided to initiate a scheme which will probably be taken as a model for the administration of justice all over the country.

The essential feature of the Birmingham scheme is that every prisoner in whose case there is any possibility of such an explanation of the crime as I have suggested, or who in any other way is unlikely to be benefited by imprisonment or fine, should be examined by an expert medical investigator, either before or after conviction, but in any case before sentence is passed. The report of this investigator is taken into consideration before sentence. In a number of cases the prisoner is placed on probation and the treatment suggested by the medical investigator made a condition of the probation. The Probation of Offenders Act has given great power to the justices; if wisely used in this way, great benefit will follow. Many cases are found to be mentally defective; this was so with three out of the first sixteen dealt with, although the Mental Deficiency Act was already being energetically administered in Birmingham; such cases are handed over to the Committee for the Care of the Mentally Defective, which usually deals with them by placing them in a suitable institution. It has been realized that without additional legislation, but merely by making proper use of the Mental Deficiency Act, much good can be accomplished. An important part of the scheme is the provision of a staff of wise and sympathetic probation officers; much depends on them.

It is not possible to find the real cause by any investigation in court. One often hears magistrates asking a prisoner what is the reason of his going wrong; in a public court it is very unlikely that the prisoner will state what is the cause even if he realizes it himself. In the majority of cases the cause can only be elicited after long and careful examination and a private interview. The springs of conduct are in the subconscious mind, and therefore often unsuspected by the individual himself; their discovery requires experience in mental analysis. Psychotherapy is often an important agent in effecting a cure. If only a proper investigation were carried out, the scandal would be avoided of the extraordinary police court notices to be seen in the paper every week, such as the statement that a boy of 9 was a confirmed criminal, and should be treated as such. Anyone who has studied the subject must know that the boy was either a moral defective to be dealt with under the Mental Deficiency Act, or else had never had a chance, and that if anyone required punishment it was not the boy but his parents. Recently the chairman of one bench said a girl of 16 "was well on the downward path, and the best place for her was prison." This was said after the probation officer had stated that "the girl had been in three homes, and had made a farce of probation arrangements." I cannot help thinking it might have been more correct to say that the court had made a farce of examining the girl, the probation arrangements having been made without any scientific investigation of the girl and her circumstances.

To make their scheme more effective the Birmingham justices induced the Home Office to appoint at the prison, instead of a part-time, a whole-time medical officer with a special knowledge of insanity and mental defect. This ensures cases overlooked before going to prison being recognized while under treatment. The justices have arranged as a matter of practical working that their medical officer shall be responsible for the examination and treatment of all cases outside the prison, while the prison medical officer shall be responsible for all those inside the prison, and that those two officers shall, whenever possible, work together, each calling in the other if he wishes the help of a colleague in coming to a decision. Everything I have described so far

has been arranged and carried out in Birmingham without any additional legislation. The Birmingham justices are by no means satisfied even with this great improvement, but have extended their scheme so that a portion of the prison infirmary will be converted into a mental hospital, where special cases can be treated on the recommendation of either of the medical men engaged in this work. The prison medical officer is responsible for the treatment of all cases inside this hospital, but the medical adviser to the justices will have the right of entry and making suggestions in regard to all cases in which he is interested. This hospital will be outside the prison wall, and the stigma of prison will be eliminated. This scheme is on the right lines. As a medical man engaged in this work I may say that the only difficulty I have had so far is that some magistrates do not seem to realize in what a large percentage of cases special medical examination is desirable, if not absolutely necessary. So far no case has ever been put before me in which the proceedings can be regarded in any way as a waste of time. There is no doubt that it will turn out to be, in the long run, one of the most economical proceedings ever devised. If the enormous cost to the community be realized of one lifelong criminal and the degenerate descendants he or she may have in a few generations, it will be recognized that the expenditure of a pound or two at the outset may save the country thousands of pounds in the end.

The most important question is how magistrates are to recognize prisoners who ought to be referred for special examination. The cases that most urgently require dealing with in this way are those not understood and cases where the crime is of an unusual nature. There are many mental defectives in addition to those who are obviously mentally defective. A girl or young woman may be feeble-minded, although she smiles pleasantly and answers ordinary questions in an ordinary way. Sometimes mental defect is exhibited by lack of attention and interest in the proceedings in court. It is often shown by frequent change of situation and inability to earn a living wage for any length of time. Placing obstructions on a railway and incendiarism when there is nothing to gain from insurance always suggest the possibility of mental defect, and so should gross sexual offences. The physical conditions that should be referred for examination include all those that look ill. Serious defects of vision and speech are often precursors of crime, and so are severe headaches, which always require investigation. Puzzling cases, where there is no obvious reason for the crime, should be referred; in many of them surprisingly good results can be obtained if the prisoner is approached in the right way, thoroughly examined, and properly treated. By modern methods of investigation we can see the inner workings of the mind. Mental analysis and psychotherapy have untold possibilities in many cases. Much can be accomplished by probation continued for a sufficient length of time under proper conditions.

In Birmingham we have been administering the Mental Deficiency Act (1913) for over five years. Out of the first 16 cases specially examined for the justices, 6, or 37 per cent., were not responsible; 3, or 18 per cent., were not fully responsible; one was a doubtful case, and the remaining 6, or 37 per cent., although responsible, were entitled to special consideration owing to circumstances connected with their health, homes, occupations, or lack of training in anything good. Yet almost everywhere except in Birmingham, these cases are still dealt with in the ordinary way. One young man convicted of stealing was found to be suffering from consumption which was poisoning his mentality; instead of being sent to prison he was, through the assistance of the medical officer of health, placed in a sanatorium. At the end of three months he was able to go home again, and was fortunate enough to obtain light work instead of the laborious and injurious occupation in which he had previously been engaged. He has now been at home several months, working well, and his conduct has been satisfactory in every way. Of the cases dealt with so far more than 18 per cent. have been found to be mentally defective, and have been dealt with under the Mental Deficiency Act, while over 12 per cent. have been of unsound mind and therefore equally irresponsible. Treatment under the Mental Deficiency Act involves considerable expense at first, but this is nothing compared with the amount incurred in keeping up large numbers of prisons, refuge homes, maternity homes, infirmaries, etc.

One man who came before the court was found to be suffering from shell shock, and was taken in charge by the military authorities, who placed him in a suitable hospital for treatment. Several other cases have been dealt with in a common-sense manner.

In order that a scheme such as that followed in Birmingham may be successful, it is essential to have an investigator who has some knowledge of mental defect, insanity, and psychotherapy. Above all he must be interested in the early signs of mental disease and not one who says there is no proof of mental disease till murder, suicide, or some other serious crime has been committed.

To show that the Birmingham scheme by no means encourages malingering or fails to set a proper example, I may cite the following case:

A young girl in regard to whom I reported to the magistrates that she was in poor physical health, and was also mentally dull and backward, although not actually mentally defective. In consequence of this disability she was entitled to all the consideration the court could give her. At the same time I stated that she was a member of a big family, and lived in a bad neighbourhood in the centre of the town; also, that one member of the family had already got into trouble. It seemed unlikely, therefore, that probation would be a suitable way of dealing with the case. The offence of stealing was a serious one, and had taken place in a large and important institution, where it was necessary to set an example. The magistrates devoted a great deal of time and consideration to the case, and asked me whether it would be more beneficial to the girl's physical and mental health to have the strict discipline and training of a special institution or to go home and live more or less undisciplined in the centre of a town. My opinion was that an institution would act better in her interest, especially as, having been dismissed from her employment, it was essential that she should be trained for some new occupation. In these circumstances the magistrates sent her for three years to a reformatory school.

The number of cases dealt with up to the present time is so small that I cannot give all the statistics and confirmation of the wisdom of the scheme I should like, but I feel justified in saying that every single case has been an object lesson in the value and necessity of work on these lines.

RETAIL PRICES OF DRUGS.

THE Standing Committee for the Investigation of Prices under the Profiteering Act, 1919, appointed a subcommittee some time ago to investigate prices, costs, and profits, at all stages, of drugs and medicinal tablets and preparations, proprietary and otherwise. The subcommittee, of which Dr. C. O. Hawthorne is the medical member, has recently presented an interim report,* in which it describes the system of production and distribution under which at the present day drugs and medicinal preparations are provided and supplied for the public use.

Wholesale and Retail Druggists.

From evidence taken by the subcommittee it appeared that drugs and medicinal preparations are in Great Britain mainly distributed by some 10,000 retail pharmacists; in addition, some of the stores in many large towns include a retail pharmacy in their organization. There are altogether 20,000 persons other than pharmacists licensed to sell "patent" medicines. Some manufacturers sell only or mainly to wholesale druggists, others also sell direct to retail pharmacists; there are also wholesale druggists who own retail shops. The business of a retail pharmacist, it is said, is in certain respects exceptional; the turnover, for instance, both in gross and in detail, is of very small monetary value and the business stock very varied in character. The subcommittee considers, therefore, that such a business cannot be treated, as regards rate of profit, on the same trade basis as businesses with a large turnover confined to comparatively few articles.

The methods of business adopted by the manufacturing firms are found to be different; some of them spend large sums in advertising; the public demand thus created compels the pharmacist to stock the articles, even though the percentage of profit allowed on them is small. Some firms spend little in propaganda, but indicate to the public selling prices which allow a relatively large percentage of profit to the retailers, and in return expect to be rewarded by a relatively large amount of preferential pushing of their products by the retailers. Other firms, still in an early stage, not only spend large sums on propaganda, with

a view to securing a public demand for them, but also fix a selling price to the public which allows both wholesaler and retailer a comparatively large profit.

A Proprietary Articles Trade Association was formed in 1896, with the object of protecting the small retail pharmacist against price-cutting by the stores and others. This association now consists of three sections—proprietors, wholesale distributors, and retail distributors. Some 310 firms owning proprietary articles are members. It is governed by a council consisting of 36 members, equally divided between manufacturers, wholesalers, and retailers. It exercises control over the price of practically 3,000 proprietary articles sold by 310 manufacturing or owning firms and retailed by 20,000 or 30,000 retailers. It determines a fair rate of profit, which is usually (in terms of selling price) 12½ per cent. to the wholesaler and 25 per cent. to the retailer. Price-cutting is avoided by an agreement that any person selling any article on this association's list at a price lower than that fixed by it may be refused a supply of all articles included in the list. Without such a protective arrangement, it is said, the profit on many of the articles would probably be so small that the retailer would be disinclined to deal in them.

Aspirin (Acetylsalicylic Acid).

The subcommittee gave attention first to the cost of manufacturing and the selling price of aspirin and aspirin tablets. "Aspirin" is one of several trade names for acetylsalicylic acid, and before the war the name was the exclusive property of the Bayer Company, of Elberfeld, Germany, and could be applied only to the acetylsalicylic acid manufactured by that firm. After the outbreak of war certain British manufacturers began experiments, and during 1915 and 1916 several of them succeeded in manufacturing acetylsalicylic acid on a commercial scale. The German trade-mark having lapsed, British-made acetylsalicylic acid was placed on the market under various names, of which "aspirin" is the best known, and the subcommittee uses this term as the synonym for acetylsalicylic acid under whatever name it is sold. It is suggested that at the first opportunity the term should be included in the *British Pharmacopoeia* as a synonym for acetylsalicylic acid which is already included. At present there is no official or pharmacopoeial definition of aspirin. Before the war the price of acetylsalicylic acid in bulk was about 2s. a lb., but the price of the Bayer aspirin was about 18s. a lb., less various discounts. After the outbreak of war the price of what was then being sold variously as aspirin or acetylsalicylic acid began to rise until in 1916 the price exceeded 40s. a lb. It afterwards declined until during 1919 the price in bulk ranged from 3s. 10d. to 4s. 6d. a lb.

One pound of aspirin represents approximately 1,400 tablets of 5 grains each. In 1914 a bottle containing 25 such tablets made of Bayer aspirin was sold retail at from 10d. to 1s. 3d., if containing tablets of acetylsalicylic acid at prices from 4½d. to 9d. In 1919 the retail price of a bottle containing 25 such tablets of acetylsalicylic acid, sold as aspirin, or under some similar name, varied from 5½d. to 1s. or thereabouts. The Government laboratory has ascertained that there is no substantial difference, either physical or chemical, between some seven aspirin tablets now on sale to the public, and that certain of the less expensive tablets are in no way inferior to their more expensive rivals.

The subcommittee concludes that under present conditions aspirin tablets made from acetylsalicylic acid answering the tests of the *British Pharmacopoeia* can, when working with large quantities, be manufactured and sold by the manufacturer with a reasonable profit at 5s. 6d. a dozen screw-capped bottles of 25 five-grain tablets in each bottle. It is stated that such bottles can at present be purchased by the public at certain shops at about 6d. each, a price which leaves a very narrow margin of profit to the retail pharmacist. The subcommittee finds, on the other hand, that the retail price of 1s. and upwards for 25 tablets, at which certain brands of aspirin are sold, is excessive in relation to the cost and manufacture, even when allowance is made for charges incurred in advertising and other methods of publicity. It is, however, of opinion that the present range of prices, when allowance is made for increased cost of labour, packing materials, etc., is not appreciably

*Cmd. 633. Price 1d.

different from that prevailing before the war. The opinion is expressed that when aspirin is sold at 10d. a bottle of 25 five-grain tablets the price, if properly apportioned, should give reasonable profit to the manufacturer, the wholesaler, and the retailer. The question of the possible promotion of a habit of self-drugging as the result of the cheapening of the price of aspirin was raised by one of the witnesses, but was not considered to come within the reference to the subcommittee. It is noted, however, that while on some packages the labels imply that the tablets should be taken only under medical direction, there are others on which no such limitation is mentioned, and it is even suggested that as many as twelve five-grain tablets may be taken daily and apparently for an unlimited period. It is pointed out that aspirin is sold by others than retail pharmacists and that the purchaser is free to obtain whatever quantity he desires.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE FRIENDLY SOCIETY.

THE thirty-seventh annual general meeting of the Society was held at 11, Chandos Street, W., on March 26th.

Dr. F. J. ALLAN, chairman of the Executive Committee, who was in the chair, said that during the past year the society had begun to get some of the business which, through the absence of many men at the front and the decline in the number qualifying, had fallen off during the war years. The number of new proposals was 305 as against 84 in the previous year, and in the current year up to the present time more than half the number received in 1919 had been received. During the past year 25 women practitioners had been admitted; it had been stipulated that if the rates charged for them proved inadequate they would have to be revised. After taking account of the deaths and resignations, the actual number of members on the society's books at the end of 1919 was 3,351. The society had disbursed in sickness and accident benefits £19,000 in 1919, as against £20,000 in the previous year. The sickness and accident funds had increased with the increased premiums, and the sickness claims were considerably below the expectation. Notwithstanding the fact that all the lives insured were practically picked lives, 25 per cent. of the total number of members claimed benefits during the year. There were 99 members on the list and the annuity fund. The life insurance fund continued to grow slowly, but the limitation of the amount of insurance to £300 did not afford much scope. The investments now yielded £4 13s. per cent. as against £4 8s. The society had suffered a great loss in the death of Dr. Caley, a very attentive member of the committee, who had greatly assisted in its deliberations. Dr. Biggs, who was retiring from public work, had resigned his membership. The management expenses of the society were going up, since practically everything cost more, and higher salaries had been given to the staff in view of the increased cost of living.

In reply to inquiries, the CHAIRMAN said that the 25 per cent. of sickness experience included twenty-two cases which were on the fund for the whole year. Excluding these cases, the average duration of illness was five weeks and one day. In 1912 it was four weeks and four days, but that probably included those who were on for the whole year; the comparison was therefore with seven weeks in the past year; in 1913 it was five weeks.

The report was adopted, and the Executive Committee and the auditor were appointed.

The meeting then resolved itself into an extraordinary general meeting.

Dr. ALLAN said that the matter of the conversion of the society into a mutual company had been considered by the committee for many years, and had been discussed at a general meeting. The society continually received complaints from members that they were unable to insure for larger amounts than those allowed under the Friendly Society Acts. The limitation was considered to be the reason why the society only had a little over 3,000 members. The fact must be faced that if the society became a mutual company an increased amount would have to be paid in income tax. The committee, however, had come to the conclusion that the increase in business that would ensue would amply cover any expenditure on

that score. It was anticipated that increase in the insurances would not cause any material increase in the clerical work, since it would be as easy to prepare a policy for £1,000 as for £300. Proposals for larger insurances were waiting to be carried through if it was decided to dissolve the present society and establish a mutual company. He formally moved the following resolution:

- (1) The name of the company is the Medical Sickness, Annuity, and Life Assurance Society, Limited.
- (2) The registered office of the company will be situated in England.
- (3) The objects for which the company is established are the payment of sums during sickness or disablement, the payment of annuities, and the effecting of life assurances.
- (4) The liability of the members is limited.
- (5) Every member of the company undertakes to contribute to the assets of the company, in the event of its being wound up while he is a member or within one year afterwards, for payment of the debts and liabilities of the company contracted before he ceases to be a member, and the costs, damages, and expenses of winding up, and for the adjustment of the rights of the contributories among themselves, such amount as may be required not exceeding two guineas.
- (6) The articles of association submitted to this meeting and signed by seven subscribers be adopted as articles of association of the company.

In reply to inquiries the CHAIRMAN said that the income tax to be paid if the conversion was carried out would amount to about £2,400. If any members did not propose to join the new company their interests in the Society would be safeguarded by earmarking the amount from the various funds which the actuary might consider necessary to meet all such claims.

The motion was then put to the meeting, and carried by the requisite three-fourths majority. The resolution will be submitted for confirmation to a further general meeting to be held on April 16th.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED

THE annual general meeting of the London and Counties Medical Protection Society, Limited, was held at 32, Craven Street, W.C., on March 17th, with Sir JOHN ROSE BRADFORD, the President, in the chair. The Council's annual report showed that there had been a considerable accession of new members, and that most of those who had resigned temporarily, while away on military service, had resumed their membership. The results of the law suits undertaken by the society for its members had again been, in general, very satisfactory. Many difficulties and disputes had been successfully dealt with, including numerous troubles arising out of panel practice, thus avoiding much litigation and publicity.

Sir JOHN ROSE BRADFORD said that the membership of the society at the end of the year was 5,688, and the net increase during 1919 was just over 500. The funds also had increased to such an extent that the treasurer could look on the prospect of litigation with some equanimity.

Dr. C. M. FEGEN, the treasurer, said that the society, like other bodies, was faced with greatly increased expenditures which diminished the balance on its profit and loss account, and there was also a net depreciation in the value of its securities amounting to £800. This depreciation, however, in no way interfered with the society's income, and, as the investments were all gilt-edged, their ultimate value would remain unchanged. As a whole, the finances were extremely good. The reserve funds had risen during the last twenty years from £1,400 to £25,800, and that period had included five years of war. Litigation during the past year had been normal, but there was in evidence at the present time a spirit of litigation, so that the liabilities of the society could not be exactly foretold.

A resolution to remunerate the members of the committee by a sum of one guinea for each attendance was proposed by Dr. VINRACE and carried *nomine contradicente*. It was stated that this would only mean, supposing every committeeman made a perfect series of attendances, an expenditure of £450 a year, and that this could not be considered an unreasonable charge for the management of a concern with a capital of nearly £26,000.

Sir John Rose Bradford was re-elected President, on the motion of Dr. FEGEN, seconded by Sir T. W. PARKINSON, and Dr. Fegen was re-elected treasurer, on the motion of Dr. J. H. STOWERS, who coupled with his proposition a hearty vote of thanks to Dr. Owen Fowler for taking over the duties of the treasurership during Dr. Fegen's absence on war service. The vice-presidents and retiring members of council were also re-elected, as were the general and financial secretaries, Dr. Hugh Woods and Mr. A. G. R. Foulerton respectively.

VILLAGE TUBERCULOSIS SETTLEMENTS.

DEPUTATION TO THE MINISTER OF HEALTH.

A DEPUTATION recently waited on the Minister of Health to urge the establishment of village settlements in connexion with the treatment of tuberculous ex-soldiers. The establishment of such settlements was recommended in the recent Report of the Interdepartmental Committee on Tuberculosis (Sanatoriums for Soldiers).

The deputation comprised Sir C. A. Montague Barlow, M.P. (Deputy Chairman of the Interdepartmental Committee), Lieut.-Colonel Nathan Raw, M.D., M.P. (who was a member of the Committee), Professor Sir German Sims Woodhead, M.D., Dr. Varrler Jones and Mrs. Marcus Dimsdale (representatives of the Papworth Tuberculosis Colony), and the Countess of Leicester and Mr. Kaikes (representatives of the Norfolk Branch of the British Red Cross Society). Dr. Addison was accompanied by Lord Astor (Parliamentary Secretary to the Ministry of Health), Sir George Newman (Chief Medical Officer), and other officials of the Ministry.

The case for the establishment of village settlements put before the Minister was broadly that sanatorium treatment for tuberculosis, even when accompanied by training in a suitable occupation, had been found to be inadequate as a means of combating the disease. The general experience had been that patients who returned from a sanatorium to their homes and former occupations were unable permanently to earn a living or maintain their health. The interest, both of the patients and of the community, required that patients should pass through a threefold course: first of sanatorium treatment, secondly of training, and thirdly of permanent settlement in suitable surroundings. The village settlement should be a natural development of the sanatorium and training colony, and the patient should be in a position to look forward to being able, on completion of his course of treatment and training, to take up his permanent residence in a settlement where, still in close touch with the sanatorium, he could work under conditions which would enable him to maintain his health and have his family or dependants with him. In the settlement the patient and his family would have to be housed, the necessary workshops and other buildings would have to be provided, and—in the case of the civilian—the patient's earnings would have to be supplemented; but the community would gain in the result by the prevention of the spread of infection and the fact that the tuberculosis patient would remain a productive worker. As illustrating the results of establishing a village settlement on these lines, it was stated that at the Cambridgeshire Tuberculosis Colony, out of thirty cases who had passed from sanatorium treatment and training into the settlement there, not one had died in four years.

Dr. ADDISON, in replying, referred to the four main recommendations in the Report of the Interdepartmental Committee, namely:

1. That an increased capital grant should be given for the provision of sanatoriums;
2. That additional sanatorium accommodation for ex-soldiers should be provided;
3. That increased provision should be made for training; and
4. That village settlements should be established.

As regards (1), the capital grant had now been increased from £90 to £180 per bed (subject to a limit of three-fifths of total cost). With regard to (2), since the issue of the committee's report 7,000 additional beds had been provided or were now in course of being provided, largely as a result of the announcement of the increased capital grant. As regards (3), negotiations were proceeding with the authorities of a number of suitable sanatoriums for the rapid provision of training facilities for 1,000 tuberculous ex-service men at an estimated total cost of £250,000. On the question of village settlements, Dr. Addison assured the deputation of his goodwill. There were, however, various difficulties to be overcome. The success of a village settlement would depend even more upon the personality of the man in charge than upon the material provision made. As regards finance, the provision of ten settlements for not less than 200 patients each, as proposed by the Interdepartmental Committee, would, he considered, cost much more than the sum of £1,000,000 suggested by the committee. Again, as Minister of Health he could not consider only the case of the ex-soldier; he had to consider also the civilian population, who had no pensions to supplement their earnings. Further, the Cambridgeshire Tuberculosis Colony was managed by a voluntary organization, but in the establishment of further settlements it would be necessary to rely in the main upon local authorities. The

problem was therefore one of much complexity; but a comprehensive scheme, dealing with all the various issues involved, was under discussion with the Treasury. There was, in addition, the important question of the situation of the projected settlements. On this Dr. Addison intimated that Dr. Nathan Raw and Dr. Varrler Jones had kindly consented to undertake, in conjunction with a medical officer of the Ministry, a series of local investigations with a view to advising him on this matter.

NEW STAFF OF OUTDOOR MEDICAL OFFICERS OF THE MINISTRY OF HEALTH.

IN connexion with the appointments of Medical Officers of the Ministry of Health announced in our columns on March 20th (p. 407), it was stated that the Minister of Health was setting up a committee to consider the applications for these appointments and to make recommendations to him of candidates suitable for appointment. We are informed that the committee includes representative medical men of high standing in the profession from different parts of the country (one of whom is chairman, and one nominated by the Civil Service Commissioners), with two representatives of the Ministry. The personnel of the committee will be announced at a later date, but we are requested to state that it is considered desirable for obvious reasons to defer making the names public until after the committee has made its recommendations.

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee held on March 9th 23 cases were considered, and £224 voted to 21 of the applicants. The following is a summary of some of the cases relieved:

Daughter, aged 50, of M.R.C.S.Eng. who died in 1915. Her only income is £40 as a daily governess, and £10 from her sister. She pays £9 2s. a year for one unfurnished room. Voted £5.

Daughter, aged 64, of F.R.C.S.Eng. who died in 1887. Only income 10s. a week by gardening. Lives with an old aunt, who provides for her. Asks for help owing to age, ill health, and the high cost of living. Voted £12 in twelve instalments.

Widow, aged 40, of M.B.Lond. who died in 1918. Was left unprotected for with three children, aged 53, 4, and 2. Income £60 a year from dividends, and £65 from letting rooms. Pays £39 for rent and rates. Relieved twice, £20. Voted £16 in two instalments.

L.R.C.P. and S.Edin., aged 73, suffers from ill health, and his practice has fallen off since the war. Has lost an annuity of £103 owing to the war. Receives about £103 from practice, and £10 an annuity. Has one daughter, who helps at home; his wife has bad health. Rent £35. Relieved once, £10. Voted £10.

Widow, aged 66, of M.D.Edin. who died in 1909. Was left with four children, one now married. Children pay £73, and she receives £12 from another charity. Pays £1 a week for lodgings, and 2s. 6d. for storing furniture. Relieved eleven times, £116. Voted £12 in twelve instalments.

Daughter, aged 56, of M.R.C.S.Eng. who died in 1895. Was left entirely without means. She receives 17s. a year from a small sum invested, and £21 from another charity. Pays £1 1s. a week for board and lodging. Is in ill health and unable to work. Relieved seven times, £57. Voted £12 in twelve instalments.

Daughter, aged 58, of M.R.C.S.Eng. who died in 1880. She lives with widowed sister, and her only income is £60 from other charities. Has very bad health. Relieved ten times, £108. Voted £12 in twelve instalments.

Widow, aged 49, of M.B.Glasg. who died in 1914. Takes in paying guests, by which she makes about £100 a year. Has two daughters, both at boarding school. Income spent in repairing and redecorating house, previous to letting it. Rent and rates, £57. Relieved twice, £22. Voted £12.

Subscriptions should be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessaries, with applications for coats and skirts for ladies and girls holding secretarial posts and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who, in happier times, would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W.1.

SATURDAY, APRIL 3RD, 1920.

DEFICIENCY DISEASES IN VIENNA.

SOME account was given last November of the early work of the mission sent to Vienna by the Accessory Food Factors Committee appointed jointly by the Lister Institute and the Medical Research Committee. The members, Dr. Harriette Chick and Miss Dalyell, have found the opportunities afforded to them very large, and have, in fact, been embarrassed by their number and variety. The mission has recently been reinforced by Miss Margaret Hume, who arrived in Vienna in February. The mission was instructed to inquire into the prevalence of scurvy, rickets, and other disorders attributable to malnutrition; to study the dietaries, and to ascertain, in the case of children, the value of methods of curing deficiency diseases which have been found effective in experiments on animals. It has concerned itself chiefly with the study of scurvy, rickets, and osteomalacia. An outbreak of infantile scurvy occurred during October and November, 1919, and the mission had the opportunity of treating several cases in the infant ward under the charge of Professor von Pirquet. A variety of substances found by experiment on animals to be the most potent antiscorbutics were added to the diet, and the results were gratifying, cures being more rapid and more complete than those usually obtained in the clinic and other hospitals where the use of raw milk was the routine method. The outbreak was ascribed to the disorganization of milk transport and repeated heating of the milk during the hot weather of September and October. Inquiries showed that outbreaks had previously occurred during the spring and summer. The very complete records kept at Professor von Pirquet's clinic justified the conclusion that, except for six or eight weeks immediately preceding the outbreak of scurvy, the proportion of antiscorbutic material in the raw diet was adequate, and that the occurrence of scurvy was to be attributed to the excessive cooking of vegetables customary in Vienna. The interesting observation is recorded that some under-nourished children immediately began to grow at an abnormal rate when they were supplied with a diet containing an adequate energy value, and that this rapid growth seemed to precipitate the onset of scurvy. The question of the relation of active growth to special vitamin requirement is to receive attention.

In a central children's home containing 500 infants, in many cases accompanied by their mothers, there was a severe outbreak of scurvy in the spring and summer of 1919, affecting both breast-fed and artificially nourished infants, and in some cases the mothers also. About 300 infants were affected, and thirty died. In the case of the breast-fed infants the defective diet of the mothers was assumed to be the cause; in bottle-fed infants, not the lack of cow's milk, but its too frequent heating and staleness. Examination of the children, ranging in age from ten months to about three years, who had suffered from this or a previous outbreak of scurvy, revealed signs of rickets and of delayed growth and development in varying degree. From observations in this institution and elsewhere the conclusion was drawn that in Vienna a large proportion of infants in whom no

symptoms of scurvy could be detected were suffering badly as regards general health, growth, and development by reason of the deficiency of antiscorbutic material in their diet. This opinion is, we believe, very generally entertained by those who have had experience of the treatment of young children in the poorer parts of London. Under conditions there existing it is difficult to prove its truth, but the free addition of oranges and lemons to the diet seems to have a most beneficial effect. With the co-operation of Dr. Zafi, the physician in charge of this home in Vienna, certain additions were made to the diet of the children; as extra antiscorbutics raw swede juice, orange juice, or neutralized lemon juice were used; extra antirachitic material was given in the form of butter and cod-liver oil; to some children both these extras were given. The effect after two or three months was so encouraging that the scope of the experiment was continually enlarged at the desire of Dr. Zafi, so that there may soon be no untreated infants left to serve for comparison.

In Vienna not only scurvy, but rickets, developed with great frequency in breast-fed infants, often when less than six months old. An experiment is in progress by which mothers nursing young infants are provided with a daily ration (50 grams) of butter and raw swede (30 grams). Careful investigations made in New York by Hess and Unger in 1917 afforded statistical evidence in favour of the common belief that cod-liver oil has an effect in preventing rickets, and it is proposed to make a similar investigation in Vienna, where almost all children of the poorer classes over one year old are rickety. On the same lines a precise study is being made in the University children's clinic; there von Pirquet's so-called "Nem" system of nutrition is adopted. Under it the energy value of the diet is nicely adjusted to the needs of the growing child, but no attention is paid to the vitamin value. Professor von Pirquet has assigned to the mission six cots in a ward served by a kitchen in which all food is prepared with laboratory exactness and subject to regular analysis.

It appears that osteomalacia became a common disease in both sexes and at all ages in the spring and summer of 1919. The cases that then occurred improved during the later part of the summer, but patients again became numerous about the beginning of December. Formerly the disease was rare and confined to pregnant women in Vienna, as elsewhere, but inquiry showed that it had been present almost continuously during the war in many of the convents of the city, where, especially since the revolution, great privation as regards both food and fuel has been suffered. In one convent a large proportion of the nuns were, in December, 1919, found to be suffering from the disease, some of them in a very severe form. Between twenty and thirty cases were treated in three groups: one received extra calories in the form of sugar and cereals, another extra food in the form of vegetable fats, the third extra fat containing "fat-soluble" accessory factor in the form of butter, eggs, and cod-liver oil. The results obtained during the first two months are held to make it probable that deficiency of the fat-soluble accessory factor is the cause. An inquiry begun at the Allgemeines Krankenhaus in January is considered to point in the same direction. Cases there are under the care of Professor Schlesinger, who is of opinion that the disease is probably nutritional and due to some special deficiency in the diet rather than to general under-nourishment. He therefore seems to be

approaching the opinion formed on the experiments here, in India, and in America, as to the importance of the accessory food factors, experiments which, it would appear, have hitherto attracted little attention in Vienna. Another inquiry is in progress in Professor Wenckebach's clinic. Cases of osteomalacia are selected from among those applying to the medical departments of the insurance benefit societies, and it is proposed to institute a trial, on a large scale, of the value of cod-liver oil. Hitherto patients in the clinic have received a regular weekly supply of a vegetable oil of unknown composition, containing a small amount of phosphorus. It has in many cases been given for several weeks or months without any very definite result; it will now be replaced by cod-liver oil.

Dr. Chick has given several lectures, including one to the medical and pediatric society: it was followed by an unusually lively and interesting discussion. A large number of physicians related their personal experience of deficiency diseases during the war, and put on record many significant observations concerning "hunger-polynuritis," "hunger-oedema," scurvy, and hemeralopia. The fact that recent work on the subject of accessory food factors is almost unknown in Germany and Vienna is to be accounted for by the circumstance that it has been published almost exclusively in English and American journals, which have for some time been out of reach of Austrian and German readers, more especially now, owing to the depreciation of their respective currencies. An appeal is made on this matter by Sir Clifford Allbutt and Sir James Mackenzie in our correspondence columns, and will no doubt meet with a generous response.

THE EPIDEMIOLOGY OF PHTHISIS.

II.

In an article published last week we dealt with the earlier parts of the third instalment of Dr. Brownlee's statistical inquiry into the epidemiology of pulmonary tuberculosis.¹ Reference was made to his view that the decline in the phthisis death rate is not due to an elimination of susceptible units by the operation of a selective fertility rate, and it was pointed out that the slackening of the rate of decline of phthisis mortality was shown by statistics of a later date than those used by Dr. Brownlee. It was also pointed out that such changes in the death rate from phthisis as have occurred in London since 1851 are consistent with the hypothesis that general hygienic improvements are responsible for it. From these subjects Dr. Brownlee passes to a brief discussion of the general decline in phthisis since 1850 and some remarks on the phthisis of old age. He then takes up the question of wind and phthisis to which Dr. William Gordon of Exeter has devoted much attention. Dr. Brownlee's statistical analysis leads him to confirm Dr. Gordon's hypothesis that exposure to south-westerly winds increases the death-rate from phthisis. The historical student is reminded of the prevalence of southerly winds in the first constitution of Thasos, and the great mortality from phthisis which accompanied it. In the areas in which the association is found phthisis is of the young adult type, and it is to this type, Dr. Brownlee believes, that the wind exposure contributes. In the following chapter Dr. Brownlee considers the relation between phthisis and the nature of the subsoil, which he thinks has some importance for young adult

phthisis but not for the disease of middle age. He does not, however, consider his results sufficiently extensive to justify a firm conclusion.

The following chapters are devoted to migration (which is not examined in detail), tuberculosis at early ages (which is differently correlated with phthisis in different districts), and the relation between tuberculosis and the milk supply. Dr. Brownlee takes as a criterion of the prevalence of bovine tuberculosis the percentage of samples of milk found to be infected, and shows that this is highly correlated with the standard death rate of the county of origin; it is also appreciably correlated positively with the death rate from "middle age" phthisis, but negatively correlated with that of "young adult" phthisis. Finally, there is a large positive correlation between the milk infection rate and the death rate under 5 from tuberculosis and with the death rates from tuberculous meningitis and abdominal tuberculosis. It is important to notice that the milk rate is highly correlated with the prevalence of forms of tuberculosis not caused by the bovine type of bacillus. Dr. Brownlee makes the tentative suggestion that bovine and human forms may be modifications of a common type, perhaps capable of saprophytic existence.

The report concludes with a geographical study of the distribution of phthisis in England and Wales as a whole, and a more detailed study of the Welsh experience. Wales was selected because in the Principality there is little middle age and much young adult phthisis. This section cannot be summarized, but the conclusion is drawn that exposure to wet and cold, together with poor feeding (in particular a lack of animal food), are important predisposing factors.

We have, perhaps, said enough to mark our sense of the importance of Dr. Brownlee's memoir. The history of opinion upon tuberculosis is full of instruction. It is thirteen years since Karl Pearson published his first paper defending with the powerful statistical weapons which he had forged and sharpened, the ancient doctrine that an inherited predisposition is an important factor of the disease as a national malady. Since then Pearson himself and his pupils—the Eldertons, Heron, and the late Charles Goring (whose death has deprived medical statistics of a gifted adherent)—have done much to reinforce the conclusions drawn and to throw doubt upon the value of panaceas. It cannot be said that any of these papers much influenced the trend of popular medical opinion at the time, and the elaborate historical and pathological essay of Bulloch and Greenwood, now nine years old, did little more to inoculate the profession with a doubt as to the claims of the various conquerors and stampers out of consumption.

Whether these investigators did in the long run have more influence than appeared, or whether the change of opinion is analogous to that spectacle, "not of argument or of conflict, but of a silent evanescence and decay," which, as Lecky said, characterized the decline of belief in witchcraft, is hard to say. It is perhaps most probable that increasing appreciation and utilization of statistical methods in the widest sense—the term not being restricted to the special technique of the biometricians, important as that is—together with some sense of disappointment due to the confrontation of promises and results in the matter of sanatorium benefit, have produced a reaction against the simple faith of fifteen years ago. However this may be, we should as soon expect to hear now in professional circles that the conquest of consumption is a simple matter of hygienic administration as we should have been surprised ten or fifteen years ago not to hear it.

¹ An Investigation into the Epidemiology of Phthisis in Great Britain and Ireland. Part III. Medical Research Committee Special Reports Series. No. 46. Stationery Office, 1920. 2s. 6d.

This change of opinion does not involve any admission of the all-sufficiency of what we may term the eugenic faith. Indeed, a reduction of the problem to exclusive terms of heredity would be as particularist as its reduction to a mere matter of segregating "open" cases and multiplying sanatoriums, and was not contemplated by Pearson or other scientific eugenicists. In fact, to quote a sentence in the introduction to Dr. Brownlee's report, the administrative control of tuberculosis "presents a more complicated, though not necessarily therefore a less soluble, set of problems if the conditions which tend to produce phthisis in young adult life, for instance, are different from those which tend to produce it in middle age." This remark is equally applicable to the other complications revealed by other investigators, such as Collis, Greenwood, and Tebb.

Although we do not face the problem of tuberculosis with the same confidence as in the days of "rare and refreshing fruits," the position is really much more satisfactory. Not only is the need of further investigation as a prelude to action properly realized, but examples of the kind of research necessary have been provided. Amongst such Dr. Brownlee's papers take an honourable place. Let us hope that other official and unofficial investigators will soon take their places in a field which can support many cultivators.

THE NATURE OF ECLAMPSIA.

In a recent paper Obata of Tokio has recorded some interesting observations which appear to shed considerable light on the etiology of eclampsia.¹ In 1911 Dold drew attention to the fact that saline extracts made from certain of the viscera possess a poisonous property which is neutralized by normal serum. Obata therefore set himself to determine, in the first place, whether the placenta contains such a poison. As soon as the placenta was expelled the umbilical cord was cut off together with the portion of the placenta surrounding its attachment. As much blood as possible was then expressed from the placenta and the decidual tissue removed. The cotyledon—preferably that portion most deficient in large villi—was then cut into pieces, ground in a mortar, and mixed with 0.85 per cent. saline solution in the proportion of 1 in 3 by weight. The mixture was stirred and allowed to stand for half an hour at room temperature, and then filtered through fine silk. The filtrate was centrifugalized, and the supernatant fluid—designated placental extract—was used for experiment. The extract had a pale pink colour, but contained no solid particles in suspension. As a rule freshly prepared extracts from placentae taken immediately after birth were employed. The animals used were Japanese dancing mice, and the placental extract was injected into their caudal vein. After an interval of ten to thirty seconds—rarely as much as a minute—the animal became excited and then fell at once into a brief clonic or tonic convulsion. This was succeeded by violent dyspnoea, coma, and finally death within one to three minutes after the beginning of the convulsion. While these symptoms occurred in the majority of cases, instances occasionally occurred in which death took place after an interval of hours or days. Even in these cases, however, the two most prominent symptoms were dyspnoea and convulsions.

The placental extract was found to kill in a dose of 0.025 to 0.15 c.c.m. in the case of normal placentae, and in a dose of 0.019 to 0.1 c.c.m. in the case of eclamptic patients. The toxicity of the eclamptic

placenta, therefore, was hardly to be distinguished from that of the placenta from normal cases. It was found that fresh serum from normal persons when injected intravenously into mice produced symptoms which differed only slightly from those produced by placental extract. No substantial difference, however, was found between the serum of normal and of eclamptic gravidae in this respect, nor could any increase in toxicity be found in the serum of a patient during an attack of eclampsia and after recovery from that condition.

Obata now proceeded to determine the relative capacity of fresh serum of normal and eclamptic patients respectively to neutralize the toxicity of the placental extract. One c.c.m. of the latter was placed in contact with amounts of serum varying from 0.7 to 0.025 c.c.m., physiological saline added to bring the mixture up to 2 c.c.m., and the fluid injected after being left for one hour at 37° C. It was found that the serum either of normal men, or of normal non-pregnant women, or of normal pregnant women, possesses a power practically uniform of neutralizing the poisonous property of placental extract, 0.2 to 0.3 c.c.m. of such serum sufficing to neutralize 1 c.c.m. of the extract. This neutralizing power was found to be considerably reduced in the serum from women during an eclamptic attack, as much as 0.6 c.c.m. being then required to neutralize the toxicity of the placental extract, whereas after recovery from eclampsia 0.3 to 0.4 c.c.m. and sometimes 0.2 c.c.m. of the patient's serum was sufficient. Experiments were made to determine whether the neutralizing power was increased during normal pregnancy, but the result was negative. Hence no evidence was found to indicate that the neutralizing power is due to an immunological process.

The lesions found in the bodies of animals that succumbed to the placental extract were broadly similar to those present in fatal cases of eclampsia in the human subject, and from the result of his observations Obata concludes that the true nature of eclampsia is nothing other than an intoxication by the placental poison, which is made possible by a weakening in its normal capacity for neutralization on the part of the maternal blood. As to the cause of this weakening, however, Obata offers at present no opinion. Work on the matter is in progress.

INCOME TAX AND SERVICE GRATUITIES.

WE have more than once drawn attention to the fact that the Finance Act for 1919-1920 provided for the repayment of income which had been deducted from gratuities on demobilization from wound pensions. It is, perhaps, advisable to call attention to the indirect effect resulting from the exemption of these receipts from income tax. Income which is not assessable cannot be brought into the computation of total income for the purpose of determining the appropriate rate of tax, with an exception in the case of certain classes of foreign residents, which does not touch the present question; consequently there may very well be cases in which the adjustment of the tax deducted would include repayment of a portion of the tax levied on other income. For instance, suppose that A, demobilized in 1917-1918, had an income of £600 from investments and was assessed by the War Office at £500 for military pay and gratuity, then he would have been taxed at 4s. 6d. on £600 and at 2s. 3d. on £500; assuming the unassessable gratuity to be £200, the correct liability would be £600 at 3s. 9d. and £300 at 1s. 9d., thus involving a repayment greater than the tax on the gratuity, because the elimination of that amount brings the total income below the limit of £1,000. These figures are taken more or less at random;

¹ Isei Obata (Forensic Institute of the Imperial Institute of Tokio), *Journal of Immunology*, 1919, vol. iv, p. 111.

the principle might, of course, operate at other limit points—for example, the £400, £600, and £700 "abatement" limits, the £800 limit point for family allowances, or the £500 limit for the lowest rate of tax. No special intimation of such claims would seem to be necessary; the repayment made on the general claim should extend to any indirect results, except in the case of "family" allowances becoming claimable as a result of the reduction in total income, where the circumstances should be stated, as otherwise the repaying authority would not be cognizant of the further repayment due.

RADIO-THERAPY IN CANCER OF THE UTERUS.

It may not, perhaps, be generally known in this country that Stockholm during the last few years has become an important centre for radiology, to which radiologists of the other Scandinavian countries resort for inspiration and guidance. The leading spirit is Professor Gösta Forssell, who has surrounded himself with an able staff of assistants. One of them, Dr. J. Heyman, recently read a paper before the Swedish Medical Society on the results of radium treatment of cancer of the uterus as judged by an observation period of five years or more. The remarkable figures he published were given in the *Epitome* on March 6th (No. 256). Discussing these figures, Professor Forssell compared them with those of operative treatment, and he prophesied that the time must inevitably come when the surgeon would have to abandon this field altogether to the radiologist. Accounts of the activities of "Radiumhemmet" in Stockholm by Danish and Finnish medical men, who have spent several weeks studying Professor Forssell's methods, reflect the glamour with which this institution is surrounded. Dr. N. Emeleus¹ writes of patients entering "Radiumhemmet" pale and debilitated, bloodless, and with an offensive vaginal discharge due to absolutely inoperable cancer of the uterus. A little later he describes the same patients on discharge, in perfect general health, without a sign of malignant disease, and with a growth of new epithelium in place of discharging ulcers. Even the patients who subsequently relapse are given a reprieve of one to three years, during which they are fit for work and are free from the pain and offensive discharge of untreated cancer. Death in these cases is, he says, easy and painless. Dr. Ib Hansen's² account is as enthusiastic, but much fuller. According to him, this treatment was begun by Professor Forssell in 1910; since then his supply of radium has been gradually increased to about 50 cg. Since 1914 he has made little alteration in his technique. "Radiumhemmet" consists of two large buildings with accommodation for in-patients and out-patients. The treatment with radium is supplemented by x-ray treatment. The results have been found to depend largely on the age of the patient, the prognosis being much worse for patients under 40 than for the higher ages. Heart disease is also of bad omen. The immediate results are so extraordinarily good that the patient is apt to neglect further treatment, assuming that a permanent cure has been effected. It is the practice, therefore, to warn the patients beforehand of this danger, and funds have been provided to defray the expenses incurred by patients coming to Stockholm for after-treatment. Once relapse has occurred, either locally or in the pelvic glands, further treatment with radium appears to be hopeless.

AN EPIDEMIC OF HEMERALOPIA.

EPIDEMICS of night blindness occurred in the armies during Napoleon's campaigns and in the Crimea campaign, but little was heard of it during the recent great war. Tricoire has recently recorded³ its occurrence in the Serbian army during its retreat in the winter of 1915. The total number of cases was 320. Previous investigators

agreed in connecting the occurrence of epidemic hemeralopia with an insufficient diet, especially want of animal food. Tricoire produces good evidence in favour of including it under the deficiency diseases. For several months the Serbian troops lived exclusively on dried beans, lentils, and decorticated rice, along with stale lard and white bread. After a certain time an epidemic of night blindness occurred, the number of cases varying from day to day without obvious reason. During the day-time the patients could carry on as usual in apparently perfect health, but as the day waned visual acuity diminished, so that by night time they were quite unable to see and had to be led by their comrades. Ophthalmoscopic examination was negative. The administration of cod-liver oil was found to be very efficacious, all the cases being cured after taking 50 to 75 grams of the oil. The epidemic ceased when more generous rations—including fresh or frozen meat and green vegetables—were supplied to the troops. Seeing that the energy value of the previous ration was about 2,000 calories, and that the patients showed no signs of anaemia, emaciation, oedema, or asthenia, but were invariably healthy-looking, mere insufficiency in quantity of diet would not seem to account for the condition. The important part that the so-called vitamins of diet play in maintaining health is now widely recognized, and the absence or deficiency of these substances in the causation of beriberi, scurvy, and pellagra is admitted. Tricoire shows that the diet of the Serbians in the retreat was deficient in fat-soluble A factor. MacCollum and Davies, by depriving rats of this substance, produced blindness, which disappeared rapidly on the resumption of a diet in which it was abundant. Cod-liver oil, that proved so beneficial in the epidemic, is rich in these. In six of his cases Tricoire found scurvy co-existent with hemeralopia. These facts go to show that epidemic night blindness is to be ranged alongside scurvy as one of the deficiency diseases, but the distinct separation of this particular condition from the others, with the exception of the six cases, would seem to support the idea that there are specific vitamins. It should be recognized, however, that there may be certain natural peculiarities to be taken into account in addition to lack of vitamins.

VISCERAL ANALGESIA IN TABES.

THAT the visceral crises of tabes may be easily mistaken for an acute abdominal emergency is well known. That visceral analgesia in tabes may⁴ mask the occurrence of such an emergency is less well known. Hauser of Mannheim recounts in great detail such a case.¹ A man, aged 45, was suddenly taken ill after a meal, and retired to bed feeling sick, but did not vomit. Two days later a doctor was sent for, but beyond the fact that the patient seemed very ill nothing definite could be made out. The next day the man was obviously very ill indeed; he was collapsed with small, thready pulse, covered with cold sweat, and the heart was almost inaudible. There was no abdominal pain, either spontaneous or to be elicited by pressure, no rigidity, and no enlargement of the liver. But the pupils were fixed, the knee-jerks absent, and on questioning it was found that the patient had had syphilis for twenty years and had undergone much treatment. The man's condition becoming still more desperate, it was obvious that he was suffering from something more than a visceral crisis, of which he had had several. A surgeon called in diagnosed retroperitoneal blood extravasation. Saline infusion was twice given intravenously. The patient died three days after the onset of the attack; the only abnormal physical sign noted was a tympanic patch in the left hypochondrium, diminishing the heart's dullness. At the necropsy a perforated duodenal ulcer was found, with general peritonitis and free gas in the abdominal cavity. This case is a

¹ *Finska Läkaresällskapets Handlingar*, November and December, 1919.

³ *Paris médical*, February 21st, 1920.

⁴ *Deut. med. Woch.*, 1919, 45, 129.

remarkable example of the manner in which tabetic visceral analgesia may entirely obscure a severe abdominal lesion. From first to last the man's abdomen was entirely painless and flaccid. The sensory portion of the reflex arc necessary for protective rigidity of the abdominal muscles was interrupted by tabes. The case is, further, an interesting example of the protective value of pain. Schüller² has published a somewhat analogous case, a sudden death in a tabetic, where severe hæmorrhage from a gastric ulcer was found. He draws a comparison between gastric ulcer in tabes and perforating ulcer of the foot, Exner and Schwarzmunn³ having shown that gastric ulcer frequently follows experimental section of the vagus. However this may be, it is more than possible that many deaths in tabetic subjects may be due to abdominal perforations. Much information on this subject might be gained from Poor Law infirmaries, wherein a wealth of clinical and pathological material is lost every year.

AMERICAN MEDICAL SCHOOLS.

The number of medical students in the United States during the year ending June 30th, 1919, excluding those attending preliminary, special, and post-graduate courses, was 13,052, a decrease of 578 as compared with the previous year. Of the total number, 12,259 (93.9 per cent.) attended regular colleges, 397 (3 per cent.) homoeopathic, and 86 (0.7 per cent.) eclectic schools, while 310 (2.4 per cent.) were enrolled in three "nondescript" colleges, consisting of two semi-osteopathic and one nominally eclectic college. The total number of graduates was 2,656. The number of graduates from the regular colleges was 2,423, less by 31 than in the previous year. The number from the homoeopathic colleges was 89, or 25 less than in the previous year; from the eclectic colleges there were 28, or 14 less than in 1918. Of all medical graduates 44.4 per cent. held degrees in arts and science, as compared with 38.4 in 1918, 32.5 per cent. in 1917, 26.9 per cent. in 1916, and 15.3 in 1910. This increase is what was expected from the general adoption by medical schools of the requirement of two years of college work before entrance. Of the 2,423 graduates from regular schools, 1,162, or 48 per cent., had a bachelor's degree in arts or science; of the homoeopathic 16, or 18 per cent., and of the eclectic graduates 2, or 7.1 per cent. Of the 116 "nondescripts" not one held such a degree. The number of women studying medicine was 686, being 105 more than in the previous year and 76 more than in 1917. The percentage of women to the whole number of medical students, 5.2, is larger than in any previous year. There were 107 women graduates, one more than in 1918. Of the women matriculants, 66 attended the one medical college for women, while 620 (90.4 per cent.) matriculated in the fifty-nine co-educational colleges. From the one women's college there were 7 graduates, while 100 (93.4 per cent.) got their degree from co-educational colleges. The *Journal of the American Medical Association* attributes this increase of women students in co-educational colleges to the fact that in recent years some of the largest and oldest medical schools in the States—Columbia, Tulane, the University of Pennsylvania, Harvard and Western Reserve University, Ohio—have opened their doors to women. Since June 30th, 1918, five colleges have been closed, leaving 85 still in existence. Of these, 76 are regular, 5 homoeopathic, 1 eclectic, and 3 nondescript. There is one doctor to every 720 of population in the United States.

LETHARGIC ENCEPHALITIS.

The position with regard to the incidence of lethargic encephalitis in Europe is not clear nor altogether free from cause for anxiety. The number of cases in England and Wales at the present time has risen to at least 13, and

most of these seem to have developed within the last few weeks. Of the 13 cases 7 are reported from the Spalding and Donnington districts of South Lincolnshire, and the Ministry of Health is making an inquiry there. No evidence has hitherto been obtained that the disease is directly communicable from man to man, but, as in Lincolnshire, it sometimes occurs in groups. It does not help matters very much to say, with Professor Bosc of Montpellier, that the disease is epidemic but not disseminated by contact. During February 18 cases were recognized in and around Montpellier, and some were rapidly fatal, owing, as was thought, to involvement of the vagus. The characteristic symptoms—ophthalmo-plegia, which may be internal, external, or both, somnolence, and some elevation of temperature—point to infection producing a low grade of inflammation at the base of the brain; but Bosc describes more general symptoms, including severe backache and pain in the abdomen, and speaks of a prodromal pharyngitis, which he thinks may indicate the port of entry of the infection whatever its nature, as is supposed to happen in acute poliomyelitis. At a recent meeting of the Académie de Médecine M. Chauffard criticized the term "lethargic encephalitis" on the ground that during the present epidemic cases are occurring in which lethargy is replaced by delirium, epileptiform convulsions, clonic spasms, and psychic disturbances; cases have also occurred in which patients have gone about, although sometimes presenting some paralysis of the ocular muscles. His suggestion is that a better term would be "epidemic encephalitis" as proposed by Hall. In individual cases it might be qualified by the addition of an adjective indicating the particular form of the clinical symptoms presented. Bosc suggests some relation with influenza, and in this connexion the cases of lethargy apparently due to that cause described by Dr. W. M. Crofton last week (p. 431) will be recalled. Influenza in England and Wales, though it has not attained serious proportions, seems still to be increasing. During the last three weeks of February 448 deaths were attributed to this cause in the ninety-six great towns, and 738 in the first three weeks of March. The sporadic occurrence of lethargic encephalitis is clearly a possibility that must at present be borne in mind. It appears to be possible to confound it not only with typhoid fever but also with syphilitic meningitis of sudden onset.

MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN.

THE Board of Education has prepared draft regulations¹ consolidating various previous regulations dealing with the medical inspection and treatment of children attending public elementary schools, the provision of meals, physical training in public elementary schools, evening play centres, and schools for blind, deaf, defective, and epileptic children. All these services are now taken into account in determining the single grant which will in future be paid to local education authorities. The consolidation of the various regulations is intended to indicate that the provisions of the Education Act, 1918, and the Ministry of Health Act, 1919, for promoting the healthy physical and mental development of children and of the population generally must be closely co-ordinated and their development determined by a common policy. One article, in providing for the appointment of the school medical officer to the local education authority, lays it down that while he will be primarily concerned with the medical supervision of children in elementary and special schools, he is to be assigned definite duties with regard to provision of meals, physical training, and other matters affecting the healthy physical and mental development of the children. As the Education Act, 1918 (Section 18), not only provides for the medical inspection of children attending secondary and continuation schools and other similar institutions, but also empowers the local education

² *Wien. klin. Woch.*, 1908.
³ *Ibid.*, 1912, p. 1455.

¹ Presented to Parliament. [Cmd. 617.] Price 3d. net.

authority to arrange for their treatment, it is considered essential that the medical officer should have before him particulars of the medical records of the children during their attendance, if any, at elementary schools; there is a provision also that should a child leave a public elementary school and enter a school under another authority, particulars of the medical record should be forwarded to the authority or the governors of the new school. The authority is required to make provision not only for the periodical medical inspection of children in special schools, but also for their appropriate medical supervision and treatment. Another article provides for the admission of children to special schools from the age of 2 instead of at 5 as at present; grants will be made for them at the same rate as for older children.

OPERATIONS ON PENSIONERS.

We are sometimes asked by readers what may happen to the pension of a disabled ex-soldier who, having been awarded a permanent pension, improves in health and earning power by reason of an operation or other medical or surgical procedure. The question is of some importance both to the medical man and to his patient, and we have therefore referred it to the Ministry of Pensions Article 5 (1) of the Royal Pensions Warrant of December 6th, 1919, lays down that "when a permanent pension has been granted, it shall not be altered on account of any change in the man's earning capacity, whether resulting from training or other cause." We are informed that "other cause" includes improvement following operation or medical treatment. Once it has been made, a permanent pension (as distinguished from a conditional award made until the disability reaches its final and stationary condition) cannot be altered to the man's detriment, even if following operation he improves so much as to become an international football player.

Medical Notes in Parliament.

Criminal Law Amendment Bills.—The Government bill of 1918 to amend the Criminal Law Acts and the bill introduced by the Bishop of London for the same purpose were both read a second time in the House of Lords on March 23rd, and referred to a Joint Select Committee. The bishop in his measure proposes to raise the age up to which consent shall be no defence against charges of carnal knowledge from 16 to 18, and he has also inserted a clause for the protection of boys against women. Otherwise his bill simply takes up several of the provisions of the Government bill.

Miners' Nystagmus.—In reply to several questions by Mr. Swan as to miners' nystagmus, Major Baird, Parliamentary Under-Secretary to the Home Office, stated that the last year for which figures are available was 1914; in it compensation was given in 5,992 cases. The total was made up of 3,218 cases continued from previous years, and 2,774 new cases. He could not give the amount of compensation. Working in the insufficient light given by miners' lamps was the main cause of the disease, and the question of improving the illumination was being investigated by a departmental committee, under the chairmanship of the Chief Inspector of Mines, appointed last May. It was taking evidence both from those engaged in the industry and from scientific and medical experts. Researches were being conducted at the Home Office Experimental Station at Eekmeals and elsewhere, and a series of practical trials were about to be made with lamps giving a better light. The importance of a good light was recognized, but the Government could not take legislative steps to ensure it while the inquiry was still proceeding.

Antityphoid Inoculation.—Mr. Churchill has informed Mr. Clement Edwards that during 1917 there were in France approximately 30,000 men who had not recently, or had never, been inoculated. During 1918 the number was approximately 70,000. Good sanitation always had a beneficial effect in checking the spread of disease. It was, however, also true that the immunity these men enjoyed was due to the fact that there was only a very small proportion of non-inoculated men in each unit.

Sweetened Condensed Milk.—Mr. Thomas Griffiths asked, on March 29th, whether the allowance of sugar for sweetening condensed milk was based on advice that this was a suitable form in which milk could be used for the feeding of infants. Mr. Parker, for the Minister of Food, replied that an answer given on March 17th to Sir Alfred Yeo was intended to indicate that a demand did in fact exist for sweetened condensed milk for the feeding of infants, but not that it was suitable for the purpose.

Stamp Duties on Patent Medicines.—Last week Mr. R. McNeill asked a question as to the increased cost of "patent medicines"

owing to increased cost of production, the prices charged to retailers leaving insufficient or no profit to the retailer after paying the stamp duty. Mr. McNeill wished to know whether the Chancellor of the Exchequer would reconsider the question of providing a margin of profit by a rearrangement of the duties, so that articles not exceeding 1s. 9d. in value might pay a stamp duty of 3d.; articles not exceeding 3s. 9d. a duty of 6d.; and articles not exceeding 6s. a stamp duty of 1s., in lieu of the duties payable under the existing law. Mr. Chamberlain said that he had received representations, and they were being considered.

Fibroid Phthisis.—Mr. Shortt, in answer to Mr. Will Thorne on March 29th, said that workers employed in certain sections of the metal grinding trade did undoubtedly incur serious risk from the disease known as fibroid phthisis or silicosis, and a special inquiry into these trades was in progress with a view to supplementing the regulations at present in force for the prevention of the disease, and to make a scheme or schemes of compensation under the special powers given for this purpose by the Workmen's Compensation (Silicosis) Act of 1918. The inquiry was difficult, and had to cover a wide field, but was being proceeded with as rapidly as possible.

Expenditure of Medical Research Committee.—Mr. Waterson asked, on March 25th, how much a year was deducted by the Insurance Commissioners from the contributions of the National Health Insurance Act and handed over to the Medical Research Committee, and how much of the amount was spent on salaries and wages. Dr. Addison replied that no deduction was made from the contributions under the National Insurance Acts for purposes of research. The sums appropriated for research were paid out of moneys provided by Parliament. An account of the receipts and payments of the Medical Research Committee, audited by the Comptroller and Auditor-General, was submitted each year to Parliament with the annual Appropriation account of the National Insurance Joint Committee. The account for 1918-19 would be found on p. 347 of the Appropriation Accounts of Civil Service and Revenue Departments for 1918-19.

Sanatorium Treatment.—In reply to Lieutenant Commander Kenworthy, on March 25th, Dr. Addison said that institutional treatment for insured persons suffering from tuberculosis was already being provided in most areas by the public health authorities under agreements made with the Insurance Committees, and it was proposed to transfer the duty of providing such treatment to appropriate public health authorities. He hoped to introduce legislation for the purpose at an early date. Domiciliary treatment for insured persons suffering from tuberculosis would be provided by Insurance Committees under Clause 4 (3) of the National Insurance Amending Bill as part of medical benefits.

National Insurance Expenses.—On the motion necessary in Committee of Supply to cover the new financial proposals contained in the National Insurance Amending Bill, Dr. Addison said that under the new scheme the Treasury contribution of two-ninths represented an expenditure of £1,772,000. The men of the army and navy and other forces had had three-halfpence a week deducted from their pay as their share of the contribution. It was proposed that this should be made good by the Exchequer, and it would represent an additional charge of £290,000 a year. There was another small item, which was estimated to cost £30,000, in respect of the penny grant towards low wage earners. In answer to a question by Mr. G. Locker-Lampson, Dr. Addison stated that the majority of deposit contributors were in this category by their own choice, and there was no evidence of any general desire for the abolition of deposit insurance. If it were at any time found that an appreciable number of insured persons was unable to obtain admission to approved societies, he would refer to the Insurance Consultative Council the question of making some alternative arrangement.

Clothing for Tuberculous Patients.—Sir James Craig, in reply to Mr. Gwynne on March 24th, stated that under the present regulations of the Pensions Ministry underclothing and great-coats were provided on loan for men in sanatoriums and others institutions, and great-coats for the use, where necessary, of men under out-patient treatment or treatment at home. Local committees provided extra blankets for men suffering from tuberculosis who were under open-air treatment at home, if certified to be necessary.

Disability Pensioners' Rights.—Sir James Craig stated, on March 24th, that a disablement pension was awarded without reference to contributions levied under the National Insurance Acts, and was not reduced because a partially disabled man might also be receiving sickness benefit under those Acts.

Indian Medical Practitioners in East Africa.—In reply to Mr. Waterson, who asked whether Indian medical practitioners in British East Africa were forbidden to carry on independent medical practice, Lieut.-Colonel Amery, Parliamentary Under-Secretary to the Colonial Office, said that the question of medical practice in the East African Protectorate was governed by the Medical Practitioners and Dentists Ordinance, 1910. Under it the holder of any British Indian degree, diploma, or licence entitling him to registration in the United Kingdom was entitled to registration as a medical practitioner in the East African Protectorate. Under the same ordinance the practice of systems of therapeutics according to native, Indian, or other Asiatic methods was permitted for persons recognized by the community to which they belong to be duly trained in such practice, subject to provisos that such systems might only be practised among the community to which the practitioner belongs, and that no act under any such system on the part of such persons as was dangerous to life should be permitted.

England and Wales.

MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN IN LONDON.

At the meeting of the London County Council on March 30th it was decided to arrange for the medical inspection of all children when leaving elementary schools. The Education Committee advised that such medical inspection would be of great value in connexion with advice as to future employment, and would also be equivalent to an entrance examination to the day continuation schools to be set up under the Education Act, 1918, for young persons up to the age of 16 or 18 years. Only those children found defective on leaving the elementary schools would be re-examined during their first year in the day continuation schools, and the general medical examination would not take place until the second year. The children in the elementary schools are in future to be examined at entry, at the age of 8 years (when retardation, dullness, and mental defect will be specially considered), at the age of 12, and again on leaving. The Council's scheme for dental inspection is also to be varied to provide for examination on entrance to elementary schools. As children of 5 are often found to be suffering from dental caries, premises are to be opened in Woolwich as a centre for operations for tonsils and adenoids, and the children may remain for two days afterwards. About 2,500 cases a year will be accommodated, the annual expenditure amounting to £1,850. Surgeons attached to the treatment centres in south-east London, which will be contributory to this operative centre, will have an opportunity of operating on their own cases.

The Education Committee proposes to recover the cost of medical and dental treatment from parents. It is stated that before the war the total amount received from parents was only 3 or 4 per cent. of the cost of treatment, and did not equal the expense of collection; and since the war, the cost of treatment having greatly increased, the position has become worse. Inquiries in seven large English cities showed that, apart from the supply of spectacles, no charge was made for treatment, except in Birmingham, where 2s. is charged for ear, nose, and throat cases, and in Liverpool, where 7s. 6d. is charged for such cases, and also for ringworm cases. In London the average cost for ear, nose, and throat cases is 8s. 5d., for minor ailment cases 7s. 1d., for dental cases 5s. 9d., and for ringworm cases £1 3s. 10d. It is proposed to make arrangements whereby parents not able to pay a private practitioner's fees but able and willing to pay the full cost to the Council should be enabled to do so. The charges to parents who cannot afford or are not prepared to pay the whole cost of treatment are to be, in the case of minor ailments, 1s. for a period up to six months, and the same for each subsequent period, but no charge is to be made for treatment not exceeding a fortnight; in all other cases, including dental cases, 2s. a case is to be charged, but the amount will be wholly remitted in the case of the necessitous.

The Board of Education criticizes the Council's scheme for part-time clinics at special remedial exercises centres, holding that one medical officer with suitable qualifications would be preferable to a system by which three of the Council's school doctors visit the centres once a month. The Board suggests that the Council should establish one whole-time clinic, properly staffed and equipped, and under the supervision of a medical officer having adequate experience of orthopaedics—a suggestion to which the Education Committee is giving consideration.

APPOINTMENT OF L.C.C. MEDICAL OFFICERS.

The London County Council recently made some readjustments of its medical staff, creating vacancies for ten permanent whole-time assistant medical officers, thirteen whole-time assistant medical officers appointed for one year, and twenty-six part-time officers, also appointed for one year. The total number of applications was 190, from 134 applicants, and 71 were selected for interview. Of the 49 doctors recommended, 42 were or had been temporarily employed in connexion with the school medical service. The salary of officers in the first of the three categories is £400, rising to £500; and of those

in the second, £400, both these salaries being based on pre-war conditions and at present subject to a temporary addition of 30 per cent., plus £60 a year. The salary of the part time officers is £180 a year, and is based on current economic conditions.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a final session on March 18th, Sir Francis Champneys in the chair. Six midwives were removed from the roll. Serious negligence, leading in three instances to fatal results, was among the charges. In two cases the Board brought into force Clause 8 of the Midwives Act, whereby the women were not only removed from the roll of midwives, but also prohibited from attending in future at childbirth in any capacity. The ordinary monthly meeting was held on March 19th. The Chairman opened the proceedings by rising to express the deep grief of the Board at the death of Sir Robert Morant, whom he described as a unique and irreplaceable man whose loss would be long and deeply felt. The Board desired to record their sorrow at his death and to send a letter of sympathy to Lady Morant. The list of examiners as submitted by the Secretary and the revised list of lecturers were approved. It was decided to extend the present approval of existing midwives certified as teachers.

Scotland.

SMALL-POX IN GLASGOW.

At the end of last week there were eight cases of small-pox under treatment at the Belvidere Hospital, Glasgow. Two new cases admitted during the week were not related to any of those previously under treatment. Dr. Chalmers, M.O.H., states that a large percentage of the children and adolescents of the city have not been vaccinated, and are unprotected from small-pox; they constitute a possible danger to the health of the community, and he strongly urges vaccination, in their own and the public interest.

RADIUM IN CANCER.

At the annual meeting of the Glasgow Royal Cancer Hospital last week, Sir George Beatson, the senior surgeon, said that the institution met a great want, and helped cases unsuitable for admission to the ordinary hospitals. It had unfortunately been necessary to close the research department, but a good deal of quiet work was going on which did not require large funds. The report showed that a number of cases had been treated with radium emanation through the agency of the West of Scotland Radium Committee, and Sir George Beatson said it had given relief in a great many cases. It was reported that 217 patients had been treated in the hospital, and the district nurse had made 1,425 visits. Though it was not considered opportune to make an appeal for the research department at present, it is hoped to do so before long.

India.

MATERNITY AND INFANT WELFARE.

INFANT mortality in India is appallingly high, and the conditions of maternity—pre-natal, natal, and post-natal, general and special—which so vitally affect infant viability and welfare, are profoundly unfavourable to both mothers and children. Medical schools, hospitals, and dispensaries, under Government encouragement and active support, have been established throughout India on a large scale, and have rendered immense service in initiating and promoting medical education, medical relief, and sanitary reform; but it has been felt by the Government, by philanthropists, and by missionaries that more special measures are desirable in behalf of the women and children of India. Accordingly various institutions and agencies have been organized for the very laudable purpose of ameliorating the health of Indian women and saving infant life. These have from

time to time been described in the *BRITISH MEDICAL JOURNAL*. The first departure in this direction was the Countess of Dufferin Fund, which provides home and hospital treatment for women by women throughout India, and, in addition, educates and trains doctors, compounders, and nurses (*BRITISH MEDICAL JOURNAL*, September 14th, 1918, p. 295). Affiliated with this fund is the Victoria Memorial Scholarship Fund, which is devoted to the education, training, and supervision of native *dhais* (midwives), a hereditary class in India (*BRITISH MEDICAL JOURNAL*, December 20th, 1919, p. 830). The Lady Hardinge College and Hospital in Delhi provides excellent facilities for the medical education of Indian women (*BRITISH MEDICAL JOURNAL*, November 8th, 1919, p. 614).

Finally, an association has been established for the provision of health and maternity supervision. Under the auspices of this institution a book on *Maternity and Infant Welfare*,¹ written by Dr. Ruth Young, has recently been published in India. It is based upon lectures delivered to pupils undergoing instruction in pursuance of the objects of this association. The subjects dealt with are: (1) The hygiene of pregnancy and the puerperium; (2) infant welfare; and (3) the work of health visitors. Under these heads all that relates to child-bearing and infant rearing is systematically expounded. The author has some misgivings as to whether she has successfully avoided the Seylla of undue elementary and superficial explanation and the Charybdis of too elaborate and scientific presentation; but this apprehension is ungrounded, for the information given is clear and sound and quite within the comprehension of educated Indians. For the uneducated oral instruction and advice are best imparted by health visitors. The conditions—climatic, domestic and personal—which affect maternal and infantile health are described, and the special evils resulting from the ignorant practices of native *dhais*, early marriages, purdah seclusion, superlactation, the improper feeding of infants, and other circumstances prejudicial to health, are pointed out and remedies suggested. In treating of maternal and infantile disabilities and diseases the propriety of consulting a doctor or resorting to hospital treatment in certain cases is indicated. In the section dealing with the work of health visitors the "causes which lead to the enormously high rate of infant mortality in India" and the "methods that can be adopted to lessen it" are systematically set forth. In this chapter information is supplied regarding arrangements made by the larger Indian municipalities—Calcutta, Bombay, Madras, Lahore, Delhi, and others—for cutertaining nurses, midwives, and health visitors. The example of the larger cities will in time be followed by the small towns, villages, and hamlets of India.

Dr. Young's treatise will undoubtedly fulfil a most useful and beneficent purpose; and, as the general and hygienic education of Indian women progresses, it cannot fail to assist in reducing sickness and mortality among mothers and infants.

LEPROSY.

A conference on leprosy was held in Calcutta during the first week of February. Sir Leonard Rogers gave a lecture on the treatment of leprosy, and the Rev. F. Oldrieve spoke on the Lepers Act and leper asylums and settlements. At a public meeting presided over by the Metropolitan resolutions were adopted urging the Government of India to amend the existing Lepers Act during the next session of the Imperial Legislative Council.

YELLOW FEVER COMMITTEE.

The Yellow Fever Committee appointed by the Government of India commenced its sittings in Calcutta on February 9th. A large amount of information is available regarding the risks of the introduction of the disease into India, and the main matter for the consideration of the committee is the means of prevention which should be taken. It is believed that it will be necessary to establish, in co-operation with Australia and other parts of the empire, a sanitary intelligence service in ports from which infection may come.

Correspondence.

MEDICAL LITERATURE FOR VIENNA.

SIR,—We have received from Professor Wenekebach sad news concerning the state of Vienna and Austria. Dr. Wenekebach, although he accepted the call to Vienna but a short time before the war, has felt it his duty to abide with the suffering people who honoured him in the days of their prosperity. On the general misery of Austria in material needs it is not our purpose to dwell—it is but too well known; the professor's appeal is for the intellectual needs of a people whose souls are starving. In their penury he says that not a farthing can be had for books or journals, home or foreign, so that for the last three or four years neither teachers nor students have been able to learn what is going on in academical circles. His direct appeal to Great Britain is for recent medical and scientific literature, for which students in all faculties are athirst. He describes the zest with which a group of students will pounce upon any fragment of a journal which may drift into their bare libraries. May we then beg your readers not to throw away journals, books, or papers, and perhaps, furthermore, to make some little sacrifice to spare such literature for the Vienna Medical School. Professor Starling was to have joined us in this appeal, but left for Bombay before his signature was secured. Packets for Professor Wenekebach may be sent to Messrs. Schenker and Co., of 93, Bishopsgate, London, E.C., who have kindly undertaken to forward them in bulk to his care. Any small donations towards transport would be thankfully received by the firm.—We are, etc.,

CLIFFORD ALBUTT,
J. MACKENZIE.

Cambridge, March 22nd.

OUR OPPORTUNITY.

SIR,—For long the practice of medicine has been unsatisfactory for the public, for the Government, for the medical profession, clinician, investigator, and medical officer of health.

There has been a long fight over the questions of remuneration and regulations, owing to the want of appreciation of each other's point of view, longer and more bitter than need have been. The profession has demanded such pay as shall enable it to do its work efficiently and has rightly been very jealous of its independence. The Government has rightly been anxious to ensure an efficient medical service in return for its expenditure of public money.

Now our differences have been, for the time at any rate, settled, and on the good use of that time depends much of the future success of the practice of medicine, both curative and preventive. If in the future the question of remuneration is raised again, our claim will be strong in proportion to the good use we have made of this time to improve the medical service that we can offer. But proper pay is not the only thing we want to make our work less burdensome and more effective; true, the better our pay the less the number of patients we need see in a given time, and so the more carefully can we do our work, but not even a guinea a head would enable us to give a much better service under the present conditions.

The public want the best treatment to be available for themselves and their neighbours. The proof of their desire is the general interest now taken in all questions of medical service.

The Government is properly desirous of improved public health and well-being, and for the purpose an improved medical service. Proof of the Government's desire for this, and to obtain it in the way most agreeable to the profession, is shown in Sir George Newman's memorandum on preventive medicine. Reading that, one can feel assured of the desire of the Ministry of Health to improve the position of the general practitioner, and assured that there is no fear of a whole time State medical service unless we, by our diffidence, drive the Government to it. They have also given proof of their intention by their frequent consultations with medical men and organizations, by their setting up of an Advisory Medical Council, by their willingness to arbitrate about terms under the Insurance Act, and the help they are beginning to give to medical research.

The medical profession wants better opportunity for every man, from the general practitioner to the consultant, to succeed in his profession. It wants better means to prevent and treat disease, better means for observation, more available hospitals, specialist services, laboratories, and so on, more time and opportunity for study and education. It wants work made more interesting, less tedious, and so better. There can be no doubt of the sincerity of the desire of medical men for these things.

We want our independence and individualism, so much of it as is essential for progress, but at the same time we want the help of the State; but it is no good for us to say the State must do this and do that, and at the same time to claim complete independence and individualism, or we shall be in the position of the umbrella merchant who, congratulated on the flourishing state of his business because of the continued wet weather, replied: "Yes, that is all very well, but there ain't nothing doing in parasols."

All the factors for progress are now at hand; everything is favourable. Now is our time; the tide is flowing; with our own goodwill and initiative we shall gain the land we seek, but we shall never get there if we wait and let ourselves be caught in the quicksands of doubt and prejudice, that prejudice born of years of mutual mistakes and misunderstandings. What can we do now? Singly and through our various associations we can do much. We can influence and lead the public. We can co-operate with and help the Government in the development of an organized health service. We can influence public men and public bodies. The sum of our individual influences, the combined power of our various associations, must be great. In a more immediate and practical way we can now help to promote the institution of hospitals of all sorts, laboratories, post-graduate clinics, ambulance services, the organization of the work of institutions and private work. We can co-operate more than we have done in the past with public health authorities.

We must watch—must even go out of our way to look for chances to help. We must see what is wanted and act, so far as we can, on our own. If we do not act ourselves in the interest of the public, the State will, must do so for us. It is for us to enrol ourselves in a great voluntary army at the service of the community or submit to conscription. The day is dawning of many much-needed and far-reaching reforms; we must be prepared when it comes.

We have now a great opportunity such as we have never had before to help in the uplifting of medicine and of our profession, and while maintaining what is essential of our individualism and our independence, to show the world that the desire we have deepest in our hearts is the welfare of mankind; we must

Seize the occasion now while it is nigh,
'Tis vain to seek it when it's once gone by.

—I am, etc.,

Bradford-on-Avon, March 27th.

CHAS. E. S. FLEMMING.

HEAT HYPERPYREXIA.

SIR,—Having experienced part of the hot season of 1916, the whole of that of 1917, and part of that of 1918 in Mesopotamia, I read with very great interest the authoritative articles by Dr. Willeox and Professor Leonard Hill, and, at the risk of appearing presumptuous, I should like to add the following remarks:

During nearly the whole of the period I was serving with a general hospital at Amara, and 280 cases of effects of heat—E.O.H. (B.)—acute and otherwise, passed through my hands.

With regard to electric fans, after experimenting with a small table fan in my own bunk, the pace of which could be regulated, I found that at high speed the current of air felt like the blast from a furnace, but that a lower speed was cool and refreshing. The high speed evidently caused a too rapid evaporation of sweat. Fans in the wards were fixed near the roof, under which the air was fearfully hot, because the roof was made with corrugated iron, covered with mud. The following year a thick layer of rushes was placed on the iron and mud was plastered over the rushes. The wards were then very much cooler and the hot blast from the fans less noticeable. The great drawback to the rushes was that rats took up their abode there. I found

that the best way to keep a ward cool was to have the fans running slowly, with the windows closed on the sunny side and open on the shaded side. The beds in the corners of the wards, where the air was more stagnant, were frequently observed to be bad spots for any one liable to heat-stroke.

With regard to alcohol, I personally believe that a "gin and ginger" at sundown was an excellent thing. Micturition between breakfast and sundown was a rare occurrence and the small tot of gin provided a useful diuretic and relieved the kidneys and bladder of highly concentrated and debris-laden urine. All patients were encouraged to drink water very freely.

As to treatment, diaphoretics were of no use at all after the onset of heat-stroke, but many of the cases I had under my care were more or less convalescent from various diseases, and I believe that by ordering them diaphoretic mixture twice daily, with unlimited water, I had fewer cases of either primary or recurrent heat-stroke than in any other ward in the hospital. I regarded constipation as a thing to be avoided at all costs, both from personal experience and observation in the wards.

In acute cases the patient's bed was drawn out from the wall under a fan, and often between the two lateral exits from the ward, which were opened to create a draught. Ice was packed under the occiput and at the sides of the neck and into each axilla, and enemata of ice-water, which Sir James Cantlie had told me of when I was a student, were undoubtedly very effectual. The cold wet sheet was always used. For convulsions and restlessness I personally came to the conclusion that a cold enema containing potassium bromide was of more use than venesection followed by saline. Ice-water enemata have their disadvantages, but, excepting the intravenous injection of quinine in hyperpyrexia complicating malaria, I believe them to be the most useful item of the routine treatment of this very terrible condition.—I am, etc.,

A. H. H. HOWARD, M.R.C.S., L.R.C.P.

Sheffield, March 24th.

THE SAFETY OF ETHYL CHLORIDE.

SIR,—In the recent numbers of the BRITISH MEDICAL JOURNAL (1919, vol. ii, pp. 558, 616, 690, 832) that have reached Australia there has been a discussion on the safety of ethyl chloride as an anaesthetic. The following figures speak for themselves.

At the Melbourne Dental Hospital all our extractions under general anaesthesia are done under ethyl chloride or somnoform (somnoform being 83 ethyl chloride, 16 ethyl bromide, and 1 methyl bromide). During the past thirteen and a half years 34,433 cases have been attended to by this method without a single fatality.

In the vast majority of these cases the anaesthetic has been given by dental students under supervision, each student being required to give forty administrations in his third year and sixty in his fourth year before obtaining his certificate. In every case the administration is given with the patient in the upright position, sitting in the dental chair, and by the open or semi-open method, the air valve of the inhaler always being wide open at the commencement of induction, and then gradually closed over. I am strongly opposed to the completely closed method of induction without the admission of air.

At the Eye and Ear Hospital, Melbourne, all post-nasal and adenoid cases are given open or semi-open ethyl chloride. During the past twelve and a half years over 9,000 cases have been attended to and without a fatality. At the Melbourne General Hospital and the Melbourne Women's Hospital in nearly every case the induction to general anaesthesia is by means of open ethyl chloride. In my own practice, which with hospital cases is certainly not under thirty cases a week, I never start induction for any operation except by open ethyl chloride, and have not done so since 1908. I have never had a fatality. I have used ethyl chloride continuously by the open or semi-open method in every class of work, not only in temperate but also in tropical climates, with the navy and with the army during the recent war, in Australia and France, winter and summer. Ethyl chloride is not fool proof—no anaesthetic is—but given with air, and by a push not a knock-out anaesthesia, it is one of the safest, if not the safest, and is certainly the most convenient form of administration and ahead of the cumbersome nitrous oxide-oxygen method

which is so much in vogue at present. Of course, I am not speaking of it as a continuous form of administration for prolonged operations.

In all my operation cases, with the exception of post-nasal and tonsil cases and dental extractions, I give to males $\frac{1}{8}$ grain morphine and $\frac{1}{12}$ grain atropine, and to females $\frac{1}{8}$ grain morphine and $\frac{1}{12}$ grain atropine, three-quarters to one hour before operation. In anaesthetic administration it is not so much the anaesthetic that counts if a fatality occurs—it is not the gun, but the man behind the gun.—I am, etc.,

R. W. HORNABROOK,

Anaesthetist, Melbourne Hospital, Women's Hospital,
Feb. 12th. Melbourne, No. 11 A.G.H., Melbourne.

AWARDS FOR MEDICAL DISCOVERY.

SIR.—After the deputation to Mr. Balfour which was reported in the *JOURNAL* of March 6th, 1920, I was asked to publish a letter clearing up several points of difficulty which had arisen; and my letter appeared in *The Times* of March 16th. I am, however, advised to publish a note for the information of medical men.

The proposal of the Conjoint Committee of the British Medical Association and the British Science Guild (see *BRITISH MEDICAL JOURNAL*, January 3rd, p. 25) was that the State should give £20,000 a year in the form of thirty or more life pensions to men whose medical researches have been of general value to the nation. When this proposal was put before Mr. Balfour several minor difficulties were raised. Thus it was suggested that the selection of recipients would not always be an easy task. But the same difficulty exists whenever any award is made, as, for instance, in selecting new Fellows for the Royal Society, or in giving medals or Nobel prizes, or, indeed, in allotting all public honours. If the mere difficulty of selection is held to be a bar to the feasibility of our scheme, no awards at all could be given. The matter appears to me to be one merely of detail. Registers of all possible candidates must be kept, particularizing the work done by each, and then a proper committee must make the selection. This is done in the similar cases mentioned above. The Council of the Royal Society makes a very careful scrutiny of the claims of candidates for its Fellowship; the procedure of the Nobel Committees is, I believe, still more rigorous, and occupies many months; and let us hope that the State is no less careful before recommending His Majesty to award the valuable distinctions conferred by him. All this costs, indeed, some trouble, but it is generally held that the stimulation of merit is worth the trouble involved. Just the same principle will have to be adopted for the proposed awards for medical discovery. I should add, however, that, in my opinion, the selecting committee should be chosen with particular reference to their own achievements in medical research; and, after the first selections are made, that the men selected should themselves have seats on that committee.

It is impossible to define our proposals further at this stage until it has been decided by what official route the awards are to be given, if and when the general principle has been accepted. Perhaps an extension of the existing Civil List pensions would suffice; but I understand that these are conferred only by the Premier on applications from influential friends of candidates, and I doubt whether this procedure will commend itself to many medical men. Another possible route is by petition to the Chancellor of the Exchequer, according to the precedent of Jenner in 1802; but by rule the Chancellor can refuse to forward such petitions to the House of Commons, and no one will know his reasons for such refusal; so that this again is not a very satisfactory route. A third possible route is to make a legal application to the Royal Commission on Awards to Inventors; but this appears to be difficult for legal reasons which apparently apply to medical discoveries and inventions as distinct from all those made outside the profession. It is argued that medical men are obliged to disclose their discoveries and inventions at once, and that therefore they have no claim for protection or compensation by the State—so that medical men are punished for their own altruism. I know of two cases in which this argument has been actually used already; but I have been informed that I may have the case argued at my expense before the Commission if I like; and, if our other proposals fail, I propose to adopt this procedure, and

trust that the profession will not object to my doing so. Personally I think that medical men would prefer a procedure which will enable them to approach the State for compensation through a legal channel and not through the influence of friends or through applications to Ministers. In our opinion, persons who have added greatly to medical science without remuneration for themselves and at the cost of much time and trouble which might have been spent by them more profitably in acquiring or increasing medical practice, have a distinct claim for compensation by the State—as was admitted by Parliament in the case of Jenner.

The personal opinions of private individuals like myself are, however, of little value, and the matter ought to be thoroughly discussed by some committee appointed by Government for the purpose. I urged this upon Mr. Balfour at the deputation and trust that he will accept the idea. But here again the committee which considers the details should contain men who have themselves done medical research of distinction and who therefore know the difficulties attending such labours.

Those who have read the original report of the Conjoint Committee will see that we were in favour of similar awards being given for other branches of science, and indeed for great labours in entirely different fields. They will also know that we do not propose in any way that the funds at the disposal of the Medical Research Committee should be diminished for the sake of the awards which we favour. We are, however, unanimous in the view that such awards should be given in addition to the subventions for current researches allotted by the Medical Research Committee; and I feel sure that the great body of the medical profession will support us in this. In the meantime we are waiting to see whether the Government is going to accept the general principle which we put before it at the deputation.

I was requested by the Conjoint Committee to keep a list of names of possible candidates furnished to me by members of the Committee. I have done so and have received about forty names. Of these I am sure that at least half are the names of men the whole profession would be glad to see rewarded in the way mentioned. Whether all of them would wish for compensation or not, I cannot say, but I am quite sure that some of them need it and that all deserve it.—I am, etc.,

London, N.W., March 26th.

RONALD ROSS.

EARLY DIAGNOSIS OF SYPHILIS.

SIR.—Dr. Bryans's letter in the *JOURNAL* of March 20th (p. 416) furnishes excellent, though quite unintentional, evidence of the danger of relying solely upon microscopical examination in the diagnosis of syphilis. Dr. Bryans apparently is only prepared to accept a diagnosis of syphilis when the *S. pallida* is shown by dark-ground illumination, and regards Fontana's method of staining as unreliable. In this he is at variance with many pathologists. However, this is a matter of secondary importance; the main point is that syphilitic chancres, which are clinically obvious, not infrequently give negative results with either method. As a result of the false teaching which places laboratory diagnosis before clinical experience, not a few of the victims of syphilis suffer from delayed treatment, or even escape treatment altogether.

With regard to chancroids, Dr. E. Harrison's statement, to which Dr. Bryans takes exception, that chancreoid is a rare condition and nearly always has "syphilis at the back of it," is in our opinion perfectly correct. One of us, after an experience of many thousands of cases of venereal diseases in the army, has come to the conclusion that there are very few cases of chancreoid pure and simple. These cases are invariably contracted from professional or amateur prostitutes, the great majority of whom are infected with syphilis as well. This accounts for the fact that nine out of ten chancreoids are followed by syphilis. Indeed, if all cases of apparent chancreoid were treated at once for syphilis, much less harm would be done than by keeping them under observation, and thereby losing invaluable time for the majority which in due course are followed by syphilis.—We are, etc.,

SHINGLES, VARICELLA, EPILEPSY, AND THE WEATHER.

SIR,—I have read Dr. James Taylor's paper (February 28th, p. 282) with keen interest, as it dealt with subjects which have attracted my attention for a good many years. There is, no doubt, a close connexion between shingles and chicken-pox. At any rate, they frequently occur together or closely follow each other. But whether the one is the cause of the other or both are dependent on a common factor must be left an open question.

There is also a very close relation between shingles and epileptic fits. For instance, on February 9th, the report of the Meteorological Office was "considerable amount of low cloud," and I saw on that day one case of shingles and a patient who had four severe epileptic fits. On February 10th, with "sky mainly covered with low cloud," I had another case of shingles and another of epileptic fits. On February 20th, with "much low cloud," I saw two fits and a case of herpes zoster. At the Exeter Poor Law Institution we know when to expect fits by noting the meteorological readings for the day. It might well be that chicken-pox, like shingles and epilepsy, are "pressor diseases" due to vasomotor changes caused by atmospheric pressure.

There is a clinical fact which I have not seen alluded to before which lends support to the theory that fits are precipitated by arterial hypertension. I allude to their complete cessation in pyrexia. Chronic epileptics who contract a disease by which the temperature is raised immediately become free from fits during that period. I believe that it is the gradual rise of temperature during the fit that brings the attack to an end. On these premises I have been in the habit of exhibiting vaso-dilators—the citrates, the nitrates—with the occasional addition of bromides to my epileptic patients. When an epileptic states that the bromides do him good, but unfortunately they bring out an ugly rash, the correct thing to do is to administer the drug in combination with vaso-dilators, and the bromide rash will not appear. In the prevention of the bromide and iodide rash vaso-dilators are infinitely superior to the much lauded arsenic.

There is one other disease which has a very close connexion with chicken-pox, and that is impetigo contagiosa. It is a very common experience with me to see this skin disease rampant during an epidemic of chicken-pox, and it is caused obviously by local inoculation in children immune by a former attack of chicken-pox.—I am, etc.,

Exeter, March 1st.

J. PEREIRA GRAY.

NASAL HYGIENE OR NASAL DRILL.

SIR,—Nasal hygiene has been systematically practised at the Roll of Honour Hospital, both in the nasal department and in the London County Council aural clinic, and also in the Westminster health centres for a couple of years.

The theory as well as the practice is taught. The mental and physical improvement in nearly every case in which the co-operation of the parents was secured have been very great, and were often obtained in a remarkably short time.

The rules laid down for clearing the nose are based on mechanical principles. Before beginning, the breathing is tested. If a full sigh can be accomplished through each nostril, tested separately, it is considered clear. Sneezing by artificial stimulation is only resorted to where the clearing cannot be effected by mere gentle blowing. Gentleness in dealing with the nose is insisted upon; no blowing is allowed unless or until there is something to come away. No ointment is used, as it is fatally easy to drive offending material inwards. The rules for blowing are:

1. The head is lowered to make an inclined plane for the discharge to invoke the aid of gravity.
2. The nostrils are left widely open so that the discharge may not be forced backwards into any of the danger zones, but, following the line of least resistance, may escape outwards.
3. The blowing is continued—not breaking the thread—till the clearance is complete, so that any of the openings of the tiny cells or sinuses may be sucked clear.

It is also taught on another mechanical principle that sniffing resembles pile driving—the catarrhal discharges being continually driven against the thin bony plates,

which may in time yield, or through the openings into the blind chambers, where they find all the conditions for incubation.

The ultimate aim of nasal hygiene, as practised on the above lines, is to get the nose into such order that it may be able to perform its almost incredible number of functions without making its presence felt by its owner.

The term "nasal hygiene" is used instead of "nasal drill" because the latter implies that all children should be enrolled—the harm and damage done to the healthy noses would then be incalculable. The strong protest implied in Dr. Francis's letter will be endorsed by all who are working on preventive lines.—I am, etc.,

London, W., March 3rd. OCTAVIA LEWIN, M.B., B.S.Lond.

Obituary.

SIR JAMES GRANT, K.C.M.G., M.D.,
Ottawa.

SIR JAMES ALEXANDER GRANT, whose death on February 6th we have already reported, was born in Inverness-shire in August, 1831. His father, Dr. James Grant, soon afterwards removed to Canada. His son was educated at Queen's and McGill Universities, graduated in 1854, and commenced practice in Ottawa, where he resided during the remainder of his long life. He entered the Canadian parliament in 1865; the original Pacific Railway Bill, which embodied the first movement towards the trans-continental railway in Canada was introduced by him, and he supported the admission of the North-West Territories and British Columbia into the Confederation. He ceased to be M.P. in 1873, but entered Parliament again as the representative for Ottawa in 1892, and retained his seat until 1896.

He was President of the Ontario Medical Council in 1868, was for some fifty years member of the Medical Council of the Ontario College of Physicians and Surgeons, and was President of the Royal Society of Canada in 1901. He was Vice-President of the Department of Surgery of the International Medical Council in Philadelphia in 1876, and of the International Medical Congress at Washington in 1887. He was a member of the Royal College of Surgeons of England, a Fellow of the Royal College of Surgeons of Edinburgh, and was elected a Fellow of the Royal College of Physicians of London in 1882. He was much interested in the British Medical Association, was elected an honorary member in 1886, and attended the annual meeting in Montreal in 1897. He received the K.C.M.G. at Queen Victoria's first Jubilee in 1887.

Sir James Grant was an effective public speaker, and during his time took a large part in Canadian public life. He had been in failing health for some years, and on January 20th suffered a fracture of the femur, when he was removed to St. Luke's Hospital, of which he was one of the founders. He took much interest in tuberculosis, a subject upon which he wrote much, and was president of the Tuberculosis Association of Canada in 1901. Sir James Grant married the daughter of Mr. Edward Malloch, M.P., in 1856, by whom and by seven children he is survived. The funeral was attended by representatives of the Governor-General and the Royal Society of Canada and by many members of the medical profession.

WE regret to record the death of a veteran practitioner, Dr. THOMAS MELANCTHON EVANS of Hull, who died on March 15th. He was born at St. Neots in 1838, and was educated at Christ's Hospital and St. Bartholomew's Hospital, taking the diplomas of M.R.C.S. and L.S.A. in 1861. He commenced practice in Hull, and succeeded his brother in the post of house-surgeon at the Hull Royal Infirmary, to which he ultimately became consulting surgeon. Up till two years ago he was surgeon to the Hull Trinity House and took great interest in the inmates. He was a past president of the East York and North Lincoln Branch of the British Medical Association and of the Hull Literary and Philosophical Society. He leaves one daughter and three sons, one of whom is Dr. H. L. Evans, in practice at Hull. The funeral took place on March 18th, and was attended, among others, by representatives of the medical profession, the Hull Royal Infirmary, and Trinity House.

DR. THOMAS MILNE of Aberdeen died on March 16th in his 73rd year. He was born at Ellon, and received his education at the Gymnasium, Old Aberdeen, and at Aberdeen University; he graduated M.A. in 1868, M.B. and C.M. with honours in 1871, and M.D. in 1874. After serving as resident assistant surgeon to the Aberdeen Royal Infirmary he practised in several places, and eventually settled at Accrington, where he held the post of M.O.H. He returned to Aberdeen in 1892 and built up a large practice. He served as president of the Aberdeen Branch of the British Medical Association in 1913, and of the Aberdeen Philosophical Society and Aberdeen Medico-Chirurgical Society. He was a retired surgeon captain of the 2nd Volunteer Brigade, East Lancashire Regiment. Dr. Milne is survived by three sons and two daughters, the youngest son being Captain Herbert Stewart Milne, R.A.M.C., M.C.

Universities and Colleges.

UNIVERSITY OF OXFORD.

CHARLES PUTNAM SYMONDS, M.A., M.D., M.R.C.P., assistant physician for nervous diseases, Guy's Hospital, has been elected to a Radcliffe Travelling Fellowship, tenable for three years.

UNIVERSITY OF LONDON.

MILITARY EDUCATION.

THE Military Education Committee, which administers the Officers' Training Corps, has recently presented its eleventh annual report, covering the year 1919. The establishment consists of one artillery unit, one engineering unit, an infantry unit (one battalion of three companies), an Army Service unit (one transport and supply company), and a medical unit consisting of four sections of a field ambulance. In the medical unit the number of officers was eleven and the number of cadets in training during the year 347. The Committee has discussed the future organization of the O.T.C. with a view to drawing attention to certain disabilities suffered during the war. A conference of past and present officers of the medical unit was held in July and its report forwarded by the Committee to the War Office. Later a conference of the combatant units was convened, and finally the Committee made certain recommendations which have been forwarded to the Secretary of State for War, with an indication that the Senate would welcome the appointment of a War Office Committee to consider the future of the Officers' Training Corps. The recommendations included a suggestion that the Senior Division O.T.C., composed of contingents provided by universities, should be organized as a distinct corps and that, save in special circumstances, commissions in the Regular Army (university commissions), Special Reserve, and Territorial Force should be granted only to persons who have received training provided in the Officers' Training Corps or equivalent training. It is suggested that the present Junior Division O.T.C. should not form part of this corps, but be given a distinct name and organization. It was suggested also that provision should be made for all branches of special military work, particularly those involving the application of science to war and that the universities should receive grants to cover all approved expenses. The report has been forwarded to other universities of the United Kingdom.

UNIVERSITY COLLEGE.

The annual report shows that the total number of students in 1918-19 was 2,048. The increase of 977 on the previous year took place mainly in January, 1919; it was due almost exclusively to entrance of ex-service men, most of whom, under special arrangements made for their benefit, were able to complete a full session's work by the beginning of August. The total revenue of the college was £77,824, leaving a deficit of £2,210, due to the necessary increases in salaries and the general increased cost of conducting the college. An appeal is made for £30,000 for a war memorial, to include the erection of a great hall for the use of the college and medical school, and the endowment of University College Hall, Ealing. Towards this amount £5,000 has been subscribed. The chairman, Sir Gregory Foster, and the vice-chairman, Dr. G. Blacker, of this War Memorial Fund of University College and University College Hospital, ask all former students of the college and medical school to send their names and addresses to the hon. secretary, Mr. Lawrence Solomon, at the college.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

THIRD M.B., CH.B. (*General Pathology and Morbid Anatomy*): R. H. Allison, V. Chadwick, N. S. Craig, Caroline M. Edwardes-Evans, A. W. Kirkham, Margaret Pownall, H. D. Preston, Bertha Ronshaw, Florence G. Sherry.
J. P. H. (*Part II*).—Ahmed Aziz, J. P. Broom, J. H. Campain, T. E. Dickinson, W. F. Fitzgerald, J. R. Jagger, E. F. Hill, M. R. Soti, A. V. Stock, C. P. White.

UNIVERSITY OF DURHAM.

THE following candidates have been approved at the examinations indicated:

THIRD M.B. (*Materia Medica, Pharmacology and Pharmacy, Public Health, Medical Jurisprudence, Pathology and Elementary Bacteriology*).—L. Myers, F. J. Benjamin, J. J. N. Daniels, Dorothy E. Elliott, R. Hewitson, J. Jackson, M. Mickler, Joan W. Nicoll, R. J. Perring, S. T. Pybus, Mary F. Richardson, Olive C. Wilson, Philomena R. Whitaker.

* With second class honours.

UNIVERSITY OF ABERDEEN.

AT the graduation ceremony on March 24th the following were among the degrees conferred:

LL.D. (*honoris causa*): Dr. William Bullock, F.R.S., Professor of Bacteriology, University of London; Sir Robert Jones, K.B.E., C.B., late Major-General A.M.S. and Inspector of Military Orthopaedics; Dr. David Nicolson, C.B., Lord Chancellor's Visitor in Lunacy and Medical Adviser of the Home Secretary in criminal mental cases.

M.D.—A. S. Garden, J. Lewis, Helen Lillie.

M.B., CH.B.—M. Y. Garden (with second class honours), Dorothy E. Bryant, A. V. R. Don, C. A. Hay, Dorothy M. Holmes, Alice M. L. Innes, R. C. MacLennan, J. M. Stuart, D. M. Thomson, Ida E. Wood.

D.P.H.—A. G. B. Duncan, R. R. Garden, E. A. Mackenzie, L. M. V. Mitchell, Anne Simpson.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examinations indicated:

M.B., CH.B. (*Medical Jurisprudence and Public Health*).—A. Barr, A. R. Black, D. E. Brown, T. C. Christie, W. Davie, P. A. Feichner, W. M. Hamilton, H. W. Howison, I. D. Hunter, D. Imrie, L. M. Johnston, J. Lavelle, W. R. McCrae, P. M. Luskie, J. M. L. Mitchell, T. N. Ray, I. MacR. Sandilands, J. Shulman, J. M. L. Strang, A. R. Waddell, J. W. Walker, R. J. Watson, J. C. Watt, J. H. Wilson, P. A. White, J. Young, Annie Barlow, Rosa Bass, Elizabeth M. V. H. B. Bird, Ellen B. Cowan, Elizabeth J. Findlay, Brunnhilde M. Grieve, Effie Niblock, Carolina J. Tesser.

M.B., CH.B. (*Materia Medica and Therapeutics*): P., *Pathology*.—R. Adam (M.), T. F. Arnott (M.), A. B. Bird (M.), J. Barlow (M.), A. A. Bell (M.), P. A. L. Brough (M.), G. Brown (M.), M. Brown (M.), A. O. Bruce (M.), T. M. Burton (M.), A. Cameron (M.), J. I. Cameron (M.), P. A. J. G. Caporn (M.), D. F. Cappell (P.), A. Chisholm (M.), J. G. Craik (M.), J. S. Currie (M.), P. A. G. Dewar (M.), F. J. Dewar (M.), M. Douglas (P.), J. A. Dunlop (M.), P. A. Gibb (M.), A. H. Greig (M.), H. G. Halliday (P.), D. R. Hamilton (P.), G. Harvey (M.), E. E. Henderson (M.), T. H. Irvine (M.), W. Jope (P.), H. Kay (M.), W. M. Kennedy (M.), A. A. Kirkland (M.), F. J. Kitt (M.), J. R. Learmonth (M.), J. Leishmann (P.), J. A. Lister (M.), Alexander Logan (M.), Andrew Logan (M.), G. H. Macartney (M.), W. M. McCash (P.), T. S. MacDonald (M.), P. J. McDougall (M.), W. D. Macfarlane (M.), W. M. Macfarlane (P.), J. J. McGehe (M.), P. D. T. J. McKarl (M.), W. McKendrick (M.), J. M. Mackenzie (M.), P. M. K. McKilip (M.), J. M. Nair (M.), P. W. B. McQueen (M.), D. Meikle (M.), P. N. Meilmond (M.), P. C. Melville (P.), H. R. Melville (M.), W. Muir (M.), I. Murray (M.), F. J. Newall (M.), R. A. S. Peacock (M.), T. D. Pyle (P.), G. W. St. C. Ramsay (M.), A. H. Rankin (M.), P. T. N. Ray (P.), A. M. Robertson (M.), W. Robinson (M.), J. Y. Scott (M.), C. M. Smith (M.), D. Stewart (M.), A. Symon (M.), W. L. Templeton (M.), D. M. Thompson (M.), J. C. Watt (P.), A. F. Whyte (M.), J. Wilson (P.), R. MacL. Wilson (M.), P. J. Yule (M.), P. Edith A. Allan (P.), Isabel P. Allan (M.), Martha L. Anderson (P.), Marion C. Boyd (M.), Mary D. A. Boyd (M.), Georgie I. Brodie (P.), Elizabeth E. Brown (M.), Margaret E. Campbell (M.), Gladys M. Chapell (P.), Christabel L. M. Charlesworth (M.), Elizabeth Coupland (P.), Isabella C. Darling (M.), Christian D. H. Eason (M.), Jean MacF. Gilchrist (P.), Christina Gray (M.), Catherine Hill (M.), Isobel R. Hill (M.), Annie W. Humble (M.), Moira E. N. MacAlpine (P.), Joan A. MacColl (M.), Mary McQuaker (P.), Henrietta L. Paterson (M.), Joanna T. Rao (P.), Helen Y. Stoddart (M.), Jeanie M. Strathie (M.), Adeline G. Vallance (P.), Jeanie L. D. Watson (P.). *Old Regulations (Pathology)*: D. S. Buchanan, A. M. C. Miller, R. R. Waters.

* With distinction.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary Comitia of the Royal College of Physicians of London was held on Monday, March 29th, at 5 p.m. The President, Sir Norman Moore, delivered the annual presidential address, in which he stated that the College list now contained the names of 357 Fellows, 506 Members, 1 Extra-Licentiate, 13,800 Licentiates, 863 Diplomates in Public Health, and 18 Diplomates in Tropical Diseases. He gave lists of the honours conferred by the King upon Fellows, Members, and Licentiates, and then read short obituary notices of the 11 Fellows who have died since the delivery of the last address a year ago—namely, Dr. F. J. Smith, Dr. Joseph Wigglesworth, Dr. G. B. Brodie, Dr. E. G. Fearnsides, Professor W. S. Greenfield, Dr. Charles Moreier, Dr. Guthrie Rankin, Sir William Osler, Dr. Laurence Humphry, Sir James Alexander Grant, and Dr. Samuel Hatch West.

The election to the office of president for the ensuing year was held, Sir Norman Moore being re-elected. He then gave his faith to the College in the prescribed form.

Licences to practise were granted to George Cleverdon Hartley, Birmingham University, and to Kathleen Suzanne Vine, Royal Free Hospital.

The President returned thanks to the College and then closed the Comitia.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE elections for the three vacancies on the Council of the Royal College of Surgeons will be held on Thursday, July 1st. Sir Anthony Bowlby, Mr. W. Harrison Cripps, and Sir D'Arcy Power, all of St. Bartholomew's Hospital, retire at the expiration of their terms of office. Mr. Harrison Cripps will not seek re-election, but the other two out-going members intend to come forward. There will thus be seven candidates, two for re-election and five for election. The new candidates are: Mr. W. Thelwall Thomas, of Liverpool, Member 1886 and Fellow 1890; Mr. John Herbert Fisher, ophthalmic surgeon, St. Thomas's Hospital, Member 1891, Fellow 1893; Mr. Herbert Stringfellow Pendlebury, Member 1896, Fellow 1897 (St. George's Hospital); Mr. Francis James Steward, Member 1895, Fellow 1898 (Guy's Hospital); and Mr. Victor Bonney, Member 1896, Fellow 1899 (the Middlesex Hospital).

The Services.

THE SPECIAL RESERVE, R.A.M.C.

A CORRESPONDENT writes: I should like to state two grievances of the Special Reserve Officer R.A.M.C. which so far have not been mentioned by any of your correspondents. It is laid down in the conditions of service for Officers Special Reserve R.A.M.S.: (1) That on mobilization £50 would be paid for disturbance and extra kit. (2) That a retaining fee of £20 per annum would be paid while disembodied.

As regards (1), officers who joined early in the war were unable to obtain this sum. As regards (2), I recently applied for the retaining fee after being disembodied over twelve months. I received a reply informing me that a War Office letter of October 30th, 1919, had stopped the payment of the retaining fees for Special Reserve Officers. That the War Office can alter the terms of service in this manner will prove the last straw in my case, and will certainly cause my resignation when this is permitted. I shall join as a temporary officer if necessary on any future occasion.

THE NEW TERRITORIAL ARMY.

THE following appointments to Divisions of the new Territorial Army are announced:

HIGHLAND DIVISION.

Medical Service.—Colonel F. Kelly, C.B.E., appointed A.D.M.S.; Captain J. F. Macintosh to command 1st Highland Field Ambulance, R.A.M.C.; Lieut.-Colonel D. Rorie, D.S.O., to command 2nd Highland Field Ambulance, R.A.M.C.; Major A. E. Kidd, O.B.E., to command 3rd Highland Field Ambulance, R.A.M.C.

EAST LANCASHIRE DIVISION.

Medical Service.—Colonel W. Ranson, D.S.O., appointed A.D.M.S.; Major G. W. Fitzgerald, O.B.E., to command 1st East Lancashire Field Ambulance, R.A.M.C.; Major A. Callam, D.S.O., to command 2nd East Lancashire Field Ambulance, R.A.M.C.; Major E. H. Cox, D.S.O., to command 3rd East Lancashire Field Ambulance, R.A.M.C.

WEST LANCASHIRE DIVISION.

Medical Service.—Major C. H. Lindsay, C.M.G., D.S.O., appointed A.D.M.S.

NORTH MIDLAND DIVISION.

Medical Service.—Major T. A. Barron to command 1st North Midland Field Ambulance, R.A.M.C.; Captain J. F. Dixon to command 2nd North Midland Field Ambulance, R.A.M.C.; Major A. E. Hodder, D.S.O. (T.F.R.), to command 3rd North Midland Field Ambulance, R.A.M.C.

SOUTH MIDLAND DIVISION.

Medical Service.—Colonel L. J. Blandford, C.B.E., appointed A.D.M.S.; Lieut.-Colonel C. H. Howkins, C.B.E., D.S.O., to command 1st South Midland Field Ambulance, R.A.M.C.; Captain R. A. Broderick, D.S.O., M.C., to command 2nd South Midland Field Ambulance, R.A.M.C.; Captain T. A. Green, D.S.O., to command 3rd South Midland Field Ambulance, R.A.M.C.

WELSH DIVISION.

Medical Service.—Major T. Donovan to command 1st Welsh Field Ambulance, R.A.M.C.; Major H. T. Samuel to command 2nd Welsh Field Ambulance, R.A.M.C.; Major C. L. Isaac to command 3rd Welsh Field Ambulance, R.A.M.C.

WESSEX DIVISION.

Medical Service.—Colonel H. Pickard, C.B., C.M.G., appointed A.D.M.S.; Captain R. Burgess, D.S.O., M.C., to command 1st Wessex Field Ambulance, R.A.M.C.; Major T. P. Puddicombe, D.S.O., to command 2nd Wessex Field Ambulance, R.A.M.C.; Brevet Lieut.-Colonel E. B. Bird, D.S.O., to command 3rd Wessex Field Ambulance, R.A.M.C.

WEST RIDING DIVISION.

Medical Service.—Colonel A. D. Sharp, C.B., C.M.G., appointed A.D.M.S.; Captain W. Lister to command 1st West Riding Field Ambulance, R.A.M.C.; Major F. Whalley, D.S.O., to command 2nd West Riding Field Ambulance, R.A.M.C.; Lieut.-Colonel J. Mackinnon, D.S.O., to command 3rd West Riding Field Ambulance, R.A.M.C.

Medical News.

THE course of lectures and demonstrations in medical psychology at the Maudsley Mental Hospital, Denmark Hill, S.E., has begun, and is, we learn, being attended by a class of 35. The course is arranged to meet the requirements for the Cambridge diploma in psychological medicine.

THE annual meeting of the Society for the Study of Intebriety will be held at the house of the Medical Society of London, 11, Chandos Street, W.1, on Tuesday, April 13th, when Dr. Maurice Nicoll will open a discussion on analytical psychology in alcoholism.

A THREE months' course of lectures and demonstrations in hospital administration will be given at the Western Hospital, Seagrave Road, Fulham, by Dr. R. M. Bruce, medical superintendent, on Tuesdays and Fridays, beginning on April 6th. The fee for the course is £3 3s., and cheques should be made payable to the Metropolitan Asylums Board.

A SERIES of post-graduate lectures, arranged by the Faculty of Medicine of the University of Sheffield, will be given during April, May, and June on Wednesdays, at 4 p.m., in the Royal Hospital, Royal Infirmary, or Pathological Museum, beginning April 7th. The lectures are open to all members of the medical profession, free of charge. They will be announced week by week in the Diary of post-graduate courses in the SUPPLEMENT.

TWO Grocers' scholarships for the encouragement of original research in sanitary science are declared vacant. Each is of the value of £300 a year, with an allowance to meet the cost of apparatus and other expenses in connexion with the work. Each scholarship is tenable for one year, but may be renewed for a second or third year. Further particulars will be found in our advertising columns.

THE Ministry of Health has revived Article 4 of the Poor Law Institutions Order, 1913 (suspended during the war), which requires the removal from workhouses of normal children over 3 years of age. The State Children's Aid Association writes to protest against suggestions which have been made to the effect that one workhouse in a district should be emptied of adult inmates to make room for children from several neighbouring unions. It is objected that large buildings and institutional discipline of work and play will not make up to a child for separation from family life. Guardians are urged to extend the system of boarding-out, and to offer better terms; and also to give increased out-relief to widows to enable them to keep their children with them. The Ministry of Health has just issued a memorandum calling the attention of guardians to Section 9 of the War Pensions Act, 1918. It imposes upon the Minister of Pensions the duty of providing for the care of children of deceased or serving officers or men in the naval, military, or air services, if such children, owing to their being motherless, or for any other reason, are suffering from neglect or want of proper care. It is asked that the guardians should in such cases communicate with the local War Pensions Subcommittee.

DR. T. F. HIGGS, medical officer of the Poor Law institution, district medical and public vaccinator of the Dudley Union, has been presented by the officers of the union with a framed portrait of himself as a mark of their high esteem. Dr. Higgs has been medical officer of the Poor Law institution for forty-four years and a district medical officer of the union for sixty years. At Dr. Higgs's request the portrait will be hung in the committee room.

THE Railway Clearing House has issued a pamphlet designed to convince the public that the increases in railway rates for the carriage of commodities do not appreciably affect the consumer. It contains much curious information, and may provide the long-suffering public with arguments when increased freight charges are assigned as a cause for raising prices. To carry fresh meat from Southampton to Birmingham costs 3d. a pound more than before the war; to carry fruit from Southampton to Sheffield less than half a 3d. a pound more. The increase on carrying fish from Grimsby to London is 1d. on 12 lb., and on the carriage of salmon

from Aberdeen to London one-third of 1d. a pound. The carriage of 25 lb. of butter from Aylesbury to London costs 1d. more, and so on. Another way of looking at the matter is that fish is conveyed by passenger train from Grimsby to London at a charge of ½d. a pound, from Aberdeen to London—a distance of 525 miles—by express train for just over ½d. a pound. Attention is called to the fact that there has been no increase in the charge for the carriage of fresh milk, nor in the goods train rates for manure, basic slag, or lime for agricultural purposes.

Letters, Notes, and Answers.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin, and of the Scottish Office, 6, Rutland Square, Edinburgh.

QUERIES AND ANSWERS.

"HEBRIDES" asks whether asthma is a common antecedent of pulmonary tuberculosis.

HAY FEVER.

DR. W. ROSSELL JUDD (Ashton-under-Lyne) writes in reply to "R. A. J." in the BRITISH MEDICAL JOURNAL of March 27th: "The worst case of hay fever I have seen was that of a lady, aged 24, who consulted me about six years ago. The attacks generally began about the middle of May or beginning of June. Owing to the severe frontal headache and facial disfigurement caused by the acute catarrhal conditions of eyes and nose she confined herself to her room and spent her time in mopping up the secretions with innumerable handkerchiefs. She derived some relief from going to the seaside for six weeks or more away from the graminaceous pollen. At the end of December following the last attack I tried the patient's susceptibility by means of the "Hay Fever Reaction Outfit" (Parke, Davis, and Co.); the red tube gave a very slight reaction, the green tube a fairly severe reaction. I therefore hit upon an intermediate course of dosage, and began in the first week in January, following the last with 0.5 c.cm. intramuscular injections of 100 units strength of pollacine (Parke, Davis, and Co.) twice weekly up to the end of March. In April and May I gave 1 c.cm. weekly. In order to ascertain the patient's immunity I advised her to take a walk in the country and amongst hay fields. Her report was "that after a two hours' walk amongst growing hay she felt a tickling sensation in the nose, with some slight watering of the eyes." Apart from this she was free from any attack. The following January (twelve months after) I gave her 1 c.cm. injections of the same strength weekly from January to the end of April, and since then she has not had any further attacks.

INCOME TAX.

"E. M." was demobilized on November 26th, 1919, and earned nothing until February 6th, 1920, when he "bought a small nucleus from which he will receive nothing in the current year to April 5th, 1920." How should he fill in his income tax declaration for that year?

"E. M." is liable on his net earnings from February 6th to April 5th, 1920, even though he may not receive any portion of those earnings in cash by the latter date; naturally it will be necessary to make an estimate for the two months, unless he can ascertain from his predecessor what a twelve months' average would be, in which case he might take $\frac{2}{3}$ of that amount. The military pay, but not the gratuity, should be shown on the statement of total income (page 3 of the form), and also the gross amount of the taxed dividends in the space provided on the same page.

LETTERS, NOTES, ETC.

ACUTE PULMONARY OEDEMA.

DR. H. CAMERON KIDD (Bromsgrove) writes: A vivid and accurate description of death from acute oedema of the lungs may be found in Zola's book, *Fecondite*, chap. III, bk. V, pp. 554-560 of the 1899 edition—a book, by the way, which I wish might be translated into plain British vernacular, and

distributed to every mother's union and infant centre in the country. It was this description that first taught me of the disease. In the case of almost any other writer of fiction one would have dismissed with a smile, as a novelist's error, the sudden attack of "congestion pulmonaire" which killed a perfectly healthy robust young woman in one night; but, knowing Zola's accuracy in matters medical, I looked up the subject, and have since been aware of the disease, though I never saw a case in thirty years of busy practice. Perhaps the disease is more frequently met with on the Continent than it is in England. In Zola's case—almost certainly authentic—the preliminaries included a severe wetting from a thunderstorm in the afternoon and a hearty supper of crayfish, which suggests urticaria from food poisoning, as pointed out by Dr. Stewart McNaughton, though the author evidently attributed the whole to the wetting, without suspecting the crayfish in any way.

CO-OPERATION IN HEALTH WORK.

ON the fifth Sunday in Lent, after evensong in Giggleswick-in-Craven Church, Dr. J. Johnstone Jervis, medical officer of health for Leeds, gave an address on "The Child." He spoke of the pre-natal effects of the racial poisons—syphilis and intemperance—and referred to the need of wise care in the management of infants during the first four weeks after birth, during which period the greatest number of deaths under 1 year took place. The mortality continued high during the first year, and in the majority of cases, he said, death was due to bad mothering. No mother, he said, had a right to delegate the feeding of her baby to a nurse or firm of patent food manufacturers; 90 per cent. of mothers could nurse their babies, but the majority would not try. The country wanted to know why only 35 per cent. of her sons were found to be AI men. Dr. Jervis suggested that the answer was that England had lost the art of producing mothers. "Let England," he said, "replace the mother on her throne, and so will she save herself and remove her reproach." We are told that the address produced a great impression on the congregation, and the vicar, the Rev. T. P. Brocklehurst, in a note appeals for more active co-operation between the medical and clerical vocations. "We need," he writes, "more of such enlightenment in our pulpits; after all, we have to deal with *this* state of existence, which we do know something about." The same post brings a statement put out by the Public Health Service of the United States. The Surgeon-General of that service has recently stated that one man in every three called up for the army of the United States was found to be physically unfit. He summoned a conference of the American Red Cross, Public Health Association, Medical Association, Tuberculosis Association, and other bodies concerned to consider a programme for co-ordinated work, founded on the results of the co-operation between the American Red Cross, the State and local health authorities, and the United States Public Health Service in the extra-cantonment work during the war. The American Red Cross has set aside some millions of dollars for health work in the United States and intends to co-operate with existing health agencies.

GOOD AND BAD JUGS.

"H. K. W." says that in jugs, if the handle is moulded in one with the body, a hollow is often left in the handle where it joins the inside of the jug. As it is practically impossible to clean this hole, milk will remain in it day after day, so that fresh liquids will be contaminated. The right jugs to buy are, he says, those with the handle pressed on to the body, leaving the inside surface unbroken.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 37, 38, 39, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 36 and 37.

THE following appointments of certifying surgeons are vacant; Bradford, North East (York, West Riding), Burton-upon-Trent (Stafford), Llandilo (Carmarthen), Waterford (Waterford).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under ...	0	7	6
Each additional line ...	0	1	3
Whole single column ...	6	0	0
Whole page ...	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

A Lecture

ON

THE SOLDIER'S HEART AND WAR
NEUROSIS :

A STUDY IN SYMPTOMATOLOGY.

DELIVERED AT THE CLINICAL INSTITUTE, ST. ANDREWS.

BY

SIR JAMES MACKENZIE, M.D., F.R.S., F.R.C.P.

INTRODUCTION.

IN the investigation of disease the necessity for the study of symptoms has been recognized since the days of Hippocrates. Yet, notwithstanding the vast amount of labour spent on the subject, our knowledge to-day is far from complete. In an attempt to improve this knowledge I have been guided by certain principles the application of which has been attended with a measure of success. I desire to-day to illustrate the application of these principles in one field of research in which I have been labouring for over thirty years. During that research I have learnt many things, one of the chief being the fact that to investigate symptoms in any branch of medicine requires a long training in the school of experience. I have frequently had to discard observations made after fifteen or twenty years' experience simply because I found out that those observations were made before I had acquired the knowledge necessary to elucidate the peculiar features of a symptom. This has happened not only with the obscure symptoms that required some apparatus for their revelation, but has occurred frequently with symptoms perceptible to the unaided senses. It is for that reason I am so insistent that you should take particular pains to educate yourselves before you start on a piece of research, for if you do not you will find, after a long time spent in laborious work, that your results have been rendered valueless through imperfect observation. I have by me a vast accumulation of observations of little or no value because they were made at a time when my training was defective. These I sometimes sadly survey, although I recognize it was through this experience that I acquired such limited knowledge of the subject as I now possess. This is really the reason why a great many investigations which have entailed an enormous amount of labour have resulted either in no advance being made, or, which not infrequently happens, wrong conclusions being drawn whose application actually hampers the progress and misleads the practice of medicine.

I shall from time to time refer to investigations drawn from my own and other peoples' failures in order to direct attention to the reason of their failure. There is more to be learnt from the discovery of the cause of failure than from the contemplation of success. To-day, however, I wish to describe to you an inquiry that has been attended by a measure of success, in order that you may realize what really constitutes clinical research. I draw far-reaching conclusions from a symptom (hyperalgesia of skin areas) which can be recognized by the unaided senses. It is so easily perceived that it has been treated as a matter of no importance. Yet a knowledge of the mechanism of its production reveals certain responses of the body the recognition of which gives a new outlook on the nature of a great many diseases. The present classification and description of disease is so faulty and frequently so misleading that, as knowledge advances, a complete reconstruction of classification and description will be called for. Without going so far as to say that the key to the reconstruction is to be found in the illustration I am about to give, I do believe that this illustration reveals so much, and presents certain diseased states in such a reasonable way that a justifiable expectation is aroused that by some such method new light will be thrown on an obscure portion of disease.

It is nearly thirty years since I found that certain diseases of the abdominal organs produced an alteration in the sensibility of the skin and other tissues of the external body wall. It occurs so frequently that every physician and surgeon must constantly meet with it, but it had been overlooked or ignored. Since I drew attention to it, only a few people have employed it as an aid in diagnosis. I have continued its investigation, and as years have passed

I have found that a long training has been necessary to bring to light the full significance of the symptom, and even to-day I am far from comprehending the wide field of research it has opened up, so that I am capable of dealing only with a fringe of the subject. It requires little foresight to recognize that, when a full knowledge of cutaneous hyperalgesia and its associated phenomena is obtained, the views of physician, surgeon, and neurologist, and even of the psychologist, will be profoundly affected, and much of that which is to-day accepted as knowledge will be found to fall far short of the truth.

I. CLASSIFICATION OF SYMPTOMS.

It is a matter of knowledge common to every general practitioner that an explanation of the complaints of a large majority of his patients cannot be found by reference to any textbook. The cases he can recognize according to textbook descriptions are mainly those where the disease has reached an advanced stage, as in dropsy from heart disease, and consumption after the lungs break down, or when some terminal affection such as apoplexy occurs. In consequence the doctor is often at a loss what name to give the complaints from which his patients suffer, and he has to resort to the substitution of symptoms in place of the real cause, so that we get names such as neurasthenia, gastralgia, hyperchlorhydria, angina pectoris, tachycardia, albuminuria, which convey no definite information. The reason for this is that the classification of diseases is not based upon a true knowledge of disease. It is the outcome of the time when pathology was dominant. With the introduction of accurate methods of observation, the nature of the diseases found after death were clearly demonstrated, and a classification of the different diseases that affected the different organs was made. This classification was so precise and definite, and seemingly so accurate and scientific that it was adopted not only by the pathologist but by the clinician. The latter used this classification as a guide to search for and explain the physical signs which he detected in the living patient, and thus this classification became the standard for clinical medicine.

For a long time this seemed quite satisfactory, and was of value, but time has shown that for the practice of medicine it is not only faulty but misleading, in that it diverts attention from the real causes of disease and from the more important symptoms—those that are not included in what are called physical signs.

The need for a presentation of disease which conforms with the aspect of disease presented by the living is urgently called for, and the communication I am about to make is given with that object.

I have already pointed out to you that there has been no orderly arrangement of the large mass of symptoms which have been recognized. So long as facts are accumulated with no orderly arrangement the progress of medicine will be hampered and matters essential to its progress will be obscured. I have therefore attempted a classification which is simple, yet helps greatly in understanding the nature of symptoms. This classification of symptoms is based upon the mechanism of their production, and are:

1. *Structural symptoms*—that is, symptoms based on a modification of the tissues of the organ, and which are chiefly revealed by physical signs.

2. *Functional symptoms*—that is, symptoms due to a modified or deranged function of an organ.

3. *Reflex symptoms*—symptoms due to a reaction on the central nervous system or on the nervous mechanism of organs.

It is to the last group I wish to direct your attention, so as to show the mechanism by which a great number of symptoms are produced, and to indicate some of the methods which are necessary to the pursuit of medical investigation.

II. THE STUDY OF REFLEX SYMPTOMS.

I have already remarked that much valuable time is often spent in research work which fails to achieve results at all commensurate with the labour devoted to it. One-half of the battle in all research work consists in having a definite object, with a clear conception of how the object is to be achieved. The principle which guides the inquiry into the nature of reflex symptoms has not only helped in the discovery of facts of great value, but has revealed the methods by which other objects essential to the progress of medicine may be pursued. It has demonstrated, for

instance, that there is an intimate relation between the organs and definite areas of the skin, or rather between the organs and the distribution of the sensory nerves in those areas, and between the organs and parts of the skeletal muscular system. A knowledge of this relation at once reveals which organ is at fault. When we detect sensory disturbances—pain or hyperalgesia—in these parts, or when we find a persistent contraction of the muscles, we are able to relate these to a definite structure within the body. This fact being established, there is given the object, which has been only partially accomplished, of the linking up the organ with the disturbed region in the external body wall. This can be accomplished by the careful examination of the disturbed regions and correlating them with the disease discovered on the operation or *post-mortem* tables.

In addition to the discovery of the organ at fault, we have the opportunity of discovering another very important matter—namely, the nature of the stimulus which is capable of producing these disturbances in the external body wall. It requires a stimulus of a peculiar kind to produce these reactions. Some disease processes produce one form of reaction and others produce other reactions. The careful noting of the different reactions and their correlation with the disease process will reveal the nature of the stimulus which may be acting, and so we get at a very early stage, from the symptoms produced in the external body wall, a sure indication, not only of the organ at fault but of the kind of disease present in the organ.

The recognition of the phenomena produced by reflex stimulation by disease will be found to open new fields of investigation in the central nervous system. The radiation of stimulation, for instance, shows there are paths in the central nervous system hitherto unrecognized. The peculiar fields of cutaneous hyperalgesia and of the radiation of pain in diseases of such organs as the heart, gall bladder, ureter, and bowel, shows that the stimulus entering the central nervous system pursues a very definite course. This is also seen in the production of such symptoms as occur in renal colic, as represented in Fig. 10.

In addition, it is only by the study of these symptoms that a full knowledge of the afferent system of the nerves belonging to the involuntary nervous system can be acquired.

I have already described to you that ill health leads to the production of a great variety of symptoms, and suggests the search for some simple cause capable of producing these effects. The trained investigator may detect the cause in a variety of ways—by the intelligent questioning of the patients as to the onset of their ill health and their sensations, by the recognition of the peculiar character of the symptoms in the way they are grouped. Certain toxins give rise to reactions peculiar to them, and we may recognize the diseases they represent by the grouping of the symptoms. These reactions are shown not only by the peculiar association of phenomena but also by specific effects upon individual organs. The recent observations of Marris and R. M. Wilson, for instance, demonstrate that certain microbes produce toxins that have a peculiar effect upon the heart. By such means there is every reason to expect that we will recognize that groups of symptoms are indications of and peculiar to certain diseased states, although at present our outlook is confused by an inability to distinguish these groups. You will thus see how incumbent it is on us to note carefully each individual symptom, to watch the development of symptoms by keeping in touch with the patients, and applying the principles which are the basis of our scheme and the reasons for our enterprise.

III. MECHANISM OF AN ORDINARY STIMULATION.

Before discussing the nature of these reflex symptoms it is necessary to appreciate the mechanism by which many symptoms are produced. When a common sensation arises in any part of the body, no matter how it is produced, it is always accompanied by a sense of locality. This sense of locality may be precise and definite, or it may be vague and diffuse, but it has a reference to some particular part of the body. Fig. 1 represents diagrammatically the simplest form of sensation with its attendant localization. It represents a portion of skin (A) which is stimulated and from which a sensation passes into the

central nervous system and reaches the sensorium (s), where the sensation is not only perceived, but the part of the body recognized to which the stimulated nerve cells are distributed.

Mechanism of the Radiation of Sensation.

The place in which the sensation is felt is not necessarily the place which received the stimulus. In most instances a local stimulus applied to the external body wall gives rise to a sensation whose localization by the sensorium corresponds to the part stimulated. It often happens that the area in which the sensation is felt is greater than the part stimulated, and it is then difficult to explain the radiation. An experience related by Professor Sherrington supplies a fitting explanation. The application of a mustard plaster to his chest over the region of the upper part of the sternum gave rise to an unpleasant sensation on the inner side of each arm just above the internal condyles.

It is known that the nerves supplying the skin of the upper part of the chest and the skin on the inner side of the elbow arise from cells situated close together in the spinal cord, and leave the cord by the second thoracic nerve—one branch of this nerve going to the chest and the other to the arm.

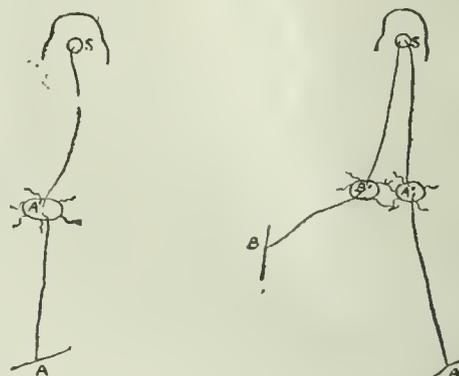

FIG. 1.

FIG. 2.

FIG. 1.—A stimulus applied to the skin, A, is not only recognized by the sensorium, s, but is referred to a definite area, A'.

FIG. 2.—Illustrates the radiation of sensation. A stimulus applied at A is felt not only at A, but in a part of the skin, B, at some distance. This is represented as taking place in some part of the central nervous system where the cells A' and B' lie in close proximity.

The manner in which the radiation of the sensation takes place is shown diagrammatically in Fig. 2. The stimulus conveyed from A enters the cell A' in connexion with the nerve fibre, and not only gives rise to a sensation referred to A, the part stimulated, but affects the cell B' in its immediate neighbourhood. The sensorium recognizes the extended stimulation, and refers the resulting sensation to that portion of the skin, B, which supplies B'. There are many other instances of this kind of referred sensation—for example, the well known instance of the knee pain in hip-joint disease.

From these facts another principle can be deduced—namely, that if any part of the nervous system which conveys the sensation of pain from the skin to the sensorium be stimulated, the resultant sensation is referred not to the part stimulated but to the distribution of the nerve at its periphery. Thus, when the cell B' was stimulated, the brain became conscious of the stimulation, but the sensation was felt in the skin at n.

IV. MECHANISM OF A MOTOR REFLEX.

A stimulus applied to the sole of the foot may give rise to a sensation of touch, or tickling, or pain, and at the same time may produce a contraction of certain muscles. It is not necessary to infer that it requires a special peripheral end-organ and a separate nerve fibre to receive and convey the stimulus to the sensorium, and another to convey the stimulus to the motor centre in the spinal cord. A simple diagram (Fig. 3) shows how this comes about. The stimulus applied to the skin, A, passes into the cell A', and from this cell one stimulus proceeds to the sensorium, and another to the motor cell C', causing a muscular contraction, o.

This reflex stimulation may affect many other centres some of them easily recognizable, others so elusive that their presence can only be inferred. Later on, when dealing with the reaction produced by visceral disease, it will be shown that a stimulus arising at the periphery may provoke a variety of demonstrable reactions differing widely in character.

V. MECHANISM OF RADIATION IN DISEASE.

These simple illustrations give a clue to the manner in which symptoms are produced by disease reacting on the central nervous system. This is shown in the simplest way when a demonstrable disease gives rise to symptoms that are easily recognized. Most of us know from personal experience what toothache is, and we have often the opportunity of studying its symptomatology on our patients, if not on ourselves. It frequently happens that the pain set up by a diseased tooth is not limited to the offending tooth, but is felt along the jaw, in the other

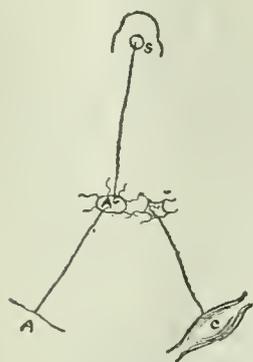

FIG. 3.

FIG. 3.—Illustrates the mechanism of a motor reflex. The stimulus to the skin A produces not only a sensation and its localization, but the stimulus passing through A affects the cell C and produces a contraction of the muscle C.

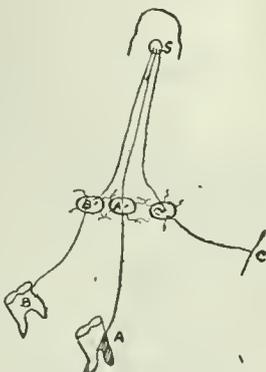

FIG. 4.

FIG. 4.—Illustrates the radiation of pain set up by disease. The diseased tooth A causes pain not only in a neighbouring tooth, B, but also in the skin of the cheek, C.

teeth, and sometimes in the cheek. Indeed, the sound teeth may be so painful, on pressure being applied to them, that the dentist may pull a sound tooth in place of the diseased one. Pain may not only be felt in the cheek, the skin may be so hypersensitive that on brushing the hair pain is produced in place of the normal sensation of touch.

It is to be noted that the spreading of the pain and tenderness in such an instance is not due to the extension of any morbid condition at the periphery—inflammation, for instance—to the neighbouring teeth, for there is no sign of anything the matter with those teeth, while the skin of the cheek is demonstrably free from any diseased condition. Moreover, the discovery and removal of the diseased tooth is followed by the complete disappearance of all pain and tenderness from the other teeth and from the skin of the cheek.

Seeing that these phenomena are produced by one diseased tooth, and seeing that the pain and tenderness of the sound teeth and of the skin of the cheek is not due to any connexion with the offending tooth at the periphery, we are driven to look elsewhere for some connexion between these widely separated parts. As there is no communication between nerves except at the cells in the central nervous system from which they arise, we seek for a relation between the nerves of these teeth and the skin of the cheek in the central nervous system. In the case of the diseased tooth the pain was felt not only in the diseased tooth or its immediate neighbourhood, but also in other teeth and in the skin of the cheek, and this radiation is explained by a reference to the diagram Fig. 4, where it is shown that a stimulus arising from the diseased tooth A sends a stimulus into the central nervous system affecting the cell A' belonging to the nerve of the diseased tooth, so that the sensorium refers the resultant pain to the diseased tooth; but the stimulus also spreads from the cell A' to the cells B' and C', and the resultant pain is referred by the sensation to the healthy tooth B and the healthy skin of the cheek C.

VI. THE TISSUES SENSITIVE AND NOT SENSITIVE TO MECHANICAL STIMULATION.

A step preliminary and necessary to understanding the nature of the symptoms of disease is a knowledge of the sensibility of the different tissues of the body. A great field for investigation still lies unexplored, and so long as it is neglected the understanding of the symptoms of disease will be defective. In the attempt to investigate this field I have only been able to make a slight advance, but such as it is, it has thrown new and unexpected light on a great many problems connected with the symptomatology of disease.

If we inquire into the response of the different tissues to such mechanical stimuli as produce the common sensations of pain, touch, heat, pressure, etc., we discover that these sensations are limited to certain portions and organs of the body, and that there are large portions of the body totally insensitive to all such stimuli. Looking at the matter broadly, we find that while all the structures which make up the external body wall are more or less sensitive to such stimuli, the viscera and the serous lining of cavities are, with one exception, irresponsive to this kind of stimulation.

Thus, if we apply a mechanical stimulus to the skin we produce a sensation peculiar to the nature of the stimulus, as, for example, touch, pain, heat, or cold. If we apply the same stimuli to the viscera or to the serous surfaces or internal structures of organs we get no response, or rarely a response of a different nature. Thus, if we prick the skin near such an orifice of the body as the anus, we can produce pain, but as soon as the mucous membrane is reached the pricking no longer produces pain. In testing other orifices of the body—for example, the mouth—a modified sensation is felt, but at a certain depth of the gullet all sensation ceases.

If we inquire into the reason for this difference in the response to stimulation we will find it in the nerve supply of these different tissues. Thus the tissues which give rise to sensation in response to mechanical stimuli are supplied by the cerebro-spinal nerves, while the tissues which do not respond receive no nerves from the cerebro-spinal nervous system, but are supplied only by the sympathetic nervous system, or what is sometimes spoken of as the involuntary nervous system.

VII. INSENSITIVENESS OF THE VISCERA TO MECHANICAL STIMULATION.

This view of the insensitiveness of the viscera to mechanical stimulation has been repeatedly demonstrated. Haller described a series of experiments where he exposed in animals certain viscera by operation, leaving an opening by which they could be reached. Afterwards, while the animal was feeding, he introduced through the opening instruments that cut and burnt the organ, and the animal paid no attention to what he was doing. I have myself repeatedly tested in the conscious human subject the various organs by cutting, stitching, and tearing, and no sensation was elicited.

The insensitiveness of the viscera and its full significance has not been grasped. Indeed, the belief is common that the viscera are endowed with common sensations, and what is supposed to be evidence is easily obtained.

VIII. METHODS FOR TESTING THE SENSIBILITY OF ORGANS.

The sensitiveness of tissues to stimulation is one of those apparently simple problems which it is assumed anyone can solve. As a matter of fact, no one has been sufficiently trained to undertake such an investigation. A large amount of work has been done on the subject by physiologists, neurologists, psychologists, physicians, and surgeons, yet notwithstanding their opportunities they have failed to investigate the matter in a manner calculated to reveal the true facts, and so the conclusions which are current to-day are based on imperfect observations and in consequence are misleading. I comment on this fact as one of many instances where the progress of medicine is hampered by a lack of understanding of the manner in which investigation should be conducted. I do not at present wish to enter fully into the matter, but mention a few points to show the imperfect methods which have been used.

The first point which arises is, that no conclusion should be drawn as to the sensitiveness of an organ which has been stimulated through a structure itself sensitive. Nearly all conclusions have been drawn from observations made by pressing on the organs through the sensitive abdominal wall. Many observers state that they have demonstrated the sensitiveness of an organ by first observing its position by various methods, such as the x rays, and later by pressing over it and eliciting pain. The error here lies in the failure of the observer to take the precaution of excluding the sensitive external body wall. If, for instance, when such sensitiveness has been detected, an attempt is made to delimit the area that is sensitive, it will be found that the size and shape of the area painful on pressure bears no relation to the size and shape of the organ supposed to be tender. I discussed this matter with a very skilled physician. He demurred to my statement that there was no evidence of the sensitiveness of organs. He declared that he had a patient with a large liver which he could demonstrate to me was extremely tender. I asked to see this patient and was shown him. The enlarged liver was easily palpated, the lower margin being sharp and well defined. On gently pressing over the liver the patient winced from the pain. I asked the physician to map out the region that was so manifestly tender, and to his surprise he found the tenderness extended 3 in. lower than the margin of the liver. (Fig. 5.)

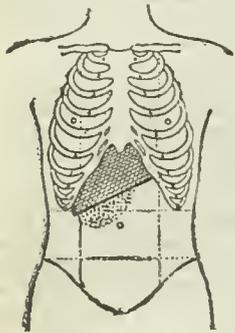

FIG. 5.—The shaded area represents the liver, the dotted area the extension of hyperalgesia beyond the liver margin, showing the pain elicited by pressure over the liver was due to an increased sensitiveness of the tissues of the external body wall.

It is well known that pain does occur in disease of the viscera, and in animals distress has been provoked by certain experiments. But here the experimenter never realized that the evidences of suffering, even if these were due to pain, gave no information as to the locality of the pain—a fact absolutely essential to the understanding of the mechanism by which visceral pain is produced. The same neglect of this essential matter is found in the observations of surgeons and others who have studied pain in the exposed organs of the human subject.

When, in testing the sensibility of organs, pain is elicited, a clear conception of the nature of the stimulus giving rise to it should always be obtained. The need for this and for the recognition of the locality in which a pain is felt is shown by the following experience. In resecting the bowel in a patient who was not under the influence of an anaesthetic, I tested the sensitivity of various organs and their coverings. On pinching the bowel the patient, after a slight delay, complained of pain. I asked him where he felt the pain, and he pointed to the region of the umbilicus. The portion of bowel stimulated lay some distance off on the left side, and it was manifest that the place to which the pain was referred had no direct relation to the part stimulated. Had I been content with simply noting that pinching of the bowel produced pain, I would have overlooked this very important matter of localization.

But there was more in the observation. There was a slight delay in the pain which came in wave-like intensity, and I observed that the pinching had set up a strong peristalsis of the bowel, and that the pain only occurred when this peristalsis was set up. So here I had evidence that the mechanical stimulus I applied only produced pain when a vital process—that is, peristalsis—was set in motion in the bowel.

There are other matters which have been overlooked in this investigation, but what I have said will suffice to show the need for a thorough undertaking of methods before we can observe accurately. Although I do not claim that I have solved the problem of visceral pain, yet the pursuit of this inquiry for many years has given me a certain amount of skill, which has enabled me to discover many facts from which I have been able to draw certain reasonable deductions. These have proved of considerable value in practice.

(To be continued.)

SOME POINTS IN THE PROGNOSIS AND TREATMENT OF CHRONIC NEPHRITIS.*

BY J. O. SYMES, M.D., D.P.H.,

PHYSICIAN TO THE BRISTOL GENERAL HOSPITAL.

THE management of cases of chronic Bright's disease in private practice is, under the methods generally employed, most tedious and uninteresting. It is the purpose of the present lecture to point out some of the newer methods of examination which not only lend a fresh interest to the cases, but which enable us to adopt a more scientific line of treatment and permit of a more accurate prognosis.

Prognosis.

In order that one may make a well considered prognosis it is necessary first to adopt some practical form of classification, and the classification which I suggest to you is that seen in the accompanying table:

Classification of Chronic Nephritis.

TYPE.	Urine.							Prognosis.	Renal Efficiency.
	Sp. gr.	Quantity.	Albumin.	Casts.	Oedema.	Uræmia.	Eye Changes.		
Degenerative (cloudy swelling)	+	-	-	-	-	-	-	Good	
Tubular nephritis (large white)	+	-	+	++	++	-	-	Fair	Fair
Glomerular	-	-	+	+	-	+	+	Bad	Bad
Secondary sclerotic (chronic interstitial)	-	+	-	-	-	++	+	Bad	Bad
Arterio-sclerotic	+	+	-	-	-	-	++	Good	Good

There are, of course, cases of chronic nephritis which cannot be fitted into any one of these categories—cases of mixed nephritis—but for practical working purposes you will find that the classification is one of great value, and that the time spent in obtaining the information under the various headings has not been wasted.

This classification splits up the old group of "chronic diffuse nephritis" into two: (a) tubular, (b) glomerular; and of these the latter is by far the more serious. It also draws a sharp distinction between the secondary sclerotic (contracted granular) kidney and the arterio-sclerotic.

The most important distinction between these varieties of chronic nephritis is the degree of "renal efficiency," by which I mean the measure of the power of the kidney to excrete water, salts, nitrogenous and other waste products.

For gauging renal efficiency most of the tests are such as can be employed in general practice, the only apparatus required being a large vessel graduated in cubic centimetres or ounces, a tall narrow cylindrical vessel, and a small specific gravity bulb. The materials for carrying out the other tests are always to be obtained at the clinical laboratory to which the specimens of urine are to be subsequently sent.

Tests of Renal Efficiency.

1. Water Excretion Test.—Empty the bladder. Two and a half hours after breakfast give 500 c.cm. (17½ oz.) of water, and collect all the urine that can be passed in the next two hours. A healthy person passes about 400 c.cm.

2. Specific Gravity Test.—The urine is to be passed every two hours from 8 a.m. to 8 p.m. Each quantity is measured, and

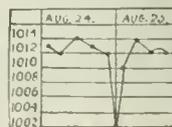

Chart 1.

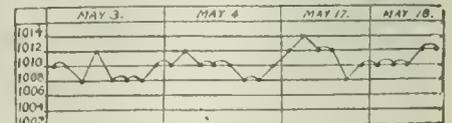

Chart 2.

CHART 1.—Two-hourly specific gravity curve of urine. Severe case of glomerular nephritis.

CHART 2.—Two-hourly specific gravity curve of urine. Case of glomerular nephritis, moderate severity.

the specific gravity taken. The urine passed between 8 p.m. and 8 a.m. is also measured, and the specific gravity taken. In health the quantity of day urine should be greater than the quantity of night urine; the specific gravity of the various day specimens should show wide variations, and at least once in the

* Abstract of a post-graduate lecture delivered at the Bristol General Hospital, July 17th, 1919.

day should reach 1020. Fixation of specific gravity, and especially a persistent low specific gravity, shows renal inefficiency. (See Charts 1, 2, 3.)

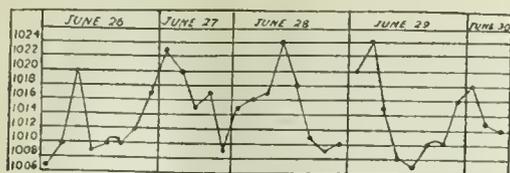

CHART 3.—Specific gravity curve of urine passed two-hourly. Case of glomerular nephritis, convalescent.

3. *Test of the Rate of Secretion.*—Inject 6 mg. of phenolsulphonaphthalin into the buttock muscles, and give the patient a drink of water. At the end of one hour and ten minutes get the patient to pass urine, and again at the end of a second hour. Send the two specimens of urine to the clinical laboratory, where the percentage of dye is estimated by the colorimeter. A healthy kidney excretes about 60 per cent. of the dye in the two hours and ten minutes. Small capsules of phenolsulphonaphthalin containing 6 mg. in solution can be obtained at any of the large chemists. The ordinary hypodermic syringe can be used.

4. *Sodium Chloride Excretion Test.*—Send to the clinical laboratory a sample of the mixed twenty-four hour urine for the estimation of sodium chloride. If the amount of sodium chloride excreted falls to one or two grams per diem (average in health 15 to 20 grams) the prognosis is grave.

5. *Estimation of Non-protein Nitrogen in the Blood.*—Draw off 10 c.cm. of blood from a vein in the arm and send this to the clinical laboratory for the estimation of the non-protein nitrogen (urea, uric acid, and creatinin). If this amounts to more than 0.4 gram per litre there is a dangerous accumulation in the blood, possibly due to alteration of kidney efficiency. The blood (together with 1 c.cm. of a solution of potassium oxalate to prevent clotting) is to be drawn off in a sterilized syringe provided for the purpose by the laboratory.

No one of these tests is by itself of great value, but the combined tests, together with the data mentioned in the table (albumin, casts, blood pressure, etc.) will enable us to form a fairly accurate estimate of not only the efficiency of the kidney in any given case of nephritis, but also of the general condition and progress of the patient.

The tests should be repeated at least every six or twelve months and any variation noted. During the whole period of examination the patient is kept on the standard renal diet, to which I shall refer later.

Tests of renal insufficiency are superior to the old tests for albumin, casts, etc., inasmuch as they enable us to detect disease of the kidney in a much earlier stage. In the future we may look forward to detecting the pre-albuminuric stage of nephritis. At present we seldom detect the chronic case until two-thirds of the kidney substance is destroyed. Such tests are also of value in distinguishing between the coma of nephritis (uraemia) and the coma of arterio-sclerosis (cerebral haemorrhage or thrombosis).

Space does not permit me to touch on other important points of prognosis, but I would point out that the outlook in cases with simple chloride retention is good, even if uraemic symptoms be present, whilst that of cases with nitrogen retention with uraemia is much more grave. In secondary sclerotic nephritis, if the patient escapes the dangers of uraemia, he is, if a man below 50 years of age, most likely to succumb to cardiac failure, whilst at any later period cerebral haemorrhage is most to be feared.

Treatment.

The greatest advance in recent years has been the recognition of the fact that many cases of chronic Bright's disease are originated and kept up by cryptic infections such as pyorrhoea, chronic nasal suppuration, diseased tonsils, and chronic bowel infections.

We are, of course, familiar with the septic origin of acute nephritis. We have had one such case recently in this hospital.

A soldier had suffered for four months from a shattered elbow with profuse suppuration. During this time he developed nephritis. On February 1st, 1919, Mr. Hey Groves amputated the arm through the lower third of the humerus; severe secondary haemorrhage a week later necessitated blood transfusion, but by February 14th the albumin which had been two parts per thousand was reduced to a mere trace, and by February 24th the urine was normal.

Similarly in chronic nephritis the removal of a septic focus in the teeth, nose, or ear, may lead to immediate

amelioration of symptoms, and ultimately to complete recovery. In this way chronic nephritis is comparable to rheumatoid arthritis and it is worthy of note that a very large percentage of the cases of rheumatoid arthritis ultimately die of chronic nephritis.

It is not my intention to touch upon the subject of drug treatment in chronic nephritis, this being of far less importance than the arrangement of the dietary and habits of living. If you follow out the tests I have indicated, then the main principles of dietetic treatment are plainly before you.

1. Where renal efficiency is low and nitrogen is retained you must limit the intake of nitrogenous food, and allow plenty of fluid.

2. When there is general oedema and the chloride elimination is low, you must cut off the supply of salt and diminish the allowance of water.

Dealing first with the cases of nitrogen retention, we find these are chiefly patients who, though suffering from chronic interstitial nephritis, are yet in moderate health and capable of conducting their business. To such we allow 2,500 to 3,000 c.cm. (4 or 5 pints) of fluid a day and limit the nitrogenous intake to about 50 grams a day. These requirements are met by a diet such as the following:

Breakfast.—Porridge prepared from 2 oz. of dry oatmeal, bacon, 3 oz. of toast, tea.

Lunch.—Milk pudding or vegetables, bread-and-butter 3 oz., jam, fruit, and sugar.

Tea.—Tea, 2 oz. bread-and-butter.

Dinner.—Vegetable soup made with milk, 3 oz. of fish, flesh, or fowl, 3 oz. potato, cooked or fresh fruit, sugar.

Sugar is given plentifully to raise the calorie value of the diet and to spare the nitrogen katabolism. Peas, beans, asparagus, onions, rhubarb, strawberries, condiments, meat extracts, alcohol, and tobacco are excluded, either as being too rich in nitrogen or as being renal irritants or stimulants.

This, which I call a standard nephritic diet, is suitable for use when the urinary tests are being made. From time to time the dietary may be varied; thus the patient may be ordered to take only a Continental breakfast of rolls and coffee, or may be directed to go for two days in the week without meat. No distinction is made between fish, fowl, and red meats.

In cases of chronic parenchymatous nephritis, with retention of chlorides and a surplus of water in the tissues, the indications are to cut off altogether the intake of salt and to reduce the consumption of water to about 1,000 c.cm. (2 pints) daily. It has been claimed that the oedema of chronic parenchymatous nephritis may be reduced entirely by adherence to a salt-free diet, with limitation of fluid intake. This is sometimes known as the *Karrell treatment*. Karrell's dietary was as follows:

One and a half pints of skim milk daily (7 oz. every four hours), 6 oz. of coffee. Unless there be uraemia or exhaustion, keep this up for one week, then add stewed fruit, bananas, rice, arrowroot, cereals and cream, toast, vegetables, and sugar. Later give eggs and meat. Use no salt for cooking or in eating. Limit liquids to one and a half pints a day.

The reduction of oedema by the adoption of a salt-free diet has not been very successful. When an oedematous case of large white kidney is first put to bed an increased flow of urine is the immediate result of the rest given to the heart, but in nine cases out of ten the oedema persists, however strictly the diet be enforced.

The reduction of the oedema by the use of diuretics is equally disappointing. Indeed, in cases of pure nephritic origin the use of diuretics is contraindicated as tending to lower renal function. Alkaline salines are least open to this objection and may be tried. On the other hand, such oedema as may be due to circulatory failure is readily removed by diuretics of the digitalis and caffeine groups.

Successful cure of the oedema of chronic parenchymatous nephritis is much more likely to follow the procedure suggested by Epstein. He pointed out that the steady loss of large quantities of albumin in this variety of nephritis caused a decrease in the osmotic pressure of the blood, which fact favours the absorption and retention of fluid by the tissues. Hence the great oedema. The blood in such cases shows a marked decrease in protein and an increase in fatty bodies (lipoids). The indications for treatment, therefore, are first to increase the protein content of the blood and thus restore its osmotic power, and secondly, to remove the excessive lipoids. To effect these ends he administers a diet rich in protein and poor in fat: Fish, lean meat, lean ham, white of egg, oysters,

lentils, peas, rice, oatmeal, bananas, skimmed milk, coffee, tea, and cocoa; fluids 1,200 to 1,500 c.cm. ($1\frac{1}{2}$ to 2 pints); salt to taste. Starchy foods are limited in order to promote the maximum assimilation of proteins and to lessen the retention of water. Fat is limited to lessen the amount of lipoids.

We have found this diet to be most efficacious in reducing nephritic cedema, and, further than this, it has resulted in a very marked improvement in the patient's general condition and in reducing the amount of albumin in the urine.

A FAMILIAL FORM OF ACOUSTIC TUMOUR.

BY

ANTHONY FEILING, M.D.CANTAB., M.R.C.P.LOND.,

PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE; ASSISTANT PHYSICIAN, METROPOLITAN HOSPITAL; CASUALTY PHYSICIAN, ST. BARTHOLOMEW'S HOSPITAL,

AND

E. WARD, M.D.CANTAB., F.R.C.S.ENG.,

TUBERCULOSIS OFFICER TO THE COUNTY OF DEVON.

Tumours of the acoustic nerve or nerves have been reported in medical literature occasionally for many years. They have usually been included under the head of "tumours of the cerebello-pontine angle." It is largely due to the work of Cushing that the acoustic tumours proper have been clearly differentiated from other tumours in this region, and he has been the first to point out their characteristic course and symptomatology. He estimates acoustic tumours to form 6 per cent. of all intracranial growths, and over 20 per cent. of those of the posterior fossa of the skull. Histologically, the isolated tumours of the acoustic nerve arise from the endoneurium; their structure, according to Cushing, consists of two kinds of tissue—a dense fibrous tissue and a looser areolar tissue, possessing some of the characters of a glioma. Bilateral tumours, however, are commonly part of a general tumour formation, which may affect many nerves—in fact, a general neurofibromatosis. Such cases have been not infrequently reported. It should be noted, however, that bilateral deafness has been found to occur in cases where only one acoustic nerve was involved. Henneberg and Koch¹ were the first to point out that tumours of the acoustic nerve could form part of generalized neurofibromatosis. Oppenheim² remarks that he has seen eight cases where a general neurofibromatosis was masked by the symptoms of intracranial tumour.

A familial or inherited tendency has been noted in only a small proportion of the cases of neurofibromatosis. Thus Alexis Thomson³ was able to collect but ten examples from the literature. As regards acoustic tumours proper, the available literature does not record any familial or hereditary tendency. Hence the history of the family recorded in this article is of unusual interest. None of the cases have been verified as yet by operation or autopsy, but the clinical histories and the condition of those patients who were under careful observation are so striking and characteristic, and the existence in one of them of multiple tumour formation renders the diagnosis of acoustic tumours practically certain. The chronological order of symptoms, as described by Cushing—namely, auditory and labyrinthine disturbances, headache, cerebellar ataxia, disturbance of the function of other cranial nerves and the increase in intracranial tension, with optic neuritis and failure of vision—are well exemplified in the history of the family, which is as follows:

First Generation Available.

Mary Ann B., aged 80, had three brothers and sisters, all healthy. One is still alive; the others died at a ripe age.

John B., aged 80, is deaf and too senile to answer questions intelligibly. He was one of a family of ten, of whom only one sister survives. Several died young, but no details have been obtained except concerning Susan, who died, aged 30, of an illness lasting a few years, accompanied by headache and deafness, and Sarah, who died, over 60, of "something the matter with her head."

Second Generation.

Mary and John B. had ten children, of whom one died in infancy; four others are alive and well. But one, Richard B., has been a patient at the Hospital for Epilepsy and Paralysis, Maida Vale (see below). He is now in a Poor Law infirmary.

bedridden, totally blind and deaf. Another, John B., died at the age of 30 after an illness of over two years' duration. He complained first of deafness and noises in the head and was noticed to stagger in walking. Some five months after the onset of his illness he was sent to the Exeter Hospital, where he remained for a month or two. On his return his sight was failing, and he eventually became quite deaf and blind, although for some time he could walk with support. No history of vomiting or headache was obtained, but his friends and relations had noticed a swelling in the neck about the size of a hen's egg for many years. He died about two years after leaving the hospital.

Elisabeth B. died at the age of 33 after an illness of two years' duration. The chief symptoms noticed by the relations were unsteadiness of gait, deafness, and progressive blindness. She was for a time an inmate of the Exeter Hospital and was considered to be suffering from a cerebral tumour. Operation was suggested but refused.

Susan B. died aged 29. Her illness began in somewhat the same way, but she died suddenly from a "stroke."

George B. died aged 52 after an illness of some years' duration, which was accompanied by deafness, blindness, and an unsteady gait.

Third Generation.

Richard 2nd, son of John 2nd, has lately been a patient at the Hospital for Epilepsy and Paralysis, Maida Vale (see below). He has multiple neurofibromata.

William, his brother, states that at one time he had some lumps about his body, but that they faded away. He looks upon himself as foredoomed to die in the same way as others of his family. At present he has no symptoms.

The following is a more detailed account of two members of the family who were recently under the care of one of us at the Hospital for Epilepsy and Paralysis, Maida Vale.

CASE I.

Richard 1st, aged 41, was admitted on July 1st, 1919, under the care of A. F., complaining of deafness, headache, and inability to walk properly. He was then so deaf that it was impossible to obtain from him any accurate history, but one of us (E. W.) had previously seen him, and was able to supply the following history. He first came under observation with suspected pulmonary tuberculosis in October, 1913, but made a good recovery, and by October, 1917, the disease had evidently become arrested. In October, 1918, he complained of headache and weakness of the legs. From January to February, 1919, he was in a sanatorium, but was sent home as his symptoms were entirely nervous in origin. In April, 1919, he was found to be suffering from headache, chiefly occipital in site, and to be getting deaf. His gait was then slightly unsteady, with a tendency to fall to the right. By May, 1919, he had become very deaf, the headache was worse, and he had begun to vomit occasionally. Vision had become defective. The gait was markedly ataxic. The pupils were unequal, the left being larger than the right, and there was well marked double optic neuritis. Nystagmus was present. On admission to hospital in July, 1919, the condition was as follows:

He suffered from a severe and continuous headache, chiefly localized to the occipital region on the left side. There was complete bilateral deafness. The pupils were equal in size and reacted normally. Examination of the fundi showed well-marked double optic neuritis, with much swelling of both discs. Nystagmus was present in all directions, but was more marked when the eyes were directed to the left. With the exception of slightly diminished sensation in the area of the first division of the fifth nerve on the left side, the functions of the other cranial nerves appeared normal. There was no paresis of either the arms or the legs. No static tremors were present. Some slight ataxia was observed in the upper limbs on voluntary movement. The gait was decidedly ataxic, with a tendency to fall to the left. The tendon reflexes were active, the abdominal reflexes present, and the plantar responses were of the flexor type. The Wassermann reaction in the blood was negative.

A diagnosis of bilateral tumours of the cerebello-pontine angle, probably of the acoustic nerves, was made. Operation was advised but refused, and the patient left the hospital. At the present time he is an inmate of a Poor Law infirmary, where he is quite bedridden, totally blind and deaf.

CASE II.

Richard B. (son of John 2nd), aged 20, was admitted to the Hospital for Epilepsy and Paralysis, Maida Vale, on January 2nd, 1920, under the care of one of us (A. F.). As he was almost completely deaf in both ears and could neither read nor write, it was impossible to obtain an accurate history of the condition. But it appeared that deafness had been noticed to begin about nine months before and to progress rapidly. He also complained of constant roaring noises in the head. There was no head-

achic and no vomiting, and no complaint of difficulty in walking nor of giddiness.

On examination the pupils were found to be unequal in size, the right being larger than the left; the right pupil reacted briskly to light and accommodation; the left pupil was contracted, slightly irregular in shape, and reacted only very sluggishly to light. There was no nystagmus and no ocular paralysis. The fundi were normal. With the exception of the deafness the functions of the other cranial nerves were not disturbed in any way. There was practically complete bilateral nerve deafness. He was examined by Mr. Muecke, who considered that the nerve conduction from the labyrinth was almost completely blocked on both sides, more so on the left.

There were no other signs of disease in the central nervous system. But there were present three subcutaneous tumours whose characters suggested that they were fibromata or neurofibromata. These were exceedingly interesting and important in view of the condition of the auditory apparatus and the family history. In the right side of the neck, underneath the sterno-mastoid muscle, was a large, rather spindle-shaped tumour, about the size of an elongated lemon, extending from the angle of the jaw nearly to the sterno-clavicular joint. It was hard, freely mobile, and quite painless. There was no evidence of surrounding inflammation and no enlargement of lymphatic glands. A second but smaller tumour was found in the subcutaneous tissues of the chest wall, just over the right costal margin in the anterior axillary line. It was about the size of a walnut, hard, irregular in shape, freely movable, and painless. A third tumour, about the size of a small date, with similar characteristics, was situated in the upper part of the left gluteal region. The patient stated that he had had these tumours as long as he could remember. The smaller one, in the chest wall, was removed under local anaesthesia for histological examination. Dr. Canti reported that it showed the structure of a soft fibroma. It is more than likely, however, that it arose from a nerve sheath, since it is not easy to demonstrate the existence of nerve tissue in these neurofibromata which have been present for a long time. Operation on the skull was not advised.

THE OPERATIVE TREATMENT OF ULCERATIVE COLITIS.

By P. LOCKHART-MUMMERY, F.R.C.S.Eng.,

SENIOR SURGEON TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM, ETC.

THE discussion on ulcerative colitis which took place at the Royal Society of Medicine in 1909 first revealed the importance of the disease both as regards its prevalence and commonly fatal consequences. Since then our knowledge of it has advanced considerably, but chiefly in respect of the epidemic forms rather than the sporadic chronic cases which are more common in this country.

Very little advance seems to have been made in the diagnosis and treatment of the truly chronic ulcerative forms. There are many reasons for this, one being that the chronic cases have proved almost a complete failure from the point of view of bacteriological investigation. In a large number of cases the stools have been investigated by most competent bacteriologists, but so many different micro-organisms are found, and the difficulties of deciding which is responsible for the disease are so great, that no useful information is, as a rule, obtained. My own experience has been that, with one or two conspicuous exceptions, bacteriology has been of little assistance.

Medical treatment also has not been very successful except in the mild cases, though here I must admit I may be prejudiced by the fact that as a surgeon I am more likely to see the cases in which medical treatment has failed.

Some of the worst cases of ulcerative colitis are those in which the chronic condition is secondary to an acute epidemic form such as amoebic or bacillary dysentery. There is a certain similarity between these cases and the

ordinary form of chronic phthisis. In both we find an acute specific infection causing lesions which become secondarily infected with other septic organisms, and it is this latter secondary infection which causes much of the trouble.

These cases of chronic ulcerative colitis are particularly important at the present time, because very large numbers of men have been infected with acute dysentery while fighting at different parts of the front during the last five years, and are now suffering from the chronic and often much more serious condition.

Not only have a large number of these cases returned to this country during the last eighteen months, but quite a considerable number of cases have occurred among men who have never left England, and among women. These latter cases do not start with acute amoebic dysentery, but are chronic from the beginning. I have little doubt, however, that they have in many cases become infected from the class of cases first mentioned. This is rather borne out by the fact that several cases of ulcerative colitis which came under my observation last year came from one seaport town where many troops from abroad were landed.

A typical case would be that of a man who contracted acute dysentery in Africa or Arabia during the war and had been more or less successfully treated at the time, but the diarrhoea has recurred subsequently until it has become almost continuous, and he has gradually begun to go downhill with constant liquid blood-stained stools, progressive loss of weight, failure of appetite, etc.

An examination with the sigmoidoscope (the value of which in these cases as a means of diagnosis does not even yet appear to be fully appreciated) shows deep and extensive ulceration of the mucous membrane of the rectum and colon. In a bad case islands of mucous membrane can be seen standing up from the ulcerated surface, presenting an appearance closely resembling a polypoid condition.

Examination of the stools show numerous bacteria, mostly of the *coli* or streptococci groups, but no sign of protozoa.

The clinical history of cases of ulcerative colitis varies considerably. In those cases in which the disease is not secondary to acute dysentery the condition often starts insidiously. The patient appears to recover satisfactorily from the initial attack, but recurrences become more and more frequent and less amenable to treatment, until the condition becomes so serious that no treatment seems to have any effect. It is generally at this stage that the surgeon is called in.

There may sometimes be confusion between chronic ulcerative colitis and other forms of chronic recurring diarrhoea, but this can at once be cleared up by an examination with the sigmoidoscope. In true ulcerative colitis the temperature is almost always raised 1° to 2° F. at night. Blood is more or less constantly present in the stools, and wasting is a marked feature of the case.

The best treatment for ulcerative colitis is appendicostomy, and I have seen very many really desperate cases recover as a result of this operation, which I and those associated with me were certain must otherwise have died. Unfortunately the surgeon is too often only called in when the patient is already very seriously ill and the ulceration has become very extensive. The operation should be performed at a much earlier stage of the disease, and recovery would be then much more rapid and more certain.

In true ulcerative colitis non-operative treatment appears to be of very little use. Even when recovery does occur it is a slow and tedious process. One of the reasons for this is that the ulcerated surface is very large and cannot be directly dealt with. Douches and enemas cannot be tolerated in sufficient quantities to ensure that they reach the whole of the diseased area.

Appendicostomy acts in two ways. The first and most important action is to allow of the large ulcerated area being kept clean and free from pus and accumulated discharge. The frequent washing of the colon by removing the products of inflammation allows the ulcers a chance to heal, and to a large extent prevents the absorption of septic by-products into the blood.

The second important action is to compensate for the great loss of body fluid, which is always present owing to the constant diarrhoea. Many of these patients are wasted till they are little more than skin and bone, and it is often quite remarkable to see the improvement that follows

frequent irrigation of the colon through an appendicostomy opening.

As already stated, the proper time to perform appendicostomy is as soon as the condition has been diagnosed; but in practice it has been my experience that the surgeon is usually not called in until medical treatment has been tried for months and failed. Then when appendicostomy is suggested it is argued that the patient is in such a poor condition that he will not stand the operation. This is, however, not the case, as the operation can quite well be performed under local anaesthesia without running any risk at all.

In a bad case the patient should after the operation be treated by continuous saline irrigation for six or eight hours at a time. This is easily arranged by using a metal bed-pan with a tap and a rubber tube attachment. Very careful nursing is, however, necessary to prevent the formation of bedsores.

As soon as the diarrhoea has been checked and improvement has set in, a 3 or 4 pint wash through twice or three times a day will be sufficient. On no account should any antiseptic be added to the fluid used for irrigation, as poisoning symptoms are almost sure to result. Solutions of silver nitrate or protargol can be used, but in the case of the former only for a short time. I have seen a very bad case of staining of the skin with silver which resulted from frequent washing through with silver nitrate. Salt water seems to give the best result in most cases.

There still are people who think that an appendicostomy opening is an objectionable thing and that it results in the escape of gas and faeces. This is, of course, not the case with a properly made opening. In ulcerative colitis the opening should be kept patent for at least six months after all symptoms have subsided, but after this it may be allowed to close, which as a rule it will readily do.

CONCLUSIONS.

1. Chronic ulcerative colitis is a very serious and often fatal disease.
2. The best treatment is by frequent washing through with saline solution after an appendicostomy opening has been established.
3. The operation should be performed as soon as a diagnosis has been made and not left as a last resort, although it may sometimes succeed even then.
4. The diagnosis should always be confirmed by sigmoidoscopy.

FIBROIDS COMPLICATING PREGNANCY: HYSTERECTOMY: RECOVERY.

BY

R. DE S. STAWELL, O.B.E., M.B. CANTAB.,

F.R.C.S. ENG.

HONORARY SURGEON, BASCHURCH SURGICAL HOME, SREWSBURY.

PREGNANCY with fibroids of the uterus, especially subserous ones, is, of course, not uncommon, but a case which I have recently had to deal with presented somewhat unusual features, and showed what a remarkable condition may be associated with a normal menstrual history and pregnancy, in the early months.

A healthy nullipara of 38, from whose mother I had, by the way, removed an ovarian cyst and subserous fibroid some years ago, had been married fourteen months, and the menstrual periods, which had always been perfectly regular and normal, had ceased for four and a half months. She had had some morning sickness, and the breasts were enlarged and tender. Pregnancy had therefore been diagnosed, but no suspicions of abnormality aroused. I was sent for on account of troublesome vomiting for two days, constipation, and sharp abdominal pain.

A rounded movable tumour, about the size of a fetal head, was felt in the upper abdomen as high as the ensiform cartilage. It was attached below to what appeared to be a pregnant uterus reaching well above the umbilicus, irregular in shape, and unduly high up. On vaginal examination the pelvis was found to be occupied by a large fixed firm rounded mass lying between the rectum and vagina, and displacing the uterus upwards, so that the cervix could only just be reached round the front of the tumour. A diagnosis of fibroids complicating pregnancy was made, and operation advised, as, owing to the size and position of the tumours, symptoms suggestive of commencing pressure, and the risk of degeneration and infection, it seemed unsafe to wait for viability of the child.

The patient was brought into a nursing home; an euema produced a fair result, the sickness and pain ceased; her general condition was good. A catheter, passed with a little difficulty, showed no distension of the bladder.

Operation.

In the Trendelenburg position, under ether, skillfully given by Dr. A. Simpson with Shipway's apparatus, an incision was made from the pubes to well above the umbilicus. A gravid uterus was revealed, covered with subserous fibroids of all sizes; many were small, but from the fundus grew two large pedunculated masses, each the size of a fetal head. These were delivered from the wound with the uterus. On lifting the viscus forward sharp haemorrhage occurred from the posterior part of the cervix, where it was attached to the pelvic tumour. There were many large veins, and everything was very vascular. The bleeding could only be controlled by pressure with pads, for it took place from a considerable torn surface in dense tissue, and no vessels could be secured. Efforts to bring up the pelvic mass, which was extra-peritoneal, by traction with strong vulsella, helped by the pressure of an assistant's fingers in vagina and rectum, failed. In view of the risk of meeting with uncontrollable bleeding if further attempts were made to remove the pelvic block, hampered as one was by the presence of the bulky uterus, it was judged that the right course was to diminish its size and vascularity, at the cost of the child. Pituitrin was therefore injected, the uterus incised where it was free from growths, and the fetus and placenta removed. The edges of the incision were clamped together, and haemorrhage quickly arrested. In spite of the advantage now obtained it seemed impracticable to save the uterus, and a subtotal hysterectomy was performed, the ovaries being spared. On the right side a small dermoid cyst, intimately adherent to the pelvis, was encountered, but left to be dealt with if necessary subsequently. The peritoneum over the pelvic fibroid was now freely divided and separated off, and the tumour brought up with the vulsellum sufficiently to give room for the fingers being worked down and round it, gradually encircling it from its bed, a watch being kept for the ureters. No definite connexion with the cervix could be identified. Haemorrhage was readily arrested, all peritoneal edges brought together with catgut sutures, and the abdomen closed.

The patient made an uninterrupted recovery, and was back at home in three weeks.

The case was of special interest to me in connexion with Dr. Herbert Spencer's Lettsomian lectures. Dr. Spencer states that he has never found it necessary to remove a uterus in the early months of pregnancy, and expresses the opinion that the practice of hysterectomy in this condition is much too common, but I believe the difficulties encountered in this case justified what I did.

Instead of panhysterectomy, subtotal hysterectomy was performed, as the position of the cervix made it easier; nor did I split the cervix for drainage, as Sir John Bland-Sutton suggests, as all looked so dry and tidy that I was tempted to leave it.

On section the tumours presented the ordinary appearance of myomata, no "red degeneration" being observed; but the pelvic fibroid showed signs of fibrocystic change. This, Dr. Herman states, is often associated with rapid growth, which presumably was the case here.

PHAGEDAENA OF HUNTERIAN CHANCRE

FOLLOWING TREATMENT WITH NOVARSENOENZOL.

BY

H. M. HANSHELL, D.S.C., M.R.C.S. ENG.,

L.R.C.P. LOND., D.T.M. AND H. CAMB.,

PATHOLOGIST SEAMEN'S HOSPITAL, ALBERT DOCK; DIRECTOR
VENEREAL DISEASES CLINIC.

In both these cases there was bacterial infection of the Hunterian chancre. In both chancres, bacteria, and the "reacting" tissue became more or less completely shut up together by the very effect of the reaction on the tissues around the chancre.

CASE I.

A labourer, aged 39, six weeks after coitus, noticed a painless lump on the under side of the penis, and three days later a "running," thin at first, then thicker. During the ensuing seven days he noticed slowly increasing discharge and difficulty in passing water, but had no pain. He denied previous gonorrhoea or chancre.

Examination showed a thick yellow discharge from meatus, and, on micturition, thin, twisted, interrupted stream. On the ventrum of the penis, in the line of the urethra, about 4 cm. from the meatus, could be seen and felt a dull red, hard mass, 1 by 0.5 cm., not tender, apparently including the urethra. The inguinal glands on both sides were large, hard, and discrete. There was no rash. No attempt was made to pass instrument.

Pending the result of laboratory investigation, irrigation of the anterior urethra with 1 in 4,000 potassium permanganate solution daily was ordered.

The Wassermann reaction was negative. Smears from the mental pus (Gram and Fontana-Tribondeau) revealed staphylococcus in pure culture and numerous *T. pallidum*, but no other micro-organisms.

When the patient was seen again, three days later, the only appreciable change in the local condition was easier micturition, the stream, still very thin, being continuous; 0.3 gram of novarsenobenzol was injected intravenously at 4 p.m. The patient returned at 5 p.m. next day; he stated that he had noticed no effects at all from the injection, until on rising that morning he had experienced great difficulty—"just a drop at a time"—in passing water, and the lump on the penis was larger and redder. He had gone to work, but had been unable to micturate all day, and was now in great pain. The temperature was 102.4° and the pulse 96. There was redness and oedema of the prepuce, especially the ventral portion, but no discharge from urethra. The lesion on the under side of the penis had become a hot, deep-red, semi-fluctuating tumour, its apex soft and purple; the whole mass was continuous with the ventral portion of the inflamed prepuce. The dorsum penis was apparently unaffected, except that a hard mass in the mid line, 1 cm. long, could be felt through its thickness at the level of the ventral lesion. Exploration with fine gum-elastic bougies showed an impassable stricture about 4 cm. from the meatus.

At 6.30 p.m. general anaesthesia was induced; the whole apex of the tumour was gangrenous. Circumcision was done and all the sloughing tissue removed. Stinking pus escaped and the gangrene was found to extend to a fistula into the urethra. Distal to this fistula the lumen was completely closed by the hard, inflamed urethral wall, a sort of solid cylinder of hard chancre. In smears from the pns only staphylococcus was found. Twenty-four hours after the operation a No. 6 gum-elastic bougie could be passed easily from the meatus along the urethra and through the fistula. Healing was rapid; the fistula closed in three weeks. Later injections of novarsenobenzol produced no ill effects; five days after operation 0.6 gram was injected intravenously; seven days later the Wassermann reaction was definitely positive.

CASE II.

A seaman, aged 26; fourteen days previously while at sea had sore, first noticed as small painless pimple on the penis; this was about seven weeks after coitus. He denied previous gonorrhoea or chancre.

Examination showed redness and oedema of the prepuce, which, with a little difficulty, was retracted to expose the ulcer (2 by 1 cm.) on the mid dorsum of the glans; the raw surface did not quite reach the corona. The base of the chancre was formed by raised red granulations, spotted with small grey sloughs; the edges were heaped, hard, rounded, sloping into the ulcer and into glans tissue. In front and at the sides induration extended for about $\frac{1}{2}$ cm. into the glans tissue; it continued above over corona into the sulcus and inner surface of the prepuce, in this last situation giving a cartilaginous feel, the plaque flicking over on its edge. No part of the lesion presented any of the characters of a soft chancre, nor were any ulcers detected elsewhere on the glans or inner surface of the prepuce. Urethritis was not present. In both groins were large hard discrete glands. There was no rash.

Circumcision was suggested; more cannot be said, for it was not pressed against the patient's reluctance to submit to operation. Pending the result of laboratory investigation, irrigation of preputial sac daily with 1 in 4,000 potassium permanganate was ordered. Smears from chancre (Fontana-Tribondeau) revealed mixed bacteria and numerous *T. pallidum*. No other micro-organisms were detected. The Wassermann reaction was doubtful.

Three days later 0.3 gram novarsenobenzol was injected intravenously at 4 p.m. The patient was seen again at 11 a.m. next day (nineteen hours after the injection); he had noticed no ill effects. There was great increase of the oedema and redness of the prepuce; with great difficulty, however, retraction was possible sufficiently to expose the chancre and corona glandis. The ulcer itself appeared clean, without sloughs, but much swollen and a darker red. The glans tissue around was swollen, very red, and patched with purple blotches—a bruising effect. The Jarisch-Herxheimer reaction was diagnosed, and in the expectation that the local condition would now rapidly improve, irrigation of the sac was repeated and the patient told to return next morning. Alarmed, however, by the size of the penis and by blood escaping from the preputial opening, he stayed in bed "to rest it." He appeared at the clinic at 3 p.m., scared and in great pain. The temperature was 103° and the pulse 110. The swelling and redness of the prepuce were now extreme, and from the opening dripped blood; retraction was possible only so far as to expose the edge of a loose grey slough overlying the meatus.

Under general anaesthesia circumcision was performed. A grey-black, stinking slough replaced the whole of the glans down to the urethra, all the corpus spongiosum being destroyed except the corona glandis, a buttress on each side of the urethra, and a thin "washer" of tissue, including the meatus. The urethra was intact.

No further destruction occurred; granulation was rapid under eusol baths and wet dressings. The circumcision wound healed quickly, no chancroids appearing on its cut edges. The inner surface of the excised prepuce was carefully examined, but showed no sign of ulceration anywhere.

Seven days after the first injection the Wassermann reaction was found to be definitely positive.

Further treatment by novarsenobenzol caused no ill effect.

It seems reasonable to conclude that the effect of the "reaction" is to damage still further the chancre tissue already damaged by the treponema. Deeper invasion of the tissue may then readily ensue by the bacteria already present in the chancre, and, the whole being shut up together, phagedaena results.

Not to labour the obvious moral of Case II, I confess I should have operated on almost any one of the four days before that on which, in fact, the operation was performed.

A CASE OF CERVICAL CARIES SIMULATING CEREBELLAR TUMOUR.

BY

RICHARD R. ARMSTRONG, M.D. CANTAB., M.R.C.P.,
PHYSICIAN IN CHARGE OF THE CHILDREN'S DEPARTMENT, CHARING
CROSS HOSPITAL; ERNEST HART SCHOLAR, BRITISH
MEDICAL ASSOCIATION.

IN an exhaustive paper published in *Brain*, Part xvi, 1901, Taylor and Collier drew attention to the occurrence of optic neuritis associated with lesions of the cervical cord, and showed that both headache and vomiting of cerebral type may occur with such lesions. The following case appears to be of interest as an example of this association, and indicates the very great importance of accurate diagnosis, for, whereas the treatment of cervical caries is essentially conservative, if an intracranial tumour be present operative procedures often hold out the only, albeit slender, hope of successful treatment.

History.

A boy, aged 7 years, was admitted to the children's ward of Charing Cross Hospital for stiffness of the neck which had lasted about three months. His mother stated that for two months he had walked as if paralysed, and had frequently fallen. He often complained of headache, particularly in the back of the head, and occasionally vomited, the vomiting being unassociated with the taking of food. A week before admission to hospital he developed a squint in the left eye.

Condition on Admission.

A slight, pale child, preferring to lie quietly in bed, he was usually drowsy, but when roused was conspicuously intelligent and docile. The head was held rigid and erect in the mid-line and definitely increased tonus of both trapezii and both sternomastoids was present, notwithstanding which movements of flexion and extension of the head and lateral movements were free and unaccompanied by pain. The boy's action when stooping to pick up a coin from the floor was stiff and awkward and strongly reminiscent of spinal caries, and when he was first seen in the out-patient department a tentative diagnosis of caries of the cervical spine was made.

Condition under Observation.

On more thorough examination well marked optic neuritis, estimated at over two dioptries of swelling, was found in both eyes; pupillary reactions were normal. All reflexes were present but difficult to obtain; no evidence of altered sensation could be found, but the seven cardinal signs of a cerebellar tumour of the left side were each in turn elicited and became more marked during the fortnight that the case was under observation, namely:

1. Inco-ordination of movements of the left arm and hand as compared with the right, dysdiadochokinesis of the left hand.
2. Bárány's test of deviation to the left on pointing with closed eyes to a stationary object a succession of times was obtained.
3. Tendency in walking to lean and to deviate to the left side—not definitely marked while crawling on all-fours.
4. Left hypotonia affecting both arm and leg.
5. Muscular weakness on the left side, particularly of the left arm.
6. The head was slightly asymmetrical in shape, the left occipital region being fuller than the right.
7. The attitude of the head, though not characteristic, was consistent with the presence of a left cerebellar tumour encroaching on the mid line.

The radiographer's report on a skiagram of the head and neck was to the effect that no evidence of spinal caries was present. No abnormality could be detected in the posterior fossae of the skull. There was no dysphagia, and nothing could be seen in the throat. In the absence of any definite indication a digital examination of the pharynx was not made, nor was a pharyngoscopic examination attempted.

Operation.

Symptoms and physical signs were in favour of cerebellar tumour, and this view was confirmed by others who examined the case. The progress of symptoms and increasing optic

neuritis indicated the need for operative interference, and subtentorial decompression by the Cushing method, combined with exploration of both lobes of the cerebellum, was performed by Mr. Norman C. Lake. On incision of the dura there was no gush of cerebro-spinal fluid to indicate increased tension, and both lobes were pulsating normally; the left, although more prominent than the right, was otherwise normal. Regrettably death occurred from respiratory failure just as the operation was successfully completed.

Post-mortem Examination.

Nothing abnormal was found in the brain to account for the optic neuritis, and there was no evidence of increased intracranial pressure. A retro-pharyngeal abscess was found behind the anterior common ligament, embracing the bodies of the third and fourth cervical vertebrae and communicating by a fistula with a cavity in the centre of the fourth cervical, from which the abscess had extended into the spinal canal and had caused pressure on the adjacent spinal cord. There were tuberculous lymphatic glands in the neck.

Despite the unfortunate termination of the case, it is difficult to see what other diagnosis could have been made on the basis of the observations recorded above.

The diagnosis of cervical spinal caries made when the case was first seen was given up with some reluctance, and the suggestion tentatively advanced that two separate lesions were present, respectively intracranial and intrathecal, but this in turn was surrendered in view of the apparently overwhelming evidence in favour of cerebellar tumour.

The case, however, affords an admirable example of how closely lesions of the upper cervical cord, especially at the level of the third cervical segment, may simulate intracranial tumour; it possesses the further interest of occurring in a child aged 7 years, the youngest in Taylor and Collier's series being a girl of 15.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ENCEPHALITIS LETHARGICA.

R. R., aged 18, who had never had any previous illness, nor any discharge from the ear, nor nasal catarrh, played football on October 25th. That night he had a shivering attack and headache. He stayed in bed next day (Sunday). When I saw him on October 27th he complained of headache, chiefly in the left parieto-temporal region; the temperature was 102° F. As he continued in this state and was slightly lethargic, I sent a specimen of his blood for examination, thinking he might be suffering from typhoid fever, but it was returned "definite negative." He continued in the same condition another week. As he got more heavy and drowsy, and the tongue was thickly coated, the blood was sent again for examination, with the same result. At this time, about fourteen days from the commencement of the illness, a rotheln-like rash appeared on the body and limbs, and lasted several days. There was some bronchial catarrh at both bases; the temperature varied between 101° and 103°. The pulse was 55 to 60. The pain was still very severe, affecting chiefly the left side.

About November 14th he had slight left ptosis, and dilatation of the pupil on the same side. For about a week vomiting was very troublesome. On November 16th lumbar puncture was performed; the fluid was clear and under slight pressure. Dr. Davies, M.O.H. for Bristol, kindly reported that there was no excess of polynuclear cells and no meningococci in the film, and that on cultivation meningococci and other organisms were not grown; reducing substances were present in normal amount, and the globulins were not increased. There was no retraction of the head, and Kernig's sign was not present. The temperature about this time came to normal, and except for two days remained so for the rest of the illness.

About November 20th he had a well marked right-sided convulsion lasting several minutes. He was still distinctly lethargic; he objected very much to the light. I now thought it might be a case of encephalitis lethargica, and I asked Dr. Charles, of Clifton, to see him with me in consultation. The patient was better on this day than he had been for some time. Dr. Charles agreed with the diagnosis; he also noticed slight right facial paralysis. It had not been present on the previous day; on the following

day it was worse. On November 25th there was partial paralysis of the left arm and left leg. The knee-jerks were absent. About this time he became aphasic. Early in December he developed paralysis of the soft palate, and had great difficulty in swallowing; for two days he took nothing, but this gradually passed off. For several days he had repeated attacks of spasmodic contraction of both arms, got very red in the face, and perspired over the forehead. He was now lying in a completely lethargic condition; cerebation was very slow; when asked to put out his tongue, after about four seconds the tongue would slowly come out. Both pupils were very dilated.

On December 23rd he had a general convulsion, and afterwards was completely blind. On January 1st he was very lethargic, control of sphincters was lost, and emaciation was becoming marked. He remained in this condition until January 17th, when he had repeated attacks of spasmodic contractions of both upper extremities, the legs not being affected. He died the same evening after nearly three months' illness. The trained nurse who looked after him aptly described it as a "living death." As far as treatment was concerned I tried hexamine but it seemed to have no effect; so very little seemed possible beyond nursing and feeding. A stained specimen of the blood appeared normal. The discs were a little pale but otherwise normal; the urine was normal. No post-mortem examination was obtained.

Bristol.

MAURICE C. BARBER, M.B., Ch.B.

PNEUMONIC HAEMORRHAGIC EFFUSION INTO PLEURA.

The case described here is sufficiently rare to make it worth recording.

A single woman, aged 32, had been attended by me early in March, 1919, for a mild attack of influenza followed by slight icterus. From this she recovered completely. On April 26th I was sent for urgently; she had had a rigor, and the temperature was 104°. She was very ill; the pulse was 108. Respirations were normal, and no physical signs could be detected. That night the temperature dropped to 100.6°. For the next three days it was irregular, gradually rising to 103.4° on April 29th. The pulse was never very rapid and did not rise beyond 106. On this day the respirations were 26. During this time marked dullness became manifest over the lower portion of the right lung with general signs of consolidation. On April 30th she appeared so ill that I got Dr. Carey Coombs to see her with me. An exploratory needle was passed into the dull area, but the syringe filled quickly and easily with pure blood. Dr. Scott Williamson, pathologist, who examined this, reported that it was pure blood containing pneumococci, and expressed the opinion that probably the lung was infected with the pneumococcus and had been penetrated by the needle. The temperature now became hectic, never rising above 102.8° in the evening; respiration ranged from 28 to 32 and the pulse from 116 to 138. As there were no signs of the lung clearing up, on April 12th an exploratory needle was again used, and a few drops of blood stained serum drawn off.

Her general condition continued to deteriorate, and on April 17th I drew off 1 drachm of thin pus. On April 18th Dr. Coombs again saw the patient with me, and, tapping more towards the axilla, 15 oz. of serum beginning to get purulent were drawn off. The next day Mr. Lansdown resected a rib, and removed, in addition to a quantity of thin purulent serum, large masses of old blood clot. From this time onwards she made an uninterrupted recovery, and now the right lung expands fairly well.

It is clear that there was pneumococcal infection, and that the lower lobe of the right lung was infected. This infection was apparently so virulent that extensive haemorrhage into the pleura took place, and it must have been some of this blood which was first drawn off. The failure to obtain more than a few drops of fluid on the two next occasions was probably due to the needle pushing the blood clot in front of it, and never entering the main effusion. The theory that the blood originally drawn off was from the pleural cavity and not the lung is strongly supported, though perhaps not absolutely proved, by the large masses of clot removed from the pleural cavity at the operation.

Wrington.

HUFERT C. BRISTOWE, M.D. Lond.

SUPPURATIVE ARTHRITIS AND PERITONITIS AFTER ACUTE BRONCHOPNEUMONIA.

DURING a recent epidemic of measles I saw a girl aged 5 years with a typical attack, but with more severe catarrhal symptoms than usual. She subsequently developed bronchopneumonia, which resolved in about a fortnight.

She did not improve, and complained of pain in the left hip. There was limitation of abduction and rotation of the left thigh, the knee was flexed, and a large abscess developed over the hip-joint. I opened and cleaned out the abscess, and applied extension with a Thomas hip splint. The abscess drained well and healed quickly. The temperature, however, became irregular, and she was extremely ill, complaining chiefly of pain in the abdomen, which in a week became tense, swollen, rigid, and shiny. The temperature fell to normal and the pulse rate increased. Free fluid was recognized in the peritoneal cavity. While making preparations for a laparotomy, pus to the extent of three pints burst through the umbilicus. She made an uninterrupted recovery, and is to-day quite healthy and strong, but with half an inch shortening of the left leg.

The case is of interest in so far as the question arises, What was the origin of the arthritis and peritonitis? They may both have been tuberculous, but in neither situation were tubercle bacilli found in the pus. The rarity of purulent effusion in tuberculous peritonitis is somewhat against it being tuberculous. She had no signs of tuberculosis of the lungs, nor were there any tubercle bacilli in the sputum. In the pus from both parts pneumococci were found, and the sequelae must have been a pneumococcal arthritis and a pneumococcal peritonitis.

The latter may have been caused by a spread of infection from the lungs through the subdiaphragmatic lymph channels, but it is more probable that both conditions were of haemic origin, and secondary to the bronchopneumonia.

Wrexham.

A. LLOYD DAVIES, M.B.

Reports of Societies.

EARLY RECOGNITION OF SYPHILIS.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, held on March 19th, the PRESIDENT, Mr. A. Ernest Maylard, being in the chair, Dr. W. H. BROWN made a "plea for the early recognition of syphilis," and cited cases from the army in which the diagnosis of syphilis was not made nor effective treatment begun until eight or ten weeks from the date of the man's reporting with a venereal sore, by which time the secondary eruption had appeared. Such faulty or delayed diagnosis increased the risk of the man's spreading the disease, prolonged his treatment, and diminished his chance of complete cure. Statistics showed that the longer the delay in treatment the worse the prognosis. Thus early primary cases with negative Wassermann reaction showed after full treatment 100 per cent. of negative reactions; late primary cases, with Wassermann becoming positive, showed after treatment 75 to 85 per cent. with negative Wassermann; while secondary cases showed after treatment only 60 per cent. with negative Wassermann. The fact that the central nervous system was early affected in syphilis increased the danger of delay. As to diagnosis, every venereal sore should be regarded as possibly syphilitic until it had been proved not to be, and the possibility of syphilis should not be excluded until the patient had been under observation for two, and preferably three, months, and at the end of that time given a negative Wassermann reaction. Dr. Brown then enumerated the points to which attention must be paid for the recognition of a primary syphilitic sore. It must be remembered that a double infection might occur at the same time, and on the same or different sites, by Ducrey's bacillus and *S. pallida*. Consequently what was clinically a soft sore might, after a short incubation period, assume the characters of a syphilitic chancre after the necessary incubation period of three or four weeks; or a chancre might follow a soft sore, but on a different spot.

In some cases judgement must be suspended till the aid of laboratory methods—dark-ground examination of serum from sore for *S. pallida*—had clinched the matter; there should always be close co-operation between the clinician and the bacteriologist. A large series of coloured drawings and photographs was shown in illustration of the appearances described.

Clinical Cases.

Dr. WILLIAM RANKINE reported two cases of ruptured jejunum.

1. A man, aged 19, who had fallen from a scaffold, landing on his abdomen, presented no external abrasion, but was collapsed and in great pain, with a very rigid abdomen. Operation a few hours later revealed an almost completely transverse tear of the jejunum, which was sutured. Patient was dismissed well on the twenty-second day.

2. A man who, having fallen down the hold of a ship and struck some beams in falling, presented a fracture of the crest of the ilium and blood in the urine. At operation, seven hours later, two tears were found in the upper part of the jejunum, which were sutured. Patient was seriously ill for four days but ultimately made an excellent recovery.

Dr. Rankine reported also a case of diaphragmatic hernia operated on through the pleural cavity.

The patient, a boy aged 8, had his abdomen run over by the wheel of a motor bread van, was in great pain and presented some bruising and a rigid abdomen. An exploratory incision above the umbilicus showed that the spleen and greater part of stomach had been displaced into the left pleural cavity through a large tear in the diaphragm. The abdominal wound was closed and an osteoplastic flap, including portions of two ribs in the axillary and posterior regions of the left thorax, was turned up to give free access to the pleural cavity. Through this the organs were replaced without difficulty and the tear in the diaphragm sutured.

The patient was dismissed well after twenty-five days, and when seen at the meeting (five and a half years later) showed no abnormality of the chest or lungs.

Dr. G. HERBERT CLARK reported "An undescribed condition of infancy and its treatment." The condition had been identified in two children, one of whom was now normal and the other slowly becoming so. The outstanding symptoms were idiocy, depression, fibrillary twitchings in the muscles, jerking movements of the limbs, convulsions, and inability to balance.

The first patient had been apparently normal till the age of 4 months, when the fits and startings began. When first seen, in 1910, at the age of 15 months, he had a well formed and plump body, a large head, with open anterior fontanelle, an abnormal staring and apparently unseeing condition of the eyes, and presented all the symptoms mentioned above. Examination of the electrical reactions gave inconclusive results. Neither carpo-pedal spasm, Trousseau's nor Chvostek phenomena were ever present. As the symptoms seemed to resemble those produced in animals by removal of the parathyroids, the effect was tried of feeding with thyroid gland tablets containing parathyroid as an impurity. On a dose of $\frac{1}{2}$ grain twice daily the child improved rapidly, was free from fits and twitchings after three weeks, and was now absolutely normal. The tablets were continued for six months, and then gradually stopped.

The second child was a girl, who had been fairly normal till about a year old, and then began to have twitchings, startings, and convulsions, with apparent indifference to surroundings and growing depression. When first seen, in September, 1919, she was aged $2\frac{1}{2}$ years, well formed, plump, with satisfactory dentition, but the anterior fontanelle not quite closed. The symptoms were similar to those in the other case. On October 16th the child was ordered parathyroid tablets, $\frac{1}{2}$ grain thrice daily; fits, startings, and twitchings at once began to diminish, and quite ceased by October 24th. The child improved in alertness, took notice of her surroundings, played with toys, and could sit up and even stand. On October 27th parathyroid treatment was discontinued, and the fits, which had been absent for five days, at once recurred with violence. By the end of the week the child was rapidly falling back into the state on admission. To ascertain the effect of thyroid gland, this was given for a week in small doses ($\frac{1}{2}$ grain t.i.d.) so as to exclude any effect of possibly present parathyroid, but without benefit. On November 10th parathyroid was resumed, and by the end of a week most marked improvement had taken place. This was maintained, and when seen on March 9th the child was running about, playing and trying to talk. The condition described was illustrated by numerous photographs of both children taken before, during, and after treatment.

A CONFERENCE on the prevention of diseases of the teeth will be held at Manchester on May 13th-15th. Particulars may be obtained by sending a 1½d. stamp to the Food Education Society, Danes Inn House, 265, Strand, W.C.2.

Rebiefus.

VISION AND COLOUR VISION.

In the *Physiology of Vision*¹ Dr. EDRIDGE-GREEN gives us the results of researches which have been spread over thirty years, gathered together from the various scientific journals in which the original papers appeared; the whole forms a most fascinating volume, which should appeal not only to the ophthalmic surgeon but also to the general reader.

The author has had the satisfaction of seeing his views, which at first met with a good deal of opposition, now generally accepted by the majority of physiologists and ophthalmic surgeons, while his colour-testing lantern is now in common use for testing candidates for the Royal Navy, signalmen, and others. The contents of the volume can be conveniently arranged in two parts: in the first, the physiology of vision is discussed, chapters being devoted to dioptries, accommodation, defects of the eye as an optical instrument, the action of light on the retina, the origin of visual impulses, light and dark adaptation, after-images and binocular vision; the important points are grouped together at the end of this section of the volume in a very convenient summary. The second part deals more particularly with colour vision; chapters are devoted to the sensations caused by simple and mixed lights, the simple character of yellow sensation, methods of examining the colour sense, hexachromic and heptachromic vision, colour blindness, the evolution of the colour sense, trichromic vision and anomalous trichromics, simultaneous and successive contrasts, and colour adaptation; here again the important points are summarized at the end of particular sections. The two final chapters deal with the author's theory of colour vision and with his objections to the other theories.

After describing his spectrometer, lantern, bead test, and card test, Dr. Edridge-Green insists that experiments on colour vision need as much care as those in any other branch of science, and points out how the results of experiments may be vitiated by imperfect apparatus, such as coloured papers, and by the admission of stray light. He has given in all cases the full experimental grounds on which he has based his theories, and when he has rejected the results of former experiments he has given his reasons for doing so; finally, he points out how necessary a knowledge of the laws of colour contrast is to the designer.

The author is to be congratulated on his book, which deals very ably with what is admittedly an extremely difficult subject. We imagine that the majority of his readers will agree with his deductions.

We have also received a copy of the author's *Card Test for Colour Blindness*,² in a neat case. The principle of this test is, that on a ground of spots of one colour a letter is formed in spots of another colour, the shape, number of spots, and relative position is the same in each of the twenty-two cards, the only way of distinguishing the spots which form the letter being a difference of colour from that of the other spots. Each card is designed with a special purpose; the colours correspond to portions of the spectrum which, when isolated, appear all of a uniform colour to a class of the colour-blind, while special cards have been designed to catch cases of shortening of either end of the spectrum. We have not yet had an opportunity of examining a case of colour-blindness with this test, but the cards appear to form a very handy and convenient addition to the armamentarium of the ophthalmic surgeon.

INDUSTRIAL MEDICINE AND SURGERY.

SCIENTIFIC management in industry has been studied with increasing vigour for many decades. At first this study concerned itself with the mechanical factors tending to increase output and with the cutting down of expenses of manufacture. Latterly, however, the working man and woman have also received the attention of scientific managers, and the attempt has been made to improve output and effect economy by studying the health of the

worker, and endeavouring to keep him physically fit for his job. The special forms taken by medical and surgical practice in striving to attain this object are set out by Dr. Mock in his large volume on *Industrial Medicine and Surgery*,³ which is based on the author's nine years' experience as chief surgeon to one of the largest industries in Chicago. Here are correlated the demands of industrial practice, medicine, surgery, and the principles of social and economic development. The book is divided into six parts. The first outlines an industrial health service, and gives details of the aims of industrial sanitation, a branch of preventive medicine. Part II deals with the prevention of ill health and accidents in industry on broad lines. Part III gives an account of the part played by industrial medicine in works—the medical examination and treatment of the employees, with a special chapter on tuberculous workers. The fourth part is on industrial surgery, wounds, infections, fractures, x-ray diagnosis, and the like. Part V is concerned with compensation, insurance, and the medico-legal questions generally that arise from industrial accidents and diseases. The last part is given to reconstruction, the reclamation of the disabled to which the war has given so great and desirable an impetus.

Dr. Mock writes with the authority and conviction of wide experience, and if in some matters he seems to set his ideals rather high, and to demand an over-Prussian or grandfatherly regimentation of the workers for their good, in many others he is able to show the excellent effects that have followed the adoption of high ideals for working measures. In matters concerning the health of the individual much depends upon the attitude towards interference by the State, the employer, and the medical expert, taken up by the individual concerned.

The style is clear and shows a highly practical spirit, and in order to widen his audience Dr. Mock has made his text as free from technical language as possible. His book may be cordially recommended to the attention of medical men with an industrial practice, and still more to laymen such as employers, industrial engineers, social workers and others, who are awake to the necessity for improving the conditions under which manual labour is performed. Here they will find plenty of practical suggestions for improvements, and countless indications for the directions in which improvements must be made.

TOTEM AND TABOO.

THE study of social anthropology is a development of relatively recent growth, and though an enormous number of facts has now been collected from various sources, the theories suggested to explain the facts are by no means always convincing. Professor FREUD, in a volume a translation of which by Dr. BRILL has been published under the title *Totem and Taboo*,⁴ has attempted to elucidate the origin of primitive customs by applying the results of psycho-analysis to the problems of racial psychology. Since psycho-analysis is essentially concerned with primitive impulses and regressive modes of thought in the individual, its conclusions, it is suggested, may shed some light on similar modes of thought and action amongst primitive races.

The first chapter is devoted to the question of exogamy, a marriage prohibition which has been regarded as a protective measure against incest. There are, however, difficulties in the way of accepting this rather obvious explanation; it seems to be established, for instance, that certain Australian tribes, the most primitive of existing races, do not connect the sexual act with impregnation, and believe that a woman may become pregnant by merely passing through certain forbidden places. Freud contends that this alleged incest dread is in close agreement with the psychic life of the neurotic: he reports some psycho-analytic observations offering, as he thinks, evidence as to the significance of the primitive mother-in-law prohibitions, which he suggests are more difficult to explain than those which concern near relations. In the chapter

¹ *Industrial Medicine and Surgery*. By Harry E. Mock, B.S., M.D., F.A.C.S., Assistant Professor of Industrial Medicine and Surgery at Rush Medical College, etc. Philadelphia and London: W. B. Saunders Co. 1919. (Roy. 8vo, pp. 846; 210 figures, 42s. net.)

² *Totem and Taboo. Resemblances between the Psychic Lives of Savages and Neurotics*. By Professor Sigmund Freud, LL.D. English translation, with introduction, by A. A. Brill, Ph.D., M.D. London: George Routledge and Sons, Ltd. 1919. (Demy 8vo, pp. xii + 268, 10s. 6d. net.)

¹ *The Physiology of Vision, with Special Reference to Colour Blindness*. By F. W. Edridge-Green, M.D., F.R.C.S. London: G. Bell and Sons, Ltd. 1920. (Demy 8vo, pp. xii + 280; 25 figures. 12s. net.)

² *Card Test for Colour Blindness*. By F. W. Edridge-Green. London: G. Bell and Sons, Ltd. (In leather envelope case, 25s. net.)

on taboo and the ambivalence of emotions a comparison is drawn between taboo and a compulsion neurosis, and it is suggested that "All taboo phenomena . . . become unified if we sum them up in the following sentence: The basis of taboo is a forbidden action for which there exists a strong inclination in the unconscious." This theory is worked out in considerable detail, but whether the proposed limitation of the definition of taboo can be established demands a fuller acquaintance with the subject than Professor Freud appears to possess. The parallel drawn between the psychic life and primitive customs of the savage and the mental mechanisms and abnormal impulses of the neurotic is unsound.

In the last two essays animism, magic, and totemism are considered. While recognizing that these subjects are exceedingly complex and cover a wide range, Professor Freud appears to commit himself to the opinion that psycho-analytic studies afford suggestions as to the possible origin of these religious-social customs; his discussion of the conclusions of leading ethnologists is of doubtful value, although the industry with which he has made extracts from the voluminous literature of the subject may be commended. In closing his study on totemism Professor Freud produces his King Charles's head, concluding that the beginning of religion, ethics, society, and art meet in the Oedipus complex. This, he adds, is in entire accord with his reading of psycho-analysis—"namely, that the nucleus of all neuroses as far as our present knowledge of them goes is the Oedipus complex." But in a footnote he adds the customary ambiguous qualification:

I am used to being misunderstood, and therefore do not think it superfluous to state clearly that in giving these deductions I am by no means oblivious of the complex nature of the phenomena which give rise to them; the only claim made is that a new factor has been added to the already known or still unrecognized origin of religion, morality, and society, which was furnished through psycho-analytic experience.

In commenting upon his conclusions it may be said that while many authorities will admit the probability that dread of incest has some relation to exogamy, the numerous theories suggested at one time or another to explain the origin of prohibitions against marriage between relatives have been so inadequate as to cause one writer to assert that they may be condensed into the simple but honest phrase, "I do not know what caused the savages to adopt the system of exogamy." Whether Freud in this book has produced an hypothesis of any real value remains to be seen. Had he been able to base it upon the mental development of children he would have been on safer ground; when he attempts to bolster it by "the reactions of neurotics" he at once excites doubt in the mind of those possessing any previous knowledge of the subject.

BLOOD PRESSURE.

TEN years ago Dr. L. GALLAVARDIN of Lyon published a monograph of 206 pages, with 70 figures, on the subject of arterial blood pressure in clinical practice, its estimation and symptomatic value; in its second edition it has now been expanded into a volume of more than 700 pages and 200 figures. In reviewing the original edition (BRITISH MEDICAL JOURNAL, 1910, ii, 20) we were able to say that it was excellent, and this verdict holds good as regards the second edition,⁵ which is really a new book, and is replete with bibliographical references, including many to British and American authors. The work is divided into two main parts—on the method of blood pressure estimations, and on their clinical bearings. The account of the methods has been expanded so as to occupy more than 200 pages, and has been brought fully up to date. The auscultatory method is fully described and compared with other procedures, full justice being done to the work of McWilliam, Melvin, and Murray, published since the first edition appeared. This method has been popularized in France by Collet, Tixier, and Laubry; the last named has invented a sphygmophone enabling two persons to make simultaneous observations.

The clinical and main part of the work begins with an account of the physiological variations of blood pressure, and in connexion with the hardly perceptible blood-pressure variations attending normal respiration it is

⁵ *La tension artérielle en clinique. Sa mesure, sa valeur sémiologique.* Par Docteur L. Gallavardin. Deuxième édition. Paris: Masson et Cie. 1920. (Roy. 8vo, pp. xii + 717; 200 figures. Fr. 30 net.)

pointed out that forced respiration may cause a difference of 10 to 15 mm. Hg in the systolic and rather less in the diastolic blood pressure; a remarkable case of a healthy man who by holding his breath for a prolonged period was able to raise his systolic pressure from 110 to 230 mm. is quoted.

A useful summary is given of the current knowledge of the conditions of blood pressure in airmen, and stress is laid on the influential factors other than barometric pressure. In commencing the consideration of pathological blood pressure, the author remarks that after the value of estimating the minimum or diastolic blood pressure was established an exaggerated importance was attached to it, especially by Pachon, and that the systolic and diastolic pressure are both indispensable. An abnormally low diastolic pressure may be due to bradycardia (pseudohypotension), to aortic regurgitation (true low diastolic pressure), to rigid arteries without aortic reflux, and to arterio-venous aneurysm. Variations of blood pressure in various parts of the body—for example, the increased pressure in the dorsalis pedis artery as compared with that in the radial artery in cases of abdominal aortitis—are described. After a chapter on the blood pressure in various diseases, this valuable treatise, which is a storehouse of information, concludes with a section on the effects of medical treatment.

A FIELD AMBULANCE IN GALLIPOLI.

COLONEL G. H. EDINGTON has reprinted from the *Glasgow Medical Journal* a sketch of the career of the 1st Lowland Field Ambulance in Gallipoli.⁶ It is a Territorial unit, and he was in command when it was mobilized on August 15th, 1914, when it started for Egypt on June 4th, 1915, when it landed at Helles on June 27th, and when it left Gallipoli on the final evacuation of the peninsula on the night of January 8th–9th, 1916. His account is detailed, and it is possible to follow the story of the unit almost from day to day. As is well known, the positions available afforded little or no cover, and what he has to say of the design and construction of the hospital trench at a camp on the Krithia road is of general and permanent interest; photographs of this camp are among those with which the volume is copiously illustrated. His notes give a vivid impression of the perils and discomforts, and of the difficulties under which the medical work was conducted. Colonel Edington states that the Turks respected the Red Cross, at the beginning at least, for later on aeroplanes were less discriminating. Living in close contact he learnt to know and appreciate the good qualities of all ranks, and he concludes his book with the following words: "The outstanding features were the undaunted cheerfulness with which all faced every danger and discomfort, and the unflinching fidelity with which they discharged whatever duty came their way. These things are surely a just reason for pride; the memory of them stands out as a bright spot, which will for me always illumine the darkness of Gallipoli."

NOTES ON BOOKS.

IN *The Scientific Authority for Total Abstinence, Part II*,⁷ Dr. C. C. WEEKS has reprinted in a pamphlet six articles from the *Journal of the Royal Army Temperance Association*, together with an interesting appreciation of the late Sir Victor Horsley. In language which is suited to the understanding of an intelligent layman, careful and accurate general descriptions are given of the nervous system, and the effects of alcohol thereon are discussed briefly, with sincerity and moderation of tone.

The chief subjects treated in the issue of *Medical Science*⁸ for April, 1920 (the first number of the second volume, and the first issued by the Medical Research Council), are the typhoid fevers, pneumonia, and syphilis. There is a note on the nervous lesion caused by beri-beri

⁶ *With the 1st Lowland Field Ambulance in Gallipoli.* By Colonel G. H. Edington, M.D., D.Sc., A.M.S.(T.F.). With illustrations Glasgow: Alex. Macdougall. 1920. (Med. 8vo, pp. 72.)

⁷ *The Scientific Authority for Total Abstinence, Part II: Alcohol in Relation to the Nervous System, with special reference to its Action on the Brain.* By Courtenay C. Weeks, M.R.C.S., L.R.C.P., Captain R.A.M.C., lately Vicar of St. Hilda's, Crofton Park; General Secretary, Royal Army Temperance Association, 47, Victoria Street, S.W.1. (Price 6d.)

⁸ Published for the Medical Research Council by the Oxford University Press. Annual subscription 21s.; a single number 2s.

in which the view that it is due to toxic polyneuritis is upheld, and the opinion of Vedder and McCarrison that the essential lesion is a degenerative change in the cells of the central nervous system is rejected. There is also an article on decapsulation and nephrotomy for nephritis in which a very cautious opinion is expressed as to the value of the former method of treatment. An index to first volume is printed with this issue.

Professor RICHET's lectures to French Red Cross helpers, which we were able to praise when first published in his own language, have now been translated into English and published in a small volume entitled *War Nursing*.⁹ It is particularly adapted to the needs of educated women who wish to know something about the principles of nursing. The lectures are full of sound information, informal, not over-practical: the work of a famous scientist who has grown old in the study of physiology. We may all congratulate ourselves that the urgent demand that called them into being is now no more. The translator has done her work excellently.

The Third Great Plague,¹⁰ by Dr. J. H. STOKES, contains a temperate discussion of syphilis, and the social problems to which it gives rise, for everyday people. The other two great plagues, it may be noted, are tuberculosis and cancer. The subject is treated adequately from all points of view, and Dr. Stokes writes clearly and with knowledge. His book may be recommended to laymen who wish to learn what syphilis is and how its spread may be limited.

In *War Diseases and Pensions*,¹¹ Drs. R. M. and W. T. WILSON have supplied medical referees, general practitioners, and those who sit on medical boards to adjudicate pensions, with a serviceable little manual of practical points in the diagnosis of such things as D.A.H., neurasthenia, trench fever, malaria, and the degree of disability present, that should be of great utility in matters of assessment. The snare of diagnosis based on symptoms is well displayed, and the importance assumed by laboratory diagnoses in patients with various chronic infections is sufficiently insisted upon. We recommend this unassuming book to the attention of those for whom it has been written; it is not, of course, exhaustive in its treatment, but it contains valuable and practical advice.

⁹ *War Nursing*. What Every Woman should Know. Red Cross Lectures. By Charles Richet, Professor in the University of Paris, etc. Translated by Helen de Vere Beauclerk. London: William Heinemann. (Fcap. 8vo, pp. xi + 120. 3s. 6d. net.)

¹⁰ *The Third Great Plague*. A Discussion of Syphilis for Everyday People. By John H. Stokes, A.B., M.D., Chief of the Section of Dermatology and Syphilology, the Mayo Clinic, Minnesota, etc. Philadelphia and London: W. B. Saunders Co. (Post 8vo, pp. 204.) 6s. 6d. net.

¹¹ *War Diseases and Pensions*. By R. M. Wilson, temporary Captain R.A.M.C., M.B., Ch.B., and W. M. T. Wilson, late temporary Captain R.A.M.C., M.B., Ch.B. London: H. Frowde, and Hodder and Stoughton. 1919. (Fcap. 8vo, pp. 71. 3s. 6d. net.)

THE MEDICAL RESEARCH COUNCIL.

PROVISIONS OF THE CHARTER.

THE Medical Research Council has been brought into existence by Royal Charter to replace the Medical Research Committee established to administer the Medical Research Fund provided by a paragraph in the first Insurance Act, which directed that a sum calculated at the rate of one penny for each insured person should be retained for purposes of medical research out of moneys provided by Parliament. The Committee ceased to exist on March 31st and the new Council came into existence on the following day.

The change is consequent on a proviso of the Ministry of Health Act, 1919 (Section 3, Subsection (1), proviso (i)), which directed that the duties of the Medical Research Committee should be transferred to a Committee of the Privy Council. The transfer has taken place and the Medical Research Council has been constituted to carry out these duties under the Committee of the Privy Council recently established, as noted a fortnight ago. This Committee consists of the Lord President of the Privy Council, the Minister of Health, the Secretary for Scotland, and the Chief Secretary for Ireland. In the absence of the Lord President the Minister of Health will preside. The constitutional position of the Medical Research Council is thus defined and its duties are formally shown to extend to all parts of the United Kingdom.

The Charter of the Medical Research Council, approved at a Council held by the King on March 25th, appoints the

first Council, as set out below. It provides that two members shall always be members of the House of Lords and of the House of Commons respectively, and that any vacancy among the other members, whether casual or due to expiration of the term of office, shall be filled after consultation with the Medical Research Council and the President for the time being of the Royal Society.

CONSTITUTION OF MEDICAL RESEARCH COUNCIL.

The first Medical Research Council is constituted as follows:

VISCOUNT GOSCHEN, C.B.E.
 Mr. WILLIAM GRAHAM, M.P. (Edinburgh Central).
 The Hon. E. F. L. WOOD, M.P. (Ripon, North Riding).
 C. J. BOND, C.M.G., F.R.C.S., Consultant Surgeon, Leicester Royal Infirmary.
 WILLIAM BULLOCH, M.D., F.R.S., Professor of Bacteriology in the University of London (London Hospital).
 T. R. ELLIOTT, C.B.E., D.S.O., M.D., F.R.S., Physician to University College Hospital, London.
 HENRY HEAD, M.D., F.R.S., formerly Physician to the London Hospital.
 F. GOWLAND HOPKINS, M.B., D.Sc., F.R.S., Professor of Biochemistry in the University of Cambridge.
 Major-General Sir W. B. LEISHMAN, K.C.M.G., C.B., M.B., F.R.S., Director of Pathology, Army Medical Service.
 D. NOEL PATON, M.D., F.R.S., Regius Professor of Physiology in the University of Glasgow.

POWERS.

The Charter creates the Medical Council a body corporate, with the usual powers of a chartered body, to hold and dispose of money or other personal property received for medical research from Parliament or from other sources. It is empowered to hold and to accept gifts and bequests of land and buildings in the United Kingdom to an amount not exceeding in annual value £50,000.

The members of the Council will hold office for two years, but will be eligible for reappointment. The members named in the Charter will hold office until September 30th, 1921, when three will retire; thereafter three members will retire at intervals of two years.

The Council will elect its own Chairman, Treasurer, and Secretary. The first Secretary is Sir Walter Fletcher, M.D., D.Sc., F.R.C.P., F.R.S., hitherto Secretary of the Medical Research Committee. The Council may appoint other officers, and remunerate them and expend such moneys for administrative purposes as it thinks fit, subject to the approval of the Committee of the Privy Council above mentioned.

Another clause gives the Medical Research Council power to alter, amend, or add to the Charter by a vote of two-thirds of the members present and voting (being an absolute majority of the whole number of the Council) subject to confirmation by a like majority at a subsequent meeting. Honoraria, subject to the approval of the Committee of the Privy Council, may be paid to members of the Medical Research Council not being members of either House of Parliament.

ROYAL MEDICAL BENEVOLENT FUND.

ANNUAL MEETING.

THE annual meeting of the Royal Medical Benevolent Fund was held on Tuesday, March 16th, with Sir CHARTERS SYMONDS, K.B.E., in the chair.

The annual report for the year ending December 30th, 1919, showed that there had been an increase of £195 in donations and subscriptions over the previous year, and that the total amount distributed on the grant account was £2,532.

Attention was drawn to the fact that owing to the increased cost of living it was necessary to increase the amount of the grants, and that at least an additional £1,000 was required for this purpose; as only about 7 per cent. of the medical profession support the Fund, the Committee expressed the hope that this sum would be forthcoming. The annuitants numbered 178. The War Emergency Fund has distributed £8,540. At the last meeting of the Committee of that Fund grants amounting to £800 were made to seven of the applicants. This Fund will be pleased to consider applications from demobilized R.A.M.C. officers with the view of assisting them to re-establish themselves in their practices.

Sympathetic reference was made to the death of the late President, Dr. Samuel West. Sir Thomas Barlow, Bt., K.C.V.O., M.D., was elected President, Sir Charters J. Symonds Honorary Treasurer, and Dr. G. Newton Pitt Honorary Secretary. The members of the Committee of Management were elected. Votes of thanks were passed to the retiring officers and to the Editors of the *BRITISH MEDICAL JOURNAL* and *Lancet* for their great help during the past year. Donations and subscriptions may be sent to the Honorary Treasurer at 11, Chaudes Street, Cavendish Square, London, W.1.

EIGHTY-EIGHTH ANNUAL MEETING

OF THE

British Medical Association,
CAMBRIDGE, 1920.

EVOLUTION OF THE MEDICAL SCHOOL

(continued).*

By the year 1700 all the natural sciences had obtained a footing in the University. Caius, the first recorded practical scientist of Cambridge, had established anatomy in 1558; but anatomy in his time was not fully emancipated from the bonds of traditional authority; it included most of the physiology then known or imagined, and doubtless still held to some absurdities which unprejudiced observation would have cleared away. Glisson in 1636 had introduced the new or philosophical anatomy and physiology, infused with the spirit of Harvey, and guided by the principles of Roger Bacon, as expounded by his namesake Francis, Lord Verulam. Ray had introduced systematic botany, and his intimate friend and collaborator, Francis Willughby, of Trinity College, had carried out extensive investigations in animal morphology, and attempted a classification of animals. Newton was living at Cambridge from 1661 till 1727, pursuing and teaching physical science and astronomy. Chemistry was a favourite subject for private study, and the distinguished chemist Viganì was imported from Italy to lecture on the science from about 1680 onwards. Finally, geology, then an embryo science, was brought to Cambridge in 1695 by John Woodward, M.D., who (being then 30 years old, and having already completed his medical education) was in that year enrolled as a member of Pembroke College, and subsequently bequeathed his collection of specimens to the University, with a sum of money to found a lectureship in geology. His fossils were the beginning of the Geological Museum, and his lectureship afterwards became the Woodwardian Professorship.

Thus it will be seen that in 1700 the time was ripe for a fuller recognition of natural science in the University curriculum. The first-fruit was the elevation of Viganì in 1703 to a professorship in chemistry, and the provision for him of a laboratory, in which Stephen Hales shortly afterwards carried on important experiments in physics and physiology, as mentioned in our previous article. The next event was the creation of a professorship of

anatomy in 1707. Anatomy had recently been taught by James Keill, who had studied medicine at Edinburgh and Leyden, and was admitted M.D. at Cambridge in 1705. But the choice for the first professorship fell upon George Rolfe, who was said to have performed several dissections "summa cum laude in usum studiosae juventutis optimum." In 1716 a building, a portion of the block which housed the University Press, at the corner of Silver Street and Queens' Lane, was assigned to the professors of anatomy and chemistry for their laboratories.

In 1723 Parliament considered and rejected a clause in an Act "for the better enabling the Faculty of Physick, in the University of Cambridge, to take the bodies of Persons executed for Felony and other Crimes, for Anatomical Dissections." Public prejudice was still strongly against dissection. It may have been partly through the difficulty of obtaining bodies that the enthusiasm of Rolfe failed,

and he became so inactive that after long warning the University in 1728 deprived him of his appointment.

Meanwhile in 1724 the professorship of botany was created. The first tenant of the chair, Richard Bradley, F.R.S., was the author of works on botany and agriculture, but (like Rolfe) was negligent as a professor. His neglect was remedied by permission to lecture being given to John Martyn, F.R.S., who in 1727 gave the first course in botany that was read in Cambridge. Martyn entered at Emmanuel in 1730, and in 1733 succeeded Bradley as professor.

No other new development took place for several years, but some contemporary events deserve notice.

One of the most honoured names in Cambridge is that of John Addenbrooke, Fellow of St. Catharine's, who was admitted M.D. in 1712, and died in 1719 at the early age of 39. He probably practised in Cambridge, and may have taught pharmacy, but on both these points evidence is

wanting. At all events he was interested in pharmacy, and made a collection of teaching specimens of *Materia Medica* which is still in possession of his college. He also in his short life earned (if he did not inherit it) sufficient money to leave £4,000 to found the first public hospital in Cambridge. The building of the hospital was delayed nearly fifty years by litigation; and meanwhile the endowment was augmented with a further sum of £7,000 by John Bowtell the bookseller. The hospital building has since been greatly enlarged, but it is always called "Addenbrooke's Hospital," and the name of Bowtell is prominent in its interior. May their names never be dissociated from it!

Another name, whose fame has extended far from Cambridge, is that of William Heberden, who entered St. John's in 1724, became Fellow of the College, graduated M.D., and practised and lectured on *Materia Medica* in Cambridge for ten years, and then removed to London.

Interesting information on the state of natural science

SIR ISAAC NEWTON.

(From the engraving by J. Smith, after Kneller's portrait.)

* Previous articles in this series of descriptive and historical notes on the University and town of Cambridge have appeared in the JOURNAL of January 3rd, p. 17; January 24th, p. 125; and March 15th, p. 353.

in Cambridge about this time has been preserved for us by Samuel Dale of Bocking in Essex, physician, distinguished botanist, dilettante in most of the arts and sciences, and intimate friend of Ray. He paid several visits to Cambridge between 1722 and 1738, and kept a diary of them, which is preserved in the Cambridge University Library. This diary, consisting of notes without embellishment jotted down for his own use only, is of considerable historical value.¹ It appears from his notes that botany was a popular study among the residents.

"The connection between botany and medicine," says Professor Hughes, "was then much closer, as simples formed a large part of the pharmacopoeia of that day. It would appear that Dr. Dale regarded the subject very much from that point of view, because so many of the plants he mentions were used in medicine. His friends [at Cambridge] gave him roots and seeds, and helped him to find others." . . . "It is mentioned that Dr. Martyn [the second Professor] laboured much to bring this science into repute, read public lectures for several years, and perambulated the country with his scholars, showing them the Cambridgeshire plants where Mr. Ray had described them to grow."

In 1737 Dale was introduced to a Mr. Jackson, who mentioned—

"That Mr. Martyn had shewn him a *New Methodus Plantarum* by a German named Lænius which much differed from that of Mr. Ray."

In Mr. Davis's rooms at Queens' (probably Dr. Richard Davies, to be mentioned again later) he saw, in 1735, "Hawksby's Pneumatick Engin," mentioned in the *Transactions of the Royal Society*. This was possibly an air-pump. In 1737 he

"went to see Mr. Wilson, who dwells over the Greate Gatehouse [of Trinity]; he shewed me the observatory, in which is a clock that goeth one month. It was the present of Sir Isaac Newton to the University. They correct it by the Sun and have in that room divers large telescopes and other Mathematical Instruments, together with a double barrell'd Pneumatick machine in that room and that under it, and above all in the Cupulo is a large sextile flxt, with two telescopes."

We further learn from Dale's diary that Dr. Woodward's collection of fossils, in four cabinets, were already housed in a separate room in the University Library in 1730, two years after Woodward's death, and were under the care of Mr. Mason, who shortly afterwards succeeded to the Woodwardian Professorship.

Dale's picture of Cambridge shows the natural sciences in general very much alive and rejoicing in their youth. But how were the specially medical sciences doing? We have mentioned that the first professor of anatomy was inactive and had to be deprived of his office. His successor, John Morgan, was apparently more energetic or less scrupulous, for during his time (1728-1737) body-snatching was more prevalent in the neighbourhood than usual, and public indignation became serious. In 1731 the University passed an ordinance for the punishment of any student or graduate found guilty of participation in the stealing of bodies.

"The prohibition," says Dr. Alexander Macalister,² "does not seem to have been effectual, for on the 2nd of April, 1732,

¹ See paper by Professor McKenny Hughes, "Dr. Dale's Visits to Cambridge, 1722-1738," in *Proc. Cambridge Antiquarian Society*, No. lxxviii, 1915 16, p. 95.

² Lecture delivered January 29th, 1891, on the opening of the new Anatomical Lecture Room. Published by Cambridge University Press.

a body exhumed from a neighbouring churchyard was traced into Emmanuel College, and the pursuers obtained a warrant from a magistrate, Mr. Pern, to search for it. . . . However, the body was too carefully concealed to be found by the searchers."

It is not clear whether this body snatching was owing to insufficiency or to total failure of the supply of bodies to which the school had a legal right. Whatever the cause, the custom continued, leading many years later to a remarkable incident—the dissection of the body of Laurence Sterne in the anatomy theatre of his own university. It was in 1768, the professor at the time being Charles Collignon. Sterne's body had been buried at St. George's Burial-Place at Tyburn (now Bayswater Road) and had been brought to Cambridge on the following day. One of his friends, invited to see the dissected body, recognized his face. Thus Yorick's grave was dishonoured like that of his namesake. It was believed that his skeleton was preserved in the Museum; but Professor Macalister was unable to identify even his skull. Though dissection was being carried on, it was only with difficulty, and meanwhile neither the professors of anatomy nor those of physic achieved anything remarkable—even personal fame. Certain other doctors gave lectures on medical subjects, among them Robert Glynn of King's College, physician to the poet Gray.

In March, 1750-1, Glynn announced a course of lectures on the Medical Institutes, in three parts:

- Part I. On the Animal Oeconomy.
- Part II. On the Operations of Medicines.
- Part III. On the History of Diseases.

In March, 1752, he further announced "A Course of Medical Lectures on the Structure and Use of the Principal Organs of the Human Body. . . . The First Course 2 Guineas—The Second Course, 1 Guinea."³

That the state of medical teaching was not satisfactory is indicated in a letter addressed by Richard Davies, M.D., of Queens' College (whose name was mentioned in Dale's diary), to Dr. Stephen Hales, the

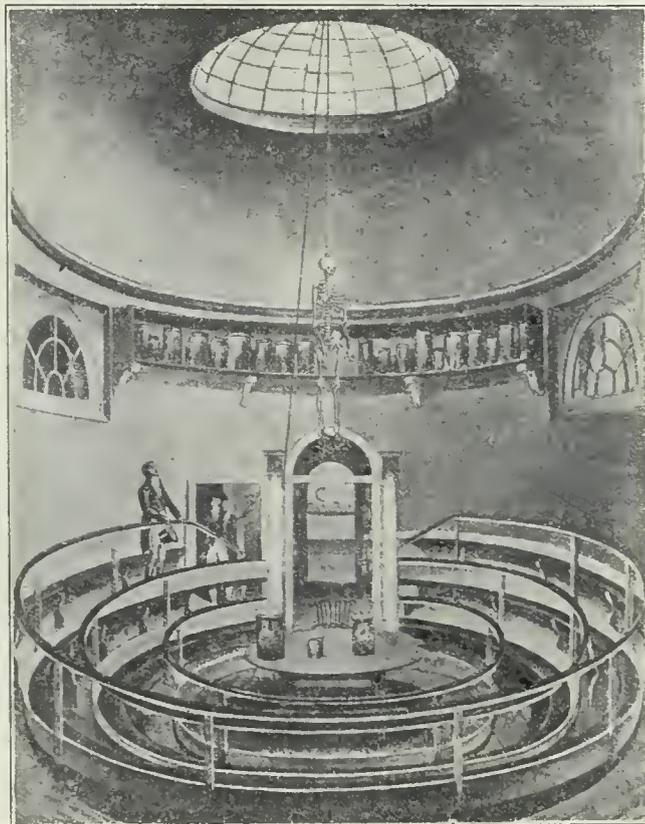

experimental physicist, in 1759.⁴

In it he says: "The Arts subservient to Medicine have no appointments to encourage teachers in them. Anatomy, Botany, Chemistry, and Pharmacy, have been but occasionally taught; when some person of superior talents has sprung up and has honoured the University by his first display of them there, before his passage into the world." Provided that the university course were supplemented by due attendance at some public hospital, which ought to be the finishing school of the clinical physician, he thought that no place was so well fitted for the early training of physicians as the English universities, on account of their discipline—if only the professors' lectures had not become a farce, those positions being looked upon as dignities rather than offices.

In 1762, three years after the date of Davies's letter, a long-felt want was supplied by the gift of the first botanical garden to Cambridge, through the munificence of Richard Walker, D.D., Vice-Master of Trinity College, an enthusiastic botanist often mentioned in Dale's diary. The land chosen was the former site of the Augustinian Friary, near the middle of the town. It is said that Thomas Martyn, who had recently succeeded his father as

³ See *Scholae Academicæ*, by Christopher Wordsworth (not the bishop), to which work we are much indebted for information concerning Cambridge men and manners.

⁴ *Scholae Academicæ*, p. 177.

THE OLD ANATOMY THEATRE ABOUT 1814

professor of botany, first taught the Linnæan system in 1763; if that was the case, there was great delay in the adoption of the system, for Dale recorded (see above) that John Martyu, the father, was already acquainted with the system in 1737, twenty-six years earlier.

In 1783 the Rev. Richard Jackson of Trinity College founded the Jacksonian Professorship of Natural Experimental Philosophy, and wisely ordered that the lectures were to be illustrated with practical experiments, chemical and otherwise. It is amusing to note that the professors were requested "to have an eye more particularly to that *opprobrium medicorum* called the gout." In those days the natural sciences were mostly regarded as accessory to medicine; and are they less so now? The writer attended the lectures of the Jacksonian professor in the seventies; and though he does not remember the mention of *gout* or any other medical term, he learnt from demonstration several fundamental physical and chemical principles which have since proved of great value to him in medical science.

The first really efficient professor of anatomy, who left a permanent impression on the school, was Sir Busick Harwood, M.D., of Christ's and Emmanuel Colleges. He was professor of anatomy 1785-1814, and also Downing professor of medicine 1800-1814.

"He took a wide view of his subject—the Professorship is one of Anatomy, not of Human Anatomy—and lectured and demonstrated on the lower vertebrates, some of which having yielded up their anatomical secrets on the dissecting-table during the morning, were said to have reappeared upon his table at the mid-afternoon dinner of the period."⁵

"Shortly after his election he commenced the publication of a large work on Comparative Anatomy, but, not receiving sufficient encouragement, one part only was published, that on the organ of smell. It is a matter of regret that the project fell through, for the part issued shows originality and erudition, and is beautifully illustrated. It was translated into German, and published under the editorship of Wiedemann. To Harwood we owe the foundation of our anatomical museum, as he prepared a series of specimens to illustrate his lectures, and the University purchased them at his death."⁶

Soon after his appointment the Anatomical Laboratory in Silver Street was rendered more convenient by the removal of the chemical department to a building at the Botanic Garden, where provision was made for the botanical, chemical, and Jacksonian professors. This gave Harwood an opportunity to fit up the building adequately. In Ackermann's *History of Cambridge*, published in 1815, the year after Harwood's death, is a print of the interior of Harwood's theatre, from which the illustration we give is a much reduced copy.

The print shows a round room, lighted from the roof, having three tiers of seats round a central table. A skeleton hangs from the ceiling. On the table are three glass jars of different sizes: one of them contains a fetus, another a twin monster. On a shelf are twenty-two similar glass jars containing specimens. Through an arch at the back is seen the museum in perspective, with mounted specimens and more glass jars.

In short, the drawing represents a well-appointed anatomical department, and confirms the written testimony as to Harwood's efficiency as a professor. If the other departments of medical science had been as well organized as his, and the several departments co-ordinated under a central management, the medical school might have taken its proper place among the schools of the time; but this was not to happen for another half-century.

⁵ Sir A. E. Shipley in *A Memoir of John Willis Clark*, p. 263. Smith, Elder, and Co. 1913.

⁶ Professor A. Macalister, *Lecture on the Opening of the New Anatomical Lecture Room*, Cambridge University Press, 1891. The specimens purchased by the University are said to have been wax models made in Italy. The real anatomical preparations were probably presented by Harwood.

Harwood's contemporary in the Regius Chair of Physic was Sir Isaac Pennington, M.D., Fellow of St. John's. He had been Professor of Chemistry from 1773 to 1793, and was Regius Professor of Physic from 1793 to 1817. He appears to have been an able man and to have helped with Harwood to form the anatomical museum, presenting to it in 1804 a collection of specimens.

An anecdote is told of these two knights—Sir Busick and Sir Isaac—the founders of the *real* medical school, which has the merit of fixing their names on the memory. Pennington, meeting Harwood one day, greeted him with "Good-morning, Sir B-u-sick?" To which Harwood replied, "Sir I-sic? I never was better in my life!"

Harwood was succeeded in 1814 by John Haviland, M.D., Fellow of St. John's, who passed to the Regius Professorship three years later, on the death of Pennington, and held the chair until 1851. Haviland was the first professor who gave regular courses on pathology and the practice of medicine, and he did much to make medical examinations real and satisfactory.⁷

When Haviland passed from the chair of anatomy to that of physic, in 1817, he was succeeded as Professor of Anatomy by William Clark, M.D., Fellow of Trinity College, who held the professorship for forty-nine years. He did more for his department than any of his predecessors.

"Conscious that the teaching of anatomy, more especially of comparative anatomy, in which, rather than in human, he was particularly interested, could not be carried on without a collection, Professor Clark added largely to the nucleus of Harwood's Museum. He procured from Italy a number of anatomical models in wax, purchased a number of specimens from Brookes's Museum, and the whole of the collection made by Professor Macartney of Dublin."⁸

This unusually valuable collection, consisting of more than 2,000 specimens, had been refused by the authorities in Dublin; it was then offered to Dr. Clark, who most willingly induced the University of Cambridge to secure it at the price of £100 a year for ten years.

With the combined collections of Harwood,

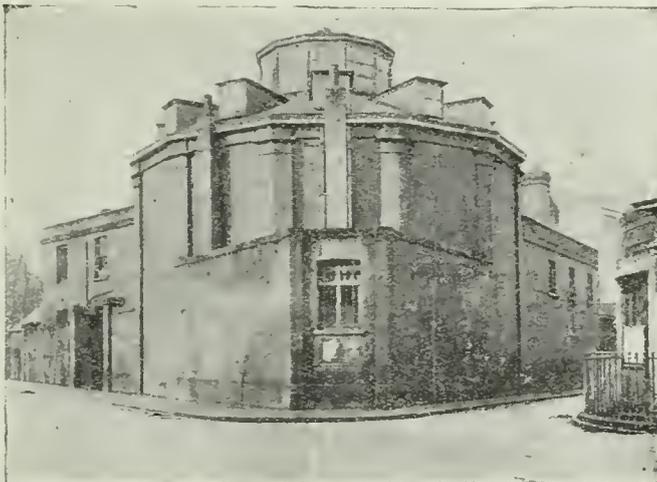

Pennington, Clark, and Macartney, a larger museum building was required, and in 1832 the collections were moved to a new building in Downing Street. The most conspicuous portion, standing at a street corner, was sometimes called the Rotunda. Though plain, it arrested attention by its form, and internally it was rather well fitted for its purpose, having two stories (floor and gallery) of shelves and glass cases, and a central table. Adjoining were the dissecting room and a theatre, the latter being no better than Harwood's, if as good.

Clark's work, with the assistance of that of Haviland, prepared the ground for the great development of the Medical School in the last third of the century. Haviland was succeeded in 1851 by H. J. H. Bond, M.D., of Corpus Christi. During the professorships of these three men all the natural sciences prospered and increased in popularity. A new botanical garden, adjoining the Trumpington Road, outside the town, was laid out in 1847, and the transference of the plants from the old garden completed in 1852. This left the site of the old garden free for the expansion of the botanical, chemical, and anatomical laboratories and museums which had been built beside it; and in course of a few years many new buildings were erected on the garden site, including a separate museum for the zoological and comparative anatomical collections.

Meanwhile the Natural Science Tripos was instituted in 1851, this being the culmination of the scientific movement in Cambridge, and acting as a great stimulus to

⁷ *Historical Register of the University of Cambridge*.

medical science. On the retirement of Clark in 1866, Dr. G. M. Humphry was appointed Professor of Anatomy, and in 1872 Dr. G. E. Paget succeeded Bond as Regius Professor of Physic. It is to these two men (afterwards Sir George Humphry and Sir George Paget) that we chiefly owe the present prosperity of the Medical School, and our next article will deal with their work and influence.

HONOURS.

A SPECIAL Supplement to the *London Gazette*, dated March 30th, contains the following promotions in and appointments to the civil division of the Order of the British Empire for services in connexion with the war:

K.B.E.

Isaac Bayley Balfour, LL.D., M.D., D.Sc., F.R.S., Professor of Botany, University of Edinburgh, Regius Keeper of Royal Botanic Gardens, Edinburgh.

Major James William Beeman Hodsdon, C.B.E., M.D., F.R.C.S., Member of Medical Advisory Board, Ministry of National Service.

Brevet Lieut.-Colonel David Wallace, C.M.G., C.B.E., M.B., F.R.C.S., Organizer and Consulting and Operating Surgeon, Dalmeny House Auxiliary Hospital; Red Cross Commissioner and Military Inspection Officer to Auxiliary Hospitals.

Brevet Colonel Arthur Lisle Ambrose Webb, C.B., C.M.G., Director-General of Medical Services, Ministry of Pensions.

C.B.E.

Francis Charles Abbott, M.S., F.R.C.S., Commandant and Surgeon in Charge, Red Gables Auxiliary Hospital, Bletchingley. Robert Craig Ackland, M.R.C.S., L.R.C.P., Medical Officer, Red Cross Hospital for Facial Injuries, Brook Street, London.

Lieut.-Colonel Sir James Barr, LL.D., M.D., F.R.C.P., F.R.S.E., County Director of Auxiliary Hospitals and Voluntary Aid Detachments in West Lancashire. Robert Cunningham Brown, O.B.E., M.D., Deputy Director-General of Medical Services, Ministry of Pensions.

William Murray Cairns, M.D., C.M., Medical Officer in Charge, Myrtle Auxiliary Hospital, Liverpool. Richard Caton, LL.D., F.R.C.P., M.D., Chairman, Nursing Service Committee, Liverpool Branch, British Red Cross Society. Colonel William Coates, C.B., V.D., D.L., M.R.C.S., L.R.C.P., Chairman, East Lancashire Branch, British Red Cross Society. John Edwards Cresswell, M.B.E., M.B., B.C., excellent work as Principal Medical Officer, Government Hospital, Suez.

Frederick William Edridge-Green, M.D., F.R.C.S., Member of Medical Board, Ministry of National Service. Evan Laming Evans, M.D., F.R.C.S.

Thomas Ashton Goodfellow, M.D., Medical Officer of Lawnhurst (Didsbury) Military Hospital, and of Didsbury Lodge Auxiliary Military Hospital. Alfred Milne Gossage, M.D., F.R.C.P., Senior Medical Assessor, Soldiers Pension Awards Branch, Ministry of Pensions. Alexander Granville, C.M.G., M.R.C.S., L.R.C.P., Commissioner for Egypt, Palestine and Syria, British Red Cross Society. Walter Spencer Anderson Griffith, M.D., F.R.C.S., F.R.C.P., Chairman of Council, H.R.I. Princess Beatrice's Hospital War Supply Depot, St. Marylebone. Charles Nixon Groves, M.D., B.Ch., Civilian Medical Officer in Charge of the Darrell Military Hospital.

John Howell, M.B., F.R.C.S., Consultant Surgeon, Cheltenham Auxiliary Hospitals, Honorary Secretary, Medical Committee, Cheltenham. Edmund Henry Howlett, F.R.C.S., professional medical services at the Royal Naval and St. John V.A.D. Hospitals, Hull.

Robert William Johnstone, O.B.E., M.D., F.R.C.S., Commissioner of Medical Services, Ministry of National Service. David Roccoy Jones, M.B., C.M., Deputy County Director of Auxiliary Hospitals, Monmouthshire.

James Rutherford Kerr, Ch.M., Medical Officer in Charge of the Pilkington Special Orthopaedic Hospital, St. Helens.

William Laird, L.R.C.P., L.R.C.S., Director of Glasgow Orthopaedic Annexe.

Edmund Dustin Maddiek, O.B.E., F.R.C.S.E., The Scala Theatre. John Howard Munnery, M.R.C.S., L.D.S., Dental Surgeon, Maxillo Facial Hospital, Kennington.

George Palmerston Newbolt, M.B., F.R.C.S., Operating Surgeon, Myrtle Auxiliary Hospital, Croxteth Hall and Royal Southern Hospital, Liverpool.

Richard Alfred O'Brien, M.D., Director, Wellcome Physiological Research Laboratories.

John Fletcher Porter, M.B., J.P., a Director of Medical Services, Ministry of Pensions.

Howell Rees, M.R.C.S., L.R.C.P., J.P. George Augustus Roberts, F.R.C.S., Medical Officer and Surgeon to Wiochester Red Cross Hospitals. James Robinson, L.R.C.P., L.R.C.S., J.P., Chairman, Executive Committee, Welsh National Hospital. Frank Mortimer Rowland, M.D., B.Ch., Assistant County Director and Honorary Treasurer, Staffordshire Branch, British Red Cross Society; Medical Officer, Freeford Hall Auxiliary Hospital.

Major Arthur de Winton Snowden, M.D., B.C., Senior Physician, British Red Cross Hospital, Netley. George Alexander Sutherland, M.D., F.R.C.P., valuable services to the Air Ministry.

William Washbourn, L.R.C.P., M.R.C.S., Medical Officer in Charge, Colchester Auxiliary Hospital. Dawson Williams, M.D., F.R.C.P., D.Sc., Editor, *BRITISH MEDICAL JOURNAL*, valuable services to the Royal Army Medical Corps throughout the war.

O.B.E.

Edward William Adams, M.D., Medical Officer, Ministry of Health. Herbert William Allan, M.R.C.S., L.R.C.P., Medical Officer, Red Cross Hospital, The Cedars, Wells, Somerset. Frederick Leigh Angier, M.R.C.S., L.R.C.P., Senior Medical Officer to the Wigan Division, British Red Cross Society. The Rev. John William Arthur, M.D., Leader, Church of Scotland Mission, British East Africa. William Ashford, M.R.C.S., L.R.C.P., Commandant and Medical Officer, Topsham Auxiliary Hospital.

Jewellyn Arnold Baiss, M.R.C.S., L.R.C.P., Commandant and Medical Officer in Charge, Clunly Auxiliary Hospital, Swanage. Alfred Ernest Barclay, M.D., Assistant County Director, Kersal and Broughton Division, British Red Cross Society, Organizer of four hospitals. Edgar G. Barnes, M.D., County Director, Auxiliary Hospitals and Voluntary Aid Detachments, Jersey. Leonard Stewart Barnes, M.R.C.S., L.R.C.P., Medical Officer, Knebworth Auxiliary Hospital. William Richard Bates, L.R.C.P., L.R.C.S., Medical Officer, Ilkley Convalescent Home. David Leslie Beath, M.R.C.S., L.R.C.P., Medical Officer, St. John's Voluntary Aid Hospital, Newton Park and Kingswood, Bath. Alexander Clarke Begg, M.D., Ch.B., Medical Officer, Brynmill Red Cross Hospital, Swansea. Frank Belben, M.B., Medical Services, Christchurch Auxiliary Hospital, Hampshire. Major Harry Poole Berry, M.B., M.R.C.S., T.D., Medical Officer, Red Cross Hospital, Grantham. Henry Bott, V.D., L.R.C.P., M.R.C.S., Senior Medical Officer, Syon House Auxiliary Hospital; Vice-Chairman, Middlesex Voluntary Aid Organization. Francis Carr Bottomley, M.D., Medical Officer, Bodorgan Road Auxiliary Hospital; Organizer of Hospital Transport, Bournemouth. Henry Briggs, D.Sc., M.B., F.R.C.S., Technical Adviser on the Medical Stores Committee, War Office. Major Frank Brightman, M.R.C.S., Assistant County Director, Thanet Division; Medical Officer, Fairfield V.A.D. Hospital, Broadstairs. Herbert Henry Brown, M.D., F.R.C.S., Medical Officer, Broadwater Hospital, Ipswich, Maryland Hospital, Sproughton, and East Suffolk and Ipswich Hospital. Henry William Langley Browne, M.D., F.R.C.S., LL.D., J.P., Medical Officer, West Bromwich Auxiliary Hospital. Lieut.-Colonel Harry Munyard Brownfield, Medical Services, Clayton Court Auxiliary Hospital, East Liss, Petersfield, Hampshire. James Marr Brydone, M.B., B.C., Resident Medical Officer, Michie Hospital, Queen's Gate, London. William James Storey Bythell, M.D., Honorary Medical Officer, East Lancashire Disabled Sailors' and Soldiers' Homes, Manchester.

William Calwell, M.D., M.Ch., Medical Officer, Craigavon Neurosthenic Hospital, Belfast. George Arthur Cardew, M.R.C.S., V.D., Medical Officer in Charge, St. John Auxiliary Hospital, Cheltenham; Chairman Cheltenham Medical Committee. Eustace George Carter, L.R.C.P., M.R.C.S., Medical Officer, Gledhow and Roundbay V.A.D. Hospitals. Walter Chapman, M.B., B.Ch., Commandant and Medical Officer, Totnes Auxiliary Hospital. Louis de Bylandt Christian, M.B., C.M., Senior Medical Officer in Charge, Auxiliary Military Hospital, Percy House Schools, Isleworth. Thomas Archer Colt, L.R.C.P., M.R.C.S., Medical Officer and Commandant, Brankmere Auxiliary Hospital, Southsea. John Galwey Cooke, M.B., B.Ch., Principal Surgeon, City and County Infirmary, Londonderry. Harold Merriman Cooper, M.B., Senior Medical Officer, Hanworth Park Auxiliary Hospital, Middlesex. Charles Cotton, F.R.C.P., M.R.C.S., Assistant County Director, Canterbury Division British Red Cross and Order of St. John; Deputy Commissioner, St. John Ambulance Brigade for Kent. Francis Ward Crossman, M.B., B.S., Medical Officer in Charge, Cleve Hill Auxiliary Hospital. Edward Cuffey, M.B., M.Ch., Principal Medical Officer, British Hospital, Port Said. Frederick Curtis, F.R.C.S., L.R.C.P., Surgeon in Charge Redhill War Hospital, Merstham Auxiliary Hospital, and Redhill Curative post.

Arthur Vernon Davies, M.B.E., M.B., Assistant County Director, Order of St. John of Jerusalem, East Lancashire. James David Davies, M.R.C.S., L.R.C.P., Medical Officer, Hazelwood Auxiliary Hospital and Quarr Abbey Hospital, Ryde, I. of W. Charles Chatterton Deane, M.D., J.P., County Director, Red Cross and Order of St. John, co. Armagh. Clarence Reginald Dearden, L.R.C.P., Medical Officer, Red Cross Hospital, Stanwell Road, Penarth, Glamorganshire. Robinson Simpson Dickson, M.D., C.M., Senior Medical Officer, Auxiliary Military Hospital, "Tottenham," Palmers Green. John Frederick Gordon Dill, M.D., Medical Officer to several Red Cross Hospitals in Brighton and Hove. Lionel Graham Dodds, M.D., Ophthalmic Surgeon, Buenos Aires. Miss Mary Janet Dodds, L.R.C.P., L.R.C.S., in charge of Scottish Churches Huts, Dregghon Camp. Edward James Downville, L.R.C.P., M.R.C.S., J.P., services in connexion with the Royal Devon and Exeter Hospital. George James Dudley, M.R.C.S., L.R.C.P., Commandant and afterwards Medical Officer, Studley Court Auxiliary Hospital, Stourbridge. Percy Edwards, M.R.C.S., L.R.C.P., Member of Advisory Medical Board, Ministry of National Service.

William Walter Fenton, M.D., Medical Officer, Red Cross Hospital, Wincanton, Somersetshire. Herbert Henry Folker, M.R.C.S., L.R.C.P., Deputy Commissioner of Medical Services, Ministry of National Service. Alfred George Francis, M.B., F.R.C.S., valuable services on Recruiting and Pensions Board,

East Central Region. Harvey Francis, M.D., Medical Officer in Charge, Arnot Hill Hospital, Nottinghamshire. George Ernest Fryer, M.R.C.S., J.R.C.P., Medical Officer, Wibbersley Hospital, Flixton, Lancashire. Willoughby Furner, M.D., F.R.C.S., Medical Officer and Administrator, Auxiliary Hospital, Third Avenue, Hove.

Alexander Rudolf Galloway, M.B., C.M., Specialist Member of Medical Boards in Scotland, Ministry of National Service. Samuel James Gillilan, M.B., Medical Superintendent, London County Asylum, Colney Hatch. Alexander Stewart Gordon, M.D., late Naval Surgeon and Agent, Rosyth, Admiralty. George Robert Gordon, M.D., B.Ch., Medical Officer, Britannia and Hartley College Hospitals, Whalley Range. Edwin Collier Green, M.R.C.S., L.R.C.P., Assistant County Director, South Derbyshire Branch, and Honorary Secretary, Derby Borough Division, British Red Cross Society; Head of War Hospital Supply Depot, Derby. Alfred John Gregory, M.D., B.S., valuable medical services to the troops. George Arthur Grierson, M.B., C.M., in medical charge of officers' wards and medical wards, Military Hospital, Grimsby.

Robert Mills Hall, M.B., C.M., Senior Medical Officer in Charge, Enfield Auxiliary Hospital. Cecil Morgan Hendricks, M.B., Medical Officer, Bicester Auxiliary Hospital, Oxfordshire. Cecil Mackenzie Hower, F.R.C.S., Medical Officer, Claveley Hall and Willington Hall Auxiliary Hospitals, Tarporley, Cheshire. Edward Septimus Earnshaw Hower, F.R.C.S., Medical Officer, Clopton War Hospital, Stratford-on-Avon. Alex Hill, M.D., Principal, University College, Southampton. Joseph Squier Hinnell, M.D., Medical Officer and Honorary Oculist, Suffolk Hospital, Ampton Hall, and West Suffolk General Hospital, Bury St. Edmunds. Alfred Hooper, M.D., Civilian Medical Officer at Aircraft Acceptance Park, Coventry. George Henry James Hooper, M.D., M.R.C.S., Commandant and Medical Officer in Charge, Benlét Hall Auxiliary Hospital, Surrey.

Gwilym Prosser James, M.R.C.S., Medical Officer, Kelvin Red Cross Hospital, Penarth. Lieut.-Colonel Richard Lane Joynt, M.D., F.R.C.S., Consultant for Orthopaedic Workshops in Ireland, and other Red Cross services.

Harold Kerr, M.D., Medical Officer of Health, Newcastle-on-Tyne. John Charles King, M.R.C.S., Medical Officer, Red Cross Hospital, Barry Dock.

Charles Ewbank Lansdown, M.D., Medical Officer in Charge, Newcourt Auxiliary Hospital, Cheltenham. Lieut.-Colonel Gerald Rowley Leighton, M.D., Veterinary Medical Inspector, Scottish Board of Health; Food Inspection Officer, Scottish Command. John Black Lendum, M.D., C.M., Medical Officer, Woodfield Hospital, Oldham. Lewis Francis Leslie, M.R.C.S., L.R.C.P., Medical Officer, Abbey Manor Auxiliary Hospital, Evesham. Llewelyn Lewis, M.D., J.P., Medical Officer, Groll Park and "The Laurels" Red Cross Hospitals, Neath. Francis Seymour Lloyd, M.D., Medical Officer, Waddon Auxiliary Hospital. Samuel Durham Lodge, M.R.C.S., L.R.C.P., Deputy Commissioner of Medical Services in Leeds and Bradford, Ministry of National Service. Percy Roycroft Lowe, M.B., B.C., late Officer in Command on Princess Christian Ambulance Train. Horace Lake Lewis, M.B., C.M., Surgeon in Charge, Camberley Military Hospital. Arnold Lyndon, M.D., Medical Officer and Organizer, Grayshott Auxiliary Hospital, Hindhead, Surrey.

Miss Anne Louise McLroy, M.D., D.Sc., Scottish Women's Hospital. Major Nathaniel Samuel Manning, F.R.C.S., L.R.C.P., Deputy Commissioner of Medical Services, Ministry of National Service. Howard Marshall, M.B., B.C., Medical Officer in Charge, Cirencester Auxiliary Hospital. Alfred Mason, M.C., M.R.C.S., Assistant County Director, British Red Cross; Medical Officer, St. Austem's V.A.D. Hospital, Walmer. William John Collings Merry, M.D., B.Ch., Senior Surgeon, Red Cross Auxiliary Hospital, Eastbourne. Alfred Miles, M.R.C.S., Medical Officer at Dinas Powis Hospital. James Millar, M.D., C.M., Medical Officer in Charge, Bowden Hospital, Nottingham. Major Robert Arthur Milligan, M.D., M.R.C.S., J.P., Operative Surgeon, Barry Road Primary Military Hospital, Northampton. George Millsom, L.R.C.P., M.R.C.S., Medical Officer of Health, Metropolitan Borough of Southwark. Isaac Gibson Modlin, M.D., B.S., Commandant and Medical Officer, 4th Durham V.A.D. Hospital, Jeffrey Hall, Sunderland. Miss Florence Muriel Morris, M.B.E., M.D., Commandant and Medical Officer, Paignton Voluntary Aid Hospital. Major John Murray, M.B., M.S., Medical Officer, Highland Moors and Rock Spa Auxiliary Hospitals; and other Red Cross services.

Frederick Lucius Nicholls, L.R.C.S., Medical Officer, Fulbourn Auxiliary Hospital, Cambridgeshire. Major Frederick Pitcairn Nunneley, M.D., Medical Officer, Lady Dudley's Red Cross Hospital for Convalescent Officers, Brighton.

William James O'Donovan, M.D., M.R.C.P., Chief Medical Adviser on Prevention of T.N.T. Poisoning, Ministry of Munitions. Eustace John Parke Olive, M.D., F.R.C.S., Medical Officer, Holmdene Auxiliary Hospital, Leamington. William Wallace Ord, M.D., Medical Officer, Salisbury Infirmary, and Wilton and Longford Castle Auxiliary Hospitals, Wiltshire. John Orr, M.B., Assistant County Director, Eccles Division, British Red Cross Society; Honorary Medical Officer, Elmbank and Eccles and Patricroft Red Cross Hospitals, Cheshire.

William Panckridge Panckridge, M.B., Medical Officer, Adhurst St. Mary Auxiliary Hospital, Petersfield, Hampshire. Benjamin Lewis Paton, M.D., Medical Officer, Ravenhill Auxiliary Hospital, Staffordshire. Nevill Coghill Penrose, M.B., Ch.B., Medical Officer, Banbury Auxiliary Hospital. Edward Verdon Perry, M.R.C.S., L.R.C.P., J.P., Medical

Officer, Cawston Manor, Reepham, and Felthorpe V.A.D. Hospitals, Norfolk. Lionel James Picton, M.B., Medical Officer, St. John Hospital, Somerford Park, Congleton, and Witton House Auxiliary Hospital, Northwich. Geoffrey Hammett France, M.D., C.M., Medical Officer, Red Cross Hospital, Aah-combe House, Weston-super-Mare. Robert Chambers Priestley, M.B., Principal Medical Officer and Medical Superintendent, Auxiliary Hospital, High Wycombe.

Robert William Quennell, M.R.C.S., L.R.C.P., Senior Medical Officer, Coombe Lodge Auxiliary Hospital, Great Warley. Daniel Richmond, M.D., F.R.C.S., Medical Officer and Operating Surgeon, St. John Ambulance Hospital, Rochdale. Joseph William Rob, M.D., Medical Officer, North Surrey Auxiliary Hospitals. Captain James Jenkins Robb, M.D., Deputy Commissioner of Medical Services in the West Midlands Region, Ministry of National Service. Frederick Field Robinson, L.D.S., Senior Dental Surgeon, British Red Cross Society, Paris Branch. Robert Leslie Romer, M.R.C.S., Medical Officer, Wall Hall Auxiliary Hospital, Stanmore, Middlesex.

George Scarr, M.B., L.R.C.S., J.P., Medical Officer, St. John Ambulance Hospital, Radcliffe, Lancashire. Charles Robert Scott, M.B., C.M., Medical Officer and Commandant, "Teedale House" Auxiliary Hospital, Marcham Road, Abingdon, Berkshire. Edmond Wallace Selby, M.D., Medical Officer, Arnold's Hospital, Doncaster. William Vernon Shaw, M.D., B.Ch., Medical Officer, Ministry of Health. Thomas William Shore, M.D., Member of Central Medical War Committee, Ministry of National Service. Major James Bertie Simpson, M.D., T.D., D.L., valuable medical war service. James Donald Sinclair, M.R.C.S., L.R.C.P., Medical Officer, 6th Durham Voluntary Aid Hospital, Woodside, Darlington. Charles William Smeeton, M.R.C.S., L.R.C.P., Commandant and Medical Officer, Hovingham Hall Auxiliary Hospital, North Yorkshire. Henry Watson Smith, M.D., Director of the Lebanon Hospital for Mental Diseases, Asfuriyeh, Syria. James Beveridge Spence, M.D., M.Ch., Resident Physician and Superintendent, Staffordshire County Asylum, William Waters Stainthorpe, M.D., J.P., Medical Officer of Health, Cleveland Rural and Urban Districts. Major John Sterry, M.R.C.S., L.R.C.P., Assistant County Director, Sevenoaks Division; Medical Officer St. John's V.A.D. Hospital, Sevenoaks.

James Maxton Thom, M.B., C.M., J.P., Member of War Executive, Scottish Branch, British Red Cross Society. William Thomas, M.R.C.S., L.R.C.P., J.P., Medical Officer, Auxiliary Hospital, Rhyd. William Edmund Thomas, M.R.C.S., L.R.C.P., Medical Officer, Red Cross Hospital, Bridgend, Glamorganshire. Norman Frederic Ticehurst, M.B., F.R.C.S., Medical Officer, Normanhurst Auxiliary Hospital, Battle, Sussex. Walter Reginald Tuckett, M.R.C.S., Medical Officer, Charnwood Auxiliary Hospital, Nantanton, near Loughborough, Leicestershire. Philip Dymoch Turner, M.D., M.R.C.S., Medical Officer, The Castle Auxiliary Hospital, Ryde, Isle of Wight.

Captain John Valerie, M.R.C.S., L.R.C.P., Senior Medical Officer, Hampton Court Auxiliary Hospital. Robert McLeod Veitch, M.D., Deputy Commissioner of Medical Services, Ministry of National Service. Charles Visger, M.R.O.S., Medical Officer, Red Cross Hospital, Oaklands, Clevedon.

George Bartram Wainwright, M.B., Medical Services, Winchester Auxiliary Hospital. Captain John William Walker, M.R.C.S., L.R.C.P., Surgeon, Wentworth House Auxiliary Hospital, Wakefield. John Wallace, M.B.E., M.B., C.M., Medical Officer in Charge and Commandant, Red Cross Hospital, Ashcombe House, Weston-super-Mare. Henry Blanchard Walters, M.R.C.S., L.R.C.P., Commandant and Medical Officer, Chudeigh Auxiliary Hospital, Devonshire. George Trustram Watson, F.R.C.S., M.B., B.C., Assistant County Director, Tnbridge Wells Division, British Red Cross and Order of St. John; Medical Officer, Bredbury V.A.D. Hospital, Tunbridge Wells. Andrew Westwood, M.B., C.M., Medical Officer, Pavilion Hospital, Old Trafford, Manchester. John Arthur Temple White, M.R.C.S., L.R.C.P., Medical Officer, Hillsborough Hospital, Harlow. John Flasby Lawrence Whittingdale, M.B., Medical Officer, Sherborne Auxiliary Hospitals, Dorset. Miss Hilda Kate Whittingham, M.B., B.S., Laboratory Assistant in Hygiene, Royal Army Medical College. Colonel Thomas James Hackett Wilkins, L.R.C.S., L.R.C.P., Deputy Commissioner of Medical Services, London Region, Ministry of National Service. James Frederick Digby Willoughby, M.R.C.S., L.R.C.P., J.P., Medical Officer in Charge, Burgence Manor and Brackenhurst Hall Auxiliary Hospitals, Southwell.

Major William Young, M.B., C.M., V.D., Chairman of the Appeal and Civil Liabilities Subcommittees, Midlothian War Pensions Committee.

(To be continued.)

G.B.E.

Dr. Arthur Everett Shipley, F.R.S., Master of Christ's College, and lately Vice-Chancellor of the University of Cambridge, who was a member of the Central Medical War Committee, is appointed a Knight Grand Cross (G.B.E.).

O.B.E. (Military Division).

Captain F. J. Collings, C.A.M.C., has been appointed O.B.E. for valuable services rendered in connexion with military operations in Siberia.

British Medical Journal.

SATURDAY, APRIL 10TH, 1920.

THE NEW COUNCIL OF MEDICAL RESEARCH.

THE Medical Research Council, which came into existence on the first day of this month, possesses wider powers and greater freedom of action than the Medical Research Committee it replaces. The new Council acts not only in an advisory but also in an executive capacity, and is responsible to the Privy Council through a special committee of that body. This committee, as was stated a fortnight ago, consists of the Lord President, the Minister of Health, and the Ministers who represent the affairs of Scotland and Ireland respectively in Parliament; its composition will ensure that the needs of all parts of the United Kingdom shall be impartially assessed, and that the acts and affairs of the Council shall be authoritatively set forth in Parliament. Technically the constitutional position of the Medical Research Council is analogous to that of the Committee of the Privy Council on Scientific and Industrial Research, but certain defects disclosed in the working of the older body have been avoided. The Medical Research Council is endowed with the independence necessary for the discharge of its important duties; it has the right to accept benefactions from the public, and to manage its own affairs.

The Council, as will be seen by the abstract of its charter published at page 504, at present consists of one member of the House of Lords, two members of the House of Commons, and seven medical members, who are all recognized as leaders in scientific medicine. Three members will retire every two years, but will be eligible for re-election. Appointments to vacancies, whether casual or otherwise, will be made by the Special Committee of the Privy Council, after consultation with the President of the Royal Society and with the Medical Research Council itself. The Council will elect its own chairman and treasurer, and appoint and remunerate its own secretary, who, being also secretary of the Special Committee of the Privy Council, will have direct access to the Minister of Health, and also, when necessary, to the Secretary for Scotland and the Chief Secretary for Ireland. The Council will appoint all its own officers and servants, and remunerate them out of the funds at its disposal. The scientific control is thus complete. The Council is free to determine its own policy and to disburse its funds to the best advantage. One purpose of the charter is to encourage the making of gifts and bequests to the Medical Research Council, which is authorized to accept bequests of money, land, or buildings made to it by individuals or corporations, and also to accept trusts in furtherance of the objects for which it exists. The independence with which the Council is endowed is further shown by the power granted to it to alter its own charter by the vote of two-thirds of its members.

So far as human foresight can ensure the future, these provisions taken together afford warrant for the belief that the Council will be preserved from the defect, to which Government bodies are particularly obnoxious, of magnifying the importance of details of

secretarial work and administration to the detriment of the real purpose of the organization to be administered.

The policy of the Council in the future can be judged from the work of the Medical Research Committee in the past, for the scientific members are the same, with the addition of Dr. T. R. Elliott; and Sir Walter Fletcher, who was Secretary of the Committee, is Secretary of the Council. The Medical Research Committee was formally appointed in August, 1913, and got to work in 1914. It was instituted to administer the Medical Research Fund provided under the first Insurance Act by a paragraph which set aside out of moneys provided by Parliament one penny in respect of each insured person for this purpose. The sum thus made available in 1914 was £55,000. The Committee had barely formed its first plans when its organization and energies were in the main turned to problems raised by the war—such as, to take a few instances, the nature and treatment of shock, the course and prevention of gas gangrene, and the diagnosis and treatment of cerebro-spinal fever, the enteric fevers, dysentery, and trench nephritis. The Medical Research Council starts in this respect under happier auspices, and will be able to devote its energies to the many problems of civil medicine which await solution.

The organization now taken over by the Medical Research Council is twofold. There is, on the one hand, the Central Research Institute at Mount Vernon, Hampstead, with departments of bacteriology and experimental pathology, biochemistry and pharmacology, and applied physiology, each with a special staff. This central organization is completed by a statistical department, a library, a bureau of information and a publication office, through which special reports and the periodical, *Medical Science Abstracts and Reviews*, are issued. The secretarial office remains in a central position in London.

It was from the first wisely decided to organize, encourage, and subsidize researches, to be conducted by individual workers in university laboratories and hospitals. Among the researches now in progress in various places may be mentioned those on tuberculosis, which is being investigated at Cambridge, Dublin, Edinburgh, Glasgow, and Reading, and on chronic rheumatoid arthritis at the Research Hospital at Cambridge. The lessons learnt from the researches at the Central Cerebro-spinal Fever Laboratory are being applied to pneumonia, puerperal fever, erysipelas, gonorrhoea, and gonorrhoeal rheumatism. Combined studies of the ante-natal factors of the conditions found in dead and premature births are in progress at Glasgow, Cardiff, and London. The scheme of inquiry into the causes of rickets, organized in Glasgow, is being maintained, and investigations are being pursued in London into the relations between the antirachitic accessory factor, the energy elements of the diet, and general metabolism. The Council is taking over from the Ministry of Munitions several grams of radium salt, which has been placed in the hands of workers at the Middlesex Hospital. The radium will be used for researches into the physiological effects of exposures to various types of radiation. The quantity, which is about ten times as great as any amount previously available for similar work, will allow experiments to be made of a kind not previously attempted. In arranging all these researches the Medical Research Council is advised by special committees. The investigations into industrial fatigue are being continued under the advice of a special committee appointed jointly with the Department of Scientific and Industrial Research.

The Medical Research Council has a great task and great obligations; it may, we are confident, be trusted to rise to the height of the occasion. The Committee it has succeeded made itself the channel through which a large part of the funds at its disposal fertilized discovery in its natural fields—the universities. As we said a few months ago, it has, without any pretence at interfering with the proper autonomy and individuality of scientific men, given to them a sense of combination and of common work, which is of great benefit to pathology and pathologists. It has upheld to the utmost the claims of freedom in research. The charter of the new Council is so drawn that it will have power to develop this enlightened policy to the utmost.

SKIAGRAPHY OF SOLID VISCERA.

EVERYBODY knows that the *x* rays unaided are incapable of giving much information as to the condition of the abdominal viscera. The introduction of the opaque meal of bismuth or barium opened up a new field of study, and added a most valuable method of diagnosis. Information as to the condition of the solid viscera has been difficult to obtain, these important organs being, in a radiographical sense, "silent." A method has been introduced, however, which bids fair to render the photography of the liver and spleen an everyday occurrence. Air or oxygen is introduced into the abdominal cavity before the radiogram is taken. The spleen and liver then stand out in sharp definition on the plate, irregularities of surface, enlargements, and new growths being clearly seen. Just as the opaque meal renders the contours and movements of the gastro-intestinal tract visible by contrast with the rest of the abdominal organs, so the new method causes the latter invisible viscera to come vividly before the eye.

This procedure, which we have called new, was first tried on live animals and on the cadaver so long ago as 1912 by Weber¹ of Kiev, but has been perfected by the work of Rautenberg² and of Goetze.³ An excellent account of the manner in which the injection is made is given by K. F. von Teubern.⁴ Unfortunately the later German papers are not illustrated owing to the difficulty and expense of reproduction. A well-illustrated paper is that of two American workers, Stein and Stewart⁵; in their pictures the solid viscera can be seen with surprising clearness and definition. To make the injections Rautenberg fills two rubber bags with air and connects them to a trocar thrust through the abdominal wall. By pressure on the bags he is able gently to inject about a litre and a half of air or oxygen; or a large syringe or small hand-pump may be used. Stein and Stewart simply use the ordinary rubber bag of a nitrous oxide anaesthesia apparatus. Von Teubern's method is probably the best. He uses a special trocar and cannula (1.0 mm. thick), the latter having a blunt closed end and a lateral eye. It is introduced halfway between the umbilicus and symphysis pubis in the mid-line under local anaesthesia. The inflow of air is controlled by a pneumothorax manometer connected in lateral series with the delivery tube. The amount of air injected was 1,500 to 2,000 c.cm. under a water pressure of 30 to 40 cm.; the highest intra-abdominal pressure reached was 11 cm. of water. The patients often complained of pain in the shoulders and around the

abdomen, and some discomfort was the rule. At the end of the examination the air is released by puncture with a large trocar (1.5 mm. wide). No serious effects have attended these manoeuvres, though Teubern once produced emphysema up to the neck when using Rautenberg's needle, which is too short (4.0 cm.).

The liver is clearly seen with the *x* rays; the sub-phrenic spaces are opened up by the gas, and can be seen as clear areas above the displaced liver. Gall stones, if present, can often, but not invariably, be made out. The spleen can always be well seen and any pathological change in it recognized. The kidneys are usually fairly clear. Rautenberg⁶ has written a special paper on this subject. The intestines are always to be distinguished, best if they have been filled with bismuth beforehand. Stein and Stewart figure myomata of the uterus, intraperitoneal adhesions (probably omental), an enlarged kidney, an enlarged lobulated spleen, a cystic ovary, the tail of the pancreas, and the normal liver and spleen. This list gives some idea of the catholicity of the method, and of the varied information that can be obtained by it. It seems possible that this artificial "pneumo-peritoneum" is destined to play an important part in the differential diagnosis of intra-abdominal tumours. British conservatism may be slow in adopting the method, but for the benefit of the cautious it may be said that Goetze has himself injected air 150 times. After all, it is but the same thing as those intraperitoneal injections of oxygen which were advised by Godwin⁷ in this country for the treatment of tuberculous peritonitis.

JUNE MEETING AT CAMBRIDGE.

THE Sections of Neurology and Psychiatry and of Pathology and Bacteriology of the Annual Meeting of the British Medical Association, which will be held in Cambridge at the end of June, have completed their preliminary arrangements. On the morning of Wednesday, June 30th, there will be in the Section first named a discussion on the early signs of nervous disease and their interpretation. It will be opened by the president, Dr. Henry Head, F.R.S., and many members have expressed their desire to take part. On Thursday morning, July 1st, a discussion on dementia praecox and its relation to other conditions will be opened by Dr. Bernard Hart; and on the morning of Friday, July 2nd, Dr. T. A. Ross will introduce a discussion on psychotherapy, to which numerous speakers have expressed their desire to contribute. It has been arranged, in conjunction with the authorities of Cambridge, to give a series of demonstrations in the Medical Buildings on one afternoon. Another afternoon will be set aside for microscopical and other demonstrations in the Physiological and Psychological Laboratories. The Section of Pathology and Bacteriology will devote the first morning (Wednesday, June 30th) to morbid anatomy, when a discussion on atrophy of the liver will be introduced by Professor Stuart McDonald of Newcastle. The morning of July 1st will be given to experimental pathology, when Dr. J. A. Murray, Director of the Imperial Cancer Research Fund, will introduce a discussion on the present position of cancer research. The third morning (July 2nd) will be given to bacteriology, and Dr. J. A. Arkwright, of the Lister Institute of Preventive Medicine, will open a discussion on the bacteriology of cerebro spinal meningitis. A collection of specimens to illustrate the three subjects will be shown. The afternoon of each of the three days will be devoted to a meeting of the Pathological Society of Great Britain and Ireland; details of the papers to be read and the demonstrations to be given will be published later.

⁷ H. S. Godwin, *Lancet*, 1912, ii, 828.

The Annual Meeting will be opened by the President, Sir Clifford Allbutt, Regius Professor of Physic in the University of Cambridge, on Tuesday evening, June 29th. The Representative Meeting will begin on the previous Friday morning.

A DOGS' BILL IN AMERICA.

We have received from Dr. Keen of Philadelphia the report of evidence before a Subcommittee of the United States Senate touching a bill to prohibit experiments on dogs. The text of the bill is short and formal. The evidence ranged over the whole subject of experiments on animals. The proceedings were less formal than those of a Parliamentary Committee in England; there were interruptions, and now and again hot controversy between opposed witnesses. The general character of the evidence was that of the evidence given before our Royal Commission on Vivisection, 1906. Here and there, in the evidence in favour of experiments on animals, one finds an exaggerated or inaccurate statement. The antivivisection evidence was, in general, rather worse than that given before our Royal Commission. Now and again it was truthful; now and again it had unearthed some wrongdoing, perhaps from thirty to fifty years old; but, on the whole, it was disgraceful to the people who gave it. We find strange mistakes made by them over English names. Mr. Lawson Tait is called Sir Lawson Tait; Dr. Arabella Kenealy is called "he"; and our Royal Commission on Vivisection is said to have been "composed of England's distinguished scientific men." A member of the medical profession in England, who was on the side of antivivisection, is called, offhand, "one of England's most distinguished physicians." Mr. Coleridge's copy of the German illustrated catalogue of instruments (1902) is said to have been "made under the authority of the British Museum." And so on. Perhaps the most wearisome thing in this report is the sense that most of these antivivisection instances and arguments were sifted and scrutinized, laboriously and thoroughly, by our own Royal Commission. Yet here they are, produced again, in Washington, ten years later, as if nobody had ever answered them. It is greatly to be desired, that the extremists of antivivisection, alike in the United States and in this country, should take to heart what Newman said, in 1851, of the extremists of prejudice against his religion: "We are dressed up like a scarecrow to gratify, on a large scale, the passions of curiosity, fright, and hatred. . . . The prejudiced man takes it for granted that we, who differ from him, are universally impostors, tyrants, hypocrites, cowards, and slaves. If he meets with any story against us, on any or no authority, which does but fall in with this notion of us, he eagerly catches at it. Authority goes for nothing; likelihood, as he considers it, does instead of testimony; what he is now told is just what he expected. . . . Perhaps it is wrong to compare sin with sin, but I declare to you, the more I think of it, the more ultimately does this prejudice seem to me to corrupt the soul, even beyond those sins which are commonly called most deadly. And why? Because it argues so astonishing a want of mere natural charity or love of our kind. They can be considerate in all matters of this life, friendly in social intercourse, charitable to the poor and outcast, merciful towards criminals, nay, kind towards the inferior creation, towards their cows, and horses, and swine; yet, as regards us, who bear the same form, speak the same tongue, breathe the same air, and walk the same streets, ruthless, relentless, believing ill of us, and wishing to believe it. They are tenacious of what they believe, they are impatient of being argued with, they are angry at being contradicted; they had rather that *we* should be guilty than *themselves* innocent; they have no wish at all *we* should not be unclean, *themselves* rogues and bloodthirsty demons. They are kinder to *the* dogs and their cats than to *us*." Happily this prejudice is dead or dying in England. Let us hope that *we* shall likewise live to see

the dying-out of the prejudice against experiments on animals. It is less than it was; the facts of the past five years have told against it.

LETHARGIC ENCEPHALITIS.

CASES of lethargic encephalitis are reported from Rumania and also from Egypt, where three have occurred at Port Said and two at Cairo. We made brief reference last week to the occurrence of a number of cases of lethargic encephalitis in and around Montpellier. The matter is of so much interest that we make no apology for recurring to it. There were eighteen cases, most of which occurred in the first fortnight of February; three of these were fatal. Among the more important symptoms were headache, intestinal and vesical paresis, sleepiness varying from simple drowsiness to lethargy, stupor, delirium, and ocular paralyse. The symptom-complex was extremely variable; thus sleepiness was not found in 40 per cent., while the brain has not been the only point of attack in the nervous system. Professor Bosc thinks that the disease is a manifestation of influenza; "In reality," he says, "we have to do with a 'grippal' infection, a *grippe* of primarily nervous type. The symptoms of invasion have been the same. There has been a coexistence of these cases and of epidemic influenza, an existence of identical cases during the influenza epidemic of 1919." At a previous meeting of the Montpellier medical society, apropos of a discussion on encephalitis lethargica opened by M. Rauzier, M. Vires called attention to passages in Sydenham connecting a fever characterized by lethargy with influenza. The passage is not cited in the report before us, but is probably that in the fifth book of the *Medical Observations*, where it is stated that a characteristic of the continued fever of 1675 was "an affection akin to coma. Patients who were attacked by it were stupid or delirious, dozed for weeks together, and were awakened only by the loudest noises." In a later chapter Sydenham correlates this fever with the epidemic cough of 1675, undoubtedly an influenza. That there is some epidemiological relationship between influenza and encephalitis lethargica has been maintained by Hamer and Crookshank in this country, and is, we think, not improbable. A contrary opinion has been chiefly defended on clinical grounds, which are seldom satisfactory foundations for epidemiological generalizations. It cannot, however, be said that the problem has yet been satisfactorily solved.

PLANT RESPONSE.

A FEW weeks ago (March 20th, p. 412) a short account was given of a lecture by Sir Jagadis Bose at the Royal Society of Medicine, describing the observations he has made on plants with an instrument of his invention, termed the "magnetic crescograph," by which movements are magnified ten million times. With it Sir J. Bose has observed movements in plants which he considers to be due to the process of growth. The lecture was illustrated by a demonstration of the instrument. Professor Waller, in some remarks afterwards, raised the question whether the movements might not be due to heating effects and be such as might be obtained with dead material. He invited Sir J. Bose to repeat the experiments under laboratory conditions here. Sir J. Bose, in his reply, maintained the truth of his deduction, and mentioned, as reported at the time, that his experiments had been tested under laboratory conditions by Professors Starling and Bayliss, among other English physiologists. Professor Bayliss, writing to *The Times* on March 20th, offered the necessary facilities for the repetition of the experiments in the Institute of Physiology, University College, and suggested that Sir J. Bose should give the names of a few gentlemen to whom he would wish to make the demonstration. Professor Bayliss went on to say that it was generally agreed that an extraordinarily sensitive instrument had been devised, but expressed the

opinion that few physiologists were prepared to agree that all the controls necessary had been shown. He concluded, however, by pointing out that even if similar phenomena were displayed by non-living structures, that fact in itself would not disprove the possibility of recording by this method the real physiological phenomena of growth and its inhibition. In a letter written on March 31st Sir J. Bose accepted Professor Bayliss's offer, and suggested the names—in addition to Professor Bayliss—of Professor Starling, Professor Oliver of University College, and Lord Rayleigh, Professor of Physics in the Imperial College of Science, South Kensington. This, he said, would give two representatives of animal physiology, one of plant physiology, and one of physics. Professor Starling, however, is in India. Sir J. Bose states that his "demonstration will deal with the definite result that the indication of the crescograph is the magnified movement 'of extremely minute changes of length of *growing organs*,' and not of physical disturbances such as that of heat."

THE CIRCUMLOCUTION OFFICE TO-DAY.

THE General Secretary of the Medical Defence Union, Dr. James Neal, has shown us a file of correspondence which forms a striking illustration of the circumlocutory methods of minor officials. The summary we give below tells how a doctor's claim for the payment of a sum due to him was bandied about from office to office until, as the result of six weeks' determined correspondence, a paymaster was at length tracked down who admitted responsibility for the payment, and undertook to make it, subject to somebody else's approval. On February 4th, 1920, a north-country doctor asked the Medical Defence Union's help in obtaining payment of about £8 for filling up a number of army forms, for which a fee of 1s. each is payable under an Army Council Instruction. In August, 1919, the A.D.M.S. Northumbrian District had told him the formalities with which he must comply in submitting his claims. He sent in his account twice to the A.D.M.S., but no notice was taken of it. Dr. Neal wrote to the D.D.M.S. Northern Command, briefly stating the circumstances and asking that the necessary steps should be taken to expedite payment. This communication was acknowledged by postcard, and on February 13th the D.D.M.S. replied that the claims, being in respect of men of the Royal Naval Division, had been forwarded to the Brigade Paymaster, R.N.D., Alnwick. The letter ended: "This department has no jurisdiction as regards the accounts of the R.N.D. I suggest that you should refer the matter to the Accountant-General for the Navy." A letter was accordingly written next day to the Accountant-General of the Navy stating the facts and repeating the request. Twelve days later came the reply that "as the services for which payment is claimed were rendered to the Royal Naval Division, which is under Army control, and as payment would be made from Army funds, your letter has been passed to the Command Paymaster, Aldershot, for any necessary action." Here we see the old game of battledore and shuttlecock being played between the naval and the military authorities—regardless, as usual, of the shuttlecock, whose account remained unpaid. Dr. Neal wrote next to the Command Paymaster, Aldershot, reciting the facts and asking him who was responsible for the payment of the account, and when payment would be made. He added that it was not right that civilian medical practitioners should experience such delay and difficulty in obtaining payment for professional services rendered at the request of a Government department; and that unless some assurance was forthcoming that the matter would be promptly settled he would have to bring the facts to the notice of the medical Members of Parliament. This letter quickly produced an answer from the Acting Paymaster, Aldershot, who said that the previous letter had been received and passed to the Command Paymaster, Northern Command, for very early action, "as the account is payable

by him and not by me." A registered letter was thereupon sent to the Northern Command Paymaster, asking for a definite assurance within four days that the matter would be dealt with by him without delay. The reply by return of post stated that these claims were payable by the Brigade Paymaster, —th Royal Naval Division, Cornwall House, London, to whom they had been forwarded on December 6th, 1919. The writer implied that he had already done his best in the matter; but added that he was sending a telegram to the Brigade Paymaster requesting an urgent settlement, and was also writing to him. On March 20th Dr. Neal wrote again to the Accountant-General of the Navy, summarizing the story up to that date, expressing in mild terms his opinion of the way in which the account was being passed from one department to another, and inquiring who was responsible for payment of it, and when it would be paid. He wrote also to the Brigade Paymaster asking him to say at once whether he was responsible for payment and when it would be made. Two days later the officer-in-charge of the Royal Naval Division pay ledgers at Cornwall House wrote that the original claim had been forwarded to the A.D.M.S., Northumbrian District, on December 10th, for various certificates, etc., required by the Northern Command Paymaster, but that the claim had evidently gone astray. The duplicate claim, however, had now been forwarded to the Northern Command Paymaster for approval of payment, and "when this approval is obtained payment will be made by me." The story speaks for itself; the appropriate comment was made many years ago by Charles Dickens. Remembering how hard the General Secretary of the Medical Defence Union has had to work, we may well wonder whether the doctor unaided would have lived to receive the sum due to him. That it would have been paid in the end we can believe, because these accountant departments in the services, though they grind slowly, are not in the habit of forgetting altogether a penny due from them to someone, or from someone to them. We have seen the greater part of an entire page of an army agent's ledger taken up with the adventures of half a crown deducted in error from a medical officer's pay when he was in France, and at last refunded to his wife after a bewildering correspondence.

THE PROGRESS OF CREMATION.

SIR CHARLES CAMERON, M.D., in his presidential address to the Cremation Society on March 31st, said that one of the results of the war had been to create a greater interest in cremation, not only in this country among returned soldiers, who had seen on the battlefields for the first time what earth burial meant, but also among the people on the Continent. Under the Austrian law cremation was forbidden, but certain Bohemians, inspired by the enthusiasm of a poet who had returned to his native land after a sojourn in the United States, founded a society which in return for an annual subscription ranging from 12 kroner (10s. at par value) in the case of persons under 35, to 50 kroner in the case of sexagenarians, undertook to have bodies cremated at Zitava in Saxony. Under this arrangement 250 cremations were carried out. A German society, Die Flamme, also erected a crematorium at Liberice, an industrial town in Bohemia, but the Austrian Government forbade its use and sealed its doors. After the revolution of October, 1918, the Austrian veto was ignored, and in the nine months following 753 cremations took place in this Bohemian crematorium, while the active membership of the Bohemian society, already over 3,000, rapidly increased. The work was at first carried out without either legal sanction or interference; but in April, 1919, the national assembly of Czecho-Slovakia passed a measure legalizing and regulating cremation. The number of crematoriums in Great Britain is now, Sir Charles Cameron stated, fourteen,

and the number of cremations last year exceeded 2,000, an increase of 15 per cent. over the figure for 1918, and of 33 per cent. over that for 1917. The large number of eminent persons included in the society's list of 22,000 cremations since its commencement proved that among the more intelligent classes of the community the propaganda had not been in vain, but the society had been able to make little headway among the poorer and less educated, although these were the people who were ready to make considerable and lifelong sacrifices to provide for funeral expenses, as instanced by the experience of the industrial insurance companies. The suggestion was made at the meeting that the charge for life membership of the society—which carries with it the payment of all expenses of cremation anywhere in the United Kingdom—should be graduated on the basis of the subscriber's expectation of life, as in the case of insurance premiums. The address of the Cremation Society of England is 324, Regent Street, London, W.1.

NYCTALOPIA OR HEMERALOPIA.

IN an annotation on an epidemic of night blindness which was published last week we used the term *hemeralopia* as meaning night blindness, following the author whose paper was discussed. This meaning has often been attached to it for the last two centuries by writers throughout Europe. The word has been used as expressing the opposite of *nyctalopia* or night vision. It seems clear, however, that *nyctalopia* should be held to mean night blindness and *hemeralopia* the rarer condition of improved vision with diminished light. A scholarly paper published by Sir John Tweedy in the *Royal London Ophthalmic Hospital Reports* in 1882 traces the history of the words from ancient Greek to modern medical writings. The term *nyctalopia* used by Hippocrates in describing the cardinal symptom of the obscure epidemic at Perinth in Thrace is defined in one of the writings attributed to Hippocrates as meaning ability to see at night, but in all the subsequent classical writers it is defined as *inability to see at night*. It is supposed that the privative *o* has been omitted in manuscript transcriptions, and Sir John Tweedy supplies cogent reasons for believing that night blindness is the correct translation. During the Middle Ages the Hippocratic writings were much neglected, and it was only on the revival of interest in them towards the eighteenth century that the supposed clerical error gave rise to the confusion of meaning. *Hemeralopia* was seldom used in medical writings before the eighteenth century. It would perhaps be better, in the circumstances, to give up the use of both terms altogether.

THE MEDICAL REGISTER.

THE *Medical Register* for 1920 has been issued.¹ It contains 44,522 names; of these 1,500 are on the Colonial list, and 165 on the Foreign list. The grand total compares with an average during the last five years of 43,794, and with an average for the last twenty-four years of 39,645. At the present time the degrees of nineteen foreign universities in Europe are registrable and those of eight in the United States of America. The right to registration on the Colonial list is possessed by graduates of certain universities and licensing bodies in Australia, Canada, Ceylon, Hong Kong, India, Malta, Newfoundland, New Zealand, and the Straits Settlements. The statistics show a total increase of 596 over the number on the *Register* in 1918, and of 2,582 over the number in 1913, the last year before the war. The number of names removed during 1919 on evidence of death was 643, the lowest number since 1912. Last year 115 names were removed under Section XIV of the Medical Act, 1858, which provides that if no reply is received by the Registrar to an

application addressed to a practitioner according to his address on the *Register* the name may be erased. It is, of course, very important that any such inquiry should be answered. Last year thirty-four names were restored to the *Register*, and the majority of these had probably been removed on account of failure to respond to the inquiry.

PROFESSOR WELCH OF BALTIMORE.

PROFESSOR WILLIAM H. WELCH, of Johns Hopkins University, Baltimore, whose reputation as a pathologist is world-wide, was born in Norfolk, Connecticut, on April 8th, 1850. In celebration of his 70th birthday, and as a new expression of the affection and admiration with which he is regarded, it has been decided to collect his chief contributions to medical literature, which are scattered through a great variety of publications, and thus more or less inaccessible. The preparation of the collected edition, which will be issued by the Johns Hopkins Press in three volumes, has been undertaken by a representative committee. The price of the set of three volumes (bound in linen) to subscribers is 16.50 dollars. Subscriptions should be sent to the Johns Hopkins Press, Homewood, Baltimore, Maryland, U.S.A.

THE South African Congress of the British Medical Association will be held next October in Durban at the invitation of the Natal Coastal Branch of the Association.

WE greatly regret to learn that a telegram has been received from Calcutta stating that Dr. Albert J. Chalmers died in the General Hospital on April 6th, at the age of 50, from acute infective jaundice after a week's illness. Dr. Chalmers was associated with Dr. Castellani in the production of the large *Manual of Tropical Medicine*, a new edition of which was issued a couple of months ago.

THE next meeting of the Congress of Physiology will be held in Paris under the presidency of Professor Charles Richet. The proceedings will begin on Friday, July 16th, and will end on the following Tuesday. The last congress was held at Groningen in September, 1913, and it was then decided that the next should be held in Paris. The subscription (35 francs) should be sent to M. Lucien Bull, l'Institut Marey, Avenue Victor-Hugo, Boulogne-sur-Seine (Seine).

Medical Notes in Parliament.

The New Minister of Pensions.

IN the list of changes announced on April 1st it was notified that Sir L. Worthington-Evans had passed from the charge of the Department of Pensions to become a Minister without portfolio, (within the Cabinet), and that Mr. Macpherson, on resignation of the Chief Secretaryship for Ireland, had been appointed Minister of Pensions. It must be a source of satisfaction to Sir L. Worthington-Evans that during his charge of the Pensions Office he has been able to do much towards the reorganization of the work there, gearing up machinery so as greatly to reduce the delays, and that he has seen through the revision of the conditions and scales of pensions. Mr. Macpherson comes to the responsible task temporarily worn by his stressful duties in Ireland; but his previous work as Under Secretary for War will stand him in good stead. As a departmental chief he is sure to show the qualities of grip and thoroughness. His unflinching courtesy and patience in the trying period when he was at the War Office won him many friends.

The Easter Recess.—The House of Commons adjourned on March 31st to April 12th.

Deaths from Influenza.—Dr. Addison, in reply to Major Entwistle, said he was advised that the recent small increase in the number of deaths from influenza might be attributed partly to the normal rise which usually occurred at this season of the year, and possibly also to some deaths from pneumonia being ascribed to influenza as a contributory cause. It was noteworthy that the number of deaths from pneumonia had remained practically constant each week since the end of January last.

TREATMENT OF INCIPIENT MENTAL DISEASE.

DURING the last few years evidence has been accumulating that there is a strong movement of opinion, both within and without the profession, in favour of a modification of the Lunacy law, the main object being to make better provision for the treatment of incipient or early cases of mental disorder.

The matter was under the consideration of the Medico-Psychological Association of Great Britain and Ireland before the war, and in 1914 a full report on the status of psychiatry was issued. The war prevented any steps being taken to translate the important resolutions then adopted into practice; but the war itself had the effect of arousing new interest in the whole subject of mental disorders, and produced a new attitude on the part of both the public and the medical profession. The Medical Psychological Association therefore felt that the ferment of reconstruction in the air, particularly as regards questions of health, made it desirable that its position on this matter should be reviewed and a further report issued representing the most recent opinion as to how the objects in view could best be accomplished, so that the association would be ready to direct and support any measures of reform that might be proposed. The matter was very carefully considered by a special committee, and its report eventually received the unanimous approval of a general meeting.

In its main features the report is in harmony with views set out from time to time in this JOURNAL; nor do they differ in principle from the recommendations made by the Board of Control in its annual reports. In regard to clinics the Board of Control proposes permissive legislation enabling cases of mental disorder incipient in character or of recent origin to receive treatment in general or special hospitals, mental institutions, nursing homes, or elsewhere for limited periods—say six months—without the necessity for certification under the Lunacy Acts, provided the place is under the supervision of the Board. This is only an enabling proposal, but the word "elsewhere" gives it an exceedingly wide scope. The report of the Medico-Psychological Association advises that the duty of providing and maintaining clinics for these purposes should be imposed on local authorities; evidently some sort of obligation will be necessary if the reforms recommended are to be widely and generally adopted within a reasonable time. It is interesting to observe that the cases under consideration are described by the Board of Control as "incipient in character or of recent origin"; presumably these two phrases are not intended to cover identical cases, and if that presumption be correct it seems to follow that the cases need not be merely "of recent origin," a phrase which it would be extremely difficult to define and when defined to apply in practice, but may be "incipient in character." This would apparently cover many cases which run a long course of an ill-defined or undeveloped type and yet remain incipient in character. Such cases are difficult to deal with at present, and for that reason the extension of the principle would be valuable. If, however, this is the intention of the Board, it is difficult to see why the duration of this mode of treatment should be limited to, "say, six months." The Medico-Psychological Association does not specify the period during which the measures proposed should be applicable, nor does it define what is meant by the term "early stages." That would no doubt have to be dealt with when the matter came before Parliament, but the expressions used by the Board of Control seem to indicate a way of meeting the difficulty and allowing sufficient elasticity for practical needs.

Proposals for Reform.

It may be convenient to set out the main conclusions arrived at in the report of the Medico-Psychological Association:

1. That no steps be taken at present to obtain a complete revision of the Lunacy Acts, but to seek to obtain amendments only to these Acts.

2. That it be made the duty of local authorities, either themselves or by arrangement with voluntary organizations, to establish and maintain clinics for the treatment of nervous and mental diseases in their early stages, special provision being made in the organization for children.

3. That these clinics should be housed in special buildings, or in an annexe to a general hospital, be staffed by a special staff trained for the work, and managed by a special committee appointed for the purpose, and that the buildings should be inspected and approved by a Central Government Department.

4. That all institutions for the insane should be allowed and encouraged to admit patients as voluntary boarders under suitable conditions, one of which is the extension of the notice required to be given by the patient of his desire to leave the institution to forty-eight hours.

5. That the Board of Control should have power to allow the reception of patients suffering from mental disease in its early stages without certification in approved homes, or as single patients in ordinary houses, in regard to which a medical practitioner gives a written recommendation stating that suitable treatment can there be obtained, the fact only of such reception to be intimated to the Board.

Several supplementary recommendations are made for improving the administration of the Act, mainly in the interests of the insane.

There can be little doubt that if anything is to be accomplished quickly it is far wiser in the present pressure upon the time of Parliament to concentrate on the most urgent amendments rather than to aim at a complete revision of the Lunacy and Mental Deficiency Acts. A single comprehensive unifying measure was drafted in 1913, but the Government decided to deal with the mental deficiency question in a separate measure which, owing to the war, has hardly yet come into full operation. The Board of Control, in its annual report for 1917, advocates amendments but not complete revision, nor does the latter process seem necessary in order to secure those reforms on which there appears to be substantial agreement.

It will be noted that the report of the Medico-Psychological Association proposes that it should be made the duty of local authorities to provide and maintain clinics. In this it goes further than the Board of Control, which suggests permissive legislation only, and the report of the committee to the conference of the visiting committees of the asylums in England and Wales, held in the Guildhall, London, in February, 1919. This conference considered that the establishment of special mental hospitals should be encouraged. There is much to be said in favour of imposing action by local authorities as a duty. For the success of the plan no half-hearted approach will be sufficient; it is necessary that it should be familiar and accessible to everyone if it is to establish itself without prejudice as a recognized method; for this we have the precedent of the duties imposed on local authorities by the Mental Deficiency Act, and no doubt provisions will have to be made in regard to financial assistance to local authorities by the Treasury similar to those made in that Act. Where such a clinic is established in a special annexe connected with a general hospital it is contemplated that the local authority should come to some arrangement with the hospital board in regard to the cost, etc. There are precedents for such a course, and it is felt that if hospitals are to be induced to organize clinics on these lines, which both for educational, scientific, and practical reasons is so desirable, such financial assistance will be necessary.

In regard to these clinics it has been felt, not only by the Medico-Psychological Association but also by the Guildhall Committee, that they should as far as possible be detached in the public mind from all association with the Board of Control. It is apparently felt that that body is so closely identified with that aspect of the matter which has to do with restraint of the liberty of the patient, with safeguards against dangerous patients, and with the protection of the hopelessly confirmed insane, that the mere fact of the supervision of the proposed clinics being in its hands would tend to give them a character which would make them distasteful to those for whose benefit they are devised. Obviously they would properly come within the purview of the Ministry of Health, and as the Board of Control will, no doubt, before long be transferred to that Ministry there will be ample facility for proper co-ordination. It is for the same reason that stress is laid on the view that these clinics should be housed in special buildings and be supervised by a committee distinct in name from the Asylums or Mental Deficiency Committee. Only as regards private patients does it seem necessary to adhere for practical reasons to the body administering the Lunacy Acts, as the prohibition for the improper reception of patients is in their hands, and they must therefore be entrusted with the administration of any relaxation of that prohibition.

The Voluntary Boarder System.

In one important respect the Board of Control has gone further than the Medico-Psychological Association. It is prepared to have the principle of the voluntary boarder extended not only to all the various classes of institution, but also made applicable to patients under single care in private houses. A proposal to this effect was put forward by Dr. Weatherley in his book *A Plea for the Insane*, which has been reviewed in these columns. Such a provision, coupled with the proposed provision for private patients in approved homes or as single cases in homes not so approved, would go far to cover all reasonable requirements for suitable treatment of the early nervous and mental disorders in this class of the community. Where detention is necessary recourse can be had to the private asylums, whether as a voluntary boarder or as a certified case. Where the asylum treatment is not necessary detention would be allowed, either under certificates or as a voluntary boarder, or as a single patient, and where neither of these arrangements are necessary or desired, the patient could be dealt with without any formality beyond the intimation to the Board that a patient was being received in a certain house and evidence that suitable treatment can there be obtained. It is proposed that the provisions applying to approved homes shall be applicable also to licensed houses and other institutions for the insane. It will be clear that with such wide and varied liberty of choice it is extremely unlikely that a medical man would recommend a patient to avail himself of any place of treatment which did not adopt one or other of these provisions, and there would be no necessary hardship to the patient in so doing, and consequently no reputable person proposing to receive patients in his house would attempt to evade such provisions. Thus would be eliminated one of the principal difficulties of members of the profession in regard to private patients—that it is not open to them to advise the treatment which they consider best for the health of their patient without the risk of running counter to the law.

The interest taken in the matter was shown a short time ago by the publication of a manifesto on psychiatric clinics for studying the treatment of mental disorders in the early stage, bearing the signatures of Sir Clifford Allbutt, Sir George Savage, Sir Frederick Mott, Dr. Edwin Goodall, Medical Superintendent of Cardiff Mental Hospital, and others more or less directly concerned with the treatment of such disorders. It was therein stated that the necessity of carrying out the reforms outlined had been repeatedly urged in the leading organs of the medical profession, and that the policy recommended would be generally endorsed. The main features of the policy indicated are the provision of clinics in large centres of population, but especially in connexion with the general hospitals and schools of medicine. It is proposed to extend the system of voluntary admission which now exists in respect of licensed houses and registered hospitals for the insane, so that patients, whether of the private or rate-aided class, may place themselves in county borough mental hospitals. It is proposed, further, that the private patient class should be received without certification but with the cognizance of the Board of Control in homes privately owned or supported wholly or partly by voluntary contributions, or in existing public and private mental hospitals (licensed houses). The two methods of admission to county borough mental hospitals, or into private hospitals are given as alternatives, but we presume that both are desired.

The establishment of clinics in psychiatry with in- and out-patient departments as a part of the general hospital system, is regarded as the most important of the above proposals, since it is by this method that the never-ending extensions of existing asylums may best be avoided. In such clinics patients would be received without reception orders or certificates, and subject to the minimum of official supervision. They might be treated under these conditions for six months, and in them students and the future holders of posts in mental hospitals should be taught, all available means of research being provided. It was with this idea that the late Dr. Henry Maudsley eleven years ago made his munificent gift, ultimately amounting to £40,000, which, after much delay, resulted in the erection of the Maudsley Neurological Hospital at Denmark Hill.

Civil and Military Cases.

The manifesto calls attention to the arrangements the army authorities made for mentally disordered soldiers during the war; they were sent into military mental hospitals without any orders or certificates, and were only removed to asylums when, after nine months, they were deemed incurable. Large numbers of men were received in very early phases of the disease, and the advantages were very great. The suggestion is then made that "if these men could be treated thus whilst in khaki, they could and should be similarly treated as civilians, and under far better medical conditions than in asylums." This may be so, but it should not be too readily assumed. Disciplinary powers over the man in khaki are great, and render the need for control by certification in his case superfluous. Whether civilian patients can be equally successfully managed will depend on the extent to which the public will be content to permit a reasonable amount of similar control being exercised in the patients' interest without regularized powers. There may be grounds for hoping that the experience of educational influences during the war may have rendered such an attitude on the part of the public general; but it cannot be denied that there is still an important section of it to whom a meticulous care for the liberty of the individual overshadows the provision for his well-being as a sick person.

There is, however, another difference between the civil and the military case. The soldier who is unfit to continue his duties owing to ill health has no inducement to go on working, and comes automatically under medical direction. The civilian may continue his work when really unfit, or retire to his home and take no steps to secure treatment, or he may refuse to act on his doctor's advice. He and his friends must therefore be taught to turn naturally to the clinic for assistance, and he will judge of the clinic and accept or refuse its help according to the type of malady which will come in time to be associated with it in the course of actual experience.

Legislative Aims.

It is understood that the Board of Control has drafted a bill to carry into effect the changes in this direction which it has recommended in its reports. Although officials speak hopefully of the probability of the early passage of the bill into law, its terms have not yet been made known, and the prospects of early legislation do not seem to onlookers very bright.

The results which will be achieved must to a large extent depend on the detailed provisions and also on the spirit in which they are interpreted. For example, there are some whose principal object is to save those suffering from acute but transitory forms of mental disorder from certification by allowing them to be dealt with under the new provisions; there are others, on the other hand, who are more anxious to secure the treatment of cases in an early stage so as to stave off mental breakdown, and for this purpose they hope to bring under treatment the antecedent stages which are little regarded by many at present.

It is clear that unless there are very special and extensive facilities, the use of the clinics for the first group of cases would tend to conflict with their utility for the second. The clinics will come to be characterized not by the name that is given to them, but by the cases to the treatment of which they are devoted; care will have to be exercised if they are not to come to be looked upon as simply an unofficial type of asylum.

LAST week we published a letter from Sir Clifford Allbutt and Sir James Mackenzie asking readers to send any medical journals and books they can spare to Vienna, where, owing to the closure of communications during the war and the present high rate of exchange, medical publications in the English language are with difficulty obtained. We have since received an appeal to persons in this country to make contributions to an Anglo-American University Library for Central Europe. The library will be organized on a broad, non-political, non-sectarian basis, and books will be lent to the faculties of the different universities in Central Europe. The proposal has the support of a very large number of scholars and men of science in this country. The secretary is Mr. B. M. Headicar, Librarian of the London School of Economics, Clare Market, London, W.C.2, to whom communications may be addressed.

MOTOR NOTES FOR MEDICAL MEN.

By H. MASSAC BUIST.

CURRENT PROBLEMS.

FIVE motoring matters of importance to medical men are to the forefront at the moment. On April 19th the Chancellor of the Exchequer has to introduce a budget, one feature of which we foreknew will be the entire recasting of the scheme of the taxation of motor vehicles to pay for the roads on a basis which, according to rumour, is estimated at an initial levy of no less than £7,000,000 a year; a sum vastly more than was raised from motoring before the war. Secondly, the new income tax allowances concern doctors and their cars. Thirdly, the fuel situation is such that it is impossible, for practical reasons, to raise the money by a tax on motor fuel; yet we are to have no relief in the price of fuel. On the contrary, it is likely to rise. There is even a prospect that we may have to be rationed for fuel this year. Fourthly, cars are coming through in quantity; yet this week Mr. Frank Lanchester, President of the Society of Motor Manufacturers and Traders, at a meeting of that body, had to explain to the public the reasons for the rises in the cost of cars to the public now, three months after the resumption of work by the moulders; production is taking place and deliveries are commencing in quantity from the various factories, while imports of cars are, of course, on a quite unprecedented scale from America. Briefly, as was forecasted in these notes more than three months ago, the cause is that the Government has invited a periodical increase of prices because there are quarterly meetings with labour at which, of course, it would be strange did the labour representatives not stipulate for an increase of price. Consequently, as long as this arrangement exists, it is impossible to prevent a continual putting up of the price until such time as the public refuses to buy cars and the workers find themselves shut out of the gates of the factories because there is no market for their products. Fifthly, in connexion with the remodelling of the road laws and so forth, the Government has entirely to reconsider the problem of headlights for road vehicles.

A LOST OPPORTUNITY.

The ideal basis of motor taxes would be fuel. But it is impossible to define motor fuel for the purposes of taxation. There is also the problem of world shortage of motor fuel, and consequently urgent need to get as much of it as possible under the British flag. We foreknew that there will be at least three years' spade work before we can get anywhere near to a normal situation in regard to supplies, far less tackle successfully the task of differentiating between home and imported fuels and, possibly, even between British raised oversea motor fuels and those obtained from foreign countries.

For these reasons the Government is resolved that the tax shall not, as motor car users wish, be transferred from the car entirely to the fuel, as the only possible basis for arriving at true taxation according to road use enjoyed. Even so there would be the alternative tax on tyres. This, however, we know to be also impracticable, because tyre manufacturing is not to be absolutely guaranteed. The man who has had luck in buying a bad tyre would be doubly penalized if he had besides to pay a second tax to get a tyre that would stand up. Nevertheless, there are alternative schemes, either for doing something in the matter of engine rating or for treating passenger like utility vehicles under the proposed scheme by taxing them according to weight. The engine scheme is wrong, but, alas! the Government is bent on carrying it through. Nevertheless, in this connexion the Treasury rating will be somewhat altered. Even so, it is impossible to alter the basis of rating without putting a premium on construction according to this plan or that, and therefore preventing the freest possible development of the motor vehicle and, above all, handicapping the industry for supply to the overseas market, because cars here must be primarily designed to meet our taxation conditions.

All this is exceedingly regrettable. Nor can it be pretended that it bears any direct relation to the amount of

road use enjoyed by the individual taxpayer. Under this head, however, certainly doctors will come off better than many classes of private vehicle users in that presumably they will at least have a certain minimum mileage a year from their motor vehicles in exchange for their tax. Nevertheless, £1 per horse-power practically predetermines the classes of cars in which they can invest their money hereafter.

Of course, the ideal method would be a tax on weight, because then the Government would not interfere with free development of design; and it would in a sense be a tax at least in some fashion related to the amount of road wear and tear which the given class of vehicle was calculated to occasion. Of course, such a tax would be at a higher rate than for the utility motor vehicle which has to compete with railways and other forms of transport; but its scale need not be any more severe than any scheme of engine tax. All that the Government has to do is to fix the amount of revenue to be raised and divide it among the various classes. Moreover, it is a democratic form of tax in that it would be possible to charge the first ten hundredweight at a lower rate than the second ten; the second ten at a lower rate than the third; and the third at a lower rate than the fourth. However, it is not to be; so, regretfully, we must leave this matter and pass on.

INCOME TAX AND CAR DEPRECIATION.

Another point which interests medical men arises in connexion with the report of the Royal Commission on the Income Tax. Paragraphs 213-216 deal with depreciation of plant and machinery. Some witnesses examined by the Commission were of the opinion that the allowance should be calculated always by a regard to the original cost, on the ground that this is theoretically the correct method. While the Commission sees no reason why the taxpayers who desire it, and who choose to put themselves to the trouble of bookkeeping that this system entails, should be barred from an allowance based on the original cost, it is, nevertheless, convinced that as a general rule neither the taxpayer nor the revenue authorities should be saddled with the burden of keeping elaborate records that would be essential if depreciation allowances were normally to be calculated on the original cost of plant. To allow depreciation on the written-down value is perfectly fair to the taxpayer and to the revenue; and the Commission recommends that this method should be continued, the right being reserved to any taxpayer who has the necessary record to have his depreciation calculated by reference to the original cost of the asset. But paragraph 214 says that there is one defect in connexion with this allowance which calls for a remedy. At present depreciation allowances are confined to traders and manufacturers. This does not apply to professional men. A business man is allowed a deduction for the depreciation of the motor car employed in his business; whereas a doctor, whose practice may equally necessitate the use of a car, is not entitled *in law* to any such deduction, even if he has managed to secure it. Therefore, as has already been noted in the BRITISH MEDICAL JOURNAL, the Royal Commission on Income Tax recommends that the allowance should no longer be restricted to traders.

This seems to mean that doctors may be allowed depreciation on their motor vehicles this year. An allowance for obsolescence of traders' machinery was in practice given as far back as 1897, but it did not receive formal legislative authority until 1918. At present the obsolescence allowance can be granted when the obsolete plant or machinery is replaced. But the Royal Commission recommends that it should be given in the case of machinery or plant disused for any reason, whether replaced or not, except where the disuse is the result of the discontinuance of the business, when it cannot properly be distinguished from the general capital loss entailed by cessation. The ordinary allowance for depreciation is deducted from the average profits when ascertained. The obsolescence allowance, on the other hand, is allowed as a trade expense in the year in which the replacement takes place. Further, any unexhausted depreciation allowance is carried forward for an indefinite period as a deduction from the average profits assessable, but obsolescence allowance is not.

WHEN A CAR IS DISCARDED AND A NEW ONE BOUGHT.

The Royal Commission recommends that in future any ordinary depreciation allowance and obsolescence allowance shall be regarded as trade expenses of the year the profits of which are being calculated. If they are so treated the necessity for carrying forward unexhausted depreciation allowances will cease, since a trading loss caused by the allowance of depreciation will be treated for income tax purposes in the same way as any other trading loss. But the Commission points out that if a taxpayer, instead of claiming a depreciation allowance, prefers to deduct the cost of renewal as and when they occur, it is allowable for him to do so. In the opinion of the Commission this right should remain to the individual taxpayer.

There was some divergence in the evidence as to the correct method of calculating the allowance for such renewal, some witnesses stating that the allowance should have reference to the cost of the machinery replaced, while others held that it should be calculated on the cost of the new machinery. The Commission considers that the allowance for renewal should be calculated by reference to the cost price of the machinery replaced. This puts it in the same position as the allowance for depreciation—which is the alternative to the allowance of renewal—for depreciation is necessarily calculated on the cost of the existing machinery.

Inasmuch as the Chancellor of the Exchequer is understood to have promised that these recommendations are to be carried into law, the situation to be expected after the Budget can be calculated. In regard to motor cars, of course, many now owned are worth more than their original cost, whereas in the next two years they will have a scrap value only; yet they will have to be replaced at post-war costs. That means a very heavy expenditure for the individual medical man in the case of a car, because he can claim depreciation or replacement only on the original cost of the vehicle. On the other hand, should the price of cars fall any time five or ten years hence, when the average medical man will be wanting yet a third car and will be able to buy it cheaply, he will get some of his money back, because he will be allowed to claim the depreciation for the car he is going to buy, say in the next six or eighteen months, at fabulous post-war prices; and all those years hence he will be able to get what will then be a fabulous depreciation allowance for the given vehicle. So that it is really only a question of laying out money without interest; and the law would certainly be much more fair if amended as proposed.

England and Wales.

CONSULTING SURGEON AND HOUSE-SURGEON.

In the Honours List recently gazetted the name of Mr. Edward J. Domville, Consulting Surgeon to the Royal Devon and Exeter Hospital, appears among the O.B.E. The reason for conferring this honour appears to have been the rather unique position occupied by him during the last three and a half years of the war. Owing to the difficulty of filling the post of house-surgeon, the committee applied to Mr. Domville to help them by resuming a post in the hospital which he had filled some forty years before. Mr. Domville consented to do this, and as the honorary medical staff was temporarily diminished in number owing to the occupation of all its members in war work, the house-surgeon was often called upon to discharge very important duties, medical as well as surgical. When he retired, on the declaration of the armistice, his active colleagues united in giving him a handsome silver rose bowl inscribed with their names, and four silver candlesticks, while the Weekly Committee gave him an antique clock and an album containing a list of subscribers, and a warm expression of their gratitude for the unselfish devotion with which he had carried out the duties of his office.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A special committee, to be called the Statistical Report Committee, was recently appointed by the Prince of Wales as President of the Fund. It consists of the Hon. Sir Arthur Stanley (chairman), Sir Cooper Perry, and Mr.

Leonard L. Cohen. The Fund first issued a statistical report in 1904. Since then it has been enlarged and improved on several occasions, but changes and progress in hospital conditions now call for additions and modifications. The necessity for economy in staff and material during the war led to the omission of various tables, and it was thought inadvisable to make any alterations not absolutely necessary. A considerable number of suggestions have been received during recent years, and the new committee is to consider these and other suggestions and to advise as to the form in which the Fund's statistical report should in future be published.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, LONDON.

At the annual meeting of Queen Charlotte's Hospital and Maternity Training School, Marylebone Road, London, on March 30th, it was reported that during the past year nearly 2,000 patients had been treated in the wards and a similar number attended in their own homes. The increase in the number of applications for admission was largely attributed to the shortage of houses. The chairman emphasized the great importance of the work in the antenatal and child welfare departments, where over 5,000 patients had been treated. A large increase in the number of medical practitioners, students, midwives and nurses attending the hospital was noted, a considerable number of the medical practitioners and nurses being members of the Dominion and American medical and nursing services who had taken out courses before leaving this country. It is recognized that a new out-patient department and other improvements are urgently needed, but the expenditure would be £100,000, and there was a deficit on the year's working of over £2,000.

LONDON DISTRICT DISCHARGE CENTRE.

At a dinner held at the Mitre Hotel, Hampton Court, on March 25th, Dr. T. W. Morcom-Harueis was the recipient of a presentation silver tea service from the members of the Medical Boards of the London District Discharge Centre. In making the presentation Dr. Taylor, J.P., Coroner for the Richmond District, expressed the personal regard of the staff for Dr. Morcom-Harueis during his term of office as D.C.M.S., and said the efficiency and smooth working of the boards was largely due to his tact and consideration for all those who worked with him. Dr. Morcom-Harueis, in replying, expressed his regret that his association with them, which had been of the pleasantest character, had now come to an end owing to the closing down of the centre. Dr. Rees Davies also spoke.

PRESENTATION TO DR. P. V. FRY.

On March 28th Dr. P. V. Fry, Sowerby Bridge, was entertained by his medical friends in the Calder Valley, Hebden Bridge, Sowerby Bridge, and Elland areas, on the occasion of his departure from the district. He was at the same time the recipient of gifts of silver as a mark of appreciation of his services in organizing the local medical society and promoting good fellowship amongst its members. Dr. Fry has represented the Calder Valley area on the West Riding Panel Committee since its inception in 1912, and has for some years been a member of the Insurance Acts Committee of the British Medical Association and of the Ministry of Health Committee.

LEICESTER GRADUATE COURSE.

The Leicester Medical Society has arranged a short course of post-graduate lectures, to start on Tuesday, April 13th, and continuing every Tuesday until May 11th. The course will be given by Dr. W. Langdon Brown, of St. Barthomew's Hospital, who has taken for his subjects: The sympathetic nervous system and the ductless glands, Glycosuria, and Disorders of the digestive system.

Scotland.

SCHOOL HEALTH ADMINISTRATION IN SCOTLAND.

In a Memorandum dated March, 1920, the Scottish Board of Health (to which have now been transferred the powers of the Scottish Education Department with regard to medical inspection and treatment of school children and

young persons) describes the leading principles which should guide education and public health authorities in the preparation of their schemes; at the same time, interesting information is given concerning the conditions now existing in Scotland. In all the large cities and eight counties the medical officer of health and school medical officer are independent; and only in twenty-three counties and one burgh is the duty of the school medical officer exercised by the medical officer of health or his assistant. Administrative unity between the two branches is commended, and its inception, where not already existing, is enjoined. Treatment of school children, as distinct from inspection, was not authorized in Scotland until 1913; and during the war "the school medical service in Scotland suffered almost to a point of total suspension," so that it is not surprising to find that schemes of treatment have been organized only by a few secondary education committees in the five burghs. These conditions contrast forcibly with those obtaining in England and Wales, where, in 1914, 266 authorities out of 318 exercised powers of treatment, and 179 provided school clinics. These figures have since been increased to 287 and 252 respectively, and in 1918 dental treatment was given by 169 English authorities. In emphasizing the importance of the provision of treatment, the memorandum insists that treatment and inspection shall be co-ordinated, under conditions of "virtual unity," within the control of the school medical officer. Other sections of the memorandum deal with the provision of school nurses (who appear to exist in very few areas), with inspection in continuation schools, and with physical education. The whole question of the latter, it is said, should come under direct medical supervision with a view, first, to guiding its development as a subject of hygienic purpose, and secondly, "to establishing it on a footing that would make it an effective basis for the application of measures touching other aspects of personal hygiene." With regard to staffing, the Board considers it desirable that all district medical officers should possess the diploma in Public Health or its equivalent; all school medical officers should have experience in as many as possible of the following: diseases of children, diseases of the eye, diseases of the ear nose and throat, diseases of the skin, and school hygiene. Before confirming appointments the Board requires that statements of candidates' qualifications and experience should in all cases be submitted to it.

Ireland.

ROYAL ACADEMY OF MEDICINE.

A MEETING of the Section of Surgery of the Royal Academy of Medicine in Ireland was held on January 30th, with Mr. J. B. Story, President of the Royal College of Surgeons in Ireland, in the chair. Mr. William Pearson showed a specimen of cancer of the caecum, with faecal fistula, successfully removed by operation. Sir W. I. de C. Wheeler read a paper on compression of the lower brachial trunk by the first dorsal rib. Referring to the work done by Stiles, Stopford, and others, he described a case operated on by himself. The condition simulated that associated with cervical rib, but x-ray examination revealed no trace of this abnormality. An unusual feature was that while the patient could scarcely write at all with the right hand in the ordinary position, he could write easily when the arm was raised above the shoulder level. The subclavian artery was found to lie well above the subclavian groove. He described the operation for removing the segment of the first rib compressing the nerve trunk. Mr. R. V. Slattery read a paper on the radical cure of inguinal hernia, and described his own method of narrowing the internal abdominal ring. He closed the defect in the transversalis fascia by splitting the fascia and overlapping it, after the method of Mayo in dealing with umbilical hernia; the upper leaf of fascia was sutured to Poupart's ligament. Mr. Adams McConnell read a paper on a case of cyst of the common bile duct. He described the clinical appearances of the caes, and noted that the tumour in the right hypochondrium, the slight icterus, and attacks of colicky pain conformed with the symptoms of other cases described. Drainage of the cyst was carried out, and ten

months afterwards the wound had to be reopened because of septic infection. After this operation the patient remained well with the fistula closed. He reviewed other cases that had been reported, and discussed the diagnosis and treatment. He pointed out the rarity of the condition, and the fact that his case appeared to be the only one which had survived after drainage alone had been carried out. Mr. C. J. Macauley described a case of acute inflammation affecting a Meckel's diverticulum which extended to but was occluded at the umbilicus. The entire diverticulum had been successfully resected.

POOR LAW MEDICAL OFFICERS.

At a largely attended meeting held in Clones, co. Monaghan, the following resolutions were unanimously passed:

1. That the salaries of Poor Law medical officers are entirely inadequate; that the salaries of dispensary medical officers be £300 per annum, rising annually by £5 to reach £400 and applied retrospectively.
2. That the salaries of union infirmary medical officers be £200 per annum, rising annually by £5 to reach £300 and applied retrospectively.
3. That the salaries of medical officers of health be £75 per annum for urban districts and £50 for rural districts.
4. That fees for inspection of and report on houses under the new housing scheme be one guinea with mileage.
5. That unless legislation is at once introduced to increase the fees for registration of births, deaths, and marriages to 2s. 6d. per entry, the registrars will cease work; that mileage be paid at 1s. 6d. per mile for journeys to superintendent's office, and that a fee of 5s. per death certificate be paid by the Registrar-General.
6. That fees for vaccination be doubled and that 1s. be fixed as fee for registration of vaccination.
7. That locumtenents be appointed at the rate of 7 guineas per week for dispensary districts and 5 guineas per week for work-house hospitals; that where both duties are combined the fee be 10 guineas per week.
8. That a full month's holiday be granted annually.

Correspondence.

AWARDS FOR MEDICAL DISCOVERY.

SIR,—In his letter in your issue of April 3rd Sir Ronald Ross invites attention to your report of the deputation to Mr. Balfour (BRITISH MEDICAL JOURNAL, March 6th, p. 347) on the above subject. Its perusal should give food for thought to medical men. Three leading members of the profession represented to Mr. Balfour that, in striking contrast to workers in other branches of science, medical men are denied direct pecuniary benefit from their labours in research; and consequently there existed special reasons that funds be placed at disposal for awards to those who, notwithstanding such unfavourable conditions, have given their labour, sacrificed private means or denied themselves pecuniary benefits in efforts which have contributed to the public weal. Sir Clifford Allbutt stated, in respect to the medical profession, "those conditions were governed by the very highest standard of ethics maintained in the profession. . . . No medical man was permitted to take out a patent." Obviously, therefore, the appeal for funds was made on grounds special to the medical profession. The statesman evidently concluded that he might in his reply spare the deputation the thrust that, rightly or wrongly, the self-imposed code of honour of the profession alone prevented medical men from reaping the fruits of their labour; and confined himself to generalizations which concerned workers in science collectively. But his well-known courteous instincts failed to remind him that not the cold charity of the Civil List Fund—obtainable by "influence"—was indicated, but the employment of ways and means of expressing a nation's gratitude for benefits placed, free of charge, at its disposal.

Parliament has no hesitation in awarding many thousands of pounds to the warrior who, at the cost of lives, saves lives and the commercial possibilities of the nation. Are men of the type of Ross, who have, by years of toil and self-sacrifice, saved thousands of lives, and not only rendered commerce possible where formerly it was hopelessly handicapped, but have held open the path for the warrior hitherto "held up" by his most formidable enemy—disease—to be afforded less substantial tokens of gratitude? Even that bugbear of officialdom, the creation of a precedent—in this case as to awards for medical research—does not bar action. A grateful nation awarded (1802) Jenner £10,000, but, repenting subsequently of its illiberal

attitude, presented him (1806) with a further gift of £20,000. Nor did he lack practical gratitude in the tropics—Calcutta sent him £6,000.

The *ad misericordiam* refuge of the Civil List Fund cannot fill the rôle desired by the deputation unless vastly altered as to scope and mode of administration. Should, therefore, the views expressed to Mr. Balfour by the deputation secure from Government no adequate response, is it not time the profession considered whether certain of the self-imposed ethical rulings which govern it with iron severity are not anachronisms? Their modification to suit the times need not imply their abolition. Even the drastic rules of Hindu caste, with its similar penalty of excommunication, possess more flexibility than the caste rules of medicine. Manu defines the "conduct of good and virtuous men" as governed by "custom" handed down from time immemorial, but acknowledges the right to alter the interpretation of the *Shastras* when custom alters with the times.

Accepting the analogy, whilst it is still undesirable a medical man should use his position to canvass his patients on politics, why should it be wrong in the present day of much extended franchise (to the advantage of certain sections of the community to an extent that may unfavourably influence the professional classes) for leaders of the profession, without the trades union taint of compulsion, openly to appeal to the profession to vote as a body for certain political ends? In the next six months, in this manner, more could be done to further medical interests than blind adherence to the fetish of old-time ethics has done in a century.

Again, why should it not be possible to frame rulings administered by leading men of the profession which shall permit the taking of patents by research workers, under circumstances not calculated to injure the honour of the profession?—I am, etc.,

April 3rd.

W. G. KING, Colonel I.M.S.(ret.).

OUR OPPORTUNITY.

SIR,—I have read with pleasure the letter headed "Our Opportunity" in your last issue.

We do want our independence, individualism, and freedom, and let us work in harmony with the help of the State. The question of remuneration has been settled by arbitration, and would have been fixed long ago, I think, if proper returns had been sent in by medical practitioners. These returns are sent for the benefit of statisticians for future use by the State, and ought to be accurate. Most men have done as much again as they have reported. I find that in 1918 and 1919, out of a panel of 450, there were 213 ill and seen on an average six times. Without a proper return of the work done no correct remuneration can be adjusted, or ever will be, so let us look more to the future than we have done in the past, and in doing so save ourselves from being conscripted, as then all independence and freedom must be taken away, never to be restored.—I am, etc.,

Buxton Spa, April 2nd.

J. McOSCAR.

SIR,—Above all things at present the nursing staff visiting the homes of the sick poor should be very largely developed. In the area in which I work I do not know what would be done at all without the help of the district nurses or kindred organizations. In most cases it is not the doctor who "cures" the patient but efficient nursing and carrying out of the doctor's instructions. In whole areas the condition of life is appalling. All the money earned seems to be spent in any other way whatever except that of home comfort. Families earning many pounds a week have often—even usually—little more than rags upon their beds, and quite inadequate quantities even then; this is not from lack of money, but simply that it is what they have been accustomed to. Then, in many cases, I have actually been afraid to accept the offered chair, owing to the verminous condition of everything. How can one expect in cases like that to cure one's patients? One gives instructions, repeats and repeats these to make them understood, and then finds they are forgotten the moment one's back is turned. The hospitals are very willing to help, but their beds are limited in number, and it is with the greatest difficulty one can get the patients to go to the infirmaries of boards of guardians. There is a social slur

connected with these, and patients will really often, as they say, "die first" before they go to them.

What I should like to see, as the first step, before everything else, is to try to deal with the sick poor at their homes. Dispensaries, even hospitals, are secondary to this. It is the bed-rock one must get to first. Develop the sanitary side and enormously increase the district nurses, and let every "panel" or "guardian" doctor be able to receive full assistance from both of these. Then, and then only, will there be the basis for a proper medical service for the poor.—I am, etc.,

Bristol, April 5th.

E. J. BALL.

CLINICAL CENTRES.

SIR,—The clearing-houses under the Ministry of Health (SUPPLEMENT, March 20th, p. 81) should have suitable accommodation for the various agencies. In addition to roomy, well-ventilated, and well-heated waiting-rooms (male and female), with proper lavatory facilities, etc., there should be separate rooms for infant welfare, maternity, tuberculosis, eye, throat and ear (with dark room), and for bacteriology and pathology. The "centre" should preferably be in close touch with the local hospital, and facilities for x ray and light examinations and treatment should be at the centre or hospital. At present nondescript and often inconvenient accommodation is in use wherein it is difficult to do good work.

Half a dozen observation beds would be very advantageous for doubtful cases. An army ambulance van and disinfecting lorry for each centre would be of great use. In choosing the caretaker or porter knowledge and experience of ambulance work and nursing should count.

If permanent buildings are not at present forthcoming, a start might be made with army or Y.M.C.A. huts. Every district provided such structures for the war, and certainly has a moral right to them for an at least equally useful purpose.

Efficient service at the "centre" will soon pay for itself by earlier diagnosis and treatment, with resulting quicker return to school or work.—I am, etc.,

Newport (Mon.), April 5th.

J. LEWIS THOMAS.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—Dr. Freer says (March 20th, p. 417), "it was surely in part to mitigate . . . improvidence . . . forcing the spendthrift to make some slight provision for a rainy day" that the Insurance Act was evolved. It was. The trouble is that it has, and must have, so completely failed. Even the Fabian Society's report shows that it has not lightened the burden of the Poor Law. It is well known that there has ever since been an unwonted run on Poor Law beds. Personally (I hold no parish appointment) I have had to have recourse to the Poor Law oftener these seven years than in all my previous professional life.

A poor law is a statutory provision for the poor out of moneys provided by the law. In this Act the major part of the moneys is frankly of the nature of a State subsidy. Even the direct contribution is forced from the employer and is of the nature of a tax deducted at the source. It does not alter the nature, it emphasizes the deteriorating quality, of the law that the majority of its beneficiaries are not in need of State aid. Dr. Freer knows that every effort was made to convince the working class that the benefit was in the main a gift. It is an abuse of terms to call such a process "insurance." The Act is clearly of the nature of a poor law; and it is a relevant corollary that the benefit, to the poor, of a poor law has always been in direct ratio to the scrupulousness of the regard of its administration for desert.

If Dr. Freer remembers that in order to preserve the shiftless from the consequences of shiftlessness both shiftless and thrifty have to be taxed all through their sunshiny days and the thrifty through the rainy days also, he will see that many deserving people are made poorer in order to enrich the shiftless in the time of stress. The process is precisely on all fours with this question of tuberculous mortality: in which the records show that if ten lives are being preserved by State measures eleven are being sacrificed. (The figures are illustrative merely; I have not calculated them out.)

The State has no right to think for England of to-day

merely, and especially not for the individual of to-day; it must think for the community as a whole, future as well as present. Evidence is accumulating day by day of the superiority—to the community—of voluntarism over compulsion. It is surely better for the State to lessen morbidity than to make provision for sickness, and a very striking example is that under voluntarism the morbidity of male workers fell in Denmark from 6.2 to 4.9 days per year during the period 1893 to 1912. In Germany in the same period it rose from 6.6 to 8.2. Now that we have done with the Imperial Government, whose interest in fostering the delusion that compulsory State insurance was for the good of a nation was shown by its large expenditure on propaganda, the truth will more and more clearly emerge; the latest German reports are highly instructive reading.

In conclusion, will you let me say, Sir, that I am grateful—and not I alone—for permission to discuss the Act from the larger standpoint of the national welfare. I have always felt it as a reproach that in the most important organ of our profession (of all classes in the world!) the only question in a measure so ambitious and so large as to be—for good or for evil—revolutionary should seem to be its peculiar reaction on our wages.—I am, etc.,

Rayleigh, Essex, March 28th.

B. G. M. BASKETT.

HEAT HYPERPYREXIA.

SIR,—Colonel Willcox, in his interesting paper on heat hyperpyrexia (BRITISH MEDICAL JOURNAL, March 20th, 1920), appears to disagree with my view (BRITISH MEDICAL JOURNAL, April 26th, 1919) that suppression of sweating is the primary cause of hyperpyrexial heatstroke. I would therefore be glad if you would kindly grant me space to make a few comments, which may help to clear the doubt that exists regarding the etiology of this important disease.

In case there may be some confusion regarding the meaning of the term hyperpyrexial heat-stroke as used by me in my note of April 26th, 1919, I would mention that it refers to a state of affairs in which the patient is totally unconscious, has a bodily temperature of 110° F. or thereabouts, and is usually in a condition of convulsions or spasms.

In my experience the lowest bodily temperature required to produce this clinical picture is about 108° F., though many cases may reach 109° F., or more, before the unconscious state is reached; my contention is, that although lower temperatures (which are rightly or wrongly attributed to "effects of heat") may be met with while the patient still retains his power of sweating, actual heat-stroke cannot occur until he has stopped sweating for some variable time previously.

It follows, then, that by taking the onset of suppressed sweating as the warning sign, we can in every case prevent the development of this highly dangerous condition by the simple process of artificially sweating the patient as suggested in my note.

Now, as regards the cases of heat hyperpyrexia mentioned by Colonel Willcox which "suddenly occurred in exposed men who were in good health, without any previous evidence of lack of skin action," and in others "though they had been under observation in hospital for several days," I would point out that suppression often comes on with remarkable suddenness and requires the closest observation to detect it. This is why I found it necessary on very hot days to carry out my inspection of all the patients in the ward hourly. During these inspections I would frequently find that a patient whose temperature and skin condition had given me no cause for anxiety at 3 p.m. had by 4 p.m. developed complete suppression of sweating and a temperature bordering on heat-stroke. Unless observation is carried out as systematically as this, it is quite possible for one to form the opinion that suppression had not preceded the attack.

I may mention that throughout the heat wave of 1917 I remained constantly in my ward during the hours of the day when attacks were at all likely to occur, and was thus able to study personally every change in the medical condition of the patients. From these observations and the results of preventive treatment (based entirely on the suggested etiology), which has not failed in one single instance,

I have no doubt whatever as to the truth of my conclusions.—I am, etc.,

Royal Infirmary, Hull, April 4th.

K. G. HEARNE.

SIR,—I was much interested in reading the papers by Drs. Willcox and Leonard Hill in your issue of March 20th. In my experience I have found two points always precede an attack of heat hyperpyrexia—namely, frequency of micturition and absence of sweating. These facts were pointed out in his lectures forty years ago by Professor McLean at Netley.—I am, etc.,

WILLIAM PIKE,
Major-General A.M.S. (ret.).

Salisbury, April 2nd.

SYME THE DISCOVERER OF WATERPROOFING.

SIR,—In the interesting note on the brothers Michelin and their famous tyre works, published in the JOURNAL for March 27th, 1920 (p. 458), it is stated that Captain Daubrée, a cousin of the grandfather of the Michelins, "married a niece of the Scottish chemist, Mackintosh, whose name, through his discovery of the solubility of rubber in benzine, has become associated with waterproof garments."

The discovery of the solubility of rubber is much more interesting to the medical profession, for it was really made by Syme. In Dr. Paterson's *Memorials of Professor Syme* (p. 11), the story is told how Syme, as a young student of medicine, only 19 years of age, worked a great deal in practical chemistry. In March, 1818, he made a short communication to the *Annals of Philosophy* announcing the discovery of a new and cheap solvent for caoutchouc distilled from coal-tar. In that communication he said, "It occurred to me that by distilling coal-tar a fluid might be procured which, like naphtha, would have the property of dissolving caoutchouc. After many trials I completely succeeded, and was enabled to carry into effect several of the applications, for which a fluid state of indiarubber had seemed so desirable. Thus I constructed flexible tubes of the substance itself, and rendered various textures waterproof by brushing a thin solution of it into their interstices."

After the appearance of this communication in the *Annals of Philosophy* (which, by the way, was published in Glasgow) the patent was taken out by Mr. Mackintosh, a manufacturer in Glasgow, for the making of waterproof cloth by means of caoutchouc dissolved in coal-tar naphtha. Syme declined the advice of his friends to take out a patent himself, though, if he had done so, as Dr. Paterson says, he might have realized a large fortune independent of his profession. Some years later, in referring to the matter, Syme said that he gained little credit and no profit by the discovery, except the confidence that results in successfully struggling with a difficulty.

Incidentally it might be remarked that in Glasgow a waterproof coat is known as a "waterproof"; it is only in England, and especially in the South of England, that such a garment is called a "mackintosh."—I am, etc.,

Glasgow, March 30th.

JOHN PATRICK.

THE TREATMENT OF UTERINE CANCER.

SIR,—I had previously read Dr. Herbert Spencer's lectures, partly because it is my duty to study whatever is published on tumours, but mainly because it gives me pleasure to read what Dr. Spencer writes. It was, however, to the argument of your leading article on the subject that I took exception. It was reactionary. It despaired of the radical treatment of cancer of the uterus; restricted operation and radium were its sole messages of hope. The former is backed up by citing three cures of cancer of the cervix in advanced pregnancy by vaginal amputation. Even Dr. Spencer himself, in spite of the successes which he recorded with restricted operation in these few cases, stated in his paper: "Operable cases should be treated by Caesarean section followed by extended abdominal hysterectomy. If the patient is in fair condition the operation is indicated equally on the ground of science and humanity." The deduction from that is obvious.

There was a surgeon of Alexandria, called Leonides, who, while his contemporaries were treating cancer of

the breast by the application of arsenic and verdigris, operated on the disease with the knife and cautery, cutting into the apparently healthy tissues around the evident growth and applying the cautery to the cut surface. He said that the heat of the latter would kill any remaining cancer in the vicinity. Without anaesthetics, ligatures, or antiseptics he probably had a higher mortality than his fellows, but possibly he was lucky enough in a very few cases to eradicate the disease completely. He was a bold man, as befitted his name, but he lived eighteen hundred years ago. No surgeon nowadays would content himself with removing the breast alone; even if the axillary glands were not palpable and though the primary growth were small, he would not think of omitting the thorough clearance of the axilla, the extirpation of the regional lymphatic zones, and the wide removal of the affected organ. The problems of the treatment of cancer of the uterus differ in no essential detail from those of the breast. The high amputation of the cervix by the cautery is the eighteen hundred year old operation of Leonides, and its success is about the same. Dr. Spencer treated three cases and had three cures—100 per cent. success. Some say that pregnancy has a bad effect on uterine cancer; some think that it would enable the cancer to be detected at an earlier stage; nobody has had sufficient experience of the uncommon conjunction to know. The numbers are too small to permit of any judgement. It is possible that if Dr. Spencer had operated by the same method on 100 such cases he might have had 97 per cent. of failures. It is a matter of luck. The statistics of 915 *post-mortem* examinations of uterine cancer which I published several years ago showed that in approximately 3 per cent. there was no evident spread of the disease beyond the cervix. If we take it that the naked-eye findings *post mortem* would correspond with what the microscope could reveal during life in the average case, then 3 per cent. would represent, with the ordinary run of luck, the possible cures that high amputation would accomplish.

I do not know what facts and statistics Mr. Dickie desires in order to form a judgement. Radical operations are founded on our knowledge of the surgical pathology of the disease, and their worth is estimated roughly by the proportion of cures to all cases seen and not merely to those selected for operation. By the latter method it is obvious that one has to judge an operative technique as it was ten or more years ago whilst all the while it and its results are improving. On both points—the requirements of pathology and the actual results of operation—I cannot do better than refer Mr. Dickie to Berkeley and Bonney's recent edition of *Gynaecological Surgery*. These authors, who have treated perhaps the largest series of cases in this country, could produce an absolute cure rate of about 25 per cent. Doubtless they and others have improved on that.—I am, etc.,

Pathological Laboratory,
The Cancer Hospital, S.W.,
March 23th. ARCHIBALD LEITCH.

A NOTE ON ARTIFICIAL PNEUMOTHORAX.

SIR,—In an article in the *JOURNAL* of March 27th (p. 432), under this heading, Dr. Frederic Coley, while describing the introduction of a stuffing box to the ordinary Saugman pneumothorax needle, makes the following reference to myself: "Dr. Clive Riviere obviates this difficulty" (prevention of the entrance of air) "by tying a piece of sheet india-rubber over the open end of the instrument. I believe he uses this either with his own trocar and cannula in primary operations, or for an ordinary needle in doing 'refills'." May I point out the facts? My own trocar and cannula possesses an obturator or stuffing box with a bayonet catch to prevent it from loosening or falling off. Incidentally, I have grown to dislike the bayonet catch, and I think Dr. Coley's screw may perhaps prove less liable to jamb. In describing the Saugman needle in my book I remarked: "This may be provided with an obturator, as is done in the most modern pattern, or the end may be covered, to prevent the entrance of air while clearing, by a thin rubber cap, through which the stilette is passed." These caps were supplied with the needles, but were not devised by me; I have never resorted to sheet rubber, as suggested. For a long time past I have

been using for refills Saugman needles provided with a stuffing box, and the March number of the new journal, *Tubercle*, contains an illustration of this modified needle with the following descriptive notice:

The illustration shows a modification of the well known Saugman needle, carried out by Messrs. Downs Bros. at my request. To the stilette used for clearing its lumen has been added a "stuffing box," and this enables the needle to be cleared while in the chest without any risk (as otherwise occurs) of gas embolism. The needle can be obtained at a cost but little above that of the usual Saugman needle, or the modification can be added to needles which have been already in use.

There are now, therefore, two sources from which Saugman needles provided with a stuffing box may be obtained.

The oblique oral point recommended by Dr. Coley is certainly a safeguard when a pointed needle is used at the first operation, and the same is found on the Forlanini and Brauns needles, and on the Morrision Davies needle in this country. A flat guard, similar to Dr. Coley's "holder," is provided with the Courmont needle, but the nut with which Dr. Coley fixes his holder seems an improvement over the lateral screw on the Courmont plate.—I am, etc.,

London, W., March 30th.

CLIVE RIVIERE.

BIOGRAPHY OF SIR WILLIAM OSLER.

SIR,—Lady Osler has requested me to prepare a biography of her husband, and I will be most grateful to any one who chances to see this note for any letters or personal reminiscences, or for information concerning others who may possibly supply letters.

Copies of all letters, no matter how brief, are requested, and if dates are omitted it is hoped that they may be supplied if possible.

If the originals are forwarded for copy they will be promptly returned.—I am, etc.,

Peter Bent Brigham Hospital,
Boston, Mass., U.S.A.

HARVEY CUSHING, M.D.

Medico-Legal.

LIABILITY UNDER THE LUNACY ACT.

THE case of *Everett v. Griffiths and Anklesaria*, in which the plaintiff in November last sought to recover damages against the defendants on the ground that they had unlawfully and without good faith or reasonable care signed a certificate that he was of unsound mind, and procured his detention as a lunatic in an asylum from March 27th to April 9th, 1919, was referred to in our issue of November 29th, 1919, page 726. It may be remembered that the jury having disagreed, the Lord Chief Justice entered judgement for the defendants upon the ground that Mr. Griffiths was acting in a judicial capacity, and that the certificate which Dr. Anklesaria had given as to the plaintiff's mental condition was not the effective cause of the latter's detention. The act of Mr. Griffiths had intervened and caused the detention. From this decision the plaintiff appealed, and conducted his case in person before the Court of Appeal, which delivered its reserved judgement last week.

Lord Justice Bankes, in his judgement, dealt with the positions of the two defendants separately. Mr. Griffiths in making the detention order was acting under special authority conferred upon him as chairman of the Islington Guardians by the Lord Chancellor under Sec. 25 of the Lunacy Act, 1891. This section provided that every order signed under that authority should have effect as if made by a justice of the peace, and the appellant had urged that this did not afford to Mr. Griffiths the protection which under Sec. 330 was given to a justice of the peace. This contention he considered to be ill founded. If Mr. Griffiths was honestly satisfied, as it was admitted that he was, that the appellant was at the time he made the reception order a lunatic and a proper person to be detained, Mr. Griffiths was justified in making the reception order and it was immaterial whether or not he used reasonable care in arriving at his decision. It therefore became unnecessary to decide whether in acting as he did Mr. Griffiths was performing a judicial or an administrative function.

Dr. Anklesaria was called in to make the examination of the appellant, which was prescribed by statute, and to give the certificate, without which the reception order could not have been made. Although the doctor was not being employed by the appellant, he was under a duty to him, nevertheless, the extent of which was to be determined by reference to the terms of the statute by which the examination was prescribed. The Legislature could only have contemplated an examination conducted with such care as in the circumstances of each case

could come up to the standard of what was reasonable. To go further and adopt the view that a medical man called in by a magistrate to express an opinion on a person who was alleged to be a lunatic might be liable in damages for making an incorrect diagnosis, though he had acted in perfect good faith and used all the care at his command, would be adopting a view which might render the working of the Act in many cases extremely difficult, if not impossible. There was no evidence that Dr. Anklesaria had failed to use reasonable care and such skill as he possessed in his examination of the appellant and in arriving at the conclusion expressed in the certificate, and the appeal in his case therefore also failed.

Lord Justice Scrutton agreed that the appeal should be dismissed, but Lord Justice Atkin, in a dissenting judgement, considered that there was evidence of want of care on the part of both respondents, and that a new trial should therefore be granted.

The result, therefore, was that the appeal was dismissed by a majority of the court, though it should be noticed that the way in which the court approached the case from a legal point of view differed very materially from that in which the Lord Chief Justice had dealt with it.

INSANITY AND CRIME.

THE decision of the Court of Criminal Appeal in the Holt murder appeal last week was chiefly noteworthy on account of the Lord Chief Justice's criticism of the medical evidence which was called in support of the plea of insanity. The question as to the legal effect of insanity as an excuse for crime was raised in debate in the House of Lords in 1843, as the result of what is now known as Macnaghten's case, and it was determined to take the opinion of the judges upon the whole subject. The opinion, which was delivered by Chief Justice Tindal, and which has been treated as the leading case on this branch of law, was as follows:

Notwithstanding the party accused did the act complained of with a view, under the influence of insane delusion, of redressing or revenging some supposed grievance or injury, or of producing some public benefit, he is nevertheless punishable according to the nature of the crime committed, if he knew at the time of committing the crime that he was acting contrary to the law.

Every man is presumed to be sane, and to possess a sufficient degree of reason to be responsible for his crimes, until the contrary is proved; and to establish a defence on the ground of insanity it must be clearly proved that, at the time of the commission of the act, the party accused was labouring under such a defect of reason from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it that he did not know he was doing what was wrong.

The accused must be considered in the same situation as to responsibility as if the facts with respect to which a delusion exists were real. For example, if under the influence of his delusion he supposes another man to be in the act of attempting to take away his life, and he kills that man, as he supposes, in self-defence, he would be exempt from punishment. If his delusion was that the deceased had inflicted a serious injury to his character and fortune, and he killed him in revenge for such supposed injury, he would be liable to punishment. A medical man who never saw the prisoner previously to the trial, but who was present during the whole trial, cannot, in strictness, be asked his opinion as to the state of the prisoner's mind at the time of the commission of the alleged crime, but where the facts are admitted or not disputed, and the question becomes substantially one of science only, it may be convenient to allow the question to be put in that general form, though the same cannot be insisted on as a matter of right.

In the Holt case the prisoner had murdered a woman at Blackpool. For some time prior to the crime he had been living with her; he had persuaded her to insure her life for £5,000, and had himself opened a banking account in her name on which she had drawn a cheque in payment of the premium; and, finally, the woman had made a will in Holt's favour.

Holt was tried at Manchester Assizes on a charge of murder, and a preliminary inquiry was held as to his fitness to plead. Eminent medical men were called to show that he was insane, but the jury decided that he was fit to plead, and the trial proceeded, with the result that he was convicted and sentenced to death. From this conviction he appealed to the Court of Criminal Appeal, mainly on the ground that he was insane when he committed the crime, and had murdered the woman under an uncontrollable impulse. He also applied to call further evidence in support of his plea of insanity, and the court allowed this to be done.

Dr. Morton (Exeter) said that in 1914 a woman who was said to be a cousin of the prisoner had been admitted into his asylum suffering from delusional insanity and hallucinations of sight, hearing, and smell. A woman who had been a servant to the prisoner's paternal grandfather said that her master was obsessed with the idea that people were trying to poison him. Another medical witness spoke to having played cards with Holt last December and noticed that he could not concentrate his mind upon the game. He considered that Holt was suffering

from hallucinations. Dr. Bernard Day said that from the description of the prisoner in the press during the trial at Manchester he had recognized him as a man he had attended in the East for syphilis at the end of 1916. He was then suffering from shell shock and it was impossible to state the effect of syphilis upon a man in that condition without testing the spinal fluid. A medical man spoke to having seen Holt in October, when he seemed "very wild"; and another said that he saw Holt last July, when he noticed that Holt was unable to concentrate his mind upon anything. Finally, two medical men were called, and said that having listened to the evidence they had formed the opinion that Holt was suffering from delusional insanity, and, probably, also from general paralysis of the insane.

The Lord Chief Justice, in delivering the judgement of the court dismissing the appeal, pointed out that it was not necessary to consider whether the tests as laid down in Macnaghten's case should be extended so as to include "uncontrollable impulse," in view of the fact that this had been left to the jury by the trial judge, and had been negated by them. He criticized the further evidence which had been called, which, he said, was substantially the same as that which had been called on the preliminary inquiry as to Holt's fitness to plead at the assizes, and emphasized the necessity that the tests laid down and established by Macnaghten's case should be complied with. The evidence which had been given as to Holt's mental condition was hypothetical, and it was not sufficient for medical experts to come into court and say generally that a criminal was insane to warrant a verdict of insanity.

Obituary.

JOHN MORTON, M.B., C.M.,
Surgeon, Western Infirmary, Glasgow.

WE regret to record the death of Dr. John Morton of Glasgow, which took place on March 21st at the age of 54. A native of Newmilns, Ayrshire, he received his medical education at Glasgow University, where he graduated as M.B., C.M., with honours, in 1892, when he was awarded the Brunton Memorial Prize as the most distinguished student of his year. He began practice in the west end of Glasgow, at the same time becoming extra dispensary surgeon to the Western Infirmary, with which institution (ultimately as visiting surgeon) he was connected to the time of his death. For seven years he acted as demonstrator in anatomy in the University of Glasgow, and was examiner in anatomy and surgery to the University of St. Andrews. Although severely taxed by the claims of an ever-enlarging consulting surgical practice he found time to make many contributions to medical journals, the chief of these being "Sarcoma," "Strangulated femoral hernia," "Enterectomy with lateral anastomosis: recovery," "Foreign body in sac of hernia, with remarks on the presence of foreign bodies in the abdominal cavity," "An analysis of a series of 400 cases of perforated gastric and duodenal ulcers"—a paper read to the Partick and District Medical Society, of which he was a valued member—was published in this JOURNAL.

Dr. WILLIAM SNODGRASS (Glasgow) writes:

The medical profession of Glasgow has sustained a heavy loss through the death of Dr. John Morton, on March 21st, after operation in a nursing home. After a brilliant career as a student, he settled in the west end of Glasgow and soon enjoyed an extensive and lucrative practice; nevertheless he was always attracted by the scientific aspects of his profession and acted for many years as demonstrator and assistant to Professor Cleland in the anatomy department of the University of Glasgow. He was also appointed dispensary surgeon in Glasgow Western Infirmary, where, on the retirement of the late Dr. Renton, he became one of the visiting surgeons, and where his teaching powers attracted large classes of students. On the outbreak of war he received a commission as Captain R.A.M.C. (T.F.), and had charge of wards in the 3rd Scottish Hospital during the period of the war. Although his health suffered from overwork, he kept resolutely to his post, where his fine personality and keen devotion to duty were widely recognized and appreciated. In his rare moments of leisure he was fond of a round of golf or a game of bowls, and his quiet, cheerful personality will be sadly missed by his many patients and friends. To a sound judgement in diagnosis he added exceptional rapidity, skill, and neatness as an operator, and his death at a comparatively early age when at the full height of his surgical power comes as an irreparable

loss to the community. He is survived by his widow and his only son, Dr. John W. Morton, to whom the medical profession of Glasgow extends its deepest sympathy.

ON Sunday, March 28th, Dr. JOHN M. CLARK, of the medical staff of the Pilkington Orthopaedic Hospital, St. Helens, Lancashire, succumbed to an attack of pneumonia consequent on influenza. For the past fifteen months since his discharge from the army Dr. Clark has given unremitting service to the hospital, and his death is deeply deplored by colleagues and patients. After a distinguished course of medical study in Glasgow University Dr. Clark acted as house-surgeon in Dr. Paterson's wards in Glasgow Royal Infirmary. In 1916 he joined the R.A.M.C., and for almost two years he shared with cheerfulness and devotion the trying life of our troops in German East Africa. To the work of the Pilkington Hospital, with its special aims and methods, Dr. Clark brought earnestness of purpose and outlook, and high professional ability. As chief of staff under Dr. Kerr, the officer in charge, he will be remembered for his unsparing work, his strong kindly personality, and his whole-hearted interest in the efficiency of the hospital and the welfare of the men.

DR. EVAN WILLIAMS, the oldest medical practitioner in Anglesey, died at Llangefni in his 80th year. He was born at Bryngwran and had lived in Llangefni throughout almost the whole of his long professional life. After studying medicine in Dublin and London, he obtained the M.R.C.S. diploma in 1866 and the L.R.C.P.I. and L.M. in the following year. Dr. Evan Williams was for many years district medical officer and medical officer of health. In 1895 he was made a justice of the peace and attended regularly at the local magistrate's court. He took a keen interest in public health matters, educational work, and parochial business. He served on the county council, was a manager of several schools, and a churchwarden. Dr. Evan Williams was a past-president of the North Wales Branch of the British Medical Association and was always a most loyal colleague and zealous member of the Association. As chairman of the Anglesey Panel Committee he further showed his active interest in all that appertained to his profession. He was a hard worker, genial and courteous to all who met him, and possessed a deep sense of duty not only as a professional man but as a citizen. He leaves a son and daughter and numerous grandchildren to mourn his loss.

We regret to record the death, which took place on March 29th, of Dr. DUNCAN FRANCIS HUNTER of Wallasey, Cheshire. He was educated at Trinity College, Dublin, and graduated M.B., B.Ch., B.A. in June, 1908, proceeding M.D. in the same year. He volunteered for Army service in November, 1915, and served in France with a Territorial division, until invalided in October, 1917. He never truly regained his health after this illness; nevertheless, on his discharge from the army, with the rank of captain, in May, 1919, he returned to private practice in Wallasey, and continued his professional work to the date of his death. He was devotedly attached to the profession of his choice, and with his varied experience and talents of no mean order he would, no doubt, have achieved a conspicuous and honoured position therein. His early death can without doubt be traced to his anxiety to serve his country. He was the only child of Mr. and Mrs. H. W. Hunter, of Lyndhurst Road, Wallasey, both of whom survive him.

DEPUTY SURGEON-GENERAL CHARLES ALEXANDER INNES, R.A.M.C. (ret.), died at Charmouth, Dorset, on March 17th, aged 88. He was born at Bruges, and was educated at King's College, Aberdeen, where he took a bursary, and graduated M.D. in 1855, at the age of 21; also he took the L.R.C.S. Edin. in the same year. He entered the army as assistant surgeon in March, 1855, and became brigade surgeon in 1881, retiring with an honorary step in that year. He served in the 52nd Foot in the Crimea, where he took part in the siege of Sebastopol, and in the expedition to Kertch, receiving the medal with a clasp, and the Turkish medal, and returning to England in charge of the

first batch of patients admitted to the Royal Victoria Hospital, Netley; and in the Indian Mutiny, when he was present at the siege, assault, and capture of Delhi, and received the medal with a clasp. His regiment, the 52nd (Oxfordshire), furnished the storming party at the Kashmir Gate. Subsequently he served in the 16th Dragoons, now the 16th Lancers, and after retiring from the army filled the post of medical officer of the prisons at Hull, Coldbath Fields, and Pentonville, successively, for fifteen years. His father, Lieutenant Alexander Innes, 42nd (Black Watch), and his uncle, Lieutenant Hector Innes, 92nd (Gordon Highlanders), served at Quatre Bras and Waterloo.

THE death occurred on March 3rd of Lieut.-Colonel JOHN PERCIVAL HUNT, R.A.M.C. (retired), in his 75th year. After studying at the University of Glasgow and St. Thomas's Hospital he obtained the L.R.C.P. Edin. and L.R.C.S.I. diplomas in 1864. In 1872 he obtained the M.D. degree of the University of Glasgow and the fellowship of the Royal College of Surgeons in Ireland. Colonel Hunt served in the Sudan in 1885-86, receiving the bronze medal and star. In 1884 he was called to the bar as a member of Lincoln's Inn.

MAJOR GEORGE BLACKER ELLIOTT, R.A.M.C., died at Brixham on March 22nd, aged 55. He was the youngest son of the late William Armstrong Elliott, F.R.C.S.I., of Dublin, and was educated in the schools of the Royal College of Surgeons in Ireland in Dublin, and at King's College, London, taking the diplomas of L.R.C.S.I. in 1885, and L.A.H. in 1887. After filling the posts of demonstrator of anatomy in the school of the Royal College of Surgeons in Ireland and of resident surgeon in various Dublin hospitals, he went into practice at Brixham, Devon, where he was medical officer of Brixham Cottage Hospital, medical officer of health to the Brixham Urban District Council, and Admiralty surgeon and agent. He took a temporary commission in the R.A.M.C. as lieutenant on July 5th, 1915, became captain after a year's service, and acting major on March 20th, 1918.

Universities and Colleges.

UNIVERSITY OF LONDON.

M.S. DEGREE: NEW BRANCHES.

THE Master of Surgery degree, which may be taken two years after taking the degrees of M.B. and B.S., has hitherto been conferred in two branches—general surgery and dental surgery. Under new regulations it may now be taken in ophthalmology, or in laryngology otology and rhinology. Candidates in the new branches must produce certificates of having spent at least two years in the study and practice of ophthalmology or laryngology otology and rhinology as the case may be, at a teaching school or schools approved by the university. In certain circumstances the M.S. degree may be taken one year after taking the M.B., B.S. degrees. The M.D. degree is now granted in six branches—medicine, pathology, mental diseases and psychology, midwifery and diseases of women, state medicine, and tropical medicine. Full particulars of all conditions can be obtained on application to the Academic Registrar, University of London, South Kensington, S.W.7.

UNIVERSITY OF LIVERPOOL.

Liverpool School of Tropical Medicine.

The diploma in tropical medicine has been awarded to the following:

W. J. W. Anderson, C. E. Cobb, Euid M. M. Cobb, D. D. Fernandes, P. T. J. O'Farrell, E. A. Renner, J. C. Vaughan.

UNIVERSITY OF DURHAM.

At the Convocation held on March 27th the following degrees were conferred:

M.D.—*Essay*: F. J. Nattrass, II. Reab. *For Practitioners of Fifteen Years' Standing*: C. Edwards, D. Fyfe, J. Livingston, R. G. Murray.
D.IV.—W. H. Rowell.
M.B.—T. H. R. Anderson, P. C. Arnold, N. R. Beattie, J. F. C. Braine, R. C. Brown, J. Hetherington, G. Hurrell, C. D. Newman, A. Patterson.
B.S.—T. H. R. Anderson, P. C. Arnold, N. R. Beattie, J. F. C. Braine, R. C. Brown, J. Hetherington, J. D. Johnson, C. D. Newman.
B.HY. AND D.P.H.—S. Scott, A. H. Towers.

UNIVERSITY OF DUBLIN.
TRINITY COLLEGE.

THE following candidates have been approved at the examinations indicated:

- FINAL M.B., PART I.—*Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology*: E. S. Horgau, E. R. Murray, L. Herzenberg, H. C. C. Deane, Edith F. Willock, P. M. J. Bobbett, Constance McIlraith, L. V. Clifford, D. V. Latham, M. R. Coolican, T. W. Panter, Rita Dillon-Leetch, *Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene*: A. H. N. Todd, Vera G. M. Medary; *Pathology*—Doris Holland, *Pathology—completing examination*: F. Y. Pratt, R. H. J. M. Corbet, J. D. Leaby, R. W. Power, R. S. Chapman, A. J. Beckett, J. M. Sempie.
- PART II.—*Medicine*: P. Jabkowitz, B. Moshal, G. H. Davis, H. A. Lavelle, A. J. D. Sojman, S. L. Feldman, W. B. J. Pemberton, J. B. Maguire, W. T. Micks, A. Blagoff, A. I. Steyn, F. Healy, D. McElwee, S. R. Hill, J. M. B. de Wet, H. V. Exner, R. E. Murphy, J. F. Sheppard, Elsie A. Burns, J. P. de Villiers, *Surgery*: S. L. Feldman, W. de V. Scholtz, G. H. Davis, W. B. Fox, Olive Baile, F. W. Robertson, Eileen H. Dowse, J. Hirschmann, Jamie M. Cummins, W. F. McConnell, J. M. B. de Wet, J. F. Sheppard, D. McElwee, Essie S. Smyth, J. R. Wangh, *Midwifery*: H. A. Lavelle, B. Moshal, A. J. L. Sojman, G. H. Davis, F. Z. Van der Merwe, M. Nurock, J. F. Wicht, H. V. Exner, J. C. Coetzee, E. W. S. Deale, F. V. Small, C. J. L. Brook, J. M. B. de Wet, W. J. A. Russell, Moira M. Brown, Doris L. Graham, Elsie A. Burns, I. Levy.
- D.P.H., PART I (*Bacteriology, Chemistry, Physics, and Meteorology*)—C. C. Boyle, C. J. McCarthy, P. Rock, J. Lyons, T. D. Power, M. J. Graham, P. A. Dorner, C. H. Comerford, J. F. Gaha, C. E. Pengelley, A. H. Price, E. L. Sturdee, W. J. Walker, Mary C. Sheppard.
- PART II (*Sanitary Engineering, Sanitary Inspection and Report, Hygiene, Epidemiology, Vital Statistics, Public Health Law*)—T. D. Power, C. J. McCarthy, E. L. Sturdee, J. Lyons, W. B. Walker, N. P. Jewell, G. F. L. Harkness, P. A. Dorner, C. C. Boyle, W. H. Sutcliffe, G. O. F. Alley.

* Passed on high marks.

The Services.

R.A.M.C. PAY IN INDIA.

THE Secretary of State for India announces the introduction of the following scale of grade pay for Regular, Special Reserve, and Territorial officers of the Royal Army Medical Corps in India, with effect from July 1st, 1919:

	Rs. per Mensem.
Lieutenants	550
Captain, on promotion	650
Captain, after five years' total service	700
Captain, after seven years' total service	750
Captain, after ten years' total service	850
Major, on promotion	950
Major, after three years as such	1,050
Lieutenant-Colonel	1,350
Lieutenant-Colonel, after three years as such	1,500

Charge allowances as laid down in Army Regulations, India, are admissible in addition to the above rates of pay. Army of Occupation bonus is not admissible concurrently with these rates, but in cases where the old rates with the bonus are more favourable they may be retained until the general abolition of the bonus or until promotion, whichever is earlier. Children's allowance, when admissible under Indian regulations, may be drawn with the new rates of pay up to December 31st, 1919.

These rates of pay will not carry exchange compensation allowance. They are provisional, and will be subject to revision when permanent rates of pay for the Medical Services in India are fixed.

GENERAL IRONSIDE in an appendix to his fourth dispatch makes special reference to Colonel G. St. C. Thom, C.B., C.M.G., A.M.S., for direction of the medical care of the forces at Archangel.

Medical News.

A PRELIMINARY committee has been formed to give to Sir George Thane, who recently resigned the chair of anatomy at University College, London, after forty-two years' service, some mark of the appreciation felt for him by his old pupils and colleagues. The intention is to ask Sir George Thane to sit for his portrait. Sir Rickman J. Godlee is honorary treasurer of the fund; subscriptions should be made payable to the Hon. Treasurer, Thane Testimonial Fund, and sent to him at University College Hospital Medical School, University Street, London, W.C.1.

THE annual meeting of the Canadian Medical Association will be held in Vancouver, British Columbia, from June 22nd to June 25th. The Canadian Public Health Association, the Canadian Association for the Prevention of Tuberculosis, the Canadian Committee on Mental Hygiene, the National Committee for Combating Venereal Diseases, and the British Columbia Hospitals Association will meet at the same place at the same time.

CAPTAIN CHARLES R. B. EYRE, B.A.M.C., has been appointed assistant surgeon to the British Ophthalmic Hospital, Jerusalem. The work of the hospital is increasingly heavy, and the administration is urging the Order of St. John to extend its activities in combating the ravages of eye disease in the Holy Land.

A DINNER will be held in London on June 10th for medical officers, sisters, and V.A.D. nurses of the hospital and other officers who were members of the mess of St. George's Hospital, Malta, 1915-17. Lieut.-Colonel A. de C. Scanlan, C.M.G., will take the chair. Those wishing to attend are asked to write as soon as possible to Miss D. C. Hare, M.D., 1, Bickenhall Mansions, W.1, or Dr. Neill Hobhouse, 146, Harley Street, W.1, enclosing remittance. Tickets (price 10s.) cannot be obtained later than May 20th.

LIEUT.-COLONEL O. E. BULWER MARSH, M.R.C.S., L.R.C.P., R.A.M.C.T. (ret.), Consulting Surgeon to the Royal Gwent Hospital, Newport (Mon.), has been placed on the Commission of the Peace for the county of Monmouth. Lieut.-Colonel Marsh has been president of the South Wales and Monmouthshire Branch, and chairman of the Monmouthshire Division of the British Medical Association.

THE Lady Priestley Memorial Lecture of the National Health Society will be given by Sir George Newman, K.C.B., M.D., F.R.C.P., on Thursday, April 22nd, at the house of the Royal Society of Medicine. The title of the lecture is "Preventive medicine: the importance of an educated public opinion." Sir James Crichton-Browne will be in the chair and the Princess Christian will present certificates to the society's students immediately before the lecture.

A MISSION from France and Great Britain is about to visit America to study its system of medical education and examination. The British members are Sir Humphry Rolleston, K.C.B., M.D., and Dr. Norman Walker of Edinburgh, Chairman of the Examination Committee of the General Medical Council.

At a meeting of the Académie de Médecine on March 2nd the President, M. Laveran, paid a tribute to the memory of Sir William Osler, who was an associate member of the Académie. Incidentally, M. Laveran recalled that Osler was one of the first to verify in America his discovery in Algeria of the haematozoon of malaria. A sympathetic notice of Sir William Osler was contributed to the *Wiener klinische Wochenschrift* of February 26th by Professor K. F. Wenkebach, director of the first university clinic in Vienna.

AMERICA, responsible for the term "post-graduate," which it now repudiates, has provided a new term—"premedical." We learn from *Science* that the north-western division of the Western Society of Naturalists, meeting on January 2nd, at Portland, Oregon, held a discussion on premedical education in chemistry, in biology, for a surgeon, and as a university course.

ON and after April 15th the address of the Wellcome Bureau of Scientific Research will be 25-27, Euston Gardens, London, N.W.1.

THE Chester Royal Infirmary will receive £5,000 under the will of the late Mr. George Barbour of Chester.

THE new German university which was inaugurated in January, 1919, at Cologne, has now more than 2,000 students and forty professors. An academy of practical medicine had been in existence at Cologne since 1904.

IN February seven cases of rabies were notified in Holland, all of them in the province of Overijssel.

PROFESSOR ERICH MEYER of Strasbourg has recently proposed that medical students in their first year should be required to study nursing and dietetics.

DURING a considerable part of the war it became a habit with German airmen visiting the south-east of England to drop bombs upon Ramsgate, both coming and going. The effect of this was disastrous on the town, which probably suffered more than any British watering-place. It may be hoped that now peace conditions are restored this pleasant and healthy sea-coast town will soon recapture its former prosperity. The leading hotel of Ramsgate—the Granville—situated high on the east cliff, has now reopened to the public after five years; during the war it was used by the military authorities as a hospital for Canadians, and later for British troops. The Granville Hotel is noteworthy for its bathing equipment, including Turkish and Russian baths, an installation for treatment by radiant light and heat, high-frequency and sinusoidal currents, iodine and other baths. This part of the hotel has been reconstructed lately under medical supervision.

DR. J. B. CLELAND has been appointed to the newly created Chair of Pathology in the Adelaide University, South Australia. Professor Cleland, who is a son of the late Dr. W. L. Cleland of Adelaide, studied first in the university of that city, and then went to the University of Sydney, where he graduated in medicine with honours in 1903. After spending a couple of years in cancer research at the London Hospital he was appointed pathologist and bacteriologist to the West Australian Government. Afterwards he did research work in Sydney, and in 1913 was put in charge of the microbiological work of the Health Department of New South Wales. His research work has been chiefly with regard to prophylactic vaccines and bacteriological diagnosis. In conjunction with Dr. Alfred W. Campbell he contributed a paper on encephalomyelitis to our columns in 1919. It dealt with an epidemic which occurred in the late summer of the years 1917 and 1918 in certain parts of New South Wales, Queensland, and Victoria. The conclusion was that the epidemic, though related to acute poliomyelitis and lethargic encephalitis, was distinct from both.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 423, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2651, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2650, Gerrard.

3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2654, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Breacillius*, Dublin; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

"H. G. M." inquires whether the special "service" rate of income tax applies to the emoluments of appointments as "civil practitioner in medical charge of troops," or those under the Ministry of National Service.

"*." It has to be remembered that the emoluments must be for service of a military or naval character. This would seem to exclude the second of the two cases mentioned. So far as the first is concerned, the answer would appear to depend partly on the amount of work involved; *prima facie* we should regard it as within the scope of the claim. (See Current Note in the SUPPLEMENT of March 27th, p. 87.)

ANÆSTHESIA IN EPILEPTICS.

DR. H. M. COHEN (Anaesthetist, St. Mary's Hospital), Manchester writes: It is occasionally stated that during the administration of anaesthetics in epileptic patients a well marked seizure takes place. Recently I administered ether in three such patients without noting any unusual phenomena. As a matter of fact, I do not recall having ever seen a seizure during anaesthesia. As this is of more than mere academic interest it should prove useful to have some reliable data on the subject, and I should be glad to learn what the experience of others has been in this direction; and if a seizure has actually been noted, what was the anaesthetic used, and the nature and duration of the operation.

LETTERS, NOTES, ETC.

NIGHT BLINDNESS IN SCURVY.

CAPTAIN C. J. H. AITKEN, M.D., R.A.M.C., writes: In a report of the discussion on the early signs of scurvy at a meeting of the Section of Medicine of the Royal Society of Medicine in the BRITISH MEDICAL JOURNAL of March 6th, 1920, p. 329, it is stated that "special attention was drawn to the symptom of night blindness, as this was the symptom which finally decided the diagnosis." Some years back a cabin boy was sent to me by his captain with a note saying that the boy was unable to get about in the dark. I decided, after examination, that the case was one of nyctalopia. The problem was—

What could I do? The next day I visited the captain on his ship and he asked me to examine one of the seamen who had teeth trouble. I found the gums red, swollen, and bleeding. Inquiry elicited the fact that the sailing ship had been much delayed in its voyage because of bad weather and the fresh food had given out. Previous to my visit, which had taken place the day after the arrival of the ship in port, the men had had no fresh food for some weeks. I had the crew paraded and I found that most of them were feeling ill, though none of them presented signs that I associated with scurvy. The case of nyctalopia and the case of bleeding gums made me decide the ship's crew were suffering from scurvy. On fresh vegetables and lemons the crew were all feeling well in a very short time. The man with bleeding gums was the only one of the lot that took some time to get better. The nyctalopia passed away very quickly.

THE APOTHECARY POET'S HOUSE.

JOHN KEATS, who died ninety-nine years ago, at the age of 25, studied medicine at the united hospitals of Guy's and St. Thomas's, and passed the Apothecaries' Hall in the summer of 1816. Thus it is proper to claim him as a member of our profession, though there is nothing to show that the splendour of his poetry owed anything to his medical studies. The house near Hampstead Heath in which he dwelt during the most active part of his literary career is now, we learn, about to be thrown into the market. A representative committee has, however, been formed for the purpose of saving this literary shrine from destruction and for securing it for the benefit of the public for ever. The house, now known as Lawn Bank, is in Keats Grove; the garden is believed to be that

melodious plot

Of beechen green, and shadows numberless,

in which the poet composed his matchless lines to a nightingale. To acquire the freehold, restore and repair the building, and adapt it as a Keats memorial house, and so maintain it, £10,000 is needed. Lists of those who contribute will be preserved in the building. The Honorary Treasurer of the Keats Memorial House Fund (Sir Sidney Colvin, the biographer of Keats) will gratefully receive contributions addressed to him at the Hampstead Town Hall, Haverstock Hill, N.W.3.

MOTOR ACCESSORIES.

MESSRS BROWN BROTHERS (Great Eastern Street, London, E.C.) have recently submitted for trial samples of motor accessories including a neat little fixture for sparking plugs, called the Duco plug tester. If one is attached to each plug it is possible to test the firing in one or more cylinders by merely pressing the insulated plungers. With their use the trouble of disinterring screwdrivers is avoided, as well as possible shocks.

The Duco rubber sponges also submitted are stated to be British-made of practically pure rubber. They last longer than ordinary sponges and are equally effective in drying off moisture. They are very effective, therefore, in the washing of motor cars; and their greater cost as compared with ordinary sponges is compensated by their durability.

"Radiator Neverleak" is a remarkable American preparation, also sold by Messrs. Brown Brothers. When added to the water in a leaky radiator it is said effectually to stop the leaks. Although the claim to effect a permanent repair is perhaps exaggerated, there is no doubt that temporary sealing up is effected, without any damage to the cooling system. By its use unnecessary labour, and possible trouble, are avoided until it is convenient to have the radiator dismantled and permanently repaired.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, 38, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

THE following appointments of certifying factory surgeons are vacant: Melksham (Wilts), Yongreve (Derby).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 423, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

A Clinical Lecture

ON THE

TREATMENT OF SEPTIC PERITONITIS.*

BY
F. J. STEWARD, M.S., F.R.C.S.,
SURGEON, GUY'S HOSPITAL.

In recent years there has been a very marked diminution in the death rate from septic peritonitis, and this is no doubt in the main due to better knowledge of the causes of the condition and of the importance of early diagnosis and treatment. There are, nevertheless, still many deaths from septic peritonitis, some of which might, I believe, be prevented by more adequate treatment, and I have for this reason chosen this subject for the present lecture.

I shall first touch upon certain points regarding causation and pathology, and then deal with treatment, and shall describe to you a method of treatment which I have used for the past two years with marked improvement in results obtained.

Septic peritonitis may be produced by a great variety of causes, which may be summarized as follows:

1. *Infection from without* by any form of wound which perforates the abdominal wall.
2. *Infection from within* by traumatic rupture of any hollow viscus, the perforation of ulcers, or by spread of infection from septic processes within the abdomen, such as appendicitis, salpingitis, cholecystitis, and abscesses of various kinds.
3. *Infection through the blood stream*, such as pneumococcal infection.

With such a diversity of causes it is obvious that the type and degree of peritonitis must vary greatly. Consequently it is necessary to make some classification of cases for practical purposes.

It is quite usual to describe cases of septic peritonitis as being either local or general, but the term general is not at all a good one, for it implies something which really very seldom occurs, and it is more in accordance with the facts to use the terms localized and spreading.

Where resistance is high and the infection not very virulent, the area of peritoneum involved quickly becomes limited by a barrier of lymph which produces adhesions between the surrounding structures, the result being a *localized peritonitis*, which may go on to the formation of a localized abscess.

Where, however, resistance is low and the infection a very virulent or massive one there will be little or no attempt at localization and a *spreading peritonitis* will rapidly develop. The area of the peritoneum involved in any given case will depend principally upon the time that has elapsed before the case is operated upon, so that in any early case the peritonitis, although not localized, may yet be local, but in a late case so much spread will have taken place that the condition may approach more nearly to a general peritonitis. There is, however, no hard and fast line between these two types, for the one form may merge into the other; thus a localized peritonitis may, under certain circumstances, become a spreading peritonitis, or peritonitis at first quickly spreading may later become localized by the formation of adhesions. Moreover, the adhesions in such a case may form in different localities, separate localized foci resulting, perhaps, in a number of abscesses being the final stage in a case of acute spreading peritonitis. Some time ago I operated upon a little girl of 5, who was in a desperate condition from a gangrenous appendix. The appendix was removed and much stinking sero-pus let out. There were no signs of adhesions. She did well for a time but relapsed on several occasions and in the end abscesses were opened in the right lumbar region, the left iliac region, and above and to the left of the umbilicus.

Now, what are the pathological results of septic infection of the peritoneum?

They are, in the first place, precisely those associated with inflammation in any other part, but, in addition, there are also special changes which have an important bearing upon treatment. In the first place, a large amount of fluid is poured out, partly as free fluid in the peritoneal cavity,

and partly into the tissues of the various organs. This fluid is highly toxic; consequently the patient suffers from an acute toxæmia. Partly owing to this toxæmia, and partly the direct result of irritation of the peritoneum, there is vomiting, which is often very severe and frequent. In the later stages the intestine becomes paralysed and obstruction results, the bowel becoming more and more distended with highly toxic fluid and gas. This in the final stages leads to permeation of the intestinal wall by the organisms in the septic bowel contents, so that a fresh cause of septic peritonitis is added to the original one.

Taken together, these various changes produce in the patient three definite conditions, which must be reckoned with when treatment is instituted:

1. *Loss of fluid* from vomiting, and from the pouring out of fluid into the tissues of the viscera and into the peritoneal cavity.
2. *Toxæmia* due to absorption from the septic peritoneal fluid, and from the septic contents of the bowel.
3. *Intestinal paralysis*, which may pass on to the production of complete obstruction.

TREATMENT.

Bearing the foregoing points in mind, it will be seen that in treating a case of septic peritonitis certain very definite indications can be recognized.

These must be considered separately, and are as follows:

1. To remove the cause.
2. To provide drainage.
3. To make good the loss of fluid.
4. To prevent or treat intestinal paralysis.

Although there can be no doubt as to the advantage of removing the cause of the infection, this should not be a fixed rule never to be departed from, or the patient's life may be sacrificed in carrying it out. For it must be remembered that these patients are many of them very ill indeed, and, above all things, they cannot stand a prolonged operation. In fact, the general condition of the patient must decide. If this is good—in other words, if the case is early—the appendix or tube may be removed or the perforation of an ulcer closed. On the other hand, if the peritonitis is of several days' standing and the patient's condition desperate it may be far wiser to make no attempt to find and remove the cause, except perhaps in the case of a gangrenous appendix which is not tied down or difficult to reach.

The second indication is to provide drainage. Now successful drainage is, I venture to say, the crux of the whole question, for the peritoneum is so tolerant and its reparative power so great that if drainage is efficient improvement as a rule commences at once.

Numerous devices are employed, and their very number is an index of the uncertainty of their efficacy. The following may be considered:

Tubes.

It is obvious that if an abscess has to be drained the simplest and most efficient plan is to make an opening in such a position that the cavity is kept empty by the action of gravity. It is equally obvious that a collection of pus in the abdomen, and especially in the pelvis, cannot be efficiently drained by a tube passed into the cavity through an opening in the anterior abdominal wall. No actual drainage will be accomplished in that way, although a small amount of advantage no doubt does result in two ways—for the tube, in the first place, acts as an overflow pipe, so that tension is relieved and the size of the cavity is no longer an increasing one; and, in the second place, the respiratory movements help by pushing the fluid up the tube.

Nevertheless, this quite inefficient plan is by no means infrequently adopted, and I have seen not a few patients dying from septic peritonitis with one or more drainage tubes full to the brim of foul fluid sticking out through openings in the anterior abdominal wall.

A short time ago I was reading an article written by a well-known surgeon. He describes a case of pelvic appendicitis in which at the operation "offensive purulent fluid welled up from the pelvis," and goes on to say, "a large drainage tube was left in the pelvic cavity." Five days later a second operation was performed for paralytic obstruction, and "the lower three feet of the ileum were

* Delivered at Guy's Hospital, December 17th, 1919.

found to be acutely inflamed and in a state of paralytic collapse."

This account clearly proves that the pelvis was not efficiently drained by the tube, or there would have been no peritonitis five days later, and therefore no paralytic obstruction. A tube may, however, at times be used to advantage if it can be placed in such a position that it will drain a given site with the help of gravity—for instance, through a stab wound in the right loin to drain the kidney pouch. Used in this manner there is nothing more efficient, but, as a general rule, a tube passed from the anterior abdominal wall into the pelvis or elsewhere is, by itself, entirely unsatisfactory.

In order to help matters where tubes are used in this way the plan of sucking them out from time to time by means of a syringe is sometimes adopted, but I cannot say that this has given much satisfaction.

Gauze Drains.

Gauze drains, either in the form of large tampons or as cigarette drains formed of gauze within a rubber tube, are very commonly used. Here the suction action of capillarity is made use of to counteract the effects of gravity, and often with considerable success, but if the amount of fluid is large the gauze soon tends to become blocked and sodden and no longer acts efficiently, so that it must be frequently changed, and herein lies the chief objection to its use.

Continuous Irrigation.

Since, owing to the physical conditions present, drainage in the ordinary sense is so difficult, it is reasonable to attempt to bring about the same effect by other means, such as continuous irrigation. This acts in at least two ways, for it not only washes the pus away but it dilutes it and so diminishes its toxicity. Two years ago I first began to employ the following method of irrigation, and I may say at once that I am more than satisfied with it, for although I have used it in a number of extremely bad cases, some of which I shall describe, the result has in every case been successful.

The method adopted is as follows: After the bulk of the pus has been gently mopped up with gauze sponges, several Carrel tubes are passed into the abdomen in different directions, one or more being carried down to the bottom of the pelvis. A large-bore rubber drainage tube is also carried down to the bottom of the pelvis and fixed to the lower part of the abdominal incision by a fishing-gut suture.

The upper part of the incision is partially closed with sutures, then lightly packed with gauze, which surrounds the tubes, and a large dressing applied. The patient is propped up in bed in the Fowler position with a bedpan beneath him, large wool pads intervening. The Carrel tubes are connected up with a saline bag with a drop regulator in the circuit, and warm normal saline solution is allowed to drip continuously at about the rate of a drop a second. At this rate the amount run in in twenty-four hours is nine pints, which, as far as one can judge, appears to be a sufficient quantity. The irrigation is continued usually from three to six days, according to the condition of the patient. The large tube and all the Carrel tubes excepting one are then removed, the one Carrel tube remaining in the pelvis a few days longer.

The striking rapidity with which the patients thus treated have shown signs of improvement is clear proof of the efficacy of the treatment, for in all of them vomiting has quickly ceased, in a few hours the general condition has improved, and up to the present no case has had any marked degree of intestinal paralysis.

The loss of fluid in these cases of septic peritonitis is very great, and it is of first rate importance to lose no time in taking measures to replace it. This may be done by saline infusion either into a vein or into the subcutaneous tissue of the axillae, or per rectum.

Axillary infusion should be commenced as soon as the patient is partly under the anaesthetic and continued during and for some time after the operation. In very bad cases the intravenous method is better because more rapid, for the fluid very quickly leaves the circulation and thus replenishes the loss of fluid from the tissues. After the patient is back in bed rectal infusion should be started and continued until vomiting has ceased, when fluid can be given by the mouth.

Paralysis of the intestine is always present in great or less degree in bad cases. If it has not become a serious feature, as judged by the character of the vomit, and the appearance of the intestine at the time of operation, it will usually pass off if drainage is efficient, but in order to assist the process pituitrin in doses of $\frac{1}{4}$ or 1 c.cm. should be given every six hours according to the age of the patient, and, after four doses, this should be followed up with a turpentine enema. In severe cases, however, the most distended coils should be incised and emptied of their contents at the time of operation. Several lengths of small intestine can be quickly emptied in this way and the incisions closed by one or two fine sutures.

Such are, in general, the main indications and the means of meeting them. I shall now describe certain points regarding the practical application of these principles to actual cases.

Many patients suffering from severe septic peritonitis are in a state of collapse when first seen, often owing to being moved some distance to the hospital. No harm will be done in such a case by a short delay before the operation is performed in order that methods of resuscitation may be applied. These consist in the application of warmth, a hypodermic injection of morphine and atropine, and the administration of fluid in the form of rectal or subcutaneous saline.

At the end of an hour the general condition of the patient will usually be so much improved that the operation may be safely proceeded with. In these critical cases details count for much and an apparently small point may make all the difference. Care must be taken, therefore, in the first place, to avoid chilling, the patient's limbs must be warmly clad, the theatre warm, and, if possible, the table specially heated. The patient, already in a toxic condition, must not be unnecessarily poisoned by the anaesthetic, chloroform must therefore be avoided and either gas and oxygen or warm ether vapour given. I do not advise spinal analgesia in these cases, as this involves turning the patient on to the side and back again, a course that must be liable to do harm. Moreover, the fall of blood pressure so often seen during spinal analgesia would be at any rate very serious and might be fatal.

As regards the operation itself, this will vary according to the condition present, and the following types of case may be considered.

A. Cases Not Requiring Drainage.

Bearing in mind the fact that the peritoneum is capable of dealing with a considerable degree of infection without harm resulting, one can, in certain cases of early septic peritonitis, be satisfied with removing the cause of infection without drainage, the abdominal wound being completely closed.

For instance, cases of perforation of gastric and duodenal ulcers, if operated upon within eight hours of the catastrophe, may usually be safely treated in this manner, provided that the perforation can be securely closed and the peritoneal cavity efficiently cleansed of escaped gastric or duodenal contents by irrigation with a large quantity of warm saline.

Again, during operation upon certain cases of acute appendicitis the question of drainage or closure of the wound without drainage arises.

Consideration of the following points will help in arriving at a correct decision.

1. *The Character of the Fluid Present.*—If this is only slightly turbid and does not smell much, it may be gently mopped out and the wound safely closed; but if the fluid is thick and more approaching to pus and is foul-smelling, the safer plan will be to drain.

2. *The Condition of the Patient.*—A healthy young adult, whose general condition shows that he is putting up a good resistance to his infection, as indicated by good colour and pulse and a temperature raised a few degrees, may usually be safely treated by complete closure of the wound; but in the case of children whose resistance to peritoneal sepsis is notoriously so poor, in old people, and when the general condition is not good, it is far better to play for safety and provide some adequate form of drainage for a few days.

The following case is a good example. The patient was a healthy boy of 16, in good condition, who was admitted to hospital on November 11th, 1919, for acute abdominal pain of three days' duration. He was tender

and rigid in the right iliac region, his pulse was 104, and temperature 100.2°. At the operation the appendix was found swollen and congested, and there was some fluid in the pelvis, slightly brown but clear. This was mopped out and the wound closed without drainage, except for a gauze wick in the subcutaneous tissue. The patient made an uninterrupted recovery.

B. Cases Suitable for Gauze Drainage.

In the next group of cases the area of involvement of peritonium is small in extent, but there is usually considerable lymph deposit and the fluid is purulent. The causal factor in these cases is usually an inflamed and possibly gangrenous appendix or an inflamed Fallopian tube. In such cases, after removing the appendix or tube, I pack the infected area with sterile gauze tampons, bringing the ends out at one end of the wound, closing the rest of the wound with a few temporary sutures.

After three days, if the patient is doing well, an anaesthetic is given, the tampons removed, and the wound closed completely. The great advantage of this plan is that the wound heals per primam, so that the risk of ventral hernia is disposed of, and, moreover, much time is saved. It may be objected that the second anaesthetic and second operation here advised would be avoided by simply draining the cavity, but to my mind the advantages already mentioned clearly outweigh this objection, and, further, the anaesthetic affords an opportunity of thoroughly inspecting the parts, and thus of detecting early and dealing with any separate collection which may be forming.

C. Late Cases.

We now come to those late cases in which a large area of peritonium is involved in a spreading peritonitis, the cases so often wrongly labelled general peritonitis. If the cause is a perforated gangrenous appendix, as frequently happens, it can be removed, but in other cases the cause may not be discovered at the operation, often because the patient's condition is so desperate that any extended search is out of the question. These are the cases in which the method of continuous irrigation I have already described to you is so valuable. Here are some cases which illustrate the practical application of the method.

CASE I.

Rose W., aged 29, was admitted into Guy's Hospital on April 4th, 1918. She had not felt well for some months, and ten days before admission became very ill with pain in the abdomen and legs and constant vomiting. She became steadily worse, and on admission was in a condition of collapse, with a rapid running pulse and subnormal temperature. The abdomen was somewhat distended, did not move on inspiration, and was rigid and tender all over.

Operation was performed immediately, a median incision evacuating a large quantity of foul pus which filled the pelvis and the lower part of the abdomen but appeared to be partially shut off by omental adhesions above. As the patient was too ill to permit of any search being made for the source of infection, the pus was as far as possible rapidly mopped up and the wound partially closed. Several Carrel tubes were introduced in different directions, one going to the bottom of the pelvis, and with it a large-bore drainage tube for return flow as already described.

The patient remained in a critical condition for several days and then slowly improved. The continuous irrigation was kept up for eight days, and as there was then very little discharge the tubes were removed. A small collection subsequently formed, and was evacuated spontaneously through the wound on the nineteenth day after operation. Apart from this, progress was uninterrupted, and the patient was discharged well on May 23rd.

CASE II.

Annie S., aged 7, was admitted on October 1st, 1918, after four days' illness, with symptoms of appendicitis. The child was obviously very ill and presented a typical picture of spreading peritonitis in an advanced stage.

At the operation the appendix was found to be gangrenous and perforated, the lower part of the abdomen, so far as seen, and the pelvis were full of foul pus, and there was practically no sign of lymph or limiting adhesions. The irrigation treatment already described was adopted and the child soon began to show signs of improvement, but the pulse remained rapid and the temperature continued to swing for several weeks. Four weeks after admission a subphrenic collection on the right side was evacuated, and a few days later signs developed at the right base and proved to be due to a localized empyema, which was drained. Moreover, a faecal fistula formed at the site of the original incision and did not finally close for over two months. However, the child eventually recovered completely and left the hospital in good health on January 16th, 1919.

CASE III.

A man, aged 37, was admitted on January 6th, 1919, having been ill for six days with pain in the lower part of the abdomen and continuous vomiting. The abdomen was distended, rigid, and tender all over, these signs being of maximum intensity in the right lower quadrant. At the operation the appendix was found to be gangrenous and perforated, and free pus was present in the abdomen and pelvis with absolutely no evidence of adhesions.

The general condition of this patient was not so serious as that of the other two, and he improved more rapidly. The irrigation was continued for five days, and after this there was very little discharge, healing being complete at the end of four weeks.

The next case was operated upon by my surgical assistant, Mr. Slesinger, who has kindly supplied me with the following notes.

CASE IV.

J. C., a woman aged 16. No previous attacks. On December 3rd began with abdominal pains and diarrhoea. On December 6th vomiting began accompanied by constipation. Pain became worse, and tended to settle in the right iliac fossa. Vomiting and constipation continued until admission on December 10th.

On admission, pulse 130, temperature 102.4°, respirations 30. Abdomen rigid, distended, and immobile. Tender all over, particularly in right iliac fossa. Tongue dry and furred; well-marked abdominal facies.

Operation December 10th: appendix incision. Appendix gangrenous at base, with perforation of caecum where it was attached discharging faeces. Generalized peritonitis with no signs of adhesions, and quantities of pus everywhere. Appendix removed, and four Carrel tubes—two into pelvis, one across abdomen towards the left, and one towards the liver—inserted, tied to large drainage tube, running down to pelvis. Axillary saline during operation, and rectal saline sodium bicarbonate given later. Continuous saline drip into peritonium for four days. Attempt to keep pelvis dry by capillary vacuum suction apparatus.

Bowels open with enema on second day and daily after with liquid paraffin. Tongue moist on third day, no vomiting, pulse and temperature settling, abdomen much more supple; general condition very good by fourth day.*

The above cases sufficiently illustrate the method, which I may say has been applied in a large number of other cases with similar results.

Treatment after the operation consists in keeping the patient propped up in the Fowler position, as this helps to prevent spread of infection upwards towards the diaphragm and chest, the administration of saline per rectum or subcutaneously, and injections of pituitrin to overcome the paralysis of the bowel. Sleep very often does not come easily to these patients, owing partly to the position and partly to general discomfort, for there is not usually much actual pain subsequent to the operation. I am sure it is unwise to give morphine if it can be avoided, and as a matter of fact sleep can usually be obtained by other means. I find that medinal gr. 10 or dial gr. 1½ are most useful, and if there is vomiting either can be given with 15 or 20 grains of aspirin in a small rectal saline, and this combination usually acts well. Failing these, heroin gr. ½ or omnopon gr. ½ should be tried before morphine is given, and one or other will usually succeed.

Under this treatment the patient usually does well, and this will be evidenced by dropping of the pulse rate, cessation of vomiting, and cleaning of the tongue.

Complications.

From this time on a sharp look-out must be kept for the onset of complications. The most likely complications are the following:

1. *Cardiac Failure.*—In elderly patients and in the subjects of organic disease an operation for septic peritonitis, although apparently successful for twelve or even twenty-four hours, is liable to be followed by heart failure which almost always is fatal. The patient, who may be otherwise doing well, becomes restless and perhaps a little delirious, and with this the pulse is noticed to be less strong and more rapid, and soon the extremities show signs of becoming cold. In such a case you will, of course, apply the usual remedies—warmth, pituitrin, camphor, and so forth—but they are not likely to be successful.

2. *Paralytic Ileus.*—I have already mentioned that there is always some paralysis of the intestine involved in peritonitis. With appropriate treatment this will usually pass

* This patient died two weeks after this lecture was delivered. She did well for a time, but subsequently developed an empyema and a number of intraperitoneal collections.

off, but sometimes, and especially in cases operated upon late and where the drainage is not really satisfactory, the paralysis after a time gives place to definite obstruction which is accompanied by all the results met with in cases of mechanical obstruction of the intestine. The bowel above the paralysed part becomes distended more and more, and finally the wall becomes sodden and no longer prevents the passage of organisms from the inside, so that a fresh cause of peritonitis may in this way be added to the original one. All this is accompanied by persistent vomiting, first of duodenal and later of intestinal contents, increasing abdominal distension, and a rising pulse rate.

The management of these cases is no easy matter, for it is difficult to say at any given moment whether or no the condition present is due to a degree of paralysis that will pass off or whether the condition has already passed this stage. Moreover, much depends upon the determination of this point, for on the one hand needless secondary operations must be avoided, and on the other hand it is important not to waste valuable time.

Unfortunately, I can give no very definite rules for your guidance, but the progress of the case and the results of treatment are the data upon which opinion must be based.

If several doses of pituitrin followed by enemata result in the passage of flatus, all will probably be well, but if vomiting continues, and no flatus is passed, in spite of these measures, and if, further, the enemata are retained entirely, the outlook is usually bad, and in this case the abdomen should be reopened under gas and oxygen, and several of the most distended coils of intestine opened, and thoroughly emptied of their contents and closed again. Except in the most advanced and hopeless cases this treatment will relieve the condition.

3. *Local collections* frequently form after a spreading peritonitis has been successfully relieved by suitable treatment, and must be carefully watched for.

The danger signal is usually a rise of temperature, and in the presence of this indication careful and repeated examination must be made for local areas of resistance and tenderness, not forgetting rectal and vaginal examination for collections in the pelvis.

If evidence of a collection is found there need not be too much haste to attempt to evacuate it, provided the general condition of the patient is good, for it is not always easy to find a small subphrenic abscess or a collection amongst coils of intestine, and, moreover, the attempt to do so may result in the formation of a faecal fistula from tearing a coil of softened intestine while separating adhesions. Again, there is no doubt that small collections may be absorbed, for a tender lump associated with a rise of temperature may persist for some days and then gradually disappear, especially in the later stages of convalescence. It must be remembered also that empyema is not an uncommon complication of septic peritonitis, so that the chest must be carefully examined from time to time, especially if the temperature continues to swing. This is illustrated in the second case I described to you, in which there was first a subphrenic collection and later an empyema.

4. *Faecal fistula* also complicates a certain proportion of these cases, and is due sometimes to the separation of a gangrenous appendix, at others to pressure from a hard drainage tube too long retained, and occasionally from the giving way of the wall of the caecum when greatly distended and exposed in the wound. In the majority of cases the fistula will close in course of time, but in a few the mucous membrane becomes continuous with the skin and a secondary operation is needed later.

Finally, *ventral hernia* must inevitably occur as a late complication in many cases, and may require an operation for its cure.

A course in dermatology and venereal diseases, open to foreign as well as French graduates, is about to begin in the Faculty of Medicine, Strasbourg. It will consist of forty clinical and ten laboratory demonstrations. It will begin on May 1st and terminate on July 14th. Full particulars can be obtained on application to Professor Pantrier at the Faculty of Medicine, Strasbourg. The fee for the course is Fr. 300. Should a sufficient number of applications be received a further practical course on the Bordet-Wassermann reaction will be arranged.

A Lecture ON THE SOLDIER'S HEART AND WAR NEUROSES: A STUDY IN SYMPTOMATOLOGY.

DELIVERED AT THE CLINICAL INSTITUTE, ST. ANDREWS.

BY

SIR JAMES MACKENZIE, M.D., F.R.S., F.R.C.P.

(Concluded from page 494.)

IX. THE MECHANISM OF VISCERAL PAIN (THE VISCERO-SENSORY REFLEX).

THE remarkable difference between the sensitiveness of the external body wall and the viscera in response to mechanical stimulation brings out clearly the difference in function of the two divisions of the nervous system—a difference which it is necessary clearly to understand if the symptoms of disease are to be fully comprehended. It shows that when pain is evoked from the organs or tissues which are not supplied by the sensory nerves of the cerebro-spinal system some other mechanism must take part in its production.

The nature of this mechanism is revealed by the study of the symptoms produced in certain forms of visceral disease. If we take the symptoms that are present in certain simple diseases—for example, a gastric ulcer, appendicitis, or renal colic—the mechanism by which a number of symptoms are produced will become clear. In many cases of gastric ulcer there is pain, limited to a small area, in the epigastric region. This pain has a different location from the ulcer. Thus the pain may be situated in the middle line, as in Fig. 6, where the shaded area, A, indicates the site of pain, while the ulcer, revealed at the *post-mortem* examination, is situated at the pylorus, which was found at x in Fig. 6. Moreover, if a patient with this pain breathes deeply, the stomach, with the ulcer, shifts its position, but the site of pain remains fixed. With these facts before us, the mechanism of pain in visceral disease becomes clear. When the disordered sensations of toothache were considered it was seen that the only reasonable explanation was that from the offending tooth a stimulus had been sent into the central nervous system. The effects of this stimulus were not limited to the cells of the nerve supplying the tooth, but spread to the cells of sensory nerves in the immediate neighbourhood, with the result that there was pain and hyperalgesia in neighbouring teeth and in the skin of the cheek.

From the stomach a stimulus is conveyed by the sympathetic nerves into the central nervous system. But as these nerves are not "sensory" nerves in the sense that they are directly connected with any perceptor in the brain, no sensation is felt (Fig. 7). In like manner, so long as the impulses conveyed from the ulcer do not spread no pain is felt. When, however, the stimulus is of such a nature that it spreads to other cells, then we get a reaction peculiar to the cells stimulated. In this case the stimulus reaching the nearest sensory cells of the cerebro-spinal system irritates them, and the pain which results is referred to the peripheral distribution of the nerve stimulated—that is, the nerves supplying the area of skin as already described in paragraph V on referred pain. Fig. 8 illustrates the mechanism by which pain is produced in visceral disease, showing how an organ itself insensitive and supplied only by sympathetic nerves can produce pain by reacting upon the cells of the cerebro-spinal sensory system. The stimulus arising in the organ x passes to the central nervous system, where its cell, x', has no direct connexion with the sensorium, s, but when an adequate

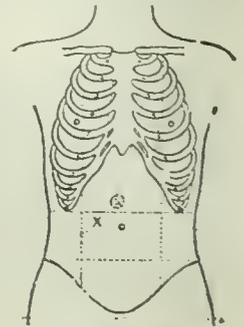

FIG. 6.—The shaded area in the centre shows the position of pain and hyperalgesia in a case of ulcer of the pylorus situated at x.

stimulus arises it affects the neighbouring cell, n', which, being a pain nerve, gives rise to the sensation of pain which is localized at its peripheral distribution, b.

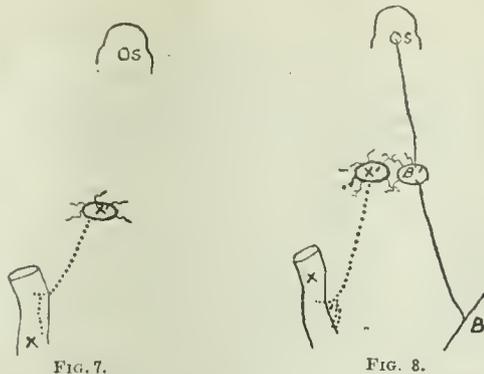

FIG. 7.—The normal movements of a viscus, x, pass into the central nervous system, x', but produce no sensation.

FIG. 8.—Shows the mechanism of a viscerosensory reflex. A stimulus arising in a diseased organ, x (as in gastric ulcer), passes into the central nervous system, x', and if the stimulus be of a particular quality or strength it will affect a neighbouring sensory cell, b', which is recognized as pain and referred to the peripheral distribution of the nerve at B.

X. THE MECHANISM OF THE VISCERO-MOTOR REFLEX.

Before dealing with other phenomena produced by visceral disease it is necessary to consider the mechanism of the reflex which produces contraction of voluntary muscles as a result of a stimulation from the viscera. When we carefully palpate the abdominal wall in patients with disease of some abdominal organ, we will frequently find certain portions of the body wall hard and resistant. This manifestly is due to a contraction of a portion of one or more of the broad muscles which form the abdominal wall. It is a reflex contraction produced by a stimulus arising in the diseased viscus and sometimes referred to as "protective rigidity" of the muscles, as its purpose is obviously to protect the diseased organ. Every doctor is aware of this hardness in the epigastrium in gastric ulcer, due to rigidity of the upper portion of the recti muscles. The manner in which it is produced is similar to that operating in the case of the cutaneous reflex contraction, and may be diagrammatically represented as in Fig. 9,

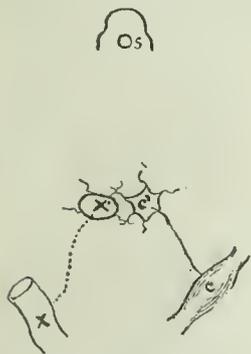

FIG. 9.—Shows the mechanism of the visceromotor reflex. A stimulus arising in a diseased organ, x, passes into the central nervous system, x', and affects a neighbouring cell, c', which causes a contraction of skeletal muscles, C.

There are different forms of reflex muscular contraction. The cutaneous reflex contraction is accompanied by a sensation; visceromotor contraction is not necessarily accompanied by a sensation. The cutaneous reflex results in a momentary contraction of the muscle. The contraction of the muscle which arises from the visceral stimulation is persistent. In this persistent contraction of the muscle we get an insight into several processes of a very instructive kind. Light is thrown on some functions of the sympathetic system at present obscure, and some characteristic features of muscular contraction which have been overlooked are revealed.

From the study of this contraction it can be demonstrated that the tone maintained by the flat muscles of the abdomen is partly dependent on the stimuli reaching the motor cells of the muscles from the viscera. If we carefully watch certain cases of visceral disease, such as gastric ulcer, we will often find a varying degree of muscular rigidity. It may be scarcely possible to distinguish this increased resistance from that of the normal

tone and resistance to palpation in unaffected muscles. This resistance often increases until the muscle is felt hard and board-like, and after a time it may subside and disappear. When the increased resistance is scarcely perceptible, it can be increased by rubbing gently along the muscle. Sometimes in walking the contraction of the muscle may be increased so that the patient walks with a stoop. The varying degrees of activity of the disease, and I have at times found them of value in the management of such diseases as gastric ulcer. But the point I wish to make here is that this increase in contraction is evidently but an exaggeration of that condition called tone which is normally present in health.

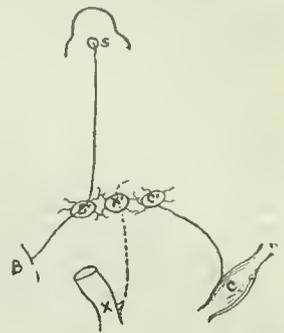

FIG. 10.—Shows the mechanism of a combined viscerosensory and visceromotor reflex. (See Figs. 8 and 9.)

Frequently these muscle contractions are associated with hyperalgesia of the skin overlying them, and the muscles themselves may be hyperalgesic. When this cutaneous hyperalgesia is present the cutaneous reflexes show some interesting variations. If the muscle is not contracted, or only slightly contracted, the reflexes may be much more lively in response to stimulation of the hyperalgesic skin. If the muscles are hard and board-like, the reflexes may seem to be abolished; little or no movement is obtained from stimulating the hyperalgesic skin, for the reason that the muscles are already contracted to their full extent.

It occasionally happens that we find the muscle distinctly contracted, with no cutaneous nor muscular hyperalgesia, as shown in Fig. 8. At other times we may find hyperalgesia of the skin only. Most frequently there is both cutaneous and muscular hyperalgesia along with a contracted muscle, as shown in Fig. 10, where the stimuli from x affect b' and c', producing in the one case pain referred to B and in the other contraction of the muscle C.

XI. MULTIPLE REFLEXES FROM VISCERAL STIMULATION.

So far, in speaking of reflexes I have referred to some as occurring singly. As a matter of fact, no stimulus produces only one reflex; there are always others. Some of these are so slight as not to be recognizable; others, quite a number of them, can be recognized.

If, for instance, we consider the symptoms provoked by the peristalsis of a hollow muscular organ the origin of a number of phenomena will be revealed. The presence of a small calculus in the pelvis of the kidney may set up a strong peristalsis of the ureter, giving rise to an attack of renal colic. With the onset of the attack uneasiness or pain is first felt, and the muscles of the abdomen become hard. In one patient the testicle was pulled up by the contraction of the cremaster muscle. The pain passes from the loins downwards into the testicle. It comes on in wave-like periods of intensity. Other symptoms arise—for example, vomiting, great prostration, with feeble action of the heart—so that partial loss of consciousness may follow. There is also pallor and profuse sweating. All these phenomena are produced by a stimulus reaching the central nervous

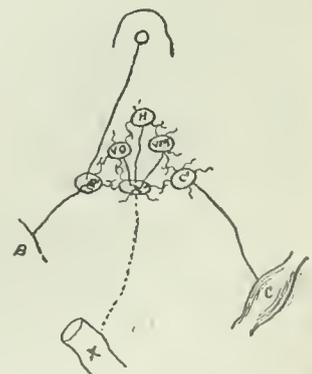

FIG. 11.—Illustrates the mechanism of multiple reflexes produced by visceral stimulation. An adequate stimulus arising in an organ, x, passes to x' in the central nervous system and affects a series of neighbouring cells, thus giving rise to pain (by stimulating b'), muscle contraction (by stimulating c'), vomiting (by stimulating v), cardiac depression (by stimulating the vagus, H), pallor and sweating (by stimulating the vasomotor centres, va).

system and there reacting on a number of special centres, such as the vomiting centres, the centre for regulating the vasomotor nerves, the centre of the vagus (Fig. 11).

When the attack passes off there is left a variety of phenomena, such as an area of cutaneous hyperalgesia with contraction of certain of the muscles of the abdomen. In addition there is usually ushered in a period of great exhaustion or prostration, lasting, it may be, for a number of days. I wish here to clear away one of those beliefs which does so much to darken understanding and hamper investigation. Phenomena, such as exhaustion and vomiting, when they accompany such an attack, are usually attributed to the pain. This is a pure assumption, for the centres which control vomiting and exhaustion are as distinct as the pain centres, and a stimulus which excites pain may, under certain circumstances, also excite those centres. When pain of great severity occurs without vomiting or exhaustion, it simply means that the stimulus which excited the pain did not affect those other centres. On the other hand, those centres may be stimulated, and vomiting and exhaustion may be produced without pain. Thus, it frequently happens that a sudden movement of the bowels resulting in the evacuation of a large loose motion is accompanied by vomiting and fainting without pain.

XII. DIMINISHED RESISTANCE TO STIMULATION (FOCAL).

I wish now to direct your attention to a feature of the nervous system which has not received from clinical observers the attention it merits—namely, the lowered resistance to stimulation which is produced by disease and other agencies.

In describing the phenomena of toothache, the well known facts of tenderness of the neighbouring healthy teeth and of the hyperalgesia of the skin of the cheek were commented on. A similar state of affairs is met with in connexion with visceral disease, for we often find in this condition that pressure over certain regions of the abdomen of a degree which in other parts of the body produces only the sensation of touch or pressure, gives rise to pain. In lightly pinching the skin, too, pain is caused over particular areas whereas no pain is felt in other areas. Frequently the skin itself is not hyperalgesic, but the deeper structures of the abdominal wall, especially the muscles, are painful on pressure.

In normal circumstances a stimulus has opposed to it a degree of resistance in producing pain. Its entrance into the pain centres is hindered, so that it must be of a certain strength or quality before it can pass. In these hyperalgesic areas which I have described the resistance to stimulation is greatly diminished, so that a stimulus much weaker than that which produces pain in other regions is sufficient to produce pain in these regions; in technical language, the "threshold of stimulation" is lowered. A similar lowering of the threshold is shown by the cutaneous reflexes. Thus when a hyperaesthetic area of skin is stimulated so as to produce a contraction, a slighter stimulus suffices for the work, and the contraction of the muscle produced is greater than in corresponding parts of the opposite side of the abdomen.

But the evidence of the diminished resistance is not limited to sensory and motor regions in the spinal cord. This may affect the whole nervous regulating mechanism of an organ. The phenomenon is best demonstrated in the circulatory system. In certain cases the movements of the heart and the vasomotor mechanism may respond to mild stimulation in an excessive manner—for example, an excessive rate of the heart on mild exertion or an excessive contraction of the blood vessels from some slight stimulus as, for instance, mental effort or exposure to cold. Thus, in a patient with aortic regurgitation, I have seen the blood pressure rise when the patient was engaged in a quiet conversation, and I have seen this rise followed by a violent attack of pain. Indeed, in certain sufferers from heart disease the nervous mechanism of the organ may become so sensitive to stimulation that this may provoke attacks of palpitation or of pain. This stimulation may consist of factors which do not directly affect the heart—for example, mental excitement, the excitation of the skin of the left chest by pressure of a stethoscope, or a mere movement of the left arm of the patient. Numerous instances of the lowering of the threshold of stimulation will occur. People in whom the fingers become cold, pale,

and numb, on exposure to a very moderate degree of cold, have an excessive sensibility of certain vasomotor centres. Some people, again, when worried or fatigued suffer from persistent vomiting.

XIII. DIMINISHED RESISTANCE TO STIMULATION (GENERAL).

The purpose of these illustrations is to call attention to a factor which has only been dimly perceived, but which is a very important element in the production of a large class of symptoms. This factor is diminished resistance to stimulation. So far instances of it have been confined to diseases of a simple kind—for example, toothache, gastric ulcer, disturbances of the heart and vasomotor system, and of the vomiting centre. It will now be profitable to inquire whether there are not conditions in which the diminished resistance may be of a much greater extent, for if such conditions be found we may find at the same time a clear explanation of the manner in which many symptoms are produced.

We know that when a patient becomes the subject of a microbic infection there is speedily induced a loss of the sense of well-being and the appearance of sensations of discomfort or suffering. The daily routine becomes laborious and difficult; it is accompanied by loss of appetite, and fatigue is easily brought on. Indeed, so readily may exhaustion be produced that, even with a mild infection, collapse of an extreme kind may occur—as, for instance, in the case of a youth training for a race who fell and lost consciousness in running a short distance. Before starting he felt seedy, but thought he could throw the feeling off by the exercise. He was found to have a slight rise of temperature; in a few days he was well and resumed his training, which he completed without mishap. If patients with a mild infection be observed it will often be found that their heart's rate is increased, and that their response to effort is accompanied by an undue acceleration of the heart's rate, while breathlessness and fatigue are more readily induced than in health. These facts are well known to every observing doctor, and their interpretation seems to be that something has occurred which has lowered the resistance to stimulation. As a result the heart is more readily stimulated to rapid action, and a disturbance of the vasomotor mechanism takes place which leads to exhaustion or loss of consciousness.

If an individual, the victim of a mild infection, persists in leading the strenuous life he may have pursued when enjoying vigorous health, other manifestations develop. The heart's exhaustion may proceed apace till breathlessness is readily produced on moderate exertion. Pain, too, may be experienced, sometimes of such severity that it is diagnosed as angina pectoris, while the skin of the left side of the chest may become extremely hyperalgesic.

The following experiences show what I am trying to demonstrate. A woman fell into ill health of a vague kind, but developed attacks of pain in the left chest, evidently of cardiac origin, of such severity that several experienced physicians diagnosed the condition as one of angina pectoris of a very grave type. Little relief was obtained, and the case dragged on for months. When I saw her I felt confident that the attacks of pain, though cardiac in origin, were not due to organic disease of the heart, but that she was suffering from some toxic condition, and a search was made for some source of infection. The only suspicious circumstance was an obscure swelling in the pelvis, whose nature an expert gynaecologist could not determine. After a few weeks an abscess burst into the bladder, and after the discharge of pus the attacks of "angina" gradually disappeared, and she made a good recovery.

A man fell into poor health. He became depressed in spirits; his brain was readily exhausted after reading a short time; he was short of breath on exertion, and easily tired. He flushed readily, and his heart beat rapidly on the slightest exertion. Nothing amiss could be detected on physical examination till, after some months, a certain degree of discomfort directed attention to his mouth, and he was found to have an abscess in his antrum. The evacuation of the pus was followed by a speedy recovery.

It is manifest, from a history of such cases, that the primary cause of trouble was an infection which poisoned certain structures of the body, in particular the nervous system and regulating mechanism of the heart and blood

vessels, and rendered those parts abnormally sensitive to stimulation, so that bodily or mental effort, which in health could be undertaken without distress, now induced the signs of exhaustion peculiar to each organ.

What is true of the circulatory system is true also of every other system. When we meet with symptoms of the disturbance of one organ a systematic inquiry will often lead to the detection of evidence of functional disturbance in other organs.

This matter can be illustrated by a consideration of experiences that have lately been familiar to most of you in the so-called "soldier's heart" and the neuroses of war.

XIV. THE SOLDIER'S HEART.

For many years before the war I had puzzled over the description of the condition called the "irritable heart of soldiers." Many years ago I had seen men in good health who had been invalided out of the army because of this affection, and I could find nothing the matter with their hearts. When the war broke out I seized the opportunity to find out the nature of this condition. At the suggestion of the Medical Research Committee a systematic investigation was undertaken by Dr. R. M. Wilson and myself, and we produced a preliminary report on the subject. The work was ultimately carried on at hospitals set apart for the purpose; but I continued my own investigations, and briefly the following are the conclusions to which I came: The condition which goes now under a variety of names—as the soldier's heart, the irritable heart of soldiers, disordered action of the heart, effort syndrome, and neuro-muscular asthenia—is not peculiar to soldiers, but is of frequent occurrence in civil life. The ill health or incapacity which is present is not limited or only due to the cardiac condition, for other organs are also affected, so that the cardiac manifestations form but a part of the picture of ill health. The main symptoms of which the soldiers complained were shortness of breath or exhaustion or palpitation easily produced on moderate effort. In some cases pain in the chest was felt, sometimes of great severity, coming on in response to effort or when at rest. An examination revealed in some an increased rate of the heart, and in many an excessive increase in response to effort. Occasionally there was a slight enlargement of the heart.

In the limitation of the response to effort (shown by breathlessness easily produced) and in the increased rate of the heart we get evidences of increased susceptibility to stimulation on the part of the organ.

A heart in this condition of undue excitability, compelled to do the same amount of work as it did when the health was good, will become sooner or later exhausted, and so we will find a series of symptoms arise which are the outcome of exhaustion.

While the over-excitability of the heart is brought about mainly by a disturbance affecting its nervous mechanism, in all probability the same injurious influence affects the myocardium itself, so that the efficiency of the heart may be impaired.

XV. WAR NEUROSES.

The foregoing are, in brief, the chief manifestations of the irritable heart of soldiers. But if the patient be more carefully scrutinized other symptoms will be found. His face is often lined and drawn; he is often nervous in manner, and occasionally he shows fine tremors in his hands and fingers. Inquiry reveals a varying degree of mental disturbance, apathy, disinclination for exertion, mental depression, and irritability of temper. The memory is not retentive, and on mental effort—for example, reading—fatigue is readily induced. In many cases other phenomena are detected, but these are sufficient to show that in nearly all these cases there is a mental side to the ill health as well as a cardiac.

If one were to concentrate the attention on the nervous phenomena in a great many of these cases, the conclusion arrived at would be that the patient suffered from a neurosis. Indeed, this is what is constantly happening, for certain doctors would unhesitatingly class some soldier patients as suffering from neurasthenia, or some other form of war neurosis, while others would class the same patients as suffering from the irritable heart of soldiers.

If the inquiry be carried further definite symptoms of derangement of other organs can be obtained. Thus a

rapid respiratory rate, not due to any lung or heart affection, may probably, as Haldane pointed out, be due to an excessive irritability of the respiratory reflex. Digestive disturbances are present in the great majority. Did we possess the knowledge we might almost certainly discover signs pointing to the deranged function of every organ of the body. Indeed, some physicians have detected signs of hyperthyroidism in so many of these cases that they attribute most of the circulatory disturbances to this condition.

XVI. THE MECHANISM OF SYMPTOMS.

The inference drawn from such experiences was that a condition of diminished resistance to stimulation had been induced, and the attempt to lead the life and do the work of healthy vigorous men had proved unavailing. Health had given way from exhaustion. The manifestations of this exhaustion were exhibited by the different organs that had been submitted to the strain; in one case the heart and circulatory system were most affected, in another the nervous system. Thus we get the variety of phenomena which these soldiers exhibit.

This way of looking at the matter illustrates a method of investigation that has not been so fully appreciated or utilized in medical research as it deserves. It shows the importance of applying the "law of associated phenomena" in all medical examinations. This law is based upon the fact that in ill health there are a great variety of phenomena. It has been the habit to a large extent to give consideration to the more prominent signs and to label the disease by the names of such dominant signs. We constantly met soldiers invalided and pensioned on account of so-called aortic or mitral disease, because a systolic murmur had been detected, yet in the vast majority of these cases there was absolutely nothing the matter with the aortic or mitral valves. If the principles underlying the classification of symptoms and the law of associated phenomena had been understood such mistakes would not have arisen.

Physicians who have been engaged in war work are now publishing their experiences, and you will find in the medical journals that the old method of docketing the soldiers' complaints according to the organ supposed to be affected is pursued. Thus we have sick men described as cases of irritable heart, of neurasthenia, and of hysteria; that is to say, the complaints are attributed to the organ whose symptoms are most prominent to the observer.

XVII. PRACTICAL IMPORTANCE OF RECOGNIZING THE MECHANISM OF SYMPTOMS.

It may seem to you that this aspect of the matter is already recognized, and that the presentation of it in this way is unnecessary. But it frequently happens that what is supposed to be well known and commonplace is in reality so imperfectly known that its true significance has been entirely missed. In the cases to which I am referring it will be seen that the procedure usually employed in medicine, of describing diseases as limited to one organ or system, is misleading.

Recognition of this general lowering of resistance to stimulation enables one to perceive that the manifestations of the different organs are but an expression of the irritability of their nervous mechanism, and compels an inquiry into the condition which has induced it. In many cases such an inquiry will result in the discovery of some focal disease or in the detection of some infection—for example, malaria or dysentery, or tubercle.

Another important result of this recognition is that we are no longer so likely to be misled in the estimation of the significance of some abnormal sign. A large number of these cases of nervous heart are labelled "valvular disease of the heart" because there is a systolic murmur present, and the limited response to effort, breathlessness on exertion, or increased rate of the heart, is taken to be evidence of an organ impaired by mitral or aortic disease. I know that large numbers of cases have been invalided out of the army and granted pensions because of misapprehension of the significance of murmurs, particularly when these murmurs were associated with the phenomena I have described. The same thing applies to affections of the nervous system. We often find this type of case called "neurasthenia" or some other form of neurosis, and subjected to various methods of treatment based upon an erroneous conception of its nature.

Furthermore, the necessity of recognizing the nature of the phenomena which lowers resistance is seen in the tests which are recommended by the military authorities for determining the fitness of a man. To ascertain the functional efficiency of the heart certain exercises are enjoined. If, in response to these, there is an increase in the rate of the heart or of the breathing, it is assumed that the organ is impaired. The evil symptoms are taken as indications of such impairment. If the principles I have been enunciating be grasped, it will be seen that it is not the heart condition that is being tested by these exercises but the susceptibility of the heart to stimulation. In some cases the increased rate may represent cardiac inefficiency, but in the vast majority of cases it represents nothing of the sort, for the cardiac irritability is but one of many phenomena the detection of which would afford a clue to the real nature of the trouble.

XVIII. ILLUSTRATION OF HARM DONE BY IGNORING THE MECHANISM OF SYMPTOMS.

I have had plenty of experience showing the widespread harm of this limited study of patients' symptoms. I have been frequently consulted by men who have been rejected for the army and pensioned because of a misconception of their symptoms. I saw recently a man who was invalided out of the army and told he had got aortic disease, and that his heart was so damaged that he would never be able to undertake any occupation requiring physical effort. He was given a full pension. When I saw him he was leading a miserable existence, creeping about a few hours a day. He was easily tired, and he attributed his exhaustion to his heart complaint. His heart was easily stimulated to rapid action, and there was present a systolic murmur at the base. When I tried to assure him that there was no aortic disease and that his heart was perfectly sound, I found it was impossible to convince him. When in the army these sensations of exhaustion came on and the army doctors had detected the murmur and called it aortic disease and had treated him for a time in bed and then invalided him out. The pensions doctors had repeatedly confirmed this view of his condition, and had backed up their opinion by giving the largest pension allowance. Is there little wonder that this man cannot be convinced as to the true nature of his condition? He is made a miserable wreck on account of a defect in medical knowledge—namely, ignorance of the nature and significance of symptoms.

XIX. THE ORIGIN OF ILL HEALTH.

In a careful inquiry into the origin of ill health in over 2,000 soldiers I found that in the case of about 80 per cent. the first onset of their illness began with some complaint of an infectious nature, such as measles, influenza, trench fever, typhoid fever, malaria, dysentery, or "P.U.O." In other cases one could gather that the onset was due to an ill-defined illness suspiciously like an infection.

In a number of cases there was no history of infection, and the onset of the illness seemed to be due to a variety of circumstances. Some of the men were weakly before they entered the army, and the unaccustomed strain had seemingly been the cause. Others, originally quite healthy, had been exposed to a long and continued bodily and mental strain; want of rest had evidently been the provoking agent in these instances.

The history of the origin of these complaints and the manifestation of ill health accorded with the experience of civil practice. We repeatedly meet with patients who, on recovery from a febrile illness, suffer in the same way for varying periods.

CONCLUSION.

I have given in this lecture a bare outline of one phase of symptomatology, merely to indicate the mechanism by which certain symptoms are produced, and the far-reaching inferences that can safely be drawn from the consideration of this phase. It will be seen that a large amount of work is necessary to complete the picture and to understand the nature of symptoms. The study also affords a guide to further research. For instance, a great number of diseases are only recognizable by the presence of their reflex symptoms—diseases like gastric ulcer and appendicitis. We want to know the nature of the stimulus capable of producing these symptoms, whether it is an exaggeration of a normal stimulus or a product of

disease. It can also be seen how important it is, in examining the sick, to be guided by the law of associated phenomena, while a definite object to be achieved—that of finding the agent which produces the diminished resistance—is held clearly before the investigator.

PUBLIC HEALTH ADMINISTRATION IN EPIDEMICS OF MEASLES.

BY

JOHN BROWNLEE, M.D., D.Sc.,

DIRECTOR OF STATISTICS, MEDICAL RESEARCH COMMITTEE.

DURING the twenty years I was engaged in active work in the Public Health Service the question of the best methods of administration in epidemics of measles came under my subconscious mind at more or less regular intervals. As I was not responsible for the field work, but only for the treatment of those suffering from the disease, there was no need for immediate decision, so that it was not until the end of my hospital experience that I seriously began to consider the subject in its different aspects. In actual practice nothing was being done to limit the spread of measles save to apply those general principles which seemed to offer a reasonable chance of success in combating the spread of all infectious diseases. These principles included notification, isolation of the infected person, and disinfection of the infected articles as a part of the process. They extended, however, much more widely, and included the destruction of unhealthy property, the prevention of overcrowding, and the improvement of general sanitation. It is one of the ironies of health administration that such obvious reforms were neglected year after year until an outbreak of typhus or small-pox brought the necessary stimulus to the lay mind to allow the medical officer to initiate these measures to control infectious diseases. The powers granted to limit infectious disease acted, however, much more to the advantage of the community in improving the standard of health than in the repression of infectious disease.

The present generation now possesses the kind of knowledge which enables it to recognize that the adequate administration of any infectious disease depends only to a small extent upon general principles and chiefly upon an exact knowledge of the natural history of the disease. Thus while the amount of typhus fever was undoubtedly limited through the application of general hygienic measures, these were definitely successful because the measures brought those possibly infected by the disease under such supervision as to ensure that both their houses and clothing were properly cleansed, and thus the louse, the active agent in the transmission of the disease, was eliminated. So also at the present day the control of malaria is found to depend upon measures which, though perhaps indirectly advantageous to the general health, are yet much more potently disadvantageous to the agent by which the disease is spread—namely, the mosquito. A well-known example of a disease which isolation, disinfection and sanitation have proved quite powerless to control is scarlet fever.

The control of measles is a problem, therefore, to be considered solely with reference to the natural history of the disease. The disease is most infectious—in fact it is of the eruptive fevers the most infectious, except small-pox. In contrast to small-pox, no protection such as that afforded by vaccination has hitherto been found. The infection, again in contrast to small-pox, is present in a very intense degree at the first onset of the catarrhal symptoms, and as these precede the appearance of the rash by at least three days, this period passes in most cases before the cause of the symptoms present has been recognized. Through the coughing due to the catarrh the infection is spread through the air. As far as can be statistically estimated at present, all but a fraction of these persons who come within the range of infection succumb at the most to two exposures to infection of the kind experienced in natural conditions.

Only one means of protection exists for any but those gifted with special immunity, and that is a previous attack. Though this is, of course, well known, it may not be inappropriate to state that it was brought very

forcibly under my notice when I visited some years ago a Highland glen from which measles had been absent for more than eighty years. An epidemic had just ended; it swept the glen from the western end to the eastern, hardly anyone—man, woman, or child—escaping the infection. Among the inhabitants whom I met was an old farmer of nearly eighty years of age who had just recovered from the disease. He discussed the matter with a curious mixture of pride and shame—pride that such an unusual experience had been his lot, shame that at his great age he had succumbed to such an infantile malady. It may be noted, by the way, in contradiction of the erroneous and quite common belief, that though the soil was practically virgin in this epidemic, not a single death occurred.

Now a disease which possesses such a degree of infectivity is quite clearly not open to administrative control in the sense that control means prevention. In saying this I do not doubt that the infection of measles might be successfully excluded from a definite area for a limited period of years if proper measures, necessarily very expensive, were adopted. The sole effect of this exclusion would be, however, to permit the development of a population open to the infection—a population which would be devastated the moment the infection were reintroduced; while, if the disease were thus reintroduced, the expense of its extermination would again have to be faced. I do not suppose—nor do I think that anyone else supposes—that there is any hope of success on the lines of prevention of infection in this manner, but that does not imply that some degree of success may not be possible on other lines.

The question of the administration of measles epidemics will now be discussed under two heads:

I. The administrative. With regard to this, there are two points of importance:

- I A. The source of infection at each age.
- I B. The variation of the death rate due to measles with age.

II. The medical. Under this heading come the points of:

- II A. Early diagnosis.
- II B. Hospital treatment.

I A. Source of Infection.

It is a general experience among middle-class parents that their children rarely take measles until the school age of the eldest begins. This is not so markedly the case with the working classes. Among these greater facilities of infection are afforded by the children playing together in the street, for such a disease as measles is practically only spread by direct contact. In spite of this, however, in the opinion of a number of medical officers the fire is lighted in the schools, and it is only then that streets and stairheads become of importance as a means of spread. That this holds true can be shown in another way.

In the table the statistics relating to Aberdeen show the rate of infection of the population by measles for each age period up to fifteen years of age. The general facts are as follows: Under the age of six months the disease is not readily taken. From the age of six months to the age of between six and seven years there is an almost uniform rate of attack. After this age the rate at which the population is attacked falls approximately in a geometrical progression. It is probable, as the result of certain calculations, that the greatest susceptibility exists between the ages of three and four years, but this point cannot certainly be determined. Now it is impossible to reason from the form of this distribution as to its probable cause, but it is possible to assume a cause and then construct an age distribution. If it be then assumed that in families of young children the children do not as a rule take measles until the eldest child has become sufficiently old to go to school, as has been suggested previously, and if it be assumed that epidemics occur more or less regularly, the age distribution of attack can be easily calculated. The result of the calculation is to give a distribution essentially identical with that found. It may thus be presumed that in the majority of cases children under five years of age are infected by the elder children who acquire the infection in school. If this be the case some hope of administrative improvement may be entertained.

Table showing the Rate of Attack from Measles per 1,000 Persons Living for Aberdeen and the Case Mortality in Aberdeen and in Glasgow.

Months	Aberdeen City, 1833-1902.			Glasgow Hospital Cases, 1885-1902.			
	Rate of Attack per 1,000 per ann.	Cases.	Deaths.	Case Mortality per 100.	Cases.	Deaths.	Case Mortality per 100.
0-3 ...	13.4	244	19	7.8	20	2	10.0
3-6 ...	38.6	665	64	9.6	97	9	9.3
6-9 ...	76.0	1,263	186	14.7	366	78	21.3
9-12 ...	53.2	862	157	18.2	387	79	20.4
Years

I B. Age Variation of Death Rate.

Here certain facts must be specially discussed. These are shown in the table; in it the number of cases and deaths occurring in the cities of Glasgow and Aberdeen are compared. In the former city the cases admitted to hospital furnish the evidence; in the latter notification was in existence for twenty years, and the death rates for the whole city are available. The same kind of variation in the death rate holds in both places, though the cases in the Glasgow hospitals have very excessive death rates. These cases are drawn largely from the slums, though this is not the whole explanation of the difference, as from year to year when the death rates at ages under five years are calculated for the cities as a whole, those in Glasgow are considerably greater than those in Aberdeen.

Referring to the table, it is seen that the death rate between six months and two years is exceedingly high and from that age declines. In the cases in the Glasgow hospitals to which the statistics refer (18,000 cases in all) the death rates between the ages of one and two years and between the ages of five and six years were respectively 26.5 per cent. and 4.3 per cent.; the average death rate of all the admitted cases was 9.1 per cent. The corresponding figures for Aberdeen between 1883 and 1902, the years of notification, are 10.0 and 0.7 per cent. respectively. But it is not only in the increased death rate at early ages that the damage due to measles is seen. Lung and eye affections, two of the worst complications associated with measles, occur almost solely under the age of five years and are specially common in the first two or three years of life. Not less important is the influence which an attack of measles possesses in lighting up latent tuberculosis. This is also much more common between the ages of one and three.

It seems desirable, therefore, to consider whether it is not possible to limit the number of cases under the age of five years. Of course complete immunity at these ages cannot be secured, but I think that the absolute number of attacks of measles under five years of age should be very much smaller than it is. It is a matter of administration. It cannot be doubted that a very large proportion of those children who take measles under five years of age are infected by elder brothers or sisters who are attending

school. The question, then, which requires to be investigated is how far this can be prevented. I am quite certain that with the machinery in existence—namely, the medical inspection of schools and the sanitary control of the district—this should be a comparatively easy matter. It will want, of course, careful thinking out in every district. It will want special training of the epidemic inspectors and of the sanitary inspectors, as in the event of an epidemic the work would be so much increased that the latter would necessarily be temporarily seconded. Once the training has been accomplished, no further difficulty should be experienced.

Each school will keep a register. When a child of five years is admitted to a class at school it will be noted in the record whether that child is the eldest, intermediate, or youngest member of the family. When measles breaks out in a class the register will be consulted. If the child exposed to infection be the youngest member of the family, nature may be left to take her way—there is no further danger. But if he or she be the eldest, especially if the younger children in the house are of ages between six months and three years, the direct action of nature is no longer a matter of indifference. What is a mild disease at the age of five years may be a matter of grave danger at the age of six months.

Now it may be taken as practically certain that very few children develop the first symptoms of measles within seven days of the infection, and the higher limit may be set at fourteen days. If therefore the child which has been exposed to the infection stay in its home for seven days after exposure no harm will ensue. It is the next seven days which are important. In the entourage of families in towns, especially where the families are very young, the house of at least one grandmother is usually available. There are also quite frequently houses of uncles and aunts in which there are either no children or in which the children have already passed through the necessary attack of measles. It is thus only a matter of arrangement that the child who has been exposed to infection stays with a grandmother or other relative for a specified seven days. It may be objected that this cannot be done. On the contrary, I have made such arrangements for many years with reference to cases of scarlet fever and diphtheria. Where on dismissal there was some doubt as to whether a patient were free from infection or not, and where it was obvious that continued residence in the hospital was not the best way to clear the patient of infection, I at once appealed to the parents. I found that the arrangements made were loyally carried out in nearly every case; the average parents are not selfish as regards their children, but much the reverse. There are, of course, a number of unreasonable and untrustworthy people, but in my dealings I have found these the exception. Once the matter has been carefully explained the ordinary person wishes to act for the best. Of course at the institution of a new method of administration there will be a considerable amount of evasion, but from the moment that the opponents of the system see their children going to the grave while those who accede find their children do not take the disease, the sarcasm of the neighbours will effect more than thousands of regulations. A few years' trial will put all the community on your side, and then the work is done.

The possibility of using reception houses requires consideration. It is of course quite futile to provide reception houses on a large scale, since the gathering together of many children who have been exposed to infection is but to exaggerate the chance of all taking the disease. It might even happen that only one child was infected on admission, and he or she might infect the whole. It is, however, not out of the question with individual cases. In certain instances where there is a large family of young children, and where there is no chance of the possibly infected child staying with friends, such an arrangement might quite well be made, especially in large towns where reception houses are kept open perpetually in view of small pox and typhus fever there would in many cases be no difficulty in taking suitable action.

II A. Early Diagnosis.

The most difficult point in the administration of measles is that which arises from the great amount of infective material given off from the very first symptoms of the disease. I have never seen any reason to believe that

there was any power of infecting prior to the first symptoms, so that the problem is reduced to the accurate observation of these. What, then, are the first symptoms? For administrative purposes there are only two which are of the smallest particle of use, nor are these of any certain value. The usual advice to look for the Koplik spots is vanity. By the time these have appeared the damage is done.

The first and most important of these symptoms is a rise of temperature. It is astonishing how often, after nine or ten days from the exposure, the temperature rises for a single evening to 101°, 102°, or 103°. Next morning it is again normal, and remains so for twenty-four to forty-eight hours after this. A chart of this form of onset is given in Wunderlich's *Medical Thermometry*. This is specially observed when measles develops in a person whose body is protected from chill, such as when a child is in bed or in hospital. If there is the slightest suspicion of infection being present administrative measures should be taken immediately on the rise of temperature. This symptom is specially of use when children are under the observation of a skilled nurse and temperatures are taken regularly as a routine.

The second symptom is oedema of the conjunctiva. This is much the earliest symptom of the catarrh to appear. The oedema is confined to the palpebral conjunctiva, and especially that of the lower lid. I have seen it stated that the first appearance of the oedema is on the ocular conjunctiva. This, however, is totally at variance with my experience. Even when the catarrh of the eye is very marked on the third and fourth days of the disease, the ocular conjunctiva is generally almost clear, the congestion and oedema being confined chiefly to the palpebral conjunctiva. When this oedema of the palpebral conjunctiva associated with a rise of temperature in a child who has been exposed to measles infection is observed the diagnosis is practically certain. If the child be removed at once there is some chance, especially if the type of epidemic be not specially infective, that those in the environment will escape. With care these symptoms might be used successfully under skilled observation in a reception house, if there was no close contact between the different children. Measles is a disease I have never found to spread from room to room if there was no direct air connexion between them, nor have I ever seen it carried by nurses from one house to another. It must be confessed, however, that even with the greatest care the effort to prevent spread of infection fails in the majority of cases. An improved technique will be required before success is possible.

II B. Hospital Treatment.

If young children have been exposed to measles what procedure is necessary? I think it essential that they be put to bed before the first symptoms appear—that is, eight days after exposure to infection—and kept there for a few days until it is certain whether the infection has been acquired or not. There is all the difference in the world between an attack of measles developing in a child exposed to body chill owing to draughts, etc., and a child developing the disease under conditions of warmth and rest. Even if this stage be missed, with the first symptoms of catarrh bed is the place.

In the next place, if the disease promises to be of great severity, I am quite certain that hospital treatment is the best. When, on the fourth or fifth day of illness, the rash begins to appear in the bronchi, great respiratory distress and cyanosis are frequent. This condition I call "suffocative catarrh" to distinguish it from bronchopneumonia. It is one of the curses of cellular pathology to group all sorts of different diseases under one name. This suffocative catarrh is a part of the disease—measles—and has no relation to true bronchopneumonia, which is quite a different disease. The catarrh kills in a few days, the bulk of the deaths occurring within eight days of the first symptoms of measles. Bronchopneumonia runs a longer course, the bulk of the deaths occurring twelve days after the onset of the disease. It is a secondary infection to measles, while the catarrh is a part of the primary disease.

This catarrh, if severe, is a condition of extreme gravity, which demands careful nursing and also environmental conditions not easily obtained in a private house. I have

not a particle of doubt that these children are very much better treated in the open air. Furthermore, the administration of oxygen in many cases makes all the difference between recovery and death. In addition, though the remark is not strictly appropriate in this connexion, these children, in my experience, are the better of a certain amount of alcohol if they are not too cyanosed to oxidize it. In making these statements I am fully aware that I am speaking somewhat rashly, because, regarding children suffering from severe suffocative catarrh in measles I have never learnt to make anything which can be called an accurate prognosis, and consequently have difficulty in stating the results of treatment statistically. Thus, in teaching I have demonstrated two cases to my students—one as likely to recover, and the other as likely to die—only to have to point out the next day that the child I thought was probably going to recover was now dead, and that the other, if not out of danger, was at least

considerably better than on the previous day. This rapid improvement is the rule in cases of suffocative catarrh if cure is to take place. A child may be within the immediate zone of death and within a couple of days be comparatively well. If bronchopneumonia is implanted on the catarrh, the change to convalescence is a matter of ten days to three weeks. The two conditions should not be confounded.

A further point of importance with regard to the treatment of severe cases of measles, and a treatment only easily obtained in hospitals, is the care of the eye. An attack of measles is quite frequently the starting-point of eye trouble. For the proper cleansing of the eye regular washing out is necessary, and the technique requires adequate training on the part of the attendants. Sometimes even hourly cleansing is required, and that cannot be provided at home except in the houses of the rich.

THE PHYSIOLOGICAL COST OF MUSCULAR WORK.

BEING THE SUBSTANCE OF A LECTURE TO THE CHELSEA POLYTECHNIC, FEBRUARY 23RD, 1920.

BY A. D. WALLER, M.D., F.R.S.

This "lecture" is essentially intended as a demonstration of method and apparatus by means of which a fundamental problem—to the answer of which an important part might be contributed by a polytechnic school—can be approached and compassed.

Shortly stated, the general problem requires numerical answer to the question—What, or rather *how much*, is the physiological cost of various forms of mechanical work as done by a dock labourer and a printer, a carpenter and a tailor?

This cost is most readily measured by measuring the CO₂ expired in consequence of the internal combustion that takes place in all living matter—in lowest degree during deepest sleep, in highest degree during heaviest muscular work. And the particular part of the problem on which, at the suggestion of the Principal, I shall invite your answer will be as follows: What is the energy output, expressed in calories per head per hour, (a) for a class sitting listening to a lecture; (b) for a class carrying out physical exercise drill?

I should like to make it possible as an outcome of this lecture (1) that every student here should be able to give a reasonably good theoretical answer on paper, and (2) that one, or preferably two, of your number should be able of their own knowledge to get out by means of the apparatus now before you a more or less accurate statement of actual fact in, say, a month's time.

The apparatus consists of three parts:

1. The *collecting bag*, with valved mouthpiece and tap, to receive the expired air of the subject for, say, a minute or half a minute.
2. The *analyser*, to measure directly the percentage of CO₂ present in that expired air.
3. The *spirometer*, to measure its volume in litres.

And here are the results of a typical observation like that which has just been made under your eyes:

At rest...	Ventilation.		CO ₂ .		Calories.*
	Per Minute. 6 litres	Per Second. 100 c.cm.	Per Cent. 3	Per Second. 3 c.cm.	Per Hour. 60
At work (walking at 3½ miles an hour)	24 ..	403 ..	4	16 ..	320

* The translation into calories per hour assumes that 1 c.cm CO₂ per second = 20 calories per hour. For this equivalence the calorific value per 1 c.cm. CO₂ has been taken = 5.55 calories.

It is obvious to you from this observation that the work of walking has caused a measurable increase of CO₂ output, and you have learned further that the

physiological cost of walking at 3½ miles an hour is 320 calories gross, or 260 calories net per hour.

The small value (60 calories per hour) represents the cost of bare life without work—that is, the basal cost; it goes on, of course, during work, and has therefore to be subtracted from the gross cost of work, leaving us with its net cost. (Obviously if we know the mechanical value of the work we can calculate out a value for the ratio

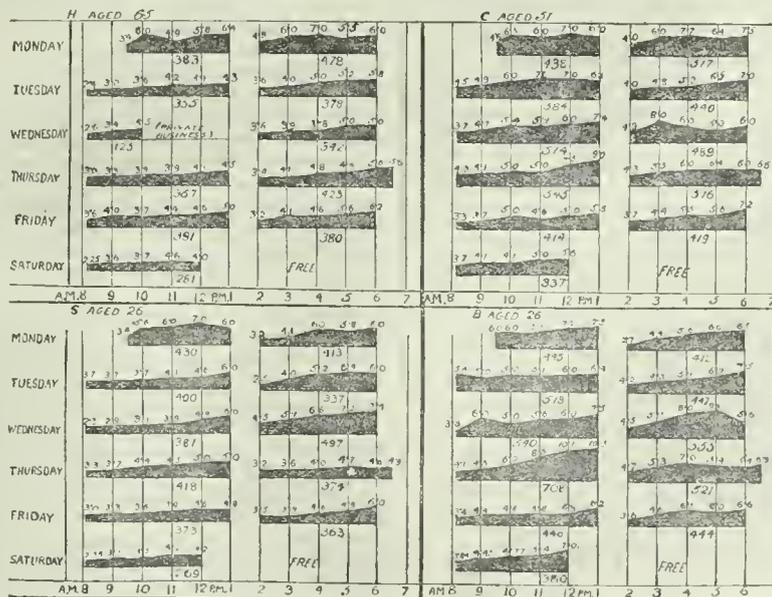

$$\frac{\text{work}}{\text{net cost of work}}$$

which is a measure

of physiological efficiency; but with this measure we are not concerned to-day.)

I will now put before you a brief report of a week's observation just concluded by Miss G. De Decker at the printing rooms of the BRITISH MEDICAL JOURNAL, with the helpful co-operation of four compositors—H., C., S., and B.

The procedure was to collect every hour from each man during the six days of work the expired air for a period of one minute. Each bagful was then dealt with as you have just seen done—that is, its volume measured by spirometer and its CO₂ percentage taken by analyser, so that the rate per second of CO₂ discharge was ascertained and plotted on squared paper. The hourly CO₂ ordinate of each man was thus recorded for each day, and the value in calories of the day's energy output was computed as a simple summation of the ordinates, as for

computed as a simple summation of the ordinates, as for

the day given below *in extenso*. (This was the first day, and our observation started at 9.30 a.m., whereas work actually began at 8 a.m., as shown in the week's summary.)

H., aged 65; Weight, 10 st.; Height, 5 ft. 5 in.; Surface, 1.71 M.
February 16th, 1920.

Time.	Ventilation.		CO ₂ .		Calories.
	Per Minute.	Per Second.	Per Cent.	Per Second.	
9.30	8.5 litres	142 c.cm.	2.4	3.4 c.cm.	383
10... ..	12.0 ..	200 ..	3.0	6.0 ..	
11... ..	9.0 ..	150 ..	3.2	4.8 ..	
12... ..	11.5 ..	192 ..	3.0	5.8 ..	
1... ..	12.0 ..	200 ..	3.2	6.4 ..	
Dinner hour ...	—	—	—	—	
2... ..	9.0 ..	150 ..	3.2	4.8 ..	478
3... ..	12.0 ..	200 ..	3.0	6.0 ..	
4... ..	12.0 ..	200 ..	3.5	7.0 ..	
5... ..	11.0 ..	183 ..	3.0	5.5 ..	
6... ..	12.0 ..	200 ..	3.0	6.0 ..	861

The working out of this day's calories is as follows:

Morning: 47+60+96+116+64=383

Afternoon: 48+120+140+110+60=478

—
861

Total: 861 calories in 7½ hours, or 115 calories per hour.

The summary account of the results of six days of observation on four workers, recorded and calculated as above, is given in graphic form on the preceding page:

Summary for the Week February 16th to 21st, 1920.

Subject.	Day.	Calories per Day.	Hours.	Calories per Hour.
No. 1, H. Age 65. Weight 63.5. Height 1.73. Surface 1.71.	Monday ...	861	7.5	115
	Tuesday ...	733	8.75	84
	Wednesday ...	467	5.75	81
	Thursday ...	790	9.25	85
	Friday ...	771	8.75	88
	Saturday ...	281	3.5	80
No. 2, C. Age 51. Weight 62.5. Height 1.70. Surface 1.68.	Monday ...	955	7.5	127
	Tuesday ...	1,024	8.75	117
	Wednesday ...	1,003	8.75	115
	Thursday ...	1,061	9.25	115
	Friday ...	833	8.75	95
	Saturday ...	337	3.5	96
No. 3, S. Age 26. Weight 63.5. Height 1.80. Surface 1.77.	Monday ...	843	7.5	112
	Tuesday ...	737	8.75	84
	Wednesday ...	878	8.75	100
	Thursday ...	792	9.25	86
	Friday ...	736	8.75	84
	Saturday ...	269	3.5	77
No. 4, B. Age 26. Weight 72.5. Height 1.78. Surface 1.86.	Monday ...	857	7.5	114
	Tuesday ...	955	8.75	110
	Wednesday ...	1,035	8.75	125
	Thursday ...	1,229	9.25	133
	Friday ...	892	8.75	102
	Saturday ...	380	3.5	109
		18,789	183.0	103 ± 2

18,789 calories in 183 hours = 103 calories per hour.

CONCLUSION.

The average rate of energy-output (gross) at the printing rooms of the BRITISH MEDICAL JOURNAL, gauged as described above on four compositors for one week, comes out as: 101 to 105 calories per hour.

I shall be very interested to learn from your own observations at the Chelsea Polytechnic what are the average rates of energy-output per head:

(a) For a class of students sitting at lecturo.

(b) For a class of students during physical exercise drill.

AN ATTENUATED TUBERCLE VACCINE.

BY

NATHAN RAW, C.M.G., M.D., M.R.C.P., M.P.,

LATE O.C. AND SENIOR PHYSICIAN, LIVERPOOL HOSPITAL, B.E.F.,
FRANCE.

The object of this short paper is to bring to the notice of the profession a vaccine which in my own experience has been of great service in the treatment of tuberculosis.

Whilst not claiming it to be a specific remedy, it has a remarkable power of controlling the disease and of limiting the spread of the infection in the human body. As is well known, tuberculosis has a tendency to spontaneous cure, and if we can in any way limit the spread of the infection we are placing the patient in a better position by his natural powers of resistance to deal successfully with the original focus. In the BRITISH MEDICAL JOURNAL of January 31st, 1903, I expressed the opinion (as I believe for the first time, and based almost exclusively on clinical and pathological evidence) that

Human and bovine tuberculosis were separate and distinct diseases, but that the human body was susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases were so rarely seen together in the human subject that there seemed strong grounds for presuming that they were antagonistic to each other, and that bovine tuberculosis may confer an immunity against human tuberculosis, and vice versa.

To take an example: A child with primary abdominal tuberculosis or tuberculous glands in the neck—both bovine infections caused by tuberculous milk—is protected against a primary pulmonary tuberculosis; on the other hand, a case of primary pulmonary tuberculosis from inhalation—always caused by the human bacillus—is protected against the lesions caused by the bovine bacillus. In other words, the two types of the bacillus—human and bovine—cannot exist in the body at the same time, and I have never been able to recover both types from the same patient.

The lungs are frequently attacked in the course of a bovine infection either by direct lymphatic extension from the abdomen to the bronchial glands; by direct extension to the apex of the lung from glands in the neck; or in the course of a general blood-stream infection.

For these reasons, and after treating over 3,000 cases of tuberculosis in hospital with tuberculin from various sources, I have come to the conclusion that the best results are obtained by treating human infections with bovine tuberculin, and bovine infections with human tuberculin. Although the results in many cases were good, I must confess on the whole to a feeling of disappointment, and I attributed it to the uncertainty of origin of the tuberculin, which was prepared in many instances from a highly virulent culture, and also to the tuberculin becoming stale and inert by lapse of time. In many cases acute and serious reactions followed its use; in others it seemed to be inert.

For these reasons I decided over fourteen years ago to endeavour to obtain attenuated cultures of bacilli, and to try the effects of a tuberculin prepared from cultures of low virulence and less toxicity. The late Professor Koch gave me in 1905 a pure culture of human tubercle prepared from the sputum of pulmonary tuberculosis; Professor Calmette of Lille, one of bovine tubercle; and Professor Bang of Copenhagen, one of avian tubercle. These original cultures have been subcultured every month since 1905 without any intermission, and to day they grow true to type, quite normally, although not quite so luxuriantly. The present cultures, which are growing at the Lister Institute, are, of course, highly attenuated and of very low virulence. I have injected them into animals, and they are practically non-pathogenic.

I treated several patients with this tuberculin in 1914, but the war came, and my work was interrupted by a long residence in France. The results were most satisfactory, but I propose to wait for some time before coming to a definite decision.

Tuberculosis is seriously increasing in all the late belligerent countries, due to the stress and rigour of war conditions and the malnutrition of the people, more especially children. We have not yet discovered a specific remedy for the disease, but it is our duty to adopt every possible means to prevent its further spread, and in my

opinion the careful administration of tuberculin on scientific lines will do a great deal to limit the infection.

I venture to make the following suggestions regarding its use:

1. Tuberculin should be prepared from attenuated and non-virulent cultures of bacilli.
2. It should be freshly prepared and used within a week.
3. Given in graduated and increasing doses at intervals of seven days.
4. Acute reactions are not necessary.
5. Not less than twelve injections should be given at intervals of one week, but in some cases a great many more injections are required.
6. The most favourable cases for treatment are local lesions, but early cases of pulmonary tuberculosis may be limited and a further spread to other parts of the lung prevented.

PARAFFIN WAX FOR FIRST-AID TREATMENT IN BURNS.

THE use of paraffin No. 7 in the treatment of burns and various forms of ulceration is well known, but it has occurred to me that ordinary hard paraffin would be an ideal first dressing for a burn through the protection it would afford and the complete absence of pain on removal. Paraffin candles, found in most houses, afford the material necessary, and it is simplicity itself to light the candle and allow the wax to gutter on to the burn.

Attention must be given to several small points: The candle must be held at a fair distance—about 10 in.—so that the paraffin is not too hot when it falls upon the injured part, and it is well not to keep dropping on one place but to dodge about over the surface; a mass of melted wax in one place is painful. The dressing can be completed by putting a small piece of clean linen or cotton-wool over the wax and dropping some more upon it. The heat of the burning candle seems to be sufficient to sterilize the wax, and, in any case, I should suppose that paraffin is not a substance likely to afford much nourishment to micro-organisms.

I have tried this method in a number of cases and found no ill effects; perhaps the healing action is not quite so rapid as with paraffin No. 7, but the painlessness is equal.

J. R. GARROD, M.D.

PARENTAL BLOOD IN HAEMORRHAGE OF THE NEWBORN.

I HAVE met with three cases of haemorrhage of the newborn during my twenty-one years of practice here. The first case died, the two last recovered.

The first case, a female infant, was treated on the usual old-fashioned lines of drug treatment, but died in spite of every effort. The necropsy revealed only the ordinary negative findings.

The two later cases were treated by the subcutaneous injection of the parent's blood, of the father in the first case and of the mother in the second. Magnesium sulphate solution, saturated, was employed to prevent clotting. The effect was immediate and successful.

The notes of the third case are these:

A female infant, full term, well nourished, was born after normal labour on March 8th, 1920. The mother's age was 40. Eight years had elapsed since the previous confinement.

At 1 a.m. on March 11th the child vomited blood and passed some eight or nine abundant stools of blood. I saw her at 1 p.m. and found her feeble and passive—in the condition, in fact, of a child who had lost a great quantity of blood.

I immediately gave the infant an injection of 6 c.cm. of the mother's blood in the right flank. To obtain this blood, some saturated solution of magnesium sulphate was placed in an egg-cup in a saucepan of boiling water, and the 5 c.cm. Record syringe was sterilized in the boiling water. Half a cubic centimetre of the magnesium sulphate solution was drawn into the syringe, and this was then filled with the mother's blood taken from the median basilic vein in the usual manner.

The next action of the bowels was at 7 p.m., and during the night there were four other stools. A stool was passed at 9 a.m. the next day, and again at 7 p.m. All these were black, but

contained no fresh blood. A stool passed at 10 p.m. was of the normal character and yellow colour. That at 7 p.m. was a mixture of black and yellow. The child, being too feeble to suck, had been fed by the spoon with mother's milk, drawn by the breast pump; as the quantity was scanty it was supplemented by diluted cow's milk. All the warm water possible was given also, between the feeds. The further progress to recovery was sure and uneventful.

It is extraordinary that since writing the above I have met with my fourth case. A male infant, born on March 31st, vomited blood on April 1st. In this case I was unable to obtain more than 1 c.cm. from the father, as he had a very serious convulsive seizure—due, I presume, to the cerebral ischaemia of a grave faint brought on by the operation—whilst I was drawing off the blood from his arm. I therefore supplemented this by a further 2 c.cm. from the mother, thus giving 3 c.cm. in all. The progress of the case was uneventfully successful.

In the first, third, and fourth cases here recorded the child was the second of the family. In the second case I am unable to trace the parents, and do not recollect what place in the family the child took, and I cannot find any note on the point.

Reports of Societies.

MODES OF ANAESTHESIA.

At a meeting of the Sheffield Medico-Chirurgical Society on April 1st a discussion was held on anaesthetics.

Mr. HERBERT HALLAM, after comparing the merits of ether and chloroform, said that the only two safeguards against overdose of the latter were a knowledge of its physiological action and the maintenance of a free airway. He enunciated his theory of the cause of chloroform overdose as follows:

Air containing chloroform enters the lung alveoli and the vapour is absorbed by the blood, such absorption depending on (1) the percentage of chloroform in the inhaled air, (2) the air pressure in the alveoli. Thus a current of air containing chloroform goes in and out of the lung alveoli, and as more vapour is absorbed the characteristic signs of anaesthesia develop. If this exchange occurs with freedom all is well, but if any interference with respiration occurs through obstruction the situation becomes one of extreme danger. Nature's remedy for obstruction is expiratory effort, and the combination of expiratory effort and obstruction raises the alveolar pressure and alters the composition of the residual air; consequently rapid absorption of chloroform occurs leading to an overdose. The patient is poisoned not from the chloroform on the mask, but from that in his alveoli.

Illustrations in support of this theory were: (1) In the operation for tonsils and adenoids a patient "lightly under" might through lingual obstruction or the manipulations of the surgeon become suddenly poisoned. (2) The absence of poisoning where intratracheal administration by catheter was employed and there was free airway. (3) The rapid recovery from poisoning when by removing obstruction and performing artificial respiration intra-alveolar pressure was rectified. Mr. Hallam also referred to the question of idiosyncrasy to chloroform and the value of suggestion before operation.

Dr. W. DAKIN MART demonstrated Boyle's gas and oxygen apparatus, laying stress on the importance of systematic preliminary arrangement of the accessory appliances. He advocated preliminary medication with morphine $\frac{1}{4}$ grain and atropine $\frac{1}{150}$ grain, twenty minutes before the start of the operation. In abdominal operations the abdominal wall should be anaesthetized (after the patient was under) by means of $\frac{1}{2}$ per cent. novocain and $\frac{1}{4}$ per cent. potassium sulphate given independently and injected layer by layer. This prevented the occurrence of pain after coming round, and so enabled the patient to breathe more deeply, and clear the lungs more quickly. It was desirable to start the induction with a pressure of one "hole" of oxygen and three of nitrous oxide. The patient first breathed air until the bag was three-quarters full of this mixture, when the valves were turned on and he breathed from the bag and into the air. Then re-breathing in and out of the bag began. The colour of the ears should be watched; if they became dusky more oxygen should be given.

The signs of complete anaesthesia were regular quiet breathing (sometimes difficult to obtain), pupils small and active, eyes moving, and a normal pink colour. The signs of deep anaesthesia were snoring (difficult to avoid with the rebreathing mechanism), dusky tinge, jactitation, rolling of the eyeballs, and dilatation of the pupils. These signs indicated that more oxygen should be given. Suitable cases were amputations, chest cases, those suffering from severe shock or from pneumonia and bronchitis. Nose and throat cases were difficult to anaesthetize by this method. Advantages over other methods were: No fall of blood pressure, very little vomiting, rapid recovery from the anaesthetic, and often an improved general condition of the patient after the operation.

Dr. FAVELL demonstrated Marshall's apparatus for gas and oxygen, and many other members took part in the discussion, including Dr. ROBERTSON, Dr. HILLIER, Dr. SNEDDON, Dr. MILNER, Dr. HOLROYD, Dr. STEDMAN, and the PRESIDENT.

CONSTRICION OF URETER.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Sheffield on March 19th, the President, Mr. MILES H. PHILLIPS, read a short paper on unilateral pelvo-abdominal pain due to constriction of the ureter. The type of patient he had in mind complained of a definite, localized and clearly described pelvic or pelvo-abdominal pain intensified by menstruation and for which the most careful pelvic examination or even abdominal exploration could find no satisfactory explanation. By a study of the following cases he showed that constriction of a ureter by scar tissue or other band was a sufficiently likely cause to warrant exploration with the cystoscope and ureteral catheter.

Case 1.—Pain in right iliac and lumbar regions, commencing three days after hysterectomy for fibroid, causing post-partum haemorrhage. Pain persisted although the general condition was steadily improving. Bladder examined a fortnight after operation, and right ureter seen to be acting less frequently and ejecting a smaller stream of urine than the left. At further examinations, a week and fourteen days later, right ureter apparently blocked. Abdomen reopened and affected ureter found dilated at pelvic brim and constricted about one inch from bladder by a tough fibrous cord containing vessels and evidently resulting from tissue dragged inwards and included in the ligature round right uterine artery at previous operation. Division of cord was followed by rapid recovery and no further pain.

Case 2.—Pain in left iliac and lumbar regions dating from confinement seventeen years previously. Menorrhagia and premenstrual exacerbation of pain. No enlargement of left kidney. Cervix deeply split on left side and firm scar in left fornix. Abdomen opened and left ureter found distended above point opposite cervix where it plunged into dense mass of scar tissue. Ureter separated with difficulty and hysterectomy performed. Operation two years ago, and no pain since.

Case 3.—Single girl. Pain in right iliac fossa, commencing in 1914. Dilatation of cervix brought no relief. Right kidney unduly mobile. Kidney fixed to fascia and muscles of loin eighteen months later, but pain continued. Abdomen opened after further interval of eighteen months. Uterus, appendages, and vermiform appendix normal. Right kidney well fixed. Extensive Jackson's membrane across ascending colon, and strong peritoneal bands about caecum. Right ureter bound by fibrous band hardly more than ridge of peritoneum, at point 2 in. above pelvic brim. Band divided and patient perfectly relieved.

In none of the cases was there any tangible enlargement of the kidney, but a hydronephrosis would probably have resulted had the obstruction not been removed. The symptoms complained of were those of early ureteric obstruction, and the fact that an increase in pain occurred before or during menstruation brought such cases under the care of the gynaecologist.

Factors in Abortion.

Drs. DOUGAL and BRIDE (Manchester) read a paper on factors causing abortion, based on a clinical and pathological examination of 100 consecutive cases of abortion admitted to the maternity department of St. Mary's Hospital, Manchester. The authors pointed out that the work was in the nature of an experiment, and that 100 cases were too small a number on which to base authoritative results. They hoped, however, to continue the

work along similar lines. The following conclusions were arrived at as the result of the investigation:

(1) Abortion occurs most commonly between the third and fourth months. (2) It is comparatively uncommon in primiparae—less than one-fifth of the series belonged to this category. Most women who abort have borne previous full-term children, and, in a majority of cases, more than one. Frequent abortions in the same patient are uncommon, and not necessarily due to syphilis. (3) As regards the factors producing abortion, accidental and reflex causes account for 18 per cent., general disease of the mother 7 per cent., disease or displacement of the mother's genital organs 12 per cent., and gross abnormalities of the fetus, cord, or placenta other than those due to haemorrhage and infarction, 6 per cent.

They considered that the importance of syphilis as a cause of abortion had been somewhat exaggerated. The Wassermann reaction was positive in 12 cases, but in half of these some other abnormal condition was present which by itself might have produced the abortion. In only one case were clinical signs of syphilis present, and in no specimen could typical syphilitic changes or spirochaetes be demonstrated. They estimated at not more than 10, and probably nearer 8, the percentage of cases in which syphilis produced abortion. The percentage of self-induced cases was difficult to estimate, but probably not less than 20 per cent. Ten patients in the series admitted that they had wilfully brought on abortion, and eight employed lead pills for the purpose. In 30 per cent. of the cases no cause could be assigned, and pathological investigation threw little additional light on the subject. It appeared, however, that in the great majority of cases the mother was at fault as the result of some diseased condition, whether of an organic nature or merely an increased irritability of the centres presiding over the expulsive action of the uterus.

Reviews.

GENERAL PHYSIOLOGY.

It is always refreshing to find a familiar subject treated in a new fashion. Will fresh light, one asks, be thrown on the old material? will thought be stimulated? Professor M. ARTHUS, in his book *La Physiologie*,¹ has in some respects broken new ground so far as the systematic treatment of his subject matter goes. Is he successful? does he stimulate thought? does he charm or irritate? does he point to new horizons? The book certainly is interesting; it has its value. Physiology is discussed in a fresh way, but somehow it fails to satisfy. It is difficult in the first place to understand for what audience the book has been prepared. At one moment it would appear to be for students of medicine who have a fair knowledge of the subject; at another it might be presumed it was for the intelligent layman without specialized knowledge. Like all such volumes it is weakened by its attempt to meet every demand.

The volume is curiously arranged. It is divided into two books called (I) the methods, and (II) the results and hypotheses, respectively. The first book is in turn subdivided into three parts: (1) Observation, (2) experiment, (3) pathology; the second book consists of one part only. Under the heading observation, the various methods by which our information is obtained are discussed in rather a perfunctory fashion; under experiments there is a wide range of discussion, from the choice of the animal on which the observations are to be made, to the interpretation to be put upon the observed facts; finally, under the heading pathology there is a rather thin disquisition on the interrelation between the study of the normal and the abnormal, and more particularly on the question whether the physiological observations made on animals can be applied to man. Such matters as cerebral localization, hepatic disease, myxoedema, and diabetes are discussed, and it is shown how the information collected by laboratory methods is applicable to the human subject. Stress is quite properly laid on the fact that there ought to be much more intimate co-operation between the physiologist and the practising medical man, that the advantages to be

¹ *La Physiologie*. Par Maurice Arthus, Correspondant national de l'Académie de Médecine, etc. Paris: Masson et Cie. 1920. (Cr. 8vo, pp. 430. Fr. 10 net.)

gained are mutual, that by keeping touch with the practical applications of his science the physiologist will perform more useful work, and that the medical man, by following the advances in physiological science, will find his work lightened and rendered infinitely more interesting.

The second book, on results and hypotheses, is much more interesting, dealing as it does with the more speculative side of the question, but it is precisely this book which causes the disappointment. The field is so inviting, so little has been done in recent years to correlate the various hypotheses or to attack the effete and the shams. The introduction is so promising. The physiologist is no mere collector of facts; he discusses them, he interprets them, he classifies them, and he arrives through them at the great laws which preside over the manifestations of life. This work is not exclusively physiological, it is also philosophical; but the physiologist can undertake it because *il y a toujours un philosophe qui sommeille au fond d'une âme physiologique*. It is true every word of it, but M. Arthus has failed to justify the faith that is in him. The mechanists, self-appointed guardians of the physiological shrine, may dissent; but it is a fact that, simply because no one has had either the courage or the necessary training, with the notable exception of Dr. John Haldane, to tackle the mass of physiological facts in a philosophic manner, modern physiology tends year by year to assume the appearance of a mass of ugly conglomerate. Some day M. Arthus may be tempted to write a shorter book in which he will allow his fancy freer rein; then we may expect an essay which will be both stimulating and charming. As it is, however, the present volume can be strongly recommended to all medical students and practitioners who desire a knowledge of the applications of physiology.

CYSTOSCOPY AND URETHROSCOPY.

THE task of translating a standard work and of ensuring that it loses as little as possible of its original vitality in the process is not light. It is fortunate, therefore, that Luys should have confided the production of the volume *Cystoscopy and Urethroscopy*² to the competent hands of Dr. ABRAHAM WOLBARST, who is himself an eminent urologist, and, as he confesses, an ardent admirer of the French author. He feels that in extending more widely amongst English-speaking urologists the knowledge of Luys's important treatise, he is not only performing an act of homage to its distinguished author, but also contributing to the progress of genito-urinary science. Luys's avowed object in writing his treatise was to illustrate and popularize the use of direct vision cystoscopy and urethroscopy. Neither in Great Britain nor in America has this method of cystoscopy received the extensive recognition that has been accorded to the indirect method. Whatever may be the reason for this marked preference for indirect cystoscopy, urology will surely gain in both countries from a clear exposition of the direct method.

Luys's book is worthy of an important position in the library of the urologist as a standard reference work on the science of endoscopy. It contains an extensive and illuminating account of the origin and development of cystoscopy and urethroscopy. Various types of urethroscope and cystoscope are described, beginning with those employed in the earlier days of the science, and concluding with the more modern instruments. Both indirect and direct methods are passed under review, the author finally giving judgement in favour of the latter. His reasons for preferring direct cystoscopy are, in the first place, that in it the personal equation is reduced to a minimum; far less experience is required in interpreting the view of the bladder obtained in direct cystoscopy than that furnished by the indirect instrument. The bladder wall may be viewed not only full-faced but in profile, a facility which permits of slight elevations and depressions being detected. In addition to this, the colour of the mucous membrane appears more natural under air than under water distension, and no difficulty is experienced in viewing a contracted viscus which cannot be properly distended. Luys also claims that haematuria

and pyuria are less troublesome with direct cystoscopy and under greater control. Finally, he claims that this method is the only one applicable to cases of vesical fistula, and that it permits of cystoscopy in pregnancy and in cases of abdominal tumour. It is, he asserts, vastly more convenient when treatment is required. As a set-off to these weighty advantages he mentions the diminution in the visual field with the direct cystoscope, the necessity for employing an instrument of large calibre, and the occasional failure to obtain sufficient unfolding of the vesical walls. To these objections we should have added the greater discomfort inflicted on the patient.

After giving Luys's reasons for preferring the direct method of cystoscopy, the translator and editor has inserted a summary of the position as viewed by an American advocate of indirect cystoscopy, Dr. W. F. Braasch; it is a very fair review of the question, and while maintaining the preference of the majority of American urologists for the indirect instrument, the advantages of direct cystoscopy in certain special cases are admitted.

The book contains a great many illustrations and coloured plates representing various pathological conditions of the bladder and urethra. Although some of these illustrate rarities that may very seldom be encountered, they are rightly included in a book that aims at being a comprehensive and complete work of reference.

ATLAS OF SYPHILIS.

INTRODUCED with a foreword by the Director-General A.M.S., the large and expensive *Atlas of the Primary and Cutaneous Lesions of Acquired Syphilis in the Male*,³ by Major WHITE and Dr. BROWN, is based on the experience gained from some 19,000 cases of syphilis seen at a large venereal hospital; of these many were suitable for the taking of photographic records. The urgency of the problem of the early diagnosis and treatment of syphilis is universally recognized, and the authors of this *Atlas* have set up as its chief aim the giving of assistance in the early diagnosis of the disease; the majority of the pictures, photographic or coloured, are of its primary and secondary manifestations.

The primary syphilitic and non-syphilitic sores are described in considerable detail, as their early recognition is so essential; the text is in no sense a treatise on syphilis, but confines itself strictly to questions of diagnosis. It is interesting to note that multiple primary chancres were observed in 19 per cent. of 9,000 cases analysed; 834 patients showed two each, and four patients had respectively as many as 14, 15, 16, and 49 primary chancres apiece; it is pointed out that the presence of external abrasions (such as those produced by *Acarus scabiei*) predisposes to multiplicity of the primary lesions in syphilis. The seventy-nine photographs, many of them in stereoscopic view, and the five coloured plates are all excellently reproduced, and do equal credit to their artists and to the printer. The authors of this *Atlas* are to be congratulated, and their work should be of great service to medical students and workers in venereal clinics all the world over.

ITALIAN WAR SURGERY.

FORNI, in a modest, workmanlike account of an Italian surgeon's experience with a surgical ambulance during the war,⁴ records 60 cases of cranial and cranio-cerebral wounds and 38 cases of penetrating wounds of the abdomen. The cases are described in detail and illustrated by 58 photographic reproductions showing the nature of the wounds. The first chapter is devoted to cranial wounds without lesion of the dura (8 in the frontal region, 9 in the parietal, 4 in the occipital, 2 at the base). The second chapter deals with wounds affecting the cerebrum as well as the cranium, and comprises 32 cases. In the next chapter the author discusses the pathological anatomy and symptomatology of both groups

² *A Treatise on Cystoscopy and Urethroscopy*. By Dr. Georges Luys. Translated and edited with additions by Abr. L. Wolbarst, M.D., Cystoscopist, Beth Israel Hospital. London: H. Kimpton, 1918. (Sup. roy. 8vo, pp. 386; 217 figures; 24 plates, including 76 drawings from original water colours.)

³ *An Atlas of the Primary and Cutaneous Lesions of Acquired Syphilis in the Male*. By Charles F. White, O.B.E., M.B., and W. Herbert Brown, M.D. London: John Bale, Sons, and Danielsson, Ltd. 1920. (Double demy 8vo, pp. 32; 79 photographs, 4 coloured plates, 27s. 6d. net.)

⁴ *Ferite del Capo e dell'Addome in un Ambulanza Chirurgica d'Armata*. By Dott. G. G. Forni, Libero docente nell'Università di Bologna. Bologna: L. Cappelli. 1919. (Sup. roy. 8vo, pp. 181; 58 figures.)

of cases. Like most surgeons he points out that there is no certain relation between the injuries of the soft parts and those of the skull and encephalon, hence the necessity of careful and thorough exploration of all the wounds. Early symptoms pointing to cerebral lesions may sometimes clear off quickly, and prove to be merely due to shock; but, on the other hand, serious injury may be slow in showing definite signs and symptoms. Arrhythmia is usually of bad omen, even when the general and local symptoms suggest a hopeful prognosis. On the important question whether the dura should be opened in cranial wounds or left alone, the author expresses the opinion that it is necessary only in a relatively small number of cases, and only when symptoms of compression develop and either do not disappear or become accentuated. The author records 26 cases in which fragments of shell or other foreign bodies were present. The much more fatal character of cranio-cerebral wounds when compared with cranial wounds is shown by the mortality—for example, out of 28 operated on for cranial wounds only 1 died, whereas out of 32 with cranio-cerebral wounds 14 died.

The second part of the book is devoted to penetrating wounds of the abdomen; the cases related comprise 24 penetrating wounds with lesions of the gastro-intestinal tube, 5 with injury to intestines and parenchymatous organs, 6 with injury to pancreas and bladder, 2 with multiple lesions, and 2 with visceral lesions. Of the 38 operated on, 20 recovered and 18 died. Ether was used as anaesthetic if possible. One of the signs to which the author attached much value as establishing the diagnosis of penetration was the abdominal pain, whether spontaneous or provoked, and the rigidity of the abdomen. The state of the pulse as regards its strength and frequency was more valuable in prognosis than in diagnosis. Absence of hepatic dullness or presence of fluid in the abdomen were of comparatively slight importance, or at any rate not much attention was paid to them.

Clear straightforward accounts of surgical experiences such as Forni provides in his book form valuable additions to the large amount of surgical war literature. The collation and critical examination of such contributions to surgery ought to add much valuable information to our knowledge of the class of cases dealt with and help to fix the best mode of treatment for some years to come. There is nothing new or specific about war surgery, but the frank records of war surgeons of capacity must always be of value.

TEAM WORK IN HOOKWORM DISEASE.

DR. H. H. HOWARD, who is Director for the West Indies under the International Health Board of the Rockefeller Foundation, has published a practical book on the control of hookworm disease.⁵ He describes very fully the work and composition of a field unit. The medical director sees all cases before curative treatment is commenced, is in administrative charge, and directs propaganda; four microscopists are recruited locally, one of whom is in charge of the others, and confirms all positive findings; twelve nurses collect specimens from the whole population of the area, and administer anthelmintic treatment as the medical director prescribes; the unit is completed by clerks and menials.

The aim of the Rockefeller Foundation in putting such teams in the field in various parts of tropical and sub-tropical America is the complete eradication of the ankylostome from the countries under treatment—its eradication, moreover, within a period of months. It is in this sense that their methods are intensive. To realize the courageousness of the undertaking it is only necessary to remember that more than half the population in these countries is infested with hookworm. Undoubtedly the intensive radical method is the only one that can in the end be successful. It is costly of course, but much less so than the treatment of those who present themselves, while the mass of the population, including of course the mild cases and the carriers, is left untouched. Eradication is of course the aim of certain tea-planters' associations whose coolies are infested with these worms; but only too often they content themselves with treating cases and effecting

sanitary improvements. The aim is too low, and in the end it is found that the work has been expensive and useless.

Dr. Howard's book deals solely with administration and the organization of a campaign. It tells us how the units are equipped and paid, how long it should take to treat a given population, and what are the dangers of the administration of thymol. Specimens of case records, microscopists' report forms, and popular handbills are given, and the index is good.

MODERN SPIRITISM.

DR. SCHOFIELD'S book, *Modern Spiritism*,⁶ it is stated in the preface, was written at the earnest request of a medical friend to present "to the public some fairly comprehensive monograph on the subject." He is anxious that his account of the matter should be found impartial; he is repelled by the publications of some recent converts, and is impressed by the danger for persons of unstable equilibrium who accept the invitation to investigate the alleged phenomena. The author's own view may perhaps best be described as orthodox in the theological, Christian sense. Thus he holds that the true Bible spiritualism is a noble science, and protests against its degradation by the modern spiritism of to-day. He points out that even spiritists recoil with disgust from the pranks, too often marked by falsehood and deception, that so frequently characterize their meetings, and quotes Maeterlinck as saying that the unknown power moves tables, produces flowers, ghosts, and so on, "all on one condition: that all performances must be without rhyme or reason, vain and puerile." The net result is not only disappointing; it is also undoubtedly dangerous to spirit and body. The atmosphere is profoundly unhealthy, repellent to common sense, and repugnant to reason. As a religion it has no firm basis, being sometimes pantheistic, at other times atheistic or purely "modernistic." Dr. Schofield holds, however, that there is a residuum of truth in so-called phenomena attributable partly to the "uncoscious" mind of the medium, and partly to the existence of evil spirits, which are not spirits of the departed. As against this ingenuous view the sceptic may say that where so much is fraud, is it not possible that the residuum may have but little better basis? There is a most illuminating story in Dr. Schofield's book of a séance at the house of Mr. W. T. Stead, whereat were all the surroundings necessary for spiritist "truth"—special atmosphere, special attitude, and special apparatus. The room was darkened, hands were held tightly; there was strained attention, earnest expectation, intense desire to see something. In this atmosphere, after grave scientists had crooned American revival hymns for two hours, manifestations took place. It was in vain that the two American performers had asserted that they were not mediums, but only professional entertainers. The effect of what Dr. Schofield calls "collective hypnosis" was such that the company went away convinced that the manifestations were genuine.

While sympathy may be felt with Dr. Schofield's plea that powers exist with which we are not fully acquainted, it may be doubted whether he is justified in asserting that "auras are facts, and not the imagination of visionaries or the fancies of the mediaeval." And is it quite fair to class together hypnotism, telepathy, and wireless telegraphy as if they were of equal validity? Perhaps Dr. Schofield is inclined to hasty statements without taking sufficient pains to verify his references. At all events, it is rare to meet with three errors in two lines of print, as in the assertion that Henry Irving founded the *Holy Apostolic Church* or Church of the *Latter Day Saints*.

NOTES ON BOOKS.

The Road to Endor? is an account of how two officers, Lieutenant E. H. JONES, I.A.R.O., and Lieutenant C. W. HILL, R.A.F., contrived their escape from a Turkish prisoners' camp. It is noteworthy for two reasons, for

⁵ *Modern Spiritism. Its Science and Religion.* By A. T. Schofield, M.D. London: J. and A. Churchill. 1920. (Cr. 8vo, 1p. viii+259. 3s. 6d. net.)

⁶ *The Road to Endor.* Being an account of how two Prisoners of War at Yozgad in Turkey won their way to Freedom. By E. H. Jones, Lieutenant I.A.R.O. With illustrations by C. W. Hill, Lieutenant R.A.F. London: John Lane. New York: John Lane Co. 1920. (Cr. 8vo, pp. xiii+351. 8s. 6d.)

⁵ *The Control of Hookworm Disease by the Intensive Method.* By H. H. Howard, M.D. New York City: The Rockefeller Foundation. 1919. (Demy 8vo, pp. 189; 24 figures.)

in it is described with much wealth of detail the *modus operandi* of avowedly "faked" mediumistic séances; the later part of the book tells how these enterprising and courageous officers simulated madness in order to obtain their release. The story of their pluck, endurance, and resource in the pursuit of freedom is enthralling. In order to complete the picture of mental derangement they even went the length of half-strangling themselves. Later on, in Constantinople, Lieutenant Jones, who was malingering as a case of general paralysis of the insane, had to undergo lumbar puncture for diagnostic purposes. "They then tackled my spine. I saw an orderly blow down the hollow needle and wipe it on the back of his breeches before handing it over to the doctors, and it nearly gave me a fit . . . for I knew enough about needles to be in mortal terror of a dirty one." There is much food for thought in this book; people who are inclined to look indulgently on spiritualism will find the subject treated with much candour and ability; its perusal may render them less likely to be dazzled by the glamour lent to the cult by some great names in modern science.

The chemistry of colloids has made great strides during the present century, finding as it does so many applications in technical chemistry as well as in the chemistry of the physiological or physical laboratory. Dr. HATSCHKE has done the science good service by publishing a *Laboratory Manual of Elementary Colloid Chemistry*,⁸ its scope is clearly expressed in the title. General theories are not discussed, but accurate and detailed directions are given for carrying out the fundamental operations, for making a number of representative preparations, and for examining them by standard methods. Simple examples have been chosen, involving little expense for apparatus or material; references to the more recent literature are given at the end of each chapter. The book is clearly written, and should be available in every physiological laboratory.

The plastic surgery of the face is one of the many special departments of surgery brought into prominence by the war. In France this led to the creation of regional chief maxillo-facial surgeons with staffs to attend to the many cases of this class. Dr. HERPIN, who was a chief surgeon in charge of stomatology at Bordeaux, has written a valuable account of the various surgical treatments adopted by himself and his colleagues in these patients in a monograph on gunshot wounds of the lower jaw⁹ which is full of detail, well illustrated, and based on a considerable personal experience. At the time of writing he was able to classify 572 of his 619 cases as "evacuated cured," and 11 were referred to auxiliary services; only 2 were discharged from the service, while 34 were convalescent or under treatment. The book is clearly written, and should be in the hands of surgeons dealing with cases of the class with which it is concerned.

Chemistry for Public Health Students,¹⁰ by E. GABRIEL JONES, contains full and clearly written instructions for the performance of the experimental work in chemistry which is required by those preparing for the D.P.H. examination. Methods are adequately described, and at the same time brief but clear accounts of the principles involved are not lacking; particular attention is devoted to calculations. Concise notes are given in each chapter on the more important matters concerning public health in connexion with water, air, milk, etc. Chiefly useful as a manual of practical instruction, this volume will also serve the candidate who is revising his knowledge, as a partial substitute for the use of larger textbooks and of monographs. It contains a number of examination questions and a useful bibliography.

⁹ *Les fractures de guerre du maxillaire inférieur*. Par Dr. A. Herpin, Chef de service de Stomatologie de la 18^e région (Centre de Bordeaux). Paris: Félix Alcan. (Royal 8vo, pp. viii + 155; 100 figures. Fr. 4.40.)

¹⁰ *Chemistry for Public Health Students*. By E. Gabriel Jones, M.Sc., F.I.C. London: Methuen and Co. 1920. (Cr. 8vo, pp. ix + 244. 6s. net.)

A SWISS medical congress will be held at Berne on June 5th and 6th.

THE deaths which occurred in the Italian sanitary service during the war were as follows: Medical officers, 1,060, including 377 killed in action, 216 students, 40 dispensers, 40 chaplains, 33 nursing sisters, and 11 Red Cross staff.

MOTOR NOTES FOR MEDICAL MEN.

BY H. MASSAC BUIST.

CAR LIGHTING PROBLEMS.

Doctors are concerned perhaps more than any other class of the community with the matter of the safe lighting of road vehicles. It is unfortunate that, in connexion with the forthcoming regulations, it has practically been decided by the authorities that, as the dazzle problem has not been settled absolutely, the limitation of headlights must be enforced, despite the evidence furnished by existing devices. An instance was afforded by a demonstration, arranged by Messrs. C. A. Vandevell, which proved that some classes of lamps give much more glare than others. Everybody knows that it is possible to be blinded by an ordinary oil bicycle lamp, or, for that matter, by a gig lamp, because in the design of such lights no attempt was made to reduce dazzle.

The committee set up by the Ministry of Transport to investigate this problem has issued an interim report; it is still pursuing its investigations with regard to headlights on motor vehicles, and though not in a position to make any definite recommendations, it states that the evidence heard, and the result of tests carried out, strongly point to the following conclusions:

1. No satisfactory practical dimming device to avoid dazzle has yet been discovered. Such devices as avoid dazzle to any appreciable extent unfortunately fail to give a safe driving light; also, of course, they cause an extremely large percentage of loss of lighting power.
2. Far too powerful headlights are in common use at the present time.
3. Pending the discovery of some satisfactory dimming device, a maximum power light sufficient to give a safe driving light should be fixed, and the reflectors in the case of all lights should be limited in size, varying in accordance with the power of the light.

This would not give us safe lighting or driving. Moreover, such a course would lead to the abandonment of the investigation of the problems of dazzle, and would put a premium on unscientific lamp construction, and cause the maximum dazzling effect with a bulb of the limit size—say 20 c.p.—because other road users would the more probably get out of the way of an oncoming vehicle so lit. All which would be regrettable.

THE FUEL QUESTION.

Governments respect votes; therefore it is to the interest of every medical man to do what he can to obtain signatures to a petition in regard to the high prices prevailing for motor fuel which the Automobile Association has organized on behalf of the public for presentation to the Prime Minister. The cost of the petition is being borne by the Automobile Association, which has over 100,000 members, all of them motorists. But it is not merely a motorists' petition; it is, on the contrary, a petition from all members of the community, including those who use omnibuses or whose concern in the present high price of fuel is due to the fact that their foodstuffs are brought to market or distributed by motor traction. Copies of the petition can be obtained from, and signatures will be received by, the Automobile Association, 66-68, Whitcomb Street, London, W.C.2.

It is not expected that a reduction in the price of petrol will be an immediate result of the petition; that would be impossible. What is required is a direct pronouncement of this kind, making it plain to the Government that the public is fully alive to the gravity of the present situation and determined to have the business put on a proper footing. Sir Hamar Greenwood, speaking as a member of the Government at the recent exhibition of marine motor plant at Olympia, Kensington, said that his colleagues were fully alive to the importance of the motor fuel question, and were taking every possible step to bring more and more of the production, as well as of the distribution, under the British flag. But this will take time, and it is useless to suggest, as Viscount Carzon, M.P., did on the same occasion, that because nothing could be done to produce an immediate effect on prices the petition to the Prime Minister would be useless. This is a mistake, for the more this or any future Government realizes that the whole public is concerned with the price of motor fuel the more prompt and the more sincere and unremitting will

be its efforts to see that new sources of production are opened up and alternative fuels provided.

WHAT IS BEING DONE.

At the moment every possible sort of oil well is being tested. Undoubtedly a result will be that the production of crude oils will be enormously expanded in the course of the next three to five years.

At the moment it is impossible to do anything material in the way of producing benzol because the coal miners are producing something like 50 per cent. short of what is needed for the bare requirements of our ordinary industries, apart altogether from the distillation of benzol from such coal. When the miners are prepared to work fairly in exchange for high wages, then we shall have sufficient coal to be able to distil much benzol. The Government is already keen on this, but it will be the keener as signatures are secured to such petitions as that being promoted by the Automobile Association and Motor Union. Therefore, as the average medical man in this age requires motor fuel in order to pursue his profession, it will be in his own interests as well as in that of the nation in general if he would, in his leisure moments this week, point out to any with whom he comes in contact that those petition forms should now be sent in to the Automobile Association, whether they have a few only or the full number of sixty signatures which each may carry. No form need be signed by a motorist. All that is needed is that the signatures should come from members of the public.

The price of fuel in America has risen. It is almost inevitable that there should be a corresponding rise in this country. Matters are likely to go worse before they become better. But in the measure in which they grow worse we are more assured of coming, and that at an earlier interval, to a more favourable state of affairs. The position at present is frankly impossible. The various nations are bidding against one another for the insufficient supplies of motor fuel in relation to the total demand.

THE ONLY WAY.

Unfortunately the motor fuel proposition is inextricably bound up with many others. It is not a case of one trust monopolizing the whole world. Instead there are many big rival corporations. Shortage of supplies in relation to world demand is the lever that raises the price. Further, the demand for motor fuel in America is advancing enormously because the motor vehicle industry there has not suffered any interruption of output and the agricultural motor, the use of which is rapidly extending, is making additional demands, so that the total world production of oil could be absorbed in the United States of America alone. Consequently it is impossible for our Government, or any other in Europe, to take up a dictatorial attitude. All that would happen as a result of that would be that the British market would be neglected and supplies sent elsewhere. So serious is the position that it is not altogether unlikely that, before the year is out, we may be rationed for motor fuel in this country just as we were during the war.

Of this the Government is better aware than the general public. It is concerned, of course, with oil as such, because we are a maritime people. The future power for ships must be furnished by oil fuel, not used in the liquid fuel internal combustion engine as far as the majority of ocean-going vessels is concerned, but by the burning of crude oil for the raising of steam. Some motorists vainly imagine that the more this market develops, the greater will be the prejudice wrought to, and the shortage of supplies for, passenger cars and utility motor vehicles. Than that nothing could be more wildly absurd. The first thing for the Government is to do everything to stimulate all the wells in the country being exploited as promptly as possible, and at the same time to bring into use all the possible oil wells in the British Empire, and after that to get as many as possible in foreign countries under British control.

The only way to do that is to encourage private enterprise of every sort and not grudge those who embark on it any profits they reap, because, provided the profits look big enough, they will go ahead in ever-increasing numbers, and the net result will be that, presently, supply will overtake demand, then commercial competition between them will cause the price to fall. This is the only possible way.

Further, by looking at the matter in a broad way, and discussing oil rather than petrol, the greatest amount of progress will be made; because we must find a market for the residuary products of the crude oil, otherwise petrol can be produced only at utterly uncommercial prices. It is a fact that petrol sold in this country to-day yields practically no profit. That is why there is a likelihood of the price rising very shortly. This, of course, does not mean that the big petrol vending companies are not making enormous profits, but they are made out of selling their motor spirit outside this country. Shipping, distribution and kindred costs are so high that the profits are relatively negligible at present prices, for it must be kept in mind that prices are varying every week, and, unfortunately, all the variations that have taken place this year have been in an upward direction.

THE DANGERS OF ADVOCATING MONOPOLIES FOR MOTORISTS.

In face of the need to encourage, not to discourage, the development of oil fields, and the fact that it is quite impossible to talk about benzol being made available in sufficient quantities in this country, since the amount of coal raised must be increased by 50 per cent. if it is to suffice for the needs of our industries alone, far less for the needs of warming our houses and for our export trade, it is idle to suppose that any miracle can be performed that will give us all the benzol we need. The Government has in mind the development of the benzol industry and hopes also that presently alcohol fuel will become available in sufficient quantities.

The point is that motorists should never cease organizing, agitating, and, above all, educating the public by conversation at every possible turn concerning the importance to itself of sufficient liquid fuel supplies of all sorts. That is one reason why we ought to use the broad term "oil." Not only does oil make for greater economy; it is, besides, something that the public can appreciate as driving the ships to bring their foodstuffs and raw materials into this country and take exports away from it. Link that problem up in the public mind with road transport for personal convenience and the cheaper marketing of foodstuffs, and the public will begin to understand the importance of the oil era to the community at large. To argue, as some do, that utility motor vehicles should not be allowed to use either benzol or petrol is the most harmful thing that could be done for motoring in a democratic country and age. We shall never succeed by urging a monopoly for car users.

Our present sorry case should stimulate the evolution of very much lighter motor vehicles to ensure less consumption. Be that as may be, the point is that the situation is so grave that the Government dare not neglect it any longer. A result will be that, if enterprise continues to be accelerated at the rate to which it is being forced now, it is likely that in three years we shall arrive at a satisfactory situation. On the other hand, were there any slacking in the present, or any inclination on the part of the public not to force the Government's hand in the matter, unquestionably we should have to start three years hence and then probably it would take six years to put the situation right.

From all this it will be understood that the coming basis of the taxation of motor vehicles, which will be announced in the Budget, cannot possibly be, as would be ideal, by process of the fuel tax. The problem is too fraught with difficulties from the point of view of the Government—which is concerned, not with taxing fuel, but with getting sufficient fuel first, and then of getting it sufficiently cheaply—for it to be possible to raise revenue in that way, in face of the differentiation for home produced fuel, and of the difficulties of defining motor fuel for taxation purposes.

The sole tax on motoring of the passenger sort will probably be on the engine; though the method of rating may be different from that at present adopted by the Treasury. Whatever the method, engine rating is the least satisfactory way. It cannot be pretended that it bears any relation to the use of his motor vehicle enjoyed by the individual taxpayer. Further, it predetermines design and utterly fails to give any encouragement to the development of chassis construction or bodywork. Infinitely the better course would have been to tax vehicle

weight, as is proposed in regard to utility motor vehicles. That would encourage more economical motoring, lighter motor vehicles, and would not prejudice the method of design in any way.

FOREIGN MINERAL WATER RESORTS.

THE fact that we are now enjoying the blessings of peace—if indeed it be a fact—is turning the thoughts of the British, who are inveterate wanderers, towards the possibility of visiting foreign countries. Among these are a certain number of persons who wish to combine a holiday with spa treatment. We have recently received two communications, one from Dr. D. W. Samways, of Mentone, about Brides-les-Bains—sometimes called the French Carlsbad—and the other from Dr. T. Gerald Garry, of Cairo, about Pistany, called before its incorporation in the Czecho-Slovak Republic "Pöstyén."

BRIDES-LES-BAINS.

Brides-les-Bains, in Savoy, lies at an elevation of 1,800 ft., amidst, as Dr. Samways says, magnificent mountain scenery. Brides-Salins is two miles away. At Brides-les-Bains, where most visitors reside, the daily yield is about 100,000 gallons of water at 95° F. It is closely analogous to the Sprudel source at Carlsbad, there being about the same total mineralization, very similar constituents, and the same quantity of free carbonic acid gas. The output of medicinal water at Brides-Salins is very abundant—about one and a half million gallons daily. The temperature is 96° to 97° F. The principal source at Nauheim (the Frederic Wilhelm) has the same temperature, and, except that it is somewhat stronger, essentially the same composition as that at Salins, though as weaker waters are commonly employed in the earlier stages of treatment, the Salins waters are suitable for these stages, and, by concentration, for the later stages also. The concentration of carbonic acid gas at Nauheim is about half as much again as at Salins, but the superabundance of water at Salins is a great asset, and the private as well as the swimming baths are commonly taken in running water. Dr. Samways continues:

Persons suffering from disorders affecting the abdominal organs, liver, stomach, intestines, or kidneys, will generally profit considerably by a course of waters at Brides. Gout, diabetes, and obesity are likewise treated. The waters at Salins are suitable for young people with enlarged glands, anaemia, chlorosis, and debility, and great numbers of French children are sent there, as also are convalescents generally. Cardiac cases are treated as at Nauheim. Women suffering from disorders peculiar to their sex were specially recommended to visit Brides by Professor Buchanan of Glasgow, who was much impressed by the value of the waters for these cases (*Glasgow Medical Journal*, December, 1889).

It is many years since I practised at this wonderful little spa, but I have never seen in England or in France any spa which can compare with it for range of possibilities or inherent merit. It has, moreover, the additional advantage of being situated in the middle of one of the most beautiful districts in France.

Brides-les-Bains is reached by passing through Aix-les-Bains to the terminus of Montiers, sixty miles beyond Aix and three miles from Brides. The best and usual season for English visitors is from the middle of May till the middle of July, after which it is almost impossible to find accommodation, while for English visitors it is too hot.

PISTANY.

Dr. Garry writes in praise of the therapeutic properties of the thermal water and mud available at Pistany in Czecho-Slovakia. They were praised in this JOURNAL as long ago as 1888 by the late Sir T. Spencer Wells, who spoke of the benefit derived by patients crippled through gout or rheumatism and by chronic discases of the joint. Inveterate cases of sciatica, he said, had been cured, and also chronic periostitis and catarrhs of certain internal organs. Sir Spencer Wells added that "after the [then] last war a great many men who had suffered from simple and compound fractures of bones, or chronic exudations after other injuries, or neuralgia after amputation or resections, recovered rapidly at" Pistany. Dr. Garry suggests that at the present time, when so many are crippled or suffer intractable pain of a rheumatic or neuralgic character due to hardship or exposure in the recent war, the experiences of so eminent an authority at Pistany cannot be too widely circulated. Both the

water and the mud have a natural temperature of 140° F., and both, but especially the mud, possess a high degree of radio-activity, the mud retaining this property while in use.

The "cure" consists in drinking the water and taking baths: (a) the basin bath of pure mineral water (mirror bath); (b) the basin bath with natural mud residuum; (c) private baths of pure mineral water; (d) private mud baths; (e) localized mud baths and poultices.

The treatment, Dr. Garry says, is efficacious in the following conditions:

In inveterate cases of arthritis (often completely cured), chronic gout and rheumatism accompanied by pain, stiffness or thickening in the muscles and joints, after injuries to bones, tendons, or the joints, especially in the painful conditions so frequently noticed as a result of defective or imperfect union of fractures, chronic sciatica, lumbago, neuralgia, and neuritis.

Chronic pelvic troubles are relieved, also the painful conditions following appendicitis or peritonitis.

Pistany has obtained a reputation in the treatment of chronic spinal affections; the cases, however, which are speedily and permanently cured are that large class comprised under the various forms of paralysis of functional origin, generally associated with peripheral neuritis, and due either to toxæmia after infectious fevers, or to gout, alcohol, or metallic poisoning.

Many cutaneous affections are greatly benefited. Obesity is also favourably influenced as well as the trophic disturbances associated with varicose veins. A British physician practises at Pistany during the summer months, and at the present time living for English-speaking people, owing to the rates of exchange, is very cheap and food is plentiful and good.

Pistany is three hours from Vienna, three and a half from Budapest, and one from Pressburg. The surrounding country is beautiful and of historical interest. Hale persons accompanying invalids will find facilities for fishing, boating, golf, and tennis. Persons who may think of trying Pistany this year will be well advised to obtain reliable recent information about the journey.

HONOURS.

A SPECIAL Supplement to the *London Gazette*, dated March 30th, contains the following promotions in and appointments to the civil division of the Order of the British Empire for services in connexion with the war:

M.B.E.

Tom Bland Abbott, L.S.A., Medical Services, Lotherford Hall Auxiliary Hospital, Aberford, West Yorkshire. George Reinhart Anderson, F.R.C.S., L.R.C.P., Surgeon, Southport Infirmary. James Edwin Anderton, M.R.C.S., L.R.C.P., Medical Officer, New Mills Auxiliary Hospital, Derbyshire. Bennett Harvey Andrew, M.D., Medical Officer, Thame Auxiliary Hospital, Oxfordshire. Henry Edward Annett, M.D., Medical Officer, Joint Committee Hospital, The Vicarage, Runcorn, Cheshire. Frederic Fairburn Armytage, L.R.C.P., L.R.C.S., Medical Officer, Askam Grange, Clifford Street and Nuntorpe Hall Auxiliary Hospitals, Yorkshire. John Parkinson Atkinson, M.R.C.S., L.R.C.P., Senior Medical Officer, Walden Place Hospital, Saffron Walden.

Edwin Baily, M.D., Medical Services, British Red Cross Convalescent Home for Officers, Hotel Califormie, Cannes. Lieut.-Colonel Frederick Rowland Barker, M.B., Secretary, Worthing Branch, British Red Cross Society. Ernest James G. Berkly, F.R.C.S., Divisional Inspector, Southwark, British Red Cross Society; Medical Officer, Divisional Hospital. William Henry Bishop, M.B., B.S., Medical Officer, 14th Northumberland V.A.D. Hospital, Holey Hall, Wylam-on-Tyne. Richard Oxley Bowman, M.D., Medical Officer in charge, Fairview Auxiliary Hospital, Ulverston. Frederick Augustus L'Estrange Burges, M.R.C.S., L.R.C.P., Member of Medical War Committee, Sheffield, Ministry of National Service. Ernest Joseph Burnett, M.B., Commandant and Medical Officer of Skelton Red Cross Auxiliary Hospital. Henry Ambrose Burrows, M.D., J.P., Medical Officer and Officer in charge, Lynn Auxiliary Hospital, Cheshire. Henry Branson Butler, F.R.C.S., Surgeon, Auxiliary Hospitals, Guildford.

William Edmund Cant, M.D., F.R.C.S., Medical Officer, Woodhouse and Great Horkesley and Gostwycke Auxiliary Hospitals, Colchester. Arthur Ernest Clarke, M.D., Medical Officer, St. Augustine's Hospital, Rickmansworth, Hertfordshire. George Cran, M.D., V.D., J.P., County Director, Kincardine Branch, British Red Cross Society; Medical Officer, Weal Auxiliary Hospital.

James Henry C. Dalton, M.D., J.P., Member of Cambridge Borough Local War Pensions Committee. George Day, F.R.C.S., Medical Officer to H.M. Cylindar Dépôt, Bucknall, Ministry of Munitions. William Thomas Dempster, M.R.C.S., L.R.C.P., Commandant and Honorary Medical Officer, South Croydon Red Cross Hospital. Major Herbert Crowley Dent, Medical Officer, V.A.D. Hospital, Colne House, Cromer. John Henry Dewhurst, M.D., M.R.C.S., Medical Officer, Norton Hall Auxiliary Hospital, Gloucestershire. Alexander Dey, M.B.,

C.M., Medical Officer, 12th Northumberland V.A.D. Hospital, Fowberry Helton, and 15th Northumberland V.A.D. Hospital, Etal Manor, Cornhill-on-Tweed. Eustace James Carey Dicks, M.D., B.S., Medical Officer, Eastor Park Hospital, Suffolk. Herbert Dobie, M.D., Principal Medical Officer, Eaton Hall Auxiliary Hospital; Medical Officer, Oakfields Auxiliary Hospital, Upton, Cheshire. Herbert Leopold Dowsing, M.R.C.S., L.R.C.P., Medical Services, St. John Voluntary Aid Hospital, Hull. Thomas Lambert Drapes, M.B., B.C., Medical Officer, Portskewett and Gwy House Auxiliary Hospital, Chepstow, Monmouthshire. Motherwell Duggan, M.R.C.S., L.R.C.P., Medical Officer, Rayner Croft and Haigh Lawn Auxiliary Hospitals, Bowdon, Cheshire, and John Leigh Officers' Hospital, Altrincham. Robert Harold W. Dunderdale, M.R.C.S., L.R.C.P., Medical Officer, Blackpool Hospital, and Secretary to Medical Board, William James Durauf, M.D., Medical Officer, United Alkali Company, Limited. John Richard Haigh Dyson, L.R.C.P., L.R.C.S., Medical Officer, Honley Auxiliary Hospital, Huddersfield.

Flavell Edmunds, M.R.C.S., L.R.C.P., Medical Officer, Chesterfield Auxiliary Hospital, Derbyshire. Bogdan Edward J. Edwards, M.B., C.M., Commandant and Medical Officer, Boothroyde Auxiliary Hospital, Brighouse, West Yorkshire. Roger Bellis Edwards, M.B., B.S., Medical Officer, Leeswood Hall Auxiliary Hospital, Mold, Flintshire. Arthur Campbell Elliott, M.B., C.M., Medical Officer in Charge, Chaseside Auxiliary Hospital, St. Anne's-on-Sea. Harry Loft Evans, M.R.C.S., L.R.C.P., Member of Hull Medical War Committee, Ministry of National Service. William Owen Evans, L.R.C.P., L.R.C.S., Voluntary Medical Services to sailors and soldiers and their dependants in the Swansea Valley.

Frank Fawcett, M.B., B.S., Medical Officer, East Chilton Hospital and St. Ann's Auxiliary Hospital, Lewes, Sussex. Edgar Hall Felton, M.R.C.S., L.R.C.P., Medical Officer, Cleethorpes Auxiliary Hospital, Lincolnshire. Bernard Gilpin Forman, M.B., Ch.B., Commandant and Medical Officer, Cober Hill Hospital, Scarborough. Alfred Wightman Forrest, M.B., C.M., Member of Sheffield Medical War Committee, Ministry of National Service. Miss Sarah Louise Fraser, M.D., B.S., Medical Officer, Nunthorpe Hall Auxiliary Hospital, York.

Henry Willoughby Gardiner, M.D., F.R.C.P., Medical Services, Quarry Place Auxiliary Hospital, Shrewsbury. Thomas Gerald Garry, M.D., Cairo Representative, St. John Ambulance Association. Captain James Albert Gibson, M.D., Medical Officer, Galcombe Auxiliary Hospital, Isle of Wight. John Cecil M. Given, M.D., Medical Officer, Holt Auxiliary Medical Hospital. Hope Wilkes Gosse, M.R.C.S., L.R.C.P., Medical Officer, Eccleshall Auxiliary Hospital, Staffordshire. Lieut.-Colonel Robert Balfour Graham, V.D., F.R.C.S., J.P., County Director, Pifeshire Branch, British Red Cross Society. George Gunn, M.D., F.R.C.S., Medical Officer, Parkgate Auxiliary Hospital, Cheshire.

Edward Marrack Hainworth, F.R.C.S., Medical Services, St. John V.A.D. Hospital, Hull. John Halliwell, M.R.C.S., L.R.C.P., Medical Officer, Winchcombe Auxiliary Hospital, Gloucestershire. Andrew Harris, F.R.C.S., L.R.C.P., Medical Officer, Red Cross Hospital, Keyford, Frome. Louis Brightwell Hayne, M.D., Medical Officer, Grove House Hospital, Harrogate. John Edridge Healey, M.B., Ch.B., Medical Officer, Moor Park Auxiliary Hospital, Preston. Captain George Brown Hillman, Medical Officer, Ledston Hall Auxiliary Hospital, Castelford, Yorkshire. Arthur Henry William Hunt, L.R.C.P., M.R.C.S., Medical Officer, Tettenhall Auxiliary Hospital, Staffordshire.

Joe Iredale, L.R.C.P., M.R.C.S., Medical Officer, Mablethorpe Auxiliary Hospital, Lincolnshire.

Daniel Noel Jackson, M.B., B.S., Medical Officer, 4th Northumberland V.A.D. Hospital, Dilston Hall, Corbridge-on-Tyne. Edward Siddall Jackson, M.D., C.M., Consulting Surgeon, Wray House Auxiliary Hospital, Wray, and Medical Officer, Bleasdale Auxiliary Hospital, Silverdale, Carnforth. Charles Saint Johnston, M.R.C.S., Medical Officer, Gloucester Red Cross Auxiliary Hospital. John Jones, L.R.C.P., D.L., J.P., Chairman, Dolgelly Subarea War Pensions Committee; Member, North Wales (Joint) Disablement Committee. Owen Thomas Jones, L.R.C.P., M.R.C.S., Medical Officer, Barry Dock Hospital, Glamorganshire.

Charles Scott Kilner, M.B., C.M., J.P., Medical Officer, West Suffolk General Hospital and Red Cross Hospital, Northgate Street, Bury St. Edmunds. Thomas Ramsay King-Edwards, M.D., Medical Officer, Swycombe House Auxiliary Hospital, Oxfordshire.

Major Frederic Charles Langford, M.D., M.R.C.S., Divisional Inspector, Cumberwell Division, British Red Cross Society. George Johnson Langley, M.D., Medical Officer, Loversal Hall Auxiliary Hospital, Doncaster. Alexander Ledingham, M.D., County Director, Banffshire Branch, British Red Cross Society. Lieut.-Colonel John Daniel Lloyd, T.D., L.R.C.P., M.R.C.S., J.P., Medical Officer, Brynkinnat Auxiliary Hospital, Chirk.

William Neil Macall, M.D., C.M., Secretary and Medical Officer, Meols Hall Auxiliary Hospital, Churchtown, Southport. John Macdonald, M.B., C.M., J.P., Acting County Director, Pifeshire Branch, British Red Cross Society. Duncan McFadyen, M.B., J.P., County Director, Inverness-shire Branch, British Red Cross Society. Kenneth Child Mackenzie, M.D., Medical Officer, Red Cross Hospital, Caerphilly, Glamorganshire. Harold Hay Brodie MacLeod, F.R.C.S., L.R.C.P., medical services, Quarry Place Auxiliary Hospital, Shrewsbury. Henry Carter Mactier, M.B., B.Ch., Member of Wolver-

hampton Medical Board, Ministry of National Service. John Ogden March, M.R.C.S., L.R.C.P., Medical Officer, Bulford Manor Hospital, Wiltshire. Herbert Harrison Marsden, M.R.C.S., L.R.C.P., Surgeon, The Cottage Hospital, Ormskirk, Lancashire. William Martin, M.B., Ch.B., J.P., Honorary Medical Superintendent, King's Road Convalescent Hospital and Railway Rest Home, Whitehead, co. Antrim. John Wright Mason, M.B., C.M., Medical Officer of Health, Hull. Walter Byron Maurice, M.R.C.S., L.R.C.P., J.P., Medical Officer, Marlborough Auxiliary Hospital, Wiltshire. Robert Mitchell, M.D., C.M., Medical Officer, Hooton Pagnell Hall Auxiliary Hospital, Doncaster. Alexander Patrick Mooney, M.D., J.P., Surgeon, St. Joseph's Auxiliary Hospital, Mount Street, Preston, Lancashire. James Murphy, F.R.C.S., Assistant County Director, Middlewich Division, Cheshire Branch, British Red Cross Society; Medical Officer, Middlewich Auxiliary Hospital and Annexe.

Arthur Edward Normington, M.B., Ch.B., Honorary Medical Officer, Reedyford Hospital, Nelson, East Lancashire.

Hugh Falconer Oldham, M.D., B.Ch., J.P., Founder and Medical Officer, St. John Auxiliary Hospital, Morecambe. John Orford, M.R.C.S., L.R.C.P., Medical Officer, Stapleford and Swillington Auxiliary Hospitals, Yorkshire. Mrs. Marie Orme, L.R.C.P., Commandant, Voluntary Aid Detachment No. 22, Derbyshire. William Fletcher Oyston, M.B., Ch.B., Medical Officer, Flounder's College Auxiliary Hospital, Ackworth, Pontefract, West Riding.

Charles O'Connor Parsons, L.R.C.P., L.R.C.S., Joint Honorary Medical Officer, Dore Auxiliary Hospital, Sheffield. John Edward Hocking Parsons, M.R.C.S., L.R.C.P., Medical Officer, Chipping Norton Auxiliary Hospital, Oxfordshire. Wallace Petherick, M.R.C.S., L.R.C.P., Medical Officer, V.A.D. Hospital, Garboldisham, Thetford, Norfolk. Joseph Henry Philpot, M.D., M.R.C.P., voluntary services in connexion with war refugees. Cecil Westland Pilcher, M.R.C.S., L.R.C.P., Medical Officer, Holden House Red Cross Hospital, Boston, Lincolnshire. James Damer Priest, M.R.C.S., Medical Officer, Royal Gunpowder Factory, Ministry of Munitions. John Skardon Prowse, M.B., B.C., Medical Officer, Basford House Auxiliary Hospital, Old Trafford.

Reginald Maurice Henry Randell, M.D., M.R.C.S., Medical Officer, Balgowan, V.A.D. Hospital, Beckenham.

Frank Reginald Sawdon, M.B., Commandant and Medical Officer, Auxiliary Hospital, Buxton, Derby. Leonard Edmund Scanlon, M.R.C.S., L.R.C.P., Medical Officer, Willow Bank Hospital, Manchester. George Edward Scholefield, M.D., C.M., Founder and Medical Officer, Aughton Auxiliary Hospital, Lancashire. Frank Scorer, M.R.C.S., L.R.C.P., Medical Officer, Crag Head Hospital, Bournemouth. Alexander Thomas Scott, M.R.C.S., J.S.A., Assistant Commander, Metropolitan Special Constabulary. Thomas James Selby, M.B., Senior Medical Officer, Auxiliary Hospital, Prodsham, Cheshire. Richard Holgate Shaw, M.R.C.S., L.R.C.P., Medical Officer, Auxiliary Military Hospital, Hamstead Garden Suburb. Thomas Frank Southam, M.D., Medical Officer, Cecil Road Auxiliary Hospital, Hale, Cheshire. Duncan Stewart, V.D., L.R.C.P., L.R.C.S., Medical Officer, Hexham V.A.D. Hospital, Northumberland. Walter Grahame Stewart, M.B., B.S., Medical Officer and Commandant, Priory Auxiliary Hospital, Ware. Robert Day Stokes, L.R.C.P., L.R.C.S., Commandant, Sidmouth Auxiliary Hospital, Devon. Charles Henry Sykes, M.R.C.S., L.R.C.P., medical services, Lotherton Hall Auxiliary Hospital, Aberford, Leeds.

William Henry Thorman, M.R.C.S., L.R.C.P., Medical Officer, Kirkburton Auxiliary Hospital, Huddersfield. Charles Augustus Thorne, L.R.C.S., L.R.C.P., J.P., Joint Honorary Medical Officer, Dore Auxiliary Hospital, Sheffield. Edward Tonge, M.B., B.S., Commandant and Medical Officer, Scaton Auxiliary Hospital, Devon.

Alfred Bertram Vine, M.B., Medical Officer, Timberburst Hospital, Bury.

Edward Walker, M.D., Member of Huddersfield Medical War Committee, Ministry of National Service. Reginald Field Walker, M.R.C.S., L.R.C.P., Medical Officer, Esher Auxiliary Hospitals, Surrey. John Thompson Wallace, M.B., Member of Bristol Medical War Committee, Ministry of National Service. Ernest Ward, M.R.C.S., L.R.C.P., Medical Officer, Ridglands, Church House, Popeswood and Buckhurst Auxiliary Hospitals, Berkshire. Howard Percy Ward, M.B., M.R.C.S., Medical Officer, Highfield Hall Auxiliary Hospital, Southampton. Arthur Muriel Watkins, M.R.C.S., L.R.C.P., Medical Officer, Broughall Cottage Hospital, Whitechurch, Shropshire. Edwin St. John Whitehouse, M.R.C.S., L.R.C.P., Medical Officer, "Hermitage" Auxiliary Hospital, Solihull, Warwickshire. Edward Richard Williams, M.R.C.S., L.R.C.P., Medical Officer, Carnarthen Auxiliary Hospital. Richard Williams, M.R.C.S., L.R.C.P., Medical Officer, Rosneath Auxiliary Hospital, Wrexham. Henry Chadwick Woodcock, M.R.C.S., L.R.C.P., Organizer of Red Cross work and Lecturer on First Aid in Enfield. Herbert Miall Woodhead, M.B., C.M., Medical Officer, Auxiliary Hospitals, Ingestre, Staffordshire, and Ashtou-ou-Mersey and Linden Lea, Cheshire.

FOREIGN DECORATION.

Honorary Colonel Sir Alexander Ogston, K.C.V.O., LL.D., R.A.M.C.(T.F.), has been appointed a Cavalier of the Order of the Crown of Italy for distinguished services rendered during the campaign.

British Medical Journal.

SATURDAY, APRIL 17TH, 1920.

THE MECHANISM OF SYMPTOMS.

OF the various methods now employed to advance the science and art of medicine—the purely clinical, the laboratory, the combination of these two as practised in the recently established whole-time hospital units, and the epidemiological—the first is the oldest; it is also the most difficult to carry out with success, though this has only recently been suggested, and is, perhaps, not yet generally recognized. It is not easy to realize that our familiar means of dealing with a patient's complaints can be so improved and organized as to yield advances equal to, perhaps even more important than, those now regarded as the natural fruits of the clinical laboratory. But by a process of somewhat relentless logic, embodied in repeated papers, Sir James Mackenzie has awakened in us a feeling of uneasiness as to the character and efficacy of the clinical methods in ordinary hospital practice. He is, however, far from being a merely destructive critic, as is proved by his energy in establishing the St. Andrews Clinical Institute, where his methods of clinical research, carefully thought out through many years of general and consulting practice, are now in active use.

The failure in the past to obtain results commensurate with the labour devoted to the clinical investigation of symptoms is explained by Sir James as fundamental and due to the absence of sound general principles, especially of a proper conception of the mechanism of production and significance of symptoms. Such principles can only be evolved, like "the holy spirit of man," to quote from *Atalanta in Calydon*, "with travail and heavy sorrow," and in his study in symptomatology, the publication of which is concluded this week, Sir James Mackenzie emphasizes the need for a thorough educational training, and refers rather pathetically to the wasted labour of years due to the want of essential guiding principles.

Although only recently opened the St. Andrews Institute for Clinical Research is the outcome of long and careful investigation by its director, who set forth its objects in our issue of January 24th last, and now follows this up with a philosophical conception of the basis of symptoms. The effort to grasp the full significance of this thesis is not free from difficulty, for it demands not only the exercise of clear thinking, but freedom from the bias, often quite unconscious, engendered by the training and custom of a professional lifetime. In this welcome instalment of his teaching he shows that each organ when strained or exhausted produces symptoms peculiar to itself, and this is illustrated towards the end of the article by the phenomena of "the soldier's heart" and of the war neuroses. The detailed study of the reflex symptoms due to a reaction in the central nervous system or in the nervous mechanism of the organs leads on to a consideration of a somewhat neglected feature of the nervous system when under the influence of disease or other agencies—namely, its lowered resistance to stimulation. This is an all-important factor in the production of symptoms which, though referred to one

or more organs, owe their appearance not so much to the local visceral condition as to a lowered threshold of the nervous system to stimuli. In various infections the general health is impaired and the organs then submitted to strain are shown by the resulting symptoms, but the underlying cause which, for successful treatment, must be combated and removed is not in these organs but in the infection.

THE LEAGUE OF RED CROSS SOCIETIES.

THE meeting of the first General Council of the League of Red Cross Societies at Geneva from March 2nd to March 8th, 1920, was briefly mentioned in our issue of March 13th. The complete proceedings of the general sessions and of the meetings of the various sections will be published in English and French during the course of the summer; but in the meanwhile the current number of the *Bulletin* of the League gives a running account of the business transacted during the week of congress and prints several of the addresses and speeches delivered at the full sessions, together with the reports presented by Sir David Henderson, Director-General of the League, and Dr. Richard P. Strong, the General Medical Director.

Twenty-seven of the thirty Red Cross Societies comprising the League were represented at the congress; delegates were sent also by the League of Nations and the International Red Cross Committee. After the opening session the council broke up into two parts—the section of organization and the medical section—which each met twice daily to ensure rapid progress in fulfilling the objects set forth in the programme. The medical section discussed the reports submitted by the various branches of the medical department of the League, and the projects brought forward by members of the General Council. The subjects included child welfare, tuberculosis, communicable diseases, nursing, medical information, sanitation, vital statistics, social hygiene, malaria, and public health laboratories. The reports relating to medical topics have been prepared in English and French, and printed copies may be had on application to the head quarters of the League at Geneva. The section of organization discussed the various phases of national Red Cross organization and peace-time activity, as outlined in a report by Mr. Frank Persons, which also may be obtained from the League.

The conclusions of the two sections were summed up in a series of resolutions, which were put into shape by a joint medical and legal committee and adopted by the Council in plenary session. The resolutions relating to medical matters will not be published until they have been discussed by the Advisory Medical Council referred to below, and by the Board of Governors, but the Director-General's report described the progress made in setting up special departments within the medical office of the League. It was thought advisable to confine the work of this department at the outset to the preparation of reports which would define the programme proposed by the League in a form suitable for discussion by the General Council. Beyond this preparations are being made for continuous communication on medical subjects with the Red Cross Societies in three different ways: The first is by means of a technical medical journal in which will appear articles of scientific medical interest on subjects in which the League is interested. "It is hoped to sustain this journal on a high level in order

that the Medical Office of the League may be reckoned as a high medical authority and its directors as experts, and also that the journal may be a medium through which recognized medical authority outside the League may be glad to make known their views and discoveries." Secondly, the *Bulletin* of the League will issue articles on medical or welfare subjects suited to popular reading. Thirdly, special articles will be distributed on subjects whose importance or urgency calls for immediate publication as separate pamphlets.

With regard to relief measures in Eastern Europe, it is said that the operations in Czecho-Slovakia are of the nature of general relief and present no serious administrative difficulties. In Poland, however, the problem is much more complicated and relief work is seriously hampered by the lack of preliminary necessities—food, fuel, clothing and transport. The provision of these on an adequate scale is beyond the resources of the voluntary societies. Further Government assistance is held to be necessary if the danger of an extension of the typhus epidemic is to be averted.

The Medical Director in his report sketched the organization of the medical department at headquarters for the improvement of public health and the prevention of disease. The planning of this department has largely followed the suggestions put forward at the medical conference at Cannes twelve months ago, which was attended by leading scientific authorities from England, France, the United States, Italy and Japan. The work has been split up into a number of divisions under the co-ordinating control of Dr. Strong, but the establishment of a Hygienic Laboratory and Museum has been deferred until its aims, functions, and equipment have been formulated. This is a matter obviously needing careful study before action is taken.

It has been decided that the International Medical Advisory Board shall be limited to fifteen members, not more than three representing any one country. The members will be kept in touch with the health work undertaken by the League by correspondence, and they in turn will be asked to keep the Medical Director informed of the progress of health work in their representative countries and of any important developments in the field of public health, or of any unusual opportunity for service which the League might render. It is proposed that the Medical Advisory Board shall meet at Geneva once a year, and at other times of emergency on the call of the Director-General or the Board of Governors. The first meeting will probably be held at the beginning of June next. Colonel S. Lyle Cummins, C.B., C.M.G., Professor of Pathology at the Royal Army Medical College, Sir Walter Fletcher, K.B.E., Secretary of the Medical Research Council, and Sir George Newman, K.C.B., Chief Medical Officer, Ministry of Health, have been asked to represent Great Britain on the Board.

It is worthy of note that the medical department regards the encouragement of scientific investigations in hygiene and sanitary science as a function proper to the League of Red Cross Societies, "since progress in the domain of public health depends upon the advancement of knowledge and the application of new principles." It does not, however, recommend that the League should forthwith organize an extensive laboratory force and set up a large laboratory of its own exclusively for research purposes. What the policy of the League should be in relation to research in public health and preventive medicine is submitted in the following words: "Its attitude in general should be to organize and to encourage and stimulate research

work in preventive medicine and hygiene in connexion with those excellent scientific institutions already established in different countries, and also to attempt to co-ordinate national efforts in research, particularly with the idea of obtaining more uniform and correct results in medical investigations regarding which different and conflicting results have been obtained by different workers or different groups of workers in various countries. It should also, where original investigations appear advisable and of an urgent character, appoint from time to time special commissions for such researches to be prosecuted either in permanent laboratories or in the field."

VOLVULUS OF THE STOMACH.

ACCORDING to Tuffier and Jeanne,¹ a volvulus of the stomach is "an error of position of this organ consisting essentially in torsion around an axis the situation and direction of which is a little variable, but usually extends from the cardia to the pylorus." This little known condition may be complete or partial; in the latter case the pars pylorica is involved. The direction of the torsion is almost invariably from below upwards and from behind forwards. Such a movement is normal during the filling of the stomach, and volvulus is merely a gross exaggeration of what is in its inception a physiological process.

It follows from this that any condition which leads to obstruction and overfilling of the viscus is, *ipso facto*, a predisposing factor in the production of volvulus. When this accident overtakes a diseased stomach the volvulus is usually described as "complicated." But it may occur when the organ is apparently perfectly healthy, and in these circumstances Continental writers refer to the condition as "simple or idiopathic volvulus." We say "Continental writers" advisedly as the vast majority of British authors make no reference to the condition at all. In this idiopathic variety there is invariably a considerable degree of gastroptosis, a long gastro-hepatic omentum and a freely mobile stomach being essential. This is further helped by the relative approximation of cardia to pylorus which this ptosis often entails.

Niosi² of Pisa, in a long and reasoned contribution to this subject, adds two more cases to those which he recorded some years ago. The first was of the idiopathic type, and here the stomach of a woman, 41 years old, had twisted through 400 degrees. There was a long-standing history of dyspepsia, with attacks of pain in the left hypochondrium and a feeling of epigastric fullness, culminating in a severe attack, with vomiting of small quantities of fluid and a tense swelling beneath the left costal margin. Gastropexy and gastro-enterostomy were performed and the patient recovered. The stomach was not diseased. It is of interest to note that the early attacks of pain had led to a mistaken diagnosis of movable kidney and a belt had been provided. In the second case a woman of 42 years was seized with a violent epigastric pain and vomiting; a tense tympanitic swelling in the upper abdomen presented a great contrast to the flat, supple, lower abdomen. Niosi diagnosed a volvulus of the stomach and was fortunate in being able to pass a stomach tube and so tided her over the emergency. There was no recurrence of the acute stage, and x rays later showed an hour-glass stomach. Operation was eventually performed and all that remained of the

¹ *Maladies de l'estomac et de l'oesophage*. Mathieu, Souciet, Tuffier. Paris, 1913.

² F. Niosi, Nuovo Contributo alla Conoscenza del Volvolo dello Stomaco, *Archiv. Ital. di Chir.*, 1919, 1, 275.

volvulus was a partial twist of the pyloric sac. Gastro-gastrostomy and gastro-enterostomy were carried out. Many cases of partial volvulus in hour-glass stomach are now on record.³

Niosi has a full discussion of the symptomatology and differential diagnosis of the condition. The most important signs are continued vomiting of very small quantities of fluid or retching only, with a resonant tense swelling in the left epigastrium, difficulty in passing the stomach tube, displacement of the heart to the left (inconstant), a subjective dragging sensation in the cervical portion of the oesophagus due to the traction of the twisted stomach, and cardiac distress. The most difficult differentiation is from diaphragmatic hernia, which Payer⁴ regards as a frequent cause of volvulus itself. In the former condition dullness at the lung base and displacement of the heart to the right are important helps to diagnosis, whilst the upper abdominal swelling and flat, soft lower abdomen in contrast are very characteristic of volvulus. As for treatment, Niosi is in favour of gastro-enterostomy to prevent overfilling and to anchor the stomach. He thinks gastropexy, which suffices for Tullier, is not enough.

UNIVERSITY OF MANCHESTER.

THE University of Manchester has issued an appeal for £500,000 to make extensions in buildings and staff which are considered absolutely necessary. All the departments, including the new Arts building recently completed, are overflowing; in some the conditions of work are described as almost impossible, and it is stated that this presses most on students of chemistry and medicine. If justice is to be done to the students and to the great opportunities for public service they represent, it is felt that expansion of the teaching staff and equipment is absolutely necessary. It was realized early last year that the university had grown so suddenly that everything must be planned upon a larger scale; subsequent developments have made the needs still greater. In the interests of medical students a large expenditure is required for the equipment and staff in the department of physiology, which are far below the actual present requirements. Increased accommodation is also needed in other scientific departments. Manchester, it is said, possesses unsurpassed opportunities for clinical study and research, which should lead to a great development of the medical school. The number of students who can be admitted to the medical school at present is restricted by the lack of space in the science departments which prepare students during the first year of their medical course. As soon as this limitation is removed the number of students will, it is believed, very greatly increase, and the school of medicine in Manchester become one of the greatest institutions in the kingdom. Not only are entirely new buildings required for at least pharmacology and pathology, but whole-time professorships of medicine, surgery, and gynaecology should be established as soon as possible. Another need produced by the great increase of students is the provision of hostel accommodation. Something has been done for women students by purchasing and equipping two houses, but further provision is needed for hostel accommodation for men. The Students' Union and refectory also are quite inadequate for the present numbers. Finally, the athletic grounds are far too small. "A university," it is said, "without proper provision for the housing and exercise of its students is not in a healthy condition." The University of Manchester, which is the senior of the four northern universities at one time grouped

together, has achieved a great reputation and set a high standard in teaching and research for its degrees. We do not doubt that an immediate response will be made to the appeal, which is signed by the Chancellor (Lord Morley), by the chairman, vice-chancellor, and treasurer. Communications may be addressed to the organizing secretary, Mr. George A. Marriott, at the university.

THE FUTURE OF DENTISTS' REGISTRATION.

THE Departmental Committee appointed to "inquire into the extent and gravity of the evils of dental practice by persons not qualified under the Dentists Act" presented a comprehensive report¹ in February, 1919. While the importance of making skilled dental treatment available for all needing it was insisted on, the Committee recognized that the number of dentists at present registered was insufficient. *The Dentists' Register*² for 1920, which has just been issued, shows that the total number of registered dentists this year is fewer by 112 than in 1919. The total of licentiates and graduates in dentistry of universities and colleges in the United Kingdom on the *Register* this year is 4,367; there are in addition 39 registered dentists holding colonial qualifications and 21 with degrees or diplomas of foreign universities. The total on the *Register* is made up of 1,030 persons placed on the *Register* at the time of the passing of the Act, as being in bona fide practice of dentistry; of these, seven hold medical or surgical qualifications and the remainder have no qualification. The Committee was of opinion that the main causes of shortage of registered dentists were two: one was the unsatisfactory state of the law, which allows the practice of dentistry by unregistered persons not qualified by a prescribed course of instruction, training, and examination; the other was the length and great expense of the minimum course of instruction and training for dental students. *The Medical and Dental Students' Register*² for 1920, which is just issued, shows that the number of dental students registered was 612, a large increase as compared with 1918, when the number was only 161. The largest number previously recorded was 361, in 1913. The Committee advised that the practice of dentistry by persons not registered should be prohibited, but that some of those who, without breaking the letter of the law, have engaged in practice without any qualification should be included in a register under certain conditions, one of which was that persons so registered should have been in practice for five years. In order to encourage students to pass through the curriculum for a registrable qualification the Committee recommended the establishment of a system of scholarships, the issue of increased grants to dental schools, and a reduction in the minimum time required to be spent by dental students in obtaining a qualification in dental surgery. It also recommended the establishment of a system of treatment for school children, for expectant mothers, and for children under five years of age, and the employment of dental dressers or assistants acting under the supervision of registered dentists in school and public dental services. The Committee considered that a new statutory board should be set up to administer any Act drafted on the lines of its report. The majority of the members of this new board would be dentists, but it would include a certain number of lay representatives, on the ground that as the Act would be passed for the public weal, the public should be represented upon any body formed for its administration. The General Medical Council will, if the proposals are carried into effect, retain a certain measure of control over the actions of the proposed statutory board.

DUBLIN RADIUM INSTITUTE.

THE annual report for 1919 of the Royal Dublin Society, which controls the Dublin Radium Institute, records the issue during the year ending October 31st, 1919, of 3,215.4 millicuries (measured by its gamma ray activity) as compared with the average issue of 4,203 millicuries during the three previous years. The emanation issued during the past year included 1,295 millicuries, supplied to two military hospitals, one at Alder Hey, Liverpool, and the other at Blackrock, co. Dublin, for the treatment of orthopaedic cases. Dr. Walter C. Stevenson gives a brief report of the treatment of 128 cases at these hospitals and of 28 civilians. With two exceptions the former group were orthopaedic cases (gunshot wounds) in whom the period of convalescence seems to have been materially abridged by the course of radium treatment. "It takes months and often years of treatment to make a limb useful where the muscles are matted together by inflammation, the joints stiff and often the nerves injured as well. Radiation aids recovery by softening scar tissue and by improving the nutrition of the part, owing to its action on the blood vessels and nerves, and by its analgesic effect on painful and tender scars. Cases have occurred where a patient has been unable to use an artificial limb until the tenderness of the stump has been allayed by radiation." Of the 28 civil cases 17 were cancerous; 15 were inoperable, and radiation was applied palliatively with much success. One case, in which the growth occurred on the hand, appeared to be cured. The most striking result was obtained in a case of Hodgkin's disease, in which the glandular enlargement in the neck was causing acute pressure symptoms. No benefit was obtained in two cases of tic-douloureux. Dr. Stevenson found it impossible to get sufficient emanation to treat efficiently the less serious conditions (such as tuberculous glands, lupus, psoriasis, sinuses, and chronic ulcers) which derive benefit from radium treatment. The emanation was in constant use, being transferred from one patient to another without delay night or day; but the number of patients whom it was possible to treat was limited by the small quantity of radium possessed by the Institute.

CALCUTTA SCHOOL OF TROPICAL MEDICINE.

SATISFACTORY progress has been made both towards the completion of the buildings and with the organization of the staff for the Calcutta School of Tropical Medicine, the foundation of which is due to the enthusiasm and persistent energy of Sir Leonard Rogers. It is intended that the school shall have six departments—tropical medicine, protozoology, entomology, pathology and bacteriology, pharmacology, and biochemistry. In addition, a course will be given on serology and immunology. Attached to the school is the Institute of Hygiene, to which it is proposed to appoint a professor of hygiene and a professor of chemistry to give courses on the analysis of food, water, and drugs. During the cold weather (October to April) the institute will give a six months' course for the diploma of public health granted by the State Medical Faculty. This course is open to qualified men of any nationality, and, in addition to members of the Indian Medical Service, applications have been received from America, and the Chinese Government has reserved two places. A shorter course, lasting three months, will be given from June to September; it is designed to afford to members of the various local medical services in India an opportunity of gaining knowledge of the practical application of the higher branches of tropical research. The Governing Body of the Calcutta School of Tropical Medicine consists of members of the medical profession, and it will enjoy a large measure of autonomy. The total amount of the annual funds at its disposal will be about £11,500. Of this three Associations—the Tea Planters', the Jute Makers', and the Mine Industry's—will contribute £2,000 a year each. For the Department

of Biochemistry an annual income of £2,000 a year is provided, of which the greater part is made up by gifts of £900 a year from Sir David Yule, one of the chief merchants in Calcutta, and £1,000 from Sir Dorab Tata's companies. A special endowment fund provides for four research appointments in the School of Tropical Medicine; the subjects to be immediately taken up are leprosy, ankylostomiasis, and pneumonia. The investigation into diabetes in Bengal begun by Dr. McCay, Professor of Physiology in the University of Calcutta, and his assistants, is to be continued by the Indian Research Fund Association, which will be provided with laboratory accommodation in the School. The new buildings will be formally opened, it is hoped by the Prince of Wales, in October or November next, but Sir Leonard Rogers will not be present to see the crowning of his twenty years' work for tropical medicine in India, as he has returned to this country with the intention of prosecuting his researches into the treatment of tuberculosis by preparations of unsaturated fatty acids, upon which he published a preliminary note in our issue of February 8th, 1919. The *Calcutta Statesman*, in its issue of March 3rd, published a very warm tribute to his services, especially to the practical application of his scientific researches in the treatment of cholera, kala-azar, dysentery and liver abscess, and leprosy. "We may be sure," our contemporary writes, "that he was touched and pleased by the appreciation shown by the members of his own profession, who subscribed for a bust, which now stands in the School of Tropical Medicine." Our contemporary expresses the opinion that the Government of India should not let Sir Leonard Rogers terminate his career in its service without some more conspicuous mark of its appreciation of his great services.

IMPROVEMENTS IN THE ASYLUM MEDICAL SERVICE.

IN a circular letter, dated March, 1920, and addressed to the visiting committees of all county and borough asylums, the Board of Control makes several interesting recommendations concerning the conditions of medical service in asylums. Allusion is made to the difficulty of filling vacant appointments, which is attributed to two chief causes. The first cause is said to be, that in view of the special knowledge required, "the salary is frequently inadequate to the responsibilities, and insufficient to enable a man to support a wife and family." A general increase in the salaries is recommended, and the suggestion is made that several of the senior members of the staff should be called senior assistant medical officers, receiving remuneration on a higher scale; the senior assistant medical officer (present style) should receive recognition of his status in the title of "deputy medical superintendent," and should be paid a salary more closely approximating to that of the superintendent. The second cause assigned for the dearth of applicants for staff appointments at asylums is that "permission to marry has usually to be obtained, and is not infrequently withheld on account of lack of suitable accommodation." This circumstance constitutes a very real grievance of asylum medical officers, and has on several occasions been mentioned in our columns. It is satisfactory to find that the Board of Control in its circular not only makes the general recommendation that in the case of permanent officers permission to marry be not refused, but also—what is a new departure from previous ordinance—that, subject to rules approved by the Secretary of State and with due regard to proper administration of the institution, permission may be granted to live out. Another suggested provision, which will tend to render the asylum service more attractive to many medical men, is the granting—as in the naval and other services—of study leave (with continuance of salary), during which assistant medical officers may take out one of the available special courses of instruction, and possibly prepare for a diploma or degree in mental diseases.

ATROPINE IN PYLOROSPASM AND PYLORIC HYPERTROPHY.

THE question whether congenital hypertrophic stenosis of the pylorus depends primarily on a pure developmental excess of muscle limited to the circular fibres of the pylorus, spasm subsequently supervening and so causing obstruction, or whether the hypertrophy is the result of spasm however excited, is still awaiting an answer. Dr. Pirie and Mr. Tyrrell Gray¹ suggested that the spasm was due to an excess of adrenalin in the blood, but this attractive speculation remains unproved. Just about the same time Haas² described the atropine treatment of pyloric spasm and stenosis based on a line of argument which is of interest in connexion with Pirie and Gray's view. Haas believes that congenital hypertrophy of the pylorus is the result of spasm, and that they are both features of what he calls the "hypertonic infant"—namely, one prone to spasm not only of the skeletal but also of the visceral muscles, as is shown clinically by colic, vomiting, visible peristalsis, and constipation. The hypertonic infant presents the symptoms of vagotonia, or overaction of that part of the autonomic system, of which the vagus is a constituent. Atropine inhibits the vagus and this part of the autonomic system, and therefore should be a rational remedy. Its use in congenital pyloric stenosis has probably failed in the past for several reasons: in the first place, it is important to use a fresh preparation of the alkaloid, as it rapidly loses its pharmacological power, and, next, to give a sufficient dose. During the previous four years, carrying out these precautions, all the cases of pylorospasm under his observation, including four on which operation had been advised, responded to treatment by atropine. The treatment was begun by giving one-thousandth of a grain of atropine by the mouth, and if no idiosyncrasy to the drug was declared the dose was rapidly increased with each feed: a common dose of atropine for an infant of a few weeks or months was $\frac{1}{16}$ to $\frac{1}{8}$ grain with an extreme of $\frac{1}{4}$ grain in the twenty-four hours, an amount he gave to an infant two weeks old. Although the explanation of the hypertonic infant and vagotonia may arouse some doubt and criticism, the results deserve notice and repetition, with attention to the use of fresh preparations and of the large doses. It would be interesting to know whether hypodermic injection of atropine acts as effectively or better. It may be pointed out that adrenalin, which increases the activity of the thoracic and not of the cephalic part of the autonomic system, does not appear to have been given to infants with pyloric spasm to see if it aggravated the symptoms; if it had been shown to have this effect, Pirie and Gray's hypothesis would be supported, and the theory of vagotonia weakened.

BRITISH MEDICAL ASSOCIATION LECTURE.

LIEUT.-COLONEL R. McCARRISON, I.M.S., will give a British Medical Association Lecture at a meeting of the South Wales and Monmouthshire Branch at Carmarthen at 3 p.m., on Thursday, April 22nd. Colonel McCarrison intends to give a brief outline of the sources and modes of action of vitamins, and the consequences of a deficiency of these substances in the diet. He will point out the various factors which influence the production of the symptoms due to a deficiency of vitamins in general terms, but will direct special attention to the bearing of the results of his recent experiments on the genesis of intestinal disorders. These results were obtained from a long research carried out at the Pasteur Institute, Coonoor, Madras, for the Indian Research Fund Association.

JUNE MEETING AT CAMBRIDGE.

THE following provisional programme has been drawn up for the discussions in the Section of Physiology and Pharmacology at the Annual Meeting of the British

Medical Association this summer. On Wednesday morning, June 30th, a discussion on acidosis in disease will be opened by the President of the Section, Professor F. Gowland Hopkins, F.R.S. On Thursday morning, July 1st, a discussion on the physiology and treatment of denervated muscle will be opened by Professor J. N. Langley, F.R.S. On Friday morning, July 2nd, a pharmacological discussion on quinine and its derivatives will be opened by Professor W. E. Dixon, F.R.S.

THE Council of the British Medical Association, at the meeting of April 14th, resolved unanimously to recommend the Annual Representative Meeting that Dr. David Drummond, C.B.E., M.D., F.R.C.P., should be elected President of the Association for the year 1921-22, to take office at the Annual Meeting to be held at Newcastle-on-Tyne in 1921. Dr. Drummond is Vice-Chancellor and Professor of Medicine, University of Durham, and Consulting Physician Royal Victoria Infirmary, Newcastle. The Council decided also to accept an invitation from the Glasgow and West of Scotland Branch to hold the Annual Meeting of 1922 in Glasgow.

Medical Notes in Parliament.

The Resumed Session.

THE House of Commons, on April 12th, resumed its sittings after the Easter vacation; it has a large amount of business to get through. The Budget will be introduced on April 19th, and it may be necessary to have two Finance Bills. It is hoped that consideration of the Insurance Bill in grand committee will begin on April 22nd. Dr. Addison is also pressing forward the arrangements for the proposed legislation dealing with health matters. The draft of the Patent Medicines Bill has been passed by the Cabinet subject to settlement of certain points affecting the wine trade. The Milk Bill has been drafted; the intention is to encourage local authorities to provide a supply, but there is no desire to interfere with private trading which fulfils requirements. The Tuberculosis Bill is not yet ready, but there will be no break between the provision at present made under the Insurance Acts and that to be made under the coming measure; the reason for the delay is that the scheme will be large and comprehensive. The Census Bill has been framed; it will differ little from that of nine years ago, but one or two fresh categories may be added. Dr. Addison still hopes that he may be able to present the bill to deal with the Poor Law system and with Health Services this session, but it cannot be discussed until the autumn.

Asylums as Military Hospitals.—Mr. Shortt, in answer to Mr. Kiley on April 12th, said that the following asylums were still being utilized for the care and treatment of soldiers and pensioners suffering from neurasthenia or loss of mental balance: (1) The Oxfordshire County and City Asylum (Ashurst War Memorial); (2) the Ewell Epileptic Colony (County of London) War Hospital; (3) a block of the Middlesex County Asylum, Wandsworth (Springfield War Hospital); (4) the Lancashire County Asylum, Winwick (the Lord Derby War Hospital). The men in these hospitals who were serving soldiers were still under military control. Pensioners could not be detained against their will. The present status of the Maudsley Hospital was that of a Ministry of Pensions Hospital, but it was to be handed back to the London County Council in July next. Mr. Shortt added that he had no information as to the Maghull, Monyhull, or Craigeith institutions, to which reference was also made in the question.

St. Luke's Hospital, Bradford.—Mr. Myers asked a question, on April 12th, as to an agreement made between the Bradford Corporation and the Bradford Board of Guardians for utilizing St. Luke's Hospital as a municipal general hospital, an arrangement which would enable the Bradford Corporation to treat the sick irrespective of their economic circumstances, and avoid placing on them the stigma attached to Poor Law treatment. He asked whether the Ministry was prepared to encourage and assist the project. Dr. Addison replied that the scheme had been approved last month.

Nurses in Malta.—Lieut.-Colonel Fremantle asked, on April 12th, whether nurses sent to Malta on active service in 1915 were ineligible for the 1915 medal, while nurses serving in Alexandria under similar conditions were entitled to it; and whether there were any reasons other than those of administrative convenience why equal services in Malta should not be equally recognized. Mr. Churchill replied that service on the establishment of a unit in a theatre of war was essential to qualify for the award of the 1914-15 Star. Malta was not a theatre of war, and nurses who served there in 1915 were consequently not eligible for the star.

Correspondence.

TREATMENT OF PULMONARY TUBERCULOSIS IN PRIVATE PRACTICE.

SIR,—Pulmonary tuberculosis has increased considerably in this country during and since the war. A recent authority¹ states that 65 per cent. of the population exhibit definite evidence of tuberculous infection of the lung. To one like myself who has returned to practice in England after many years' absence, the number of tuberculous patients encountered is appalling. The condition of these cases and their families is sad and depressing—depressing to the practitioner especially, because of the utter failure of the present system of treatment either to deal effectively with existing cases or to prevent others from developing.

This decade has been called the era of preventive medicine, but in many parts of England preventive medicine is still unknown. Take, for instance, the construction of the dwelling house. Is it not essential that the child (born of tuberculous parents) in whom we wish to prevent the development of the disease should live in a dry, airy, healthy building, with plenty of sunlight? Where do we find such buildings? Many of the towns of Devonshire are built in narrow combs or valleys, into which the sunlight only penetrates for a few hours. The houses are dripping with moisture, moss grows on many of the walls, and a strong smell of mould pervades the tiny dwelling rooms. The windows, even if not fixed, are seldom opened. Such houses (I speak as I find them in the old fishing town of Brixham, but the description fits the poorer quarters of many towns in South Devon) could scarcely be better selected for fostering the growth of tubercle. Damp-proof courses, which in this humid climate of ours are as essential as a weather-proof roof, are practically unknown. Air bricks, or modes of ventilating the interiors independently of the open window, are absent, and sanitation is defective. What are the chances that a child, born and reared in such unhealthy surroundings, and brought in contact with tuberculous subjects, will not acquire a disease which, according to a considerable majority of authorities, is definitely communicable? Either the child should be removed from contact with its infected relations or the latter should be removed from it.

We all know that the sanatoriums are quite inadequate to deal with more than a very small proportion of the cases—namely, the early ones. The advanced and most dangerous cases remain at home to infect the children. The early cases are given a certain time at the sanatorium and then discharged; about two-thirds of these cases relapse and become eventually "advanced cases." It is these cases especially that the private practitioner has to treat in most unfavourable surroundings. His treatment for the most part becomes the treatment of symptoms; it does not strike at the root of the disease, but it makes the remaining life of the patient more comfortable. It is eminently unsatisfying to the keen practitioner, who often feels uncertain as to the efficacy of his remedies, and yet has no research treatment institution to apply to in order that they may be tested.

Treatment, which is the only thing the patient cares about, has been much more neglected than any other branches of medical knowledge. The profession is too apt to imagine that it must thoroughly understand the pathology of a disease before it can begin its treatment; meanwhile patients are dying of the disease. Many of our most potent remedies have been discovered by experiment, trial, or intelligent thought—quite apart from a knowledge of the pathology of the disease. If more time were spent on therapeutic research, the general practitioner would be enabled to deal more efficiently with diseased conditions.

What can the general practitioner do against such a mountain of difficulty? He can only work and pray—pray that the people may become more enlightened and co-operate; pray that the Ministry of Health will come to his rescue and help in the sanitation of his town, and that the country will build proper houses in proper situations, and let the air and sunlight into the alleys. He

must pray also that the proper authority will build hospitals or open wards for advanced and infective cases and remove them from contact with the young, and that the Government will not only sanction but press forward the foundation of a research treatment institution, which shall test remedies submitted to it and issue authoritative reports thereon.—I am, etc.,

W. SIDNEY SWEET, B.Sc., M.D., B.S.Lond.,
Bachelor of Civil Engineering; late Chief
Resident Medical Officer of the Perth
Public Hospital and Sabiaco Sanatorium,
Western Australia.

Brixham, March 31st.

VILLAGE TUBERCULOSIS SETTLEMENTS.

SIR,—In your report of the interview between Dr. Addison and the deputation headed by Sir Montague Barlow, M.P., I notice that "the case for the establishment of village settlements" was put forward on two grounds—namely:

Firstly, *the patient* should be in a position to look forward to being able, on completion of his course of treatment and training, to take up his permanent residence in a settlement where, still in close touch with the sanatorium, he could work under conditions which would enable him to maintain his health and have his family or dependants with him.

Secondly, *the community* would gain in the result by the prevention of the spread of infection and the fact that the tuberculous patient would remain a productive worker.

These two objects seem on the face of them highly desirable and most ideal if they are not incompatible.

As illustrating the results of establishing a village settlement on these lines it was stated that at the Cambridgeshire Tuberculosis Colony, out of thirty cases who had passed from sanatorium treatment and training into the settlement there, not one had died in four years.

How many of these were cases in which the tubercle bacillus was found? Dr. Bardswell has recently shown that of 1,390 persons with tubercle bacilli present in the sputum who applied to the London Insurance Committee in 1914 for sanatorium benefit, 997, or 71.7 per cent., were dead in December, 1918, while some observations (unpublished) of my own in North Kensington showed a similar result, and even suggested that, with a certain proportion of exceptions, those in whose sputum tubercle bacilli were found in large numbers seldom lived much longer than six to twelve months after this discovery. Nor are the lives of cases with tubercle bacilli greatly lengthened by even the most efficient sanatorium treatment. Dr. Bardswell himself, one of the greatest advocates of sanatorium treatment in this country, practically acknowledges in his report that they are not, and the paragraph preceding Table IV in his report is merely an elaborate paraphrase of this opinion.

A very large proportion of the cases discharged from our sanatoriums as "arrested" or "cured," and who are alive five years later, are cases in whose sputum tubercle bacilli have never been found, and a certain proportion of these are undoubtedly cases in which the diagnosis of tuberculosis was wrong in the first place.

It seems to me that these are the cases which will inevitably fill the village settlements. And, if so, it is a puzzle to see how the community will benefit by "the prevention of the spread of infection." Already one of the new colonies demands a negative bacteriological report on the sputum by the tuberculosis officer who signs the application form.

These colonies and settlements are going to cost an enormous amount of money, and it would be interesting to know how many tuberculosis officers have been consulted as to their practicability and value. That there is a limited number of men patients (with tubercle bacilli in their sputum) who would appreciate the opportunities offered and who could and would benefit thereby is undoubted. But that their number will prove comparatively infinitesimal I feel assured. Meanwhile what seems to me the most urgent necessity of the antituberculosis campaign—what I believe every practical tuberculosis officer in the country most desires—is the provision of increased and improved accommodation (free from all stigma of pauperism) for the isolation of the far advanced and also of the less advanced but chronic ambulant cases with tubercle bacilli in their sputum (who are together, I believe, the source of nine-tenths of the infective material). This takes a secondary place and appears to be in danger of being indefinitely postponed "for want of funds."

¹ Dr. Thomas Beattie, BRITISH MEDICAL JOURNAL, JANUARY 24th, 1920

If only these cases with tubercle bacilli could be isolated more effectively and a milk supply free from tuberculous contamination be attained, it is my firm belief that tuberculosis could be almost eradicated in one generation. This object will never be achieved, in my opinion, by any further attempts (costly as they are) to bolster up our present defective means of treatment and prolong the lives of a few isolated cases.—I am, etc.,

D. J. WILLIAMSON,

April 6th. Chief Tuberculosis Officer, Portsmouth.

THE ILEO-CAECAL VALVE.

SIR,—In the BRITISH MEDICAL JOURNAL of August 9th, 1919, Mr. Short reports a case in which he had the ileo-caecal valve under observation. There is an important difference in this case to the one I reported in 1914 (*Ileo-caecal Valve*, Lewis). In Mr. Short's case there is a "prolapse of the bowel about the size of an orange," . . . "in the centre of the protuberant mass the ileo-caecal valve is plainly visible all the time."

In the case mentioned by me in 1914 the ileo-caecal valve was not prolapsed, and could only be observed when peristalsis was active. When seen the ileo-caecal valve resembled half a red cherry, with a dimple in the centre, from which five radiating corrugations ran out for about 6 mm. It was in tonic contraction and circular. When peristalsis was sluggish the papilla remained hidden under the folds of mucous membrane, and fluid faeces welled up from the colon and caput caecum coli. But faeces were passing through the ileo-caecal valve all the time.

In the case described by Mr. Short the ileo-caecal valve was oval in shape, and faecal matter only voided when food was taken by the mouth; also the ileo-caecal valve was insensitive to touch. These differences may be due to the fact that in the case reported by Mr. Short there was a prolapse of a mass of caecum and ileo-caecal valve. The pulling of the mesentery of the small bowel is probably responsible for the oval shape of the ileo-caecal valve in his case, because he says even "when the sphincter is contracted [the slit-like orifice] is about three-quarters of an inch long." . . . "It grips the inserted finger."

A circular muscle in a state of contraction, as the above evidently was, must assume a circular shape unless other forces are brought to bear. The pylorus is circular, also the internal anal sphincter. In the case described by the writer in 1914 the ileo-caecal valve was free to move and was always circular, even when relaxed in the discharge of semi-fluid faecal matter. It is inconceivable that a sphincter should be otherwise than circular when free to move and in tonic contraction.

In spite of the above references, the case reported by Mr. Short corroborates in a marked degree the case the writer reported in 1914, to which Mr. Short kindly refers.

The time to observe the ileo-caecal valve is within a very few hours after death, when it will be found as a circular mass, in tonic contraction, about 1.8 cm. in diameter, with a dimple in the middle. Soon after death the muscular fibres of the valve relax and the orifice becomes a slit. Later there is complete relaxation of the muscular fibres, with the familiar slit-like orifice of the dissecting room.

In your issue of August 16th Professor Keith claims to be the first to announce, in the *Proceedings* of the Anatomical Society, November, 1903, "that the ileo-caecal orifice is guarded by a sphincter in man and in all other vertebrate animals." Professor Keith is evidently not aware that this same statement was made in 1877 by Bureau in his *Thèse de Paris*, quoted by Peirier and Charpy 1901, p. 329, Tome IV. In regard to the evidence brought forward by Professor Keith in 1903: In his anatomical evidence he states that (1) the longitudinal fibres common to the bowel do not enter into the ileo-caecal valve; (2) that the muscular fibres surrounding the orifice form a series of racket-shaped loops, which, springing from the posterior frenulum, encircle the anterior angle of the orifice and return to end in the posterior frenulum. The posterior frenulum is the basis from which these fibres act.

Keith describes the closure of the valve as due to the pulling of the handle of the racket, aided by the fibres surrounding the orifice. In the microscopical evidence submitted by the writer in 1914 it is shown that (1) the longitudinal fibres common to the small and large bowel

passed at the top of the valve between the circular fibres; (2) that thick bands of circular muscular fibres surround the orifice of the ileo-caecal valve. If the writer's interpretation of the microscopical section published in 1914 as frontispiece to his book is correct, there is a special circular bundle of fibres in the ileo-caecal valve over and above the circular bundles continuous of those from the small and large intestine.

Now, Bureau in 1877, Professor Keith and Professor Elliott in 1903, stated there was a muscular sphincter at the ileo-caecal orifice. Not one of them, however, has brought forward sufficient proof that is necessary to establish such an important fact. By proof necessary the writer means anatomical and microscopical evidence. To obtain this it is necessary, first, to study the ileo-caecal valve *in situ*, as described by the writer in 1914, not prolapsed, as Mr. Short's case; secondly, to use only specimens secured immediately after death. From Professor Keith's anatomical description it appears he did not do this, or he would have described a sphincter with longitudinal muscular bundles running between the circular to the summit of the valve. This sphincter would have been strong enough to act without the aid of the handle of the racket he mentions, formed by muscular bundles in the right frenulum. He says "the posterior frenulum is the basis from which these fibres act."

Mr. Short reports and figures the ileo-caecal valve as oval. Now the writer must emphatically state that the normal valve is circular, not oval. This is true not only in man, but also in the dog, as has been already mentioned in his book in 1914.—I am, etc.,

Sydney, Dec. 2nd, 1919.

A. H. RUTHERFORD.

THE DIAGNOSIS OF DISEASE OF THE PANCREAS.

SIR,—I have read with very great interest the Schorstein Lecture by Sir Archibald Garrod published in your issue of April 3rd.

He refers to Loewi's adrenalin mydriasis test. The dilatation of the pupil that follows the application of a few drops of 1 in 1,000 adrenalin solution to the conjunctiva is, as he explains, due to excessive irritability of the true sympathetic, as the result of the removal of the restraining influence of the pancreas. He mentions a few of the pitfalls in connexion with the test, but has omitted the fact that in some individuals there is normally a predominating action of the sympathetic—the so-called sympathicotonic group of Eppinger and Hess. Such individuals would respond to the adrenalin test even in the absence of any pancreatic mischief. Possibly those cases in which Sir Archibald Garrod obtained a positive result without there having been any gross lesion of the gland may have belonged to this group. It is difficult to see how altogether to exclude this error unless the normal response of the patient to vagotonic or sympathicotonic drugs, before the onset of the suspected pancreatic disease, is known. In patients who are known to be vagotonic a positive Loewi's test should be of extremely great value.

It would also be interesting to know from Sir Archibald Garrod whether he tried the effect of pancreas feeding on the adrenalin mydriasis test. Should the administration of pancreas gland result in giving a negative Loewi's test in a case in which the test was at first positive, the evidence in favour of pancreatic disease should be practically conclusive.

I wish to suggest one or two other tests which are based upon the same physiological principle, and would therefore be subject to the same reservations as Loewi's test. The advantage of the following tests over Loewi's is their rapidity, the response occurring within a few seconds instead of about an hour, as well as the fact that they can be utilized even in cases of irides fixed by synechiae. Loewi's test is also, for obvious reasons, not suitable in cases of glaucoma. The tests I suggest are the following:

(a) *Aschner's Oculo-cardiac Reflex*.—This test consists in observing the effect upon the pulse of compressing the eyeball with the thumb. In vagotonics (and, indeed, in my own limited experience, in most people) a retardation of the pulse by about ten beats per minute is noticed within a very few seconds. In known sympathicotonic there is either no retardation or there is an actual acceleration of the pulse. If, therefore, the response in a case of

suspected disease of the pancreas is sympathicotonic in type, especially in a case previously known to be vagotonic, there should be strong presumptive evidence in favour of disease of the gland.

(b) *The Respiratory-cardiac Reflex*.—Vagotonics, as well as those who have some septic focus about them such as furunculosis or rheumatism, show, on taking a deep breath, a retardation in pulse frequency as well as a diminution in the volume of the pulse as shown by the sphygmograph (Wilson and Carroll). It may therefore be expected that in disease of the pancreas this reflex would be either diminished or abolished.—I am, etc.,

London, W., April 5th.

W. M. FELDMAN.

THE TREATMENT OF UTERINE CANCER.

SIR,—Your leading article has had a curious effect on Dr. A. Leitch, who says he is sad, but shows no signs of it in his letter published on April 10th, p. 521, which reminds me of the author of *Alice in Wonderland*. He has proved that my three cases of cure of cancer were due to luck by asserting it three distinct times. As for poor old Leonides, who had the temerity to live and operate eighteen hundred years ago, "off with his head"; it is evidently the only kind of amputation of the cervix Dr. A. Leitch believes in. "Curiouser and curiouser" is his knowledge of that old fellow's mortality statistics. Curiouser of all—and here the Cheshire cat would have enlarged its smile—is his opinion that only 3 per cent. of cases of cancer of the cervix can be cured by amputation, because only 3 per cent. of cases dead of the disease show no extension beyond the uterus. Sad? No, Sir, the writer (like the reader) of his letter must be a merry fellow.—I am, etc.,

London, W., April 10th.

HERBERT R. SPENCER.

FIBROIDS COMPLICATING PREGNANCY: HYSTERECTOMY: RECOVERY.

SIR,—Mr. Stawell (April 10th, p. 498) omits to give the date of the operation in his interesting case. I cannot suppress a hope that it occurred previously to the publication of my Lettsoman lecture on the subject, which he quotes. For one of the chief reasons for that lecture was to show that infanticidal hysterectomy is rarely necessary. Judging from the particulars given of Mr. Stawell's case, in which an enema removed the only symptoms from which the patient suffered, I think it highly probable that pregnancy might have been allowed to progress until the child was viable, when Caesarean section, followed by total abdominal hysterectomy (and the removal of the dermoid tumour at the same time), would, I doubt not, in Mr. Stawell's hands have caused the patient to rejoice at getting completely rid of her neoplasms and at having a living child.—I am, etc.,

London, W., April 10th.

HERBERT R. SPENCER.

THE MENTALLY DEFECTIVE.

SIR,—It was with pleasure I read the article on the Birmingham scheme, by Dr. W. A. Potts in your issue of April 3rd, 1920, p. 472. Anyone who has had much experience of prisons, more particularly of prisoners, must feel that an educative policy should be vigorously prosecuted, preparatory to legislative reform in our penal systems. Not only the laymen and medical men, but even the medical staffs of asylums, require education in this direction. Medical officers of asylums and of institutions for the mentally defective have excellent opportunities of gaining valuable information concerning the lower grades of mental deficiency; but the prison medical officers have much better opportunities of observing the higher types.

In all my experience among inebriates I have never yet seen one who did not present evidence of mental defect. It is quite true, I admit, that in some cases—in fact in the majority—the defect is of the higher grade, while in a relatively small number it is not manifested till the patient has been some considerable time under observation and treatment in the institution.

Mental deficiency is a more complex disorder and is a more difficult subject to investigate and study than what we call "insanity." No one will dispute that there are many cases of either disorder which can be recognized as soon as they come before the examiners. There

are, however, certain types of insanity which cannot be certified till seen several times; and a proportion of cases, though undoubtedly insane, cannot be certified at all.

Many of the higher grades of mental deficiency require prolonged study before correct diagnosis can be made. These are the cases which are the gravest danger to society, because they can carry out schemes of cunning which the average medical man would not credit. I have had prolonged conversations with the acknowledged premier criminal in Scotland. Very few medical men would admit he was a higher grade defective from anything seen or elicited; but that a man fails to unmask signs and symptoms is no proof that they are absent.

Let me conclude by saying that the specialist should have training and experience so as to be considered as such before his appointment to the highly important position as medical officer of a large prison. This may be one of the advantages—perhaps the only one—of having criminal lunatics in a special department of a prison; and in Scotland, where this has been in force for many years, this expert opinion has been freely used by the courts in the case of untried prisoners.—I am, etc.,

H. FERGUSON WATSON, M.D.,
D.P.H., L.R.C.P.

Edinburgh, April 5th.

THE INDIAN MEDICAL SERVICE.

SIR,—I enclose a cutting received from *The Pioneer*. The information it contains, emanating from the Director-General of the I.M.S., and the confidant of the Government of India, is of such a nature as to deserve the most careful attention of all who think of entering the I.M.S. and of all who are responsible for guiding them in their choice.

I shall not, for the moment, offer any further comment on it.—I am, etc.,

R. H. ELLIOT, Lieut.-Colonel I.M.S. (ret.).

* * * The cutting enclosed by Colonel Elliot is from *The Pioneer* of March 11th, 1920, and is a portion of the report of a speech by the Director-General I.M.S. in the Viceroy's Legislative Council:

"General Edwards in conclusion referred to the Indian Medical Service, which, until recent years, did not contain more than 7 per cent. of Indians. The Secretary of State decided not long ago that one-third of the new recruits should be Indians, and the latest private information was that this number might still further be increased. More than this there was a proposal that in order to facilitate the entry of Indians scholarships or nominations should be given to the most promising Indian students who wished to enter the service. In the former case they would proceed to England to complete their curriculum and then compete for the Indian Medical Service. In the latter case they would proceed to England for a further course of instruction only. Indians should no longer regard this service as one in which they had no interest. For the first time India was beginning to control her destinies. It was at such a crisis in the history of the nation that they may look for the birth of men great in the highest sense of the word. He earnestly desired that Indians should come to the front in the medical and scientific world. The Indian Medical Service had been a great asset to India in the past, and attracted her best intellects from the British medical schools. Let it now attract the best from the schools of India."

RARE ACCIDENTS PRESUMED DUE TO NEGLIGENCE.

SIR,—In the Court of King's Bench on March 24th, 1920, in the course of his judgement in an action for damages brought against a dental surgeon, Mr. Justice Bailhache laid down a principle of great importance and wide application. As it seems to be unsound, both in law and logic, it ought not to pass unchallenged, especially as the fallacy of it is not readily apparent to most people. Mr. Justice Bailhache said:

One must remember that an operation of this kind, with this carburettum wheel, is a very common, and indeed I should suppose, an everyday dental operation. One asks one's self whether that operation is attended commonly, or even rarely, with any danger of injury to the tongue or mouth. The very competent witnesses who have been called for the defendant have all said that in their own experience with such a wheel as this they have never heard of such an accident, or such an incident as happened in this particular case. They have not heard of it, nor, according to one of the witnesses, can such an instance be found in the textbooks on the subject. One starts with this, therefore; here is a very common operation practically never producing any detrimental results, and never producing any injury to the mouth, but on this particular

occasion inflicting a severe wound in the floor of the mouth. It seems to me, under those circumstances, it lies upon the dentist who was conducting the operation to give some satisfactory explanation to the court as to why, in this particular instance, the unexpected happened; why it was that in this particular instance an operation of this kind resulted in an injury which nobody has ever before heard of in connexion with this particular operation.

Later on this point of view is emphasized, and the judge says:

Of course, if this were an injury that often happened one would come to a different conclusion; but it is an injury, as I say, which nobody has ever heard of in practice before.

This last statement of the judge, as I can myself testify, although somewhat supported by the evidence in the case referred to, is quite inaccurate. The accident does occur from time to time. The principle of the decision is, however, what concerns us most. The decision amounts to this: "Where an extremely rare accident occurs in a very common operation, the onus falls on the defendant of proving that he was not guilty of negligence which will otherwise be assumed." From the legal point of view it ought not to be presumed that a man is guilty solely because he cannot prove his innocence. The accident referred to by the judge happened in so short a space of time and under such circumstances as to make it impossible to do more than guess at the causes of it. There was not a particle of evidence of any negligence of which anyone present at the operation was aware. The defendant was found to have been negligent because he could not bring any evidence beyond his own statement on oath that he had not been negligent. The fact that the accident had occurred was regarded as in itself establishing negligence unless some cause for the accident was established inconsistent with the presumption of negligence.

It is hardly necessary to explain to surgeons that in the performance of many operations the most skilful and careful operators will from time to time cause accidental injury to a patient. In some cases these accidents are very rare and in others not uncommon. In abdominal operations, for instance, with all care and skill an operator occasionally makes an opening into the intestine unintentionally. If improved methods make a particular accident very rare, does that make it an indication of carelessness although when more common it did not indicate negligence? Even the rarest of unavoidable accidents will usually be found to occur with a wonderful regularity if a large enough experience is available, and the mathematical principles of the theory of chances will apply. Accidents due to negligence, on the other hand, will multiply or diminish according to the presence or absence of conditions conducing to negligence, and will therefore be liable to considerable fluctuations in frequency. There are, of course, accidents which by their very nature indicate negligence. If a barber in shaving a customer cuts the carotid artery, negligence might be assumed in the absence of evidence to the contrary, but not because the accident is "practically unknown." As regards the particular accident which gave rise to the legal proceedings referred to above, I remember an instance of its occurrence in which it was, in my opinion, due to negligence because there was evidence of negligence. When there is no evidence of negligence, it is quite wrong to assume negligence because the accident is rare. Any competent dental operator knows that this particular accident may happen without any negligence or want of skill whatever. As Mr. Hopson said in his evidence, the accident had never happened to him, but he attributed that fact to good luck. In other words, an accident which happens on an average once in 100,000 cases may befall one operator and not another without any difference in care or skill between them.—I am, etc.,

32, Craven Street, Strand, W.C.2,
April 1st.

HUGH WOODS, M.D.

NYCTALOPIA OR HEMERALOPIA.

SIR,—With reference to your remarks (April 10th, p. 514) regarding the double use of the term "nyctalopia," the uncertainty as to its meaning arose long before the Middle Ages. St. Isidore of Seville (d. A.D. 636) says in his *Etymol.*, Bk. IV, *De Medicina*, cap. 8: "Nyctalmus is a disease in which those suffering from it lose their sight by day and regain it as night approaches; or vice versa, as

many say, they can see by day and are blind at night." This statement Isidore may have taken directly from the *Isagoge*, attributed to Galen, cap. 16: "Nyctalopes are those whose sight is dim during the daytime, who see better as the sun declines, but see best at night; or the reverse, they see not too well by day and not at all in the evening." In the *Medical Definitions* (No. 343) of Galen, if they are his, nyctalops is an affection of the eyes in which, without apparent cause, the patient cannot see by day but is able to do so at night. This agrees with the opinion usually ascribed to Hippocrates, his great authority. Theodorus Priscianus (*Euph.*, 12, 39) uses the term in the same sense. Nyctalopia, "the night eye," may be compared with nycticerax, which Isidore (*Etymol.*, 12, 7, 41), on the authority of St. Jerome, describes as the night bird which loves the night and avoids the day, because it cannot see in the sunlight.

On the other hand, the weight of evidence is in favour of nyctalopia as "night blindness." It is used in that sense by Aristotle, Pliny, Celsus, Aetius, Oribasius, Alexander and Paul.

Nor was the ambiguity of meaning confined to the Greek word. The early Latin term was *luscitio*: "luciosos . . . nyctalopas a Graecis dictos" (Pliny, *N. H.*, 28, 11, 47, 170). Paulus ex Festo (that is probably Verrius Flaccus, 1st century B.C.) "*luscitio vitium ocnlorum quod clarius vesperi quam meridie cernit*"; but on the other hand, Varro, the contemporary of Verrius, "*vesperi non videre quos appellant lusciosos*" (Varro apud Non, 135, 12). Vegetius calls the disease "*lunaticus oculus*."

According to Hippocrates (*Pror.*) and Aristotle (*De Gen. An.*, 5, 1), the disease is more apt to attack young persons and, adds the latter writer, those who have dark eyes. For, says Aristotle, there is more fluid in dark eyes and also in the eyes of the young because their brain is more fluid. This excess of fluid interferes with the transparency of their eyes so they see less well in the twilight, as the light is then weak.—I am, etc.,

London, S.W., April 10th.

RORY FLETCHER.

WAR HONOURS.

SIR,—In several recent numbers of the *JOURNAL* there have appeared letters by civil surgeons complaining that there is no issue to them of war medals or other simple recognition of services rendered by civilian doctors in connexion with the war.

The following paragraph, which has appeared in the *Cape Times*, will be read, therefore, with both interest and surprise by English medical men:

As a result of strong representations made by the Union Government to the Imperial authorities, the grant of the British war medal has now been extended to South African troops who were employed for a period of not less than thirty days between August 4th, 1914, and November 11th, 1918, within the Union of South Africa on coast defence, or other military duties directly connected with the war; also to European civilians employed on the staffs of the South African military hospitals, or as a member of recognized organizations who actually handled sick and wounded soldiers and who served forty-eight hours a week for not less than fifty-two weeks, whether continuously or not.

Surely it is not too much to suggest that what can be done for lay persons who have rendered services—often of a very minor kind—out here and at this distance from the seat of war should also be done for the many civilian doctors who—often under great personal difficulties, strain, and self-sacrifice—put in hard professional work in the treatment of wounded and sick soldiers.

I was myself a whole-time civil member of the medical staff of a large war hospital in England for two years, and therefore had a good opportunity of seeing the greatness of the work done by civil doctors, for which the pecuniary remuneration allowed by the War Office was a mere bagatelle—less, indeed, than the pay of many a girl munition worker.

Perhaps the British Medical Association may see its way to move in this matter—with a little real spirit.

Although I do not personally seek any such recognition I prefer not to subscribe my name.—I am, etc.,

Cape Town, March 26th.

ONE WHO WAS OVER AGE.

TAXATION OF MOTORS.

SIR,—In the various press reports forecasting provisions in the forthcoming Budget and predicting an increased tax on motor cars estimated at 15s. or 20s. per horse-power,

I have failed to observe any mention of relief to medical men. The medical profession surely should not be classed with those who use cars as a luxury or simply as a personal convenience.

It is to be hoped that our interests are being looked to in the House of Commons.—I am, etc.,

Harrogate, April 10th.

R. RAINES.

Obituary.

G. A. WRIGHT, F.R.C.S.,

Consulting Surgeon Royal Infirmary, Manchester.

THE death in retirement of Mr. G. A. Wright has caused much regret to old students of the Manchester School of Medicine. George Arthur Wright, who was in his 69th year, was a son of the rector of Vange, Essex, and was educated at Marlborough and Oxford, and afterwards at Guy's Hospital. He graduated M.B.Oxford in 1877, and became M.R.C.S. in the same year. He took the F.R.C.S. in 1878, and held the appointments of house-surgeon and surgical registrar to Guy's Hospital. His connexion with Manchester began when in 1880 he became resident surgical officer at the Royal Infirmary; two years later he was appointed honorary assistant surgeon to the infirmary and surgeon to the Pendlebury Children's Hospital. This latter appointment and the fact that he did not become full surgeon to the Royal Infirmary for eighteen years probably account for the fact that his greatest interest was in the surgery of childhood. His first publication was a book on hip diseases in childhood, published in 1887, but the work by which his name is best known to the profession generally is that on *The Diseases of Children*, which he wrote in conjunction with the late Dr. Henry Ashby; it was published in 1889, and was founded on the experience of the authors during the previous ten years at the General Hospital for Sick Children, Pendlebury, Manchester. The book was both learned and practical, and immediately took its place as at that time by far the most comprehensive work on the subject. A fifth edition was published in 1905. Wright put his best work into the book. He was a pioneer in the treatment of tuberculous disease of bone and of the spine, and one of the first to treat spinal abscesses by evacuation without drainage—a method which he described to the American Orthopaedic Association in 1891. He was a bold but careful operator, with a profound knowledge of anatomy; in 1902 he published a *Handbook of Surgical Applied Anatomy*, written in conjunction with Mr. C. H. Preston; it reached a second edition in 1904. He was for some time lecturer on operative and practical surgery in the University of Manchester, and on the death of Professor Tom Jones in South Africa in 1900, succeeded him as professor of surgery. When he retired in 1911 under the age rules, he was appointed Emeritus professor.

Mr. Wright was a member of the Council of the Royal College of Surgeons of England from 1906 to 1910. He was secretary of the Section of Surgery at the Annual Meeting of the British Medical Association at Bristol in 1894, vice-president of the same section at Manchester in 1902, and president at Exeter in 1907. He was a lieutenant-colonel R.A.M.C. and administrator of the 2nd Western General Hospital T.F. He had retired before the war, but returned to work and was attached first to the Red Cross Auxiliary Hospital at Worsley Hall and afterwards to the Military Hospital at Whalley.

Mr. Wright was greatly esteemed by the profession in Manchester and many miles around. He was at various times president of the Manchester Pathological and Medical Societies. As a clinical teacher he was most successful and the warm interest he took in all matters affecting the welfare of the students of the school won their respect and affection.

JOHN ALFRED CODD, M.D., B.Sc.Lond.,

Physician, Wolverhampton General Hospital.

We regret to record the death, which took place suddenly on March 3rd, at the age of 51, of Dr. J. A. Codd, of Wolverhampton. A son of the late Rev. John Codd, of that city, John Alfred Codd was educated at Leeds, and graduated B.Sc.Lond. in 1886, M.B. in 1891, and M.D. in 1896. After holding the posts of assistant demonstrator

of anatomy in the Yorkshire College and house-physician at Leeds General Infirmary, he went to Wolverhampton in 1893 as house-physician to the General Hospital, subsequently becoming honorary physician, and physician to the ear, nose, and throat, electro-therapeutic and radiographic departments. For many years he served as M.O.H. of Heath Town.

Dr. Codd had an extensive consulting practice in Wolverhampton and district, and made a number of useful contributions to medical periodical literature, notably "The dosage of tuberculin," "Treatment of malignant disease by x rays," and "Angeioneurotic oedema cured by adrenalin," published in this JOURNAL. He was also the author of "The utility of intubation of the larynx" and other short monographs. He was prominently associated with local social and religious organizations, and took a keen interest in many non-medical branches of science, notably conchology. He was president of the South Staffordshire Naturalists' Society.

Dr. Codd rendered many valuable services to the British Medical Association. He was from 1903 to 1910 honorary secretary, and in 1915 chairman, of the South Staffordshire Division. In 1910 he was elected president of the Staffordshire Branch, and in the following year he served as vice-president of the Electro-Therapeutic Section at the annual meeting of the Association at Birmingham. He was president of the Midland Branch of the Society of Medical Officers of Health. He was appointed by the Insurance Commissioners a member of the Wolverhampton Insurance Committee in 1912, and was a very regular attendant at its meetings. His death is mourned, not only by a large circle of patients, colleagues, and friends, but also by the many charitable and scientific associations for whom he worked with such conspicuous zeal and devotion.

The Services.

DEATHS IN THE SERVICES.

SURGEON LIEUTENANT PETER BURROWES KELLY, D.S.O., late R.N., died at Crookstown House, Ballytore, county Kildare, on April 6th, aged 31. He was educated at the Cecilia Street Hospital, Dublin, and at St. Bartholomew's and Charing Cross Hospitals. He took the Irish double qualification in 1911, and the day after war was declared, August 5th, 1914, entered the navy as a temporary surgeon. He served in the Dardanelles in 1915, taking part in the landing of the expeditionary force, when he was wounded, mentioned in dispatches, and received the D.S.O. The last post he held, before he was demobilized in April, 1919, was that of medical officer to the Royal Naval College at Osborne, Isle of Wight.

Major Thomas Henry Balfour, M.C., R.A.M.C., died at Quetta on March 16th. He was the youngest son of the late Dr. Andrew Balfour, of Portobello, and graduated M.B. and Ch.B. Edin. in 1909, taking the D.P.H. of the Scottish Colleges in 1911. He entered the R.A.M.C. in 1912, was promoted captain on March 30th, 1915, and to acting Major on February 25th, 1918. Before going to India he had served for most of the war in France, first with the 2nd Battalion Argyll and Sutherland Highlanders, and then as D.A.D.M.S. with the 12th Division and 15th Corps. He received the Military Cross on February 18th, 1915.

Colonel Douglas French-Mullen, Bengal Medical Service (retired), died on April 2nd, aged 68. He was educated at Queen's College, Galway, and Stevens's Hospital, Dublin, and graduated M.D. Queen's University, Ireland in 1873. He entered the I.M.S. in 1877, and attained the rank of full colonel in 1907, and retired in 1912. Most of his service was spent in political employment, as medical officer of various states in Rapputana; latterly he held the post of D.D.M.S. at Simla. He was joint author, with Lieut.-Colonel P. D. Fank, I.M.S., of *A Medico-topographical Account of Ljmere*, 1900. Colonel-French-Mullen was the third of four brothers, all of whom entered the public medical services. The eldest was in the navy, and after his retirement stood unsuccessfully for South Dublin as a Parnellite in 1892. The second, the late Lieut.-Colonel Thomas French-Mullen, entered the I.M.S. in 1866, retired in 1896, and died on October 12th, 1896. The fourth, Lieut.-Colonel Jarlath French-Mullen served in the Colonial Medical Service in Jamaica from 1874-76, in the R.A.M.C. for six months in 1877-78, and in the I.M.S. from 1878 to 1903, and still survives.

Brigade Surgeon Lieut.-Colonel Joseph Forbes Keith, Bombay Medical Service, retired, died on April 1st, aged 79. He was educated at Aberdeen, where he graduated M.B. and C.M. in 1866 and M.D. in 1870. He entered the I.M.S. as assistant-surgeon in 1867, and retired in 1894. He served in the Abyssinian war of 1868, at the general hospital at Zoolah, receiving the medal; in the second Afghan war of 1879-80, when he took part in the defence of Kandahar, the sortie of Deh Khoja, and the battle of Kandahar on September 1st, 1880; was mentioned in dispatches, and gained the medal with a clasp; and in Burma in 1886-88, when he got the medal with two clasps.

Universities and Colleges.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on March 24th. It was resolved to institute a university chair of physiology at St. Mary's Hospital Medical School.

Professor A. D. Waller, F.R.S., was re-elected director and Dr. T. D. Lister treasurer of the Physiological Laboratory for 1920.

Dr. Philip Hamill has been appointed a member of the Board of Examiners in Pharmacology for the second examination for medical degrees. Part II, vice Dr. E. Mellanby, resigned, and Dr. F. Ransom has been elected chairman of the board for the remainder of the session 1919-20.

Dr. W. G. Savage has been appointed an external examiner in hygiene and bacteriology for the university diploma in household and social science in July, 1920. Professor E. Mellanby will give a course of eight lectures on nutrition at the Household and Sanitary Science Department, King's College for Women, Campden Hill Road, on May 3rd, 4th, 10th, 11th, 17th, 18th, 31st, and June 1st, at 5 p.m.

Presentation day will be held in the Royal Albert Hall on Wednesday, May 19th, and not May 5th, as formerly arranged. A service will be held at Westminster Abbey at 6 p.m., and a graduation dinner will be held in the evening at the Guildhall.

Applications for the Beit fellowships for scientific research to be awarded in July, 1920, must be received by the Rector, Imperial College, South Kensington, S.W. 7, by April 19th.

KING'S COLLEGE OLD STUDENTS' ASSOCIATION.

At a general meeting of old students, held recently at King's College, Strand, it was decided to form the King's College, London, Old Students' Association, for the purpose of promoting social intercourse, and of keeping the members in touch with their old college. The association hopes to include students from all faculties, and the subscription of 10s. 6d. per annum will include the *King's College Review*, published once a term, and a list of members with their addresses (and possibly the work on which they are engaged). This should prove to be of great value to members wishing to renew acquaintanceship with contemporaries who may be in the same locality as themselves. Further particulars and forms of application for membership may be obtained from Miss M. A. V. Fairlie, Honorary Secretary, 3, St. Julian's Farm Road, West Norwood, S.E.27.

Medical News.

PROFESSOR STARLING, who has gone to India to advise the Government with regard to the foundation of a central medical research institute for India, will visit Bombay, Poona, Bangalore, Calcutta, Delhi, and Kasauli. He will be accompanied on his tour of inspection by Lieut.-Colonel Greig, C.I.E., I.M.S.

COLONEL C. PYE OLIVER, C.M.G., M.D., Assistant Director of Medical Services, Home Counties Division, has been appointed to the Commission of the Peace for the County of Kent.

A COURSE of ten lectures on the theory and application of mathematical statistics to social, educational, economic, meteorological, and medical problems will be given by Dr. E. C. SNOW, M.A., at the Sir John Cass Technical Institute, Jewry Street, Aldgate, E.C., during the summer term. The first lecture will be given at 7 p.m. on Friday, April 23rd. The fee for the course is 5s.

DR. A. T. SCOTT, M.B.E., Assistant Commander of the Y Division, Metropolitan Special Constabulary, has been appointed an honorary associate of the Order of St. John of Jerusalem, in recognition of his services to the wounded, etc., during the air raids.

OWING to the increase of the cost of labour and materials—steel alone has risen 50 per cent. since the armistice—the prices of the Austin "Twenty" cars have been raised to £695 for the touring car and £875 for the landaulette. The price of the chassis only is £550.

THE fuel difficulty lends interest to the announcement by the Department of Scientific and Industrial Research that the Board of Trade has issued a licence to the Scottish Shale Oil Scientific and Industrial Research Association, which is found to comply with the conditions laid down in the Government scheme for the encouragement of industrial research.

A SCHOOL of puericulture in connexion with the Faculty of Medicine will shortly be inaugurated at the Edith Cavell Hospital in Paris. The school will be under the direction of Professor Pinard, and will consist of three sections—pre-natal period, infancy, and childhood—under the charge of Professors Couvelaire, Marfan, and Léon Bernard respectively.

At a meeting of the Child Study Society on Thursday, April 29th, at 6 p.m., Sir A. E. Shipley, G.B.E., D.Sc., F.R.S., will give a lecture, illustrated by lantern slides, on biting insects and children. The lecture will be given at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1.

A LIEBIG museum was opened at Giessen on March 26th, when an address was given by Professor Burger on the relation of Liebig to medicine.

THE University of Louvain has been reopened, and 3,141 students have been enrolled in the various faculties.

THE thirty-second meeting of the Deutsche Kongress für Innere Medizin will be held on April 20th-23rd in Dresden under the presidency of Professor Minkowski. The chief subject for discussion will be the present position of immunotherapy and chemotherapy in infectious diseases. Professors Kraus, R. Schmidt, Pfeiffer, and Morgenroth will take part in the discussion.

M. EMILE J. B. BAILLIÈRE, the head of the well-known medical publishing firm of Paris, has recently died at the age of 89.

AT the Serum Institute in Copenhagen investigations are being conducted into the various types of pneumococcus existing in Denmark. Danish practitioners are urged to send specimens of sputum from their pneumonia cases, and pus from cases of otitis and other suppurative conditions that may be due to pneumococci. It is intended to prepare specific serums.

A COMMISSION appointed by the Swedish Government has recently issued a report in which the introduction of compulsory insurance against sickness is unanimously advocated. Maternity insurance is also recommended. It is calculated that 80 per cent. of the total population will be included in this scheme. The highest and lowest daily sickness benefits will be 10 kr. and ½ kr. respectively. It is anticipated that the annual cost of medical treatment and drugs will be 39 million kr., medical benefit will cost 60,800,000 kr., maternity benefit 11 million kr., administration 7½ million kr., the total cost being about 118,300,000 kr. On this basis the State would contribute 73½ million kr., the remainder being found by the insured, with the exception that employers would contribute to cover certain risks.

THE National Health Week for 1920 is to begin (after six years' suspension) on May 2nd. Its object is to focus public attention on matters of health, and arouse a sense of individual responsibility among all sections of the community. The improvement of health is held to be "fast approaching its limit on present lines," and the dominant idea for 1920 is to be "self-help, and the consideration of what each individual can do for himself and his neighbour in securing a healthy life." The King and Queen are patrons of the movement, and the preliminary committee includes the names of twenty medical men and women prominently associated with public health and kindred branches of medical science. Local committees are to be organized, and the Health Week Committee has many suggestions to make concerning lectures, exhibitions, demonstrations, etc. The secretary is Mr. E. White Wallis, Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.

IN a paper on industrial lighting and its relation to efficiency, read before the Royal Society of Arts, Mr. Leon Gaster quoted some recent statistics collected by one of the large American insurance companies. It was estimated that of 91,000 accidents in 1910, 23.8 per cent. were due to imperfect illumination; after eight years' propaganda work on the lines of "safety first" this proportion was reduced to 18 per cent. During these eight years an aggregate of 100,000 years of work has been lost to industry through accidents which might have been prevented had the illumination been efficient. In the United States it has been calculated that increased expenditure on the lighting of factories, amounting to not more than 5 per cent. of the pay roll, would lead to an increased production of quite 15 per cent. That particular phase of industrial lighting which concerns the illumination of mines was the subject of a paper by Dr. T. Lister Llewellyn at the meeting of the Illuminating Engineering Society on February 25th, reported in our issue of March 6th, p. 327. At that meeting, which was attended by members of the Council of British Ophthalmologists and of the Ophthalmological Section of the Royal Society of Medicine, it was suggested that the question should be thoroughly studied by a joint committee representative of the three bodies. The suggestion is being placed before the Home Office, where a committee on miners' lamps is now sitting.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR OF THE BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

H. E. B. desires to hear of suitable home in apartments for an elderly gentleman suffering from epilepsy, and his wife. Very moderate means.

H. G. asks for authenticated examples dating before 1914 of several persons under one roof contracting pneumonia in a manner which has recently become common.

INCOME TAX.

B. C. G. inquires whether he is entitled to deduct cost of keep from any income derived from occasional resident patients.

The "income" so derived is the profit, and the cost of food, laundry, domestic service, and similar expenses incurred on behalf of the resident patients can without doubt be properly deducted from the gross receipts in calculating the profit.

TRADE TEACHING FOR FEEBLE-MINDED YOUTH.

F. M.—The most appropriate place for a feeble-minded youth of 20 to be sent to "learn a trade" is The Royal Earlswood Institution, Red Hill, Surrey, where there is a series of workshops for practical instruction in printing, carpentering, tailoring, shoemaking, matmaking, etc., besides a farm and large gardens and grounds for outdoor work. Particulars can be obtained from the Secretary, H. Howard, Esq., Earlswood Offices, 14-16, Ludgate Hill, E.C.4. Payments vary according to means of parents and class of accommodation required.

ANAESTHESIA IN EPILEPTICS.

DR. C. LANGTON HEWER (Assistant Anaesthetist to St. Bartholomew's and to St. Andrew's Hospitals) writes: With reference to Dr. Cohen's letter re anaesthesia in epileptic subjects (p. 526), I might mention that some four months ago I anaesthetized an epileptic, who had two distinct seizures on the operating table. The first occurred just as the surgeon had begun, and the second about a quarter of an hour later. They consisted of clonic spasms of most of the voluntary muscles, and were sufficiently pronounced to stop the operation while they lasted. They were quite different in character from the fairly frequently observed "ether clonus," and lasted about two minutes. No initial tonic stage was observed. The patient was a young man who was being operated upon for tuberculous cervical glands. The anaesthetics used were gas and ether for induction, and then a mixture of C₂E₂ on an open mask. The patient made a good recovery, and had no more fits while in hospital.

DR. A. M. BARFORD (Chichester) writes: During the time I was giving anaesthetics in London I had occasion to administer to four epileptics. On each occasion I gave chloroform only, and there was no seizure during or after the administration. The patients were acute abdominal cases. Recently I had occasion to operate upon an epileptic child for tonsils and adenoids. The usual ether and chloroform mixture was used, and there was a marked seizure before and after the operation. Dr. Cohen's cases are interesting, as I have always thought epileptics could not tolerate ether.

DR. J. FREIREIRA GRAY (Exeter) writes: The following experience of mine may be of interest to Dr. H. M. Cohen. On January 3rd last I was summoned to the Exeter Poor Law institution to deliver a woman, aged 22, whose labour was unduly prolonged. I found an occipito-posterior position. I gave chloroform and delivered. The anaesthetic was discontinued, the woman was lying quietly on her left side, and I was waiting for the expulsion of the placenta. Suddenly she stopped breathing, began to twitch, and then was convulsed. In fact, she had a typical epileptic fit. At its height a smart haemorrhage ensued, and the placenta was expelled. The whole affair took place between two and three minutes. She passed again into quiet anaesthetic sleep. There was

never any albumin in the urine. Mine was a case, not of anaesthesia in epileptics, but of an epileptic fit in anaesthesia. The woman stated she was not subject to fits.

LETTERS, NOTES, ETC.

LENGTH OF GESTATION.

"M.R.C.S.," writing with reference to the correspondence on the length of gestation which appeared in the JOURNAL last year, sends the following facts: Last April I menstruated from April 24th to 28th inclusive. There was only one day during the following month on which connexion took place, this being May 2nd. Our baby, the fourth child, was born at 1 a.m. on February 3rd, 1920.

QUADRUPLETS.

M. PINARD reported recently to the Académie de Médecine a case in which quadruple pregnancy was brought to a successful termination. The children (two boys and two girls) were born on January 17th, 1915, have grown well, and were all alive on their fifth birthday. The mother was attended by a midwife (Madame Verdon) and Dr. Cronzat. The first child, a girl, which presented by the head, was born at 4 a.m. and Dr. Cronzat assisted delivery by forceps. The second child, a boy, which presented by the breech, was born an hour and a half later. In another half hour a third child, a girl, which presented by the breech, was born, and the fourth child, a boy, which presented by the breech, was born two and a half hours after the birth of his eldest sister. The three younger were born without instrumental assistance. Twenty minutes after the birth of the fourth severe haemorrhage occurred; it was treated successfully by delivering the placenta and the injection of hot water. The placenta was single, very large, and presented four distinct sacs. The mother suffered during the last month of pregnancy from the great size of the abdomen and from oedema in the lower part of the abdomen, the vulva, and legs. The urine did not contain albumin. She had previously had six children, born singly after normal confinements. A very complete family history was obtained, and on the side of neither parent was there any record of previous multiple pregnancies. M. Pinard stated that in France, according to Puché, quadruplets occurred once in 2,074,306 pregnancies.

ADVERTISING'S ARTFUL AID.

THE art of advertising is developing, and there are, we believe, schools where professors give instruction. The day of the simple-minded advertiser who tries to "direct attention to the subject" by using three or four sizes and kinds of type in as many lines is passing. The modern advertiser employs other methods. A word of praise may be given to the ingenuity of a little publication recently issued by Messrs. Oppenheimer. It consists of a number of more or less familiar proverbial sayings, with recommendations of the firm's products dropped in here and there; the author has so ingeniously arranged matters that the collocation of proverb and recommendation is sometimes distinctly amusing, so that the reader will be disposed to show his discoveries to friends. For instance, "All our geese are swans." "A therapeutic consideration of Roboleine supports all claims for it as the reconstructive." Or, again, "Bread is the staff of life." "By its palatability and general excellence has taken high rank." Again, "For hope is but the dream of those that wake." "Favourably spoken of in relieving bronchial catarrh, asthma, and irritable winter coughs." And finally, Mark Twain and the BRITISH MEDICAL JOURNAL.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 38, 39, 40, 41, and 42 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 36 and 37.

THE following appointments of certifying factory surgeons are vacant: Hebden Bridge (York, West Riding), Liskeard (Cornwall), Markfield (Leicester), Singleton (Sussex), Stonehaven (Kincardine), Stornoway (Ross and Cromarty), Wolverhampton (Stafford).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	7	6
Each additional line	0	1	3
Whole single column	6	0	0
Whole page	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-restant letters addressed either in initials or numbers.

NEW VIEWS ON THE PATHOLOGY, DIAGNOSIS, AND TREATMENT OF GASTRIC AND DUODENAL ULCER.

A BRITISH MEDICAL ASSOCIATION LECTURE DELIVERED BEFORE THE TUNBRIDGE WELLS DIVISION ON JANUARY 20TH, 1920.

BY
ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

THE GASTRIC ULCER AND DUODENAL ULCER "DIATHESSES."

The exciting conditions which give rise to gastric and duodenal ulceration are common to many people who never develop an ulcer, so that the question arises, What is it about one individual that makes him liable to gastric ulcer, about a second that makes him liable to duodenal ulcer, and about others—the majority of people—that save them from being liable to either?

I propose to offer an answer to this question, which will in turn suggest methods of prophylaxis and of after-care which should render the patient treated by the most approved medical

means even less liable to relapse than the patient who has undergone an operation, but without running the small but undoubted risks inseparable from the latter.

Although there is a certain shape and position which may be regarded as the average normal stomach (Fig. 1), considerable variations occur in two directions. Whereas with a standard opaque meal the greater curvature of the average or orthotonic stomach reaches the umbilicus or just below it in the erect position, in some normal individuals the stomach is hypertonic, and in others it is hypotonic. In the former the stomach curves obliquely to the pylorus, which is almost its lowest point, and the greater curvature is situated some distance above the umbilicus (Fig. 2); in the latter the stomach is hook-shaped, and the greater curvature is situated more than an inch below the umbilicus, the upper level of the gastric contents being correspondingly low (Fig. 3). The hypertonic stomach generally empties itself more rapidly than the average normal one, and the hypotonic stomach generally, but not so constantly, empties itself less rapidly.

Rehuss has recently introduced a method of gastric analysis which is destined, I believe, to have a profound influence on our knowledge of the physiology and pathology of the stomach. Instead of passing a tube an hour after a meal and then emptying the stomach, a perforated metal bulb is swallowed just before the meal; attached to it is a fine rubber tube, the end of which remains hanging out of the patient's mouth. The stomach is emptied of its fasting contents; the test meal is then taken and a small quantity is aspirated through the tube every quarter of an hour until digestion is finished. By means of this "fractional test meal" a curve can be constructed showing the quantity of free and active hydrochloric acid present at each period of digestion. Rehuss and Crohn of New York have found three types of curve in normal individuals—the average normal or isosecretion, hypersecretion, and hyposecretion.

Although comparative investigations of the motor functions, as ascertained with the x rays, and of the secretory functions, as determined by the fractional test meal, have not yet been carried out on a large scale, there is reason to believe that the hypertonic stomach generally shows hypersecretion. The hypotonic stomach generally shows hyposecretion, but it may—and this is a very important fact—also show hypersecretion.

Barelay and I, working independently, found that the stomach in cases of duodenal ulcer is hypertonic (Fig. 4) and empties with unusual rapidity, the onset of pain corresponding with the moment when the stomach has almost entirely emptied itself. More recently it has become recognized that the stomach in cases of gastric ulcer is generally somewhat hypotonic, and almost invariably empties itself more slowly than the average normal.

One of the earliest discoveries resulting from gastric analysis was the frequent association of hyperchlorhydria with gastric and duodenal ulcer. The more accurate investigations of Crohn by means of fractional test meals show that hypersecretion and hyperchlorhydria are constantly present in both of these conditions.

I have had several opportunities of examining patients who have recovered from duodenal ulcer as a result of medical treatment, occasionally after many years of com-

plete freedom from symptoms. The hypertonic, rapidly emptying stomach has always been found to be still present. One of the group of six patients with symptoms of duodenal ulcer upon whom Sir Berkeley Moynihan operated when I visited his clinic for the first time in 1909 was found at the operation to have no trace of an ulcer,

and therefore nothing more was done. This was his first attack, and the symptoms had only been present a few months. But I had previously demonstrated with the x rays that his stomach was hypertonic and emptied rapidly, just like the other five cases in which an ulcer was found. These observations prove, I think, that the characteristic x-ray appearance of the stomach in duodenal ulcer is not due to the ulcer, as it is present before it develops and persists after it has healed.

The same thing is true with regard to secretion, as Crohn has found that the curve shows the same hypersecretion and hyperchlorhydria after a gastric or duodenal ulcer has healed under medical treatment as it did before treatment began.

The conclusion which can, I think, be reasonably drawn from these facts is that there is one type of stomach in which a gastric ulcer will develop and another type which is likely to lead to ulceration of the duodenum, if the necessary exciting causes are present, but the latter will not give rise to ulceration at all in an individual with the average normal type of stomach.

I have seen a number of cases in which two or more brothers and sisters have suffered from gastric and from duodenal ulcer, and still more in which brothers and sisters of a patient with a gastric or duodenal ulcer have had symptoms of a similar character,

but so much less severe that it seemed impossible that actual ulceration was present. In the most remarkable duodenal ulcer family I have met with the father and two out of nine children were dyspeptic, and four others had typical symptoms of duodenal ulcer, one dying from a perforation. It is a remarkable fact that I have never seen one member of a family with a gastric ulcer and another with a duodenal ulcer. This suggests that the types of stomach which predispose to the development of gastric and of duodenal ulcer respectively are congenital, and either one or the other may exist in several members of a family.

THE EXISTING CAUSES OF GASTRIC AND DUODENAL ULCER.

An ulcer of the peculiar type found in the stomach occurs nowhere else in the body except the first part of the duodenum and the part of the jejunum immediately adjoining the stoma of a gastro-enterostomy. The one

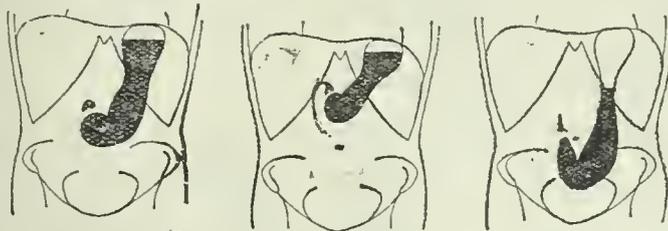

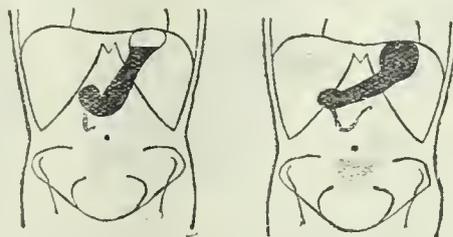

FIG. 1.—Average normal stomach. FIG. 2.—Hypertonic type of normal stomach. FIG. 3.—Hypotonic type of normal stomach.

(A) Vertical position. (B) Horizontal position. FIG. 4.—Duodenal ulcer with thirty years' history. Hypertonic stomach hides duodenal cap.

common feature of these three situations is the presence of gastric juice. But gastric juice will not digest the normal mucous membrane. Only if a small area of mucous membrane has had its vitality so lowered that it can no longer resist digestion does a superficial erosion form, which may develop into an acute ulcer and ultimately into the typical chronic gastric or duodenal ulcer. The vitality is most likely to be lowered by the action of toxins, which are generally of bacterial origin. The two most important sources are the teeth and the appendix. Bacterial toxins produced by chronic periodontitis (pyorrhoea alveolaris) and by root infection may be excreted by the gastric or duodenal mucous membrane after absorption into the blood stream, and may lead to local necrosis, just as the toxins produced by burns may in rare instances damage the duodenal mucous membrane, and those of uraemia may cause ulcerative colitis. In twenty-four hours very large quantities of pus are produced by the ulcerated areas in pyorrhoea alveolaris, and as all of this is swallowed, it can hardly be doubted that it leads to irritation of the gastric and duodenal mucous membrane, especially in the night, when it is no longer diluted by the food, and when the bacteria are no longer destroyed by acid gastric juice. Some organisms are probably absorbed from the mucous membrane, particularly if it has been damaged as a result of any of the other factors which will be mentioned. The minute submucous lymphoid follicles thus become inflamed, and may finally break down and open into the stomach, producing minute erosions, the precursors of definite

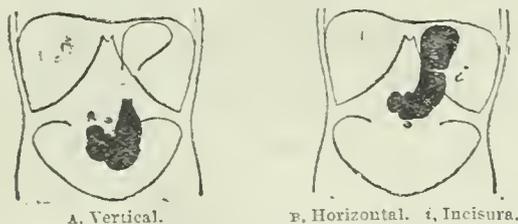

FIG. 5.—Spasmodic hour-glass stomach, due to a gastric ulcer.

ulcers. Septic foci in the pharynx and nasal sinuses probably act in the same two ways.

The association of chronic appendicitis with both acute and chronic gastric and duodenal ulcer is too common to be a coincidence, and the greatly diminished tendency to relapse, especially of acute ulcers, following removal of the appendix without interfering with the ulcer, shows that the appendicitis is the primary condition. It probably leads to ulceration in much the same way as the first of the two channels described in connexion with dental infection.

Chemical irritants, such as alcohol, especially when taken on an empty stomach, vinegar, the acids of unripe fruits, and mustard, pepper, and curry, taken in excess, may irritate the mucous membrane to such an extent that it becomes less capable of resisting digestion by the gastric juice. Insufficiently masticated food, and hard indigestible particles, such as pips and skins of fruit, fibres of raw vegetables, such as celery, and nuts have a still greater effect. When the movements of the stomach are watched with the *x* rays it is seen that the peristaltic waves at the pyloric end are so deep that they divide the extreme distal end of the stomach almost completely from the rest, and as the wave passes on, some of the contents are pushed forcibly through the very narrow pyloric canal, whilst the rest is pushed back into the body of the stomach through the equally narrow channel in the centre of the ring formed by the advancing wave of contraction. The muscular coat of the pyloric end of the stomach thus does the mechanical work which should have been done by the muscles of the jaws and tongue, and the hard particles of food are consequently rubbed against the delicate mucous membrane. It is not surprising that minute erosions develop, which may form the starting point of ulcers; this no doubt explains why ulcers are so much more common in the pyloric end of the stomach than elsewhere.

The occurrence of ulceration is rare in comparison with the frequency of the various exciting causes just described, because it is unlikely for the injured mucous membrane to be digested by the gastric juice unless the stomach has

the physiological characteristics already described as predisposing to the production of gastric or duodenal ulcer. The explanation of this is clear. In the gastric ulcer type not only is the acidity high but the emptying of the stomach is slow, so that an exceptionally strong gastric juice remains in contact with the gastric mucous membrane for an exceptionally long period, and the passage of acid chyme through the duodenum is so slow and intermittent that the alkaline duodenal contents are capable of neutralizing it to a great extent. On the other hand, in the duodenal ulcer type the first part of the duodenum is kept constantly filled with exceptionally acid chyme, and neutralization with the alkaline duodenal juice is impossible; even when the stomach is empty gastric juice continues to be secreted, and passes rapidly into the duodenum without being diluted and partially neutralized by admixture with food.

I am convinced that the tendency to develop a duodenal ulcer is increased by excessive smoking; the nicotine apparently acts through the autonomic nervous system, and increases the hypertonus and hypersecretion of the stomach.

DIAGNOSIS.

We owe most of the accurate knowledge we possess concerning the symptoms of gastric and duodenal ulcer to the pioneer work of a number of surgeons, chief of whom should be mentioned Sir Berkeley Moynihan in England and the Mayo brothers in America. A diagnosis can generally be made from an accurate history of the

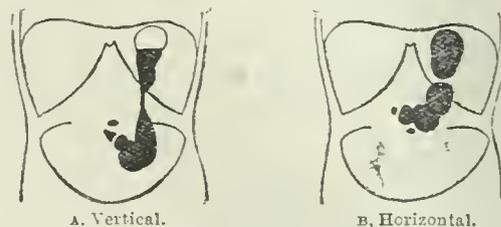

FIG. 6.—Spasmodic hour-glass stomach, due to a gastric ulcer.

symptoms, together with the results of an *x*-ray examination, which gives much information obtainable in no other way. A fractional test meal and the examination of the faeces for occult blood are of some value; direct inspection and palpation of the abdomen rarely give much information.

I presume that you are all familiar with the writings of Sir Berkeley Moynihan on the symptoms of gastric and duodenal ulcer. I need only briefly summarize his description, to which I can add little of importance. The symptoms tend to appear in attacks which are generally brought on by an indiscretion in diet, overwork, especially if associated with worry, or exposure to sudden changes of temperature. The attacks are more common and generally more prolonged in winter than in summer. This periodicity is more constantly observed with duodenal than with gastric ulcers.

The one constant symptom is pain. It differs from the pain in all other abdominal disorders in the regularity of its relation to meals. In a given case the pain comes on at a definite interval after a meal of a given size, so that if a patient has pain an hour after dinner one day, he will have pain at exactly the same time every day if his dinner is of approximately the same size. The pain comes on immediately after taking food if the ulcer is close to the cardia; the onset is progressively later as an ulcer approaches the pylorus, and with a pre-pyloric ulcer it generally begins from an hour and a half to two hours after a meal of moderate size. In duodenal ulcer the onset of pain is still later, the usual time being between two and three hours after a meal; it is very characteristic for the pain in duodenal ulcer to be delayed after the last meal so as to wake the patient at 1 or 2 a.m. The pain is always in the epigastrium, and tends to be higher up the nearer the ulcer is to the cardia. In gastric ulcer it may spread towards the left and in duodenal ulcer towards the right, but this is by no means constant. The pain may radiate to the back, especially if the ulcer is on the posterior wall of the stomach and eroding the pancreas. The pain is always relieved by food unless the ulcer is at the cardiac orifice.

The relief is more marked and more prolonged the nearer the ulcer is to the pylorus, and particularly when the ulcer is in the duodenum. The pain is also relieved immediately by alkalis, and there is no doubt that, whatever its actual cause may be, it is associated with the presence of free acid in the stomach, and food acts by diluting and to some slight extent by neutralizing the acid. Localized deep tenderness is almost always present when spontaneous pain is actually felt, but in the intervals it may be completely absent. When the ulcer has penetrated so deeply that local peritonitis is produced, the situation of

Some residue after six hours is therefore strong evidence that actual ulceration has occurred in the hypotonic or hypertonic stomach, although the latter has probably existed since childhood or even since birth.

In gastric ulcer spasm of part of the stomach is frequently present. The spasm may be confined to a very narrow segment corresponding with that in which the ulcer is situated; it then gives rise to a characteristic "incisura" (Fig. 5). In other cases a wider area is involved (Fig. 6), and the appearance may suggest the presence of an organic hour-glass constriction, but the upper segment

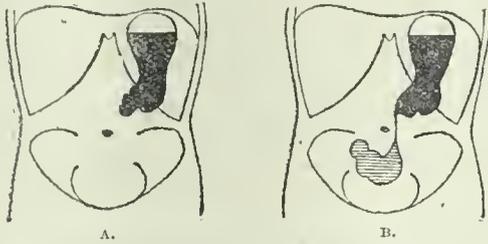

FIG. 7.—Hour-glass stomach, due to cicatrization of a gastric ulcer. A, Half an hour after opaque meal. B, Six hours after opaque meal. C, Three weeks after gastro-gastrostomy by Mr. R. P. Rowlands.

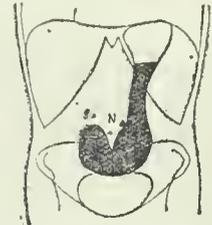

FIG. 8.—Gastric ulcer, producing "niche," N, in hypotonic stomach.

the tenderness is found with the x rays to correspond precisely with that of the ulcer.

Vomiting is not uncommon in gastric ulcer, but is rare in duodenal ulcer. Its presence in the later stage of either generally indicates that the ulcer is invading the pylorus and producing obstruction, or, in the case of gastric ulcer, that an hour-glass contraction is developing. The pain is at once relieved by vomiting, which removes the acid contents of the stomach.

Haematemesis is far less common than is generally supposed. It is important to exclude such conditions as cirrhosis of the liver and splenic anaemia, which may also give rise to it, but its association with ulcer symptoms clinches the diagnosis. Much more commonly traces of occult blood, which can only be found by chemical means, are present in the stools, but the test is so delicate that this is only of importance if the patient is on a diet which contains no flesh food. The presence of melaena is of the same significance as haematemesis. It should be remembered that if the blood in the stools is bright red it cannot come from a gastric or duodenal ulcer.

In every case in which the possibility of gastric or duodenal ulceration exists an x-ray examination should be carried out. A standard opaque meal is given when the stomach is empty, and a second examination should be made six hours later, nothing having been eaten or drunk in the interval. The type of stomach present can at once be recognized, whether it has the average normal orthotonic appearance, or whether it is hypotonic or hypertonic—the types which are likely to be associated with gastric and duodenal ulcer respectively. The activity of peristalsis and the rate at which the contents of the stomach pass into the duodenum are next observed, the slow rate characteristic of a gastric ulcer being in marked contrast with the rapid rate characteristic of a duodenal ulcer.

Although both hypotonic and hypertonic stomachs in healthy individuals without symptoms are invariably empty within six hours, and the latter generally within a couple of hours, some residue is frequently found after six hours when a gastric ulcer and occasionally when a duodenal ulcer is present, even in the absence of organic pyloric obstruction; this is due to the occurrence in the later stages of gastric digestion of pylorospasm, or more frequently to pyloric achalasia—absence of the normal relaxation of the pyloric sphincter when each peristaltic wave reaches it in the later stages of gastric digestion.

never sags below the neck joining it to the lower one, as is invariably the case in organic hour-glass stomach (Fig. 7).

The same two varieties of gastric spasm sometimes occur in duodenal ulcer, and still more frequently in chronic appendicitis and gall stones. But in these conditions it is only present intermittently, and may come and go during the course of the x-ray examination; it disappears when the stomach is gently massaged and on injection of gr. $\frac{1}{100}$ atropine sulphate, whereas the spasm in a case of gastric ulcer is generally unaffected under these conditions.

The x-ray signs so far described are present in acute as well as in chronic ulcer. The former is so shallow that no direct evidence of its presence can be expected, but the latter almost invariably gives rise to a highly characteristic picture. In gastric ulcer this consists in the production of a minute diverticulum or "niche," which represents the crater of the ulcer filled with the opaque salt (Fig. 8); in duodenal ulcer there is a more or less definite deformity of the duodenal cap, which is partly caused by the ulcer itself, and partly a result of spasm (Fig. 9). The

visualized ulcer is often found to be the seat of considerable tenderness, strictly localized to the area of ulceration, especially in the case of the stomach, as duodenal ulcers are more deeply seated and less accessible to palpation.

The x rays also give quite definite evidence of the existence of organic hour-glass contraction (Fig. 7), the appearance of which is quite distinct from that caused by spasm, though the two are often associated together so that the degree of narrowing found at operation may be much less than what the x rays would suggest. Dilatation, even with a history of duodenal ulcer, and marked delay in evacuation in spite of abnormally vigorous peristalsis, which may be associated with occasional antiperistaltic waves, prove that pyloric obstruction is present.

PROPHYLAXIS.

I have already referred to a patient with all the symptoms of duodenal ulcer as well as the characteristic hypertonic and rapid evacuation of the stomach in whom nothing abnormal was found at operation. The symptoms had only appeared a few months before, and it is highly probable that a pre-ulcerative condition was present, which would have led to the development of an ulcer if no prophylactic treatment had been undertaken. It is not at

FIG. 9.—Duodenal ulcer. P.C., Pyloric canal. P.S., Pyloric sphincter. D.C., Duodenal cap. C, Crater of ulcer. A, Diagram of normal x-ray appearance of pyloric end of stomach. B, Duodenal ulcer, deforming duodenal cap and invading pylorus. (Reproduced from skiagram by Mr. Reitz.) C, Section of pyloric end of stomach and duodenal cap, reconstructed from B, to show extent of ulceration.

all uncommon to find people suffering from slight symptoms, which have either been present for only a short time, or, if for longer, have been intermittent and have rarely lasted for more than a few days at a time, but which are otherwise quite characteristic of gastric or of duodenal ulcer. In all such cases the type of stomach characteristic of gastric or duodenal ulcer is found, but no deformity of stomach or of duodenal cap, which alone proves conclusively the presence of an actual ulcer, can be seen with the x-rays; there is no residue of food six hours after the barium meal, and no occult blood is present in the stools.

These patients are, I believe, suffering from a pre-ulcerative condition, which will certainly lead to actual ulceration in time unless all the exciting causes I have already described are removed. The teeth should, therefore, be put into perfect order, and the patient should in the future have his teeth thoroughly overhauled every six months. The pharynx and nasal sinuses should be examined for possible sources of infection, which should be dealt with if any are discovered. The appendix should be removed if there is evidence of chronic inflammation. The stomach, duodenum, and gall bladder should be inspected at the same time, but a gastro-enterostomy should not be performed unless, after all, an ulcer of considerable size in the immediate neighbourhood of the pylorus is found, but this is not likely to occur under the conditions described, especially in the absence of any six-hour food residue.

The patient should be made to realize the danger he runs of an ulcer developing unless he eats slowly and chews his food very thoroughly. He should take nothing which is chemically irritating to the stomach, such as alcohol, vinegar, unripe fruit, mustard, pepper, chutney, pickles, and curry; a little well diluted whisky is, however, permissible, but only if taken with meals. Very hot and very cold drinks should be sipped, and ices allowed to melt in the mouth before swallowing. Any food which cannot be chewed to a fluid consistence should be avoided; this includes tough meat, new bread, raw vegetables in the form of salads, and indeed all green vegetables unless prepared as purées, pips and skins of fruit, whether raw, cooked, in jam or marmalade, nuts, and especially currants and raisins in cakes and puddings. Smoking should only be permitted in strict moderation.

With the gastric ulcer type of stomach, which empties slowly, three good meals without any intermediate feeds, such as afternoon tea, should be taken. But with the duodenal ulcer type of stomach, which empties itself too rapidly, a tablespoonful of olive oil, which delays the evacuation, should be taken before each of the three chief meals; this has the further effect of diminishing the secretion of gastric juice, as Craven Moore has conclusively proved. Some milk should also be taken about three hours after breakfast, and afternoon tea should be taken at 4.30 or 5 p.m. More milk should be drunk just before going to bed, and a little should always be kept at the bedside to drink if the patient should wake in the night.

Care should be taken to avoid exposure to sudden changes of temperature, and if the patient is accidentally chilled he should as quickly as possible get thoroughly warmed, and, if necessary, have a hot bath and go to bed. It is quite unnecessary for patients of this kind to stay in bed or have a period of stricter dieting than what I have described, but the precautions mentioned should be continued for an indefinite period. The patient should also be given a powder containing equal quantities of oxide of magnesia, calcium carbonate and bismuth carbonate, which he can take whenever he has the least discomfort, in frequently repeated but very small doses—just sufficient to keep himself completely comfortable. He should also be careful to keep his bowels regular by means of paraffin, which has the advantage of being entirely devoid of irritant action, and, if necessary, with oxide of magnesia after each meal, as this has the additional advantage of neutralizing the excessive gastric secretion without irritating the mucous membrane.

MEDICAL TREATMENT.

As a preliminary to the treatment of the actual gastric or duodenal ulcer the teeth should be put into perfect condition, and any infected foci in the nose or throat should be treated. Throughout the treatment the mouth should be kept absolutely clean, and the tongue frequently scraped with a wooden spatula if any fur accumulates on

it. If chronic appendicitis is present the appendix should be removed, but a gastro-enterostomy should not be performed unless the ulcer is very large, or is giving rise to mechanical difficulties owing to hour-glass contraction or pyloric obstruction.

The patient should be kept warm in bed throughout the treatment, but he should get up every day to have a bath and to open his bowels, the difficulties with which are greatly reduced if a bed-pan can be avoided.

The object of treatment is to reduce the secretion of gastric juice as much as possible, and to keep the hydrochloric acid in the stomach completely neutralized throughout the day, and, what is almost invariably neglected, throughout the night. The evidence is conclusive that free hydrochloric acid prevents an ulcer healing, whatever additional factors may have contributed towards its production in the first instance. At the same time as much food as possible is required to maintain the patient's nutrition, especially when he has lost much weight, as is often the case with gastric, though rarely with duodenal, ulcer. Finally, the food should be as unirritating in its mechanical and chemical characteristics as possible.

These are the commonly accepted principles of treatment, but several years ago I realized how inadequately it was carried out by the various methods in use both in England and abroad. I tried in various ways to fulfil these principles more satisfactorily, but it was not until I read a paper by Dr. Sippey of Chicago just before the war that I realized how far short of perfection my improved methods still remained. I had the good fortune to meet Dr. Sippey during my recent visit to America, and I have now adopted his method of treatment with certain modifications based on my previous experience.

Five ounces of milk (or preferably milk and cream in equal quantities) are given every hour from 8 a.m. to 8 p.m. inclusive. To each feed gr. x of sodium citrate, which combines with the lime in the milk, and consequently prevents the formation of irritating clots by the remnant of the gastric juice, dissolved in 2 drachms of emulsion of magnesia are added; the latter contains gr. v oxide of magnesia to the drachm. This has the advantage over sodium bicarbonate in having four times its neutralizing power, in giving off no carbon dioxide, which is liable to distend the stomach on reacting with the hydrochloric acid, in having a mild aperient action, and in producing a very much smaller secondary increase in secretion after the initial neutralization than sodium bicarbonate, which Crohn has shown by the fractional test meal to be the most powerful stimulant of gastric juice in existence.

Immediately before alternate feeds, beginning at 7.30 a.m., half an ounce of olive oil is taken. This inhibits the secretion of gastric juice; at the same time it supplies a digestible and absolutely unirritating food of very high nutritive value in a concentrated form. Immediately before the remaining feeds *m v tinct. belladonnae*, which has a similar inhibiting effect, is given, as oil before each feed sometimes gives rise to nausea and is more than can generally be digested.

Half an hour after every feed, and at 9, 9.30, and 10 p.m. a powder containing gr. x calcium carbonate and gr. xxx bismuth carbonate is taken in a little water. The former has two and a half times, the latter only one-third the neutralizing power of sodium bicarbonate, but neither gives rise to any secondary hypersecretion, and they neutralize the acid so slowly that the carbon dioxide set free is dissolved in the gastric contents as rapidly as it forms. At 6 a.m. half an ounce of bismuth carbonate, shaken up but not suspended in five to ten ounces of water is swallowed, and the patient then lies on his right side, or in such a position that the powder is likely to come in contact with the ulcer. This forms a protective covering to the ulcer, and at the same time neutralizes any acid present, and calls forth a local secretion of protective mucus.

By these means the contents of the stomach are kept neutral or alkaline from 6 a.m. to 10 p.m. If the ulcer is in the neighbourhood of the pylorus, and especially if it is giving rise to any obstruction, continuous hypersecretion of gastric juice will occur throughout the night. It is then impossible for the ulcer to heal, and in the past it has been supposed that such cases must be operated upon. But the obstruction is generally due entirely, or in great part, to surrounding oedema and inflammatory swelling

and pylorospasm, and in such cases, if the ulcer can be caused to heal by medical or surgical treatment, any scarring produced is insufficient to give rise to obstruction.

Sippy has shown that by preventing the accumulation of acid in the stomach during the night these ulcers heal, and a cure can be obtained in most cases without resorting to surgery. At 11 p.m. the stomach is completely emptied by Senoran's evacuator; if not more than two ounces of fluid are present on two consecutive nights, this can be discontinued. If half a pint or more is removed at 11 p.m., the stomach should be evacuated again at 1 a.m. At 11 p.m. atropine sulphate is injected subcutaneously in order to inhibit the further secretion of gastric juice; the largest dose which does not produce unpleasant dryness of the mouth should be given, beginning with gr. $\frac{1}{16}$. At the same time the alkaline powder should be given, and if more than two ounces of fluid were evacuated it should be repeated every two hours through the night. In most cases the continued nocturnal secretion is rapidly controlled by this treatment.

If the patient is constipated the dose of magnesia should be increased, and if the bowels are not opened on two consecutive days an enema should be given. If diarrhoea occurs some magnesia should be replaced by an equivalent amount of bismuth carbonate.

The strict treatment just described should be continued until for three weeks the patient has had no spontaneous pain, no trace of tenderness has been present, no occult blood has been found in the stools, not more than two ounces of fluid have been removed on any one evening, and the x rays show no evidence of active ulceration. The pain and tenderness generally disappear within forty eight hours; the other signs of healing appear considerably later, the exact time depending upon the size and age of the ulcer and its proximity to the pylorus.

The diet can now be rapidly increased until at the end of a week everything is taken with the exceptions I mentioned in discussing prophylaxis.

Before returning to his ordinary occupation the patient should be given written instructions as to how he is to prevent a recurrence of his ulcer on the lines laid down under prophylaxis. With large and chronic ulcers he should in addition take a small quantity of the alkaline powder as nearly as possible at hourly intervals between meals for at least six months, but in the case of duodenal ulcer a small feed is equally or more efficacious.

SURGICAL TREATMENT.

Everyone must agree that the surgical treatment of gastric and duodenal ulcer is a confession of failure. If the prophylaxis I have spoken about could become universal, or even if ulcers were adequately treated at a sufficiently early stage in their development, operations would only be required for such rare emergencies as the perforation of an ulcer which had previously given few if any signs of its presence. It is not as if a gastro-enterostomy was completely without danger, invariably cured an ulcer, and never gave rise to unpleasant after-effects. I can recall three patients who died as a direct result of a gastro-enterostomy, although all the conditions appeared to be most favourable for success. I have seen a small number both of gastric and duodenal ulcers which have not improved as a result of the operation, or have recurred later, and several surgeons have recorded cases in which cancer has developed in the scar of an ulcer several years after the performance of a gastro-enterostomy. A jejunal ulcer is the most serious sequel; I believe it always heals eventually under the complete neutralization régime I have described. More frequently a certain amount of discomfort after meals, often associated with diarrhoea, which is occasionally very severe, follows the operation, sometimes only after several years of freedom from symptoms. It is true that the worst results follow gastro-enterostomy, when it has been performed for indigestion in spite of no ulcer being found at the operation. Excluding these cases, which all agree should never have been operated upon, a gastro-enterostomy is most likely to be successful when an ulcer is producing definite pyloric obstruction; equally good results follow a gastro-gastrostomy for organic hour-glass contraction. Moynihan has become so convinced that a gastro-enterostomy is unsatisfactory for gastric ulcers not causing obstruction that he now performs a partial gastrectomy instead, simple excision of the ulcer being in his

opinion insufficient. Although this operation or destruction of the base of the ulcer by a cautery, combined, if the ulcer is very large, with a jejunostomy, may occasionally be indicated, the operation is such a serious one that it should never be resorted to until the most thorough and prolonged medical treatment has failed.

Indications for Operation.

There must thus still be some uncertainty as to the exact indications for operation, but at present I would state them as follows:

1. At the earliest moment after a perforation.
 2. For pyloric obstruction without symptoms of active ulceration.
 3. For pyloric obstruction with symptoms of active ulceration, if the x rays still show well marked stasis after ten days of the complete neutralization treatment.
 4. For gastric ulcer causing organic hour-glass contraction.
 5. When the symptoms recur after one or more courses of thorough medical treatment followed by adequate after-treatment. The number of such courses which should be tried depends upon such circumstances as the age, social position, occupation, and place of residence of the patient; thus, the older a patient, the better his social position, the less strenuous his occupation and the less important occasional absences from business, and the warmer and more equable the climate, the less urgent is the necessity for operation.
 6. If severe haemorrhage occurs more than once, especially in patients past middle age, when it probably comes from a sclerotic vessel which cannot contract. An attempt should then be made to excise the ulcer, or, if this is impossible, to ligature the bleeding point; failing this a series of sutures should be tied round the ulcer so as to cut off as much as possible of its blood supply. Whenever possible it is best to wait until the patient has got over the initial collapse following a severe haemorrhage.
 7. When for any reason—such as the persistence of pain or of occult blood in the stools in spite of treatment—it appears possible that a growth is present, the abdomen should be explored, and unless a growth can be excluded with certainty partial gastrectomy should be performed.
- After any operation for gastric or duodenal ulcer the patient should follow exactly the same after-treatment as after medical treatment, or various ill results, which I have already mentioned, may ensue.
- In conclusion, I think we may look forward with confidence to a time when not only the medical treatment of gastric and duodenal ulcer will have become so efficient that operations will no longer be required for them, but prophylaxis will be brought into play so early and so adequately that actual ulceration will be regarded as a rare condition which should never be allowed to occur.

An Address

ON

SURPRISES IN DIAGNOSIS.

DELIVERED TO THE ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

BY

EDMUND I. SPRIGGS, M.D., F.R.C.P.

THE late Dr. Gee has recently been quoted as having said: "Medicine has three parts: the first is diagnosis; the second is diagnosis; and the third is diagnosis." Which is an allegory. If we look back on the progress of the art of diagnosis we observe that for centuries able minds had given themselves to the study of symptoms and signs, checking their deductions by the later development of the disorder. In the nineteenth century, to which Gee belonged, the study of morbid anatomy became general, with the result that enormous strides were made in the recognition and classification of diseases. No one can say how much more is to be learned by these methods as time goes on, though we must admit that we cannot hope to excel, if indeed to equal, those who have gone before in acuity of observation and reasoning. The introduction of aseptic surgery led to another great advance in the knowledge of disease by allowing the study of morbid anatomy during life. An exploratory operation is often a most valuable means of diagnosis, though all will agree that,

provided time and the condition of the patient allow, it should follow and not precede other investigations.

But in addition to the study of symptoms, aided as it is by a general knowledge of medicine founded upon normal and morbid anatomy and physiology, various scientific methods, belonging to the laboratory rather than the consulting room, have come into use, by which we may get closer to the knowledge of many disorders at an earlier stage. In some cases facts can be recognized which until recently could be learned only on the operating table; in others conditions can be found during life which were not revealed formerly until after death; and in yet others we can get information, for example, of the functional efficiency of the heart, digestive glands, stomach, and intestines, which neither the surgeon nor the morbid anatomist has ever been able to supply.

The progress of discovery of scientific methods such as may be used in the diagnosis of disease has naturally been faster than the growth of facilities for applying those methods to the needs of the general mass of sick folk. The poor in the large teaching hospitals have been the most fortunately placed, especially as regards the use of bacteriological and chemical methods of diagnosis. Medical work outside hospitals has also had the advantage of the services of excellent clinical laboratories in the great centres of population from which accurate reports can be obtained quickly by letter or telegram. Sanatoriums for special diseases have also long existed on the Continent, and a few in this country; and in many of these laboratory investigations were made either in the sanatorium or in its neighbourhood. It has been my lot to work at a private hospital which is, I suppose, as regards its particular character and range, the first of its kind in Europe, in so far as the physicians are able to follow the investigation of their patients—whether chemical, radiological, bacteriological, or protozoological—under one roof, and to control the food, drink, rest, exercise, and general mode of life during the process. Looking back over seven years the chief impression which remains, after the consciousness of errors and shortcomings of all sorts, is the impression of the constant interest which frequent surprises in diagnosis have given; an interest common, indeed, to all medical work, but shared especially, as I hope to be able to show you, by this particular kind of work.

I propose to relate briefly a few such surprises. The examples of unexpected diagnoses taken are, with one exception, not extraordinary. No attempt has been made to select rare complaints or find cases in which the disease has been thought to be in one part of the body and found in another; such outstanding surprises occur to all of us from time to time. My object is rather to illustrate the working of a routine in which clinical and laboratory methods are used together. Seven out of the eight diseases quoted are common or fairly common. The eighth, diagnosed as sprue, is included because of its special interest.

Hypochlorhydria (Achyilia).

This complaint may give rise to considerable derangement of health, and is, in my experience, seldom diagnosed from the symptoms.

1358. A middle-aged man complained of three months' discomfort in the upper abdomen and lower chest, coming on after food, relieved by application of heat but not by alkalis. Three years ago a diseased appendix had been removed; the gall bladder, duodenum, and stomach were then looked at and appeared healthy. A further operation was now contemplated. Chemical analysis of the gastric contents showed that the patient was the subject of a persistently poor gastric juice. On x-ray examination no evidence of a gross lesion of the stomach or duodenum was obtained. Treatment by dry diet, gastric lavage, acid and pepsin led to disappearance of symptoms.

677. A man, aged 43, after some years of overwork, had for six months felt weight in the epigastrium with regurgitation and loss of appetite. He had consulted distinguished members of our profession, who thought, as, indeed, my physician of experience might think from his story, that he was the subject of hyperacidity and perhaps duodenal ulcer. The analysis of the gastric contents (by Mr. A. d. Leigh, B.Sc.) showed -

	Free HCl.	Total Acidity.	Active Chlorides.
Test breakfast	Trace	3	Per cent. 0.01
Test lunch	Trace	14	0.01

The digestion of fibrin was very slow; it was improved by the addition of 0.04 per cent. HCl. X-ray examination of the alimentary tract showed nothing abnormal except some delay in the ileum. The urine and faeces were normal.

With treatment for hypochlorhydria steady progress was made, and the symptoms disappeared. Six weeks later the active chlorides were 0.03 per cent., a slight improvement. He continued at home the regimen advised, and has remained well. From time to time tests were made, with the following results:

	Free HCl.	Total Acidity.	Active Chlorides.
Three months later	Present	22	Per cent. 0.08
Nine months later	Present	34	0.13
Fifteen months later	Present	40	0.13
Eighteen months later	Present	46	0.18

showing that the gastric juice gradually regained its strength.

The diagnosis of hypochlorhydria must not be made upon one test meal, or even, unless all elements of doubt can be excluded, upon two results. The accidental factors which are most likely to alter the composition of the gastric contents, especially dilution with mucus or inadvertent taking of alkaline medicine, are factors which lessen the acidity of the material tested. Errors in analysis are also likely to tend the same way.

Amoebic Dysentery.

In the following case the diagnosis, though unsuspected, was made at once from the routine examination of faeces for protozoa.

1218. A patient had suffered from diarrhoea for eight years, during which time he had had the advice of several of our most able physicians and surgeons. He had been treated by vaccines, tuberculin, and rectal injections. The appendix and caecum had been removed. He was sent to Duff House by a surgeon for further observation before another operation was undertaken. The routine examination showed that cysts of *Entamoeba histolytica* were present in numbers. The sigmoidoscope showed superficial ulcers. With x rays the colon was seen to have an irregular ragged outline. The diagnosis made was "chronic amoebic dysentery with secondary ulcerative colitis." Under treatment with emetine the cysts disappeared in a month. The colon had suffered much damage during the eight years of illness, and improvement of the general state was slow though definite.

The patient had not lived in the tropics, and that was why the diagnosis of dysentery had not suggested itself to his former advisers, or to us before examination was made.

Sprue.

£51. A young middle-aged woman was admitted with a diagnosis of atony of the large bowel, ascribed to autoinfection, and leading to severe attacks of tetany. She had been ill on and off for years and a complete invalid for more than one year. Large motions had been passed since infancy. The average weight of the stools (taken over seven days) in the first weeks of her stay varied from 250 grams (with 85 per cent. of water) to 600 grams a day, the normal weight for a healthy woman of her small build being about 100 grams a day. Ulcers of the mouth and tongue were troublesome. X-ray examination revealed nothing abnormal. The faeces were light and semi-liquid; a chemical examination of them, the patient being upon a fixed diet, showed that absorption of fat and protein was deficient. The following table shows the amount of nitrogen, carbohydrate, and fat in the diet and faeces and the proportion absorbed:

	Grams per Day.		Percentage of Dry Faeces.	Percentage Absorbed.
	In Diet.	In Faeces		
Nitrogen	13	2	4	85
Carbohydrate	178	2	5	99
Fat	98	20	47	80

Pancreatic disease was suspected, but the pancreatic ferments, trypsin (in faeces) and diastase (in urine), proved to be present in normal proportion. A diagnosis of sprue was then made, although the patient had only once been in the tropics, and some of her symptoms had been present before she made that journey. Appropriate treatment by a meat diet was instituted. In three months the ulceration of the mouth was gone, and there was no tetany. A steady recovery followed, and faecal analysis six months later showed that assimilation had

become normal, the daily weight of faeces being 97 grams, with 74 per cent. water.

	Grams per Day.		Percentage of Dry Faeces.	Percentage Absorbed.
	In Diet.	In Faeces.		
Nitrogen	18	2	7	90
Carbohydrate ...	237	0.4	1.5	99.8
Fat	131	6	24	95

The average daily weight of stools sank to 90 grams.

Glycosuria.

A gratifying class of case is that in which diabetes is suspected but the glycosuria turns out to be of different type. In these patients there has often been a lesion or operation about the epigastrium, from which, presumably, the pancreas has been affected.

845. A woman over 50 was sent for treatment for glycosuria, but also complained of pain and vomiting. She had had cholecysto-duodenostomy performed for jaundice. The sugar in the urine never exceeded 9 grams a day, with plentiful carbohydrate in the food, and was evidently not the cause of the loss in weight. X-ray examination showed that the stomach did not empty itself and that a constriction of the duodenum was present, for which a further operation became necessary. The symptoms had been masked by the daily use of an opium pill.

92. A man approaching 60, suffering from loss of weight and energy, with glycosuria, was found to be also the subject of anaemia and a hypotonic dropped stomach. Tests showed that the quantity of sugar passed was always small, between 1 and 6 grams per day, and bore no reasonable relation to the carbohydrate in the food.

Date.	Sugar (per Day).	Carbohydrate in Food (per Day).
August 7th	3.1 grams	154 grams.
September 6th ...	1.0 gram	13 grams (strict diet).
September 8th ...	6.4 grams	100 grams dextrose and an ordinary diet.
September 9th ...	2.8 "	Ordinary diet.

The opinion was given that the glycosuria was not of importance. Six years have passed, during which there has been no restriction of carbohydrate in the food, and the patient remains well.

Such patients have come to us less frequently of late; perhaps because tolerance tests are made more often than they were formerly.

Chronic Appendicitis.

The following case illustrates the value of x-ray examination after a barium and buttermilk meal in the diagnosis of chronic appendicitis:

554. A young man had ill health at intervals since childhood, including pneumonia, pleurisy, intermittent pyrexia, and "colitis." He was thought to be tuberculous. These illnesses had prevented him from remaining at school. He joined the army, but was invalided out. X-rays showed that the appendix filled in its proximal part and showed vigorous contractions. The shallow bayoud was dilated with an irregular cupped or V appearance due to barium reaching round the sides of a faecal mass. This part and the base of the appendix were tender.

At operation two inflamed enlargements of the appendix were found. There was no appearance of tuberculosis in the appendix or surrounding peritonium. The subsequent progress makes it probable that the pyrexial attacks he had suffered for years were due to chronic appendicitis.

Carcinoma Recti.

532. An elderly man was sent for colitis of fifteen months' duration. The routine microscopic examination of the motions showed the presence of pus and blood. With x-rays dilated ileal coils were seen and the sigmoid was segmented irregularly. The sigmoidoscope was then used and a growth found 12 cm. from the anus. Surgical aid was sought and a colostomy done, which enabled him to follow his occupation for more than two years.

Mediastinal Growth.

550. An elderly man was sent for treatment for diabetes, his doctor mentioning that he had an irritable cough, which might be due to too much smoking, and had had one or two febrile attacks. On examination some rhonchi were heard at the right base, with diminished breath sounds. Three days later a faint stridor was heard. The x-ray screen showed the presence of a mediastinal growth.

Calculus.

936. An elderly man complained of constipation, piles, frequency of micturition and sometimes discomfort or pain. He had passed blood in the water seven years before and had been x-rayed twice and told there was no stone. X-ray examination showed a large stone in the bladder, of which I show you a radiograph on the screen. It was removed with complete relief.

At former x-ray examinations the whole urinary tract had been screened but photographs had been taken of the kidney region only.

In considering such surprises in diagnosis as those related, and many others, I became curious to know how often they occurred; and it seemed that it might be of interest to express by figures the assistance given by laboratory methods in the diagnosis of a series of cases. So far, about 1,500 cases have been admitted, but for the present purpose I have confined myself to an analysis of the last 500, and have made a comparison between the preliminary diagnosis and the diagnosis after investigation. In considering this analysis one or two points must be borne in mind:

First, the patients are not average patients, but are selected, many of them not having been sent to Duff House until after they had been suffering for some years. In a good proportion the medical advisers of the patients had taken them for consultation to various physicians and surgeons. We may fairly assume that in most of these cases considerable skill and experience had been brought to bear upon the diagnosis of the condition, so far as that can be made from the symptoms, signs, and history. In many cases also certain investigations, such as x-ray examinations, had been made before admission. Nearly two-thirds of the cases (62 per cent.) were abdominal in type.

The second point which I wish to make clear is that in the following series I am not comparing the diagnosis before admission with the diagnosis made after admission. The comparison lies between the first diagnosis made by us upon the history, symptoms, and physical signs, with the valuable help given by the patient's medical adviser or advisers, and the second diagnosis made after such scientific investigation as seemed desirable had been carried out. On admission the patient's history is taken, his symptoms are noted down, and a physical examination made. It is from this information that what I call the preliminary diagnosis is noted. I need hardly say that in most cases it corresponds with the opinion expressed by the patient's medical man in his letter about the case. After investigation the case is reviewed again, and then is made what is called in the following classification the second diagnosis.

The third point is sufficiently obvious. It is that when I speak of the routine examination I do not mean that every patient is subjected to the same routine. The examinations made are those which appear to be directed to the symptoms complained of. The more general ones are chemical and microscopical examination of urine and faeces, including examination for bacteria and protozoa, of gastric contents, and sputum if present, special examination of nose, throat, and rectum, x-ray screening of the chest, photographing of the abdomen for opacities, and examination after a barium meal. In cases of deficient absorption, particularly suspected pancreatic disease, a valuable test is the analysis of the total excreta upon a fixed diet for a period of three days.

Sources of Error.

Fourthly, we do not, of course, assume that the second diagnosis is final and comprehensive. Although in most instances the development of the case or an operation showed that it was near to the truth, there was a proportion of errors and inaccuracies, and of these I shall speak in discussing the various classes in which the cases are ranged. There are doubtless also other errors, so far undiscovered or not known to us.

CLASS I.

In the 500 cases, 53 were of diabetes, in which the diagnosis itself offered no difficulty, though the determination of the kind of case and the appropriate treatment calls for prolonged daily dietetic and chemical observations; 2 others were thought to be diabetes but proved to be a different form of glycosuria, and are not included. Of the

53 diabetic cases, in 48 there was no unexpected complication. In 5 others were found: in 2 heart disease, one Bright's disease, one a large abscess in the leg, and one tobacco poisoning.

CLASS II.

In 143 cases the diagnosis made after investigation coincided in all important respects with the first diagnosis made on the history, symptoms, and physical signs. If we add to these 143 the 53 cases in Class I we find that in 196 cases—namely, 39 per cent. of the whole—the preliminary diagnosis, so far as we were able to test it, was correct.

CLASS III.

In another large class the second diagnosis confirmed the first one, but some material and important point was added by the investigation. For example, a case diagnosed as gastric ulcer found to have a severe constriction of the stomach, a case of ulcerative colitis found to have a cancer of the sigmoid, a case of obesity found also to be suffering from malaria, would be put in Class III. In this class there were 96 cases, made up as follows: In 10, in addition to the condition diagnosed, an affection of the appendix was present, confirmed by operation in 5. In 5 others the presence of gall stones was detected. In 5 the diagnosis was corrected as to the position of an ulcer, a supposed duodenal ulcer being found to be gastric or vice versa. The other findings were: Hyperchlorhydria, 8 cases; hypochlorhydria, 5 cases; amoebic dysentery, adhesions of the bowels, 4 cases; constriction of stomach (verified by operation), gastric ulcer, duodenal adhesion, constipation, alcoholism, over-smoking, nervous exhaustion, 3 each. There were also 3 cases in which intestinal stasis had been diagnosed, but in which the delay proved to be rectal only. Cancer of the bowel, cancer of the stomach, anaemia, ulcerative colitis, 2 cases each; diabetes, constriction of the oesophagus, deformity of stomach, constriction of the colon, adhesions about the gall bladder, colitis, sigmoiditis, *fistula in ano*, sprue, renal calculus, pyelitis, bacilluria, paratyphoid carrier, septic tonsils, deficient teeth, pyorrhoea, heart disease, fibroid lung, bronchitis, pleuritic effusion, climacteric, post-influenzal toxæmia, malaria, 1 each. Diverticula of the intestine were also found in several cases, but did not seem to be associated with symptoms.

CLASS IV.

Is really a subclass of Class III. It contains 83 cases admitted with a diagnosis of one of two or more gastrointestinal lesions—that is to say, the case was regarded as probable appendix, or duodenum; or gastric or duodenal ulcer; or ulcer or gall stones, without specifying which; and it was desired to ascertain, if possible, whether such a lesion were present, and if so where it lay. In 74 of the 83 the diagnosis was justified, evidence of lesion being found. The second diagnosis was as follows: Duodenal ulcer 16 cases (9 operations); chronic appendicitis 30 cases (22 operations); gastric ulcer 7 cases (2 operations); growth of bowel or stomach 5 cases (2 operations); ileal bands or adhesions 4 cases (2 operations); severe constriction of bowel or stomach 3 cases (3 operations); lesion of gall bladder 3 cases; retrocaecal appendix 2 cases (1 operation); deformity of duodenum, cancer of liver, adhesions after operation, and pancreatic disease—1 each. In 9 cases no mechanical lesion was found; 2 were the subjects of hyperchlorhydria, 2 of achylia, and in 5 no disease of importance was discovered.

CLASS V.

Next is a small class of 18 cases of patients seeking relief after gastro-jejunostomy. In 16 of these evidence of some abnormality in the working of the stoma or a lesion in the neighbourhood was found; 6 of these have so far been operated upon again with excellent results; in 2 the stoma was working well and no mechanical abnormality was found.

CLASS VI.

I come now to a class in which the second diagnosis differed materially from the first, having neither been

mentioned by the medical adviser of the patient nor diagnosed by ourselves in our preliminary examination of the case. In this class there were 95 patients, and the second diagnoses were as follows: Chronic appendicitis 16 cases (5 operations so far); achylia 9 cases; duodenal ulcer, gastric ulcer, heart disease—4 each. There were also 4 cases in which intestinal stasis had been diagnosed but was not found present. Bronchiectasis, tobacco poisoning, caseous masses in the abdomen, phthisis, renal calculus, mediastinal growth, necrosis—3 each. Uterine myomata, prostatitis, hyperpiesis, hyperchlorhydria, colitis—2 each; amoebic dysentery, fibroid lung, bronchitis, anaemia, constriction of duodenum, growth of the bowel, adhesions of the bowel, growth of the stomach, volvulus, atonic stomach, enteroptosis, pancreatitis, gall stones, cholecystitis, constipation, sprue, uterine retroflexion, lesion in splenoidal cell—1 each.

It will be noticed that cases have been included in this group—phthisis, bronchitis, fibroid lung—in which the diagnoses may have been made by physical examination. These were patients in whom either a lesion which had not been detected was found during continued observation, or in whom the effects produced had been ascribed to some other cause which was not found to be present.

I have also added to this class 5 cases in which no first diagnosis, except that of a symptom, was made. Two complained of headaches: one was found to have chronic appendicitis, and the headache was relieved by removal of the appendix; the second was found to be suffering from an error of refraction and hyperchlorhydria. A third patient complained of irregular mild indigestion, and was found to be the subject of constipation and hyperchlorhydria. The fourth complained of headaches and constipation, and was taking excess of tobacco; and the fifth complained of palpitation, and was the subject of anaemia and basal bronchitis.

CLASS VII.

In this class are three cases in which no diagnosis was made and the examinations were negative.

CLASS VIII.

The last class consists of 8 cases in which errors in diagnosis were made. In 4 cases the second diagnosis was frankly wrong. In one of them a shadow was diagnosed as a renal calculus, which proved to be a gall stone. A second diagnosed as splenic anaemia proved to be malignant disease. In another the diagnosis was made of a retrocaecal appendix and deformity of the duodenum; the appendix was retrocaecal and diseased, but no lesion of the duodenum was found. In a fourth a diseased appendix was diagnosed and a lesion of the stomach; cancer of the stomach was present, but the appendix was healthy.

In a fifth case the appendix, which lay deeply in the pelvis, filled in part only and was tender, and was thought to be abnormal; at the operation it was reported healthy and the symptoms ascribed to ptosis of the caecum. The case is not, however, conclusive, as no microscopical examination of the appendix was made. We have repeatedly found small lesions of the mucosa causing symptoms of appendicitis which are not detected by external examination of the appendix.

In the remaining three cases, although the diagnosis made was correct so far as it went, something important was missed. In one chronic appendicitis was diagnosed, but gall stones were also present and had not been detected. In another cancer of the stomach was diagnosed successfully, gall stones again being missed. In a third chronic appendicitis was diagnosed and was present, but a tumour of the pancreas had not been detected, although the surgeon's attention was directed by us to that region because an unusual deformity of the duodenum, which we could not explain, was caused by the tumour. I show you the radiograph on the screen.

In palliation of these errors it may be said that in every one of the patients in this class, with the doubtful exception of the fifth case, the operation advised was necessary.

The following table summarizes the figures which have been quoted.

Summary of Statistics.

		No. of Cases.	Per cent.
Class I ...	Diabetes	53	19.6
Class II ...	First diagnosis confirmed	143	28.6
Class III ...	First diagnosis confirmed with addition	96	19.2
Class IV ...	(a) First diagnosis confirmed with differentiation	74	14.8
	(b) First diagnosis not confirmed	9	1.8
Class V ...	Gastro-jejunostomy	13	3.6
Class VI ...	Second diagnosis differing materially from the first	96	19.2
Class VII ...	No diagnosis	3	0.6
Class VIII...	Errors in second diagnosis	8	1.6
		500	100.0

It has probably occurred to my readers that the various classes into which I have divided the cases run into one another and that the boundary line must often have been indefinite. This was so, and on that account the actual figures must not be taken too seriously. If there has been bias in the process of classifying I have tried to direct it towards the swelling of Class II—cases in which the first diagnosis was confirmed—and Classes III and IV a—in which the diagnosis was added to or made more accurate, rather than towards Class VI, in which the diagnosis was altered.

In the following table some of the classes are thrown together to obtain a general view.

General Classification.

		No. of Cases.	Per cent.
Class I	First diagnosis confirmed	196	39.2—40
Class II			
Class III	First diagnosis confirmed with important addition or differentiation	170	34.0
Class IV a			
Class VI			
Class IV b	Diagnosis altered after examination	105	21.0

Therefore, in 40 per cent the diagnosis was confirmed, and in 55 per cent. it was modified or altered.

We may summarize the figures by the statement that out of 500 consecutive cases of varying nature, of which two-thirds were abdominal cases, the first diagnosis made on the history, symptoms and signs was confirmed by appropriate laboratory examinations and tests in 40 per cent. of the cases, was materially added to or modified in 34 per cent., and was altered in 21 per cent.

It appears, therefore, that in over half of the cases a material advance was made in diagnosis by the methods of investigation used.

We must never forget, ladies and gentlemen, that the ultimate unit is the patient and not the case. No objective investigation will ever enable us to do without personal observation. A laboratory report may be the corner-stone of the diagnosis, but it cannot of itself be the diagnosis. For example, a man may harbour the germ of an infective disease or may have a stone in his kidney whilst his ill health is due to another complaint or condition altogether. The doctor must observe and appraise the patient himself, his symptoms, signs, temperament and circumstances, using also all other means that the growth of knowledge has given.

[The address was illustrated by lantern slides.]

CONCLUSIONS.

1. The first need in diagnosis is the careful study of the history, symptoms, signs, and general condition of the individual patient. By such means an accurate diagnosis was made in 40 per cent. of 500 patients.

2. In a large proportion of cases, especially those in which the functions of secretion, nutrition and excretion are affected, or in which infections, calculi or growths are present, the routine use of scientific methods of investiga-

tion is an invaluable aid. In over half of the series of 500 cases the preliminary clinical diagnosis was modified or changed after routine investigations had been made.

3. Facilities for such examinations are at present widely needed, especially for folk of moderate means as compared with those who are treated in public hospitals and with the well-to-do.

4. For want of such investigations large numbers of patients are given advice and treatment which is not the best suited to their complaints, hundreds of unnecessary operations are done, and hundreds of operations that ought to be done are left undone.

RESULTS OF THE PEPTONE TREATMENT OF ASTHMA.

WITH A NOTE ON THE TREATMENT IN CERTAIN PATHOLOGICALLY ALLIED CONDITIONS.

BY

A. G. AULD, M.D., M.R.C.P., D.P.H. OXON.,
LONDON.

In previous communications¹ the peptone² treatment of asthma was described in detail, and it may now be profitable to consider the extended results. These are based on a fairly large number of cases, all of which received treatment over a year ago. It was formerly pointed out, *inter alia*, that certain types of cases were amenable to the treatment; that the method of immunizing depended on the type of case; that no reaction appreciable to the patient should follow the injection (intravenous); and that the latter should be made slowly.

The treatment has been instructive in respect of the grouping of asthmatical cases. Two main groups occur which show no tendency to pass into each other. One group comprises such as quickly respond to the treatment, and the effect is more or less lasting, the recurrences being infrequent and milder in character. The other group is resistant, and is subdivisible into such as are totally resistant and those in which, by careful immunization, the disease may be largely overcome.

Group I.

The first group presents as a rule most of the following characteristics: General good health, little family predisposition, limited duration of the disease (though a variable factor), regularity in recurrence of attacks, freedom from bronchitis and emphysema. This group is illustrated by such cases as the following:

Male, aged 22. Has suffered for four years. Attacks occur regularly every night during winter and spring; less frequent in summer. They last from one to three hours, and some relief is obtained by burning asthma powder. Is quite well in the daytime. After seven injections the attacks began to yield and ceased entirely after the tenth. The patient remained quite free of asthma for about a year, when he returned desirous of having some treatment as a prophylactic for the winter months. There has been no return of the asthma.

The relief, however, is not usually as complete as this. More frequently the history is somewhat as follows:

Female, aged 37. Asthma four and a half years; worse in summer. Is disturbed practically every night by slight attacks, for which she burns the usual powders, but, in addition, about every three weeks she suffers a bad attack which prostrates her one or two days. The response to treatment was very rapid, she soon began to have good nights, and could exert herself without any respiratory discomfort. After eleven injections she remained quite free for five months, when the disease returned in a milder form. Another short course of treatment was given, and during the next year she only had three slight attacks.

Such cases might be multiplied almost indefinitely. The treatment is simple and the results very gratifying. The only trouble encountered is the taking of "colds," to which our population is doomed during the greater part of the year. This is often a most distressing factor, and one can only wait and resume.

Occasionally cases are encountered which, from the

¹ Although it is the proteose fraction of the peptone of commerce which is the active ingredient, I have retained the term "peptone," as it has not yet been proved that the peptone fraction is without any effect.

history, would seem to belong to the second group, but in reality are of the simpler type. As an instance:

Female, aged 45. Has suffered for eighteen years, the asthma developing after childbirth. At first the attacks occurred about monthly, but then changed to weekly. Worse in summer. Attacks last on an average twelve hours. A short course of treatment brought the attacks to an end, no trace of the disease appearing for many months. During the past year she has only had occasional mild attacks, brought on, as she thinks, by indigestion.

None respond better to the treatment than children. In them I make the injection into the spinal muscles, basing the practice on an observation by Meltzer that the venous arrangements in these muscles are such as to cause the absorption of the medicament to approximate more to an intravenous injection. Witte's peptone must not be used, as it may cause a severe local reaction. Most other varieties, however, are innocuous in this respect. The same dose as that used intravenously for an adult should be given, but in double concentration.

Boy, aged 6. Shortly after birth developed eczema, which lasted for two years. On its disappearance asthma set in. The attacks lasted from a few hours to a week; then about a week's respite. All the year round. The attacks quickly began to yield and ceased after eight injections. He remained perfectly well for three months, when an attack supervened. Seven months elapsed before he had another, then three months, and four months. It has not been necessary as yet to repeat the treatment.

Girl, aged 3½. Attacks since the age of one year, lasting for three days. Then about four weeks free, with perfect health. She received eight injections into the spinal muscles, and now seventeen months have passed without any recurrence.

Boy, aged 15. Asthma for five years. Attacks lasted seven days with two months' interval; all the year round, and also after exercise, such as games. Since treatment two years ago, he has not had a trace of asthma, and can play a strenuous game of football.

Bronchitis complicating asthma in a child is not the bar to treatment which it presents in an adult. None of the children hitherto treated have been refractory.

Group 2.

A few observations may first be made regarding cases which resist the treatment. They include nearly all those with chronic bronchitis and developed emphysema, and cases presenting any degree of cyanosis, even without bronchitis. Also those in whom, apart from the asthmatical paroxysms, a more or less oppressed condition of the respiration is practically never absent. As a rule, the affection has lasted many years, dating from childhood, or from the age of puberty, and a family history of asthma can nearly always be elicited; sometimes hay fever also is found. Often the only effect that can be produced in such cases by means of peptone—and it has very important bearings—is the complete suppression of the attacks for a short period by a mildly toxic dose. For two or three weeks the patient for the first time experiences complete relief and thinks a cure has at last been made, only to be sadly disappointed. The dose of peptone necessary to effect this desensitization must be carefully considered in relation to the individual case, and should produce, in from one to two hours, headache, malaise, shivering, slight rise of temperature, sickness, with pain in the abdomen and diarrhoea. Sometimes a herpetic eruption occurs about the mouth or more widespread.

But this group also includes many cases in which very satisfactory results may be obtained, as follows:

Male, aged 29. Asthma for twenty years, induced without any obvious cause, but also precipitated by what he described as "horse dust." Of rather an asthmatic "habit," breathing slightly laboured, a low degree of emphysema, with a fairly good chest expansion. Bronchitis was occasionally troublesome, and there was considerable expectoration after the attacks. These occurred as a rule nightly, but from time to time he had bouts lasting a few days. After three weeks' treatment there was no definite improvement. The method of immunizing was modified, and the dermal reaction to peptone recorded. In the fifth week a definite improvement set in, and after eight weeks the asthma had ceased; there was no oppression of the chest, and he could easily and freely expand it. A year later he wrote: "During the past year I have not had one bad day or night; only one or two slight attacks owing to weather changes."

Immunization in Certain Cases.

In regard to the immunization in difficult cases there are two if not three necessary considerations: (a) The rate of injection of the peptone and its dilution, (b) the peptone

to be used, and (c) the indications afforded by the dermal reactions as the case proceeds. If the patient takes the peptone well larger doses may succeed, given by very slow injection to avoid reaction. If the patient is sensitive to peptone, however, great care is required, as the larger dose given in this way may precipitate an attack of asthma. Rarely this occurs very quickly—in a few minutes—with concomitant flushing of the face, especially if Witte's peptone be used, which seems to contain a toxic ingredient not present in muscle peptone. Again, a mixture of peptones sometimes succeeds best. The dermal reaction (which may be produced by a von Pirquet cover) is not of much value at the beginning, as non-asthmatical subjects may give it, and it varies considerably in different persons, but as immunization proceeds it ought to lessen, and finally disappear—that is, show no distinction from the control made with the solution in which the peptone is dissolved. Experience proves that the immunizing injection should never reach the critical point; it only injures the immunity mechanism. As a general rule also, there ought to be three clear days between each injection. Another case in which the result was very satisfactory may be cited:

Female, aged 23. Had suffered severely since 3 years old. Had tried every known alleged remedy without any benefit. The attacks lasted from four days to a week, with about three weeks' remission. During this time, however, she suffered from constant nocturnal asthma, lasting from 2 a.m. to 7 a.m. Had but little bronchitis and a very moderate degree of emphysema. Improvement did not set in until the fifth week, and from this time onwards the patient had "tightness" in the chest but no definite attack. This sense of tightness or oppression was only induced on exertion. She continued so for three months, when attacks began, but lighter in type. Another course of treatment was given, with the result that only the "tightness" remained as before, and a few months elapsed ere the attacks recommenced. They did not last long, and for months past the patient has been better than ever before.

Reference may finally be made to two cases which closely resembled each other and showed features of considerable interest:

Boy, aged 14. Fairly well grown, but of the asthmatical "habit." The disease had existed "ever since birth." Family history of asthma. Attacks occurred about every ten days, and lasted three to five days, when he had to be propped up in bed. Was well between the attacks. Dieting was without any influence. The attacks were preceded and ushered in with sneezing, headache, sickness with vomiting, diarrhoea, and fainting fits. Treatment revealed that the boy was sensitive to peptone, 10 minims of a 2 per cent. solution of Witte's peptone producing a distinct reaction. It was diluted with beef peptone and carefully regulated. Practically to time the attack came on, but the next attack, though punctual, only lasted one day. The next, however, did not arrive until the eighteenth day, and was of a light character. Treatment was continued for two months, with an interval of ten days after the first month (this is often advisable in sensitive cases). The attacks had now ceased, and during the next two months he had only two minor attacks. For the last eighteen months occasional but much lighter attacks have occurred, and the boy has gained much in weight and looks ruddy.

The interesting point in the case is that the onset of the attack was accompanied by symptoms identical with those following a mildly toxic dose of peptone, and herein may lie the explanation of the condition of sensitiveness to that substance on the patient's part. Curiously enough, while this boy was under treatment another case, also in a boy, with practically identical history and symptoms was encountered. The attacks also began with headache, shivering, vomiting, etc., and for years he had suffered severely. The result of treatment was excellent, as he has only had two minor attacks in the course of the past year.

In the large number of cases of asthma treated during the past three years the patient's diet has been largely a negligible factor. The diet must, of course, be regulated, but the cutting out of certain articles rarely produces any marked or lasting effect. No doubt there are cases, but they form a small class, in which idiosyncrasy exists in respect to some particular food (which may be entirely carbohydrate). The same applies to asthmas caused by animal or vegetable emanations. Again, the dyspnoeic attacks in bronchitis may be due to the products of bacteria locally. But in the great majority of genuine asthmatics the explanation is rather to be sought in a defect in the hydrolysis or metamorphosis of foreign protein residing in the digestive organs or in the lymph or the body cells. To this protein poison the asthmatic

individual is sensitive, and the bronchial muscles contain the dominant receptors for it.* This sensitiveness may be either hereditary or acquired, and is influenced by climatic and other environmental conditions. This leads one to consider the likelihood of other organs or tissues behaving in a similar manner, and causing recurrent fulminant disorders in which no local gross lesion is discoverable. The fact that in animal experiments the protein poison or a foreign protein selects different organs in relation to the species may be of some significance in this connexion.

The Application of Peptone Therapy to Cases Pathologically Allied to Asthma.

It has just been stated that where sensitiveness to a particular foreign protein exists, it is common to the organism as a whole, though the brunt of the attack seems to fall on a particular part—in the case of asthma, on the smooth muscle of the bronchi. Such a part or organ possesses a positive chemotactic relationship to the antigen, either from some peculiarity in itself or in the antigen. An antigen similar in nature, therefore, to that which provokes asthma in one individual may cause explosive attacks in the stomach or liver or central nervous system or circulatory system, etc., in others. I first put this view to the test some little time ago in a case of migraine:

Female, aged 37. Had had right-sided migraine since the age of puberty. Looked well, and was otherwise in good health. At first the attacks occurred about once a month, but during recent years they recurred regularly once a week. No family history of migraine or asthma. Diet was without any influence. Worse in spring. They began with pain and throbbing in the right side of the head, which gradually got worse, and attained its maximum in twelve hours. Then sickness with vomiting came on and lasted about half an hour, which seemed to bring some relief. The pain then gradually subsided, and in another twelve hours the attack was over. The peptone was administered as for asthma. A day or two after the second injection the attack was due, but did not appear. The patient, however, reacted to the third peptone injection (showing sensitiveness), and this caused a headache which lasted a few hours. The dose was reduced, and the peptone slightly altered. Excellent progress was made, the attacks becoming slight and infrequent, the last report stating that the patient was completely free from headaches.

Of course one swallow does not make a summer, but as a beginning it is encouraging. Treatment is also being tried in cases of severe recurrent gastric and hepatic attacks which prostrate the patient at the time and are succeeded by a variable period of good health, but the time for their discussion is not yet ripe.

Rationale of the Treatment.

It must in the first place be recognized that, though it may be convenient and indeed correct to speak of these cases as "anaphylactic," yet there is no such thing in nature as the anaphylactic shock which we artificially produce. Clinically, "anaphylactic" means sensitive. But when we inquire how the immunization by means of peptone may be supposed to act, the phenomenon of artificial anaphylaxis forms the basis of our conceptions. This phenomenon is brought about by whole protein as the antigen. Proteose, on the other hand, is only feebly antigenic—that is, it has but slight power of sensitizing to itself; it does not form complement binding antibodies, nor does it produce a precipitate with the homologous serum. In view of the importance of the latter point in anaphylaxis, serums from two cases treated with peptone were kindly examined for me at the Lister Institute, but with entirely negative results. As to the power of proteose to desensitize to whole protein, the experimental results are rather conflicting, as many of them were obtained by denatured proteoses, but there is certainly an effect.

In artificial anaphylaxis a shock is produced which in no respect differs from primary peptone shock. This is true not only of the general reaction, but also as regards those local reactions which are characteristic of the species, and extends even to the microscopical changes. Thus, in the guinea-pig the bronchial spasm; in the dog the swollen and highly congested liver; and in the rabbit the block in the cardio pulmonary circulation are equally produced. It was also found by Dale and Laidlaw⁴ that

the isolated virgin uterus of the guinea-pig, when placed in a bath containing a solution of Witte's peptone, responded by a contraction identical with that given by the sensitized uterus when bathed with the antigen. Hence it looks as though the toxic substance were identical in the two cases, the substance in the case of anaphylaxis being produced by lysis of the antigen by antibody and complement, and in the case of the peptone being more or less openly present.

But the matter is not so simple. Van Slyke and Whipple⁵ have demonstrated that when a toxic or subtoxic dose of proteose is introduced into the blood there is a great and rapid increase in autolysis of body protein. The non-protein nitrogen of the blood is increased by 40 per cent., chiefly blood urea nitrogen, though the amino and peptide nitrogens are also increased. The possibility is not excluded that "among the products of induced autolysis there may be toxic proteoses which add their effect to the injected or absorbed proteose." Hisanobu⁶ lately confirmed these results, and also obtained precisely similar but rather more intense changes in anaphylaxis. He concludes that the poison in both must be identical. It may be noted that support is given to the view that the poison may be a specialized product of tissue autolysis from the fact that the reaction can be induced by certain non-protein substances which can only be supposed to exert their effects through injury to the protein of the host. Certain inorganic colloids have very remarkable powers. Thus, colloidal silicic acid is capable of taking the place of immune body in the lysis of red blood cells by complement. The toxic body, if produced from the interaction of antigen and body protein, is related to the rapidity of the injection, as a similar amount of antigen slowly injected may be void. At a certain point cell oxidation may be suddenly paralysed and a product result of the type of histamine or muscarine. Some observers have regarded this poison as originating in the liver.

The view that there is a toxic substance common to anaphylaxis and peptone shock does not commend itself to Dale. In his recent Croonian Lecture⁵ he inclines to the view that these factors have a similar action because a change in the state of dispersal of the cell colloids is common to both, which, in the case of anaphylaxis, does not call for the intervention of a poison at all. No doubt such an aggregation might be produced in either case, and cause changes in surface action and osmotic pressure, together with a certain amount of depolarization of the cell membrane, but it is scarcely likely that such an excessively minute quantity of native protein would cause the extreme permeability which occurs in the endothelium of the blood capillaries, as in those of the liver in the dog, and other profound effects of the shock. Dale counters this with the statement that the antigen, when applied to the isolated anaphylactic uterus, acts in about ten seconds, and it is difficult, he says to suppose that this time suffices for the elaboration of a poison. He also finds that the reaction is largely governed by a stereo-chemical relationship of antibody and antigen. But is not the very object of this configuration on the part of the antibody the rupture of the molecule?

Another consideration introduced by Dale is rather puzzling. The instructive fact is recorded that the serum of the immune animal is capable of conferring passive anaphylaxis even better than that of the anaphylactic animal, its efficiency being closely parallel to the intensity of its precipitating quality. It is found in immunity experiments that the anaphylactic antibody fluctuates with the precipitin, and the two may be identical. The resistance of the immune animal Dale considers to be due to abundance of antibody in the blood which uses up the antigen before it can reach the tissue cells, the shock being caused exclusively by the cellular reaction, as it can be produced in the isolated uterus of the immune animal. But it is admitted that the blood of the anaphylactic animal contains no precipitin, and the shock is attributed by Dale to the absence of antibodies from the blood which have migrated to the tissue cells. How, then, it may be asked, is this blood, deprived of antibody (and precipitin), capable of conferring passive anaphylaxis?

Contraction of an isolated muscular organ is only one element in a very extensive picture, and until some more convincing evidence is forthcoming, the anaphylactic shock and peptone shock may be regarded as produced by an identical toxic substance. Immunization by peptone

* This view was put forward by the writer in the JOURNAL in 1903 as "a defect of metabolism the burden of which comes to be thrown on the lungs."

therefore is applicable to cases in which the symptoms may be caused either by whole or split foreign protein. The milder cases of asthma are probably associated with the latter, clinical evidence for which has already been recorded, and one attack affords little or no protection. A good example of the same thing is afforded in the malarial paroxysm. In many of the severe cases of asthma no doubt a larger molecule operates which is antigenic, and is succeeded by a period of desensitization. In either case protease confers on the body fluids a resistance to the induced poison, when used either in small immunizing doses, or in one dose large enough to produce a definite reaction.

Non-specific immunization does not possess the independence of action which is the prerogative of the specific (in the bacteriological sense). Hence the necessity during treatment of a carefully regulated mode of life. This comprises strict moderation in diet, and, above all, abstinence from alcoholic stimulants, the avoidance of chills, the avoidance of any exercise entailing a marked degree of hyperpnoea, and of anything which raises the normal body temperature, as hot baths of any kind. The patient should go to bed early, and ought not to indulge in social or other excitations, or in changes of residence. After the treatment, preventive measures will naturally be thought of in relation to many of the cases. The protein poison has been found to pertain to the acidic portion of the molecule, and its effects are to some extent neutralized by the simultaneous introduction into the body of alkali. A course of mildly alkaline treatment by natural waters or otherwise from time to time may therefore prove of some service as a prophylactic.

THE MYOCLONIC FORM OF EPIDEMIC ENCEPHALITIS.

By PIERO BOVERI, M.D.,

PRIVAT DOCENT OF THE UNIVERSITIES OF PAVIA AND TURIN;
FORMERLY DIRECTOR OF THE FIRST SECTION OF THE NEURO-
LOGICAL MILITARY CENTRAL HOSPITAL, MILAN.

The systematic and comparative study of many cases of encephalitis in the principal hospital in Milan enables us to state that besides the classical form of lethargic encephalitis, in which lethargy, fever, and ocular paralysis are the cardinal symptoms, other clinical varieties, less frequent and greatly different, are to be recognized. We can sometimes observe cases in which the symptoms are not lethargy, but excitement, delirium, and myoclonic contractions.

The two following cases are of this second or myoclonic type:

CASE I.

A girl, aged 19, entered the hospital on January 21st last. No hereditary antecedents; she had had influenza with bronchopneumonia in October, 1918, and typhoid fever in January, 1919. On January 17th she began to feel great pain in the muscles of the neck and shoulders, and a few days later she had fever and delirium.

The symptoms present were: Slight cyanosis of the face, injection of the ocular conjunctiva, irregular contractions of the hands, and delirium; the temperature was 38.2° C., the pulse 104, and the respirations were 25; arterial blood pressure 145 mm. (Riva-Rocci). No paralysis of the eyes nor of the cranial nerves. Pupil reflexes to light and to accommodation present and well maintained. Cutaneous and tendon reflexes normal. A lumbar puncture gave the following result: Liquid perfectly clear, at almost normal pressure; albumin just noticeable; Nonne and Boveri's reactions negative; six lymphocytes per cubic millimetre (Cellule de Nageotte). Cultures from the blood and cerebro-spinal fluid gave negative results.

The patient remained in this condition for about ten days. On February 4th there appeared in the flexor muscles of the arm and of the hand and fingers on both sides, but mostly on the right side, short rhythmic contractions at the rate of 66 to 68 per minute. In the right thigh a contraction of the quadriceps was observed, which produced attempts at flexion of the hip. No sensory troubles were present. Two days later, to the above movements were added slight inspiratory contractions of the diaphragm, synchronizing with the contractions of the arm. These movements continued even during sleep. There was no lethargy. The pupillary reflexes to light

and to accommodation were always regular and no paralysis of the cranial nerves was demonstrable.

This is still the condition of the patient, who at present has pain in the arms.

CASE II.

A woman, aged 40, entered hospital on February 16th last. No hereditary antecedents; no history of influenza. On January 25th there had been great pain in the left arm and shoulder, passing to the right side and the abdominal wall. Shortly afterwards rapid and rhythmical muscular contractions appeared which convulsed the patient. There was delirium, with slight fever; no lethargy, no affection of ocular motion nor of sight.

On entering the hospital this woman, who was of average physical development and well nourished, presented a curious and striking symptom-complex. The right sterno-cleido-mastoid and trapezius muscles and the diaphragm exhibited rhythmic contractions, forty-eight per minute. She perspired freely, and was agitated and delirious. No paralysis of the ocular and cranial nerves. No symptoms in the lower limbs. All reflexes normal. Lumbar puncture gave clear liquid, with increased pressure; albumin 0.2 per cent. Nonne and Boveri's reactions negative: five elements per cubic millimetre (Cellule de Nageotte); temperature 37.8° to 38° C.

Five days later the contractions of the neck ceased; at the same time strong rhythmic contractions, which never for a moment left the patient, appeared in the abdominal wall. Synchronizing with the abdominal and diaphragmatic convulsions, the right thigh presented rhythmic contractions of the abductor muscles and sometimes of the sartorius. Such is the patient's condition at present. All these muscles are painful, as well as the back and the whole arm.

The striking symptom in these two cases was the presence of myoclonic movements, both rhythmic and partial, as though produced by an electric current.

We can therefore speak of a myoclonic type differing from the lethargic type, for a certain period of the disease at least. Thus, while waiting for etiological enlightenment we should speak of epidemic encephalitis in general, and should divide it into lethargic and myoclonic types according to the different symptoms noted.

This myoclonic form of encephalitis naturally leads us to ask whether we are in the presence of the disease described by Dubini,¹ and called by him "electric chorea." It has not been mentioned since his time (1840-1870). He presented to the seventh meeting of Italian scientists (1846) a memorandum describing a new disease of which he had studied 38 cases in a period of nine years. "It is," Dubini writes, "nearly always a fatal disease," characterized "by muscular contractions occurring at different intervals, but always identical in each case, as if produced by a repeated electric current. These convulsions affect at first a finger or limb (more frequently the right upper limb) or one-half of the face (the right) and in a few days invade the whole of that side of the body." Dubini added that, in addition to these rhythmic movements, convulsive attacks might occur two or three or even more times a day, giving way afterwards to paresis and paralysis. Dubini's description was followed by those of Fraa,² Morganti,³ Pignacca,⁴ Stefanini,⁵ Behrend,⁶ and, later, Grocco, 1884.⁷

However accurate were the observations made by these scientists in the middle of the last century, the limited pathological knowledge which then existed did not enable them fully to appreciate their significance; reading to-day all these memoranda, we see described under the name of Dubini's disease a great number of cases which could better be classed as typhoid or malarial fevers, or Jacksonian epilepsies. Apart from this question, it seems to us that Dubini's disease might be connected with the myoclonic form of epidemic encephalitis as we see it at present.

The difference of the symptoms seen in the lethargic and the myoclonic types suggests a different pathological localization of the virus. In the lethargic form the encephalitis is localized particularly in the regions of the cerebral peduncles and the locus niger. It is a question whether in the myoclonic type the centres of infection might not in different degrees and in a transitory manner be localized in the optic thalamus.

* See P. Boveri, Société de Neurologie de Paris, March 4, 1920. It is there stated that in the lethargic form of encephalitis one of the first and most important signs is the paralysis of pupillary accommodation, while the reflex to light may be maintained.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SPONTANEOUS RUPTURE OF MALARIAL SPLEEN.

AN ex-soldier, aged 25, was admitted to King Edward VII Hospital, Windsor, sent in by Dr. Osborn of Windsor. On the morning of admission, while wheeling a wheelbarrow he was attacked by violent pain in the back and in the abdomen on the left side.

On admission the pulse was soft and fluttering, 124, and the respiration rate was 42. The rigidity of the abdomen was extreme above the umbilicus, and the patient laid particular stress on pain in the left shoulder and behind the shoulder blade. He gave a history of malaria contracted in Turkey in 1919 and repeated slight attacks since.

Under an anaesthetic a large spleen could be felt easily, and incision showed the peritoneum full of blood. The large spleen presented in the median incision, and on examination showed on the posterior superior surface a rent some 2½ in. long, which was bleeding freely. Sutures proving useless; the spleen was excised, the operation presenting no difficulty.

Examination of the removed organ showed great enlargement but no sign of "ague cake." On the superior surface were the remains of some fine adhesions, and the remnants of one of these by the edge of the tear in the spleen leads one to suppose that the fixation of the spleen by these adhesions led to the rupture. Fourteen hours after removal the spleen weighed 1 lb. 9 oz., though it had partly dried.

With the exception of two slight malarial attacks the patient made an uninterrupted recovery and left the hospital in excellent health twenty-six days after operation. The blood contained a large quantity of malaria parasites.

In this case time and blood were lost by endeavours to check the haemorrhage instead of at once proceeding to splenectomy. The median incision was found very suitable for removal of the spleen, as the hilum could be reached with ease.

VENTRIFIXATION BEFORE THE MENOPAUSE.

THE following case may be worth recording if only as a warning to those surgeons—and there are some—who consider that the operation of ventrifixation can be performed with impunity in all cases of prolapsus uteri, notwithstanding warnings as to its danger of performance in most textbooks.

Mrs. P., aged 26, a unipara, suffered from prolapsus uteri after the birth of her child, aged 4, and was operated on in 1915, ventrifixation and shortening of the round ligaments being performed.

She again became pregnant, and the child was expected to be born in the first fortnight of July, 1918. Throughout this pregnancy she complained of pain and "a lump" in the right side of the abdomen, apparently the fetal head. This gradually rose higher until finally it was in contact with the rib in the region of the gall bladder; during the last two months she remained in bed owing to the discomfort. On July 6th I was sent for to see the patient as she was having labour pains. I was again sent for on July 16th; for some hours she had been having regular pains, apparently those of the first stage of labour. I did not see her again until the following night. The pains had continued, but there had been no vaginal discharge. She was becoming exhausted. I now made a vaginal examination for the first time; no part was presenting and the os could not be felt. The vagina was filled in front by a tense swelling, and it was some time before I realized what had happened—namely, that the uterus had practically turned a somersault, the fundus being down in the pelvis and the os at the gall bladder, with the vagina stretched and elongated into a narrow tube.

She was removed to the Forest Hospital, and in the early hours of the morning I performed Caesarean section, Dr. B. F. Pendred assisting. On opening the abdomen the fundus uteri was found attached, by a strong fibrous

band just above the pubis, to the anterior abdominal wall. The os was in the region of the gall bladder; consequently the posterior wall of the uterus was forwards, and through this I had to make my incision. The uterine wall was not more than ½ in. thick. A dead female child and placenta were delivered. I was then surprised to find a second child; its head was partly through the os, and so firmly grasped by the ring of Bandl that it took some minutes to deliver. I sutured the walls of the uterus, and the fibrous band having been divided, it contracted and righted itself, so that my sutures then became posterior.

The patient and second child made an uneventful recovery, excepting for a slight rise of temperature for one or two days in the second week, for which I could not account.

GEO. NORMAN.

ACUTE OEDEMA OF THE LUNGS.

IN connexion with the descriptions of this condition which have recently appeared in the JOURNAL, the following case may be of interest. It is very similar to that reported by Dr. Brown in the issue of March 27th.

A retired farmer, aged 65, the subject of chronic nephritis, with high blood pressure, generally about 200 mm. Hg, had six months ago a small cerebral haemorrhage, from which he recovered well, and, except for some dyspnoea, was in fairly good health. He went to bed as usual on the night of March 22nd, 1920, and awoke at midnight with a sensation of suffocation, and began to expectorate quantities of pink froth. When I saw him he was cyanosed (ashy grey), sitting up in bed, and constantly spitting up this froth. Fine crepitations could be heard all over both lungs; the pulse was rapid and irregular, but the restlessness, which had been very marked at first, had ceased. I gave him morphine sulphate gr. ¼ hypodermically, and made preparations to perform venesection. However, in a short time his colour had improved, the expectoration was less, and in an hour he was asleep. Later in the day he seemed fairly well; except for coarse moist sounds at the bases the lungs were clear, but the pulse remained rapid. He was given a mixture of ammonium carbonate, tincture of digitalis, and trinitrin, and has now practically regained his former state of health, except that his blood pressure is 230 mm. Hg.

Dr. R. A. Young, writing in Latham and English's *System of Treatment*, recommends prompt venesection, followed by injections of strychnine and atropine. In my case the man's general appearance certainly suggested venesection, and I should have performed it if the more easily available remedy had not been successful.

KENNETH ANDERSON, M.B.Lond.,

Banwell, Somerset.

M.R.C.S., L.R.C.P.

I HAVE read with interest the various accounts given recently of experiences of acute pulmonary oedema. In twenty years' experience of general practice I have seen two cases.

The first was a tragic occurrence. During my very early years as an assistant in Warwickshire I was asked to see a platelayer who had been working in his garden in the morning apparently in his usual health when a sudden attack of pain in the chest forced him to go to bed. When I saw him about noon he was sitting up in bed spitting up large quantities of white frothy fluid. His temperature was normal, and there was no cardiac or respiratory distress. The chest was amazingly full of râles. I told his wife to apply a poultice, mainly, I am afraid, to give her something to do, and to give me, in my inexperience, something to say. I did tell her that I was not sure what was the matter, and asked her to send for some medicine. I mounted my horse and rode away. After I left the wife busied herself in the kitchen getting materials for the poultice. She then went upstairs and found her husband dead. Apparently he was drowned in his own secretions. This occurred within fifteen minutes of my departure. I happened to see the late Sir Robert Simon that day, and he gave me the diagnosis of acute pulmonary oedema—a condition I had never heard of. He also directed my attention to five recorded cases, four of them rapidly fatal; the fifth recovered because the visiting physician dosed him with heroic doses of tincture of belladonna, of which he fortunately had a supply in his pocket.

My second case occurred in 1918, when I was in charge of the medical division of the 36th Stationary Hospital at Gaza. A man, aged 50, belonging to a garrison battalion of the Northants Regiment, was brought in late one night with symptoms similar to those in the case described above but with much dyspnoea and cyanosis in addition. The orderly officer (Captain Soden, R.A.M.C., T.) did not call me but treated the case with hypodermic injections of atropine, which promptly relieved the urgent symptoms. The lungs cleared up rapidly within two or three days.

Winchcombe.

WILLIAM S. SCOTT.

Reports of Societies.

AT a meeting of the Pathological Section of the Liverpool Medical Institution, held on March 18th, with the President, Dr. J. E. GEMMELL, in the chair, Professor ERNEST GLYNN contributed a critical review of so-called "ovarian hypernephromas." He was of the opinion that such tumours were exceedingly rare, if they ever did occur, and gave three reasons for his view: (1) there was only one recorded case of a cortical rest in the ovary (1913), and even this was doubtful and unconfirmed by other observers. It was undoubted that such rests were frequently found in the broad ligament. (2) Ovarian hypernephromas were never associated with hirsuties and changes in the sex characters so common in primary neoplasms of the adrenal cortex in women before the menopause. (3) There was little if any difference, clinically and histologically, between ovarian tumours described as "hypernephroma" and as "malignant lutein" formations respectively, yet both these tumours were apparently quite unlike true neoplasms of the adrenal cortex itself. Dr. G. F. R. SMITH read a paper on the urine after anaesthesia, based on a quantitative investigation of acidosis following various types of anaesthesia. He noted the development of acidosis after ethyl chloride and ether as well as chloroform, and discussed predisposing causes. He was of the opinion that warmed ether given by the open method to a patient not unduly starved before operation was the safest anaesthetic available.

Reviews.

ANTE-NATAL AND POST-NATAL PHYSIOLOGY.

DR. FELDMAN'S book, *The Principles of Ante-natal and Post-natal Child Physiology, Pure and Applied*,¹ marks a distinct step forwards in our knowledge of young life in its intimate and essentially most important characters. It does more than this, but it does this in the first place. With this book in hand we start afresh and from a new vantage point in our understanding of the physiology of the most obscure part of child life (the ante-natal) and of the most dangerous to health (the neonatal); and it will not be Dr. Feldman's fault if the clinicians and the hygienists do not pass onward to new triumphs of preventive and curative medicine founded thereupon. It may be possible with great labour to find much of the content of the book in monographs and periodicals scattered through the literature of all countries, and in that sense novelty may be lacking; yet it is a strikingly novel work, by reason of the fresh facts and conclusions revealed by the simple bringing together of the many data in it. It has the resultant novelty of a wider and a newer outlook, which is also more penetrating in its intensity.

It is admirable in its arrangement. After a general introductory chapter which has for its heading Samuel Butler's paradoxical truth, "birth . . . is commonly considered as the point at which we begin to live; more truly it is the point at which we leave off knowing how to live," Dr. Feldman divides his subject matter into three parts—ante-natal physiology, natal, and post-natal—and subdivides the first of these into ante-conceptual, conceptual, and post-conceptual or intra-uterine, with a further subdivision of the post-conceptual into germinal, embryonic

and fetal. The life after birth is dealt with under the four headings of neonatal, infancy, childhood, and puberty. The continuity of the life which begins in the germ cells is thus traced onward up to the time when it in its turn is ready to initiate a new life at puberty. At each stage in this process the characters of the vitality differ, in the earliest stages most startlingly, and Dr. Feldman succeeds well in tracing the physiology of each, so that in his chapters fertilization, Mendelism, heredity, development, pre-natal metabolism, neonatal rearrangement of function, child life all fall into their proper places and serve to explain each other. To the physiologist as well as to the pediatric physician there will not be a chapter which does not supply some new seed-thought from which others will spring. One of the most striking features of the book is the evidence it affords upon almost every page of the modern tendency of physiology to become increasingly mathematical, and perhaps on that account more exact; not only is this seen in such a chapter as that on the bio-dynamics of growth (where it was to be expected) and in those on the mechanics of development and of the child's body, but also in those dealing with the circulation and the nervous system both before and after birth. The physiology of the prematurely born—a subject of immense importance from the point of view of life-saving—is treated at the end in a special chapter; but we miss an adequate consideration of the companion and yet widely different problem of the infant post-maturely born. There are, of course, many blanks in our knowledge of the physiology of all these periods of life, and more especially in the ante-natal, and these are necessarily reflected in this work: but they are not faults in the author; indeed, but for him we should not be able to put our finger upon them, and his book will do much to stimulate others to undertake the task of expanding our scientific acquaintance so as to fill up all such lacunae.

There are some 700 pages in the work, and on almost every one of them will be found a thought-stimulating statement. There are numerous plates, including some photographs of well-known workers in this most modern field of research; there are 129 illustrations, and there are crowds of tables and schemes. There are two excellent indexes. The language is always clear and terse, if at times a little inclined to the bare condensation of the textbook which aims at curtailment of space; now and then the greatness of his subject grips the author and shows itself in a sort of restrained enthusiasm, restrained as befits a scientific work and yet enthusiastic because here one is dealing with the very springs of life and its feeling after measures of preventive medicine with almost unthought-of beneficent possibilities. Dr. Feldman has not only written a good book: he has accomplished the yet more valuable achievement of putting forth a work which will stimulate physiologists, obstetricians, and pediatric physicians everywhere, and which will give origin to many other books, small and large. His own book will be often quoted, and it will be many a time utilized without being quoted, as all really stimulating and progress-making books are. The science of child welfare, ante-natal and post-natal, is making great strides in these days, both in its scientific and in its practical aspects, and it has found an invaluable ally in the present work.

MINERS' NYSTAGMUS.

DR. STASSEN of Liège, in his book on fatigue of the visual apparatus in miners,² has written a very useful little monograph on miners' nystagmus. This disease, as is well known, has only recently attracted the attention it deserves. The coal miners of the past, although daily running the risk of explosion, do not seem to have suffered from nystagmus. By 1860, however, the use of the safety lamp had extended, and the results of diminished illumination began to be observed. Stassen traces his subject from the pit-head, where the miner enters the cage with his eyes adapted to "cone" vision in bright light and with his aerial apparatus adapted to atmospheric pressure, to the bottom of the shaft and the coal face, where his eyes have now to be adapted to "rod" vision in a dim light and his labyrinth subjected to a higher pressure. The author has

¹ *The Principles of Ante-natal and Post-natal Child Physiology, Pure and Applied*. By W. M. Feldman, M.B., B.S. Lond. Longmans, Green, and Co., London, New York, etc. 1920. (Demy 8vo, pp. 721; 6 plates; 129 figures. 52s. net.)

² *La fatigue de l'appareil visuel chez les ouvriers mineurs*. By Dr. M. Stassen. Liège: H. Vaillant-Carmanne, 1914-1919. (Demy 8vo, pp. 233; 20 figures.)

examined also the conditions obtaining in iron and zinc mines, where nystagmus among the workers, though not unknown, appears to be much less common than among those who work in coal mines.

A full account is given of the various sources of illumination employed and of the different lamps in use. Numerous illustrative cases and statistical tables add greatly to the value of the book. Stassen considers that deficient illumination and strained position at work are the main causes of nystagmus, and, in agreement with most of the authorities in this country, considers that the former plays the more important part.

The last two chapters in the book deal with the law of accidents occurring in cases of nystagmus while at work, and also with the prevention and treatment of the disease. A good bibliography accompanies the monograph, but it is disfigured by faulty spelling of the names of English writers.

DIPHTHERIA, MEASLES, AND SCARLATINA.

DIPHTHERIA, measles, and scarlet fever are important causes of death, especially in the young; thus, in the year 1919 there were just over 500,000 deaths in England and Wales, and nearly 9,500 of them were due to one or other of these three specific fevers. An excellent account of their symptoms, diagnosis, prognosis, and treatment is given by Dr. F. V. G. SCHOLLS in his *Lectures to Students on Diphtheria, Measles, Scarlatina*.⁵ The author is Medical Superintendent of the Fairfield Hospital at Melbourne, and writes with the authority of what is clearly a very large experience of these diseases.

Half the book is taken up with the consideration of diphtheria; Dr. Scholles is very firm and precise in his instructions as to the early and adequate use of antibiotic serum in these cases, and brings out many interesting points as regards prognosis and treatment in the analysis of the 19,000 cases he has dealt with. It would be interesting to know what line of treatment he would adopt in the case of the inveterate and incurable carriers of virulent diphtheria bacilli sometimes met with, that resist all ordinary forms of local disinfection and treatment; fortunately they are very rare. In his chapters on measles he notes the rarity with which second attacks of the disease actually occur—something over a hundred seem to have been reported—and contrasts it with the frequency with which patients give a history of two or more attacks; such histories he rejects, and adds that he has himself seen but one "possible case" of recurrence. Describing scarlatina, he gives an interesting discussion on its incubation period—which seems to be from two to seven days in one group of cases, from eight to twelve days in another—and on surgical scarlet fever: the difficulty lies in the existence of numerous atypical cases of the disease, in which fever or sore throat or the characteristic eruption may fail to appear.

The book is full of facts, clearly written, and well arranged; the treatments advised are fully described and practical hints abound. We recommend the volume very warmly to senior medical students engaged in doing their course of instruction in "fevers," and to medical men, who will find in it a thoroughly practical discussion of an important subject.

CHLORINATION OF WATER.

THE *Chlorination of Water*,⁴ by Dr. JOSEPH RACE, is a most excellent and painstaking account of the whole subject in its various aspects, handled in a manner which denotes first-hand knowledge of facts. The book is dedicated to Sir Alexander Houston, whose great services in the purification of drinking water are so well known. After a few preliminary historical notes, the author considers the *modus operandi* of chlorine and hypochlorites, discusses the bacteriological aspect of chlorination, and explains the quantity of "bleach" required, its admixture and accurate estimation. The fifth chapter is

founded on the author's extensive experience in dealing with complaints received from persons using chlorinated water. While laying stress on the importance of giving very careful attention to such complaints, he makes the observation, with which others having experience in the matter will agree, that auto-suggestion has frequently much to do with the objections made. He takes as an example the causation of colic; in the amounts of chlorine used for purifying a drinking water, a person would have to drink 140 gallons of chlorinated water in order to obtain the very ordinary medicinal dose of one grain. During the war, on several occasions, such complaints were heard in France when in point of fact the water had not been chlorinated at all; in many of these cases the complaints were lodged by members of the medical profession. The advantages and disadvantages of various plants are discussed, as are also economic considerations. The work ends with a clear summary of results. There is an appendix and a good bibliography. Mr. Race is to be most heartily congratulated on the production of a book which will be a standard work on the subject of chlorination of water; it will undoubtedly interest and quite conceivably instruct all those authorities in whose hands lies the control of drinking water.

INDIGESTION.

THE fourth edition of the late Dr. HERSHELL'S *Textbook of Indigestion*,⁶ revised and rewritten by Dr. ABRAHAM, has been extensively remodelled by its editor. Though containing chapters on organic disease of the stomach, a subject excluded from previous editions, the book is notably smaller than its predecessor; Dr. Abrahams employs an economy of words and repetitions for which his readers will be grateful to him. The first two chapters deal with normal digestion and the general nature and causation of indigestion; the next seven are given to the various methods of investigation to be employed in cases of indigestion, and the author is to be congratulated upon the sound judgement with which he assesses their relative values and trustworthiness. The remaining ten chapters are devoted to acute and chronic gastritis, gastric and duodenal ulcer, malignant disease and dilatation of the stomach, pancreatic and reflex indigestion, the association of indigestion with organic affections other than gastric, and nervous indigestion.

An appendix of fifty pages, mainly the work of the late Dr. Hershell, deals with the cooking of food for patients with indigestion. Dr. Abrahams has produced an excellent book full of practical advice and common sense, which should enjoy wide popularity.

NARCOTIC ADDICTION.

PROFESSOR BISHOP'S little book on *The Narcotic Drug Problem*⁶ gives a highly sympathetic account of the subject, a picture of the light in which sufferers from the drug habit would wish their proclivity to be regarded. The condemnatory terms "drug habit" and "drug fiend" Professor Bishop would replace by the non-committal names "drug addiction," "narcotic addiction," "drug disease," and "drug addict"; he believes that neurotic tendencies, weakness of will, perverted appetite, and the like are of no importance in the production of the average drug "addict." The majority of them, he says, acquired their narcotic addiction accidentally or innocently, and "had no voice nor conscious part in the early administration of opiate, realizing no desire or need for it by name, but only wishing for the unknown medicine which relieved their sufferings." In an appendix Professor Bishop quotes a practising physician who says that "there are estimated to be as many as 500,000 or more addiction cases in the State of New York alone." It is not easy to realize the circumstances in which the majority of so large a number of people could come to be taking opiate drugs by accident or in innocence.

Professor Bishop would treat drug "addicts" by reducing the opiate gradually to the minimum found by experience

⁵ *Lectures to Students on Diphtheria, Measles, Scarlatina*. By Frank V. G. Scholles, M.D., B.S. (Melb.), D.P.H. (Camb.). Medical Superintendent, Infectious Diseases Hospital, Fairfield, Melbourne. Melbourne: Modern Printing Company Pty., Ltd. 1920. (Demy 8vo, pp. 236.)

⁴ *Chlorination of Water*. By Joseph Race, F.I.C., City Bacteriologist and Chemist, Ottawa. London: Chapman and Hall, Ltd. New York: John Wiley and Sons, Inc. 1918. (Demy 8vo, pp. viii + 158; 12 figures, 16 diagrams. 7s. net.)

⁵ *Dr. G. Hershell's Textbook of Indigestion*. Revised and rewritten by Adolphe Abrahams, O.B.E., M.D. (Camb.), M.R.C.P. (Lond.). Fourth edition. London: Edward Arnold, 1920. (Demy 8vo, pp. 228; 8 plates, 10s. 6d. net.)

⁶ *The Narcotic Drug Problem*. By Ernest S. Bishop, M.D., F.A.C.P., Clinical Professor of Medicine, New York Polytechnical Medical School, etc. New York: The Macmillan Company, 1920. (Cr. 8vo, pp. 165, 8s. net.)

necessary in each individual case; he disapproves of the treatment by sudden withdrawal and the substitution of other drugs, such as belladonna, hyoscyamus, and pilocarpine, for the opiate. Many "addicts" can be cured completely; in others the disease can be arrested, and the patient will continue to take the minimum daily quantum of opiate, in doses at intervals as wide apart as possible. The co-operation of the patient, it is said, is rarely withheld if he is treated rationally by his medical attendant. The book gives a gloomy view of the present outlook of the rational drug "addict" in New York, where the strict laws regulating the use and abuse of opiates make no allowance for his needs and existence.

AUSTRIAN MEDICINE.

A CAREFUL effort to rehabilitate Austrian medical science and the ancient school of medicine at Vienna lies before us in the form of the first number of a new periodical, the *Wiener Archiv für Innere Medizin*,⁷ dated March 1st, 1920. Under the editorship of Professors FALTA and WENCKEBACH, two painstaking, honest, ingenious, and speculative medical men, this periodical bears on its cover the names of the most eminent professors of medicine and its allied subjects in Austria; its contents are to deal with the clinical and experimental sides of the whole subject of internal medicine. The first number contains six papers: the first of these, by Professor Wenckebach, is on pathological forms of the thorax and of respiration, and all six are on subjects of clinical importance. One could wish that the editors had thought fit to make all their contributors summarize their conclusions or deductions under a few numbered headings at the end of their articles. This practice has the double virtue of compelling the long-winded to be at any rate in part concise, and of enabling the reader to extract with speed the few needles of valuable fact that so often lie hidden in the haystacks of verbiage to which those who write for archives, particularly archives in the German tongue, are so notoriously prone.

NOTES ON BOOKS.

DR. SOUTHARD presents *Shell-shock and other Neuropsychiatric Problems*⁸ to physicians and experts in mental disease, in the form of nearly six hundred case histories drawn from the vast literature of the subject. At the end of the volume is a briskly written summary or epicrisis, in which the use of the term "shell-shock" is defended: the various types of shell-shock cases are noticed, and diagnosis and treatment are briefly discussed. Over two thousand references to the literature are appended to the volume. An interesting feature of the book is Dr. Southard's use of the first two hundred cases to illustrate defects or pathological conditions which furnish weak spots for the development of "psychopathia martialis" when the sufferer is exposed to a strain too great for his individual endurance or moral.

Mr. STANLEY UNWIN'S little book on *The Work of V.A.D. London 1 during the War*⁹ gives a clear and admirably written account of the doings of this detachment, contributed by half a score of authors who were the officers most closely identified with the work described in its eleven chapters. Varied the duties of the detachment certainly were. They included such things as attendance at Buckingham Palace, transport of the wounded, air-raid duties, entertaining the wounded, and many other less well defined businesses. The work of the Voluntary Aid Detachments during the war has not hitherto received due notice, commendation, or reward, largely, no doubt, for want of proper knowledge of their performances. We commend Mr. Unwin's volume to all our readers, and trust it may be successful in drawing attention to the merits of a most hard-working branch of Red Cross activities.

TAXATION OF MOTOR CARS.

THE NEW TAXATION.

BY H. MASSAC BUIST.

THE Government's new scheme for the taxation of motor vehicles follows the suggestions of the Departmental Committee on the taxation and regulation of motor vehicles in Great Britain and Ireland in the Interim Report, details of which are published at page 575. Those concerned with the use of privately owned passenger vehicles regret that, beyond recognizing the desirability of a single tax on the motor movement as has been urged in these columns at intervals for years past, there is no evidence in the scheme of recommendations that any progress is to be made towards adopting a suitable basis of taxation. While motorists in the aggregate are sufficiently broad minded to recognize that the fuel situation is too complex for the revenue to be raised by taxing motor spirits of every sort; nevertheless, they did not expect that the only alternative would be what is in effect an aggravation of past errors by retaining the Treasury R.A.C. engine rating, and employing it as the sole means of arriving at a single tax; yet, where motor bicycles are concerned, the method of tax is precisely that proposed for motor vehicles, and advocated in these columns for privately owned passenger cars, namely, weight. Moreover, as showing the unfairness of the proposed law, it may be pointed out that a firm might design and build a motor bicycle of any size and power not weighing more than 7 cwt., so that, in effect, it might be rigged up as a Rolls-Royce limousine, yet the maximum tax in respect of the use and ownership of it would be £3 a year. That point is the basis of a very amusing illustration in *The Motor*.

Theoretically and Practically Undesirable.

The two bodies concerned with the interests of passenger motor vehicle owners are the Royal Automobile Club and the Automobile Association. The representatives of the former body are, in effect, silenced on the point of tactics, because the Treasury rating is practically based on the R.A.C. formula; but the A.A.'s representative, Major Stenson Cooke, is responsible for the minority report noted below. The Automobile Association itself is strongly opposing the proposals of the Taxation Committee, and has started a vigorous parliamentary campaign on what are, however, lines doomed to failure, and deservedly so, because they are based on the mere iteration of the point that motor spirit is the fairest basis of taxation. While the bodies which profess to represent the views of motor users reveal such an absence of mental grasp it is not to be expected that this or any other Government will do that which is best in the interests of passenger car users.

The seriousness of the situation is that this obstinate adherence to an attitude that has been proved impossible leads to the institution of a single tax on another wrong basis, namely, by Treasury horse-power engine rating, which for perhaps half a generation is likely to determine design in favour, for example, of a relatively long-stroke and, in any case, high-speed engine. If the argument is that there is no positive committal on the part of the Government to an indefinite continuance of the proposed scheme of taxation of privately owned passenger motor vehicles, then we find only that injury of another sort is being done, for designers and manufacturers will have to live from year to year in apprehension of yet another change in taxation schemes, and owners will never know to what they are committing themselves when they buy any given type of car.

Making Confusion Worse Confounded.

Of course, what we want in taxation, as in individual and collective activities, is a fixed basis for reconstruction and an end of all disturbances and doubts. But obviously, before we fix our basis, we should make sure that it is satisfactory. For example, while the proposed quarterly licence scheme as a concession towards recognizing the amount of road use a motorist shall enjoy for his tax is a step in the right direction, there is bound to be ill feeling on the part of numerous owners of Ford cars about the country when they find that they have to pay £21 a year where the owner of a post-war Rover, for example, has to

pay £13 a year. Yet we cannot expect the engine-rating scheme to be reversed to favour the Ford car against the bulk of the English cars which have been designed for years past under the influence of the Treasury horse-power rating scheme.

Far from being proportionate to road wear and tear, the proposed tax is based on the principle that the more you motor the lighter the tax and the less you motor the heavier. For example, the theory is that a Ford owner driving 10,000 miles a year would really be economizing £4 14s. 10d. under the proposed scheme because the existing horse-power and petrol tax on that mileage would work out at £22 19s. 4d. On the other hand, if the mileage were 7,500, the new tax would represent an extra expenditure of 2s. 4d.; if it were 5,000 miles, he would be £4 19s. 7d. out of pocket; while if he motored 2,500 miles a year only, he would have to pay £9 16s. 10d. more than his present horse-power and petrol taxes combined.

Doubtless the proposal to abolish the rebates hitherto granted to medical men is based on the assumption that as their cars are used for their work they get the advantage of having an annual mileage of round about 10,000 as distinct from the 5,000 mark, which would mean that with petrol rebates currently in force they would be saving about £12 a year on a Ford car on a 10,000 miles basis, for it should be noted that the official figures of the Ministry of Transport omit the rebates granted to medical men. In one sense, too, the withdrawal of the tax from the fuel is a greater boon to the medical man than to the average motorist, because the very nature of a doctor's work necessitates his undertaking the maximum amount of acceleration, as in constantly starting on a series of relatively short runs, so that he uses proportionately more fuel.

The curious thing is that the committee on whose report the Government is acting states that it considered various other suggested bases of taxation, and that the only one which showed any prospect of providing a possible solution was a tax on tyres. Yet for purposes of taxation it classifies motor bicycles and commercial motor vehicles in relation to weight. Why is unladen weight impracticable for privately owned passenger vehicles while it is practicable for motor cycles and commercial motor vehicles? No light is thrown on this.

The scale of horse-power basis of rating private cars is now much more finely graduated than the present Treasury rating in force, and a refund is allowed in respect of the ownership of old engines, which means incidentally that Ford cars of pre-war production should be in more demand than the post-war series. Fortunately the new scheme is not to come into force in any case until the end of the year. Whatever the fate of that part of the Budget proposals which concerns the basis of taxation on passenger cars, it is certain that all motorists will have to carry yet another "gadget" on their motor vehicles, for the new style licence will have to be displayed on them. The report says that this must be done "in a conspicuous place where it [the licence] can be seen by any passenger or when the vehicle is stationary by any police or taxation officer, and to be protected against damage by rain or other causes." How it is expected, as the report hints, that this scheme will probably check the stealing of cars is at present a mystery.

RECOMMENDATIONS OF THE DEPARTMENTAL COMMITTEE.

The interim report of the Departmental Committee on Taxation and Regulation of Road Vehicles in Great Britain and Ireland,¹ referred to above by Mr. Massac Buist, was issued on April 16th, two working days before the Budget. The problem the Committee was set to solve was how might best be raised an annual revenue estimated at £7,000,000, which, after payment of the contemplated contributions by the central Government towards the maintenance of the first and second class roads, would still leave in the hands of the Ministry of Transport a sufficient sum to enable a substantial measure of new road construction and road improvement to be undertaken forthwith.

¹ Under the proposals of the Committee the whole of the increased contributions towards roads will be borne by the owners of mechanically propelled vehicles. It is not

much consolation to be told that the Committee regards this as a temporary arrangement due to the immediate necessity to provide moneys for roads and to the existing financial conditions. It holds that at the earliest opportunity the Exchequer should provide out of general funds a fair proportion of the highway expenses.

The Committee by a majority advises the abolition of the motor spirit duty because the system of rebates occasions difficulty of collection, because it fails to cover all the liquid fuels used for mechanical traction, and because it applies to imported fuel only. The petrol companies have given an assurance that if the duty of 6d. be taken off they will immediately reduce the price to the public by 7d., the additional 1d. representing a saving to the suppliers in respect of administration expenses. The Committee points out that the price of petrol to-day is governed by the fact that the demand has outrun the supply and that the market is a closed one, in which there is no effective competition. The Committee is thus in disagreement with the Central Committee on Motor Fuel under the Profiteering Act, 1919, which expressed the view that so long as any special taxation is thought necessary in the case of motor cars, a tax on motor fuel would be more equitable than a tax on cars. The Committee received applications from clergymen, road surveyors, commercial travellers, and relieving officers, asking that they should be granted rebates similar in character to those granted to medical practitioners and veterinary surgeons. The Committee, however, decided to recommend the abandonment of the principle of rebate in respect of any classes of car, commercial or other. The Committee has, however, made two exceptions. The first is in the case of private cars the engines of which were constructed prior to 1913, for which they recommend an allowance of 25 per cent., because the rating of this engine is considerably higher than of a modern car developing the same horse-power. The concession is considered expedient in order not to hamper the continued use of cars of obsolete type at a time when the supply of new cars is not equal to the demand. The other exception will apply to power alcohol, to home produced benzol and to shale motor spirit. The Committee advises that in the event of any duty or excise being charged on such fuel, or mixtures containing such fuel, the duty or excise shall be recoverable by any consumer who has paid a statutory vehicle duty.

The Committee recommends that all licences should expire on fixed dates—yearly licences on December 31st, and quarterly licences on the last day of March, June, September or December. It is recommended that the new rates should come into force on January 1st, 1921. The following are the rates for motor cycles, motor vehicles for invalids, and private vehicles; the rates for commercial goods vehicles are added for comparison.

	£	s.	d.
<i>Motor cycles</i> (including motor scooters and other motor-assisted cycles)—			
Weight not exceeding 200 lb. unladen ...	1	10	0
Weight exceeding 200 lb. ...	3	0	0
With trailer or side car, and other motor three-wheelers ...	4	0	0
<i>Motor vehicles for invalids</i> electrically or mechanically propelled, bath chairs or other vehicles for invalids, not exceeding 5 cwt. in weight, inclusive of any batteries ...	0	5	0
<i>Private motor cars</i> , including three-wheelers weighing 7 cwt. or over unladen: £1 per unit h.p. with minimum of ...	6	0	0
Electrically propelled private cars to pay only the minimum rate of ...	6	0	0
Owners of private motor cars the engine of which was constructed prior to January 1st, 1913, are entitled to a rebate of 25 per cent. of the duty.			

Quarterly licences on private motor cars to be issued on payment of 20 per cent. above one-fourth of the annual duty (that is, 30 per cent. of full annual duty). Motor cycle licences taken out in the last quarter to be 50 per cent. of the annual charge.

	£	s.	d.
<i>Commercial goods vehicles</i> including three-wheelers weighing 7 cwt. or over will pay according to weight, unladen—			
If not exceeding 12 cwt. ...	10	0	0
Above 12 cwt., but not exceeding 1 ton ...	16	0	0
" 1 ton " " 2 tons ...	21	0	0
" 2 tons " " 3 tons ...	25	0	0
" 3 tons " " 4 tons ...	28	0	0
Over 4 tons ...	30	0	0
With right to draw trailer ...	2	0	0

¹ Command Paper, Cmd. 660. Price 3d.

The Chancellor of the Exchequer in his Budget speech said: "We propose substantially to adopt the recommendations of the committee." It appears, however, that in fact all the recommendations have been adopted and the Estimates presented to the House of Commons refer "for fuller details" to the text of the report. The only point open is whether three-wheelers weighing 7 cwt. or over unladen will be subject to the tax of £1 per unit h.p., but from the reference in the report this is no doubt intended. Mr. Chamberlain stated that he proposed to continue the existing motor car tax and motor car duties until December 31st, 1920, when they will be superseded by the new tax, and "the abatement of duty granted in the case of motor cars used by medical practitioners or veterinary surgeons will cease."

MINORITY REPORT.

One of the members of the Departmental Committee, Major Stenson Cooke, secretary of the Automobile Association and Motor Union, presented a Minority Report. He expresses the opinion that the substitution for the petrol duty of a heavy initial tax will have a disastrous effect on the development of motoring. His dissent is influenced by the following considerations:

"(a) That despite the proposed heavy increase, which presumably is intended to include the petrol tax already paid by the motorist, the Government are clearly unable to give any guarantee that when the duty is removed the petrol groups will give the consumer the benefit of any permanent reduction in price.

"(b) That the payment of a heavy initial tax, regardless of the extent to which the vehicle is used, will operate unfairly:

1. Upon owners of low priced cars of moderate speed. (Powerful cars, costing four times as much as the cheap low powered car usually owned by the motorist of moderate means, will actually pay less in taxation.)

2. Upon persons owning two or three cars, only one of which is on the road at a time.

3. Upon the large number of owner-drivers who by force of circumstances are, throughout the whole year, only able to use their cars occasionally or at week ends.

"(c) That this special taxation of motorists is a road tax, but on the unit system the amount of tax paid bears no true relation to the extent to which the road is used.

"(d) That the removal of the petrol duty automatically withdraws the preferential treatment rightly accorded to benzol, the chief home produced fuel, and thereby strengthens the already powerful grip of the petrol groups upon both industry and user.

"(e) That the heavy taxation proposed will discourage motoring, resulting in a reduction in the output of new cars and the restriction of the use of those already existing, with a consequent loss of revenue."

He goes on to say that the tax recommended by the majority of the Committee is calculated on an estimate of the total number of vehicles which will be in use at midsummer, 1920, when the output of cars will still be restricted; the proposed new tax will not be operative until 1921, in which year the number of vehicles will have greatly increased, so that the contributions required from the individual to the total sum would be much smaller. He contends that so long as special taxation of vehicles for road revenue is considered necessary there can be no justification for imposing the whole burden of it on one particular class of road users, and that all classes of vehicular traffic should contribute their proper quota for road purposes.

Major Stenson Cooke would continue the taxation on imported motor spirit on a flat rate basis, excluding all rebates, and would provide for a reasonable adjustment of the existing taxation with certain necessary amendments for the issue of quarterly licences, for the transfer of licences from one owner to another when a car or motor cycle changes hands, and for abatement of tax on old cars.

Transport Ministry's Calculations.

Appended to the report is a table prepared by the Ministry of Transport showing the relative burden of the present and proposed taxation. The calculations are based on the present taxes—namely, licence according to horse-power, and petrol tax 6d. a gallon, and the proposed new tax of 1s. per horse-power with no petrol tax.

The estimate is founded on the assumption that the reduction of 7d. per gallon promised by the petrol companies will be maintained, but, as the Committee points out, no guarantee that this will happen can be given. The

character of the table may be illustrated by one or two items:

It is calculated that on a car 21.9 rating, with a consumption of 15 miles to a gallon and covering 7,500 miles a year, the present licence and petrol tax would be £18 16s.; the new horse-power tax, without petrol tax, would be £19 18s. 4d.

On a car 16.3 rating, with the same number of miles per annum, the present licence and petrol tax would be £18 16s.; the new horse-power tax, without petrol tax, £14 18s. 4d., a saving of £3 17s. 8d.

On a light car, 11.5, the present tax would be £10 13s., the new tax £10 15s., an increase of 2s.

These calculations do not take into consideration the rebate to medical men, and the estimates therefore are not applicable to their case. For instance, on a car 21.9 rating, the old licence was £3 3s. and the rebate on petrol £6 5s.; this is to be deducted from the present licence and petrol tax amounting to £18 16s., which is to be compared with the proposed new horse-power tax of £22.

ACTION BY THE BRITISH MEDICAL ASSOCIATION.

The Chairman of the Medico-Political Committee of the British Medical Association has addressed the following letter to the Chancellor of the Exchequer, asking him to receive a deputation from the Association to lay before him the manner in which the medical profession will be affected by the new proposals:

Sir,

20th April, 1920.

As Chairman of the Medico-Political Committee of the British Medical Association, which represents a very large proportion of medical practitioners of the country, I desire to take the earliest opportunity of pointing out to you that the medical profession will be injuriously affected by the proposed changes in the motor car taxation set forth in the Budget. Their cars are used exclusively for purposes of their practice, and many of them have cars the power of which is much exaggerated by the R.A.C. formula; if all rebates are abolished the extra cost to the owner of a 21 h.p. car (R.A.C. rating), doing a mileage of 7,500 in the course of the year, will be £11 12s. In addition to this, it is absolutely necessary that some medical practitioners in rural and sparsely populated districts should keep two cars in order that they may not be prevented attending an urgent call owing to a car breakdown.

I beg to ask you to be good enough to receive a deputation from the British Medical Association to discuss this and other cognate matters which may be deemed desirable to lay before you.

Yours faithfully,

E. B. TURNER.

A communication has also been addressed to the Secretary of the Committee of Medical Members of Parliament, asking them to meet the members of the Medico-Political Committee in conference.

THE OWNER OF TWO CARS.

Dr. W. ROBINSON (Sunderland) writes: It must be remembered that it is necessary for most doctors to keep two cars in order that one may always be in running order, because of the liability of all cars in constant use to break down, and still more because of the great length of time—weeks or months—which it now takes to get a car repaired. Thus medical men will have to pay a double tax. For example, I use 400 gallons of petrol a year (net tax £5) and keep two cars (15 and 21 h.p.). The new tax will be £35 in full. It is to be hoped that only half the tax will be payable by medical men. The petrol tax is much the fairest, and those who use the roads most pay most.

THE AUTOMOBILE ASSOCIATION.

The Automobile Association intends strongly to oppose the proposals of the Committee, and has issued a letter to every member of the House of Commons who is a member of the association. The letter states that the executive committee of the Automobile Association has unanimously resolved that the petrol tax should be retained as against any alternative proposal for a largely increased tax on the motor vehicle, which it considers would be contrary to the interests of the country and have a disastrous effect on the development of motoring. It is urged that the equitable adjustment of the individual contribution for road purposes cannot be achieved by the payment of a lump sum per annum calculated upon horse-power or any other basis which excludes the graduation of the tax in proportion to the extent of road used. A list is given of the injustices to certain classes of motorists, among whom are (1) owners of cheap low-powered cars of moderate speed which, on the horse-power basis, actually pay more in taxation than powerful cars costing four times as much; (2) persons owning two or three vehicles, only one of which is on the road at a time. The opinion is expressed that the plan of taxing horse-power will defeat the object to raise a larger revenue, and a strong plea is made for putting the tax on motor spirit.

British Medical Journal.

SATURDAY, APRIL 24TH, 1920.

THE BUDGET.

To members of the professional classes the most important feature of the Budget introduced by the Chancellor of the Exchequer on April 19th is his undertaking to adopt, "with one or two trifling modifications in favour of the taxpayer," all the recommendations of the Royal Commission on the Income Tax with regard to differentiation and graduation of tax. The broad effect of the new system will be to do away with sudden jumps as an income rises, and to produce an effective rate of taxation which will progress uniformly as the income of the individual taxpayer increases. It also has the effect of transferring a certain portion of the charge hitherto borne by the smallest incomes to the larger and largest. Increased consideration is given to the responsibilities of the taxpayer who is married and has a family. A single person with an earned income up to £150 will pay nothing; a married couple without children will pay nothing up to £250, and a married couple with three children will pay nothing up to £350. A married couple with three children will pay £6 15s. if the earned income is £400; this is equivalent to a rate of 4d. in the £. At £500 the rate is 9½d.; at £800, 2s. 2½d.; at £1,000, 2s. 10d.; and at £1,250, 3s. 4d. All these rates are lower than hitherto paid. The super-tax will apply to all incomes exceeding £2,000, an alteration which it is considered will bring an additional 30,000 persons within the scope of the Act. Mr. Chamberlain's statement that he intends to embody the recommendations of the Royal Commission on Income Tax in a Finance Bill absolves us from going into further details here, for the whole system was fully explained in an article on income tax reconstruction published in the *JOURNAL* of March 27th last, p. 442.

A point of considerable interest and importance is that Mr. Chamberlain has accepted the suggestion to abolish the term "unearned income." It reflected a certain phase of political propaganda which has followed the doctrine of land values duties into limbo. It is now admitted that most unearned income is income from savings a man makes to provide for his own old age or for the maintenance of his widow and children. It is in future to be called "investment income," and although it will pay more it will not pay so much more as the doctrine of the past would have required. This principle was, indeed, admitted when allowance was made for premiums for life assurance. In some cases, when allowances for wife and children operate, an investment income will pay less than it did. A married couple without children with an investment income of £700 a year will in future pay exactly the same as before: with an investment income of £600 a year they will not pay so much. Thus the position of a man who has saved his money approximates to that of a man whose conditions of employment entitle him to a pension. On the other hand, married couples with earned income of £800, £900, and £1,000 a year will pay rather more. An earned income of £800 will pay £2 5s. more, of £900, £6 15s. more, and of £1,000, £18 15s. more. A married couple with an earned income of £800, entitled to the allowance for three children, will pay

£11 5s. less than before; with £900, £14 5s. less, and with £1,000, £2 5s. less. These calculations are to be deduced from the tables in the Financial Statement issued on the day the Budget was introduced. A single person with an income above £350 will always pay more than hitherto, whether his or her income is earned or derived from investments. A single person with an earned income of £900 will now pay £168 15s. instead of £135, and with £1,000 he or she will pay £195 15s. instead of £150.

The result of the changes now to be made may be further illustrated by taking the effective rates of income tax on an earned income of £1,250, the amount in the tables which most nearly approaches the £1,300 a year which it was claimed during the arbitration on the rate of insurance medical remuneration should be the average income "for a good general practitioner successful enough to have enough work to occupy his whole time and filling up that time properly and conscientiously." For a single person the amount at present paid is £234 7s. 6d., an effective rate of 3s. 9d.; the proposed charge will amount to £263 5s., an effective rate of 4s. 2½d. For a married couple without children the charge now is £234 7s. 6d., an effective rate of 3s. 9d.; it will be £236 5s., an effective rate of 3s. 9½d. For a married couple entitled to the allowance for three children the amount now is £234 7s. 6d., an effective rate of 3s. 9d.; it will be £209 5s., an effective rate of 3s. 4d.

The supertax will in future affect incomes over £2,000, but the rate of increase on incomes near the margin rises slowly. Thus for the married couple entitled to an allowance for three children the supertax on £2,250 will be £19, and the total charge will be less than hitherto; it will be £506 in place of £591. The new rate is calculated to be equivalent to 4s. 6d. in the £. With an income of £4,000 a year the effective rate begins to rise rapidly; it is in the same case 6s. 1d. at that amount, 8s. 7d. at £10,000, 9s. 9d. at £20,000, 11s. at £50,000, 11s. 6d. at £100,000, and 11s. 8d. at £150,000, the limit of income beyond which the imagination of the Treasury does not extend.

In the changes proposed in the method of taxation of motor vehicles the Chancellor of the Exchequer has closely followed the recommendations of the Departmental Committee, details of which are given at p. 575. The effect will be to increase the amount medical practitioners will be called upon to pay when the effect of rebates now enjoyed is taken into consideration. Mr. Massac Buist dealt with the matter in an article published on April 10th, and deals with it again this week (p. 574); and on p. 576 is a letter the Chairman of the Medico-Political Committee of the British Medical Association has addressed to the Chancellor of the Exchequer, asking him to receive a deputation from the Association to lay before him the manner in which the medical profession will be affected by the new proposals. In this letter Mr. Turner lays special stress on two points: The first is that the R.A.C. rating is not a sound basis of calculation, since the calculation of horse-power by that formula ignores the length of stroke and relies upon the diameter of the piston and the number of cylinders. The second point is that medical practitioners in sparsely populated districts are often practically compelled to keep two cars to avoid the risk of a breakdown in one. We invite all members who use motors to read carefully the articles to which reference has been made and Mr. Turner's letter. The matter will be fully considered by the Committee of the Association at an early date. The whole scheme will come in for a good deal of opposition, and many members of Parliament have already expressed their intention to submit amendments.

TYPES AND TREATMENT OF EPIDEMIC
ENCEPHALITIS.

M. NETTER, who has been so diligent in the study of lethargic encephalitis that some of his countrymen apply his name to the disease, recently communicated to the Académie de Médecine an account of his views on its treatment.¹ Before reproducing his recommendations we may note his statement that there have been more than 1,500 cases in Paris and about 10,000 in other parts of France. He admits that it is difficult to fix the rate of mortality, owing to the number of abortive, slight, and ambulant cases, but he estimates that about a third of the patients in whom a definite diagnosis can be made die. The high rate of mortality he attributes to several causes: firstly, the frequent affection of the medulla oblongata; secondly, the occurrence of pneumonia secondary to paralysis of the vagus or the glosso-pharyngeal; and thirdly, the marasmus, often complicated by bedsores, which is the fate of patients in whom symptoms last for several months.

Drs. Farquhar Buzzard and Greenfield, in a paper in the current issue of *Brain*,² in commenting on several cases of mild encephalitis in which the physical signs were generally trivial and but for careful examination would easily have escaped notice, express the view that the total number of cases must have been very numerous during the last two years. Mild cases, they state, are characterized by an inclination to fall asleep while sitting down to rest, a tendency to forget the small things of everyday life, and sometimes by an alteration of temperament. The patient may complain that although he is always dropping off to sleep in the daytime, at night he is restless and disturbed by mild cramps or pains in the limbs, so that he wakes every hour or two. In such cases there may be neither headache nor fever, and diplopia may be very transitory: diagnosis therefore may be difficult and the history given by the patient a most important factor. Yet early diagnosis is a matter of great importance, since patients suffering from inflammation of the brain should be prevented from carrying on their normal activities, even though not troubled with headache, vomiting, or pyrexia. In more severe attacks the symptoms vary very much, but, as is observed, this is to be expected in inflammation of an organ with so many functions. The diagnosis must be determined by a consideration of the onset and course of the disease and by the elimination of other pathological conditions capable of producing similar symptoms and physical signs. Thus in one class of cases hemiplegia or hemianaesthesia is present: in another the symptoms resemble those of paralysis agitans (the basal ganglia group); while those of a third class are characterized by disturbances of function of the cranial nerves, the commonest evidences of which are diplopia and ptosis.

G. Sabatini³ proposes to classify the cases, according to the predominant symptoms, into four varieties. In the first, lethargy is the chief feature: ocular palsies are limited and delirium and symptoms of motor irritation are absent. In the second or hyperkinetic form,⁴ after a short prodromal stage characterized by headache, pains in the bones, restlessness and slight rise of temperature, choreiform movements (clonic muscular jerks) of the abdominal muscles, face, and limbs, develop, accompanied by muscular hyper-

tonus and rigidity of the vertebral column, with high fever and delirium. Cases of this type may die within a few days, but in others there is a remission, followed often by lethargy, which may deepen into coma ending in death. In a third type paralysis of the cranial and spinal nerves predominates, and the general condition and mental state are unaffected. The fourth or mental form is rare: in it the patient is in a state of confusion with regard to time, place, and personality, critical power and will being abolished.

Buzzard and Greenfield call attention to the fact that months after the original illness relapse may occur, attended by involuntary movements, which may be irregular and choreiform and limited in distribution. They are present when the patient is resting, but disappear during sleep and when the limb is in voluntary use. The paper contains a report of careful histological examinations of the brain in a series of fatal cases. The appearances varied, but the features common to all cases were vascular congestions, toxic degeneration of the nerve cells and neuronophagy, infiltration of the nervous tissue by proliferating cells of the vessel walls, small cell infiltration of the space around the veins, and glial proliferation. Venous thrombosis and haemorrhage were observed in a considerable number of cases; sometimes the haemorrhage surrounded a congested vessel, but in others it had broken through and spread into the tissues for some distance beyond.

Professor Netter is convinced that the virus of lethargic encephalitis is of the same type as that of poliomyelitis, and, like it, is filtrable, and to be found not only in the nervous system, but in the nose, throat, and the mouth. He bases his treatment upon this conception. Though he thinks that some value is to be attached to specific treatment by the intrathecal injection at the onset of the disease of serum taken from a patient who has recovered from it, he considers it premature to recommend this method, for the reason that there is no evidence that an antibody appears in the blood in lethargic encephalitis at an early date, and also for the further reason that in a case lasting several months it would be necessary frequently to repeat the injection. He believes that the administration of hexamine is likely to be useful, but insists that it must be given by the mouth and not by intravenous injection, since the object is to produce a continuous action on the nerve centres, and the drug if injected into the blood disappears very rapidly. The fact that in some cases swelling of the salivary glands and salivation has been observed, and the further fact that the virus of rabies and of poliomyelitis may be found in the mouth, led him to recommend resort to pilocarpin, in the hope of hastening the elimination of the virus; he would combine with it adrenalin to counteract the depressing effect of pilocarpin on the heart. His great standby in treatment, however, is the production of a local abscess by an injection of turpentine. In all serious cases he injects at the earliest possible date one or two cubic centimetres (16 to 32 minims) of turpentine into the outer side of the thigh. In 27 cases so treated an abscess, requiring incision, was produced in 19; only two of the 19 died, and 13 of them, who had been in an apparently hopeless condition, recovered completely; that is to say, he had 17 recoveries out of 19 cases in which an abscess formed, whereas of 25 serious cases not so treated, 13 died. Of the 19 cases 14 were of the myoclonic type in which the prognosis is said to be particularly bad. He recalls the fact that Hippecrates, who knew a disease called lethargus, said that the patients who recovered generally had an

⁴ Two examples of this form are recorded by Dr. Boveri of Milan at p. 570.

empyema, by which is to be understood an abscess in any part. Why the injection of turpentine, leading to the formation of an abscess, should produce such a favourable effect, Netter does not find it possible to explain, but he suggests that the reaction caused by the turpentine affects the organs which produce the bodies that enable the system to defend itself against the disease: he mentions that his house-physician had shown that myelocytes appear in the blood, indicating, as he thinks, that the bone marrow is stimulated to special activity. He considers that the various serums, vaccines, prepeptones, and nucleinates that have been recommended have probably produced their effect in the same way, but are not so free from danger as the production of an artificial abscess. Finally, he condemns very strongly the use of arsenic, having seen neo-salvarsan produce a disastrous result, and of antimony he says that it seems to have no effect.

"*Hic morbus non est novus*," Dr. F. G. Crookshank quotes from Polydore Vergil in an article⁵ founded on a paper contributed last year to the Section of the History of Medicine of the Royal Society of Medicine. It will be remembered that at a discussion⁶ at that Society in October, 1918, Dr. Hamer, medical officer of health for London, dwelt on the epidemiological relations of influenza, cerebro-spinal fever, and lethargic encephalitis. Dr. Crookshank also goes back to Hippocrates, who described paraplegias occurring in association with burning fevers, by which is to be understood influenza. He, however, contents himself with asserting that clinical cases of the nature now ascribed to encephalomyelitis or encephalo-myelo-meningitis, have been reported for the last 450 years at least, and that they have occurred and been noted as incidental to major prevalences, known historically as the sweating sicknesses, the epidemic catarrhs, influenzas, and the like. Special prevalences of such cases have been described as manifestations of special diseases, but have usually appeared shortly before or after major influenzal epidemics or in geographical proximity. Epidemic encephalo-myelo-meningitis, Dr. Crookshank considers, represents an intensive and specialized reaction that has the same epidemiological relation to pandemic influenza as have the prevalences and epidemics of "septic" pneumonia, of gastro-intestinal illness, and of other maladies described as occurring before and after the wide diffusions generally referred to as pandemic influenza.

We must accept the epidemiological evidence for these associations, but their explanation remains mysterious, for the epidemiologists must not convince us that influenza and poliomyelitis or lethargic encephalitis are due to the same virus.

PATHOLOGICAL MUSEUM AT THE CAMBRIDGE MEETING.

The Committee appointed to organize the Pathological Museum in connexion with the Annual Meeting of the British Medical Association at Cambridge in June propose to arrange the material under the following heads: (1) Exhibits bearing on discussions and papers in the various Sections. (2) Specimens and illustrations relating to any recent research work. (3) Individual specimens of special interest or a series illustrating some special subject. (4) Instruments or appliances relating to clinical diagnosis and pathological investigation. The Museum will comprise a series of exhibits illustrating the following subjects: "War specimens," arthritis, cerebro-spinal

meningitis, parasitology. The committee will be glad to take charge of and place in the Museum for exhibition any specimens, casts, photographs, diagrams, or microscopic slides during the time they are not required by those who are reading papers or taking part in the discussions. The Museum will occupy a central position in two temporary buildings in the first court of the Medical Schools. It will be open during the entire week beginning Monday, June 28th. So far as practicable each section will be under the charge of a curator for demonstration purposes; but arrangements will be made for exhibitors to have an opportunity of demonstrating their own specimens. Every care will be taken of the specimens, and the contents of the Museum will be insured. The chairman of the Pathological Museum Committee is Sir G. Sims Woodhead, K.B.E., Professor of Pathology in the University of Cambridge. The honorary secretary is Dr. H. B. Roderick, to whom communications regarding material for exhibition should be addressed at the Surgical Department, Medical School, Cambridge.

A TIME FOR SPEECH.

THE *Nottingham Guardian*, on April 12th, published a very good letter under the heading "Nottingham M.P.s taken to task." Plainly, it is written by one of our profession in Nottingham; he writes well and with authority, and he deals faithfully with two members of the House of Commons who are favouring antivivisection. They are probably feeling some surprise that they are thus called to account. For Nottingham is accustomed to antivivisection statements, and our profession in Nottingham was working too hard through the war to give attention to them, or was indifferent to them. It is likely enough that these two members of Parliament thought that nobody would be seriously offended by their action. But here is somebody who is very seriously and very properly offended. And he has set a good example to all of us, especially to our profession in Nottingham. Of course the public is well aware that "the doctors" are solidly hostile to antivivisection. How could they not be when it is furiously attacking the use of diphtheria antitoxin and the protective treatments against typhoid and paratyphoid and tetanus? But so long as it can find among 50,000 doctors half a dozen on its side it will tell the public that "medical opinion is divided on these questions of treatment," and will advise people not to let the doctors "pump animal filth" into them. That, indeed, is why we hate antivivisection. Over a good many points we are willing to make allowance, concessions, compromises; but when we find antivivisection, with its nonsense about antitoxin, behaving as an enemy of the people, then we, who are honest servants of the people, do well to hate it. For example, one of the antivivisection societies is distributing everywhere a tract which says: "It is admitted, even by the supporters of antitoxin, that this 'remedy' is accountable for a great increase in the cases of paralysis. . . . Antitoxin is useless, unscientific, and harmful." We must not be polite to the devil when we find him sowing tares among our wheat. It is most unlikely that the two Nottingham members would countenance this "evidently effective piece of propaganda," as one antivivisection society calls the tract from which we have quoted. Still, it is a good thing that a Nottingham doctor has taken them to task. And some of us may have occasion to follow his example. It is of little use to say anything during the rush and excitement of election time. Every member, or would-be member, of the House of Commons is at that time besieged and overwhelmed with all sorts of appeals, but we can say something in quieter times if our local representatives in Parliament give their support to a "propaganda" which misrepresents us, derides our faith, abuses our works, and is dangerous to the public health. We may be content to say it privately or we may feel bound to say it in the press. One way or the other we ought to say it.

POST-GRADUATE EDUCATION IN LONDON.

THE co-ordination and organization of medical post-graduate education in London is being methodically and effectively continued by the Fellowship of Medicine upon the sound lines laid down by its promoters at their foundation meeting. One of the original aims of the Fellowship was the establishment of a central bureau from which information respecting post-graduate facilities in Great Britain could easily be obtained. This has now been established and the Fellowship has become a recognized centre for such information. Inquiries daily arrive from medical men in all parts of the world who wish to map out courses of work in London and the provinces. Visitors from the Continent and from Overseas seem usually to find their way to the offices of the Fellowship within a few hours of their arrival. Last year's energies are also bearing gratifying fruit: the graduates who attended the London hospitals and schools last summer have clearly given a satisfactory account of their reception, for most of those who are coming over now from the Dominions and the United States are "personally recommended." The legend that London is a "cold place" for the medical stranger (a widely-spread reputation which has done incalculable harm to post-graduate work in this country) is at last being destroyed. It is admitted that London offers not only a vast field of work, but also a warm welcome to those who wish to avail themselves of such opportunities. The last issue of the weekly *Bulletin* of the Fellowship shows clearly the possibilities of the work as now co-ordinated by the present organization. The medical graduate, after a short study of the daily programme, can easily plan a course of study in any department and carry it out at almost any time of the day. These advantages are certainly not being fully appreciated by practitioners in London and the provinces, and the fact is somewhat disappointing. Whilst the London courses are attracting graduates from Overseas and from the Continent, they have not yet aroused the enthusiasm of men who are within easy access of such valuable facilities. Many reasons may be suggested, but perhaps one explanation is that the present courses arranged by the Fellowship are not sufficiently known to the British medical man. If this be so he cannot do better than write to the Secretary of the Fellowship of Medicine, 1, Wimpole Street, London, W.1, for a copy of the *Bulletin*. If he states the special department of work in which he is interested his name will be registered, and it will be strange if his needs are not met.

THE MIDDLESEX HOSPITAL.

WE recorded in the early part of this year the endowment by Mr. S. B. and Mr. J. B. Joel of a chair of physics in the Middlesex Hospital and the appointment to the hospital of a professor of pathology and radiology, both, like the Joel professor, professors in the University of London. Of the 500 beds in the Middlesex Hospital, 100 are reserved for patients suffering from cancer; it possesses special cancer investigation laboratories, and the Bland-Sutton Institute of Pathology, both admirably equipped for investigation and teaching, and all these, together with the medical school, are closely connected. The governors of the hospital, at a special meeting on April 15th, showed their appreciation of the importance of promoting medical research. Lord Athlone, who presided, moved a resolution whereby the scheme for the amalgamation of the cancer research department and Bland-Sutton Institute of Pathology with the medical school, as adopted by the weekly board of governors, was approved, and subsequently the necessary alterations were made in the laws of the hospital. The scheme not only provides for the closer union of research, teaching, and treatment, but contemplates also a considerable enlargement of the provision for cancer and other research. If sufficient philanthropic aid be forthcoming, it is sought to endow chairs of chemistry

and pharmacology, and thus it is hoped to have professors of chemistry, physics, radiology, anatomy, physiology, pathology, and pharmacology, each of whom shall be a professor of the University of London, and shall at the same time be attached both to the medical school and hospital. At the latter each will have direct access to the wards and at the former he can conduct his investigations in the laboratory and communicate his findings in the classroom, so that research, treatment, and teaching will be systematically bound together. Benefit is bound to accrue from the close association and co-operation within one institution of the workers in all the different departments. Problems arising in medical research are of such complexity as to demand for their ultimate analysis and solution knowledge of many branches of pure and applied science; advantage must, therefore, be derived from close co-ordination and interrelation of kindred groups of workers.

DRIED MILK AND VITAMINES.

A CORRESPONDENT informs us that he has been told by an analytical chemist of his acquaintance that at least 30 per cent. of the milk sold in London is compounded from dried milk, and that so long as this mixture shows the presence of the minimum legal amounts of fat and non-fatty solids it can be lawfully sold as cow's milk. He assumes that "dried milk has lost its vitamins," and suggests that such milk, given in good faith to infants, may have a deleterious effect on their growth. The suggestion that a considerable proportion of London milk is made from desiccated milk powder should not be too readily accepted, although a solution of dried skimmed milk would no doubt serve for diluting milk to the legal standard of fat content. Samples of milk are regularly examined by the Public Health Department of the London County Council in connexion with the feeding of school children. In 1917 and 1918 the extent to which they were found to be adulterated was great; 37 per cent. showed evidence of adulteration in 1917. Conditions have greatly improved since, and samples recently taken have usually been normal in appearance and have not shown the white deposit or other peculiarities of diluted dried milk. The Department, we understand, has no reason to believe that the compounding of milk for sale in London from dried milk takes place to any great extent. The assumption that "dried milk has lost its vitamins" is only partially correct. It is true that the antiscorbutic vitamin (water-soluble C) is rapidly destroyed by heat, and is absent from even the most powerful antiscorbutics when they have been desiccated; but the water-soluble B, or anti-beri-beri vitamin, is resistant to heat, and only very slowly undergoes disintegration at the temperature of 100° C. The stability of the fat-soluble A factor is not so clearly established. Osborne and Mendel, and also Drummond, believed it to be very resistant to heat; but according to American experiments, confirmed in this country, and mentioned in the Report of the Medical Research Committee¹ (p. 23), the fat-soluble accessory substance A is gradually destroyed at 100° C., and four hours' exposure to that temperature is sufficient to render butter fat of little greater value, as far as vitamins are concerned, than an equivalent quantity of lard. It seems clear, therefore, that in the process of desiccation there is a risk of losing the antiscorbutic vitamin (C); the extent to which the other two accessory factors are destroyed depends upon the particular method used by the manufacturer. Dr. F. J. H. Coutts, in his report to the Local Government Board (1918), shows that the degree of heat employed in the various commercial processes varies greatly; in some the milk, it is said, does not attain a temperature of more than 50° C., but in others temperatures considerably higher than 100° C. are used. The freezing process described in 1910 by Lecomte and

¹Report of Medical Research Committee, 1919. H.M. Stationery Office

Lainville, which would appear to be ideal so far as the preservation of vitamins is concerned, does not seem to have been used on a commercial scale. Besides the possible destruction in preparation, however, disintegration of vitamins may occur (as Dr. Coutts has pointed out) when the dried milk is kept for long periods of time. The medical officers of many infant welfare centres where much dried milk is dispensed have prescribed fruit and vegetable juices to supplement a possible vitamin deficiency of the dietary; some, however, have come to the conclusion, as a matter of experience, that this precaution is not needed.

THE MACKENZIE DAVIDSON MEMORIAL LECTURE.
The first Mackenzie Davidson Memorial Lecture was delivered by Sir Ernest Rutherford, F.R.S., at the meeting of the Section of Electro-therapeutics of the Royal Society of Medicine on April 16th. Professor Rutherford paid a tribute to the scientific enthusiasm and imagination of the man the lecture commemorated, and in particular to his remarkable readiness to help his colleagues and give freely of his time and ideas. He referred also to the Mackenzie Davidson Memorial Fund, which has in view the establishment of an institute for teaching and research in radiology, to which possibly a chair at some university could be attached. Radiology had arrived at the parting of the ways, and the old haphazard organization would not suffice if a steady advance was to be maintained in knowledge and in methods. In the past there had been little or no systematic teaching of radiology, and it spoke volumes for the enthusiasm of many workers in this field that they had surmounted the difficulties attaching to the subject and acquired a working knowledge of not a profound knowledge of its physical as well as of its medical side. The University of Cambridge had established a diploma in radiology and electrology, and in London, under Sir William Bragg at University College, about thirty students were now taking the first course with a view to that diploma. Until the diploma was well established it seemed desirable to have systematic courses of instruction in two or three convenient centres. In the second part of his lecture Sir Ernest Rutherford devoted himself to a review of the effects of radiations upon matter. He pointed out that the effects of α rays in treatment were in most respects similar to those of the beta and gamma rays of radium. This similarity of effect produced by two sets of rays proceeding from such different sources was only what would be anticipated from the standpoint of physics; for the effects of α rays, and of radium rays also, were due not to the direct action of the rays themselves on the tissues, but to their power of causing the ejection of a high-speed electron from matter. All radiological effects were ultimately reducible to the effect of electrons in motion. The therapeutic effects of α rays and radium rays were to be ascribed to chemical action; the physical changes observed in treatment, however important these might be, were only secondary and a consequence of the primary chemical changes produced by the radiation. The researches of C. T. R. Wilson and others had shown that radiations did produce such chemical changes in gases, and it was extremely probable that the same kind and order of changes took place in the tissues. The main problem of radiology was to find out the conditions under which α rays and radium rays passing into the tissues could exercise a beneficial action and not a detrimental one, and with a view to its solution he pleaded for a closer co-operation between the physicist and the medical man in research.

THE MEDICAL STUDENTS' REGISTER.

The new *Medical and Dental Students' Register*,¹ issued by the General Medical Council, gives the names and other particulars of all students registered during the year 1919,

together with statistical matter. There is also the usual tabular statement of the number of medical students registered in each year in each of the three divisions of the United Kingdom from the beginning of students' registration in 1865 to the end of the year under review. In our issue of November 1st, 1919, p. 565, the analytical table given in the *Students' Register* for 1918 was summarized, and we printed a chart showing in graphic form the numbers of medical students registered in each of the preceding fifty-four years. From 1865 until 1881 the total number of registrations in the United Kingdom mounted steadily from 600 to 2,171; then for the next nine years it fluctuated around 1,900. In 1891—the year before the enforcement of a compulsory five years' curriculum—there was a sharp rise to 2,405, with an even more abrupt fall in the following year. Throughout the two following decades the total gradually declined to 1,232 in 1911—the smallest entry since 1873. From this low level it mounted year by year until 2,253 was reached in 1918. The figures for 1919 far surpassed all previous records. The total number of registrations in the United Kingdom was 3,420, being more than 1,000 greater than the record entry of 1891. Scotland again heads the list, with 1,387 new students; England and Wales had 1,375, and Ireland had 658. During the fifty-five years of students' registration rather more than 89,500 medical students were registered in the United Kingdom, the percentages being approximately 47.5 for England and Wales, 32.9 for Scotland, and 19.6 for Ireland.

MEDICAL INSPECTION IN SECONDARY AND CONTINUATION SCHOOLS.

The Education Act of 1918 greatly extended the responsibility of local education authorities with regard to medical inspection of schools. Previously the duties of these authorities were limited to elementary schools; the Act imposed on them responsibilities with regard to secondary schools, continuation schools, pupil teacher centres, junior technical schools, and other similar schools or institutions provided by an authority. The provisions came into force in August, 1918, but they were not obligatory. The Board of Education has now made an Order fixing April 1st last as the day on which the operative section (18) of the Act came fully into force, and has issued a memorandum explaining the object in view, together with draft statutory rules,¹ which will come into force unless objection is raised to them in Parliament. The order applies only to pupils in secondary schools provided by an authority, but it is hoped that authorities will show themselves willing to provide for the medical inspection of pupils attending any school or educational institution if so requested by the governing body. The board considers that the medical examination at the age of 12 should as a rule be complete, and holds that the examination at the age of 15, which comes at the end of the school career of the majority of pupils, is of special importance, and should be complete in all cases. The memorandum goes on to point out that medical inspection is not an end in itself, but is intended to provide data for appropriate action, remedial or preventive. It is considered that the remedial provision to be made by an authority would probably be limited in practice to the examination of eye defects and the provision of spectacles, to dental inspection and treatment, to the operative treatment of tonsils and adenoids, to the treatment of such minor ailments as skin diseases, running ears and sore eyes, and to remedial exercises. The medical inspector would give attention also to the sufficiency of the general measures for the prevention of infectious diseases, to the adequacy of the ventilation, lighting, and sanitation, to the suitability of the physical training, and to the means taken to avoid over-pressure in the course of preparation for examinations. The order enumerates the conditions upon which grants will be made; they include,

¹ London: Constable and Co.

in addition to initial medical inspection in the term following admission, inspections in subsequent years; adequate steps are to be taken to co-ordinate the system with other activities of the school medical service, and also with the work of the public health service in the area. It is recommended that a woman doctor should, where practicable, be employed to inspect girls. A model schedule is given to be used as a form of record; this follows closely the lines of that which is in use in elementary schools, but additional headings are inserted for inspiratory and expiratory chest measurements, near vision, colour sense, flat-foot, and catamenia.

ANNUAL OPHTHALMOLOGICAL CONGRESS.

THE annual congress of the Ophthalmological Society of the United Kingdom will be held in London at the house of the Royal Society of Medicine during the last week of April. The proceedings will be opened on Thursday, April 29th, when the president, Mr. J. B. Story, F.R.C.S.I., will deliver an address. A series of papers will afterwards be read, and in the afternoon there will be a clinical meeting at the Royal London Ophthalmic Hospital, when cases and specimens will be shown; afterwards Mr. Percy Flemming will give an address on "The neighbourhood of Moorfields in former days," illustrated by lantern slides of maps of old London. This will be followed by a discussion of cases, and in the evening the members will dine at Oddenino's Restaurant. On the morning of Friday, April 30th a discussion on diabetes in relation to diseases of the eye will be opened by Sir Archibald Garrod and Mr. R. Foster Moore. At the business meeting on the afternoon of that day two proposals of the council will be discussed: one is that the annual subscription should be raised to £1 11s. 6d., and the other that subscriptions and donations should be invited to a special reserve fund for publication, so as to obviate the necessity of asking members who read papers before the society to contribute towards the cost of illustrations. In the evening a series of papers will be read. On Saturday morning a visit will be paid to the special hospital of the Metropolitan Asylums Board for cases of ophthalmia neonatorum, and there will be a discussion on the prevention and treatment of that disease, to be opened by Dr. Gibbon FitzGibbon, Master of the Rotunda Hospital, Dublin, and Mr. M. S. Mayou. The Council of British Ophthalmologists will hold a meeting, which all British ophthalmologists are invited to attend, at the house of the Royal Society of Medicine on Friday, April 30th, at 4 p.m., when a report of the council on the work done during the last two years will be submitted.

SIR WILLIAM ARTHUR ROBINSON, K.C.B., C.B.E., has been appointed to be First Secretary of the Ministry of Health, in succession to the late Sir Robert Morant. Sir William Robinson, who was born in Westmorland in 1874, was educated at Appleby School and Queen's College, Oxford, and took a double first in classics. He entered the Civil Service in 1897, was the secretary of the Dominions Royal Commission, 1911-12, and assistant secretary, Office of Works, 1912-18; he has been permanent secretary to the Air Council since 1918.

A JOINT meeting of the Obstetric and Gynaecological Section of the Royal Society of Medicine and the North of England and Midland Obstetrical and Gynaecological Societies will be held in London at the Royal Society's house, 1, Wimpole Street, on Thursday, May 6th. The discussion at the morning session (10.30) on the treatment of ante-partum haemorrhage will be opened by Dr. Hastings Tweedy, and at the afternoon session (2.30) Dr. Eustley Holland will read a paper on rupture of the Caesarean section scar in subsequent pregnancy and labour. A dinner will be held at the Great Central Hotel; Mr. J. D. Malcolm, President of the Section, will take the chair at 7.30.

Medical Notes in Parliament.

The Budget.

THE Budget figures have become so colossal that they are difficult to follow. It was generally agreed, however, that Mr. Chamberlain's exposition on April 19th was exceedingly well prepared, and as lucid as it could possibly be in the circumstances. This clarity was necessarily achieved by much elimination of details, and only the main outlines can be traced here. Broadly there were three statements: the first concerned the financial year ended on March 31st, and on this the accounts show a realized deficit of £326,000,000; secondly, this was followed by a statement of what the position would be at the end of the current year—that is, on March 31st, 1921—on the basis of estimated expenditure and of revenue on the basis of existing taxation: this would afford a balance of £164,198,000 for debt reduction, due mainly to reduction in the service expenditures. The third statement set out the effect of the proposed new taxation. The changes, it was estimated, would produce in full £198,230,000, or, excluding the £9,500,000 to be drawn from extra Post Office charges, £189,000,000, derived as follows: From direct taxation, £125,000,000; from indirect taxation, £64,000,000. The net additional revenue from these resources for the current year is estimated to be £76,650,000, making a total revenue for the current year of £1,418,300,000. The grand totals for the current year were estimated as under:

Revenue	£1,418,300,000
Expenditure	£1,181,012,000
Balance for reduction of National Debt	£234,288,000

The particular interest of the speech was, of course, in the narration of the methods by which it was intended to raise the extra money. A fuller explanation of the income tax changes will be found elsewhere. They follow the recommendations of the Royal Commission, and the Treasury gains under the whole scheme of alterations mainly from the fact that the supertax limit is reduced from £2,500 to £2,000 and the rate is advanced. Mr. Chamberlain follows the scale put forward by Lord Colwyn's Committee, and goes beyond it as regards incomes of over £30,000 a year, adding 6d. to the maximum of 6s. set forth in Lord Colwyn's scheme. Mr. Chamberlain did not, as was expected, remove the excess profits tax and substitute a tax on limited liability companies on their gross profits. Instead he announced that the excess profits tax would be retained and increased from 40 per cent. to 60 per cent., and that in addition there would be a company tax technically called a corporation tax of 1s. in the £, but not deductible until the excess profits tax had been reckoned in the accounts; in no case is this duty to exceed the equivalent of 2s. in the £ on net profits after payment of interest and fixed dividends. The tax will not apply to the first £500 of profits. Mr. Chamberlain gave the impression that he is still hopeful of a practical recommendation for a war profits levy, in which case he will introduce a supplementary budget, and obviously the excess profits tax would in that case have to be revised. Mr. Chamberlain's argument is that the excess profits duty is necessary in existing circumstances as an equitable balance to the supertax imposed on private traders and professional men.

Over and above these new serious burdens there is the feeling that the Budget inflicts numerous vexatious pinpricks on trade, and is liable especially to hurt the small business men who are trying to make good. The fact that the Post Office is no longer a profit-making concern, but a subsidized undertaking, has to be recognized, but the view is strongly held that its activity on the largest possible scale is a vital necessity to business enterprise. With the advance in the charge for inland letters from 1½ to 2d., for telegrams from 9d. to 1s., and ultimately for postcards from 1d. to 1½d., a blow has been struck at the hope of averaging cost beneficially by a larger output. The extra halfpenny for newspapers comes also at a most inopportune time, when the cost of paper has gone up 500 per cent. and establishment expenses have more than doubled.

The proposals with regard to motor taxes are fully dealt with elsewhere in this issue. The proposal to get an extra six million from the stamp duties has caused a good deal of perturbation, but Mr. Chamberlain's motive is to lessen company transactions which tend to divert money from Treasury securities into speculative ventures.

The increase in the excise on beer of about 50 per cent. (calculated to mean about a penny a pint extra) will not be popular. The increase in the duty on whiskey is about 2s. 6d. a bottle, and the retail price is to be 12s. 6d.; of this amount nearly 8s. 6d. is represented by duty. The excise on light wines is raised from 1s. 3d. to 2s. 6d., and on heavy wines, such as port, from 3s. to 6s. The duty on sparkling wines imported in bottles is also doubled, and a 50 per cent. *ad valorem* duty added. Mr. Chamberlain, however, stated that the total duty payable on champagne will be not more than about 6s. a bottle. The yield from the *ad valorem* duty on sparkling wines is estimated to amount to £1,800,000 in the current year, and £1,900,000 in a full year. The proposals in the Budget received on the whole a favourable reception from the House, as it is recognized

that the Chancellor of the Exchequer has been reasonably impartial.

In the course of the debate in Committee, on April 20th, Sir John Butcher said that the abolition of the abatement granted to doctors and veterinary surgeons in respect of motor car duty would be a hardship to men who had to do a great deal of travelling in the course of their professional work. He hoped that the Chancellor of the Exchequer would reconsider the matter. Mr. Chamberlain said he would convey what had been said to the Minister of Transport, who was dealing with that part of the proposals.

Municipal General Hospitals.—Mr. Lyle asked, on April 14th, with regard to the approval given by the Minister of Health to the establishment of a municipal hospital at Bradford, for what special reason, and on what conditions it was given, and whether consent would be extended to other local authorities putting forward similar proposals; whether it agreed with his policy as enunciated on February 26th, 1919, in the House and elsewhere at other times; whether he was prepared to make a statement as to his policy in regard to voluntary hospitals; and whether, before sanctioning further hospitals supported out of public funds, he would consider the position of voluntary hospitals which had for years done invaluable public work, which were now hard pressed for funds to continue their efforts, and which were bound to be most prejudicially affected by competition on the part of organizations that would never experience stress in respect of either upkeep, maintenance, or administration. Dr. Addison replied: I have sanctioned a scheme supported by all parties on the Bradford Council for the establishment of a municipal hospital which appeared to me the only practicable method of providing institutional accommodation necessary to meet the needs of the city. I see nothing in this decision inconsistent with the statement to which the hon. member refers. As regards the last part of the question I fully appreciate the value of the work done by the voluntary hospitals, and I am aware of the difficulties under which they are now labouring, but I am not yet in a position to make any definite statement. Mr. Lyle inquired whether this meant that every other borough and town would be enabled to set up hospitals if it applied in the same way. Dr. Addison said that pending further legislation which was now being prepared, he had to consider cases on their merits as they arose. This was the only way of meeting the necessities of the case.

Medical Aspects of the Divorce Law.—In the debate raised in the House of Commons, on April 14th, on Mr. Rendall's motion that legislative effect should be given without delay to the recommendations in the majority report of the Royal Commission on Divorce, Lieut.-Colonel Raw dealt with three recommendations of the majority report—namely, those in reference to incurable insanity, habitual drunkenness, and the position of one who was the wife or husband of a person under a commuted death sentence. There were in the United Kingdom 140,000 persons certified as insane under the Lunacy Acts, and of that number 53,000 were suffering from incurable dementia, which should be considered as a ground for divorce. Between 30,000 and 40,000 of these people were married, and in a very large number of instances the husband or wife might not know each other; a great many of them did not realize that they were married at all. It was suggested in the majority report that after five years of detention a person suffering from this form of insanity should be examined at the request of wife or husband by a body of medical experts who would then be satisfied whether or not the case was curable. If they were satisfied that it was incurable, that might be a ground for divorce. These cases were particularly hard amongst the poor. He did not suggest that any other form of physical or mental disease should be a ground; but sufferers from this disease might live for forty or fifty years before death came. He hoped that the day would come when marriage would be prohibited to those suffering from epilepsy and from other forms of mental disease. With regard to habitual drunkenness it was proposed that after a separation order had been in force for three years, if the drunkenness continued and there was no evidence of any improvement, the husband or wife might petition for divorce. It was said on very high authority by those who had great experience of cases of this kind that from 90 to 95 per cent. of habitual drunkards died drunkards. Long experience had shown that if habitual drunkenness continued for three, four, or five years without evidence of improvement, there was no possibility or hope of cure, and it should be a ground for petition for divorce. On the third point, the position of the wife or husband of one who had been sentenced to death and reprieved, he said that there was nothing more distressing than that an innocent woman had to remain the wife of a convict for twenty or twenty-five years without any possible means of improvement. Lady Astor, while sympathizing with the position of those referred to by Lieut.-Colonel Raw, doubted whether relaxation in the divorce laws would help the great bulk of men and women in the country, and therefore voted against the motion. The Government left the House to express its opinion by vote as it thought fit, and on the division the motion was rejected by 134 votes to 91.

Treatment Allowances to Pensioners.—In reply to a question by Colonel Ashley, on April 14th, Major Tryon said that treatment allowances under Article 6 of the Royal Warrant set out in the revised Circular 204 were confined to cases in which the Ministry had certified that a man should undergo a course of treatment, and was in consequence rendered unable to support himself. They were not given as compensation for incapacity, whether total or partial, resulting from disablement. The provision of

such compensation was the function of the disablement pension. If the principle of average assessment were questioned, it should be remembered that the only alternative was repeated re-boarding at short intervals—a process which would be costly to the State and intolerable to disabled men. In reply to Lieut.-Colonel Guinness, on April 15th, Mr. Macpherson said that the administration of Article 4 of the Royal Warrant, under which a pension could be reduced for refusal to accept treatment, or for such misconduct as was deemed to constitute refusal, was in the hands of the regional Commissioners of Medical Services of the Ministry, to whom recommendations were made by the Local War Pensions Committees. The instructions given to the committees in the handbook and to the Commissioners of Medical Services were generally found to be satisfactory, and he did not consider that they needed to be amended. He was aware that the local administration of pensions in Ireland was beset with difficulties which were not experienced in other parts of the United Kingdom, but he was not aware that these difficulties related in any disproportionate degree to the men leaving an institution or being discharged for breach of discipline.

Medical Assessors.—Major Molson asked, on April 19th, whether, as the medical men employed as assessors on sessional rates were continuously employed for the same hours as the Medical Commissioners, the Minister of Pensions could see his way to pay them as equitably and allow them leave with pay and sick leave with pay. Major Tryon (Parliamentary Secretary to the Ministry of Pensions) replied it was not considered that medical assessors employed at sessional rates were inequitably paid. Their conditions of service were different from those of whole-time Medical Commissioners or Deputy Commissioners. The question of leave with pay could not arise in the case of men who were engaged on a sessional and not a salaried basis.

Medical Staff of the Ministry of Pensions.—Mr. Robert Young asked the Minister of Pensions, on April 19th, the number of naval and military medical officers of the regular services employed by the Ministry who were in receipt of pensions, and how many received pensions over £500 a year. Major Tryon replied that there were twelve regular naval or military men employed on a salaried basis in the Ministry in various parts of the country who were in receipt of pension in respect of naval or military service. Inquiry would be made as to the amount in each case.

Medical Examination for Government Employment.—Mr. Crooks asked, on April 19th, whether, in view of the physical deterioration consequent on the experience of the war, instructions would be given for discontinuance of the practice of medically examining the applicants for employment in the various Government departments. Mr. Baldwin (Financial Secretary to the Treasury) said that the Order in Council of March 22nd, 1918, adopted the recommendations of Viscount Gladstone's Committee (Cmd. 34) in regard to the conditions under which Civil Service certificates for permanent appointments should be issued to candidates whose health had been impaired by war service, and gave power to relax to a very great extent the ordinary physical standard for certification. The power of relaxation had been largely used, and he thought it would be generally agreed that these concessions went as far as could reasonably be expected.

The Provision of Artificial Limbs.—In reply to Mr. Alfred Davies, Major Tryon said that the number of pensioners in the North-Western Region with amputations of a leg and arm respectively was 3,550 and 1,500. All these pensioners had been fitted with artificial limbs. In addition there were about 140 serving soldiers who were not yet ready to be so fitted. The cost of maintaining the limbs in repair, both prior to the supply of the second artificial limb and after was borne by the Ministry of Pensions. The issue of second limbs had been proceeding steadily since last October.

Milk Adulteration.—In reply to Lieut.-Colonel Pinkham, Commander Eyres-Moossell, for the Minister of Agriculture, said that the warranty defence provisions of the Food and Drugs Act in the case of milk was amended by the Milk and Dairies (Consolidation) Act of 1915, but the operation of this Act was suspended during the war, and it was proposed to introduce legislation to amend it in certain particulars before bringing it into operation.

The Health of the People.—On April 14th Mr. Clough asked the Minister of Health a question on the report on the physical examination of men of military age by National Service medical boards. Dr. Addison replied that the report was only part of a mass of evidence indicative of the need for a reorganization and extension of public health services and for better housing, and it was impossible within the limits of a reply to a parliamentary question to set out all the steps to this end which had been taken or were in contemplation.

The Administration of Anaesthetics.—Mr. Gilbert inquired, on April 14th, whether, in view of the number of inquests held in London on persons who had died under anaesthetics, the Minister of Health would ask the Medical Research Council to inquire into the question of anaesthetics and their administration; and whether, if this could not be done, he would have the recommendations of the Home Office Departmental Committee of 1910 on the same subject put into practice. Dr. Addison replied that, having regard to the scientific investigations that had been made in comparatively recent years, he was not at present convinced that there was need for a further investigation of the character suggested, but he would give the matter his careful consideration.

Scotland.

GENERAL NURSING COUNCIL FOR SCOTLAND.

THE constitution of the General Nursing Council for Scotland, established by the Nurses' Registration (Scotland) Act, 1919, has now been completed. The Privy Council has appointed Captain Charles B. Balfour, C.B., Lord Lieutenant of Berwickshire, and the Scottish Education Department Miss Norah Milnes, B.Sc., Director of the School of Social Study in the University of Edinburgh. The Scottish Board of Health has appointed Dr. A. K. Chalmers, M.O.H. Glasgow; Dr. Katherine Clark, assistant medical officer, Edinburgh Education Authority; Dr. H. E. Fraser, Medical Superintendent, Royal Infirmary, Dundee; Colonel D. J. Mackintosh, C.B., M.V.O., M.B., Superintendent to the Western Infirmary, Glasgow; and nine nurses, including the lady superintendents of the Royal Infirmary, and the Royal Hospital for Sick Children, Edinburgh, and of the Royal Infirmary, Glasgow.

SMALL-POX IN GLASGOW.

Though the number of cases of small-pox in Glasgow is not large the prevalence has not ended; 6 fresh cases recently reported raise the total number in Glasgow since the outbreak began to 28, and there have been 2 cases outside the city boundary. One of the cases most recently admitted is an unvaccinated child. In a recent report Dr. A. K. Chalmers, M.O.H. for Glasgow, states that the cases have fallen into groups between which no connexion has been discovered. This fact, together with the occurrence of certain detached cases, suggests that the infection in some instances may have been derived from unrecognized cases among the population. In one group of 7 cases 2 were discovered before the first was recognized. The infection is believed to have been derived from a ship on which small-pox was known to have occurred; it reached the Thames on January 24th, and the stewardess, who was not herself known to have suffered from small-pox, reached Glasgow on January 25th; her parents sickened, the one eighteen days after the daughter's arrival, and the second fourteen days later. The first case of another group was a miner, who also carried on business as a fruit hawker, and went about his work until the eruption appeared on February 28th; his wife and two children, who had been removed to the reception house for observation, were transferred to hospital on March 16th and 17th respectively. In another small group the source of infection could not be traced. Two cases at Govan were sisters of a man who worked as a carpenter on a vessel which had arrived in London early in March from Alexandria; small-pox is prevalent there, and several cases occurred on the voyage. The carpenter, as also another man, in whom, before the diagnosis of small-pox was made, malignant scarlet fever was suspected, died. Dr. Chalmers considers it established that unrecognized cases of small-pox are occurring among the population, most likely in mild forms, and thinks it probable that the patients are continuing their daily avocations. He states that since the passing of the Vaccination Act of 1917 the proportion of infants successfully vaccinated in Glasgow has continuously decreased, until at the present time probably no more than half the number born are protected, in place of about 84 per cent. before the passing of the Act. Little difficulty, he states, is being found in inducing those in whose neighbourhood cases are occurring to submit to vaccination. It is proposed to open the tuberculosis dispensaries in the evenings for the purposes of vaccination.

England and Wales.

TRAINING FOR BLIND, DEAF, AND CRIPPLED STUDENTS.

SCHOOLS for the blind have been provided and maintained by local education authorities since the passing of the Education Act of 1893, and the voluntary associations for giving employment to the blind now receive grants from public funds, in accordance with the regulations made in 1919 by the Ministry of Health. In draft statutory rules

and orders,¹ issued under Section 44 of the Education Act, 1918, the Board of Education now makes provision for the linking up of these first and last stages in the training of the blind, and the conditions are set forth on which are dependent the payments of grants to training institutions, whether provided by local authorities or by voluntary agencies. As a rule, the pupils will be those who, at the age of 16, have left the special elementary schools, but others may be admitted, subject to the Board's approval. Care is to be taken that besides acquiring manipulative skill in his branch of training, the student shall receive such instruction in the commercial aspects of the trade (especially the source and cost of materials and the business of buying and selling) as will qualify him later on to acquire and conduct a business of his own. Provisions of similar nature are to be made for the deaf and crippled.

MEDICAL DINNER AT HARROGATE.

THE first post-war annual dinner of the Harrogate Medical Society took place at the Prospect Hotel on April 15th, and was attended by some seventy medical men of Harrogate and district. Dr. W. Bertram Watson, President of the society, occupied the chair. The guests included Sir Berkeley Moynihan of Leeds, Dr. Bedford Pierce, President of the Medico-Psychological Association, Dr. W. H. Willeox, physician to St. Mary's Hospital, London, and the Mayor of Harrogate (Alderman J. Shepherd). After the loyal toasts, the Mayor, in reply to the toast of the Corporation, proposed by Dr. Solly, affirmed the willingness of the corporation to carry out the improvements necessary for the advancement of the town. Sir Berkeley Moynihan, in proposing the health of the Society, referred to the proposed institute for investigation, somewhat on the lines of Duff House, where patients exhibiting early errors of metabolism would find at their disposal the best pathologist, radiographer, and biochemist they could get. He hoped the scheme would shortly materialize, as it was a long-felt want, for team work was essential to-day. Harrogate was extraordinarily fortunate in the opportunities for research. The President, in reply, said that the Society now numbered eighty-six members. The keynote of medical work must be increased efficiency; the founding of the new institute was a great step forward. The toast of the Visitors, proposed by Mr. Frankling, was responded to by Dr. Bedford Pierce and Dr. Willeox; the latter, in the course of his remarks, said he would look forward to seeing the Royal Bath Hospital with its 160 beds fully equipped as a model for scientific research for the benefit of each patient. In the course of the evening the Gordon Black Golf Cup was presented to Dr. H. P. Thompson by the donor. The proceedings terminated with a vote of thanks to the President, proposed by Dr. David Brown.

NORTH OF ENGLAND EDINBURGH UNIVERSITY CLUB.

THE annual dinner of the North of England Edinburgh University Graduates' Club, which had been in abeyance since 1914, was held on April 13th at the Central Station Hotel, Newcastle. The President of the Club, Professor T. Eustace Hill, M.O.H. for Durham, was in the chair, and the guest of the evening was Dr. Claude B. Ker, Medical Superintendent of the City Hospital, Edinburgh. The toast of Alma Mater, proposed by the President with musical honours, was responded to by Dr. C. B. Ker in a racy speech full of reminiscences of past and present teachers in the Edinburgh School. Later in the evening he delighted the gathering with a recitation of the "Hunky Kid" in his own inimitable style. The toast of the sister universities was proposed by Mr. Robert Pybus, M.A., and responded to by Professor W. E. Hume. During the course of the evening songs were contributed by Mr. J. Duncan and Mr. T. Edwards. The dinner was very successful and was much enjoyed.

¹ Cm 1. 653. Price 1d.

THE report of the Fuel Research Board of the Department of Scientific and Industrial Research for the years 1918 and 1919 has been placed on sale and can be obtained through any bookseller, price 1s. 6d., or direct by post from H.M. Stationery Office, Imperial House, Kingsway, London, W.C.2, price 1s. 8jd. Among the subjects dealt with are air pollution, domestic heating, and alcohol as fuel.

Correspondence.

TUBERCULOSIS AS AFFECTED BY THE WAR.

SIR.—Are we not rather tending to emphasize unduly the effect of the war on the incidence of tuberculosis in this country? Press allusions are frequent to “alarming results” in this direction. In the *JOURNAL* of last week there are two references of the kind.

What are the facts? A certain increase in mortality from tuberculosis has been recorded for England and Wales during the period. The increase is not equal in distribution or universal. In some parts of the country the contrary is the case—there has been a decrease.

In Scotland the mortality “from all forms of tuberculosis” and “from pulmonary tuberculosis” has fallen notably since the outbreak of the war up to the end of 1919. The Registrar-General’s figures show:

Death Rates per 100,000 of the Population.

	From All Forms.	From Pulmonary Tuberculosis.
1913 ...	170 ...	108 ...
1919 ...	129 ...	88 ...

It is particularly to be noted that during 1919 there has been a phenomenal drop in both columns—namely, from 158 (1918) to 129 per 100,000 in the one case and from 107 (1918) to 88 per 100,000 in the other. A similar remarkable drop during the past year is recorded from New York State.

In the face of such evidence the alarmist attitude seems hardly justifiable or helpful.—I am, etc.,

Edinburgh, April 18th.

R. W. PHILIP.

THE TREATMENT OF CANCER OF THE UTERUS.

SIR.—Dr. Herbert Spencer’s humour lacks neither robustness nor avoirdupois. But it is ineptitude.

In England and Wales alone 4,000 women a year die of cancer of the uterus. What are we going to do about it? A leader writer in the principal organ of medical opinion in this country, despairing of what he imagines to be the results of radical operative treatment, bids us pause and contemplate three fortunate results that followed a sort of operation (which, by inference, Dr. Spencer in his paper condemned), and asks us to listen to the note of confident hope from certain foreign radium “merchants.” I cannot understand the psychology of any one who can affect gladness at the pronouncement.

A considerable number of observations have been made in this country and abroad on the frequency with which the parametrial tissues are invaded in operable cases of cancer of the cervix. In from 50 to 70 per cent. these tissues are found to be involved, whilst the pelvic glands show cancerous deposits in at least one-third of the cases. Further, in an appreciable number of cases the pelvic glands are affected where the parametrial involvement has escaped detection. The figures relating to the parametrium are, beyond doubt, understated, for the obvious reasons that it is impossible for anybody to examine microscopically the whole of the parametrial tissues or to be sure of recognizing isolated cancer cells. No man can palpate a solitary cell in a lymphatic vessel, and a single cancer cell left behind may be responsible for the recurrence. In fact, it is doubtful if any gynaecologist could recognize by palpation even a million such cells distributed through the parametrium. Such being the case, we can appreciate the absurdity of the claim to be able to select for operation cases of cancer of the cervix at such an early stage that lymphatic dissemination has not yet occurred. If, then, the surgeon does a kind of operation that cannot possibly encompass these danger zones and the patient remains free from recurrence, what is such a “proud result” to be called? “Luck” is my name for it. Perhaps Dr. Spencer can supply a more fastidious designation?

But, some may say, granting the pathological conditions are such as you describe (and none can seriously dispute them), what about the mortality of the radical operation? The more restricted the operation the lower is the operative mortality but the higher the recurrence mortality. Which would you choose if you were the patient—to have a 2 to 3 chance of absolute cure and run the risk of not surviving the extended operation, or to survive the restricted operation and have the odds of at least 30 to 1 against the possibility of cure, to live through weeks of

anguished waiting for the sure but laggard footsteps of remorseless death? The answer is not doubtful.

The successful treatment of cancer in general demands a knowledge of the broad facts of surgical pathology and the most exacting surgical technique. The better the latter, the lower the operative mortality.—I am, etc.,

Pathological Laboratory,
The Cancer Hospital, S.W.,
April 19th.

ARCHIBALD LEITCH.

DENTAL CARIES AND ORAL OSMOSIS.

SIR.—You have done me the honour of criticizing my theory, and I am very pleased to see my name in your famous journal.

That in a conservative country like England a new theory must be beaten is evident. Why? Of course, because it is new. But the matter is a little different in this case. A new theory of the population of Jupiter or the currents of the Arctic Sea can be crushed or favourably taken up, and the world moves on without any perceptible disturbances. But in this case, as said, the matter is somewhat different. Every year that the dental and medical world embraces the carbohydrate theory means that millions of British children lose many millions of teeth with its social and individual consequences.

For, you must confess, the hypothetical knowledge of the origin of dental caries being caused by lodging fermented carbohydrates has in no direction helped us to stop the increasing wave of decay.

Certainly you will also agree with me that it is easier to crush a theory than to smoke a cigarette, and you will also agree that the usual way of doing this is to carefully avoid or extract the strong points and concentrate upon any weak or subordinate facts.

I adduce a series of proofs showing the untenability of Miller’s theory. As I have said in the critique of the chapter in question, some of these proofs are weaker, others are stronger. You skip all the irrefragable ones and take up only the weakest, citing that I “triumphantly point to the cessation of the carious process after burial as a proof of the innocence of the bacteria, ignoring the lower temperature and absence of food supply.” But how is this explained in my book?

It is a singular fact that whereas the body, buried in the earth, will quickly be completely annihilated, the teeth, on the contrary, offer for many thousand years a resistance against decomposition. Among these teeth some may also be carious. Death has stopped instead of hastening the decomposition of the teeth, whereas, in conformity with the hypothetical chemo-parasitic theory, we should have expected the contrary, independently of the question if parasites or saprophytes are the cause of the annihilation. The destruction of the teeth seems, consequently, to be dependent upon a natural power which is irrespective of the common chemical utilization process of animal life.

As you see, you have quite misunderstood my meaning. In this connexion you further accuse me of turning “a blind eye to awkward facts,” and refer this to bacteriology. I do not agree with you that medical science has a correct idea of the bacteriological principles and the relationship between bacteria and disease.

To a medical man bacteria and disease are, as a rule, synonymous. And to him bacteria are the origin of a disease. But a scientist in biology has a somewhat different opinion. To him the matter presents itself as follows: We have inside and outside the body millions of micro-organisms, perhaps twenty to thirty of which are injurious, and this under quite special circumstances only. These circumstances just involve the rather or partially unknown factor which makes it possible for microbes to enter the body, where the micro-organisms are thus the secondary factor. In my theory you get detailed proofs of what it is in teeth that forms the base for the micro-organismal invasion, which also there is a secondary factor. I never said that caries is independent of bacteria.

You write: “We would, however, prefer to adopt the generally accepted opinion that it is only in later stages of decay that a discoloured tract extends to the pulp.” You thus “prefer to adopt” my discovery proven by plenty of sections and easily controlled by everybody who wishes to find the truth, as a fancy, and why? Because in this easy way you will be able to disregard disagreeable facts.

My claim as to symmetrical caries being inexplicable under the carbohydrate theory you simply turn to the

favour of this latter theory, saying that the symmetrically appearing caries gets its natural explanation from "symmetrically" lodging food. If you will kindly re-read the chapter in discussion you will certainly find that the cases I relate absolutely exclude any possibility of ascribing them to "lodgement of germs and carbohydrates." You quite misunderstand my figure of caries spread along the interg'obular layer. I have—well to observe—given this plate of caries without the plasmoid canal. A broad carious attack must, however, have a correspondingly broad plasmoid canal, which is invariably the case. I quite understand your joy in being able to invent, instead of the disagreeable name "osmosis," such a happy sentence as "merely an expression of the normal life-activity of the dentine." But my claim that osmosis is the principal factor of caries is the result of careful experiments.

Crystalloid sugar you cannot reckon to carbohydrates, and its power, if any, of forming acids is minimum, and yet you must agree that sugar is the principal caries devastator in human teeth. How will you explain this?

Finally, I once more repeat that the careful study and acceptance of my theory will be of benefit by saving millions of teeth to the British nation.—I am, etc.,

Malmö. RAGNAR ECKERMAN, Dr.Sc., L.D.S.Malmö.

Our reviewer writes that he must abide by the opinion of Mr. Eckermann's theory expressed in the review and that he has looked for but failed to find the caries canals, on the presence of which so large a part of Mr. Eckermann's theory depends.

CARCINOMA OF THE THYROID.

SIR.—Malignancy of the thyroid gland, whatever the type, is rare. Mr. A. J. Blaxland's case of adeno-carcinoma of the thyroid gland (March 27th, p. 454) is interesting, both from the point of view of the patient's age and the early recognition and so far successful eradication of the growth.

The common age of appearance of these tumours is about forty years, and the appearance of a hard swelling in the thyroid gland of a patient forty years and upwards which gradually increases in size should always arouse a suspicion of malignancy.

Unfortunately it has never been my experience to come across a case of adeno-carcinoma of the thyroid gland in which operation could be said definitely to have effected a cure. The early involvement of the trachea and surrounding structures in this situation as the growth becomes extracapsular, renders this type of tumour perhaps the most difficult of any to eradicate. Indeed the earliest symptom may be cough and a blood-stained expectoration caused by ulceration of the growth into the trachea.

A very early recognition before the growth has become extracapsular is the clue to successful eradication, and on the first the prognosis will depend. Mr. Blaxland's Case 1, so far, well illustrates this point.

Some years ago I saw two cases of adeno-carcinoma of the thyroid gland. The patients were in a Poor Law institution, and some weeks previously what proved to be unsuccessful attempts had been made to remove the growths. Recurrence had taken place in the operation wounds of both and advanced malignant manifestations were present, in that nerves were involved causing pain of a most intolerable kind, the wounds were fangating and foul, dyspnoea was a conspicuous symptom and dysphagia was present in one of them. The facies, portraying fear of suffocation, coupled with the physical pain these two poor creatures endured, formed a picture of human suffering never to be forgotten. One died from septic pneumonia as a result of ulceration of the growth into the trachea, whereas a brisk secondary haemorrhage mercifully and rapidly ended the other's suffering.

Glandular involvement in these cases I have found to be a later manifestation, and in this respect differs from the papillary carcinoma. Its occurrence is of very bad omen.—I am, etc.,

Bradford, March 29th.

BASIL HUGHES.

AORTITIS AND AORTIC REGURGITATION.

SIR.—The record of a case published in the issue of your contemporary the *Lancet* of April 10th tempts me to comment upon the paper by Dr. MacIlwaine dealing with the connexion of syphilitic aortitis with aortic

regurgitation (*BRITISH MEDICAL JOURNAL*, March 27th p. 428).

The case recorded by Dr. W. Gordon in the *Lancet* is one in which a case of aortic regurgitation of rheumatic origin lasted for thirty years. Although this is exceptional even for a rheumatic case, it illustrates the less serious nature of aortic regurgitation of rheumatic origin compared with that of aortic regurgitation following aortitis. One important detail of the morbid anatomy of aortic regurgitation following aortitis has possibly not been sufficiently noted by Dr. MacIlwaine. This is the disease of the cardiac muscle which follows interference with the circulation through the coronary arteries, the orifices of which are almost invariably seriously obstructed by the disease of the aorta. It is this disease of the cardiac muscle which entails the risk of sudden death, and also, it may be mentioned, gives rise to the pain on the presence of which Dr. MacIlwaine lays stress.

It should be stated, perhaps, that in cases of aortic regurgitation of rheumatic origin the cardiac muscle often shows considerable disease—more, it seems to me, than can be accounted for by previous rheumatic myocarditis. While this is so, it is in the cases of aortic valvular disease associated with syphilitic aortitis that disease of the cardiac muscle is of predominant importance.—I am, etc.,

Norwich, April 17th.

THEODORE FISHER.

PUBLIC HEALTH VERSUS THE STATE.

SIR.—With your indulgence I would remind Dr. Baskett that during the war a considerable number of beds in our civil hospitals were reserved for sick and wounded soldiers, and would explain to a large extent the unwonted run on Poor Law beds, and I would also remind him that times of stress are not entirely confined to the shiftless.—I am, etc.,

H. W. FREER, M.R.C.S.Eug.,

Colwyn Bay, April 14th.

L.R.C.P.Lond.

WAR HONOURS.

SIR.—I believe every third man called up for military service will receive a pension or some equivalent form of compensation. Then there are those who have had bestowed upon them medals or letters of distinction after their names. Again, of the civil honours already conferred the daily papers remind us how liberally these have been distributed. The long chain of organization in the execution of this great war needed all the acumen, intelligence, skill, and ingenuity in piecing its links together. They gave way repeatedly, but were fearlessly adjusted. And as each broken link was renewed the strain of the pull seemed strengthened. We learnt the power of its resistance when the final effort came. It was not one, two, or more links which gave this vim to the organization of the chain, but it was the one long piece of machinery—British grit. And thus the enormous difficulty of the Government in bestowing their war honours. Everyone, then, appears to be entitled to a reward, monetary or other, and, if in one case, so in hundreds of other professional men—are they not worthy of war honours?

In serving at the home front, for I was beyond military age, I systematically released my professional brethren in a large city for the period of the war. But what is doubly interesting to me, as an old member of the British Medical Association, I was able to help support a professional front. And in reviewing the cement of our professional work, I find that the "pointing" shows no cracks. Professional rivalries, disputes, jealousies, and whispered confidences have linked themselves together into a solid unbroken chain. I have received my war honour at a professional dinner in this city in which members rose remarking, "not only has my practice been kept together, nay it has been improved." Again, the chief medical officer writes me: "What you have done in the borough during the last four or five years has won you the esteem of the profession."—I am, etc.,

April 17th.

ANOTHER WHO WAS OVER AGE.

THE Civil Governor of Madrid has made vaccination against small-pox and enteric fever compulsory for all the inhabitants.

INTERNATIONAL HEALTH CONFERENCE.

The delegates attending the International Health Conference held at the Ministry of Health last week were the guests of the Government on April 15th at a luncheon given at the Carlton Hotel, London. The Minister of Health, Dr. Addison, presided.

The Conference was convened by Dr. Addison at the request of the Council of the League of Nations. Its first purpose was to consider the constitution of an International Health Office under the League, an idea roughly parallel to that of an International Labour Office under the League. Although the Covenant of the League did not provide for the establishment of an International Health Office in quite the same way that it provided for the establishment of an International Labour Office, nevertheless the Covenant clearly contemplates such an office, and it was in the knowledge that it would meet with sympathetic support from other nations of the League that Dr. Addison took the initiative and convened a preliminary informal Conference in July, 1919, which has been followed by the formal Conference last week.

A second purpose of the Conference was to discuss and advise as to measures to be taken in connexion with the typhus outbreak in Poland. Poland lies between the West of Europe and the typhus epidemic which is now raging in Russia. The country is without sufficient means to establish any satisfactory barrier against the spreading westwards of that disease. Not only is there difficulty owing to the indeterminate state at present of Poland's eastern boundaries, but there are the difficulties also arising from lack of medical personnel, sanitary stores, and money. The Conference discussed how best these difficulties might be met in the interests not only of Poland but of all Europe alike. The chairman of the Conference was Viscount Astor. The delegate representing Great Britain was Dr. G. S. Buchanan, C.B., with Dr. Steegmann as technical adviser. Sir George Newman, K.C.B., attended when his other engagements permitted, but the British vote was given by Dr. Buchanan.

The Services.

R.A.M.C. FUND AND OFFICERS' BENEVOLENT SOCIETY.

The annual general meeting of the Royal Army Medical Corps Fund (Regular Army) will be held in the Library of the Royal Army Medical College, Grosvenor Road, S.W., at 2.30 p.m. on Monday, June 14th. The Director-General will preside. It is hoped that all subscribers who can spare the time will be present and will freely express their views on any point connected with the fund.

The annual general meeting of the Royal Army Medical Corps Benevolent Society (Regular Army) will take place immediately afterwards.

Any officers desiring information regarding these funds are requested to communicate with the Secretary, Lieut.-Colonel E. M. Wilson (76, Claverton Street, S.W.1, Tel. Victoria 2722), beforehand, so that there may be no delay in dealing with any questions asked.

R.A.M.C. CENTRAL MESS FUND.

The annual general meeting of subscribers to the Royal Army Medical Corps Central Mess Fund will be held in the Library of the Royal Army Medical College on June 14th, following immediately that of the Royal Army Medical Corps Officers' Benevolent Society. Officers desiring information about this fund are asked to communicate with the Honorary Secretary beforehand, so that there may be no delay in dealing with any questions which may be asked. Notice of any definite proposal which it may be desired to bring forward should be sent to the Honorary Secretary, Captain J. T. Clapham (3, Homefield Road, Wimbledon, S.W.; Tel. Wimbledon 750), in order that it may appear on the agenda paper.

The annual corps dinner will take place the same evening at the Wharnclyffe Rooms, Great Central Hotel, at 7.30 p.m. A separate notice will be issued.

UNITED SERVICES MEDICAL SOCIETY.

There will be a meeting of the United Services Medical Society in the Library of the Royal Army Medical College, Grosvenor Road, S.W., at 3.30 p.m. on May 28th, 1920, to discuss the proposed amalgamation of the Society with the War Section of the Royal Society of Medicine.

A PENSIONS HANDBOOK.

The *Local War Pensions Committees' Handbook*, which consolidates the circulars and instructions issued by the Ministry of Pensions, other than those concerning the functions of the Special Grants Committee, has now been placed on sale (price 2s.) by H.M. Stationery Office. It is arranged in five parts, corresponding with the main divisions of the work of the Local Committees; it replaces the Instructions for the Assessment of Alternative Pensions, 1917, Instructions and Notes on the Treatment and Training of Disabled Men, 1917, Instructions on the Treatment of Disabled Men, 1918, and Ministry of Pensions Circulars issued prior to January 1st, 1920. Among the Appendices is the complete text of the Royal Warrant of December 6th, 1919, under which soldiers' pensions are awarded. This handbook should be of value to Local Committees and medical officers, and facilitate the working of Pensions administration.

Universities and Colleges.

UNIVERSITY OF GLASGOW.

THE History of Medicine Prize, value about £50, will be awarded for the best essay on some subject in the history of the science or practice of medicine, other than a subject of recent development in some limited branch thereof. Candidates must be graduates of the university. A work on the history of medicine, published by a candidate within the years 1919, 1920, and 1921, will be admissible.

Faulds Fellowships.

Regulations for the Faulds Fellowships instituted under the will of Mr. W. B. Faulds, writer, in Glasgow in the faculties of Arts, Medicine, Divinity, and Law respectively have been approved. A fellowship will be awarded by the Senatus, on the recommendation of the Faculty concerned. In considering the applications of candidates the Faculty will take into account the candidate's general academic record, the evidence of his capacity for advanced study inquiry or research, and the results of any independent work, published or unpublished; which he may have undertaken. The Faculty may, if it thinks fit, arrange for such trial and oral or practical examination as it may deem necessary to distinguish between candidates of apparently equal merit. Each Fellow must devote himself to a branch of advanced study, inquiry, or research recommended by the Faculty, which may appoint one of its number or a lecturer of the university to be responsible for the general direction of the Fellow's work and to make an annual report on its progress. A Fellow may be required to deliver lectures or otherwise assist in the public teaching of the Faculty in a subject connected with his special work, but may be authorized to carry on his work, during one year, elsewhere than at the University of Glasgow. No Fellow must engage in professional work or practice or any other occupation during his tenure of office, save with the express permission of the Senatus, which shall not be granted unless found expedient in the interest of his work as Fellow. Candidates for the fellowship in medicine must be men who have within the three academical years immediately preceding the award completed the medical curriculum by passing the final professional examination required for graduation and taken the degrees of M.B., Ch.B.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY council was held on April 8th, when Sir George Makins, president, was in the chair.

Election to the Fellowship of Members of Twenty Years' Standing.—The following were elected: Henry Alexis Thomson, C.M.G., Professor of Surgery in the University of Edinburgh; Wilfred Thomason Grenfell, C.M.G., Superintendent of the Labrador Medical Mission of the Royal National Mission to Deep Sea Fishermen.

Donations.—The thanks of the Council were given to Sir C. Kirkman Finlay for presenting, through Mr. J. G. Turner, F.R.C.S., the skulls of twenty Burmese and four Chinese, who were executed in gaols in Burmah. Thanks were given also to Sir Rickman Godlee for presenting the original drawings which he made for his *Atlas of Human Anatomy*, 1880; and the calvaria of the patient he trephined in 1884 for the removal of a cortical tumour—the first operation of its kind.

The late Mr. George Arthur Wright.—A vote of condolence was passed on the death of Mr. George Arthur Wright, who died March 23rd at the age of 68, and who was a past member of the Council.

Three vacancies on the Council of the Royal College of Surgeons of England will be filled on Thursday, July 1st. The retiring members are Sir Anthony Bowlby, Mr. W. Harrison Cripps, and Sir D'Arcy Power. Mr. Cripps is not seeking re-election, the other two retiring members are coming forward again.

The constitution of the Council at present is as follows:

President.—Sir George Henry Makins, G.C.M.G., C.B. (1) 1903, (2) 1911, P. 1917.

Vice-Presidents.—Sir Anthony Alfred Bowlby, K.C.B., K.C.M.G., K.C.V.O., C. (1) 1904, (2) 1912; Sir John Bland-Sutton, C. (1) 1910 (2) 1918.

Other Members of Council.—William Harrison Cripps, C. (1) 1905 (substitute till 1908), (2) 1909, (3) 1917 (substitute till 1920); Sir Charters James Symonds, K.B.E., C.B., C. (1) 1907, (2) 1915; Mr. William Frederick Haslam (Birmingham), C. (1) 1908, (2) 1916; Sir Charles Alfred Brance, K.C.M.G., C.B., M.V.O., C. (1) 1910, (2) 1914; Sir D'Arcy Power, K.B.E., C. 1912; Sir Berkeley G. A. Moynihan, K.C.M.G., C.B. (Leeds), C. (1) 1912 (substitute till 1919), (2) 1919; Mr. James Ernest Lane, C. 1913; Mr. Holburt Jacob Waring, C. 1915; Sir William Thorburn, K.B.E., C.B., C.M.G. (Manchester), C. 1914; Mr. William McAdam Eccles, C. 1914; Mr. Charles Ryall, C.B.E., C. (1) 1914 (substitute till 1915); Mr. Walter George Spencer, O.B.E., C. (1) 1915 (substitute till 1918); Mr. Frédéric François Burglard, C.B., C. 1915 (substitute till 1921); Sir Herbert Furnivall Waterhouse, C. 1915; Mr. Thomas Horrocks Openshaw, C.B., C.M.G., C. 1915; Mr. Raymond Johnsoo, O.B.E., C. 1915; Mr. Vincent Warren Low, C.B., C. (1) 1915 (substitute till 1917); Mr. James Sherren, C.B.F., (1) 1917; Sir John Lynton Thomas, K.B.E., C.B., C.M.G. (Cardiff), C. 1918 (substitute till 1925); Mr. Ernest William Hey Groves (Bristol), 1918; Sir Cuthbert Sidney Wallace, K.C.M.G., C.B., 1919.

The medical schools are represented as follows:

<i>London:</i>	
St. Bartholomew's	5*
Charing Cross	1
Guy's	1
King's College	2
London	1
Middlesex	2
St. Mary's	3
St. Thomas's	1
University College	1
Westminster	1

Total London	13
<i>Provincial:</i>	
Birmingham	1
Bristol	1
Cardiff	1
Leeds	1
Manchester	1
Total Provincial	5
Total Council	24

* Out of the five, two offer themselves for re-election this year and one retires.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Representative on General Medical Council.

At the monthly meeting of the Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, on April 12th, Dr. James Alexander Adams, Senior Surgeon to the Glasgow Royal Infirmary, was elected the Representative of the Faculty to the General Medical Council for the period of five years. Dr. Adams succeeds Dr. D. N. Knox, who has resigned on the ground of ill health. Dr. Knox held the office for twelve years.

CONJOINT BOARD IN SCOTLAND.

The following candidates have been approved at the examinations indicated:

FINAL EXAMINATION.—Medicine: D. C. Scotland, T. Poole, J. MacGonigal, T. A. du Toit, J. S. Durward. **Surgery:** J. MacGonigal, J. S. Durward, J. H. Bain. **Midwifery:** W. S. Patrick, D. C. Scotland, A. Cuthbertson, T. Poole, W. W. Glucksmann, H. W. Whytock, J. MacGonigal, W. G. Carew, A. J. Yakil. **Medical Jurisprudence:** J. G. Collee, R. E. Hopton, J. Hagard, Alexandra M. Limont, R. G. Clouston, Pauline Figgdor, Gracie O. D. Evans, A. W. Smith.

The following candidates, having passed the Final Examination, have been admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.

A. C. Lornie, H. Barlow, R. C. Dow, W. Grant, R. Smith, G. S. Barnett, O. Fitzpatrick, G. H. S. Lindsay, H. Coheo, F. P. McN. Clarke, G. M. Kenny, A. S. Paganipe, E. Isserow, J. F. E. Burns.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The President, Vice-President, and Council have elected Professor G. Elliot Smith, M.A., M.D., F.R.C.P., F.R.S., to the Mary Louisa Prentice Montgomery Lectureship in Ophthalmology. The subject of his first lecture will be "The influence of stereoscopic vision on the evolution of man." The lecture will be given in October, 1920.

Obituary.

JOHN BATTY TUKE, M.D., F.R.C.P. EDIN.,
New Saughton Hall, Midlothian.

Dr. JOHN BATTY TUKE, who only survived his distinguished father, Sir John, by some seven years, died in a nursing home in London on April 11th. It was known that he was suffering from a serious disease, but the end came unexpectedly early. He was born in 1860, and after passing through the Edinburgh Academy graduated M.B., C.M. Edin. in 1881, and took the degree of M.D. in 1890; he was elected a Fellow of the Royal College of Physicians of Edinburgh in 1889. He first acted as assistant medical officer to the Royal Lunatic Asylum at

Montrose, and then as resident clinical assistant to the West Riding Asylum, Wakefield. Thereafter he was associated with his father in the management of the asylum near Edinburgh, first at Saughton Hall (now converted into the beautiful Gorgie Public Gardens), and then at New Saughton Hall, near Polton, Midlothian; latterly he was superintendent in the last-named institution, and had consulting rooms in Edinburgh. He published articles dealing with mental disease, notably a paper on "Recovery after seventeen years' continuous residence in an asylum," and another on "Divorce and insanity," both in 1915. Dr. Batty Tuke was an unassuming man, doing his day's duty silently and well, and he leaves many friends in the profession who will miss him much.

EDWIN ALLAN MALING, M.R.C.S.,
Darlington.

On April 12th there passed peacefully away, at the ripe age of 81, at Blackwell Hall, Darlington, Mr. E. A. Maling. It is given to few men to lead such a busy, happy, and successful life as his. He was the representative of a well known Sunderland family; his father, Mr. E. Haygarth Maling, was surgeon to the Royal Infirmary, and the founder of the Durham County and Sunderland Eye Infirmary. Mr. E. A. Maling was educated in the Grange School, Sunderland, and King's College Hospital, London. He was the house-surgeon of the Royal Infirmary, Sunderland, for five years from 1860. In those days infectious diseases were received in the general wards, and for some months he attended, practically single-handed, many cases of small-pox and typhus fever during severe epidemics in the town. On leaving the infirmary Mr. E. A. Maling was a partner for ten years of Mr. George Welford, the first surgeon in the North of England to perform ovariectomy successfully. Later he was appointed an assistant surgeon and then full surgeon to the infirmary, a post which he resigned in 1892 in order to make way for his then partner, Mr. John Whitehouse, F.R.C.S., who unfortunately died in November, 1893. From 1892 Mr. E. A. Maling held the post of honorary consulting surgeon. During his surgeoncy Mr. Maling's biggest operation was the amputation of the entire upper extremity of a man for sarcoma of the scapula, which was an operative success. From 1894 to 1903 his partner was Mr. William Robinson, F.R.C.S., the present senior surgeon to the Royal Infirmary.

For forty years Mr. Maling was one of the best known medical men of the town and district; his brisk step, his courteous manners, genial disposition, cheery voice, even temper, and constant readiness for work made him one of the busiest practitioners of the North of England in his day, and although he retired from practice in December, 1903, and went to live in the country, hundreds of his old patients look upon his decease as the loss of a constant friend. Though reserved in speech, Mr. Maling was an excellent judge of character, and his great experience and sound judgement made him a rapid diagnostician. For forty years Mr. Maling was a J.P. for the County of Durham, and for many years past he was chairman of the Sunderland County Bench. He was a keen fisherman.

Mr. Maling married a daughter of the late Mr. James Hartley, for some time M.P. for the borough of Sunderland, who survives him. There are also three sons and three daughters left to mourn his loss. His youngest son, George A. Maling, B.M.Oxon., gained the V.C. early in the war whilst in the R.A.M.C. Mr. Maling read his **BRITISH MEDICAL JOURNAL** to the last.

Dr. GUTHRIE NEVILLE CALEY, of Ealing, who died a short time ago, after an operation, was 58 years of age. He was educated at Durham University and St. Mary's Hospital, took the M.R.C.S. and L.R.C.P. Lond. in 1885, and graduated at Durham M.B. with honours, and M.S. in 1886, and M.D. in 1888. After serving as house-physician, house-surgeon, and ophthalmic clinical assistant at St. Mary's, he went into private practice, and settled some one-and-twenty years ago at Ealing, where he gradually built up a large practice, till at the time of his death he was generally regarded as the leading medical man in the town, and had a large consulting practice. During the war he was consulting medical officer to the Ealing auxiliary military hospital. He was greatly overworked in the later years of the war, when most of his juniors were absent on military service.

Medico-Legal.

AN ABORTIONIST SENTENCED.

THE trial was held last week at the Central Criminal Court, before Mr. Justice Shearman, of Devi Dayal Sasun, L.R.C.P. and S. Edin., L.R.F.P.S. Glasg., of Brady Street, Bethnal Green, for the murder of a young single woman. Sir Richard Muir for the prosecution said that the accused was a panel doctor with 3,600 patients, and was well known in the East-end of London. The allegation was that the woman died as the result of an illegal operation performed by the prisoner for a fee of £10. The prosecution submitted that her body was carried downstairs from his surgery by Dr. Sasun and deposited under an archway. The prisoner himself went up to some policemen in the early hours of the morning and told them "there is a woman lying drunk under the archway," and he accompanied them to the archway. Prisoner's object, said counsel, in calling the attention of the police to the body would perhaps be plain when the jury heard that Dr. Sasun, being the first person to discover the woman, would have been called by the coroner to give evidence and to make a *post-mortem* examination; there could be no safer way for him to get rid of the body and of any suspicion that might attach to himself. Dr. Spilsbury gave evidence that, in his opinion, death was due to shock following an illegal operation. Such occurrences were very rare, but during his long practice he had known of five instances. The prisoner, in the witness box, gave his version of the woman's visit to him and of the finding of the body. Mr. Curtis Beunett, K.C., for the defence, called Dr. Russell Andrews, Dr. Comyns Berkeley, and Dr. Fairbairn, who gave evidence voluntarily; they disagreed with the evidence for the prosecution that death occurred from shock in the circumstances stated. Dr. Fairbairn said that death from shock under such conditions was so rare that it was without his knowledge. The jury acquitted the prisoner of the charge of murder, but found him guilty of manslaughter. Sir Robert Muir said there was another indictment on the file charging Sasun with performing illegal operations on three separate women on different dates, but the judge did not think it necessary to proceed with that charge. A detective inspector stated that he found in the prisoner's safe a large number of documents signed by women, that he took statements from 116 of the women whose names and addresses were on the documents, and that as a result of his inquiries it appeared that abortion had been performed or attempted on all these women. In reply to the judge, he expressed the opinion that prisoner had been carrying on such practices for about fifteen years. In passing sentence of ten years' penal servitude, Mr. Justice Shearman said it was clear to him that Sasun had been a professional abortionist. He had perhaps been a little unlucky in this case because death had resulted, and they did not know whether death had resulted before or not. It was a very bad case.

Medical News.

THE Memorial Brass and Bed to thirty old students of Sir Patrick Dun's Hospital, Dublin, who fell or died on active service, subscribed for by their comrades who also served in the war, are now nearly ready. A circular was sent to 415 old Dun's men who were on active service concerning this memorial, but it may not have reached some. Any who may wish to subscribe will please accept this notice, and communicate at once with the honorary secretary at the hospital.

A POST-GRADUATE course on spa treatment will be held in Bath during June; it has been arranged in conjunction with the Fellowship of Medicine and Post-Graduate Medical Association. It will comprise clinical lectures, demonstrations, and visits to hospital wards during the early part of each day and a lecture each afternoon. The course will open on Monday, June 7th, when an introductory lecture will be given by Dr. Cave, and there will afterwards be a reception at the Royal Mineral Water Hospital. The course will conclude on Saturday, June 19th. An exhibition of x-ray photographs, microscopic and pathological specimens, and bacteriological cultures will be open on each day during the course. Further particulars can be obtained from the secretary, Dr. R. G. Gordon, 6, Queen Square, Bath.

A REUNION dinner of those who served with the 1st London (City of London) General Hospital, including its sections and auxiliaries, will be held in the Wharcliffe Rooms, Hotel Great Central, Marylebone Road, N.W.1, on Wednesday, May 12th, at 7.30 p.m. Tickets, price £1 1s., can be obtained before May 7th from the honorary secretary, Lieut.-Colonel W. McAdam Eccles, 124, Harley Street, W.1. Evening or service dress will be worn.

A POST-GRADUATE course of instruction, for qualified medical women, in the treatment of venereal diseases has been arranged jointly by the London (Royal Free Hospital) School of Medicine for Women, the Royal Free

Hospital, the Elizabeth Garrett Anderson Hospital, and the London Lock Hospital. The fee for the course, which commences on May 17th at 5 p.m., and concludes on Saturday, May 29th, is 5 guineas. The course will be repeated during the second fortnight of September, beginning Monday, September 13th. Applications should be addressed to the Warden and Secretary, London School of Medicine for Women, Hunter Street, Brunswick Square, W.C.1.

A COURSE of forty lectures on tuberculosis has been arranged at the Medical School, Royal Chest Hospital, City Road, E.C.1, commencing on Monday, May 3rd, and terminating on Friday, June 25th. The fee for the course is 5 guineas.

A 23rd Divisional medical dinner will be held at Oddenino's, Regent Street, London, W., on June 5th, 1920, at 7.15. All ex-medical officers of the above division who wish to attend are requested to send their names (with remittance of 15s. for dinner, exclusive of wine) to Major W. J. Pearson, New University Club, St. James's Street, London, W. Names should be submitted by May 20th.

THE proposal to convert the Medical Sickness, Annuity, and Life Assurance Friendly Society into a company limited by guarantee under the Companies Acts was confirmed at a second extraordinary general meeting held at 11, Chandos Street, W., on April 16th. The reasons for the change were explained in the report of the first extraordinary general meeting published in our issue of April 3rd, p. 475.

INFLUENZA was made notifiable in Vienna at the end of last January.

DURING December, 1919, 1,093 fatal cases of plague occurred in Java.

PROFESSOR ENRICO MORELLI, founder and editor of *Il Policlinico*, died on February 13th.

THE Académie de Médecine has recently elected M. Guillaumin to be a member, and MM. Truc of Montpellier, Imbert of Marseilles, Mouré of Bordeaux, Weill of Lyons, Dévé of Rouen, Girard of Toulon, Mirallié of Nantes, and Crespín of Algiers, to be corresponding members.

THE net amount received in the year ending March, 1919, by the excise authorities for patent medicine labels in Great Britain only, after deducting drawbacks, rebates, repayments, and allowances was £1,055,694. The annual return has not been published during the last few years, but for the year ending March 3rd, 1914, it was £360,377.

DR. CHARLES EDWARDS has been appointed to the Commission of Peace for the Borough of Bridport.

DR. JOHN MACLEAN CARVELL has been appointed M.B.E. for ambulance training and organization, London District, Order of St. John.

SIR JAMES BARR, C.B.E., LL.D., M.D., has been appointed a Knight of Grace in the Order of the Hospital of St. John of Jerusalem in England.

DR. GEORGE E. SCHOLEFIELD, M.B.E., M.O.H. West Lancashire Rural District Council, has been appointed an honorary Associate of the Order of St. John of Jerusalem in England in recognition of services rendered to the St. John Ambulance Association during the past forty years.

PRUSSIA and Baden have decided to create a doctorate of dentistry (*doctor med. dentariæ*), with an academic education, eight terms' study, and the licence in dentistry as necessary qualifications.

THE Duty and Discipline Movement has, since it was founded by the Earl of Meath in 1911, collected much useful information concerning the upbringing of children and the formation of character. The Executive Committee are now putting their theories into practice in a manner which should prove of great benefit to parents. Their scheme, called the Parents' Advisory Bureau, is likely also to prove of value to the medical profession, particularly those members who specialize in child psychology. Briefly, the system is as follows: A parent unable to control a child is invited to come to the bureau for advice. A visit is then paid to the home, or perhaps the parent is asked to bring the child to see one of the officers of the movement. By sympathetic questioning, the cause of the conduct complained of can generally be found, but this questioning requires a certain amount of skill and tact which are not found in everyone. Care has been taken that the advice given shall be sound and wholesome. Such case receives personal attention by Mr. C. J. Mead-Allen, the director of the movement, Mr. C. Montgomerie, the secretary, or Dr. Hamilton-Pearson, of 72, Wimpole Street. Practitioners who meet with cases which present interesting features, or which are likely to

add to the store of knowledge in dealing with children, are invited to communicate with the movement, 117, Victoria Street, London, S.W.1, with a view to co-operation.

THE Italian Society of Paediatrics will meet at Trieste from September 23rd to 26th, when the following subjects will be discussed: (1) Vaccine treatment of children's diseases, introduced by Professor Di Cristina of Palermo and Professor Caronia of Naples; (2) infant welfare, introduced by Professor Allaria of Turin and Professor Modigliani of Rome. Communications should be addressed to the Secretary, Professor E. Modigliani, Via Palermo 28, Rome.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the **BRITISH MEDICAL JOURNAL** are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that **ALL** letters on the editorial business of the **JOURNAL** be addressed to the Editor at the Office of the **JOURNAL**.

THE postal address of the **BRITISH MEDICAL ASSOCIATION** and **BRITISH MEDICAL JOURNAL** is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. **EDITOR** of the **BRITISH MEDICAL JOURNAL**, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. **FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. **MEDICAL SECRETARY**, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the **British Medical Association** is 15, South Frederick Street, Dublin (telegrams: *Dacillus, Dublin*; telephone, 4757, Dublin), and of the **Scottish Office**, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

X asks for suggestions as to the treatment of chyluria in a man who has never resided out of the British Isles, and otherwise is in good health.

ESTABLISHMENT LICENCES.

W. asks whether a medical practitioner is liable to a tax for a driver of a car used for professional purposes.

The point is by no means free from difficulty. A "male servant" is defined to include a motor-car driver, and no exemption is given because the driver is employed for professional purposes. *Prima facie* our correspondent would be liable, but it can hardly be supposed that licences are required in the case of all motor-car drivers—for example, bus drivers, or the drivers of tradesmen's delivery vans; in such cases they would probably be regarded as trade employees rather than as male servants. A medical practitioner's driver often acts in both capacities, and in such cases we think that the licence would have to be taken out. Whether it could be insisted on in the case of a driver who did no non-professional driving or any other work may be open to doubt.

ARTIFICIAL APPLIANCE FOR AMPUTATION BELOW THE ANKLE.

A CORRESPONDENT in a remote part of the world asked recently for hints as to how to direct an artificial stump to be made in the case of a supramalleolar amputation; the apparatus would have to be constructed not by an expert, but in the shop of a ship-repairing company.

We are indebted to Mr. Muirhead Little, F.R.C.S., for the following reply to this question: A great deal depends upon the nature of the stump. If it has a Syme flap and is suitable for end-bearing, the problem is much simplified. In any case a plaster-of-Paris cast of the stump from the knee-joint down to and including the end should be taken. This should be covered with a thin stocking, and then a blocked leather (sole leather) socket made to fit it closely, taking as much bearing as possible under the head of the tibia. The leather should be well soaked in cold water, applied to the cast wet, and held with a bandage while it dries on the cast. A steel plate about 15 mm. wide and 3 or 4 mm. thick, and long enough to project at least 2 in. below the bottom of the leather socket and to reach nearly to the top of it, should be fixed with copper rivets to each side of the socket. The lower ends of these steels must be fixed with screws on to a hard wood block, of sufficient thickness to equalize the length of the limbs, below the end of the socket. A piece of sole leather or a rubber heel should be fixed to the lower surface of this block. Before applying the leather to the cast to form the socket, a piece of felt at least half an inch thick should be

put inside the stocking at the end of the cast, so as to allow a space between the end of the stump and the bottom of the socket. If the stump can bear end-pressure this space is filled by a pad in the finished appliance. If not, it is left empty. If enough support is not obtained by the appliance here described, the side steels must be carried up to form knee joints, and thigh corset and steels added.

LETTERS, NOTES, ETC.

T.F. AND S.R.

"OPTIMIST" writes: The advice concerning the Territorial Force and Special Reserve given by your correspondent "Quoth the Raven" (March 20th, p. 417) is so thoroughly sound that no medical man can seriously dispute it; but how can his first recommendation—"If you are in either, get out as soon as you can"—be carried into effect? As far as I know suicide is the only method.

JAMAICA AS A HOLIDAY RESORT.

DR. H. G. WHARRY (London, W.1), writing as a recent visitor to Jamaica, strongly advises any medical man who contemplates going there or sending a patient, to make careful inquiries beforehand. By the direct route, which he thinks should be avoided, the voyage, generally unpleasant in winter, may, he says, take from fourteen to twenty-three days, and on arrival at Kingston there may be great difficulty in finding rooms, even though a promise may have been made to reserve them. In other places on the island the same congestion, he says, exists. The prices in Jamaica, he found, were not low, and his view is that a visitor must make up his mind to rough it and pay heavily for the privilege.

LIGHT WINES AND HEAVY PRICES.

PEOPLE with long memories can recall how Mr. Gladstone in one of his budget speeches sang the praises of light French wines, and, to encourage the British to consume more of what he considered a wholesome as well as a palatable beverage, reduced the duty. His recommendation, if not the reduction of the duty, undoubtedly encouraged the importation of light wines, and for a time "Gladstone claret" was a common name for light red French wine. Ever since the duty has been 1s. 3d. or less per gallon—on the average, say, twopence a bottle. Mr. Chamberlain has now doubled it, yet still it is only about fourpence a bottle; but the price of "Gladstone claret" was about 1s. 6d. a bottle, or less, and very ordinary Bordeaux wine now costs 4s. or 5s. a bottle at the wine merchant's. The cause of the greater part of this increase is to be found in the very great increase in the price at Bordeaux. It is now three or four times as much as it was a few years ago. The explanation given by the Bordeaux merchants is that the supply has been diminished by neglect of the vineyards during the war, and also, it is asserted, by the large purchases made for the French army. Some newspapers have interpreted the increase in the excise duty in the Budget as ungracious treatment of our allies, but in this connexion it is only fair to remember that the increase due to the duty is only 5 or 6 per cent. of the total increase in the price to the consumer here.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 34, 38, 39, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 35, 36, and 37.

THE following vacant appointments of certifying factory surgeons are announced: Blarney (Cork), Kingston-on-Thames (Surrey), Menai Bridge (Anglesey), North Berwick (Haddington).

A SECOND medical referee under the Workmen's Compensation Act, 1906, for the Marylebone and West London (Frompton) County Courts (Circuit No. 43) is to be appointed. Applications to the Private Secretary, Home Office, by May 5th.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

A Lecture

ON

BRONCHIECTASIS.

DELIVERED AT THE HOSPITAL FOR CONSUMPTION, BROMPTON, NOVEMBER 19TH, 1919.

BY

A. J. JEX-BLAKE, M.A., M.D. OXON., F.R.C.P.

PHYSICIAN TO ST. GEORGE'S HOSPITAL; ASSISTANT PHYSICIAN, HOSPITAL FOR CONSUMPTION, BROMPTON.

BRONCHIECTASIS, or dilatation of the bronchi, both large and small, is a condition quite commonly met with among the in-patients and the out-patients at this hospital. Except perhaps in a few rare congenital cases, it is not a primary disease of the lungs, but is always secondary to some preceding disorder, such as pulmonary tuberculosis, bronchitis, pneumonia, or bronchial obstruction, and as a rule it is a chronic complaint. I make particular mention of the fact that in bronchiectasis both the large and the small bronchi are dilated, because there is a condition known as bronchiolectasis, or dilatation of the bronchioles, in which only the smaller bronchi are involved, the larger not being dilated. Bronchiectasis is, generally speaking, an acute condition met with in fatal cases of bronchopneumonia, particularly in children; a good many instances of bronchiolectasis have been recorded in fatal cases of influenzal bronchopneumonia during the epidemics of influenza in this and other countries during the last few years. It is a condition secondary to the bronchopneumonia in which it occurs, and does not alter the clinical picture of the primary disease in any way. It is, however, evidence of the severity of the infection in the bronchioles in which it is seen.

For the purposes of this lecture I have made a study of the clinical notes and *post-mortem* records of over 100 cases of bronchiectasis treated at this hospital and at St. George's Hospital, excluding all instances in which the condition was due to chronic pulmonary tuberculosis. My remarks will be based mainly on the analysis of these records, and I wish to thank my colleagues at those institutions for permission to make use of them.

FREQUENCY.

During the last twenty years some 29,700 patients have been admitted to the Brompton Hospital, 567 of them with the clinical diagnosis bronchiectasis, or 1.9 per cent. But these figures do not by any means give a true picture of the frequency with which it occurs. Bronchiectasis is always secondary to some other pulmonary disease; and in the milder degrees is so overshadowed by the more obvious and important primary disorder as to escape comment. For example, a mild degree of bronchiectasis occurs in practically every case of fibroid phthisis, or chronic pulmonary tuberculosis of the fibrotic type, that comes up for examination in the *post-mortem* room. The physician will no doubt suspect bronchiectasis in such patients while they are in the wards, although he may find it very hard to decide in any given instance whether he has to do with bronchiectatic cavities or the common tuberculous excavation of lung tissue, because the physical signs of the two conditions are similar, and indeed the two conditions often occur together. In such cases the primary disease is so much the more important that the secondary bronchiectasis is apt to be disregarded. In fact, it is probable that, pathologically speaking, some degree of bronchiectasis is present in quite 5 per cent. of the patients admitted to the Brompton Hospital.

Sex and Age.—Bronchiectasis is commoner in men than in women; of the 567 cases mentioned above 332 (or 59 per cent.) were males, 235 females. Among 112 cases examined after death, 90 (or 80 per cent.) were males, 22 females; the ages of these patients were as follows:

Under 10	...	5	31-40	...	27
10-20	...	19	41-60	...	34
21-30	...	19	Over 60	...	8

The youngest patient was twelve months old, the oldest 72 years. In no case was the bronchiectasis thought to have been congenital.

PATHOLOGICAL ANATOMY.

The pathological anatomy of bronchiectasis is well described in the ordinary textbooks; it suffices to say here

that there may be either a diffuse more or less uniform cylindrical widening of the tubes or else irregular and sacculated dilatation. The distinction is quite unimportant clinically, and as a rule both conditions are present together, with more or less collapse and fibrosis of the intervening lung tissue. Special attention may be drawn to the apparently invariable presence of dense pleural adhesions over any lobes or areas of lung affected with bronchiectasis. In a few instances these adhesions precede the widening of the tubes, and are the chief cause of it, but in the majority of the cases now under consideration they are the result and not the cause of the bronchiectasis, and are due to the outward spread of infection from the bronchi. In all cases the dilated bronchi contain much septic secretion, usually offensive and highly tryptic.

As regards the distribution of bronchiectasis in the lungs, the disease was bilateral in 47 cases and unilateral in 61 out of 108; the right lung was affected in 29 and the left in 32 of the 61. All five lobes of the two lungs were bronchiectatic in 18 of the patients, but there is a tendency for the lower lobes to be more affected than the upper, and in 34 patients with only a single lobe involved the bronchiectasis was in an upper lobe in 8 (right 2, left 6), in a lower lobe in 26 (right 11, left 15). The number of instances in which the different lobes of the lungs were involved in the 108 cases is shown in the following table:

Right upper lobe	50
Right middle lobe	51
Right lower lobe	61
Left upper lobe	49
Left lower lobe	73

Aspiration of the highly septic bronchiectatic sputum into previously uninfected parts of the lung may occur at any time, producing a local aspiration pneumonia or bronchopneumonia. If small in extent, this process may lead to gangrene and excavation of the lung; more or less extensive pulmonary cavities communicating with dilated bronchi were present in five cases. The diagnosis between bronchiectatic and pulmonary cavities is often impossible to the naked eye, though the walls of the latter are usually the more ragged and irregular. Microscopically, however, bronchial unstriped muscle or cartilage will be found in the walls of bronchiectatic cavities. But, if such an aspiration pneumonia is extensive, it is likely to be a terminal event, bringing about the death of the patient by asphyxia or exhaustion before the stage of pulmonary gangrene has been reached or cavities formed. Multiple pulmonary abscesses occurred in three cases.

As would be expected in a chronic septic condition like bronchiectasis, amyloid disease is not rare in it, and was recorded in six out of 103 *post-mortem* examinations. Bronchial calculi were present in the dilated tubes in one case of long standing.

The bronchial secretion in bronchiectasis is copious, purulent, and often possesses strong powers of tryptic digestion. This no doubt explains its highly solvent action on the bronchial walls, which commonly lose their lining of ciliated epithelium and much of the involuntary muscle and the cartilage in their walls in the process of dilating.

Bronchiectasis being always secondary to some other pulmonary disease, the following table shows the primary disorder from which it resulted in 105 fatal cases so far as could be judged from the histories recorded and *post-mortem* examinations:

Prime Cause of Bronchiectasis in 105 Fatal Cases.				
Chronic bronchitis	41
Pleurisy or pneumonia	27
Bronchial obstruction by—				
New growth	27
Foreign body	6
Aortic aneurysm	3
Syphilitic stenosis	1

Apart from the fact that all the common cases due to fibrotic pulmonary tuberculosis are excluded from this list, it should be pointed out that these are figures from the *post-mortem* room, and do not represent the relative frequency of the causes of bronchiectasis among the living. Thus, speaking generally, the various forms of bronchial obstruction do not account for anything like one-third of the cases of bronchiectasis met with in the wards; but they lead to a progressive and rapidly fatal type of bronchiectasis, and are associated with other features of great clinical interest, and so occupy a disproportionately large share of the *post-mortem* statistics. The cases in which either pleurisy or pneumonia gave

rise to bronchiectasis have been grouped together, because it is often impossible to ascertain from a patient who had one or other of these diseases many years previously which it was.

With regard to the 27 cases of new growth in the lung compressing or directly obstructing bronchi, it is often impossible to say exactly where such neoplasms originate, owing to the extensive spread of the growth by the time death takes place. The following table can therefore be given only approximately correct:

Nature of New Growths causing Bronchial Obstruction and Bronchiectasis in 27 Fatal Cases.

Primary:			
Mediastinal sarcoma or lymphosarcoma	9
Sarcoma of the root of the lung	8
Carcinoma of the bronchus	5
Endothelioma of pulmonary alveolus	1
Direct spread of—			
Oesophageal carcinoma	1
Scapular perithelioma	1
Secondary:			
From carcinoma of the oesophagus	1
From carcinoma of the duodenum	1

The left lung was affected in 15 cases, the right in 10, and both lungs only in the two instances of secondary invasion. The upper lobes showed bronchiectasis in 3, the lower in 10, and both in 12 of the unilateral cases. In only a few of these 27 cases was the bronchiectasis either a prominent clinical feature or well developed from the pathological point of view by the time the patient came to die. The chief signs and symptoms were mostly those of intrathoracic new growth exciting pressure on adjoining structures, or cachexia. In many the presence of bronchiectasis was hardly suspected *ante mortem*.

PATHOGENESIS.

The pathological anatomy of these 105 cases of bronchiectasis having been outlined, it is now possible to consider the pathogenesis of the condition. In all cases two main factors are at work in the production of bronchial dilatation:

- I. Softening and disorganization of the bronchial wall by virulent bacterial infection, acute or chronic.
- II. Dilatation of the weakened bronchi by—
 - (a) Pressure from within (retained secretion, frequent cough, with its high intrabronchial air pressure).
 - (b) Traction from without (forced inspiration, pleural adhesions, pulmonary collapse and fibrosis).

The way in which these various factors work can best be shown by considering pathogenetically different examples of bronchiectasis.

1. In *chronic bronchitis and emphysema* the patient normally lives for many decades without the supervention of bronchiectasis. Should his lungs, however, become infected by some unusually virulent strain of bacteria, a more acute and destructive inflammation of the bronchi sets in. The sputum increases and becomes more purulent and finally offensive, tending to accumulate and stagnate in the more dependent parts of the lungs. Such a patient is likely to get a symmetrical bronchiectasis, at first of the lower lobes only but later throughout the lungs, the inflamed and softened bronchial walls yielding under the combined strains of retention of secretion, repeated prolonged bouts of coughing, and violent inspiratory efforts.

2. In *pleurisy the primum moriens* of bronchiectasis is the formation of dense pleural adhesions. Thus fixed the lung is unable to expand, and hence cannot be adequately ventilated by respiration, so that the bronchial secretions cannot be coughed up, but tend to accumulate in the tubes and weaken their walls. The adjacent pulmonary alveoli collapse for want of air, and ultimately the affected part of the lung becomes fibrosed by the slow outward spread of infection from the bronchi. The same condition is reached in one step by *slowly resolving pneumonia*. In both cases the newly formed fibrous tissue in the lung contracts, with the result that the softened bronchial tubes are dilated by traction from without. Bronchopneumonia is often bilateral, and so may give rise directly to bilateral bronchiectasis. Pleurisy (with or without effusion) and lobar pneumonia are usually unilateral, and so are likely to give rise to bronchiectasis on one side only. But in such cases the virulently infected bronchiectatic secretion may be spread, by coughing, into the sound lung, with the production of bilateral bronchiectasis later.

3. In *bronchial obstruction* by the pressure of new growths or aneurysms from without, or by the growth of,

say, a carcinoma originating in the bronchial wall and obstructing its lumen, the first impulse toward bronchiectasis comes from stagnation of the infected bronchial secretion behind the obstruction. Such secretion is often not sterile; the infection spreads onwards through the corresponding lung tissue, which becomes collapsed for want of proper ventilation, till finally pleurisy and pleural adhesions are set up. The collapsed lung tissue passes into a state of chronic interstitial pneumonia with the formation of fibrous tissue; this inflammatory tissue contracts, and as it does so increases the dilatation of the septic and softened bronchi. It is in this way that the "aneurysmal phthisis" of the older pathological textbooks, or conversion of one or more lobes of a lung (usually the left) into a matted collection of bronchiectatic cavities, takes place when an aortic aneurysm compresses and obstructs a bronchus. In the three such cases tabulated above the bronchiectasis was confined to the left lower lobe in each; the left upper lobe escaping no doubt because the expectoration of its bronchial secretion was aided adequately by gravity.

It must be mentioned that bronchiectasis is not by any means always seen in cases of bronchial obstruction by new growth or aneurysm. If the bronchi distal to the obstruction are sterile they do not become the seat of bronchitis followed by bronchiectasis and chronic pneumonia; instead, the lung merely collapses.

4. In the case of *foreign bodies in the bronchi*, in addition to the resulting bronchial obstruction, which produces the effects described just above, must be considered the fact that the foreign body is invariably charged with bacteria of all sorts, and is, indeed, highly septic. Thus in one of the cases included in the statistics the sputum was fetid on the second day, and the pulmonary infection ran a rapid course, proving fatal in four months. In such instances bronchiectasis, usually a very chronic process, may truly be described as acute in its onset and course.

There is one point in the pathogenesis of bronchiectasis that affords matter for dispute, and that is whether it is the abnormal raising of the intrabronchial air pressure during coughing and forced expiration, or the abnormal lowering of this pressure during violent inspiratory efforts, if either, that most tends to dilate the weakened bronchial tubes in bronchiectasis. This is a hard matter to decide: a question for physicists. Again, how far may the slight but steady outward pull of the elastic tissue in the lungs be considered responsible for bronchiectasis when the two layers of the pleura are united by adhesions?

SYMPTOMS AND SIGNS.

Bronchiectasis, as we have seen, always occurs as a complication of some other disease of the lungs. The patient is already unwell, and in its early stages bronchiectasis will only add to his troubles the spitting up of increased quantities of sputum which is at times, or in parts, offensive in smell and unpleasant in taste. When the bronchiectasis is well established the patient is often cachectic, with irregular fever, sweating, and all the signs of prolonged septic absorption. He has violent bouts of coughing, particularly on change of position, and may bring up as much as 10 oz. of sputum at a single effort. The sputum is highly offensive—its smell is often compared with justice to that of Limburger cheese—and copious, as a rule, particularly in cases where the bronchial dilatation follows on chronic bronchitis, pleurisy, or pneumonia; here it averages perhaps a pint in the twenty-four hours, and reached 71 oz. in one of the patients in this series. Placed in a tall glass such sputum settles into three layers, as is well known to you. The offensive odour of bronchiectatic sputum appears to be due to the setting free of butyric, caproic, and other volatile acids of the paraffin series from the fatty substances in the purulent sputum by the bacteria of putrefaction it commonly contains.

Haemoptysis is of common occurrence in bronchiectasis, and is often copious. As in pulmonary tuberculosis, it may be an early and frequently repeated sign throughout the course of the disease. It was the immediate cause of death in 5 of the 105 patients tabulated above; in one, however, being due to the rupture of an aortic aneurysm into the left bronchus it was compressing. It had occurred in over 90 per cent. of the patients, and may be taken as proof of bronchial ulceration.

Except for its variety and richness, I believe there is nothing characteristic about the bacterial flora in bronchiectatic sputum, unless it be the frequent presence of influenza bacilli. The offensive sputum contains in addition pus cells, crystals of fatty acids, small yellowish masses known as Dittrich's plugs, and in cases where the dilated bronchi have given way with the formation of pulmonary cavities, alveolar elastic tissue also.

The pulmonary physical signs in the early stages are likely to be those of chronic bronchitis in the symmetrical cases; in the unsymmetrical pulmonary tuberculosis is well imitated. When the bronchiectasis is well developed and the sputum copious, the physical signs vary widely with the amount of sputum present in the dilated tubes at the moment of examination. If the tubes are full the vocal fremitus is lessened, resonance on percussion is much diminished, and on auscultation the breath sounds—which are bronchial, tubular, or even amphoric—will be distant and accompanied by comparatively few adventitious sounds. But if the tubes have been emptied by recent cough and expectoration the physical signs will be very different, because the dilated bronchi are now full of air and in free communication with the trachea. The percussion note over the bronchiectatic lung will be more resonant, the vocal fremitus will be increased and much more than the normal, and on auscultation the loud breath sounds and the extraordinary variety of metallic moist sounds suggest the diagnosis of pulmonary consolidation and excavation. Here again pulmonary tuberculosis may be well imitated; I have met with two cases of obstruction of the bronchus to the left upper lobe by new growth, and in each there proved to be extensive bronchiectasis confined to that lobe, but the physical signs were precisely those of tuberculous infiltration and excavation, though tubercle bacilli could not be found in the sputum.

Some degree of clubbing of the finger-tips was recorded in 70 out of 103 of the cases of bronchiectasis, and may well have been present in more. Clubbing of the toes was present in a few of the patients, and clubbing of the end of the nose also was recorded in two instances. In two cases the clubbing of the fingers was associated with Marie's chronic pulmonary hypertrophic osteo-arthritis.

COMPLICATIONS.

The most interesting of the complications of bronchiectasis is intracranial abscess, 15 instances of which occurred in 103 fatal cases of the disease. The abscesses were cerebral in 9 instances, cerebellar in 3, both in 2, and in one case meningitis and ependymitis were present, but no intracranial abscess was located. The abscess was single in 9 patients, multiple in 6, and in one instance from 20 to 30 abscesses were present throughout the brain. In addition two cases of secondary intracranial new growth were recorded in this series: one patient had a primary new growth at the root of the left lung, with secondary deposits in the pancreas and brain; the other a primary endothelioma of a pulmonary alveolus compressing the left bronchus, with secondary growth in the brain.

Apart from these intracranial complications, the common complications of bronchiectasis are inhalation or aspiration bronchopneumonia, empyema, gangrene and abscess of the lung, and old or recent pulmonary tuberculosis.

Empyema apparently secondary to the bronchiectasis occurred in 17 of the 103 cases, and its occurrence may be regarded as due to the spread of a more than usually virulent bacterial infection from a dilated bronchus to the pleura; in the other 91 patients the organisms reaching the pleura set up no more than an adherent pleurisy. The empyema discharged itself through a dilated bronchus in 4 cases; pyopneumothorax was present in 3, in 2 the empyema was interlobar, in 1 apical, and in 2 was operated on and drained by the surgeon. In 2 other cases that came up for operation pulmonary abscess, not empyema, was found and drained. Extensive gangrene of the lung was noted in 5 instances, multiple small pulmonary abscesses in 3. Old pulmonary tuberculosis independent of the bronchiectasis was present in 5 cases; recent miliary or caseating tuberculosis was seen in 5 also. Acute pleuropericarditis—an unusual complication—was present in the case of a girl of 15, who had a primary periosteal sarcoma of the femur with secondary deposits in both lungs; the left bronchus was completely obstructed, and the left lung converted into a honeycombed mass of bronchiectatic and bronchiectatic cavities.

COURSE AND DURATION.

The course and duration of bronchiectasis are very variable, depending as they do upon the severity of the

bacterial infection present in the dilated tubes. This in turn depends upon the pathogenesis of the condition to a large extent, as will be seen on consideration of the following figures:

Duration of Cough in 105 Cases of Bronchiectasis.

Principle Cause of Bronchiectasis.	No. of Cases.	Duration in Months.		
		Average.	Maximum.	Minimum.
Bronchitis	40	110	600	4
Pleurisy and pneumonia	50	39	144	2
New growth... ..	24	9	24	2
Foreign body	8	25	60	4
Aortic aneurysm	3	15	24	7

These figures can only be offered with the reservation that they are but very approximately correct. It is not possible to say at what moment bronchitis ends and bronchiectasis begins in any series of cases, which is what the above table attempts to do. There is no clinical criterion to mark the onset of bronchial dilatation. Still, the figures in the column showing the average duration of cough in the cases may fairly be taken as indicating that bronchiectasis secondary to bronchitis or to pleurisy or pneumonia is likely to last for several years; whereas the duration of that due to bronchial obstruction is more likely to be a matter of months.

The causes of death common in bronchiectasis are set out below. This table, too, must be offered with reservations. Thus, the term "exhaustion" might from certain points of view be replaced by "chronic septic absorption," with a low or falling terminal temperature.

The Cause of Death in 110 Cases of Bronchiectasis.

Bronchopneumonia	34
Exhaustion	34
Exhaustion and asphyxia	8
Intracranial abscess	15
Intracranial new growth	2
Haemoptysis	5
Heart failure	3
Intercurrent disease	3
Post-operative collapse	3
Septic diarrhoea	1
Lobar pneumonia	1
Influenzal bronchopneumonia... ..	1

The deaths from exhaustion and asphyxia were all in cases of bronchial obstruction. The intercurrent diseases were uraemia, haematemesis from gastric ulcer, and oxalic acid poisoning.

DIAGNOSIS.

The diagnosis of bronchiectasis is easy enough in a typical case of long standing, with its copious offensive sputum, occasional haemoptysis, its fever and wasting, and the signs of excavation and fibrosis at the base of one or both lungs. But in its early stages there may be nothing to distinguish such a bronchiectasis from chronic bronchitis. Again, when the disease occurs at the apex of a lung, the physical signs may be precisely those of the common apical tuberculosis, the only *ante-mortem* distinction being the absence of tubercle bacilli in the case of bronchiectasis; and even then it must be remembered that an acute pulmonary tuberculosis is not rare as a complication of bronchiectasis. And wherever the bronchiectasis is located in the lung, the physical signs may be just those of tuberculous consolidation, fibrosis, and excavation.

The diagnosis may be very difficult in cases of bronchial obstruction by aneurysm or new growth. It must be remembered that in some such patients the lung merely collapses, and the bronchi, probably for want of infection with sufficiently virulent bacteria, do not develop bronchiectasis at all. In others the bronchiectasis may develop, but little or no sputum (and that inoffensive) may be able to make its way past the obstruction. In all these difficult cases good x-ray pictures of the lungs are of great help in diagnosis, the thickened and dilated bronchi being distinguishable as opaque strands converging towards the hilus of the lung.

To illustrate the difficulty of diagnosing acute bronchiectasis such as may follow the inhalation of a foreign body,

I have the permission of a colleague to quote the following case, which I saw while it was under his care at another hospital in 1906:

July 12th. A. E. S., aged 21 months, inhaled a pea into the left bronchus; had a very violent bout of coughing, turned black in the face.

July 19th. Admitted to dispensary; diagnosis of pneumonia made; later, dry paracentesis.

July 28th. Sent on to hospital; diagnosis, (?) empyema.

August 5th. History of inhalation of pea picked up from the floor obtained for the first time from the parents. Skiagram shows opacity of left lung, displacement of the heart to the left.

August 6th. Low tracheotomy, exploration of left bronchus, no obstruction or foreign body found.

August 28th. Paracentesis of left chest, half a drachm of blood-stained serum removed. Impaired note, weak breath sounds, occasional rale over the whole of the left lung; (?) pulmonary tuberculosis.

September 19th. Paracentesis, a little pus withdrawn.

September 20th. Operation, piece of sixth left rib removed; half an ounce of pus drained from a ragged cavity, no empyema found. Tube.

October 2nd. Death from wasting and exhaustion; irregular hectic fever since July 19th, occasional bouts of cough ending in vomiting. The left lung was found to be densely adherent, enlarged, airless, and on section composed of a honeycombed series of small bronchiectatic cavities filled with thick inoffensive green pus, with collapsed lung tissue in between. No bronchial obstruction or ulceration found. Corresponding to empyema operation, a small ragged cavity, into which pus could be squeezed from the adjoining lung.

I imagine that the interpretation of this case would be that the child inhaled a dirty and insatiated pea into its left bronchus on July 12th and developed an acute septic bronchitis on the left side, passing rapidly on to bronchiectasis. The pea must have been got rid of before August 6th.

TREATMENT.

In all cases inversion of the patient, or letting him cough with his head and chest hanging downwards so as to facilitate the emptying of his bronchiectatic cavities, is a serviceable practice, best carried out on waking. For the rest the treatment of bronchiectasis may be either medical or surgical. The medical treatment aims at combating the infection in the bronchial tubes by antiseptics, the most widely used of which is creosote. The creosote may be administered in three ways: (1) By the mouth in capsule form; absorbed from the alimentary tract, some of the creosote is excreted into the lungs, and may there act as an antiseptic. I have never seen much good result from this mode of treatment, and it has the disadvantage of tending to upset the stomach. (2) By intratracheal injection; creosote, thymol, menthol, or some other organic antiseptic, dissolved in five or ten parts of olive oil, is injected into the trachea through the curved nozzle of a syringe, below the vocal cords, after cocaineization of the pharynx and larynx. A few drachms of the oily antiseptic can be introduced thus daily, in the hope that some of it will gravitate into the dilated tubes and help to sterilize them and their contents. In the few cases in which I have seen it tried this treatment has not proved strikingly successful. (3) By inhalation; up to a point this method gives admirable results, of a palliative order. The creosote, mixed perhaps in equal parts with eucalyptus oil and oleum pini silvestris, may be given on a Burney Yeo inhaler, worn for many hours a day. A more effective method of administration is to have a small closed chamber in which creosote can be volatilized by heat; the patient, his eyes protected from the pungent vapour by goggles, inhales the white clouds of creosote fumes deep into his lungs. The fumes bring on violent coughing which empties the dilated tubes, and no doubt also exert a beneficial antiseptic action on their infected and inflamed walls. A creosote vapour bath can be given daily, at first for five minutes only, but after practice for fifteen or twenty minutes; care should be taken to see that the fumes are not too strong, and that the creosote is not carbonized by overheating the dish from which it is evaporated in the creosote chamber. The benefits to be expected from this treatment are a great reduction in the quantity of the sputum, which often falls from 20 to 30 ounces a day to 2 or 3; loss of its offensive odour; diminution in the patient's fever; and much improvement in his appetite and general condition. But in the great majority of cases it is palliative only, and relapse is likely to follow its discontinuance. It would be interesting to know the result

of the treatment of bronchiectasis by the inhalation of a 2 per cent. solution of, say, Dakin's chloramine-T sprayed into the air by a steam atomizer—a treatment that proved successful a few years ago in the sterilization of the nasopharynx of carriers of the meningococcus.

The surgical treatment of bronchiectasis consists in the operative removal of many inches each from a large number of ribs over the bronchiectatic lung, in order that it may be made to fall in completely and obliterate the bronchiectatic cavities by fibrosis and collapse. The operation is obviously very severe, and it has been practised on the Continent, and particularly in Scandinavia, much more frequently than in this country, and usually under local—not general—anaesthesia. It is applicable only to unilateral cases of bronchiectasis, preferably those in which the lower lobe of the lung is involved, and to those not due to bronchial obstruction by new growth or aneurysm. I have hitherto had occasion to recommend it in two cases only, in 1917; in one the result was unfortunate, in the other excellent; the patient has been able to return to work for the last six months, and the sputum has been reduced to half an ounce of inoffensive muco-pus brought up on rising. Three successive partial removals of ribs were performed in this instance, and extensive collapse of the affected lung has been effected.

THE EPIDEMIOLOGY OF PHTHISIS.

BY

WILLIAM GORDON, M.D., F.R.C.P.,

PHYSICIAN TO THE DEVON AND EXETER HOSPITAL.

I HAVE read with great interest Dr. Brownlee's recent papers on "The epidemiology of phthisis in Great Britain and Ireland,"¹ and, as they bear upon some of my own work on the climatology of phthisis, I should like to say something about them.

PART I.—PHTHISIS DEATH RATES AT DIFFERENT AGES.

First of all I would congratulate Dr. Brownlee on having introduced into the investigation of phthisis-prevalence a new method of comparing death rates at successive age periods—a method likely to yield very interesting and valuable information.

PHTHISIS NOT A SINGLE DISEASE.

Dr. Brownlee concludes, from a study of the age curves of male mortalities, that phthisis can no longer be regarded as a single disease, but that two or perhaps three types are to be recognized, "distinguished by the characters of their incidence at different ages"; death most commonly occurring in one type between 20 and 25, in another type between 45 and 50, and perhaps in a third type between 55 and 65.

Obviously this is a proposition which can only be accepted on the most convincing evidence, for the conception of *age selective* types is quite a different thing from the conception of such types as are met with in the diseases to which reference is made in his paper—namely, enteric, bacillary dysentery, tetanus, pneumonia, and cerebro-spinal fever—types which do not select different ages for their attack. Moreover, since we shall find that the male curves differ from the female curves for the same districts, in such a way that the further assumption is needed that his types of phthisis are not merely age selective, but to some extent *sex selective* as well, the difference between them and the types of those other diseases becomes still more pronounced.

Also it must be remembered that neither clinicians nor bacteriologists have any knowledge of the existence of separate types of "human" tubercle bacilli.

Now nothing has impressed itself so strongly on my mind, in the course of my work on phthisis environment, as the conviction that, if the subject is to be raised out of the chaos of mere surmise in which it has always been involved, and if it is to be placed on a solid scientific basis, a principle, which I have called "the principle of the approximate isolation of influences," must be recognized and applied.² By such "approximate isolation" I mean the enumeration of all possible appreciable conflicting influences and their successive elimination the problem so far as that is possible. I need not illustrate the various ways

in which such eliminations can be carried out, as abundant illustrations exist in my publications. That the idea is feasible and effective has been amply demonstrated.

Of the many influences known to affect the prevalence of phthisis, one of the most powerful is the influence of occupation; and occupation is generally far more diverse, and therefore far more disturbing, among males than among females. To eliminate it as far as possible, only female death-rates should be primarily considered. In my

work I have been most careful, wherever possible, to deal with female death-rates only, and I have no sort of doubt of the advantage of so doing.

I would suggest therefore considering the corresponding age curves for female phthisis death-rates in the areas which Dr. Brownlee has chosen for his diagrams.

Fig. 1 shows the result of comparing the female age curves of all the English areas for the decade 1881-90, and Fig. 2 shows the same for the Scottish areas and Ireland for 1881 to 1900; the latter gives the curves supplied by Dr. Brownlee himself in his Diagrams 14 to 17 and 19, curves in the former have been calculated for the first decade of the same period.

From a study of these curves I do not think one would be justified in deducing the existence of two or three types of "human" tuberculosis. The top of the curve, in nearly every area, lies between the ages of 25 and 35. Only Ireland and Cornwall have curves culminating five years earlier; only London has one culminating between 35 and 45; Lancashire and Midlothian show a level summit from 25 to 45. Surely, if two or three types of phthisis existed, they would manifest themselves in the female curves more plainly than this.

From all the foregoing considerations I cannot but conclude that some conflicting influence or influences have modified the male curves and given rise to mistake. I believe that this is the case, and, from former experience, suspect that the influences of occupation and density of population are the delinquents.

For if we re-examine the male curves given by Dr. Brownlee we find that those which culminate in early adult life—Shetland, Caithness to Argyll, Norfolk, Devon, North Wales, South Wales—belong to areas to which outdoor occupations in open country are predominant, whereas the curves which culminate at middle life—Stafford, Lancashire, London, Midlothian including Edinburgh—belong to areas in which indoor occupations in towns are predominant; also it will be observed in the diagrams of the male curves, in areas where, as time has gone on, industrial life in towns has grown at the expense of outdoor life in the country—Staffordshire, Lancashire, England and Wales generally—the summits of the curves have tended to sweep in successive decades towards higher ages.

Therefore I strongly incline to the view that the differences in the male curves are due, not to differences in the organism of phthisis but to differences of occupation and of density of population affecting the predisposition of the male inhabitants to invasion by the disease.

PART II.—DECLINE IN PHTHISIS MORTALITY DUE TO THE INHERENT BIOLOGICAL PROPERTIES OF THE DISEASE.

In the second part of his investigation Dr. Brownlee attributes the undoubted decline in phthisis prevalence in England during the last seventy years (and perhaps before that) not to any change, sanitary or other, in its environment, but to "the ebb of a long epidemic wave" due to "the inherent biological properties of the disease."

I am afraid, on the evidence, which he submits to us with admirable candour, we cannot accept so sweeping a conclusion. It might be as he says, but such figures cannot prove it. He has, however, in Part III, himself demolished the idea.

For his evidence was obtained from the Mortality Bills of London, and yet here he has supplied us with a very valuable proof that the decline of phthisis death-rate in London is due chiefly, if not solely, to improved hygiene. "Phthisis," he writes, "has not decreased in London during the epoch for which accurate knowledge is available, except so far as the general improvement in hygiene would explain."

PART III.—STRONG PREVALENT RAINY WINDS AND PHTHISIS.

In one section of Part III Dr. Brownlee has ably re-investigated my work in Devonshire on rain-bearing winds and phthisis, using different periods to mine, and has added to the value of my proof by the manner of his confirmation. I am very grateful to him for doing what for many a day I vainly hoped someone would do—fairly take in hand the proof or disproof of my contention. His courteous reference to my work I cordially appreciate. His confirmation of this work is clearly of very far-reaching importance; for the influence on phthisis of strong prevalent

rain-bearing winds is a very powerful influence and needless to say, if it is admitted to be exercised in Devonshire, it must be also admitted to be exercised elsewhere, wherever those winds are met with. So important do I consider this influence, and so lamentable the results, scientific and practical, which have flowed from ignorance of it, that I make no apology for very briefly summarizing here the mass of evidence now accumulated on the matter.

I. Evidence from Many Parts of the World.—All over the world, wherever sufficiently reliable information was available, I collected data for examining into the relations of wind and phthisis. This work was done less in search

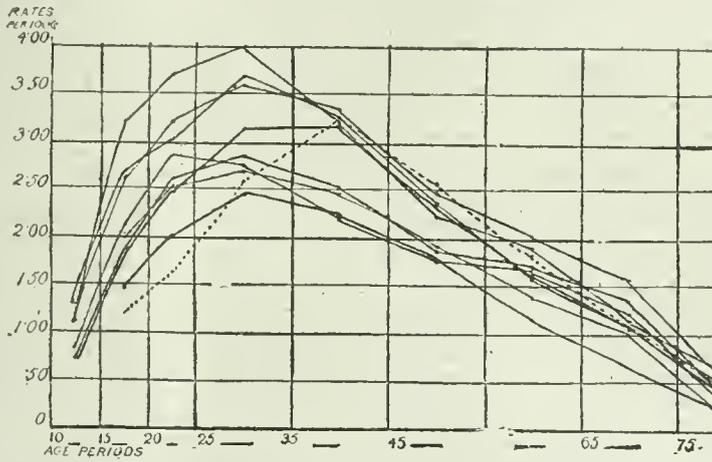

FIG. 1.—Female phthisis death-rates, 1881-90. The curves, in order from above downwards, as they cut the 25 to 35 co-ordinate line, are those of North Wales, Northumberland, South Wales, Lancashire, Devon, Cornwall, Norfolk, London (dotted), Stafford.

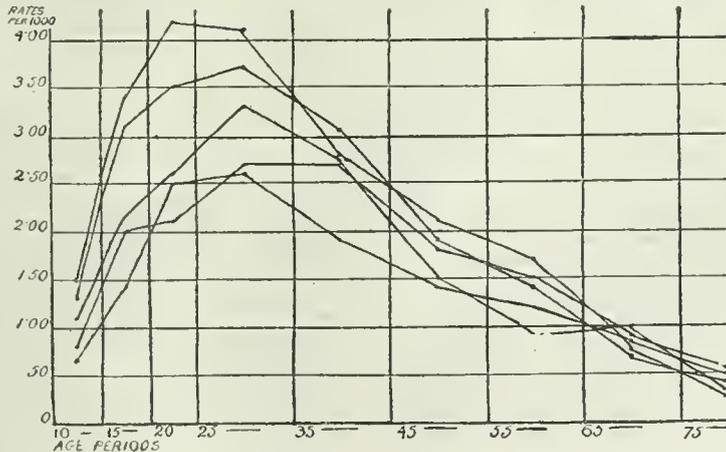

FIG. 2.—Female phthisis death-rates, 1881-1900. (From Dr. Buchanan's Diagrams 14-17 and 19.) The curves, in order from above downwards, as they cut the 25 to 35 co-ordinate line, are those of Ireland, Lanark, etc., Shetland, Midlothian, etc., Caithness, etc.

of confirmation than in seeking for exceptions whose existence would point to some fallacy in my proof. No such exceptions were found, but much valuable and interesting confirmation was forthcoming.

2. *Effect of these Winds on Phthisis Patients.*⁵—Cases of phthisis in Devonshire exposed to these winds have been shown to run a shorter course than cases sheltered from them. Unpublished clinical evidence also has accumulated pointing strongly in the same direction. I have also tried to compare the statistics from variously placed sanatoriums; this proved impossible, but it was significant that some exceptionally exposed sanatoriums kept no records of results! There seems to me no doubt that some at least of the disappointment generally expressed with the results of sanatorium treatment in this country is due to the ill-chosen sites of some of our sanatoriums.

Perhaps now that an able independent investigator has confirmed my conclusions, a little pains may be taken to place the new sanatoriums for our phthisical sailors and soldiers in situations where failure shall be less of a foregone conclusion!

3. *Effect of these Winds on Bovine Tuberculosis.*—Bovine tuberculosis is much commoner in areas exposed to strong rain-bearing winds than in areas sheltered from them.⁶ Professor Delépine's valuable paper⁷ on tuberculosis in the farms supplying Manchester with milk gave me a unique opportunity of investigating this important point. This fact surely calls for some attention.

4. *Altitude and Phthisis.*⁸—When the influence of rain-bearing winds had been taken into account and, as far as possible, eliminated by considering only localities sheltered from them, the contradictions, which had rendered a satisfactory conclusion on the relations of altitude and phthisis prevalence impossible, disappeared, and the important generalization was reached that altitude, *per se*, has no influence on phthisis prevalence. The fact is that, as altitude increases, exposed situations increase so much in bleakness that the population is more and more forced into shelter; consequently, as altitude increases the proportion of the population living in shelter increases and the prevalence of phthisis falls. This conclusion does not affect my belief in the beneficial effect of high altitudes in shelter on phthisis patients.

5. *Subsoil and Phthisis.*—Dr. Brownlee must have given my paper⁹ on this subject a very hasty glance, or he would have recognized that not only did it deal with a much more extensive field than Buchanan's—all England as against three counties—but that it was much more elaborate and safeguarded from error; also (most important of all) that instead of leaving the question one of mere surmise, mine left it practically proved that certain geological formations are definitely associated with higher phthisis death rates than others. I say "practically" proved because, until larger populations in pronounced shelter from rain-bearing winds have been dealt with, I shall not consider the investigation complete. Dr. Brownlee's results in Norfolk, Suffolk, and Essex are very suggestive, but, in view of the varying exposures of his districts, must be regarded as inconclusive.

6. *Occupation and Phthisis.*—I wrote in 1913¹⁰: "The evil eminence of the tin-miner may not be entirely occupational; he lives for the most part in a district swept by strong rainy winds. Also the Midland coal-miner, who suffers less from phthisis than coal-miners in other parts of England, may not owe his good fortune altogether to the conditions of his work, but partly also to the slighter exposure of his district to rain-bearing winds."

7. *Density of Population and Phthisis.*¹¹—I have shown that in certain rainy wind-swept regions the self-protection of a town from winds may more than compensate for its comparative crowding.

PHTHISIS IN WALES.

Dr. Brownlee's section on this subject is instructive and interesting. But I fear he will find the problem of subsoil in Wales as disappointing as he found his Welsh study of rainy winds. I have tried it myself, for I observed how heavy were the death rates on some of the Welsh formations. Rainy winds, race, modes of life and occupation, seem perversely arranged so as to confuse the problem and almost to defy elimination. It will be observed that Dr. Brownlee's map of the districts is almost as suggestive of

the effect of rain-bearing wind as of subsoil, when it is remembered that in the east and south-east of Wales the mountains afford much shelter, and that, in the south-east, occupation must modify the figures, the phthisis death rate of coal-miners generally tending to be low. My table of the phthisis death rates in the Welsh registration districts, 1881-90,¹¹ indicates at least some effect produced by rain-bearing winds.

A MISAPPREHENSION.

Before concluding, I should like to clear up a misapprehension. Dr. Brownlee has referred to me as a "follower in Haviland's footsteps." So far from being a follower of Haviland, I was fortunately quite unaware of his work until I had found the fact on which I lay such stress. Haviland's statements were quite different from mine, and had I been familiar with them, it is not unlikely that I should have missed my point, as he did.

SUMMARY.

1. Dr. Brownlee has introduced a new method of investigating phthisis death rates at successive age periods which promises to be valuable.
2. He has not proved his first proposition regarding the existence of two or three types of human tubercle.
3. He has himself disproved his second proposition, dealing with the cause of the decline of phthisis.
4. His confirmation of my conclusions in Devonshire in respect of the influence of strong prevalent rain-bearing winds on the prevalence of phthisis, once more emphasizes the necessity for recognizing this influence.
5. Incidentally his papers illustrate the need for applying, in climatological research, what I have called "the principle of approximate isolation of influences."

FURTHER WORK ON ANTIMONY INTRAVENOUSLY IN FILARIASIS.

BY

LIEUT.-COLONEL SIR LEONARD ROGERS, Kt., C.I.E.,
M.D., F.R.C.P., F.R.S., I.M.S.

LAST year I published a preliminary report on short trials of sodium antimonyl tartrate solutions injected intravenously in filariasis, and showed that the drug had some action in reducing the number of embryo filaria in the evening peripheral blood and in lessening their motility, but I had not been able to follow up the cases long enough to ascertain if the effect was permanent or not, although I had arranged to do so. Thanks to the kindness of Lieut.-Colonel Thornley, I.M.S., Civil Surgeon of Cuttack, I have now been able to follow up a series of eight cases in the central jail of that filarial infected station, with the results recorded in this communication.

Method of Investigation.

Thick blood films of 100 prisoners under sentences of three months and over were sent to me for examination, while 50 more were taken during a visit to Cuttack; all were taken at 9 p.m., which is quite late enough for Indian patients. In 18 per cent. of these healthy men filaria embryos were found, and eight, who showed from 17 to 126 embryo filaria in 20 cubic millimetres of blood and a total of 732 in the eight slides, were selected for treatment. Five controls were also taken with from 22 to 117 filaria in a slide and a total of 168. The blood slides were taken every evening at 9 p.m. at first and later at longer intervals, but always at the same hour, and the injections of a 2 per cent. solution of sodium antimonyl tartrate were given in the mornings. I am greatly indebted to Subassistant Surgeon Kailas Chandra Rao, demonstrator

* Average of last four weekly counts.

of pathology in the Orissa Medical School, for his careful work in taking the slides and giving the injections. All the counts were made by me.

Doses, Duration of Treatment, and the Effects Produced.

During the first six days the doses were respectively 3, 4, 4.5, 5, 5, and 5 c.cm. of the 2 per cent. solution, after which, as toxic symptoms appeared, the latter dose was given every other day as far as possible up to six weeks from the commencement of the treatment. On one occasion all the injections were stopped for three days on account of toxic symptoms in the form of nausea or sickness, while the same trouble or difficulties due to inflammation of the injected veins reduced the doses in several of the cases, so that the number of doses and the total amount of the drug in grams were as shown in Table I, in which the cases are classed as those who eventually showed very great reduction in the number of the filaria embryos, indicating success of the treatment, and these in which a rapid return to about the original numbers took place as soon as the injections were stopped, showing failure to kill the adult worms.

It so happens that the number of doses given was the same in each group and the total amounts of the drug also almost identical, although the amounts varied considerably in individual cases, showing that it is not yet possible to lay down the amount of treatment required in any given case.

Results of the Treatment.

The results are best brought out by the accompanying chart, showing the percentages of embryos as compared with the original numbers before the treatment was commenced, found at each count, which were made daily for eighteen days, then every third day up to twelve days after the injections were stopped, and finally weekly for the succeeding four months up to the date of discharge from the jail of some of the patients. Separate curves are given of the combined figures of the four successful (broken lines) and of the four unsuccessful cases (continued line) so as to bring out important points of difference between the two, which became apparent on studying the figures obtained during some weeks after the injections were stopped. The two curves closely coincide throughout the course of the injections, although that of the eventually unsuccessful cases showed greater fluctuations and tendency to occasional rises in the number of the embryos than that of the successful ones. Both showed an extremely rapid and great fall in the numbers during the first six days of daily injections to reach a minimum of 13

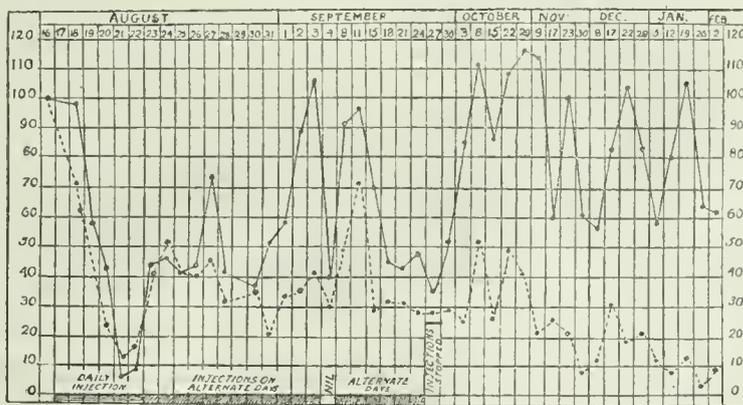

and 6 per cent. of the original numbers on the fifth day; both showed a considerable rise when the injections were given only on alternate days, while both showed a steady low rate of 30 to 40 per cent. of the original numbers during the last twelve days of the injections. On cessation of the treatment a striking contrast between the two curves for the first time showed itself, for, whereas in the four unsuccessful cases the number of embryos showed an immediate rapid rise, carrying them up to the original count within nine days, in the successful ones there was no rise during the first six days after the drug was stopped, and subsequently only small fluctuations—such as also occurred to an even greater extent in the control cases—accompanied by a steady general decline in the curve to from 13 to 3 per cent. of the original numbers during the last four weeks. In these four cases I think there can be little doubt that the adult female worms

had been killed by the antimony salt—a conclusion which I believe is confirmed by an interesting observation I made in the unsuccessful cases—namely, that the rapid increase in the embryos immediately after the injections were stopped was accompanied by the appearance in the slides of very numerous long, thin, and presumably young forms, indicating that the adult females were

once more producing a numerous progeny; no such change was noticed in the successful cases. The immediate great rise in the number of embryos in the failures on stopping the injections is also of practical importance, as regular counts on the plan I adopted will enable a judgement to be formed in any individual case as to the duration of treatment required, any rapid increase in the embryos of too sustained a nature to be attributed to periodic variations being an indication for further treatment; the appearance of a number of long, thin forms would point in the same direction.

Variations in the Counts in Control Cases.

During the first seven weeks, and occasionally later, counts were also made by me in the five control cases, and a curve has been worked out showing the variations from the average count. It will suffice to say that, owing to great fluctuations in the one case with a large number of embryo filaria, the percentages varied between 45 and 160 per cent., and showed rapid variations without any very regular periodicity, thus indicating that prolonged and repeated counts are necessary to establish the effect of any given treatment. The control curve showed no such immediate rapid fall as occurred at first in all the treated cases, or any such continued low counts as in the successful cases after cessation of the injections, indicating that the latter were due to the antimony injections.

Periodicity in the Daily Numbers of Filarial Embryos at the same Hour of the Evening.

The periodical variations in the number of embryo filaria in the peripheral blood at different hours of the day and night is well known, but as far as I am aware less attention has been paid to the variations at the same hour from day to day, such as are well illustrated in the latter part of the upper curve of the four cases in which the antimony treatment failed permanently to reduce their numbers. During the four months from October to January there was a regular rise in the numbers at about new moon, and a fall at full moon, which is very suggestive in view of the popular opinion that filarial fever is influenced by the phases of the moon. To examine this hypothesis further I have plotted out the curves of each of the four cases separately, and found that in two months three of the four curves followed this rule, but in the other two months only two of them did so, which indicates that the coincidence in the combined curve is probably accidental. Moreover, the daily counts in the control cases showed great fluctuations occurring at shorter intervals and less regularly. These daily variations are deserving of more detailed study, as they may well furnish a clue to the periodicity of filarial fever, which has always puzzled me, but which may possibly be explained, if the fluctuations referred to are produced by a periodical discharge into the circulation of a large number of newly-born embryo filaria, as, indeed, has been suggested by Bahr. As long as the lymphatic channels are free this need not cause any material inconvenience to the host, but when the lymphatics become blocked by inflammatory changes, then such a brood of young embryos may well cause some further blocking of the lymphatic channels with the excitation of inflammatory changes in the already damaged tissues, without invoking the aid of Manson's hypothesis of the abortion of immature ova. Secondary infections, with staphylococci and streptococci, doubtless also often play an important part in the febrile process, as I (unpublished records), as well as others, have cultivated these organisms from the inflamed superficial tissues of the legs in cases of elephantiasis and obtained considerable amelioration of the febrile attacks by auto-vaccines. On the other hand, cultures during these attacks have often failed, while the frequently very regular periodicity in filarial fever attacks could be more easily explained by the above hypothesis, which may serve a useful purpose if it stimulates further research into the variations of the filarial embryos in the blood from day to day on similar lines to those adopted in my present research, which circumstances will not allow of my continuing at present.

Further Investigations at Puri by Dr. P. N. Das.

In my first paper I mentioned that Dr. P. N. Das was continuing the investigation I commenced at Puri with his help, and he has kindly sent me reports of his progress. As he recently read a paper on the subject at the Indian Science Congress at Nagpur, which will eventually appear in the *Indian Journal of Medical Research*, it will suffice here to say that in five out of eight cases the embryo filaria had completely disappeared from the peripheral blood after from twelve to thirty-seven intravenous injections of sodium antimonyl tartrate, and had remained absent for from a few days up to one month and a half, while in the remaining three cases the parasites had become greatly reduced. Moreover, in two additional patients, who were suffering from weekly attacks of filarial fever, the attacks had ceased under the treatment, and in one case had remained absent up to three and a half months. These are most promising results.

Recent Cases Treated by the Writer.

The following brief notes of cases recently treated by me may also be of interest, although I cannot follow them up very long, as I am about to proceed on leave.

CASE I.—Early Elephantiasis.

A European lady consulted me for recently developed swelling of the forearms just above the wrists and of the feet highly suggestive of commencing elephantiasis. The evening blood showed 50 embryo filaria in 20 c.mm., so I gave thirteen injections of sodium antimonyl tartrate, mostly in 4 c.cm. doses, into a small wrist vein, which was the only one available. At the end of this course the swelling had gone down by nearly an inch, only two filaria could be found in 20 c.mm. of blood, and she had lost the slight periodical febrile attacks she formerly suffered from.

CASE II.—Filarial Orchitis.

A European patient was admitted to the General Hospital for orchitis; numerous filaria were found in his night blood. Major Green Armitage, I.M.S., very kindly treated him with sodium antimonyl tartrate, and sent me blood films of measured quantities taken at 10 p.m. Counts on five consecutive evenings prior to treatment varied between 44 and 96, and averaged 64. They were also made on alternate evenings while the injections were being given daily, working up to 4 c.cm. of the 2 per cent. solution. During the first ten days of the treatment the filaria varied between 21 (the first day) and 5, and averaged 9, while the next three counts gave 4 on one day and none on the other two days. Another count after only one injection had been given in four days also showed only one embryo in two slides, so as the decrease of the drug has not been followed by any definite increase in the filarial embryos the result is promising.

CASE III.—Chyluria.

I am indebted to my colleague, Lieut.-Colonel D. McCay, I.M.S., for an opportunity of treating this Indian patient in the Medical College Hospital. The average of four counts before treatment showed 86 embryo filaria in 20 c.mm. evening blood. The man then received nine injections of a 1 in 500 solution of colloid antimony sulphide, varying from 2 to 6 c.cm., such as I have previously found to be more effective in kala-azar than sodium antimonyl tartrate, while it is very much less toxic for man. This solution, however, failed to reduce the filarial embryos, which averaged 93 on the evenings of the injections. As the solution employed contains only approximately one-fifth the amount of antimony in the sodium tartrate this is not altogether surprising, as such a worm as the adult *P. a. sanguinis hominis* is likely to be more resistant than a minute protozoal parasite to the prolonged action of a colloid preparation, which is retained in the blood longer than a soluble salt.

Dr. P. N. Das has just reported to me four cases in which 5 to 6 injections up to 5 c.cm. doses of the colloid preparation also failed to reduce the filarial embryos, so it is evidently not very active against them, although longer trials might possibly yield better results.

CONCLUSION.

The results above recorded appear to indicate that intravenous injections of soluble antimony salts have a definite effect in greatly reducing or causing the disappearance of the filarial embryos from the peripheral blood, presumably as a result of the destruction of the adult filaria, as the effect may last in some cases in an increasing degree for several months after cessation of the treatment. Moreover, clinically favourable results have been obtained in a few cases of filarial fever and elephantiasis. A rather long course of intravenous injections of a highly toxic drug is, however, required to produce this effect, so the new method of treatment requires care in its use, and much further experience will be necessary before its precise value can be decided.

CYCLOPLEGIA IN ROUTINE REFRACTION WORK.*

By N. BISHOP HARMAN, M.A., M.B. CANTAB.,
F.R.C.S. ENG.,

OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL AND THE
BELGRAVE HOSPITAL FOR CHILDREN.

ONE of your number recently put a question to me which may very well form the subject of our consideration to-day. He asked: "What is the best means of obtaining cycloplegia for routine refraction work in children?" That is a very pertinent question. There is a vast amount of refraction work being done for children. A cycloplegic is necessary for satisfactory work. We must be satisfied of the efficiency and safety of the drug used, and that the manner of its usage gives the least inconvenience to the child, its parents, the school teachers, and to your own department where the eye work is done. It is scarcely necessary to defend the statement that cycloplegia is necessary for satisfactory work in children. It is true that, given unlimited time, much skill in handling children and in the use of the mirror, it is often possible to make a good retinoscopy without a cycloplegic; but the most experienced will agree that, even under the best conditions, the results so obtained are open to doubt. When, however, we have to deal with a dozen or more children at the out-patient department of a hospital or a school clinic, it is manifest that without a cycloplegic the work could not be done at all.

* A lecture delivered at the West London Post-Graduate College.

The choice of drugs is happily limited. Homatropine and atropine are the only effective claimants for attention. Hyoscyamus was extensively tried a few years ago, but some rather startling experiences of its toxic effects damped the enthusiasm of its most ardent advocates. I would counsel you to leave this drug severely alone for diagnostic purposes. Homatropine and atropine have each strong points in their favour and it will be well to weigh these.

Homatropine.

Homatropine is a most valuable drug. It is quick in action. Its effects pass off speedily and they can be neutralized at will. I have never known it produce toxic symptoms when administered in the way set out here. Its disadvantages are its high cost and the care necessary to get efficient results. We may use it in a watery solution of the salt, the oily solution of the pure alkaloid, or in one of the minute solid discs or tablets prepared by well known firms. The cost of the drug should rule out the use of the watery solution, at any rate in hospital practice. There is a story that a well known manufacturer of mustard said that he made his fortune out of the mustard that folk left on their plates. Priceless quantities of homatropine have run down the cheeks of patients and watered the floors of out-patient departments. Further, to secure full effects, two to four instillations are required, spread out over an hour. These disadvantages can be overcome by thickening the watery solution. I did this during the war when the pure alkaloid necessary for the preparation of the oily solution was scarce. To the watery solution of the salt small lumps of gum arabic were added and allowed to dissolve until the solution was so viscid that it could be lifted in drops with a narrow probe. If this gummy solution be used it must be made antiseptic, otherwise moulds speedily grow in it. I have found the addition of menthol gr. 2, ol. gaultheria minims 2, and tincture of iodine minims 2 to the pint of water makes a most efficient preservative both for this gummy solution and also for watery solutions of cocaine.

The oily solution of the pure alkaloids of homatropine and cocaine, 2 per cent. of each dissolved in castor oil, forms, in my experience, the most convenient and efficient quick-acting cycloplegic. It needs very careful preparation. The mixture must be warmed gently over a water bath for some six hours to secure solution. Too high a temperature will cause some of the homatropine to be reconverted into atropine, so that the brevity of the effect of the homatropine is lost. The advantages of the oil lie in the small quantity needed and the single instillation. One drop, no larger than the head of a wax vesta, will secure complete cycloplegia of the eyes of a child within one hour, provided it be properly used.

Some years ago, in furtherance of a piece of research work, I worked out the refraction of all the children in a large higher grade school: 1,100 children between the ages of 4 and 14 years were examined. The method adopted was as follows:

Three rooms were chosen leading from one to the other. The group of children to be examined were collected in one with a teacher; one by one they came into the middle room where their eyes were anointed; then each passed into the third room where it was put into a seat and told to put its arms on the desk, its head on its arms, and go to sleep. There they remained for a full hour, when they were told to sit up and look about until wanted for examination. After the examination the effect of the drug was neutralized by the instillation of a minute droplet of eserine 1 per cent. in castor oil, so that the pupils of the eyes were closed down before the children left school. The examination was made with the consent of the parents, many of whom were present at the time. Certain euphemisms helped a successful working. The first instillation was described as "smoothing the eyes with oil," the second as "washing out the oil." That satisfied parental desire to know what was being done. At the first instillation the child was told that it would "tickle"; that made the smart of the oil (rather like soap getting into the eyes) seem a joke. If the smart proved too much for some child so that it cried the fact that no other children were present prevented the disturbance affecting the rest of the children.

The actual instillation of the oil needs skill. The oil should be lifted on a short probe no thicker than a wax vesta. Large glass rods lift too much and make a mess. The child should be told to look at the surgeon's eyes. The surgeon with thumb and forefinger of left hand pulls down simultaneously both lower eyelids so as to expose the conjunctiva, then quickly first one then the other lid is touched with the same oil drop before the child has time to blink. If a blink intervenes between the two anointings the smart will cause the child to screw up its lids, so that the second anointing may be impossible or a failure.

Once the oil is on the conjunctiva it spreads over the whole area; it cannot be rubbed out or washed out by tears. It is absorbed over a large area simultaneously and is consequently most effective. The hour of quiescence of the child prevents the muscles striving against the action of the drug. I adopted this practice after noting how quickly deaf children reacted who, after anointing, were kept in a darkened room; with a total absence of stimuli most of the children fell asleep, and cycloplegia was obtained exceptionally quickly. A last point remains to be noted. The children are told to open the eyes and look about shortly before the time of the examination. This is to secure by blinking that the remains of the oil shall be swept away and the cornea left clean and bright.

If some of the eyes be examined by the plane mirror reflex before the completion of the cycloplegia, a curious phenomenon may be noted. The reflex seen in the full round pupil may be divided into two zones separated from each other by a bright circular line, just as though the nucleus of the lens had a different refractive index to the outer layers of the lens. I take it that this is an indication of the gradual relaxation of the lens fibres as the influence of the ciliary muscle is withdrawn, for I noted the phenomenon most often where the error of refraction was a considerable degree of hypermetropia. If at the end of the hour a child's reflex should show this ring mark, the child should be put back to wait a while longer.

With such a procedure as the foregoing, the oily homatropine and cocaine solution can be most efficient and safe in routine refraction work. But it will be evident its use requires time, patience, and spacious premises. A crowded out-patient department does not furnish these conditions, the risk of one child of uncertain temper upsetting the rest of the children by an outburst of crying is great, so that for routine hospital work I prefer atropine for home use.

A word must be said on the solid preparation of homatropine. The minute tablets or discs are most convenient for travelling purposes; they are clean, dry, small in bulk, and efficient. But they are niggly little things, and for that one reason I do not find them so satisfactory for routine use as solutions.

Atropine.

Atropine requires several hours to attain its full action. Once its action is established it is a week before it passes off, and it cannot be neutralized by eserine. Its slowness of action makes its instillation at the same session as the main examination impossible; so that after the child is seen at the first session, atropine must be ordered for home use until the time of the next examination. The loss of accommodation for a week to ten days is unpleasant to children of older years, and their work in the school is practically stopped for the time. These are the real drawbacks of its use; but they are small when balanced by the convenience which its use presents in the heavy routine work of an eye department.

Atropine may be prepared in four forms—(1) watery solution, (2) oily solution, (3) tablets, (4) ointment. The watery solution I rule out because of its extravagance, so much of a watery solution is wasted. Further, bottles and droppers are required and these are costly. The oily solution is also ruled out, for the more costly alkaloid is needed and also bottles. The tablets should, in my judgement, be ruled out also, for the average patient of the hospital class is not up to the task of placing these minute discs within the eyelid. The tiny disc has to be shaken out of a glass tube, picked up with a brush or rod dampened to make it adhesive, then the disc has to be transferred to the eyelid. Parents will damp brush or rod by putting it to their lips, an unwholesome procedure. Discs get lost. There is a risk that small children may think they are sweets. And, finally, there is the risk that parents may use pointed instruments to insert the discs and possibly damage the eye of the child by a sudden jerk of the hand or of the child's head.

The use of the ointment avoids these difficulties, and presents certain advantages. It can be kept in bulk in the dispensary, put up in small cardboard boxes ready labelled with a red "poison" label in the quiet times of the dispensary officers, and served out rapidly when the rush comes. I had the curiosity recently to examine the supply issued by the Belgrave Hospital Dispensary. The boxes contained sufficient for use thrice daily for one week. Several specimens were weighed up, and it was found that the average quantity weighed nine grains, the extremes were 7 and 10 grains. The dispenser therefore showed

good judgement in picking up the required quantity with the knife-point.

At the Belgrave Hospital printed directions for the use of the ointment are given to each parent by the surgeon in charge. They read as follows:

BELGRAVE HOSPITAL FOR CHILDREN.

Eye Department.

Put a small piece of the ointment (the size of a match head) inside the lower lid of EACH eye three times every day, after breakfast, dinner, and tea, until you come next time. Use a wax match with the head cut off to put in the ointment.

The eyes will open wide, and the child will not be able to read, but may go to school. The ointment will be stopped when the doctor has examined the eyes and ordered the glasses.

Do not forget to use the ointment, or your visit will be wasted. Be careful with it, for it is very costly. Do not let any one else use it.

From an experience of many years I find these directions are readily understood and carried out by the parents. They have a further advantage, in that the simple explanation of the reasons for the use of the ointment, its effects, and their duration forestall objections from querulous parents.

On the second visit a nurse looks at each child, and should she find one in which the effects look incomplete, she at once puts a drop of the oily homatropine into the eye; the child is put to the end of the row, and is ready for examination when its turn comes.

There are some children for whom this routine practice is unsatisfactory. Children with chronic blepharitis or eyes scarred from relapsing phlyctenular ulcers often react badly to atropine. These are directed to attend very early at the next session, when the nurse prepares them for examination by instilling the oily homatropine.

Adults.

It may be convenient to end this lecture by making a few observations on the use of these drugs for adults. For the examination of young adults, let us say for those over school age up to 30 years, a cycloplegic is often necessary. It should be a rule never to use atropine for these for purely diagnostic purposes. The discomfort and loss of effective work occasioned by the suppression of accommodation and pupil reaction for a week or more is serious, and should be avoided. Consider the circumstances of a clerk, of a seamstress, or of any other skilled worker whose near vision is put out of action in this fashion, or of a driver whose eyes are dazzled by the blaze of light entering his widely opened pupils. In all but the rarest cases the oily homatropine and cocaine solution will do the necessary work then and there, and its effects can be neutralized speedily by a final instillation of the oily eserine. Cases of suspected spasm of the accommodation are few and far between; in these atropine is needed, and should be ordered for home use with due explanation.

In adults over 30 years of age atropine is never needed for diagnostic purposes. It is not only a serious inconvenience to the patient by reason of the dazzling and disturbance of near vision, but there is a serious risk of glaucoma in susceptible subjects. For these reasons, where a mydriatic is needed for effective examination—and you will note that I here use the term "mydriatic" and not "cycloplegic"—the mydriatic should be homatropine. As little as is possible should be used, and that little should be neutralized by eserine before the patient is allowed to leave the consulting room.

THE TREATMENT OF MALARIA.

BY

W. S. DAWSON, M.A., M.B.,

HOUSE-PHYSICIAN, ST. THOMAS'S HOSPITAL; LATE 15TH STATIONARY HOSPITAL, EAST AFRICAN EXPEDITIONARY FORCE.

The methods advocated for the treatment of malaria are innumerable. After experience of many hundreds of cases of malaria amongst Europeans in the campaign in East Africa, and after suffering severely myself from repeated attacks, I came to certain definite conclusions as to the treatment of this disease.

1. Routine "stock" treatment often fails, and is justifiable only when the medical staff is insufficient to deal with the number of patients. Every case has its peculiarities.

2. Antimony plays no part in the treatment. Arsenic is most useful in the convalescent stage, especially in

cachectic cases, and after the acute stage of blackwater fever, when one or two intramuscular injections of "914" have often seemed to be beneficial.

3. After a preliminary dose of calomel or blue pill, quinine, preferably the hydrochloride, should be given as early as possible in an attack of malaria. *Bis dat qui cito dat.* Ten grains in a small quantity of water should be given every three hours to a maximum of 45 grains. The aim should be to produce tinnitus aurium, and the dose regulated accordingly. The heroic dose (20 or 30 grains) is not more effectual than the smaller, and is far more liable to incite vomiting. I doubt whether, by the mouth, one can absorb more than 10 grains of quinine during the course of two or three hours. At the same time the patient should drink freely of water, lemonade, etc. But all food, even milk, should be withheld during the acute stage, and even for several hours after defervescence.

4. In most cases this form of treatment will suffice. Vomiting is the commonest and most troublesome complication. A dose of quinine, if rejected, should be repeated—two or three times, if necessary. A little firmness is often necessary, especially with a patient who has made up his mind that he cannot retain quinine. A large tender spleen, which often incites vomiting, is less felt after the application of a plaster and by lying on the left side.

5. The chronic cases present the greatest difficulty. We rely too much on drugs and pay too little attention to the stimulation of the patient's natural powers of resistance. The advocates of various forms of treatment in claiming their successes forget the *vis medicatrix naturae*. Even quinine fails when a patient is kept in a relaxing, unhealthy climate; while in healthier surroundings relapsing cases tend to get better, even without the use of drugs. I do not believe in the long-continued administration of quinine, even in small doses, whether as a curative or as a prophylactic measure. I suspect that the *plasmodium* becomes resistant to quinine in course of time; or perhaps the drug, owing to its irritant action, becomes less easily absorbed in the intestinal tract.

In chronic cases the relapses should be treated intensively and early. To give quinine between the attacks is to bombard the enemy's line when he is safe in his dug-outs. Rather the aim should be to catch him when he makes his raids.

6. Only in cases of uncontrollable vomiting, in cerebral and in a few other complications will it be necessary to administer quinine otherwise than by the mouth. In my opinion, subcutaneous and intramuscular injections are always contraindicated. High rectal and intravenous injections, slowly given, rarely fail to influence an attack in the acute stages. The most useful proof that we have of the absorption of quinine is the production of tinnitus aurium and slight deafness. Only after big doses and a long interval (a day or so) did we obtain this effect after subcutaneous and intramuscular injections. There is no evidence that quinine is absorbed sufficiently quickly from the muscles and subcutaneous tissues to be of any use in an attack of malaria, and the other disadvantages are obvious.

7. A great physician said that a man who could not control malaria with quinine should give up the practice of medicine. Drugs must be given with the head as well as with the hand. The ideal of a *therapia magna sterilisans* has so far proved illusory. Quinine is as much a specific in malaria as is arsenic in syphilis, but in both cases there is a time to give and a time to refrain from giving.

8. Blood films should be taken not once but several times during the course of an attack, and treatment judged and regulated accordingly.

Attention to these details will, I think, be rewarded by greater success in the use of quinine by the mouth than seems to be the experience of many medical officers, and more complicated methods of treatment will more rarely be necessary.

The following extract from Buchan's *Prevention and Cure of Diseases* (London, 1774) is of interest:

After proper evacuations, the patient may safely use the Peruvian bark. Two ounces of the best jesuit's bark, finely powdered, may be divided into twenty-four doses. In an ague which returns each day one of the above doses may be taken every two hours . . . in a tertian, or third-day ague, it will be sufficient to take a dose every third hour.

There is much other sound advice, and the last words of the chapter on agues are "the only method to obtain a

safe and lasting cure is gradually to assist Nature in removing the cause of the disease." This is an axiom too often overlooked.

A CASE OF TUBERCULOUS MENINGITIS WITH COMPLETE RECOVERY.

BY

HUGH BARBER, M.D.LOND.,
HONORARY PHYSICIAN, DERBYSHIRE ROYAL INFIRMARY.

ALTHOUGH tuberculous meningitis is almost always fatal, most physicians with a wide experience have seen one or two cases which have suggested that recovery is possible. Most of these have been in children, with perhaps only partial subsequent recovery; and only in few cases has the diagnosis been proved bacteriologically.

These notes record the case of an adult, proved bacteriologically to have tuberculous meningitis, who has made a complete recovery. Had one supposed that the patient could get well, fuller clinical and pathological investigations would have been undertaken; but, although only one examination of the cerebro-spinal fluid was made, it is possibly more reliable in that there was no knowledge in the laboratory of the patient's antecedent tuberculous infection.

Clinically the case was never doubtful; the first lumbar puncture was performed in the fourth week of the illness, to relieve symptoms of intracranial pressure; the benefit was considerable, as was also the case after the second and third punctures; and although the fourth puncture, made in the eighth week, did not seem to do any good, and the case was regarded as hopeless, I certainly think that but for the earlier lumbar punctures the patient would have died from increased intracranial pressure.

A woman, aged 37 years, admitted on June 11th, 1919, was discharged quite well on December 14th, 1919.

Past History.—Twelve years ago she was treated by Sir Richard Luce, who removed a tuberculous kidney; has been quite well since.

Present illness began one week before admission; pains in limbs followed by intense headache; when seen in consultation with Dr. G. D. Moon two days before admission she was very irritable and rather excited; neck stiff, severe headache.

On Admission: Temperature 100°, pulse 88, respirations 24; drowsy, but at times very restless; head rather retracted, neck and legs stiff, Kernig's sign present, reflexes normal; no strabismus; lungs and heart normal; urine normal.

Diagnosis—in view of the symptoms and history—was never in doubt. Lumbar puncture was not performed until July 1st; the fluid was under pressure, appeared clear, and contained a few lymphocytes; tubercle bacilli were found.

Course.—For thirteen weeks the temperature was of an irregular intermittent or remittent type, usually reaching 102° or 103° in the evening; the pulse was irregular, but usually below 100, until the ninth or tenth week, by which time there was an extreme degree of prostration; the general condition varied between coma and delirium, with signs of distress and headache. In the twelfth and thirteenth weeks the temperature was not so high, and from the fourteenth onwards it was normal or subnormal, and she made a slow but steady convalescence. She was taking full diet in the nineteenth week. On her discharge in the twenty-eighth week, after having gained 18 lb. in eight weeks, she was perfectly well in every way. Her mental condition was normal, and there was no loss of memory, nor headache; the eyes were quite normal and the limbs were strong, with no rigidity nor increase of reflexes. Three months after discharge she returned to her household duties, looking and feeling quite well.

Lumbar puncture was not performed until the fourth week from the onset; it seemed to relieve the symptoms of intracranial pressure, and was repeated in the fifth, sixth, and eighth weeks (four times in all), but there was little relief if any after the last time, and the case was regarded as hopeless. On one day in each of the tenth, eleventh, and twelfth weeks morphine was administered to relieve noisy delirium.

Specific therapy in tuberculosis is not very satisfactory at present, but most infected persons have good natural powers of recovery. Possibly repeated lumbar puncture is worthy of routine trial in cases of tuberculous meningitis; by the opportune relief of intracranial pressure an odd case or two may "get its chance."

G. BOUCHE (*Le Scalpel*, March 6th, 1920) records two typical cases of lethargic encephalitis which occurred at Anderlecht and Ieuis (Hainault) respectively. Two other cases had recently been recorded to the Medico-Chirurgical Society of Brabant and others had been observed in the neighbourhood of Bruges.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

NOTES OF TWO CASES OF HORSESHOE KIDNEY.

THE following two cases of horseshoe kidney were both discovered in the course of operations for renal calculi. In neither of them did the symptoms nor the examination of the patients give any indication of the presence of the abnormality. The condition itself, of course, does not usually give rise to any definite symptoms, and it is the exception for it to be diagnosed previous to operation or until a *post-mortem* examination is made, although in recent years a certain number of the more marked cases with abnormality of the pelvis or ureter have been diagnosed by the use of the cystoscope and pyelography. The frequency of its occurrence has been variously estimated: Morris,¹ from *post-mortem* examinations, places it at 1 in 1,000, but Thompson² puts it as high as 1 in 300. There is, however, a marked tendency for these kidneys to be the seat of pathological changes, so that the possibility of encountering it at operations on the kidney is probably higher than these statistics would indicate.

CASE I.

A woman, aged 33, gave a history of attacks of pain in the left lumbar region for two years. They came on suddenly, sometimes with vomiting and with pain radiating towards the groin. No definite tumour could be felt in the left renal area, but there was tenderness and some rigidity of the muscles. The urine contained a small amount of pus. An x-ray photograph showed the shadow of a large calculus in the left kidney.

Cystoscopic Examination.—The bladder was healthy and the ureters normally situated. The right ureter was normal, and urine could be seen coming from it; the left was somewhat swollen and congested, and no urine was seen coming, although it was seen to contract. Indigo carmine was injected into the buttock, and was seen coming freely from the right ureter in twenty minutes, but none came from the left even at the end of forty minutes. Catheterization of the ureters confirmed this, normal urine being obtained from the right and nothing from the left.

Operation.—The left kidney was exposed by a lumbar incision. It was found lying rather lower than usual. There was a large stone in the pelvis, and marked atrophy of the kidney substance. The lower pole could not be brought up, and on further investigation it was found to be attached by a thick band of tissue to the lower pole of the right kidney. The right kidney lay partially across the middle line and its lower pole, which appeared normal in shape, could be distinctly seen. The connecting tissue was divided, and the left kidney removed. The patient made an uneventful recovery.

Specimen.—The kidney consisted of thinned and atrophied renal tissue round the pelvis, which was contracted on a stone the size of a bautam's egg. The connecting isthmus was composed of fibrous tissue.

CASE II.

A man, aged 29, gave a history of attacks of severe pain in the left renal region for about a year. The attacks were occasionally followed by slight haematuria. In the intervals he was perfectly well. Nothing abnormal was detected in the renal region. The urine was normal. An x-ray photograph showed a small shadow in the left renal area.

Cystoscopic Examination.—The bladder was healthy, and both ureters were normal and in the usual position. Indigo carmine was injected, and appeared freely at both ureters in twenty minutes.

Operation.—The kidney was exposed by a lumbar incision. It could only be partially raised up with some difficulty. The pelvis was small, and was situated on the anterior aspect, and behind it there was a mass of kidney substance about 2 in. broad extending across to the right side in front of the great vessels. The renal vessels entered the kidney from above and in front of this tissue. A small stone was found in the pelvis, and was removed by nephrolithotomy. When seen a year later the patient was perfectly well and had no pain or discomfort.

These two cases illustrate two of the varieties of horseshoe kidney: the first, where the lower poles are united either by fibrous tissue or by actual renal tissue, is probably the commoner; the second is not so common, as here the connecting renal tissue passed from the posterior part of the left kidney, and both poles were distinct and unattached. The fact that this second case was well and able to do manual work a year later is of interest in view

of Rovsing's³ description of symptoms of discomfort and inability to do heavy work from the presence of the renal isthmus in the middle line.

J. MILL RENTON, M.B., Ch.B., F.R.C.S.E.

Assistant Surgeon, Western Infirmary, Glasgow; Surgeon to Out-patients, Royal Hospital for Sick Children; Surgeon, Elder Hospital, Govan.

FOREIGN BODY IN THE LEFT BRONCHUS.

On June 17th, 1919, I was asked to see a girl, aged 11, in the Oldham Royal Infirmary. The story was that on June 14th, while playing with a toy air balloon, she laughed, the balloon disappeared into her mouth, and she became cyanosed and could not speak. She rushed into the street, attracted the attention of a man there and, by pointing to her mouth, indicated what was wrong. He inserted his finger into the child's mouth and "pushed something down her throat." She was then able to breathe with comfort and to speak.

When I saw her, three days after, she looked like a patient suffering from pneumonia, very different from the picture of laryngeal or tracheal obstruction. The cheeks were flushed, the temperature 101°, respirations 46, pulse 104. She had slight cough, with a little muco-purulent expectoration. The whole of the left lung was dull to percussion; the breath sounds were markedly diminished over the whole of the left side of the chest, and resonance was slightly increased.

From the story and the physical signs I concluded that the object, described to me as consisting of a wooden mouthpiece, with elastic balloon attached, was in the upper part of the left bronchus. No skiagram was taken, as I considered the chances of seeing any shadow small, and I did not wish to move the patient any more than could be helped, on account of the risk of moving the object into the trachea or larynx.

The patient was anaesthetized with chloroform. A Brüning's tube passed through the glottis showed the mouthpiece of the balloon about three-quarters of an inch below the bifurcation of the trachea, in the left bronchus, with the balloon folded between the mouthpiece and the spur of the bifurcation. The mouthpiece seemed pretty well fixed. Cocaine and adrenalin were applied to the spur and to the left bronchus above the object, which was gently freed with Brüning's spoon forceps, and then removed at the end of the tube with Paterson's forceps. The whole operation was comparatively simple, as it was easy to see and seize the object. The patient was perfectly well and the lung appeared quite clear in four days.

The wooden mouthpiece was 1½ inches long, ⅜ of an inch in diameter, and slightly expanded at either end. The fabric was more than twice the length of the mouthpiece, but being very thin occupied little space.

W. R. CAMMOCK, F.R.C.S.Ed.,

Surgeon, Ear, Nose and Throat Department, Oldham Royal Infirmary.

THE INCISION IN CAESAREAN SECTION.

In connexion with the discussion on the incision for Caesarean section (BRITISH MEDICAL JOURNAL, November 15th, 1919, p. 633) the following facts may be of interest:

Since August, 1908, there have been ninety-two such operations at the S.P.G. Mission hospitals at Delhi and Karnal, Punjab; I performed twenty-two. Eight women were delivered by this method for the second time. In three cases I was the operator, and in two others I assisted. The line of incision adopted by me and most of the other surgeons has been the longitudinal in the upper part of the uterus, and the stitches (of silk or catgut) have been through the depth of the uterine wall not including the mucous membrane, with a second row of superficial stitches.

It was interesting to note that of the five "second Caesareans" within my experience only one had any signs of a scar in the uterus; the first operation on this patient had been performed eight years earlier in Quetta, and the scar was situated in the lower uterine segment. A few adhesions and the abdominal scar were the only indications of any previous operation in the others.

In contrast to what is usually taught in the British Isles, we have found that although almost all these cases have been in labour for three or four days, and have been examined by untrained native midwives before admission to hospital, we have had no cause to regret leaving the uterus *in situ*. The patients who have died have been few in comparison with the number who seemed so hopeless on admission that it was inadvisable to add to the shock by hysterectomy.

S.P.G. Mission, Delhi.

MINNIE W. BAZELY, M.D.

Reports of Societies.

RUPTURE OF VAGINA.

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine held on April 8th, with the President, Mr. J. D. MALCOLM, in the chair, Dr. A. C. PALMER read a short communication on two cases of rupture of the vagina during labour, admitted to the obstetric department of the London Hospital.

Case 1.—An 8-para, aged 35, was brought by her doctor, who stated that the case was one of prolonged second stage with the head delayed in the pelvis. He had extracted a child, stillborn, weighing between 13 and 14 lb., after a hard pull with forceps. The perineum was torn. The placenta did not follow, and since the patient continued bleeding he decided to remove it. Following the umbilical cord, his hand passed into the abdominal cavity, where he found and removed the placenta. The case was then brought to hospital. Pulse 120, temperature 98° F., abdomen very tender. The uterus was found almost completely separated from the vagina, except for a narrow bridge in the region of the left uterine artery, and a small portion of the anterior wall of the cervix close to the bladder. There was much free blood in the peritoneal cavity. The uterus was removed as rapidly as possible, and the patient made a good recovery. Dr. Palmer believed that the difficulty was due to relative pelvic contraction owing to the very large size of the child.

Case 2.—A multipara was brought to hospital in a state of collapse (pulse 120, temperature 96.5° F.) by a midwife, having been in labour twenty-four hours. There had been good pains for fifteen hours, and since then the pains were described as stormy and different in character from the preceding ones. No manipulation and only one vaginal examination had been made. On the right of the fetus was a hard tumour about the size of a fetal head, and thought by the resident accoucheur to be possibly a fibroid. A moderate pull with forceps being unsuccessful, the child was delivered after perforation and crushing of the head by Mr. V. J. F. Lack, the resident accoucheur, who then noticed that the tumour was the contracted uterus, and that the child had been lying in the abdominal cavity, whence the placenta was removed manually. At an exploratory laparotomy Dr. Palmer found a large T-shaped tear in the posterior vaginal wall, beginning at the cervico-vaginal junction and extending almost down to the vulva, and much free blood in the peritoneal cavity. The uterus was rapidly removed. The patient was now convalescent. Four easy labours had occurred in spite of well-marked general contraction of the pelvis; the fifth had required forceps; the sixth was the case described.

In each case the object of the hysterectomy was the control of haemorrhage and the removal of damaged and devitalized tissue as a prophylactic against puerperal sepsis.

Mr. EARDLEY HOLLAND said that rupture of the vagina in association with rupture of the lower uterine segment was much more common than was generally believed. It was not sufficiently realized how very greatly the vagina was stretched and drawn up by the uterus during obstructed labour. As an example of this he gave an epidiascopic demonstration of sections through the lower uterine segment from the case of a patient who had died undelivered during obstructed labour. In this case the retraction ring lay at a level of 11.5 cm. above the symphysis pubis, and below the ring the fetal head was enclosed by what was at first thought to be an enormously distended and elongated lower uterine segment. The sections showed, however, that only the upper 4.5 cm. consisted of the extended cervix, all below that consisted of the elongated and stretched vagina. The sections further demonstrated that in this case the lower uterine segment consisted of cervix only; if rupture had occurred, it would almost certainly have been in the vagina.

Dr. HERBERT SPENCER said that it was sometimes difficult to see the line of demarcation between the cervix and vagina in the second stage of labour, but he thought it was

³ Rovsing: *Zeitschr. f. Urol.*, 1911, vol. v, No. 8.

absurd to speak of the vagina as taking part in the formation of the lower segment of the uterus.

Blood Transfusion before Operation.

Dr. HERBERT WILLIAMSON read a note on the value of blood transfusion before operation in severe secondary anaemia.

A patient, aged 45, was admitted to St. Bartholomew's Hospital on May 11th, 1919. She was extremely anaemic and breathless; pulse 130 and of poor volume, temperature 101°. There was incontinence of urine and faeces, frequent vomiting, and the urine contained albumin. The blood count was 1,670,000 red cells and 52,000 white cells per c.mm., haemoglobin 22.5, and colour index 0.7. There was a history of continuous and profuse vaginal bleeding for a month prior to her admission. On examination, a large hard tumour could be felt reaching from the pelvis to the costal margin. After admission the patient gradually became more ill; the temperature rose to 102° to 104°, vomiting was frequent, and incontinence of urine and faeces persisted. On the 17th the red blood cells had fallen to 845,000 and the white had risen to 65,000 per c.mm. On this day the patient was transfused with 600 c.cm. of blood derived from a donor belonging to Group IV. Three days later the temperature was normal, vomiting had ceased, the patient had regained control over the rectum and bladder, the red blood cells had risen to 3,400,000 and the white had fallen to 29,000 per c.mm. On June 5th Dr. Williamson operated and removed the uterus, enlarged by the presence of multiple fibroids, together with a cyst adenoma of the ovary. The patient made an uninterrupted recovery and left the hospital well at the end of three weeks. On the day of discharge the red cells numbered 4,250,000 and the white 10,400.

Dr. MALCOLM DONALDSON said that the astonishing results obtained on the wounded during the war had advanced this line of treatment enormously. At the same time he feared that the method could not be used in emergencies until some reliable way of storing blood without interfering with its action had been devised.

The PRESIDENT stated that the subject was of the utmost practical importance. When successful, the effects of the transfusion of blood in suitable cases were almost miraculous. He asked for details of the method employed.

In reply, Dr. WILLIAMSON said that the method of transfusion adopted was that described as the "citrate method," and the apparatus employed was that devised by the late Dr. Stansfeld. In answer to Dr. AMAND ROUTH, he said that whenever possible he preferred to use blood, but if this was not available he would use the 6 per cent. gum arabic solution as recommended by Bayliss.

High Ammonia Coefficient.

Lady BARRETT read a short communication on high ammonia coefficient.

A munition worker, aged 22, married, was admitted to the maternity block of the Royal Free Hospital when nearly three months pregnant, having been vomiting frequently for six weeks in spite of treatment. Her urine was greatly diminished—7 oz. in twenty-four hours—contained slight traces of albumin and diacetic acid, and the ammonia coefficient two days after admission was 38, rising within a few days to 78. The vomiting was controlled by abolishing all mouth feeding for a few days and the administration of glucose salines per rectum; ordinary food was gradually resumed, albumin water, oranges, and tea being first retained. The excretion of nitrogen as ammonia gradually declined after a few recurrent rises with renewed vomiting, and was 19 per cent. of the total nitrogen when the patient left hospital. The pulse remained at 80 to 84 throughout, and the temperature was normal. Diacetic acid and albumin appeared from time to time, but were not constant. It was not found necessary to induce labour, and the patient was delivered of a normal child on February 15th, 1919, her nitrogen excretion at that time being normal.

The case seemed to indicate that a consideration of the general condition, especially the pulse, the quantity of urine passed, and the presence or disappearance of diacetic acid in the urine, was of more importance than a high ammonia coefficient in deciding the necessity for induction of labour.

Dr. MACKENZIE WALLIS raised as an important point the question as to the method used in the determination of the ammonia in the urine, as he thought it possible that the amino acids might be included in this result. In pregnancy toxæmia the diastase was always markedly increased, and there did not seem to be any relation between the high ammonia coefficient in this case and the presence of aceto-acetic acid in the urine. He gave particulars of a case of persistent vomiting, in the wards of St. Bartholomew's Hospital, which he was investigating. He had

come to the conclusion that the ammonia coefficient was of no value either for prognostic or operative purposes, and that it did not bear any definite relation to the severity of the toxæmia.

Dr. T. W. EDEN gave details of a similar case he had had under observation, and said that he thought the excessive vomiting might have been a factor in the high ammonia excretion.

Dr. LAMTORN SMITH mentioned the success that he had obtained by treating vomiting of pregnancy with sodium bicarbonate.

In reply, Lady BARRETT stated that during the patient's first illness no difference was made between the amino acids and ammonia, but that later investigations in February, 1919, showed that the average difference between the amino acids and ammonia was approximately 2 per cent. Diacetic acid was present only in traces. She agreed that the excessive vomiting might have been a factor in the high ammonia excretion. She had tried sodium bicarbonate in salines in toxæmic cases without any appreciable difference in the results from salines without carbonate.

ANTE-NATAL AND POST-NATAL SYPHILIS.

A MEETING of the Hunterian Society was held on April 14th at the Venereal Diseases Centre for Pregnant Women, 18, Thavies Inn, Holborn Circus, E.C., by invitation of Mr. JOHN ADAMS, F.R.C.S., who demonstrated cases treated at the Centre and the methods used in treatment of syphilitic mothers and their babies. A large number of Fellows were present, and the cases described and demonstrations given were followed with keen interest. As recorded in this JOURNAL, the Centre was established in 1917, and the results set out gave a good idea of the type of work done there and the great advances made in treatment, particularly of syphilitic babies.

1917-18:

Total number of syphilitic mothers treated at the Centre	28
Babies of these mothers born with a positive Wassermann reaction	17
Babies born with a negative Wassermann reaction	6
Stillborn babies	5

Of those with a positive Wassermann reaction at birth 3 died—one aged 6 hours, one aged 14 days, one aged 36 days.

1918-19:

Total number of syphilitic mothers treated at the Centre	39
Babies with a positive Wassermann reaction	8
Babies with a negative Wassermann reaction	21
Stillborn baby	1

Of those with a positive Wassermann reaction one died aged 2 months.

Nine cases of this series were shown at the meeting, as also the babies ranging in age up to 2½ years. The results of the treatment were obvious from the appearance of the mothers and their babies. The statement was made that every child born during the past year and actively treated at the Centre was free from any syphilitic manifestations. As a result of his experience, Mr. John Adams concluded that treatment of the pregnant woman could be carried out up to the day of confinement with safety and success, and a mother so treated might be delivered of a child whose blood gave a negative blood test. Such a child might thrive and continue to give a negative Wassermann test. Treatment of syphilitic infants began immediately after birth. The combined intramuscular injection of galyol in glucose and of grey oil succeeded in producing a negative Wassermann reaction with greater rapidity and more certainty than if galyol alone were used. Children so treated appeared to become quite healthy, put on weight, and their blood, which previously gave positive reactions, became negative and remained so. The mode of administration of the galyol solution to babies was demonstrated, and the importance of intramuscular injections of a solution of galyol in glucose solution emphasized.

A dose of 1.5 cg. of galyol is injected into one buttock on the first day of birth, and repeated after one week. From this time onwards gradually increasing doses are given up to 5 cg. at fortnightly intervals. This treatment after the first week is combined with intramuscular injections of mercury, beginning with ½ grain, then ¼ grain, and ultimately ⅓ grain. In addition hydrargyri cum creta is given orally. The mercury is given in

the form of grey oil, 20 per cent. strength for the babies and 40 per cent. for the mothers. A special syringe is employed, with 15 divisions each of $\frac{1}{10}$ c.c.m. capacity, and so arranged that one division in the syringe corresponds to 1 cg. of mercury, when the 40 per cent. grey oil is used. The intramuscular injections are given into each buttock every fortnight to the babies, and weekly to the mothers.

A rapid and easy method of collecting blood for the Wassermann test from the heel of an infant was also demonstrated. The whole foot of the infant is immersed in hot water, carefully dried, and the foot gripped with the left hand. By means of a sharp needle three stabs are made close together in the base of the heel. By means of gentle squeezing the blood can be "milked" out of the heel and a sufficient quantity of blood removed with ease and rapidity.

As a general rule, with this combined treatment, the Wassermann test is negative before or about the seventy-eighth day. Where the Wassermann test is found to be definitely positive at any future time or after the 176th day of treatment by intramuscular injections of galy glucose solution and grey oil, then it is necessary to start the treatment again.

The President of the Hunterian Society (Dr. LANGDON BROWN) voiced the opinion of the meeting in thanking Mr. John Adams for his excellent demonstrations. The Society last year conferred its Hunterian medal upon Mr. John Adams for this pioneer work on ante-natal and post-natal syphilis. The medal is awarded annually for the best individual effort of a general practitioner resident in Great Britain and Ireland in advancing the science and art of medicine.

TUBAL STERILITY.

At the meeting, held on February 20th. of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, the President, Dr. HASTINGS TWEEDY, showed his instruments for passing catgut through the tube. He said that a fine stiff needle with a blunt point should be used; it should pass first through the ovary, where the catgut should be knotted, then through the tube, and lastly through the mucous membrane. Mucous membrane should be sewn to mucous membrane. In every case of sterility the tubes, even though apparently normal, should be tested for permeability by the air test. The impervious part should be cut away. It had been suggested that the short tube would prevent pregnancy, but he had seen pregnancies in women whose tubes were certainly not more than $1\frac{1}{2}$ in. long.

Dr. SOLOMONS said the paper dealt not so much with tubal sterility as with sterility in women with long tubes. He would feel very diffident about resecting tubes just because they were long. He blew them up with air when there was a kink and resected them, not on account of their length, but because of disease. In excision for length did Dr. Tweedy have the excised part examined microscopically? In view of the difference in bore of the parts to be brought into apposition, that of the smaller one being only $\frac{1}{25}$ in., the removal of the uterine ends of both tubes in these cases was a very big undertaking. The instruments, he thought, would prove very useful. When resecting a tube he did not use forceps, but had special needles, the ends of the tubes being held one by him and one by an assistant, in an end-to-end anastomosis; but Dr. Tweedy was dealing with resection of the uterine ends of the tubes. This question of sterility embraced all the pathological conditions in the tube. Since October, 1919, when he read the opening address in the Biological Society, he had seen many cases to prove that the tubes were usually at fault—many without gross lesions. It was difficult to know what to do in these cases. If the abdominal end was diseased, a new ostium should be made and the fimbriated ends removed; if the middle part, he performed an end-to-end anastomosis, using a long straight needle, and resecting the tube when catgut had been passed through the lumen. In cases of disease of the uterine end the prognosis was very bad, especially if the condition was bilateral. He wished to know through what part of the ovary the catgut passed before going through the tube, and if this step were necessary. He thought any ova in the neighbourhood should find their way into the tube without help.

Dr. SHELL said that the first thing to prove was that a woman was really sterile, or successes might be claimed which were not earned. He was not sure that dilatation of the tubes with air was a sufficient test of the condition of the tubes. The only proof of sterility was a microscopic

examination of the parts removed. With regard to the passage of the needle, if a false passage were made at the uterine end it was possible that the epithelium would follow this, especially if ehromicized gut were used instead of ordinary six-day catgut.

The MASTER OF THE ROTUNDA said that the getting into apposition of the wide and narrow parts of the tube was the great difficulty.

Dr. TWEEDY, replying, said he hoped that by next year the technique of the operation would be greatly improved. Dr. SOLOMONS had referred to the long tube. The speaker said not that a long tube should be resected, but that a long tube which was obstructed, as most long ones were, should be resected. He had observed the greatest difference in the calibre of tubes in different individuals. As regarded the microscope test, serial sections would have to be taken of the $1\frac{1}{2}$ in. of tube removed; the obstruction might only be $\frac{1}{100}$ of a millimetre. He thought the method employed by Dr. SOLOMONS would lead to tubal pregnancy, as it had done in one case already, and also in one of his own cases when this method was employed.

He related this case, in which he resected one tube for concretions, the other being almost normal; this patient had a fixed retroversion. An end-to-end anastomosis was done, and she returned to Steevens's Hospital still sterile. The abdomen was opened; the anastomosis was found to have given way and the lumen had become closed. The tube was again resected, and the woman appeared at the Rotunda Hospital with a tubal pregnancy on the side of the resected tube. It was possible to pass a big sound through the fimbriated extremity to the uterus, and the probe could pass over the ovum into the uterus.

The other tube would not let anything through, therefore the technique was at fault. A continuity of epithelium was absolutely necessary. He used to agree with Dr. SOLOMONS that tubal pregnancy was due to inflammation, but now believed that the lack of epithelial continuity was responsible. Blair Bell had a case of pregnancy after stitching the fimbriated extremity to the cornu of the uterus.

CLASS FERTILITY IN ENGLAND AND WALES.

At a meeting of the Royal Statistical Society on April 20th, with Sir BERNARD MALLET, K.C.B., in the chair, Dr. T. H. C. STEVENSON, C.B.E., read a paper on the fertility of various social classes in England and Wales from the middle of the nineteenth century to 1911, based upon the information obtained in the last census as to the duration of marriages and the number of children born and surviving. Dr. STEVENSON stated that in considering the differences in fertility between various sections of the population it was necessary to bear in mind the differences in their recorded child mortality. Taking the population as a whole, large families implied high, and small families low, child mortality; it was possible, therefore, that the small families of the middle classes were in part due to the low mortality of their children, as well as the latter to the smallness of their families. In a typical case—wives married at 20 to 25 whose marriages had lasted fifteen to twenty years—child mortality rose from 102 per 1,000 born in one-child families to 339 in twelve-child families, and 407 in those of over twelve children. This was due to the rapidity of births implied as well as to their number. At the same time high fertility did not necessarily involve high mortality. Agricultural labourers were 37 per cent. more fertile than textile workers, but the mortality of their children was 35 per cent. less. In measuring the fertility of the various social grades allowance must be made for the difference in the average size of families and the age at which it was customary to marry in the given class. Dr. STEVENSON described the method of standardization which had been used for making this allowance, and the way in which the class division had been made for the purposes of this inquiry. It was, of course, necessary to infer the social status of families from such facts as the census offers, and those relating to occupation were found in the end to provide the most satisfactory basis.

The classification is into eight social groups. Of these, Classes I to V are in descending order of the social scale, Class I including the upper and middle classes and Class V unskilled labour, while Classes VI, VII, VIII consist of textile workers, miners, and agricultural labourers. The results obtained not only confirm previously published statistics in showing that fertility increases downwards throughout the

social scale, but they also suggest that this difference is of comparatively recent origin—in other words, that the defective fertility of the classes which are presumably the most successful and efficient, is a new fact, the consequences of which are not yet apparent and will have to be faced. Comparatively little class variation in fertility is observable in marriages contracted before 1861. Marriages of more recent date have been subject to the influences, whatever they may be, which have led to the fall in the birth rate from 1877 onwards. Their fertility has rapidly declined, and at the same time the class variation has greatly increased, which suggests that artificial restraint of fertility is the main cause of its decline. This is confirmed by several other facts. The decline began in the higher social strata and spread gradually downwards; occupied mothers show a very low fertility; and infertility increases in the higher classes with increase of marriage duration up to twenty-five years. It is to be noted that the comparatively low mortality in these, the less fertile classes, goes very little way towards compensating for their low fertility and that the classes which are least fertile are also those which marry late in life. The lowest fertility rates of all are those of the professional classes; persons describing themselves as of "private means" also show a very low rate. These are all included in Class I, the smallest of the five graded classes, but by far the most heterogeneous socially.

In two interesting tables Dr. Stevenson showed the detailed rates of fertility and child mortality for a few of the constituent occupations of Class I. The lowest fertility quoted was that of naval officers, and the highest rates were those of clerks and of commercial travellers. Outside Class I, textile workers came far down in the scale, and Dr. Stevenson considered that this might be due to the extent to which the wives worked in the mills. He concluded his paper with some figures relating to the effect of female occupation upon married fertility, which showed that the fertility of occupied wives was, almost without exception, considerably lower than that of all wives whose husbands had the occupation in question. The fertility of male teachers, for instance, was 70 per cent. of the average for all classes, but that of female teachers was only 52 per cent.

SURGERY AT THE ENDELL STREET HOSPITAL:

At a meeting of the London Association of the Medical Women's Federation held at 11, Chandos Street, W., on April 20th, with Dr. HELEN BOYLE in the chair, Dr. GARRETT ANDERSON, C.B.E., formerly chief surgeon to the Military Hospital, Endell Street, gave an account of the work at that hospital from 1915 to 1919, illustrating her remarks with lantern slides. She said that the surgical work fell into three groups: In 1915 to 1916 large numbers of head wounds were received, and fractured skulls, with every kind of complication, were treated; in 1916 and 1917, compound fractures of thigh were received; in 1918, a fine series of penetrating wounds of joints, especially the knee-joint, were admitted. She emphasized the valuable results obtained by the use of bipp, which was first tried in 1916. It was used afterwards for a very large number of cases of compound fracture, and always with the best results. It replaced other disinfectants. It minimized the ward work enormously, as cases which previously had been dressed twice or thrice daily were left undisturbed with bipp for a week or more. It improved the prognosis of cases in a striking way and shortened the time of treatment in hospital. Over 26,000 men passed through the hospital and 7,000 operations were performed; 300 beds were set aside for orthopaedic cases. The speaker discussed the advance in the treatment of fractured thighs and wounds complicating joints. By disciples of Sir Robert Jones—notably, Major Sinclair, R.A.M.C., and Major Everidge, R.A.M.C.—the treatment of these cases had been revolutionized. In 1914 a case of compound fracture of the femur was a source of infinite anxiety to the surgeon. The recollection of these cases in the first year of the war suggested great suffering on the part of the patient: dressings at frequent intervals, drainage tubes, constant operations for the removal of sequestra, and, at the end of months of misery, a weak leg, considerably shortened, possibly with a stiff knee. A very different picture arose from the modern treatment, with bipp applied to the wound, after thorough preliminary investigation and cleaning, suspension on a net bed or a Balkan frame, a well fitted Thomas splint, and early movements of the knee. The evolution of technique for dealing with penetrating wounds of joints was equally striking. In 1918 it was not uncommon to regain a full or almost full range of joint mobility.

trating wounds of joints was equally striking. In 1918 it was not uncommon to regain a full or almost full range of joint mobility.

A CLINICAL meeting of the Psycho-Neurological Society was held at Lancaster Gate, W., on April 22nd, with Dr. H. E. DAVISON in the chair. The following cases were demonstrated:—Dr. C. WORSTER-DROUGHT: (1) Case of concussion of the spinal cord in the cervical region with Brown-Séquard syndrome and injury to the sixth and seventh left cervical nerve roots. (2) Case of fracture-dislocation of the spine in the lower dorsal region, with partial Brown-Séquard syndrome. (3) Case of proximal myopathy (Landonzy-Dejerine type). (4) Case of aphasia, agraphia, and alexia, with right homonymous hemianopia, in a man aged 30. (5) Case of early tabes dorsalis, with double intention tremor. Dr. DANVERS-ATKINSON: Case of myotonia congenita. Dr. P. BOUSFIELD: Case of motor aphasia and agraphia, due to cerebral haemorrhage, in a young man.

Rebicus.

TWO TYPES OF SMALL-POX.

THE reappearance in this country of fatal small pox and the outbreaks of "alastrim" which attracted attention in East Anglia give special interest to the hypothesis developed by Dr. JOHN McVAIL in his Milroy lectures of 1919, reported in our columns at the time. He has now published them in a volume¹ which many will desire to keep on their shelves, for Dr. McVail raised a general question of great significance. He pointed out that in the pre-statistical period the fatality of small-pox varied greatly in different epidemics, and quoted statistics showing that between 1870 and 1895 the fatality declined; the London rate in 1893-94 was less than half that of 1870-72. This decline continued in the provinces, and was noted in the prevalences of the years 1902-5; but in London the fatality rate (Metropolitan Asylums Board hospitals) was much higher in the epidemic of 1901-2 than it had been ten years earlier. In seeking for an explanation of the difference in severity of the types prevalent almost contemporaneously in London and the provinces Dr. McVail utilized the valuable statistics published by the Local Government Board (Dr. Bruce Low) proving the high malignancy of the form of small-pox, which seems to have invaded France in 1900-3 from North Africa, and the evidence of Sir Shirley Murphy that the disease was introduced into London from Paris. On the other hand, the mildness of small-pox in America, and its undoubted introduction into Nottingham from Salt Lake City, to which Dr. Boobbyer called attention in this JOURNAL in 1901, afford an explanation of the provincial experience. Dr. McVail adduces other evidence to the same effect, such as that of the late Dr. Franklin Parsons, who described two outbreaks in one town—an outbreak of a mild type traceable to America and an outbreak of a severe type which came from Paris by way of London.

That we are dealing with types of the same disease, not with a distinction analogous to that between typhoid and paratyphoid, is shown by the fact that vaccination confers protection equally against the mild and severe forms.

Dr. McVail left open the question as to the factors causing the difference. Variations of virulence in zymoties, uncomplicated by the artificial immunization of a community, are well known; the most familiar example is that of scarlet fever. In this latter case the decline of fatality has been general, and might therefore be deemed a secular phenomenon. The instance of small-pox is of special interest because of the coexistence of the types. Are we to explain the greater severity of the African form in terms of local conditions operating upon the human population, or is it a resultant of something directly modifying the *materies morbi*? This is a subject which, as Dr. McVail remarks, needs special research. It would be rash to hazard any opinion, but, if the cause of

¹Half a Century of Small-pox and Vaccination. By John C. McVail, M.D., LL.D. Edinburgh: E. and S. Livingstone. 1919. (Demy 8vo, pp. viii+86. 5s. 6d. net.)

differentiation is a lowered state of bodily resistance, then the appalling conditions now prevailing in large tracts of Europe give grounds for the apprehension that it is not typhus only that will have to be reckoned with in the near future.

RENAL SECRETION AND NEPHRITIS.

THE secretory activity of the kidneys has long been a matter of great interest to physiologists, the more so because the renal secreting cell and its working have often served as the field where philosophical mechanists and vitalists have met in battle. A fairly recent work (see BRITISH MEDICAL JOURNAL, 1917, ii, 620), by Professor CUSHNY, dealing with the secretion of urine, sets out the view that the renal cells in part enjoy the power of active rather than passive secretory activity. A similar conclusion must be reached after perusal of Professor AMBARD'S treatise on the normal and pathological physiology of the kidneys,² although no definite statement on the subject seems to be made in its pages.

In the first half of the book he deals with the physiology of the kidney; the renal elimination of substances, he maintains, may take place in three distinct ways—by "effraction" (a pathological process, as when blood escapes into the renal tubules), by diffusion, and by secretion. Elimination by renal diffusion has been observed and measured in the case of methyl, ethyl, and propyl alcohols, acetone, ethyl acetate, and perhaps chloroform; in other words, these substances escape from the circulating blood into the urine by the mere physical process of diffusion, for their concentration in the two fluids at any given moment is always found to be the same. Elimination by renal secretion implies the collection of some substance from the blood and its concentration in the urine, and is the way in which the kidney most commonly works. Emphasis is laid on the fact that it is able to concentrate all such substances to one and the same isotonic level of concentration, and that this concentration can be shown experimentally to have a maximum value for each which is independent of the presence of other substances that are being excreted in the urine—a relation comparable to Dalton's law of partial pressures in gaseous mixtures. Some of these substances—the chlorine ion and certain salts, glucose, glycerin, and water, for example—are described as "substances with a threshold"; others, like urea, ammonia, iodides, sulphates, methylene blue, and phenol sulphone-phthalein, are "substances without a threshold," for their excretion takes place whatever their concentration in the blood stream may be, and is not postponed until this concentration has reached a certain limiting value or "threshold." Compounds with a "threshold" are in general useful to the organism; those without it are of no value to the living cells. Such "thresholds" have very different values for different substances, and have levels variable under changed conditions for any one substance.

The second half of the volume deals with the physiology of the kidneys in different forms of nephritis, and will be found of particular interest to physicians, though less interesting, or even discouraging, to the pathologist. Professor Ambard rejects all histological or pathological classifications of the various types of nephritis as unsatisfactory, offering in their place a classification based on the functional efficiency of the diseased kidneys. Vidal speaks of "nephritis with excess of chlorides in the blood," or "with excess of nitrogen in the blood" (azotaemia), or "with hypertension," combining these characteristics if need be. Professor Ambard considers only "nephritis with oedema" and "nephritis with azotaemia." As in the first half of the book, his method is mainly concerned with experimental investigation, and he gives many pages of experimental results and calculations exhibiting different phases of renal activity in patients with nephritis. In nephritis with oedema he finds that substances without a threshold are eliminated with normal constants, but slowly; while in the case of those with a threshold the value of the threshold is raised. With nephritis of azotaemic type the action of the kidneys is highly unsatis-

factory, though the thresholds are not raised, but are actually lowered. In mixed nephritis, or nephritis with both oedema and azotaemia, there appears to be a special failure to excrete water. Full directions for the experimental recognition of these three types of nephritis are given, and chapters are devoted to their symptomatology and prognosis. The value and limitations of the lacto-vegetarian diet in nephritis are discussed, and a somewhat half-hearted approval is given to the practical methylene blue test of renal activity.

The book is clearly written and well documented, and affords the careful reader much food for physiological and clinical reflection. It is of particular interest to notice that Professor Ambard writes from Strasbourg University, which was reopened to French students under French direction once again in January, 1919.

DIFFICULT LABOUR.

FOR any one other than its original author to revise an admitted medical classic such as *Herman's Difficult Labour*³ may appear to some to savour of an attempt "to gild refined gold, to paint the lily." And in the case of a writer whose work bears so strongly the stamp of individuality, both in its substance and in its method of presentation, the difficulties of the reviser must have been extreme. But if a classic, Herman's work is a modern classic, and it is also a very practical working handbook, so that, far from committing a sacrilege, Mr. CARLTON OLDFIELD and the publishers have done the profession a distinct service in bringing the book up to date. It would have been regrettable if by the neglect of modern advances in obstetric treatment the advice of this friend in need to many a practitioner had been allowed to become of less value.

Mr. Oldfield has very wisely abstained as far as possible from making textual alterations, and such as he has made consist for the most part of the deletion of matter which has become obsolete, and the addition of new. The latter deals mainly with treatment, and in particular with the widening indications for Caesarean section in contracted pelvis and in ante-partum haemorrhage. Several excellent figures have been added also. Distinctly modern notes are struck in the description of the treatment of rupture of the uterine, in which the use of Carrel's tubes is advocated, and in the reference to such a transient cause of accidental haemorrhage—or so one would hope—as T.N.T. poisoning. But these are merely minor criticisms.

The substance of the book is so well known as to need no discussion here. Suffice it that the work of revision seems to have been both skilfully and delicately done. The temptation to add too much recent matter, some of which has perhaps not yet fully emerged from the zone of controversy, must have been hard to resist, but Mr. Oldfield has kept ever clearly before him the special nature of the material upon which he was working, and has performed his task with praiseworthy conservatism and discretion.

A TEXTBOOK OF OPHTHALMIC OPERATIONS.

THIRTEEN years have passed since the issue of the first edition of GRIMSDALE and BREWERTON'S *Textbook of Ophthalmic Operations*.⁴ During this time the operative treatment of glaucoma has undergone important modifications, and for this reason, if for no other, we welcome the appearance of the second edition, which contains about 100 more pages than its predecessor; the use of a slightly thinner paper has prevented any material increase in its bulk.

New chapters have been added on diseases of the conjunctiva and on intraocular and intraorbital foreign bodies, while the chapter on glaucoma has been rewritten; the general plan of the work, however, remains the same, the authors' object being to give the reader an outline of the operations which can be performed for any particular condition, so that he may make his own choice and adapt them to his own needs.

Although the chapter on the conjunctiva is new, its

³ *Herman's Difficult Labour*. Revised and enlarged by Carlton Oldfield. M.D. Lond., F.R.C.S. Eng. London: Cassell and Co., Ltd. 1920. (Cr. 8vo, pp. xii + 573; 198 figures, 16s. net.)

⁴ *A Textbook of Ophthalmic Operations*. By Harold B. Grimsdale, M.B., F.R.C.S., and E. Brewerton, F.R.C.S. Second edition. London: Baillière, Tindall, and Cox. 1920. (Demy 8vo, pp. viii + 438; 129 figures, 18s. net.)

² *Physiologie normale et pathologique des reins*. Par L. Ambard, Ancien Chef du Laboratoire de Chimie, de la Clinique des Maladies des voies urinaires à l'Hôpital Necker. Professeur à la Faculté de Strasbourg. Deuxième édition. Paris: Masson et Cie. 1920. (Roy. 8vo, pp. 268; 43 figures. Fr. 18 net.)

contents were for the most part contained in the first edition, arranged under the section on the lids; the new arrangement is certainly an improvement.

This work, the only one of its kind on this special subject in our language, is a most valuable one, and reflects the greatest credit on its authors. No ophthalmic surgeon in this country can, we are confident, afford to be without it. The illustrations are largely diagrammatic, the authors holding that a good diagram is preferable to photographic representation of an ophthalmic operation, an opinion which will be shared by most ophthalmic surgeons. A word of praise is due for the very complete index.

HOUSE-FLIES.

THE latest number of the Economic Series of pamphlets published by the Natural History Museum is entitled *The House-fly: its Life-History and Practical Measures for its Suppression*.⁵ Like the previous pamphlet of the same series on *The House-fly as a Danger to Health*, it is from the pen of Major E. E. AUSTEN, D.S.O., Assistant in the Department of Entomology. The objects of both publications are much the same; but Major Austen here draws on his experience on three fronts during the late war, and takes into consideration the requirements of the army as well as of the civil population. He gives a clear account of the distinctive characteristics of the house-fly and of certain other flies often mistaken for it, and then narrates the life-history of the house-fly. The question, What becomes of the house-fly in winter in the British Isles and North America? still remains unanswered, for the French naturalist's announcement at the end of last year that he had discovered house fly larvae in live snails in winter has not yet been confirmed in England.

In the section on house-flies and disease Major Austen sets out lucidly the reasons for regarding these insects as a serious menace to health. "There can be no doubt whatever," he adds, "that it is by far the most important of British insects from the standpoint of public hygiene. . . . It is therefore the bounden duty of everyone, by the employment of all possible means, to assist in protecting the community from the perils inseparable from the presence of these living vehicles of infection." Regarding preventive measures and remedies, he lays down two rules of universal application:

1. It is far better to prevent house-flies from breeding than to permit them to breed unchecked, and then endeavour to kill the resultant broods after they have invaded houses or other habitations.

2. No system of sanitary control can be regarded as efficient which allows house-flies to have access to material containing, or possibly containing, the germs of disease.

Before giving an outline of the most practical methods of checking the breeding of house-flies in horse-manure, household or kitchen refuse, and human faeces, he states emphatically that chloride of lime is utterly useless in any material whatever. The pamphlet closes with a short account of the best methods of dealing with flies which develop in spite of all precautions, or which negligence or ignorance have allowed to come into being. Of these methods preference appears to be given to formalin, and it seems worth while to note the author's statement that in the hygienic department of the Royal Army Medical College, Millbank, it was found that a solution of formalin in water soon becomes acid and consequently unattractive to flies. The best way of using formalin is stated to be to mix two teaspoonfuls of commercial formalin (40 per cent.), two heaped tablespoonfuls of sugar, and lime-water to make a pint. This mixture can either be exposed in soup plates having in the centre of each a cube of bread on which the insects may settle, or on pads of lint or cotton-wool in shallow trays, or it may be placed in closed tins with perforated lids through which are passed wicks having their lower end dipping into the fluid. It is stated that the formalin generally works best in the early morning, when, in kitchens, dining-rooms and offices, it is possible to ensure that no other source of refreshment is accessible to the flies.

⁵ *The House-fly: its Life-History and Practical Measures for its Suppression*. By Major E. E. Austen, D.S.O. British Museum (Natural History) Economic Series, No. 1A. Sold at the British Museum, and by B. Quaritch, Ltd., and Dulau and Co., Ltd. (Demy 8vo, pp. 52; 11 figures. 1s. 6d. net.)

The illustrative plates and figures in the text are clear and helpful, and Major Austen and the trustees of the British Museum deserve the thanks of the community for producing this useful little work in time for its lessons to be applied during the coming summer.

NOTES ON BOOKS.

Legal Chemistry and Scientific Criminal Investigation,⁶ by Mr. LUCAS of Cairo, is a book dealing with work in Egypt and the East, and consists of notes on all sorts of questions arising in the course of criminal investigations in which a knowledge of chemistry may prove of service in the tracking of crime and the administration of justice. The chemical expert must have a detailed and various knowledge of materials of every kind—alcoholic beverages, antiquities, blood stains, building materials, bullets, clothing, counterfeit coin, crops, documents, dust and dirt, and so on through the alphabet. A great deal of useful information and detailed advice will be found on the chemical, medical, and legal bearings of all these matters. The book should be of great service to coroners, medical experts, and chemists who deal with the detection of crime, particularly if their work lies in the East.

In the volume *Child Welfare*,⁷ in which Dr. SIM WALLACE has collected a number of essays most of which have been previously published in medical or dental journals, he claims to set forth the modern views with regard to oral hygiene. In the first chapter, on prophylaxis at different ages, he emphasizes the following points: (1) Mouth-breathing must not be induced by allowing the infant to breathe unduly cold and damp air. On this account the practice of allowing the infant to sleep in an unwarmed room with the windows open is strongly condemned. (2) Gnawing must not be prevented by withholding suitable articles, or, later, foods which may be gnawed and sucked. (3) Cleanliness of the food must be secured, otherwise unhygienic states of the mouth and alimentary canal are likely to be produced and the nutrition of the infant interfered with. In a chapter on the principles of dietetics he insists on the importance of the meals being of such a nature that they will leave the mouth physiologically clean. Such forms of food as jam rolls, bread and marmalade, are to be condemned as the last course of a meal, their effect being the opposite of fruit, which leaves the mouth in a hygienic state. In discussing the duty of the State towards the child, it is urged that oral hygiene should be regarded as a vital part of the curriculum for a diploma in public health or state medicine. Dr. Sim Wallace's book, if at times too diffuse and polemical, may nevertheless be recommended to those who are interested in child welfare and dietetics.

When lecturing on sanitation in Macedonia during the war to the officers of his battalion, Captain P. WOOD was struck by the importance of *Moses, the Founder of Preventive Medicine*,⁸ which is the title of a well written little volume published by the Society for Promoting Christian Knowledge. He finds that scattered through the Mosaic code there are many fragments which, when gathered together, form a fairly complete system of preventive medicine, which was lost sight of for thousands of years and has suffered the fate of anachronisms by not being understood. In an introductory chapter the training of Moses is described; the ten plagues of Egypt are then shown to provide useful lessons on defective sanitation and an introduction to the succeeding chapters on hygienic legislation, the control of infectious diseases, and diet. In connexion with the credit ascribed to Moses, the more modern views as to authorship of the Pentateuch, or the first five books of the Old Testament, traditionally considered to be written by Moses, should be borne in mind; for though Moses gave certain laws to the Israelites, it is highly uncritical to regard him as responsible for all the laws: it has been shown that some of them cannot be earlier than 440 B.C., or about 800 years after Moses.

⁶ *Legal Chemistry and Scientific Criminal Investigation*. By A. Lucas, F.I.C., Director Government Analytical Laboratory and Assay Office, Cairo, etc. London: Edward Arnold, 1920. (Demy 8vo, pp. viii + 181. 10s. 6d. net.)

⁷ *Child Welfare and the Teachings of Certain Dentists, School Medical Officers, Medical Officers of Health, and other Medical Men*. By J. Sim Wallace, D.Sc., M.D., L.D.S. London: Baillière, Tindall, and Cox, 1919. (Demy 8vo, pp. x + 102. 5s. net.)

⁸ *Moses, the Founder of Preventive Medicine*. By Percival Wood, M.R.C.S., L.R.C.P., Captain R.A.M.C. London: Society for Promoting Christian Knowledge, 1910. (Cr. 8vo, pp. xi + 116. 4s. net.)

UNIVERSITY GRANTS.

THE total estimate for parliamentary grants in aid of the expenses of universities, colleges, medical schools, etc., in the United Kingdom for the year 1920-21 is £1,000,000, an amount which includes unallocated grants amounting to £210,500; the amount unallocated compares with £531,500 unallocated in 1919-20.

The following are the amounts of the grants made: the first column shows the amounts, if any, last year and the second column the amounts this year:

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on April 13th, 27 cases were considered and £374 9s. voted to 24 of the applicants. The following is a summary of some of the cases relieved:

Widow, aged 34, of M.B. Edin. who died in December, 1919. Her only income is £30 from investments, and she has a child aged 4 months, which at present she cannot leave to earn her own living. Pays £2 2s. a week for board and lodging. Voted £18 in two instalments.

Widow, aged 38, of M.R.C.S. Eng. who died in February, 1920. Was left with four children, aged 4 to 1 year, and has no income whatever. At present the guardians are allowing her to live in the resident medical officer's house, where she lived previously. Voted £18 in two instalments.

Daughter, aged 60, of M.R.C.S. Eng. who died in 1873. She has no income, and lives with her sister, who lets rooms. Suffers from chronic rheumatism. Relieved thirty-five times, £290. Voted £18 in twelve instalments.

Daughter, aged 58, of M.R.C.S. Eng. who died in 1892. Was left totally unprovided for, and her only income is £21 from another charity. Pays 7s. 6d. a week rent. Is in ill health and cannot manage owing to the high cost of living. Relieved nine times, £117. Voted £18 in twelve instalments.

Widow, aged 58, of M.R.C.S. Eng. who died in 1914. Was left entirely without means, with one daughter, now aged 26, who is a children's nurse. Applicant has been earning £33 a year as a housekeeper, but is now ill and out of employment. Relieved seven times, £61. Voted £18 in twelve instalments.

M.R.C.S. Eng., aged 83, widower, whose only income is a pension of £100. Suffers from ill health. Has one daughter, who looks after him. Rent and rates £39, part of which is paid by friends. Relieved once, £25. Voted £26 in twelve instalments.

Daughter, aged 52, of M.R.C.S. Eng. who died in 1873. Has taken charge of a mental case for fourteen years, for which she receives £1 a week. Rent and rates £16 a year. The high cost of living makes it impossible for her to manage. Relieved eight times, £93. Voted £18 in twelve instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at II, Chandos Street, Cavendish Square, London, W. 1.

The Royal Medical Benevolent Fund Guild is overwhelmed, in these days of exorbitant prices for clothing and household necessaries, with applications for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles for the benefit of the widows and children who, in happier times, would not have needed assistance. The gifts should be sent to the Secretary of the Guild, 43, Bolsover Street, W. 1.

MEDICAL EXAMINATION OF CIVILIAN AVIATORS.

THE Department of Civil Aviation of the Air Ministry has issued a pamphlet on the medical examination of airmen, prepared by Lieut.-Colonel C. B. Heald, C.B.E., medical adviser to the department. It is described as an explanation of the methods and standards now in use in England for the examination of applicants for licences as civilian aviators.

The international medical requirements for air navigation, as laid down by the Convention relating to International Air Navigation, 1919, are indicated. The standard of fitness is prescribed by the Convention in general terms: one clause states that "Each contracting State shall for the present fix its own method of examination until the detail of tests and the minimum standard of requirements have been finally settled by the authorized medical representatives of the International Commission for Air Navigation." Re-examination is required at least every six months and after sickness or accident.

In the introduction to the pamphlet it is stated that the accurate estimation of physical and mental efficiency as regards flying is in its infancy, and that while the pamphlet is intended to serve as a general guide, the final word must be left to medical judgement and common sense.

In describing the methods of examination concise guidance is given as to the important matters of family and personal history, and the particular diseases and injuries to which special attention should be paid are set out. The notes on the rest of the examination are classified under "General Medical," "General Surgical," with special sections on the investigation of the condition of eyes, ears, nose, and the throat. A specimen form for recording the results of the examination is given, and a list of the apparatus required is illustrated by photographs and drawings. Finally, there is a list of references to British, American, French, and Italian publications.

The arrangement of the pamphlet is excellent, and, while the amount of information given might easily fill a book three or four times as large, the subject matter has, on the whole, been expressed so clearly and concisely that examining medical officers should find the explanations quite sufficient for practical guidance.

The general impression conveyed is that the examination of the civil aviator is divided into two parts—one a careful general surgical and medical "overhaul," and the other the application of special flying tests. Great stress is laid on the point that these special tests are merely

*The Medical Examination of Civilian Pilots, Navigators, and Engineers. H.M. Stationery Office. Through any bookseller, price 6d.

adjuncts to the general clinical and temperamental examinations. This attitude is much to be commended in view of the short time many of these special tests have been in use and the consequent lack of experience of their true value. At the same time, in a summary of the general examination, it is stated that the special tests have been so consistently satisfactory that high minimum responses can be safely demanded. A short table is given of minimum standards for some of the special tests. Among these is a test for "expiratory force," as shown by readings on a U tube manometer, and it is stated that when the expiratory force is under 80 mm. of Hg "it suggests that the subject will probably be incapable of sustained effort in routine aerial work." It is difficult to imagine exactly what this test is intended to represent. An expiratory force of 80 mm. Hg is extremely low and the subject would probably be rejected on more obvious grounds.

It is interesting to note that the methods of body measurements advocated by Professor Dreyer have been adopted. They are likely to prove of great value, not only as representing the actual state of fitness of the subject at the moment, but as providing coefficients, deviation from which at subsequent examinations will at once draw attention to improved or impaired condition.

During the war it was recognized in this country that experience and ability in various forms of sport were valuable to the flying man. With reference to special mental tests such as reaction-time tests, to which the Italians and others have paid special attention, the following sentence is deserving of quotation: "The British have not adopted these special tests to any large extent, because they have felt that a history of aptitude at various sports requiring eye is of equal value, as compared with a somewhat elaborate experiment carried out on a special occasion under circumstances frequently trying to the applicant." This attitude is extremely wise in that it encourages a careful weighing up of the aviator's temperament, and recognizes the value of his previous training and education. Psychological tests as applied to the aviator are so much in their infancy that at present they should be left rather to the laboratory than to the examining medical officer. There is little doubt, however, that electrically recorded psychological tests will before long be included in the examination of the civil aviator.

For practical purposes this medical examination is long and elaborate, yet the data to be acquired by such an examination will be of the greatest value from the research point of view.

The Civil Aviation Branch of the Air Ministry is to be congratulated on a medical service which can produce so excellent a guide to the medical examination of civilian aviators; it may well serve as a model when the international tests are decided on by the medical representatives of the International Commission for Air Navigation.

THE BUDGET.

MR. AUSTEN CHAMBERLAIN, in his Budget speech, pointed out that in general the position with regard to the past year's accounts was substantially better than had been suggested in his forecast last October. For instance, customs and excise gave an increase of £7,000,000 over what was then anticipated, and he drew the conclusion that, in the case of tea and tobacco at least, "it reflected an increased consumption and therefore an increased spending power in the mass of our people"—a conclusion not without interest in these days of rising wages. Incidentally he also attributed the increased yield of the tobacco duties in part to "the growth of the habit of smoking among women." The figures for the total debt were sufficiently alarming; the total dead-weight debt he put at £7,835,000,000, the floating debt being £1,312,205,000; the latter had been reduced by £100,000,000 during 1919-20, though the month of April was disappointing in that connexion. The Chancellor announced that the Government had decided that in future there should be no more borrowings to balance revenue and expenditure, but as further capital would still be required for local and national purposes the issue of Savings Certificates would be continued, and it was hoped that this would foster a spirit of thrift. The existing taxes apart from the new proposals were estimated to produce a revenue of £1,341,650,000, against an expendi-

ture of £1,177,452,000, and would leave £164,000,000 for the reduction of debt; but the Government did not consider that sufficient, and he proposed further taxation, the result of which would be to produce a surplus of £234,193,000 for that purpose.

Mr. Austen Chamberlain stated that the amount of the anticipated surplus was such that its maintenance for twenty years would pay off the whole war debt, but added later that he did not contemplate that the country would continue to make the abnormal sacrifices that such a course would necessitate.

The proposals taken in detail provide for the following new or additional duties, in addition to the changes in motor taxation which were fully stated in our last issue:

The *Land Values Duties* are to be repealed, but the existing staff will apparently be retained for other purposes, such as for rating or death duty valuations.

Spirits and Beer and Wines.—On spirits the duties are increased from 50s. to 72s. 6d. the proof gallon and on beer from 70s. to 100s. the standard barrel respectively, the retail prices to be fixed by the Food Controller in such a way as to divide the burden between the manufacturer and the retailer. The duty on wines generally is doubled, being raised for light wines from 1s. 3d. to 2s. 6d. a gallon, subject to a rebate of 40 per cent. from countries entitled to preferential rate. The duty on stronger wines will be raised from 3s. to 6s., with 6d. extra for every degree beyond 42°, but this is subject to a rebate of one-third for wines from countries entitled to preferential treatment. There is an additional duty on still wine imported in bottle of 2s. in place of 1s., and on sparkling wine of 5s. in place of 2s. 6d., plus 50 per cent. *ad valorem*, but these charges are subject to rebates as in the case of wine in cask.

Cigars came in for special treatment, and are to bear an additional duty—50 per cent. *ad valorem*.

Stamp Duties.—It is proposed to double the "receipts" duty and to increase the stamp duties on transfers of stocks and on the registration of new limited companies.

Post Office Charges.—Mr. Chamberlain stated that the net surplus revenue from the Post Office of £6,500,000 before the war had been converted into a deficit of £11,000,000. He proposed increased charges estimated to produce £6,500,000 this year; he stated further that proposals for the increase of telephone rates would be laid before a Select Committee, and took power to increase the rates for inland postcards (to 1½d.) and for printed papers proportionately, as soon as the international rate can be raised, the date depending upon the decision of the International Congress which is to meet in Madrid in the autumn.

Inland letter rates are to be raised to 2d. for every 3 oz., with 3d. for every additional ounce. The charge for letters to British possessions and the United States of America will be raised to 2d. for 1 oz., with 1d. for every additional ounce. The inland charge for a copy of a registered newspaper not exceeding 6 oz. in weight is 3d., it is to be raised to 1d., with, as now, 3d. for every additional 6 oz. Inland parcel rates will be raised from 6d. for 3 lb. to 9d. for 2 lb., with similar increases for heavier weights. Inland telegrams are to be increased from 9d. for twelve words, with 2d. for every additional word, to 1s. for twelve words, with 1d. for every additional word. Telegrams handed in on Sunday will be subject to an additional charge of 6d., and postage is raised from 3d. to 6d. a mile from the limit of free delivery. The charges on inland money orders and postal orders are also to be increased. Before the increases come into effect due notice will be given.

Income Tax.—The administrative questions dealt with in the Report of the Royal Commission on Income Tax are postponed for consideration later in the year, while the changes suggested in the method of graduating the tax are to be put in operation. These changes were dealt with in an article in our issue of March 27th (p. 441), and it is sufficient to say here that the earned income is reduced by 10 per cent. and the various allowances are for wife, £100, formerly £50; children, £40 and £30, in lieu of the existing £40 and £25; dependent relatives and house-keeper are deducted from the total to arrive at the "assessable" income, of which £225 is chargeable at one-half and the balance at the full standard rate of 6s. Supertax is to begin at the £2,000 limit, instead of at £2,500, and the rates are increased. Broadly, the effect will be to relieve the middle class and the taxpayer with family responsibilities. It will be realized that this very complete change in the method of steepening the effective rate of tax as the total income rises will ultimately simplify the individual taxpayer's assessments, though the transition from one method to another will inevitably cause some confusion. The three years' average basis of assessment of profits is to be retained for the present.

The *Excess Profits Duty*, which had in many quarters been regarded as marked out for extinction, is to be raised to 60 per cent. as from January 1st, 1920, with the proviso that the additional 20 per cent. may be foregone if a war levy on capital is raised.

The *Corporation Tax* is a new feature of our fiscal system, and is probably destined to supersede in due course the excess profits duty. It is to take the form of a special tax on the trade profits of limited liability companies, levied at 1s. in the £ on the company's profits, after deduction is made for any excess profits duty that may be payable. In a full year, and when unrestricted by the simultaneous operation of excess profits duty, this tax is estimated to produce £50,000,000.

British Medical Journal.

SATURDAY, MAY 1st, 1920.

THE BUDGET.

WE described the Budget of last year as a transition Budget; the present Budget is the first step in the direction of debt reduction. Last week we dealt with some of the points which most directly concern the medical profession, but it appears desirable to take a general view in order to get the various matters into proper proportion.

With regard to debt reduction it was hoped by many financial experts that the Chancellor would cease to regard the sale of stocks of munitions and similar war purchases as ordinary Exchequer receipts, and would earmark them in future for the repayment of loans with which such stocks were bought. Mr. Chamberlain justified his failure to fulfil these expectations by showing a surplus on the estimated revenue for the forthcoming year, which is to be used for payment of debt: he spoke of it as a matter of book-keeping, but the net result is that whereas the sales are expected this year to yield 202 millions, the present estimate for the redemption of debt is 234 millions.

The Chancellor's attitude on the question of the excess profits duty came as a complete surprise. The general expectation was that that duty—which was reduced under the previous Budget from 80 per cent. to 40 per cent. as from January 1st, 1919—would be completely discarded and in its place some other tax would be introduced to make good the resulting revenue deficiency in part, if not entirely. In this connexion a new tax on the business profits of limited liability companies had been thought probable, and the surmise proved correct: what was not expected, however, was that this new tax is to run concurrently with the excess profits duty: and, to the further confusion of "intelligent anticipations," that duty is not only to be maintained, but even to be increased to 60 per cent. as from January 1st, 1920, though the Chancellor did hold out some hope that the additional 20 per cent. might be foregone if a workable scheme for a capital levy on war fortunes could be evolved in time for it to be put into operation this year.

It is due to the Chancellor to say that the Budget has clearly been framed without fear either of his friends or his opponents: the outstanding need of the moment is the repayment of debt, and the proposals which have been laid before Parliament are conceived with the courage and perception of financial conditions which are essential if that need is to be met. Memories are short and commercial prosperity is periodic; the recognition of these facts has evidently braced the Chancellor, and indeed the House of Commons as a whole, to face the financial demands of the moment boldly and successfully. The magnitude of these demands are as striking as their urgency. The Budgets of to-day reach figures undreamt of by our forefathers, and we believe that the Government has correctly located the only source from which the Exchequer can draw the income necessary to put the national accounts on a better footing. Mr. Chamberlain frankly admitted that he fell into the general error in supposing that the signing of the Armistice and the consequent

suspension or cessation of munition work would usher in a not inconsiderable period of industrial and commercial difficulty before the transition to peacetime activity could be achieved; "the excess profits assessed during the year," however, "showed an upward trend," proving that the dislocation of industry was much less than had been feared. With income tax at its present levels, we have no hesitation in saying that there is only one quarter in which the Chancellor can have any hope of finding the capacity to bear the additional taxation necessary for the repayment of debt, and that is in the world of business, and more particularly in the world of "big business." That the Chancellor appreciates the truth of that reading of the position is evidenced by the maintenance or increase of the excess profits duty, coupled, as it now is, with the special tax on the business profits of limited liability companies—the Corporation Tax, as it is to be called. Whether any scheme for the special taxation of war fortunes will ever achieve fruition is open to very grave doubt, but in the meantime it is a matter for congratulation that the big burden is being placed on the broad shoulder.

There is one feature of the income tax proposals as to which we entertain a good deal of doubt, and that is as to whether the proposed rebate of 10 per cent. in favour of earned incomes is sufficient. On the 1919-20 scale the taxpayer whose total income did not exceed £1,000 received a rebate of 20 per cent., and if it did not exceed £1,500 then 17½ per cent., and so on. What is really wanted is a system under which a taxpayer's own savings should be differentiated from inherited funds: if that is impossible we are thrown back on a discrimination between earned or precarious as against unearned or investment incomes, inasmuch as the former class of income implies the duty of saving to a greater extent than the latter. It must be freely admitted that in this, as in many other fiscal questions, the interaction of other taxes must not be overlooked; the source of investment incomes ultimately bears a death duty taxation from which earnings are free, and an increase in death duties logically implies a lowering of the advantage given to them in the matter of the income tax. But that notwithstanding, it is only to be supposed that many "earners" will feel some sense of grievance in seeing their differential advantage reduced from 20 per cent. or 17½ per cent. to 10 per cent.

Another additional charge levied in the form of increased duties on the transfer of stocks and shares will affect many medical men, more particularly, perhaps, those who are making provision for their dependants by accumulating and investing such savings as may be possible under present conditions of expenditure. The duties, even on their revised basis, would be small as compared with the amount of capital invested, so that their deterrent effect would probably not be great in the case of genuine investment, but might come into operation where shares are bought and sold with any degree of frequency. It is to be hoped that the Chancellor is not relying too much on this aspect of the matter to justify the increased levy. The existing taxes are already sufficient to discourage saving in many cases, and any further deterrent, however slight, may operate in such circumstances with surprising results.

We referred last week to the new motor-car taxation to be put into force at the beginning of 1921, and pointed out that in this matter the medical profession is being harshly treated. The profession need feel no false modesty in pressing its claim to fair treatment, for its patriotism is indubitable and the weight of

taxation is such that no addition to its due proportion can be carried without great hardship. It is proposed to put the new motor tax into operation as from January 1st, 1921. The proposals differentiate between different kinds of vehicles, the classifications being framed so as to give preferential treatment on the basis of units of weight to, *inter alia*, "vehicles used for the conveyance of goods," and the White Paper states "the abatement of duty granted in the case of motor cars used by medical practitioners or veterinary surgeons will cease." The legislature has repeatedly admitted that such cars are in a different position from cars used for pleasure, and we find it hard to believe that it will now reverse that view. We submit that, if the intention is that the tax should ultimately be borne by the practitioner, it is unfair; and if it is to be borne by his patient, through the operation of increased fees, it is clumsy; and, further, that any fiscal impediment to the purchase of the speediest means of locomotion is in the case of a medical practitioner impolitic on public grounds. We suggest very strongly that equity demands the grant of some substantial rebate from the proposed tax on the lines of that granted in the tax which it is to supersede. The steps already taken by the British Medical Association were stated last week (p. 576), and the Association's further action is recorded in a Current Note in the SUPPLEMENT this week.

An aspect of the national finances that is rightly receiving attention is the cause of the national expenditure, as well as the methods by which it is to be met. It must be admitted that in this connexion the Chancellor's position is extremely difficult. When the sums to be raised by taxation were smaller, and taxation was less intricate and burdensome, he might reasonably be expected to act as a watchdog to prevent the intrusion of extravagance; to-day the dual rôle is perhaps more than any one man can fill, for economy in expenditure can be effected only by close and almost daily criticism of the proposals, not only of members in the House of Commons, but also of the State departments, and even then that criticism must be backed by detailed knowledge and a power of veto that no single individual would desire to possess or be able to exercise properly. A committee system in the all-important field of finance is not congenial to the British genius, but we seem to be approaching a point at which that will have to be tried if the present system fails to retain public confidence in its power to achieve a proper standard of economy in administration.

THE DECLINING BIRTH RATE.

We publish elsewhere a summary of the paper read to the Royal Statistical Society on April 20th by Dr. T. H. C. Stevenson, Superintendent of Statistics in the General Register Office. The most striking result brought out by the tabulation of the census returns is the decline of fertility in the middle and upper classes. In Dr. Stevenson's words: "We were already well aware that the more successful and prosperous classes were behindhand in their contribution to the upkeep of the nation; but it was possible to suppose that this might long have been the case, and that, therefore, experience had proved it to be compatible with such prosperity and advancement as had been achieved. Now, however, this comforting view is no longer tenable. In the deficient fertility of the classes which, having achieved most success in life, are presumably best endowed with the qualifications for its achievement, we see that we have to face a new and formidable fact—how formidable is a question which

must be left for the consideration of authorities on eugenics."

It is not unnatural that Dr. Stevenson, the custodian of our national statistics, should deem a proposition unproven until it has been put to the test of census machinery. For ourselves, we should prefer to speak of his results as a verification of what Professor Karl Pearson and his pupils, particularly Dr. David Heron, had rendered highly probable more than ten years ago. Much as we are indebted to official vital statisticians in connexion with this subject, our debt to the late Sir Francis Galton and to his most brilliant disciple, Professor Karl Pearson, is far greater. To Professor Pearson we owe both the best means of making statistical discoveries, and discoveries themselves which the fuller records of the national census confirm. Most can raise the flower now for all have got the seed; the smart of wounds received in ephemeral controversies—and medical men have not come within range of the biometric artillery without some injury—ought not to diminish our gratitude to the Galton Professor of National Eugenics, or to prevent us from congratulating him on the official adhesion to his main doctrine which such words as those of Dr. Stevenson convey.

Are we to infer from these results that, unless the middle and upper classes can be induced to make a larger proportional contribution to the rising generation, national decay is certain? Upon this there is room for difference of opinion. We should suppose that, if prosperity depends upon fulfilment of the proviso, the future is gloomy. Financial encouragements of parenthood amongst the middle and upper classes so large as to be calculated to have a sensible influence are not very likely to find favour in any form of state now existing. Most of the detailed proposals we have seen bear a strong family resemblance to the advice tendered annually to the Chancellor of the Exchequer in the matter of taxing cats; again, historians tell us that the *Jus trium liberorum* never had the desired effect. On the other hand, while it does seem probable that the absolute fecundity of the very poor and miserable can and will be reduced, there are likely to remain vast numbers of persons who will not place even the restraint upon their sexual impulses which the use of contraceptives involves.

Perhaps a gleam of hope is afforded by the consideration that social selection is not infallible, and that the fittest may not be the best. The obvious argument is that nearly all persons struggle to pass out of the social group in which they are born, that those who succeed are the best members of their class, usually also the least fertile, and that on attaining promotion their fertility is still further reduced. It is, however, possible that there is a flaw in the reasoning. It may be that those who are socially and economically failures, inasmuch as they do not secure class promotion, may be, intellectually and morally, better citizens than the successes. Within the circle of middle and upper class occupations there is not a perfect correlation between the social or economic prestige of a profession and the average intellectual endowments of its members. Perhaps the qualities which lead to effective greatness in the world are much more specialized than has been assumed, and comfort may be drawn from *The Admirable Crichton* of Sir J. M. Barrie.

It is at least certain that, during the war, capacity for social service was discovered in unexpected quarters. But even if this be admitted, it only amounts to saying that disaster is not so imminent as

an extreme pessimist would suppose. If any criterion of success—the imperfect one of worldly prosperity, which we now employ, or some better one yet to be devised—is in practice always correlated with relative sterility, ultimate national decadence would seem to be assured.

SECTIONS AT THE CAMBRIDGE MEETING.

ARRANGEMENTS have now been made for the discussions and demonstrations in the Section of Venereal Diseases at the annual meeting of the British Medical Association at Cambridge this summer. This Section will meet on Thursday, July 1st, under the presidency of Mr. E. B. Turner, F.R.C.S. The three morning hours will be confined to the subject of venereal diseases in women and children, and discussion will be based on two papers: (1) The treatment of venereal disease in women, by Dr. Morna Rawlins, surgeon for venereal diseases to the New Hospital for Women and gynaecologist to the Female Lock Hospital; (2) Venereal diseases in children, by Dr. Leonard Findlay, physician to the Hospital for Sick Children, Glasgow, and lecturer on diseases of infancy and childhood in the University of Glasgow. In the afternoon there will be a clinical demonstration at the Venereal Diseases Clinic, Addenbrooke's Hospital, and a laboratory demonstration, under the direction of Professor Bernard, in the medical schools. It is hoped to show models of a standard type of clinic, made from an army hut according to the design of Colonel L. W. Harrison. The honorary secretaries of the Section are Dr. W. H. Harvey and Dr. Otto May. The Section of Obstetrics and Gynaecology will meet on Wednesday, June 30th, when the main topic for discussion will be puerperal sepsis. Mr. Victor Bonney (London) will contribute the opening paper on the prevention and treatment of puerperal sepsis. Mr. H. Beckwith Whitehouse (Birmingham) will deal with the surgical treatment of the uterus in puerperal sepsis; Dr. A. E. Gow (London) with intravenous protein therapy in the treatment of puerperal septicaemia; and Dr. Leith Murray (Liverpool) with the use of serums and vaccines in puerperal sepsis. It is proposed to hold a joint session with the Electre-Therapeutics Section to discuss the treatment of fibroids by x rays. During the meeting Dr. R. Mackenzie Wallace will give a demonstration of the diastase reaction. The president of the Section is Dr. Herbert Williamson, and the secretaries are Dr. Malcolm Donaldson and Dr. W. R. Grove. Particulars regarding accommodation for visitors at Cambridge, and other matters, are printed in an inset to the SUPPLEMENT this week.

GOVERNMENT POLICY AS TO MUNICIPAL GENERAL HOSPITALS.

Our lobby correspondent writes that while Dr. Addison is unlikely to go further in statement of policy as to the establishment of municipal hospitals than he did in answer to a question by Mr. Lyle, reported in the BRITISH MEDICAL JOURNAL of April 24th, p. 583, it is understood that he intends to act fully up to what he then said. He intimated that he had given his sanction to the establishment of a municipal hospital at Bradford because it seemed to him the only practicable method of providing the institutional accommodation needed by the city, and that pending further legislation, which was now being prepared, he would consider cases on their merits as they arose. It was open to Dr. Addison to have said that for the time being he would more or less limit his sanction to the cases of localities where fresh population had accumulated and was without institutional service except at a considerable distance. Clearly, however, having made the Bradford precedent, he is prepared to consider appeals where existing accommodation in large towns is not equal to the

urgent demands of the population as a whole, and he may be willing, in such applications, to sanction the setting up of municipal hospitals, possibly to serve in a secondary capacity—that is, to relieve the voluntary hospitals of cases of minor importance which do not require their high equipment. Indeed the Medical Consultative Council is said to favour such a course, but it does not appear that sufficient information is available for this to be done on a large scale, nor does Dr. Addison wish to anticipate legislation which should be of a comprehensive character.

MAGIC AND MEDICINE.

AN address given three months ago to the British Academy is a good illustration of the application of scientific principles to historical research in medicine, of which Dr. Charles Singer of Oxford is so enthusiastic an exponent. By dint of much industry and the use of many modern mechanical devices he collects his facts, and then applies the comparative method. The subject of his address was early English magic and medicine,¹ and he explains how magical and medical practice of early England has come down, though in a fragmentary state, by two channels—manuscripts and folklore—but he relies mainly on the former. Native magic and medicine was at an early date affected by imported elements of classical, ecclesiastical, or Salernitan origin, but its four characteristic elements were the doctrines of specific venoms, of the magical quality of the number nine, of the worm as the cause of disease (in which we may see the appearance of the widely prevalent belief in the dragon), and lastly the doctrine of the elf-shot, which embodied the belief that a large amount of disease was due not to occupation by, but to the malevolent action of supernatural beings—elves, smiths, or witches—who fired shafts at the sufferer. When English magic and medicine was first influenced from the Mediterranean it was by the debased Greek or Byzantine system, a combination of at least four more or less discordant elements. First, the purely scientific medicine which took its rise from the Ionian philosophers of the seventh century B.C., and was already far advanced by the time of Hippocrates in the fifth century B.C. Secondly, the demoniac medicine inherited from Babylonia and Assyria and based on the theory that disease was due to the entry of a demon into the patient's body, and therefore to be cured by exorcism. Since it was to be assumed that what was bad for the demon must be good for the patient there arose the idea, not yet dead, that nauseous drugs were of particular value; they were intended to disgust the demon and weary him of his habitation in the patient's body. The third element was magic, founded on a primitive unorganized belief as to the relation of cause and effect; the fourth element was common sense or empirical knowledge. Nordic medicine does not seem to have suffered from the demoniac idea; Anglo-Saxon magical processes were designed to remove the *materies morbi* projected into the body of the patient by supernatural beings; they were formulae for the extraction of the elf-shot. In the later part of his address Dr. Singer dealt with the lessons to be learnt from a careful study of manuscript herbals. The earliest showed Mediterranean influences, the figures being, in part at least, copied, for some of them can be identified as Mediterranean species unknown in this country. But the object of a herbal was mainly utilitarian, since it was designed to enable the herb gatherer to recognize the plant; consequently conventions were thrown off, and a herbal prepared at St. Albans about 1120 contains good drawings of native plants made from actual living models. Later the correct English style was swamped by Norman influences, and the true drawings were replaced by gorgeous, elaborate, and beautifully painted plant designs, excellent as decorations, but bearing little resemblance to nature. The

¹ It has been reprinted in a pamphlet, price 4s. net, by the Oxford University Press.

pamphlet is interesting in itself, but of more interest for the scientific method it illustrates. Dr. Singer, we believe, has the ambition to write a history of science, and we may note that at 5.30 p.m. on May 12th he is to give a lecture on Greek Science and Modern Science, a Comparison and a Contrast, at University College, London.

TRIFLING WITH SYPHILIS.

WE have received a pamphlet, "Venereal diseases and their treatment: how not to do it," published by the National Association of Medical Herbalists of Great Britain, Limited. It appears that this association was founded in 1864 and incorporated in 1895. One of its objects is "the diffusion of a knowledge of the therapeutic properties of plants." We shall not quarrel with it over that. We are all of us herbalists; we all make use of the therapeutic properties of plants. The only question is, What is the value of herbs for the treatment of the venereal diseases? We are all for "non-poisonous drugs" if only they will act. We can feel ourselves in touch with Friar Laurence moralizing over his herbs:

Many for many virtues excellent,
None but for some, and yet all different.

Our only desire is to do the right thing for our patients. How would Friar Laurence have treated syphilis? What, for example, is the value—the real, ascertained, measured, proven value—of sarsaparilla? A medical herbalist was among the witnesses before the Royal Commission on Venereal Diseases, 1913: his evidence had a touch of Friar Laurence's vague hopefulness, but none of his poetry. The pamphlet is anonymous. It appeals, with some cleverness, to the distrust and the dislike of "orthodox medicine," which are to be found, here and there, among all classes of the community. Some of us are hardly conscious of the existence of this antipathy against our profession; or are content, offhand, to reckon those who are possessed of it as cranks, or as "anti's." But there it is: and this pamphlet is a good instance of it. The writer of it begins, as we should expect, with a reference to some old errors which were "orthodox" enough, more's the pity, once upon a time: John Hunter's mistaken experiment on himself in 1767; Ricord's false notion of gonorrhoea as a non-specific infection—Ricord was a man with a rather nasty mind—and the excessive use of mercury to salivation, and so forth. It seems that any old stick will do to beat us with. Next, the writer comes to the Royal Commission of 1913, with its approval of "the mineral poison treatment" and of "the essential quackery of orthodox claims." *Essential* is good. He thinks that he has discovered the Society for the Prevention of Venereal Disease in a violation of Section 2 of the Venereal Diseases Act, which forbids advertisements of drugs to be used externally or internally as medicines for the prevention, cure, or relief of venereal disease; but, apart from any question as to the interpretation of the words of the section, he has forgotten the proviso which permits advertisement, notification or announcement, or recommendation, published by any public authority or with the sanction of the Local Government Board in England and Wales, Scotland, or Ireland. Finally, he comes to "the modern orthodox treatment of syphilis." He has put together, in the usual paste-and-scissors way, certain statements against salvarsan and the like drugs. As we all know, they are not drugs to play with; but neither is syphilis a disease to play with. He gives a strange twist to an offhand remark by one of the witnesses before the Royal Commission that the venereal diseases are "primarily filthy diseases." For he uses it as an argument that "a hygienic treatment of syphilis and gonorrhoea, supplemented by non-poisonous herbal medication, may well be superior to all other forms of treatment." By hygiene he means attention to the general health; but that is part of the "orthodox" treatment. He says that if he published the praises of his herbs he might be prosecuted under the

Venereal Diseases Act. Is there no escape from this lame and impotent conclusion? Surely he could find one if he would try hard enough.

UNIVERSITY OF LEEDS.

THE University of Leeds is about to follow the example of the Universities of Liverpool and Manchester by making an appeal for large funds for extensions in various departments. The vice-chancellor, Sir Michael Sadler, at a meeting of the University Court last week, said that the sum of £500,000 was needed in order to enable the university to provide the education and training required by a rapidly increasing number of students, and make it possible for it to take its proper share in research and the advancement of learning. At present the university is unable to admit the large number of students qualified to take advantage of it who are seeking admission. The great majority of the applicants come from Yorkshire schools. The university needs new laboratories for teaching and research in pure and allied science, especially in chemistry, physics, engineering, leather industries, textiles, dyeing, fuel, and mining. The pro-chancellor, Mr. A. G. Lupton, said that help received from local authorities had enabled the university to become the foremost educational institution in that part of the country, and he believed that Leeds would become the greatest university in the country for applied science. Employers and manufacturers, he said, no longer hesitate to employ university trained men, and the great number of students the university now had to deal with was in a large measure the result of the commercial demand for men who had undergone a real scientific training. He added that when he was elected to the Council there were 368 regular students and 602 occasional students, a total of 970, and the fees paid by them amounted to £2,463. In 1904, when the university charter was granted, there were 1,278 students, and the fees they paid amounted to £10,319. In 1919 there were 1,750 students, and the fees received exceeded £22,000. Sir Michael Sadler said that large developments and extensions to the School of Medicine and to the School of Dentistry were needed. Another urgent requirement was a new building for the university library. The demand from all over Yorkshire for college life in association with the university was one of the most striking changes in recent university life at Leeds; the new estate at Weetwood afforded an admirable site for new halls for residents. The university needed also a new large institute as a centre of the students' corporate life and a new gymnasium, which was a necessary part of the physical education given in the university. It was right that those who could afford to pay for university education should contribute towards its cost, and great sacrifices were made by the very large majority of students and their parents, but no higher education in the world was self-supporting. It had to be remembered that above the individual interest and individual gain were the national interest and collective gain. At the same meeting the resignation of Mr. Lupton, the pro-chancellor, was received with much regret, and a resolution recording his great services to the university was unanimously adopted.

ADDITIONS TO THE FRENCH PHARMACOPOEIA.

THE last edition of the French pharmacopoeia, *Codex Medicamentarius Gallicus*, was issued in 1908. The previous edition had appeared in 1884, but a supplement was issued in 1895. A supplement to the *Codex* of 1908 has now been issued. A commission to prepare it was established in April, 1910, and it had nearly completed its task in August, 1914, when its labours were interrupted by the war. The commission was re-appointed in 1918, and the supplement came into force on April 1st, 1920. Only four new drugs are added; these are *diethylmalonylurée*, which appears in the *British Pharmacopoeia* under the name *barbitonum* (diethyl-barbituric acid), commonly

called veronal; *chlorhydrate de diméthylamino-diméthyl-éthyl-benzoyl carbinal*, or amylocaine hydrochloride, introduced as a local anaesthetic under the name *stovaine*; *hexaméthylène-tétramine*, which is in the *British Pharmacopœia* under the name hexamine; the value of this drug was first ascertained in France in 1892, when it was given the name formine; it was afterwards exploited by German manufacturers under the name urotropine; *chlorhydrate de para-aminobenzoyldiéthylaminoéthanol*, which appears in the *British Pharmacopœia* under the name novocain. The other alterations in the supplement are of minor importance; for instance, piperazin, which was inserted in the last edition under the belief that it was of value in the treatment of gout, was found inconvenient to dispense owing to the readiness with which it absorbed water and carbonic acid; it is replaced by its hydrate, which contains 44 per cent. of water. A new formula is given for a tincture of iodine which is a little weaker than the strong tincture of iodine of the *British Pharmacopœia*. A liquid extract of red cinchona bark has been introduced containing 3.5 per cent. of total alkaloids, as compared with 5 per cent. in the liquid extract of cinchona of the *British Pharmacopœia*. A solution of silver nitrate has been inserted for use as a preventive of ophthalmia neonatorum. The most interesting additions made in the supplement, however, are two serums—antidysenteric and antimeningococci. The former is directed to be the serum of horses immunized by the injection of cultures of the bacillus of Shiga. The test for it is—"one cubic centimetre of dysenteric toxin mixed with one cubic centimetre of the serum must be innocuous when administered by subcutaneous injection to a rabbit; half a cubic centimetre of the serum injected into a rabbit weighing two kilograms must preserve it against the injection of three to four cubic centimetres of a culture of dysenteric bacilli." The antimeningococcus serum is to be obtained from horses immunized by injections of meningococci. Dr. B. Lyonnet of Lyons¹ finds fault with the supplement on the ground of its omissions, particularly of a large number of drugs which are contained in the pharmaceutical formulary for military hospitals, and especially because no organic arsenic preparation for the treatment of syphilis has been inserted. The interval between the last edition and its predecessor was twenty-four years, and Dr. Lyonnet expresses the hope that the new commission, which consists of twenty-four persons, will accomplish its task more speedily, and in this connexion quotes the advice of M. Clemenceau in his speech at Strasbourg on November 4th last: "Do not let us be afraid of overworking ourselves."

TYPHUS IN POLAND.

An interesting account of the prevalence of typhus in Poland during the years 1916 to 1919 was given to the Section of Epidemiology and State Medicine of the Royal Society of Medicine by its president, Dr. E. W. Goodall, at a meeting on April 23rd. He had studied conditions in Warsaw and in a manufacturing town, Zawiercia, about 170 miles from Warsaw. The prevalence of the disease was considerable; between 1915 and March, 1919, probably not less than 400,000 cases had occurred in the whole country. The general fatality was low—from 7 to 10 per cent., increasing rapidly with age. The epidemic curve showed a winter maximum, but numerous cases continued to occur during the summer. The form of the curve in the two towns studied did not seem much modified by such administrative measures as were found practicable. The chief causes of the prevalence were constant warfare, influx of prisoners, and lack of soap, clothing, transport, fuel, and food. During the war the Germans made vigorous efforts to keep down typhus, compelling de-lousing

at the point of the bayonet. After the armistice, not only did economic conditions fail to improve, but there was more circulation of the civilian inhabitants, and thousands of Russian prisoners passed through eastwards. The general conditions at the end of 1918 were extremely bad. Housing was very unsatisfactory, and there were large numbers of old wooden huts which could not be cleansed short of burning them down. The Polish authorities attempted to maintain a sanitary cordon on the south-east frontier, but both staff and material were lacking. The paper was discussed by Dr. G. S. Buchanan, C.B., who was in the chair, Colonel Hunter, Major General Sir William Macpherson, Dr. Hamer, and Major Byam.

THE OSLER MEMORIAL VOLUMES.

THE contributions to medical and biological research made by his friends and pupils as a tribute to Sir William Osler on his 70th birthday last July, have now reached this country. They form two volumes, well printed and well illustrated, which are now being distributed to the subscribers. The contributors number nearly 150, and are drawn from both sides of the Atlantic. In the arrangement of their articles a rough classification into four groups may be noted—the first mainly historical, the third mainly biographical, the second and fourth clinical and biological. The first paper in the volumes, appropriately enough, is an account by Dr. T. D. Acland, of the Oxford University Museum, illustrated by a picture of it and by portraits of Ruskin, Sir Henry Acland and Sir John Burdon-Sanderson; Dr. Arnold Chaplin has added a short essay on the Oxford Medical School in the eighteenth century; Sir Archibald Garrod, Sir William Osler's successor, has an essay on the laboratory and the ward, and Sir Anekland Geddes another on social reconstruction and the medical profession. Professor Arthur Keith writes a characteristic essay, a mixture of history, gossip, and science, on the cradle of the Hunterian school. Later Dr. Walsh contributes an impression of the influence of English medicine upon American medicine in its formative period, which, as distinguished from Scottish medicine, was, he says, most marked in the later part of the eighteenth and the first three decades of the nineteenth century, and came largely from the great London surgeons, Percival Pott and John Hunter, and their successors, especially Abernethy and Astley Cooper. Of the clinical papers we cannot profess to give any account, only noting that Professor Lewellys Barker, who succeeded Osler at Johns Hopkins, writes on the diagnosis of general and regional atherosclerotic processes; Dr. Koplik on the intimate relation of chorea, rheumatism, and cardiac diseases; Dr. Councilman on the heart and kidneys of old people, and Dr. Simon Flexner on the epidemiology of poliomyelitis. Sir Clifford Allbutt has contributed an historical paper on the innate heat; and the short address he gave at the meeting held on July 11th, 1920, to celebrate Osler's birthday on the following day, serves as a preface to the volumes.

THE Society of Apothecaries has subscribed £10 10s. to the Keats Memorial House Fund. The poet Keats was one of the earliest licentiates of the society; he was examined by the celebrated Dr. Brande, and qualified in 1816.

THE complimentary dinner to Sir G. H. Makins, G.C.M.G., P.R.C.S., will be held on Monday, May 10th, at the Wharnclyffe Rooms, Hotel Great Central, at 7.30 p.m. for 7.45. Sir Cuthbert Wallace will take the chair. Any of Sir George Makins's friends who would like to be present are asked (if they have not already done so) to notify Mr. C. Max Page, 134, Harley Street, W.1, in order that seating arrangements may be made. Payment for the dinner (one guinea, not including wine) will be made at the Wharnclyffe Rooms. No tickets will be issued.

Medical Notes in Parliament.

National Insurance Bill.

Measure through Committee.

THE National Health Insurance Amending Bill was passed through Grand Committee of the House of Commons on April 27th.

Mr. Godfrey Locker-Lampson moved an amendment that local authorities providing treatment for sufferers from tuberculosis should co-opt persons with experience of the working of tuberculosis treatment. Dr. Addison said that the reason for taking sanatorium benefit out of the National Insurance Bill was that health services were in contemplation which would deal with tuberculosis. A certain amount of work had already been done at the tuberculosis dispensaries by local authorities. The county councils had, with a few exceptions, provided sanatoriums, and the Insurance Committees had made arrangements for the reception of their cases. It had been however found, partly as a result of the war, that a great many patients after they returned to their work relapsed and died from the disease. Last year the Treasury made grants to enable the local authorities to provide training as an adjunct to sanatorium treatment; it would be possible to secure training in alternative occupations, and this would have enormously beneficial effects. There must be one authority competent to deal with the whole question. He promised there should be an opportunity of co-opting on the new authorities members of Insurance Committees who had special experience of tuberculosis. The amendment was withdrawn.

An amendment to Part II of the Fourth Schedule of the Act of 1911 was made to alter the wage limit from £150 to £250, up to which voluntary contributors might come in for medical benefits.

Major Farquharson moved to insert after Clause 8 of the bill a new clause to provide that any medical practitioner who felt aggrieved by a decision of the Minister of Health, or of any special body through which the powers of the Minister were exercised, to remove his name from the list of medical practitioners (or a panel), might appeal against the decision to the High Court. Major Farquharson, in a vigorous speech, said this was a very serious matter. A medical man should not be liable to be put by a departmental or interdepartmental judicial process in such a position as was indicated. With every respect for the department and the departmental officials, he felt that a practitioner who was struck off might have a grievance. The right of appeal was one which did not arise out of contract law, but out of common law, and it was the constitutional right of aggrieved persons that they should be able to appeal to a higher authority. Dr. Addison, in refusing to accept the proposal, said that when after due inquiry by fellow practitioners a medical man on a panel was found not to be rendering such services as he ought to render in view of the obligations he had entered into, then his services could be dispensed with. The same rule might be applied to any other officers engaged on any other duty. It was quite impossible that in every circumstance of that kind in the administration of a great organization there should be power of appeal to the courts as to whether or not that man was doing his duty.

Dr. Farquharson said he should press for a division, but the amendment was negatived without one.

Revision of the Dentists Act.—Dr. Addison, in answer to Mr. Raffan, regretted that he could not say when legislation would be introduced to carry out the recommendations of the Departmental Committee on the Dentists Act, 1878, but he thought very probably he could make a statement on the subject before Whitsuntide.

Blinded Soldiers.—On an inquiry by Mr. Foreman, on April 22nd, Major Tryon said that approximately 1,300 soldiers discharged for total blindness had been pensioned under the Royal Warrant, and 110 had been refused pensions. The latter were men whose blindness arose from causes not connected with military service or due to their own serious negligence or misconduct. All men discharged for blindness were sent to St. Dunstan's (or in Scotland to Newington House, Edinburgh), where they were trained to new occupations. The disablement pension for total blindness carried from 40s. to 60s. according to rank, with a constant attendant allowance of 10s. to 20s. a week, a wife's allowance of 10s. a week, and an additional allowance for children. Any men sent to St. Dunstan's were provided for.

Pensions for the Blind.—On April 26th Dr. Addison introduced a bill in regard to the treatment of the blind, and it was read a first time. No particulars were given, but the chief feature is

understood to be to bring all blind persons who cannot earn their living at the age of 50 within the privileges that belong to old age pensioners normally at the age of 70.

Surgeon Rear Admirals.—Sir Watson Cheyne asked, on April 21st, whether, in the April Navy List, only four officers were shown under the heading of Surgeon Rear Admiral; whether no surgeon captains had been promoted to fill the two vacancies created by a retirement in February last, and the addition of one surgeon rear admiral to the list, as announced in March; and whether there was any reason why surgeon captains should not be promoted at once on the occurrence of vacancies in the same way as captains in the executive branch were promoted to fill vacancies in the rear admirals list. Sir James Craig replied that the question of promoting officers to fill the vacancies on the surgeon rear admirals list was now under the consideration of the Board of Admiralty, and it was hoped to announce the promotions at an early date. With regard to the second part of the question, the reason was that promotion to the rank of surgeon rear admiral was by selection, whereas promotion to rear admiral was normally made by seniority.

Medical Examinations in Elementary Schools.—In reply to Mr. Doyle, on April 21st, the Minister of Health said that it was not necessary nor practicable to ask education authorities to arrange for the weekly attendance of school doctors at each school. Out of 318 local education authorities in England and Wales, school nurses were performing some of the functions to which reference was made in 310. In reply to Mr. Billing, Dr. Addison said that he believed tooth cleaning drill for small children was already in operation. In reply to Mr. Dan Irving, he said that there were not enough doctors and nurses in the country to review every child every day. The school teachers, who were well trained and instructed in the matter, reviewed the children every day.

The Cost of Public Vaccination.—In reply to Mr. Waterson, on April 22nd, Dr. Addison said that the approximate cost of public vaccination in England and Wales was £168,000 in the financial year 1912-13 and £112,000 in the financial year 1918-19. He had no separate information as to the cost of vaccination officers.

Treatment Allowances to ex-Service Men.—In reply to Mr. Irving, on April 21st, Major Tryon (Ministry of Pensions) said that Circular 204 of February 6th did not involve any modification of the rights of disabled men. The primary function of the Deputy Commissioner of Medical Service under the circular was to procure for the men the form of treatment most suitable. Many men had in the past been recommended for home treatment who would have been better treated in one or other of the special institutions of the Ministry, a matter on which medical referees were of necessity not so well informed as the medical officers of the department. It was also the function of the Deputy Commissioner to assist in the protection of public funds by insuring that treatment allowances were confined to those cases for which they were intended by Article 6 of the Royal Warrant. The suggestion to revert to the earlier arrangement could not be entertained.

Bread.—Lieut.-Colonel Raw asked, on April 21st, whether under the present system of flour milling the germ and certain other constituents of wheat necessary to provide the most nutritious form of bread were removed from the flour. Dr. Addison said he understood that the percentage of extraction required by regulation was a minimum. There was nothing to prevent the making of bread from flour containing a higher percentage of the wheat if the demand existed.

Service in Northern Nigeria.—Earl Winterton asked a question, on April 21st, as to the regular tour of service for civil servants in Northern Nigeria. Lieut.-Colonel Amery said that probably the reference was to the eighteen months' tour for political and police officers only, which was introduced in Northern Nigeria in 1903 and abandoned in 1907. Health conditions in West Africa had greatly improved since then, and a committee, which included the recently retired director of the Medical and Sanitary Service of Nigeria, had unanimously recommended that the normal length of tour should be lengthened, and that the rule should be made more elastic so as to enable the length of tour to be varied according to circumstances. The report of the committee was being referred to the West African Governments. In reply to a subsequent question, he said that the number of European officers in the Nigerian service was 1,657 and in the Gold Coast service 673. The European medical officers were: in Nigeria, establishment 128, strength 91; in the Gold Coast, establishment 67, strength 48.

Answers in Brief.

The distress caused to many householders living on main thoroughfares by the noise of heavy vehicles at night has been included in the terms of reference to the Departmental Committee on the Taxation and Regulation of Road Vehicles, to which also the matter of the registration of motor vehicles has been referred.

Mr. Chamberlain can hold out no hope that the duties on table waters will be reduced, notwithstanding the allegation that the tax is greater in proportion than that on spirits or beer.

Major Tryon denies that there is any avoidable delay in settling the claims of officers' widows to alternative pensions, having regard to the difficulties in the verification of pre-war earnings.

England and Wales.

WELSH NATIONAL MEDICAL SCHOOL.

At the inaugural meeting of the scientific section of the Cardiff Medical Students' Club last week, Sir Robert Jones gave an address on the future of the Welsh National Medical School. The school had, he said, been in existence for over a quarter of a century, but had remained in the chrysalis state. The Welsh student could obtain in Wales instruction in the preliminary sciences, and in Cardiff training in anatomy and physiology, but after that he had to become a wanderer. There was no reason, he said, why this should continue. The Welsh National Medical School would only be born when it was self-dependent and could train its own students for the final medical degrees. To produce great surgeons and great physicians in adequate numbers they must be afforded opportunities to teach, for the most promising got into routine and humdrum ways unless they were kept up to the mark by students; nothing educated a teacher more than to be asked reasons for his acts. The understanding which grew up between teacher and student in a complete medical school was a valuable asset, creating an affection for the Alma Mater, keeping the old student in contact with the new, and fostering a desire for post-graduate courses. Teaching posts in the Welsh National Medical School ought to be made so attractive that the best men from all parts of the world would feel honoured by an invitation to join it.

The clinical opportunities afforded by Cardiff might be made unrivalled. At his first visit to the King Edward VII Hospital in 1900 he found it to be one of the most perfect hospitals, well equipped, well ventilated, and not overcrowded. Unfortunately, with the growth of the city of Cardiff and of the population within its sphere, an attempt was made to meet the demand for beds by putting up additional buildings on the site, thus using up the lungs of the hospital. Apart from that, the number of beds provided (400) was hopelessly inadequate; 1,500 beds with opportunities for extension were needed from the point of view both of the public and of the National Medical School. He had recently been asked to make a report on the provision for orthopaedics at the King Edward VII Hospital, and he had laid it down as a fundamental principle and condition that no in-patient hospital for children should be tolerated in the centre of the city. The present hospital should provide only in-patient clinics and a few beds for urgent cases; these urgent cases should, as soon as possible, be transferred to the country beds. Experience had taught him the injustice of segregating sick and crippled children in city hospital wards. He praised the hospital established by Sir John Lynn-Thomas for the Welsh National Memorial at Glanely, a few miles from Cardiff. In such a hospital it was impossible to close a ward, and through sunshine and storm one side was always open. A visit to the children in such hospitals was an inspiration; moreover, infectious diseases, which were the bane of children's hospital wards, never spread, nor did the children catch cold or develop pneumonia.

Cardiff, Sir Robert Jones continued, had a great opportunity to start the clinical side of its hospital and medical school on modern lines. There should be provided 1,500 beds in the country within easy reach of the centre of the city, and to the new site the in-patient activities of the complete staff of the hospital should be transferred. Of the total number of beds, at least 150 would be required for orthopaedic cases in adults and children. With a sufficient number of beds it would no longer be necessary to send patients home half-cured to make room for urgent cases.

Another point Sir Robert Jones made was the importance of giving responsibility to the junior members of the staff—a lesson learnt during the war, when the advances came from the younger men, who were the backbone of the medical services. An assistant surgeon should have beds placed at his disposal early before his mental activities waned; only so could that originality of outlook so necessary for his full development be attained. Cardiff possessed other institutions—the Glanely Hospital for Surgical Tuberculosis to which reference had already been made, the Royal Hamadryad Seamen's Hospital, the Prince

of Wales's Hospital for the Limbless (established through the efforts of Sir John Lynn-Thomas), a sanatorium for infectious diseases, and one of the finest mental hospitals in the world, under a distinguished expert, Dr. Goodall. The M.D. and M.Ch. degrees of the Welsh University should be of a standard which would fit a man to fill the highest posts. In conclusion, Sir Robert Jones spoke of the pleasure with which he had learned that the education of Cardiff students in orthopaedics was not neglected; most of his life had been spent in the study and practice of that branch of surgery, and he expressed the opinion that if orthopaedics were adequately and efficiently taught the so-called bonesetters who visited every town would find their vocation gone.

A vote of thanks to Sir Robert Jones, moved by the Principal of the University College, Cardiff, and seconded by Professor Hepburn, was supported by the Lord Mayor of Cardiff, who said that the city was vitally interested in the medical school, and desired it to be equipped in the best manner; to achieve that end there was ample room for private generosity.

GENERAL NURSING COUNCIL.

The Ministry of Health announces that the following have been appointed to form the first General Nursing Council under the Nurses' Registration Act of 1919. The duty of the Council is to form and keep a register of nurses in accordance with the provisions of the Act.

Appointed by the Privy Council. Lady Hobhouse, Mr. J. C. Priestley, K.C.

Appointed by the Board of Education.—Hon. Mrs. Eustace Hills, Miss Batty Tuke, Bedford College.

Appointed by the Minister of Health.—The Rev. G. B. Croushaw, Radcliffe Infirmary, Oxford; Dr. E. W. Goodall, Professor A. Bostock Hill, M.D., Dr. Bedford Pierce, Sir T. Jenner Verrall, L.L.D.

Nurses appointed by the Minister of Health.—Miss A. Cattell, private practice; Mr. T. Christian, Nurse Banstead Lunatic Asylum; Miss A. Coulton, Matron Shadwell Children's Hospital; Miss R. Cox-Davies, R.R.C., Matron Royal Free Hospital; Miss A. Dowbiggin, C.B.E., R.R.C., Matron Edmonton Poor Law Infirmary; Mrs. E. G. B. Fenwick, formerly Matron St. Bartholomew's Hospital; Miss A. Lloyd-Still, C.B.E., M.R.C., Matron St. Thomas's Hospital; Miss M. MacCullum, Professional Union of Trained Nurses; Miss I. Macdonald, Royal British Nursing Association; Miss A. M. Peterkin, General Superintendent Queen Victoria Jubilee Nurses; Miss E. Smith, Welsh Superintendent Queen Victoria's Jubilee Institute for Nurses; Miss M. E. Sparshott, C.B.E., R.R.C., Matron Royal Infirmary, Manchester; Miss E. C. Swiss, Health Visitor for Willesden; Miss S. F. Villiers, Matron Stockwell Fever Hospital; Miss C. Worsley, Matron Liverpool Children's Hospital; Miss C. S. Yapp, Matron, Ashton-under-Lyne Poor Law Infirmary.

Mr. Priestley has been appointed to be the Chairman of the Council.

CONSULTING SURGEON AND HOUSE-SURGEON.

In relating recently how Mr. E. J. Douville, O.B.E., consulting surgeon to the Royal Devon and Exeter Hospital, had acted as house-surgeon in that hospital during the war, we ventured a doubt whether anyone else had had a similar experience. We now learn that Mr. J. T. Williams, honorary consulting surgeon to the North Lonsdale Hospital, Barrow-in-Furness, is in exactly parallel case. After being honorary surgeon to the hospital from 1873 he retired in May, 1914, but in the autumn of that year, as the authorities were unable to obtain house surgeons, he took up that work, which he has carried on down to the present time.

CENTRAL MIDWIVES BOARD.

At a penal meeting of the Central Midwives Board for England and Wales, held on April 21st, Sir Francis Champneys presiding, five midwives were struck off the roll and two were put on probation. One of the midwives who was in attendance on a puerperal patient, and who, notwithstanding, visited other lying-in women, stated in her defence that the doctor who was called in to her infectious case, gave her permission to finish three cases she was visiting, after which she was to abstain from practice for a month. The board decided to forward this statement to the local supervising authority for inquiry, and to call attention to its bearing on the jurisdiction of the board. The ordinary monthly meeting was held on April 22nd, when Sir Francis Champneys, who has held the post now for eighteen years, was unanimously re-elected

chairman. The Finance and Penal Cases Committees were re-elected. It was reported that the Minister of Health had approved, for the purpose of the apportionment of contributions from local supervising authorities, the balance of £3,395 7s. 10d., shown against the board in the finance statement for the year 1919. The list, as submitted by the secretary, of institutions, honours, and midwives at which and under whom pupil midwives may be trained, was approved until March 31st next.

Scotland.

EXTENSIONS AT THE UNIVERSITY OF EDINBURGH.

THE KING has promised to lay the foundation stone of the new chemical laboratory of the University of Edinburgh in July next. The laboratory will be the first building on the University's 150 acres at Craigmillar, into possession of which it came last November. The King is expected to arrive at Holyrood on July 3rd and to stay there until July 10th. New laboratories for the histological department have been provided by adding another story to the Forestry building in George Square; the work was only begun last December, but the new laboratories will be ready to receive 150 students this week. Under the direction of Sir Edward Sharpey Schafer three large laboratories, with a professor's room, assistants' and preparing rooms, have been equipped. The rooms are well lighted, ventilated, and heated. It is intended to have two classes a day, so that it will be possible to pass 300 students through the course. The University Grants Committee will visit the University of Edinburgh on May 13th and 14th.

GREATER EDINBURGH.

How closely modern medicine and civic matters are interlocked is being clearly demonstrated in the inquiry which has been going on before the Select Committee of the House of Lords in connexion with the Edinburgh Boundaries Extension and Tramways Bill. Some years ago such questions as rates and trade and convenience would have been the all-important deciding factors; now health administration, the checking of the spread of infection, housing as part of hygiene, mother and child welfare schemes, the provision of maternity accommodation and of small-pox hospitals, are all playing a considerable part in the evidence which is being presented more especially in relation to the proposed inclusion of Leith within Greater Edinburgh. "None of us liveth to himself" is true not only of the individual man but also of the individual city, especially when it touches so closely as to be indistinguishable (when seen by aeroplane) from its neighbour city. Other plans instead of absorption may be devised and carried out, but there seems no doubt that for the health and well being of two contiguous towns something of the nature of common action and joint control is to be sought for.

SMALL-POX IN GLASGOW.

Down to April 24th the outbreak of small-pox, which began early in March, had led to the recognition of twenty-eight cases, of which four proved fatal. Two other deaths were due, it is believed, to unrecognized forms of the disease. The majority of the patients are children. This is to be attributed to the fact, noted last week, that the proportion of infants successfully vaccinated in Glasgow has declined continuously since the Vaccination Act of 1907, so that at the present time not more than half the number born are protected. Of the twenty-five cases of small-pox in hospital, nine are children under 15 years of age who had not been vaccinated, in another case there was no record or evidence of vaccination, and nine had been vaccinated in infancy but were now, with one exception, over 15 years of age.

INSPECTOR OF ANATOMY.

The Secretary for Scotland has appointed Dr. Norman Walker to be Inspector of Anatomy, a post he has held temporarily during the last two years. During Dr. Walker's absence in America his place will be taken by Dr. F. W. N. Haultain.

Ireland.

OBJECTIONS TO PROPOSED SITE FOR BELFAST TUBERCULOSIS SANATORIUM.

DR. N. C. PATRICK, Local Government Board inspector, opened an inquiry in Belfast on April 21st in regard to the application of the County Council of Down for sanction to a loan of £27,000 for the purpose of providing a sanatorium for tuberculosis.

Craigavon is the residence of Sir James Craig, Bt., and was lent by him to the Ulster Volunteer Force Hospital Board, which organized a hospital for pensioners suffering from neurasthenia and allied conditions, built an annexe containing seventy-four beds, and provided workshops for carpentry, mechanics, bootmaking, tailoring, and other trades, and also training in outdoor work. The garden was taken over, but has not yet been used by the patients. The Down County Council was on the look-out before the war for a tuberculosis sanatorium. The project fell into abeyance, but the Council has now made an offer of £26,000 for the place as it stands. Strong opposition has arisen from various quarters, among the opponents being the trustees of the Ker estate, the ratepayers of the district, the Castlereagh Rural District Council, the Bangor Urban District Council, and the Belfast Corporation.

Counsel, in stating the case for the Down County Council, said that efforts made in 1913 for the acquisition of several sites had all fallen through for varying reasons. In December, 1919, a letter from the Local Government Board called for increased facilities in the institutional treatment of consumption. The reports of the officers of the Down County Council stated that Craigavon would be suitable, and as it was estimated that a sum of £66,000 would be required to erect similar buildings, the Down County Council had made the present offer.

Evidence was given on the financial and general aspect by various witnesses. Dr. J. R. Gillespie, chief tuberculosis officer for co. Down, said that Craigavon was a suitable site, and that its proximity to Belfast would be helpful; both water and sewerage were satisfactory, and the place was sheltered by trees from the north. He considered that the effluvia from the lough had much abated in latter years, and thought there was no fear of infection spreading to the homes of the petitioners.

Dr. W. J. Wilson, lecturer in public health, Queen's University, Belfast, said he had known the district for fifteen years, and had recently made a special inspection of Craigavon. He considered patients could be admirably treated there, and that none of the objections brought forward were very serious. There would be no danger to the boys attending Campbell College in the vicinity, and the nearest resident to Craigavon was about a fifth of a mile away. He admitted that the patients could travel to Belfast in the tramcars and visit the cinemas, and he could understand the objections of the citizens to patients in an advanced stage coming into the city, but that was a matter of internal arrangement and control.

Dr. Charles J. Alexander, medical superintendent of the Forster Green Hospital for Consumption, Belfast, also gave evidence as to the suitability of Craigavon as a sanatorium. Building developments had taken place round the Forster Green Hospital and the land around used for grazing cattle, yet no complaints had ever been received as to infection arising therefrom.

Counsel, in stating the case for the petitioners, said that the county had a population of roughly 200,000, the larger part residing in the southern area. A sum of £17,000 had been expended on Craigavon for the benefit of the neurasthenic soldiers and was to be applied for that purpose until the hospital became unnecessary; it was now full and was still urgently needed; if the County Council once acquired this property it would be bound to continue the project, no matter what the cost—or the unsuitability of the place.

Mr. T. S. Kirk, surgeon to the Royal Victoria Hospital, Belfast, and surgeon in charge of the Throne Children's Hospital, said that Craigavon was not an ideal site, because cases of tuberculosis did badly in Belfast; he thought the cause of this was climatic and due to the conditions of the Lagan Valley; any situation in this valley was unsuitable. The fact that the site was adjacent to a large manufacturing town made it still more unsuitable.

Dr. Benjamin H. Steede, medical superintendent of the Rostrevor Sanatorium, stated that he had four chief objections to the present site: it was too low, too near Belfast Lough, too near the city, and had no proper natural shelter. The principal thing was to get dry, pure, bracing air; the liability of Craigavon to fog was increased by its low level; he thought it would be exceedingly difficult to prevent patients going into the town.

Professor J. A. Lindsay, F.R.C.P., of Queen's University, said that he had formed the opinion that Craigavon was highly unsuitable for a sanatorium, both as regards its site and buildings. It was too near the city, and he could not recall an instance of placing a modern sanatorium so near a large town. Belfast was highly infected by tuberculosis mainly because it lay low, on a damp soil, and the atmosphere was

contaminated by various industries. The tuberculosis rate varied from 2.2 to 2.5 per 1,000, which was much higher than in the large towns of England. Belfast had also a high rate of mortality for diseases of the lungs in general, and he was at a loss to know why tuberculous cases should be brought into a highly infected area. The buildings had a wrong aspect, facing W.N.W., and lay from east to north-east of the city, so that the prevailing south-west winds carried pollution and dust towards Craigavon. The fact that there was at present a great deal of hostile criticism of sanatoriums and their value made it all the more desirable that any sanatorium established should not be open to any serious objection. Regulated exercise was a part of the treatment, but Craigavon was close to the tram lines. It was an advantage that the house had thirty-five acres of land and was self-contained, and that the soil was light and sandy; but Professor Lindsay said that in the vicinity the soil was heavy and clayey.

Numerous residents gave evidence of the prevalence of fogs and in the summer of obnoxious smells from the lough. Dr. Charles O'Neill, on behalf of the Castlereagh Council, Dr. Mitchell, M.O.H. Bangor, and Dr. Baillie, M.O.H. Belfast, gave evidence against the project.

ULSTER MEDICAL SOCIETY.

The president, Mr. Andrew Fullerton, C.B., C.M.G., F.R.C.S.I., and Mrs. Fullerton, held a reception at the Ulster Medical Institute on April 22nd, which was attended by members of the society and their wives to the number of about 200. The hospitality of the president and Mrs. Fullerton and the excellent music, both vocal and instrumental, were highly appreciated.

India.

MATERNITY AND CHILD WELFARE EXHIBITION AT DELHI.

FOR a week during last February an exhibition was held at Delhi for the purpose of demonstrating by means of models, pictures, lantern and film representation, lectures, discussions, talks, pamphlets, posters, etc., the influences, good and bad, conditioning health generally, and especially the health and welfare of mothers and children. It was the first time such an exhibition had been held in India, and the suggestion came from the Association of Medical Women in India. The exhibition was organized by an influential general committee and a number of subcommittees for special purposes. It was divided into seven main sections dealing with pre-maternity, maternity, infant welfare, childhood, first aid, home nursing and domestic hygiene, and sanitation. The exhibits in these sections are well represented in a series of excellent photographs which have been sent to us. The proceedings in each section appear to have been highly interesting and complete. It is hoped that similar exhibitions will be held in other large Indian cities. That in Delhi was opened by Lady Chelmsford, wife of the Viceroy. In a very sympathetic speech she announced that a league was about to be created under her name and patronage for the purpose of providing increased accommodation throughout India for lying-in women in hospitals or maternity homes; to promote the better education of *dais*; to establish centres for the loan or gift of necessary articles for women who cannot attend hospitals during the time of their confinement, and to multiply the number of maternity and infant welfare centres and schools for mothers; to raise an endowment to prevent privation among women at the time of childbirth; and, finally, to educate and qualify health visitors and to assist in paying their stipends. The attendance at the exhibition was large, and included Indian noblemen and their families, medical men and women, nurses, and a crowd of Indians of both sexes, for whom reduced railway fares, a camp, refreshments, and amusements were provided. The good resulting from this and other similar enterprises cannot be otherwise than substantial and widespread. Apart from the special objects of the show, it must also make for general enlightenment and the improvement of public health.

THE LEPER PROBLEM.

Forty-six missionaries including six medical men, took part in a conference, summoned by the Mission to Lepers,

in Calcutta in February. Sir Leonard Rogers, I.M.S., and Colonel F. H. G. Hutchinson, I.M.S., attended as delegates of the Indian Government, and the Hon. Sir Henry Wheeler welcomed the members on behalf of the Government of Bengal. The conference recognized that leprosy is a slowly contagious disease, in which the nasal discharge is frequently infectious before the stage of ulceration has been reached; that, although it is not hereditary, children are peculiarly susceptible of infection; and that segregation is the most effective measure for reducing the prevalence of the disease. It was recommended that voluntary segregation should be encouraged, except in the case of pauper lepers, in respect of whom compulsory powers should be obtained and settlements established.

The conference recommended that facilities should be provided for the training of medical assistants in the diagnosis and treatment of leprosy, and that grants for research should be sought. In view of the considerable degree of fecundity of lepers, especially of females, the separation of the sexes—when possible—was advised; where this was not practicable, married lepers should only be allowed to live together on the understanding that any children born to them should be taken away at the earliest possible age. It was also recommended that the definition of a leper in the Indian Leprosy Act of 1918 should be so altered by the omission of the words "in whom the process of ulceration has commenced" as to read: "any person suffering from any variety of leprosy." A bill which has since been introduced in the Imperial Legislative Council to amend the Act of 1918 follows very closely the recommendations of the Calcutta conference.

INDIGENOUS MEDICINE.

At a recent meeting of the Imperial Legislative Council at Delhi Mr. Jaffer proposed that a sum of five lakhs should be granted to the Ayurvedic and Yunani Tibbi College at Delhi for building and equipment. The proposal was supported by a number of Indian members. Sir William Vincent, replying for the Government, said that it was anxious to co-operate, and he would gladly receive a deputation and do his best to get financial aid from the Finance Minister. The Viceroy, he believed, would open the building later on. The motion was withdrawn after the mover had thanked Sir William Vincent. Recently the Government of Bihar and Orissa, in answer to a request for recognition of an Ayurvedic dispensary, said that the policy of the Government had been to recognize only such dispensaries as were in the charge of medical practitioners trained in Government schools of medicine and under the control and supervision of civil surgeons and of the inspector-general of civil hospitals. Recognition of an Ayurvedic dispensary was, therefore, barred by the rules for the management of Government hospitals and dispensaries.

INFLUENZA.

A report issued by the Sanitary Commissioner with the Government of India, issued on March 23rd, stated that influenza was prevalent in the Bombay Presidency and had been the cause of 940 deaths during the previous two weeks. In the United Provinces the disease had prevailed in a mild form during the last fortnight of February, and in the Madras Presidency the incidence was small. In Bengal deaths from the disease were recorded in twenty-two municipalities. In the city of Calcutta it appeared to be declining. A severe outbreak occurred near the Naini Tal district, and the disease was reported to be present among the coolies in the Simla catchment area. The epidemic was present in Darjeeling; the mortality was increasing in the gardens.

SMALL POX IN CALCUTTA.

An epidemic of small-pox now prevailing in Calcutta has swelled the total mortality rate to 59.3 per 1,000 as against 51.1, the highest figure recorded during the corresponding period of the previous five years. During the week ending January 31st last, after a brief lull, there was a general increase of the disease all over the city, the deaths from the disease numbered 227 as compared with 169 in the previous week.

China.

PROPOSED NEW BRANCH OF THE ASSOCIATION.

At a meeting of British doctors recently held in Peking, it was decided that, owing to the considerable developments which had recently taken place in the practice of western medicine in China, the time was ripe for the formation of a new Branch of the British Medical Association, larger than the existing Hong Kong and China Branch which was established thirty years ago. The honorary secretary, Dr. Oswald Marriott, was requested to make preliminary arrangements.

JOINT CONFERENCE OF ENGLISH AND CHINESE DOCTORS.

The biennial joint conference of the China Medical Missionary Society and the National Medical Association—a body of foreign-trained Chinese medical men—was held at Peking in February. One hundred and seventy members of the former body attended. Mr. C. J. Davenport, F.R.C.S., of Shanghai, being in the chair; 65 members of the latter society took part, under the presidency of Dr. Wu Lien Têh, who stated that his fellow members desired at all times to work in co-operation with their English colleagues.

In a historical paper Dr. E. T. Hsieh reviewed the conditions of anatomical investigation and knowledge from the Huang-ti period (2697 B.C.), and pointed out that the accurate study of human dissections not having been possible, little or no advance had been made since the Ming dynasty (1644). Dr. S. P. Chen reported that the Chinese Government now recognized that students should have opportunities for dissection; they were willing to authorize the use of unclaimed bodies, but were to some extent hampered by popular feeling, which was still far from favourable. Other speakers referred to recent changes in attitude of the Chinese Government towards medicine and surgery, which were formerly regarded with suspicion and animosity: the founding of the China Medical Board (the Rockefeller Endowment), Hong Kong University, and the Chinanfu and other medical colleges had led medical activities to be tolerated and even encouraged, and very large numbers of Chinese students were now entering the profession.

In the section of surgery Dr. Oscar Thomson reported a series of 3,000 operations for vesical calculus, and Dr. J. A. B. Branch recorded favourable results from the treatment of empyema by lavage with Dakin's solution. Dr. H. J. Howard discussed the origin and physiology of the vitreous humour. Professor M. Inouye of Tokyo, in a paper based on dissection as well as on experimental and clinical findings, put forward the view that the muscles of the soft palate were innervated, not from the pharyngeal plexus, but from the second division of the trigeminal, by way of the palatine nerves. Drs. J. W. Chun and L. T. Wu described the management of the last cholera outbreak at Harbin, and reported that by the use of Rogers's hypertonic saline infusions the mortality in a series of 2,000 cases had been reduced to 14 per cent.; Dr. Braffadt advocated the exhibition of kaolin (aluminium silicate) infusions being reserved for the most severe cases. Dr. W. W. Cabbury discussed the treatment of leprosy, and Dr. P. T. Watson advised widespread prophylactic vaccination against plague.

A general review of public health problems in China was given by Dr. S. Woo, and papers were read by Dr. Van Buskirk on the diet of Koreans, and by Dr. S. D. Wilson on that of the Chinese. Dr. Wu Lien Têh, in an address on the latest phase of the narcotic problem, pointed out that the Chinese imports of morphine had increased fivefold between 1911 and 1919; the conference passed a resolution urging that immediate action should be taken to secure better control of the production of opium, and the limitation of the manufacture of morphine and other derivatives to a quantity not exceeding that necessary for legitimate medical purposes.

THE medical profession of New York have contributed 10,000 dollars to supply food to medical practitioners in Vienna. Dr. Linsly R. Williams has left Paris for Vienna to arrange for its distribution.

Correspondence.

DIAGNOSIS AND TREATMENT.

SIR.—The two addresses appearing in the *JOURNAL* of April 24th, one by Dr. A. F. Hurst on the "Pathology, Diagnosis, and Treatment of Gastric and Duodenal Ulcer," and the other by Dr. Edmund I. Spriggs on "Surprises in Diagnosis," must make us all think how inadequate are our present opportunities and means of treating the diseases referred to in these two papers.

It seems to me that for the vast bulk of our patients, whether hospital or private, it is impossible to carry out any thorough examination or treatment as recommended by these authors.

Of course, the few rich can have this advantage, also the hospital poor, where special men and departments exist. How many hospitals in England, apart from the large towns, contain the complete x ray apparatus, bacteriological and chemical apparatus, etc., with trained men? Comparatively few.

It is almost useless to recommend these detailed and almost impossible methods until the laboratories and the men able to carry out these examinations are forthcoming. It is this great difficulty of making a full diagnosis and carrying out a complete treatment which needs most careful thought.

The panel system as regards the "whole" treatment of the patient has failed, for all special treatment, if it is carried out, has to be carried out elsewhere.

What we require is some great scheme for the treatment of the whole body, adaptable to every town. To decide how this is to be done will require great vision and statesmanship; whether it is possible without State help is doubtful.

What I fear is this, that a plan may be started and forced upon us—this has happened once before—before the scheme has been thoroughly digested and approved by the men who know most about the subject.—I am, etc.,

Folkestone, April 25th.

W. J. TYSON, M.D., F.R.C.P.

TUBERCULOSIS SANATORIUMS.

SIR.—In connexion with the discussion on the decrease in the decline of the consumption death rate, may I point out, first, that a mild form of tuberculous infection is almost universal in the early life of town populations, and secondly, that malignant cases appear to give rise to similar cases?

In sanatoriums a very malignant form is always present in the wards, and those who are admitted with a mild form probably contract there a severer form and convey it to their family. Before the sanatorium regulations came into being I was strongly impressed by one or two cases which seemed to show that there might be a tendency for persons with chronic or mild consumption to receive a more virulent form whilst in a sanatorium, and after a temporary improvement to burst out in rapid consumption, although previously likely to last for years.

The same sort of process may be observed in scarlet fever hospitals, where mild cases appear to contract a severer form after admission, and, after discharge, sometimes convey a severer form to their families. During the small-pox epidemic at the end of the South African war it was observed in quite a number of districts that after the local infectious disease hospitals had been closed there was an actual decrease in the number of notified cases of scarlet fever.

Again, I have had cases of infantile paralysis that have developed severe tuberculosis after a short stay in a convalescent hospital.

The prevalence of influenza is another cause. Lately I have had under my care two elderly men, both with large numbers of tubercle bacilli in their sputum. One of these had a severe influenzal pneumonic attack a year ago, from which he dated his illness. Both of these old men had numerous attacks of hæmoptysis when young, thirty to forty years ago.—I am, etc.,

Wallasey, April 24th.

F. WM. INMAN, M.B.

SIR.—As some confirmation of Dr. Williamson's statement in his letter (April 17th, 1920) on this subject, that a certain proportion of the cured cases from tuberculosis sanatoriums are cases in which a wrong diagnosis has been

made, it may be worth recording that I have cured cases confidently diagnosed as pulmonary tuberculosis by extracting septic teeth. Further, where the disease is truly tuberculous, septic teeth must be a powerful cause of secondary infection, and I have seen enough of sanatorium treatment to have formed the opinion that free extraction of septic teeth is a great benefit to consumptives. I suspect that thorough dental treatment on these lines would eliminate a large proportion of mistaken diagnoses and give the truly tuberculous settlers a much better chance.—I am, etc.,

London, W.1, April 29th. J. G. TURNER, F.R.C.S., L.D.S.

SAND-FLY FEVER IN MESOPOTAMIA.

SIR,—In the interesting paper by Dr. Willcox on heat hyperpyrexia, published in your issue of March 20th, 1920, he states: "In the great incidence of heat-stroke in July and August, 1917, sand-fly fever was entirely absent." I cannot understand this statement, for during this period a great epidemic of the disease was raging at Basra.

I am convinced from my own observations that some of the milder cases of hyperpyrexia, diagnosed "effects of heat B," were sand-fly fever, for during normal summer weather in Mesopotamia it was not very uncommon to find patients with temperatures of 105° F. and higher in sand-fly fever. I was in Baghdad when the heat wave commenced and there sand-flies caused me little inconvenience, but on returning to Basra a few days later I found the torment from these pests was so unbearable that few of us could sleep.

Sand-fly fever may have been absent at Baghdad, but it was certainly raging at Basra throughout the summer of 1917, including the heat-wave period. I quite agree with Dr. K. G. Hearn's theory (BRITISH MEDICAL JOURNAL, April 26th, 1919), endorsed by Dr. Willcox (BRITISH MEDICAL JOURNAL, March 20th, 1920), that sand-fly fever was entirely out of the question in the majority of cases which he describes as "hyperpyrexial heat-stroke."—I am, etc.,

Bridlington, April 20th.

C. R. TAYLOR.

THE EARLY DIAGNOSIS OF SYPHILIS.

SIR.—The diagnosis of syphilis depends on the laboratory report, the clinical aspect of the case, and the period of incubation. In any case of untreated venereal sore the procedure I adopt is as follows: (1) The incubation period is noted, and a careful examination of the patient is made; (2) a warm saline dressing is applied to the sore, and no other dressing is used, unless, of course, the sore should be phagadaenic. Several dark-ground examinations are made, an interval of a few hours elapsing between each examination; if no *Sp. pallida* is found, an inguinal lymphatic gland (if present) is punctured, and some fluid removed and examined by dark-ground illumination (following Mr. C. W. Mills's procedure). Should no *Sp. pallida* be found, an injection of 0.45 gram of novarsenobenzol is given intravenously, and in seven days' time a blood test is made; if this is negative another test is done seven days after the first; if the result is again negative, the patient is told to have another injection of 0.45 gram novarsenobenzol in two weeks, and a blood test a week after the injection. A careful clinical examination is made at the time of each test.

In this way a diagnosis of syphilis is either eliminated or proved, and there is little time lost in treatment. To treat every sore as syphilitic is hardly in accordance with modern teaching. We have advanced tremendously in our methods of diagnosis of syphilis, but to condemn every man with a venereal sore to several years' treatment for syphilis is surely going backwards. The time lost in making a diagnosis is compensated by the loss of anxiety to the patient. I have seen several patients lately in whom no laboratory tests have been made, but have yet been started on a course of injections for syphilis. Three or four injections mask the clinical symptoms and upset the Wassermann reaction, and a definite diagnosis is difficult to make. In my last hundred cases I have had twelve undoubted cases of simple chancre.—I am, etc.,

REGINALD JOHNSON, M.D.,

M.O. de V.D. Wards, Brompton Military Hospital,

April 5th.

Ladywell, S.E.

SIR.—In commenting on Dr. Bryan's letter published in your issue of March 20th Mr. Marshall and Major French give their opinion in support of Dr. E. Harrison that "chancreoid is a rare condition, and nearly always has syphilis at the back of it." I think this statement should be qualified by adding: "in this country at the present time."

In France there has recently been quite an epidemic of simple chancre, and it would be easy to see as many as fifty or more any day of the week at St. Louis. I need hardly add that the French physicians insist on keeping these patients under observation, and that, while many cases turn out to be mixed, a large number remain simple throughout.

The advice given that "all cases of apparent chancreoid should be treated at once for syphilis" will hardly meet with universal acceptance.—I am, etc.,

London, W., April 5th.

M. G. HANNAY, F.R.C.P.E.

SIR.—Might I suggest that, while appreciating the interest of Drs. C. F. Marshall and E. G. French in my criticism of Dr. E. Harrison's previous letter, I think that a more careful perusal of my letter would have prevented them from making the entirely erroneous assumption that I am only prepared to accept a diagnosis of syphilis when *Sp. pallida* is shown by dark-ground illumination? They would then see that I merely wish to emphasize the risk of condemning a person suffering only from chancreoid to a diagnosis of syphilis, with the prolonged course of treatment involved, on the strength of a faulty microscopic diagnosis.

As to the alleged rarity of chancreoids pure and simple, Drs. Marshall and French's own figures seem to me to support my contention, as I consider that even 1 in 10 is a very considerable number. My own cases at the Middlesbrough clinic during the last year give a proportion of 1 in 4. These cases have been under observation not less than three months; the number (12) is, of course, one much too small on which to generalize, but the results confirm the impression I formed while serving in a military venereal hospital, which treated 4,000 to 5,000 venereal cases annually.

Referring to the remarks of Drs. Marshall and French as to "the false teaching which places laboratory diagnosis before clinical experience," might I quote the following extract from the report of the Medical Research Committee, 1918:

That too much emphasis cannot be laid upon the importance of the detection of the spirochete as affording the earliest means of diagnosis of syphilis, and this at a period when, clinically, it is not possible to arrive otherwise at a definite decision, and undoubtedly the ideal method of demonstrating the *Sp. pallida* is by the dark-ground condenser.

Allusion is made also to the disadvantages of staining methods, namely:

Lack of affinity the *Sp. pallida* has for most staining reagents, the distortion caused by drying, and the absence of the characteristic movements.

From the report of Dr. E. Harrison in the BRITISH MEDICAL JOURNAL I am unable to decide which microscopic method he adopts; perhaps he will kindly enlighten us.—I am, etc.,

Middlesbrough, April 5th.

A. BRYANS.

CIRCUMCISION—A BARBAROUS AND UNNECESSARY MUTILATION.

SIR.—While I agree with Mr. G. S. Thompson, in his communication of March 27th, that circumcision is often performed unnecessarily, it is an error to lay the blame entirely on the Jews for this practice. This piece of religious ritual originated with the Heliolithic culture which arose in the Nile valley thousands of years before the Jews became a nation, spread at first all over the East by trade routes, and after 800 B.C. was carried by the daring Phoenician mariners to all parts of the world, including Great Britain, the Pacific Islands, and even the American littoral.

Professor Elliot Smith has conclusively proved that this worship of the sun and the serpent was thus disseminated, together with the practices such as circumcision, mummification of the dead, massage, and piercing of the ears, to mention but a few.

I have no doubt that the Jewish ritual has influenced this country to a certain extent, and it might be wiser if we employed the method as practised by them, which is unattended by any danger from an anaesthetic.

Circumcision was performed in the neolithic age by the Egyptians, but probably became popular in Palestine after the Exodus, and perhaps received an additional stimulus after the Assyrian and Babylonian captivities, both of which regions were pervaded by the Heliolithic culture from the Nile; it would obviously appeal to the inhabitants of Palestine who were intensely phallic in their ideas. In Egypt the actual operation disappeared about the pyramid age (2600 B.C.), but persisted in adjacent localities from which the Phoenicians recruited their sailors, and so spread this custom.

The use of the chipped flint method is referred to in Exodus iv. 25, where Jahveh attempts to murder Moses, so the latter's wife "took a sharp flint and cut off the foreskin of her son" as a blood sacrifice to pacify the tribal deity.

Whatever opinion one may hold about the advisability of keeping women in bed after childbirth, the male members of our community should certainly thank the Jews for not adopting that other Heliolithic custom, the "convade," which still exists in parts of China, where the husband is kept in bed to receive the congratulations of his friends, and attended by his wife.—I am, etc.,

Bexhill-on-Sea, April 2nd.

G. LOWELL WEBB, M.D.

SIR,—It may interest some members to know that, like Mr. G. S. Thompson, F.R.C.S., I have not done a circumcision for upwards of twenty-five years. I separate the adhesions with a probe and partially dilate with Lister's sinus forceps; the dilatation is completed in three sittings twenty-four to forty-eight hours apart, each time withdrawing the prepucce repeatedly until it can easily be drawn forward, as I find sometimes that the constriction caused by the orifice is tight enough to cause swelling of the glans after the first dilatation. I have many times done this from 10 days up to 10 or 12 years; in one a man of about 28 (married, but no children), who could not spare time for operation, was successfully treated though the aperture was smaller than the meatus. He continued the stretching for three weeks with ironine "glove stretchers," and became a father less than twelve months after. The foreskin also gradually withered, leaving part of the glans exposed.

I have often found in babies that as the organ grows out of proportion to the prepucce the glans is nearly completely exposed in a few years. There is next to no pain and generally no blood.—I am, etc.,

South Ealing, March 29th. HARDING H. TOMKINS, M.R.C.S.

ENCEPHALITIS LETHARGICA.

SIR,—May I venture to suggest that, although it may not fall within the province of the epidemiologists to demonstrate by laboratory methods a common virus for influenza and the forms of epidemic encephalomyelitis, nevertheless the proof of a certain degree of association over long periods of time between two recurrent sets of phenomena goes some way to establishing the propriety of assuming a common cause for them. Such an association, one is glad to observe, is now admitted to have been proved for influenza and encephalomyelitis.¹ But the remarkable paper by G. Re, in *La Riforma Medica* (October 4th, 1919), and the series of articles that have appeared in the same periodical since the beginning of this year, form a body of collective clinical and pathological opinion which supports in no small degree the views put forward first by Dr. Hamer and then by myself at the meeting of the Royal Society of Medicine in October, 1918, and later reinforced by the historical evidence² to which you have been good enough to allude in your editorial article this week. It was, however, Boström who, in 1757, plaintively observed, concerning the peculiar influenza at Upsala, "*Hic morbus non est novus*": Polydore Vergil, according to Cervantes, merely failed to tell us who was the first in the world to be troubled by a catarrh,

while Brorström, who is, I believe, a descendant of the first named, in 1910 pretty clearly proved, in his *Akute Kinderlähmung und Influenza*, in respect of poliomyelitis, what some of us now believe in respect of the expanded Heine-Medin conception, or "epidemic encephalomyelitis." I am, etc.,

London, W 1, April 23rd.

F. G. CROOKSHANK.

Obituary.

THE LATE PROFESSOR ALEXANDER FERGUSON.

THE death of Dr. Alexander Ferguson, professor of Pathology in the School of Medicine, Cairo, was recorded in our issue of March 20th, p. 422. We have since received the following personal appreciations:

Professor ROBERT MUIR, of Glasgow, writes:

When I was first associated with Professor Ferguson, in 1899, he was already an experienced pathologist. He had had an excellent training under the late Professor Coats, and this, combined with his natural aptitude for and enthusiasm in the work, had resulted in a wide and varied knowledge of his subject. He was also an accomplished bacteriologist, and for several years conducted the advanced course in bacteriology. Routine reporting on pathological material formed an important part of his duties at the Western Infirmary, and in this department I have known few men whose opinion I considered of so much weight. For he possessed, along with the scientific knowledge, that rare quality of balanced judgement, closely allied to clinical instinct, which enabled him to view in due proportion all the points of a case, and made his opinion much valued by physicians and surgeons. To the students of medicine in Glasgow University Ferguson was for several years a well known and attractive teacher. Possessed by a wide grasp of his subject and of its practical bearings, and gifted with a faculty of interesting exposition, he had a stimulating influence on his students, whilst his sympathetic regard for their welfare won their confidence and interest to an ever-increasing extent; and I have received abundant testimony that his teaching in Cairo was attended by an even greater success.

Dr. Ferguson was essentially a student and investigator, and it is quite in keeping with his character that, in proportion to the amount of research which he did, the number of his publications is not large. When in Glasgow he published various papers and notes on a number of subjects—for example, intestinal sand, congenital heart lesions, immunity, etc.—but his chief work was concerned with the pathology of small-pox, to which he devoted much labour over a long period. His chief results, dealing with the blood changes and tissue lesions, were incorporated in a thesis for which he received the degree of M.D. in 1905, and was awarded a gold medal. The part dealing with the blood (which was the first detailed account in this country), and that dealing with the skin, appeared in the *Journal of Pathology* in 1903-4, and added to his reputation as an accomplished pathologist. Although busy with teaching and hospital work at Cairo he was constantly carrying on investigation, and I always looked forward to the opportunity of discussing the subjects concerned, and learning his views. Reference to his investigations there has been made by another writer. I may merely mention his important papers on splenomegaly, on "parasitic granuloma," and on bilharziosis. All these are of an authoritative order, and constitute real additions to our knowledge. In them, as in all his work, we find the qualities of careful and accurate observation, and fine judgement and criticism, whilst his writing possessed marked literary charm. His removal by death when at the zenith of his powers, means a great misfortune to the cause of medical education and pathological science in Egypt. Few are privileged to win the affection and esteem of their fellows to such a degree as Ferguson did. He was a man of straightforward simplicity of character and of unusual charm; modest, gentle, and courteous, he was at the same time immovable in resolve when he considered a question of right involved, and while he applied severe standards to his own conduct, he was always indulgent where the failings of others were concerned. He had a keen interest in, and great enjoyment of life in its many aspects, a rich fund of anecdote, and a marked trait of quaint humour; all these enhanced

² *Proc. Roy. Soc. Med.*, vol. xii (Section of History of Medicine); and *Medical Press and Circular*, November 19th, 26th, and December 10th, 1919.

the pleasure of intercourse with him. But above all, it was the character of his life and his bigness of heart which endeared him to his compeers. His memory will always be cherished by those who had the advantage of his friendship.

Professor W. H. WILSON, of Cairo, writes:

The unlooked-for death of Alexander Ferguson at the comparatively early age of 49 is a loss to the Cairo School of Medicine which it will be difficult to repair; it takes place at a time of reconstruction and evolution when a man of his knowledge, geniality, and experience could ill be spared.

During the past nine months, when the measures for the reorganization of the school have been under discussion and illness made his attendance at the meetings of the School Council impossible, we have constantly felt how much might have been gained from his insight and strong common sense. By his friends and colleagues his loss is doubly deplored; none could fail to be attracted by the modesty, kindness, and humour which characterized his personality, or fail to admire the technical ability and wide knowledge of morbid anatomy, the subject in which he was really eminent, which he acquired in his close association with Coats and Muir, with both of whom he formerly worked for some years as assistant. In 1906 W. St.C. Symmers left Cairo for Belfast, and Ferguson was selected from a considerable number of candidates for the Professorship of Pathology at the School of Medicine, Kasr-el-Aini. The appointment was determined by the number and varied nature of Ferguson's published papers and the brilliant testimonials to his capacity as a teacher which he received from those who knew him. In addition to his teaching work he acted as pathologist to the hospital. He was constantly engaged in research, but the large amount of routine work attached to his post, combined with ill health, which his colleagues could not fail to notice but which he himself persistently refused to acknowledge or give way to, accounts for the fact that little of his work was published between the years 1907 and 1915, when his military duties gave him no further chance of scientific work.

Three papers may be referred to illustrating the type of scientific work to which he gave his time: "An account of a form of splenomegaly with hepatic cirrhosis endemic in Egypt," in collaboration with H. B. Day, M.D.Lond., *Annals of Tropical Medicine and Parasitology*, vol. iii, No. 3, November, 1909; "Parasitic granuloma," in collaboration with Owen Richards, F.R.C.S., M.Ch.Oxon., *Ibid.*, vol. iv, No. 2, July, 1910; "Lesions of bilharzial disease," *Glasgow Medical Journal*, January, 1913.

Ferguson recorded in the second of the above papers the discovery of the *Leishmania tropica* in the peculiar circumscribed epidemic papillomata of the disease, an observation of some significance in relation to the condition described in the first paper and the possible occurrence of kala-azar in this country. The third of these papers is a very brief and partial account of the mass of investigation Ferguson carried out on this disease.

It was to the subject of bilharziosis that he devoted most of the time he could spare for research. The unique collection of specimens prepared by him from the rich *post-mortem* material now in the pathological museum of the school is evidence of the interest he took in a disease in regard to the morbid anatomy of which he was the recognized authority. It is a matter of profound regret that much of his work must remain unrecorded; fortunately he was able to contribute the pathological section of the chapter on bilharziosis in Byam's *System of Tropical Medicine* (in the press).

Many of Ferguson's observations may also be found in F. C. Madden's *Surgical Diseases of Egypt*. His opinion, which I cannot find recorded, but which I recollect his expressing in a paper read before the Cairo Scientific Society some years ago, that the travelling of the ova through the tissues to the mucous surfaces was due to the excretion by the myracidium of a digestive enzyme, which softened the tissues in the path of the ovum, is of considerable interest and is perhaps supported by the eosinophil character of the surrounding leucocyte invasion.

Probably the most difficult task he carried out was the compilation of the admirable descriptive catalogue of the pathological collection attached to his department.

In the autumn of 1915 Ferguson received a commission with the rank of major in the R.A.M.C. This rank he retained, although for the greater part of the time carrying out the duties of a consultant, until the end of his service in 1919. The first duty he took over was that of Director of the Central Laboratory for the Alexandria District at

No. 21 General Hospital. His success in co-ordinating the work of the various laboratories in that district led to his being given the task of directing the work of the bacteriological and other laboratories attached to all hospital units with the Egyptian Expeditionary Force. This took him to Kantara and eventually to Palestine and Syria; there is little doubt that the hardships and exposure to which he was inevitably subjected aggravated a latent weakness of the lungs and was responsible for the condition which eventually carried him off. In November, 1918, he was appointed to direct the Pathological Section of the Commission to inquire into the incidence of Pellagra among the Turkish prisoners of war in Egypt. The work of this Commission was crowded into a short two months, and the share of it which fell to Ferguson was far too strenuous for his failing health. For his services he received the Order of the O.B.E.

Late in May of 1919 he went on leave to England. The state of his health, overfatigued by the voyage home, gave great anxiety to his friends on his arrival in Scotland. During the next six months considerable improvement took place, and in December he thought himself fit to return to his duties at the Medical School in Cairo. A chill taken on board ship during the journey gravely aggravated his condition, and he arrived in Cairo suffering from severe bronchial trouble. After two months' illness he passed away quite suddenly while reading in bed at 8 p.m. on February 22nd, the cause of death being heart failure. No one could wish for a more peaceful end.

He leaves a widow and two sons of 6 and 7 years of age, at present at school at Dollar, N.B. His family have the sympathy of all his friends. The funeral, which took place next day, was attended by a great part of the British colony in Cairo and many of his old students.

The Services.

DEATHS IN THE SERVICES.

MAJOR NORMAN SEPTIMUS WELLS, I.M.S., died in the Middlesex Hospital on April 20th, aged 43. He was born on December 22nd, 1876, educated at Edinburgh, where he graduated M.B. and B.Ch. in 1900, and entered the I.M.S. on January 29th, 1901, attaining the rank of major on July 29th, 1912. Before the war he was in civil employ in the United Provinces, but rejoined the army for military duty, and served throughout the war, being mentioned in dispatches in the *London Gazette* of July 13th, 1916, and receiving the O.B.E. on June 3rd, 1919.

Universities and Colleges.

UNIVERSITY OF GLASGOW.

At the graduation ceremony on April 20th the following degrees were conferred:

M.D.—Daisy A. M. Clark (Mrs. Gale).
D.Sc.—Dr. John W. McNece, Dr. John B. Orr.
M.B., Ch.B.—J. W. S. Blacklock, A. D. Brown, *P. A. Mackay, R. G. Howat, A. M. Benton, A. K. Pegg, R. R. S. Bowker, Annie B. Cameron, J. P. Chisholm, G. M. Cooper, W. N. Duguid, R. Fletcher, T. Fletcher, R. A. Forsyth, T. D. Hunter, G. Jamieson, Chung U. Lee, B. Levine, A. M. C. Macintosh, W. McKendrick, J. M. K. Maxton, J. S. Meighan, Marjorie Mitchell, T. F. Noble, P. C. Rankin, R. S. Reid, J. Sachs, Marguerite L. Sclanders, Cecilia Siskin, T. S. Stirling, A. Strang, H. A. Summers, J. L. Turpie, J. D. Williamson.

* With commendation.

† With honours.

The Bellahouston Gold Medal for eminent merit in thesis for M.D. has been awarded to Dr. Harry S. Hutchison, and Dr. R. T. Leiper has been awarded the Straits Settlements Gold Medal in tropical medicine.

The Asher Asher Gold Medal in laryngology and rhinology has been conferred upon Mr. James N. Tennent.

In the notice of the annual report of the Medical Department of the Local Government Board for 1918-1919, published on January 31st, 1920, p. 164, attention was directed to the disquieting remarks made by Dr. A. W. J. Macfadden, C.B., in the section dealing with the work of inspectors of food. This part of the report is now published separately by H.M. Stationery Office, and can be obtained, price 3d., through any bookseller. In it the insanitary condition of many private slaughterhouses is described, the inadequacy of existing arrangements for their inspection pointed out, and important recommendations for their improvement made.

DR. THOMAS LEWIS has in the press with Messrs. Shaw and Sons a volume on *The Mechanism and Graphic Registration of the Heart Beat*. It is an enlarged and revised edition of his earlier volume entitled *The Mechanism of the Heart Beat*.

Medical News.

ON the evening of presentation day at the University of London (Wednesday, May 19th) a graduation dinner will be held at the Guildhall; it will be attended by the Lord Mayor and Sheriffs in state, and the President of the Board of Education intends to be present. The graduation ceremony will take place in the afternoon at the Albert Hall. This is, we believe, the first occasion on which a graduation dinner has been held.

SIR JAMES CRICHTON-BROWNE, M.D., F.R.S., will deliver the first Maudsley memorial lecture before the Medico-Psychological Association of Great Britain and Ireland. The lecture will be given on May 20th at 3.30 p.m. at the house of the Royal Society of Medicine, 1, Wimpole Street, W.

ON Wednesday next, May 5th, at 5 p.m., Dr. W. Blair Bell, gynaecological surgeon to the Royal Infirmary, Liverpool, will deliver a lecture on the surgical treatment of prolapse of the uterus and vagina at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1. All members of the profession are invited to attend.

A MEETING of the Medico-Legal Society will be held to-day (Friday, April 30th) at 8.30 p.m., at 11, Chandos Street, W.1, when a paper will be read by Dr. Mackenzie Wallis, lecturer in chemical pathology, St. Bartholomew's Hospital, on the purity of ether and chloroform in its relation to anaesthesia. Dr. Bernard H. Spilsbury will exhibit specimens.

IT is proposed to commemorate the opening of the 48th General Hospital, Salonica, by a dinner in London on June 24th. Officers who have been connected with the unit and wish to take part are requested to communicate with Mr. B. Holroyd Slater, F.R.C.S., St. Luke's Hospital, Bradford.

A THIRD post-graduate course of instruction in the diagnosis and treatment of venereal disease is being arranged by Mr. K. M. Walker at St. Bartholomew's Hospital Clinic, Golden Lane, E.C., established by the Corporation of London. The course will be held on Thursday afternoons, at 5.30 p.m., commencing May 13th. In addition to work in the out-patient department the beds attached to the clinic are available for the reception and study of suitable cases. There are still a certain number of vacancies. Any medical practitioner wishing to attend is invited to send his name to the Secretary, National Council for Combating Venereal Diseases, 81, Avenue Chambers, Vernon Place, Southampton Row, W.C.1. (Telephone: Museum 2432.)

THE Lord Mayor will preside at a meeting to be held at the Mansion House on May 11th at 3 p.m. for the purpose of bringing before the Lord Mayors and Mayors of the country the objects and scope of the People's League of Health.

RULES (No. 560, price 1d.) have been published by the Minister of Health for the procedure to be adopted when a local authority has refused permission to demolish a house, and the owner wishes to appeal to the tribunal established under Section 5 (2) of the Housing (Additional Powers) Act, 1919.

IT is proposed to hold a reunion dinner for officers who were attached to No. 2 British General Hospital, Mesopotamia. Officers are requested to communicate without delay with Dr. Urban Marks, 1, Trinity Place, Swansea.

SIR ARTHUR NEWSHOLME, who has returned from America, has in the press a volume of American addresses on Public Health and Insurance, which will be published by the Johns Hopkins University Press.

AT a special general meeting of the Röntgen Society to be held at 11, Chandos Street, W.1, on May 4th, at 8.15 p.m., a proposal will be submitted to raise the annual subscription of ordinary members from £1 1s. to £2 2s.

WE learn from the *Journal of the American Medical Association* that under the new internal revenue regulation relating to the supply of alcoholic liquor to doctors in the United States, it is necessary for those who desire to purchase or prescribe such liquors for their patients to procure a permit. The permit allows the prescription of liquor for medicinal purposes only. A doctor is also allowed to purchase not more than six quarts of alcoholic liquor during any calendar year for professional purposes only.

MR. H. E. POWELL, for some years sublibrarian, has been appointed librarian to the Royal Society of Medicine, in succession to Mr. C. R. Hewitt, who, as was recently

announced, has been appointed librarian to the League of Red Cross Societies. Mr. Powell first joined the staff of the library as a pupil about eighteen years ago, and has earned his promotion by making himself thoroughly acquainted with the contents and purpose of the library and placing his knowledge at the disposal of readers.

DR. RUSSELL WELLS, Vice-Chancellor of London University, presided over the medical missions meeting held on April 21st in connexion with the 219th anniversary of the Society for the Propagation of the Gospel. He deprecated the idea that medical missions meant the dispensing of so much medical skill on the understanding that the recipients listened to so much teaching. It was the duty of Christians to distribute the great gifts which had come to them, not for the purpose of securing direct conversion, but as the natural overflow of a grateful heart; those who received the benefit of medical missions would regard a religion that prompted such altruism as something worth inquiring into. If asked to choose between a medical missionary one who had an indifferent knowledge of medicine but had the gift of preaching, or one who knew medicine well but had no such preaching gift, he would unhesitatingly prefer the latter. It was stated at the meeting that more medical men were badly needed in the fields covered by the operations of the society, especially at Singapore and Malacca. Medical men attached to the society are taking part in medical education at Peking and Tsi Nan Fu. The income of the medical missions department of the society last year was £15,178.

A LETTER, signed by Lord Willoughby de Broke, Sir Bryan Donkin, Sir W. Arbuthnot Lane, Sir James Crichton-Browne, and Dr. H. Wansey Bayly, has been addressed by the Society for the Prevention of Venereal Disease to county councils, county boroughs and municipal boroughs, and to medical officers of health throughout Great Britain. In this communication allusion is made to the serious effect of venereal disease on the national health and to the misery and suffering of which it is the cause; at the same time it is declared that "the clearest and most definite evidence exists to show that venereal diseases can be readily prevented by the adoption of immediate disinfection after exposure to infection." The society states that its members favour all measures which, by promoting a higher standard of morality, tend to prevent the spread of venereal infections, but realize that there will always remain a large class who will continue to practise promiscuous intercourse. The policy of the society is stated to be purely educative; the authorities are not asked to provide "packets" or anything of that kind, but to issue advice in the same way as about tuberculosis and influenza, pointing out how persons should protect themselves against venereal disease.

IN consequence of the general increase in masters' salaries and in the cost of living, as well as in order to provide alterations in masters' superannuation grants on the lines of the Superannuation Act of 1918, the Council of Epsom College have been compelled to increase the school fees as from September next for all boys, whether entering the school for the first time or at present there. The fees have been increased for the sons of medical men from 70 guineas to 100 guineas; for lay boys from 80 guineas to 120 guineas, and for day boys from 25 guineas to £40. The Council felt that it had no alternative but to make these increases, as the loss on the working of the school for the past year amounted to £3,779 15s. 10d. The charitable contributions in aid of the foundation cannot of course be expended in defraying any of the expenses of the school beyond paying for the education of foundationers.

THE legislature of South Carolina has passed a bill framed by the State Medical Society requiring all "chiropractors, osteopaths, and other healers" to submit to examination before the State board of medical examiners.

THE Surgeon-General of the United States Army has asked for a grant for the publication of the medical and surgical history of the war. Much of the material for this history, *The Journal of the American Medical Association* states, is already collected and its publication depends on the action of Congress. The first portion of an unofficial history of the Canadian Army Medical Corps appeared at the end of 1918, and the German history, in nine volumes, is promised this year. Our contemporary emphasizes the importance of prompt publication of records which have so great scientific and historical value, and trusts that there will be no repetition of the twenty years' delay which followed the War of the Rebellion. Considerable progress has already been made with the British official medical history of the war, of which Major-General Sir W. G. Macpherson is Editor-in-Chief; the offices are at Stanhope House, Kean Street, Kingsway.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Meliscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Burellas, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

P. Q. R. has hitherto deducted two-thirds of the rent of his house from his gross receipts for the purpose of his income tax return. What will he be able to deduct if he buys the house?

* Two-thirds of the amount on which he pays income tax plus two-thirds of general expenditure on repairs, redecoration, etc. The fact that he may be forced to purchase the house for a larger sum than might be considered reasonable in less abnormal circumstances does not affect the question, but the realization of investments for that purpose of course will reduce his private income and *pro tanto* the tax payable thereon.

O. R. J. L. inquires as to the possibility of claiming repayment in respect of the right of being charged at the "service" rate of tax.

From the figures supplied it would seem that the two sums £19 0s. 3d. plus £2 2s. 4d., or £21 2s. 7d., together make up the correct liability for the financial year ending April 5th, 1919. Assuming that the £13 5s. 6d. represents the tax paid for the period from September 12th, 1917, to April 5th, 1918, and that our correspondent had no other source of income during the year ending at the latter date, she would apparently be entitled to repayment of rather more than £10. The claim can be put forward on Form No. 40, to be obtained from the office of the local inspector of taxes. We may perhaps add that in allocating the various payments of tax, O. R. J. L. has been misled by the due "date of payment"; all income tax assessments are made in respect of financial years ending on April 5th.

ANAESTHESIA IN EPILEPTICS.

DR. G. W. HASSALL (Assistant Anaesthetist to the General Hospital, Birmingham) writes: A few years ago I had a case in which epilepsy made itself manifest during anaesthesia. The operation was for acute appendicitis with complications in a girl about 7 years old and lasted about half an hour. The child was in deep chloroform anaesthesia and the peritoneum had just been opened when clonic spasms occurred chiefly in the muscles of the extremities. They lasted a few seconds. The breathing was embarrassed and some duskeness resulted, but the operator was able to proceed. When the appendix was found another attack occurred. I then changed to open ether, but before ether anaesthesia was fully established there was another attack. After this the child was kept deeply under ether and everything went smoothly. The child had a history of epilepsy. I have had a few other epileptics through my hands, but in them nothing peculiar happened although ether was given part of the time.

LETTERS, NOTES, ETC.

A WARNING.

SIR ALFRED KEOGH, G.C.B. (Rector Imperial College of Science, South Kensington) writes: It has come to my knowledge that at various times and places a person falsely representing herself to be a near relation of mine, has imposed upon members of the medical profession and others. I shall be glad if you will allow me to call the attention of the profession to this imposition, and I shall be obliged if reference be made to me in future attempts.

BLIND MASSEURS.

SIR ARTHUR PEARSON, Bt., G.B.E., Chairman, Blinded Soldiers' and Sailors' Care Committee, writes: Will you allow me to draw the attention of your readers to the fact that at the recent examinations of the Incorporated Society of Trained Masseurs, which are known throughout the world for their completeness, Cpl. Herbert Vickers, a blinded soldier of St. Dunstan's, passed first in all subjects. That this was no mean accomplishment may be judged by the fact that there were nearly three hundred entrants for this examination. Of these less than fifty per cent. passed, while of the sixteen St. Dunstan's entrants, of whom Cpl. Vickers was one, fifteen passed, nine being amongst the first twenty-six on the Pass List, and the one failure was accounted for by the fact that the unsuccessful candidate had for some weeks before the examination suffered severely from neuralgia, which had almost entirely robbed him of sleep.

T.F. AND S.R.

EX-T.F. MAJOR writes: "Optimist" (April 24th, p. 593) appears in doubt as to how he can "get out" of the T.F. or S.R. I have recently left the T.F. by writing to the Secretary, War Office, asking that I be permitted to resign my commission. The reply was: "... I am to add that resignations can now be accepted, and a notification resigning your commission will appear in the *London Gazette* at an early date." I write this in case the information should be of use to any of your correspondents. I may add that after serving as Volunteer or Territorial from 1907 until now I am so thoroughly disgusted with the inconsiderate treatment meted out to me by the authorities that I shall make no attempt to assist in the reconstruction of the T.F. It appears to me high time that medical and other professional men should make it abundantly clear to the authorities that reasonable treatment must be guaranteed before busy men will give their spare time to covering up the deficiencies of our system of national defence.

SUDDEN DEATH AT ATTEMPTED ABORTION.

DR. A. C. GEMMILL (Brighton) writes: In a recent criminal trial the question was raised whether attempted abortion could cause sudden death. I came across to-day in an old volume of the BRITISH MEDICAL JOURNAL a reference to this subject. It occurs in the *Epitome of Current Medical Literature*, BRITISH MEDICAL JOURNAL, June 14th, 1913, p. 94. From this it would appear that such sudden deaths do occur.

ANTISCORBUTIC LEMON JUICE TABLETS.

THE work at the Lister Institute having shown the futility of the issue of ordinary lime juice as previously supplied to the navy as an antiscorbatic, Surgeon Captain P. W. Bassett-Smith, C.B., C.M.G., carried out experiments at the Royal Naval Medical School, Greenwich, in order to devise a method of preserving lime juice in a convenient and active form. In the method of preparation eventually devised heat is not used, and an efficient portable and palatable compound, rich in antiscorbatic vitamins, is obtained; when tested on guinea pigs it was found to retain its potency at ordinary temperatures. The method used is as follows: "The juice is roughly filtered through muslin, and then through filter-paper under reduced pressure. The filtered juice is evaporated *in vacuo* over sulphuric acid at ordinary temperature (15 °C.). The residue of non-crystallizable syrup is worked up into as stiff a paste as possible with a mixture of anhydrous lactose 97 per cent., and gum tragacanth 3 per cent. The paste is cut into sections, each containing the juice of half a lemon. These are rolled, faced with the mixture, and pressed to assume the lozenge form."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 39, 40, 44, 45, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 41, 42, and 43.

The following appointments of certifying factory surgeons are vacant: Tarbert (Argyll), Yatton (Somerset).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

THE TREATMENT OF ECLAMPSIA BY TRANSFUSION OF BLOOD.

BY

W. BLAIR BELL, B.S., M.D.LOND.,

GYNÆCOLOGICAL SURGEON TO THE ROYAL INFIRMARY AND LECTURER ON CLINICAL GYNÆCOLOGY IN THE UNIVERSITY OF LIVERPOOL.

ECLAMPSIA is a very grave condition, both to the mother and child. According to statistics, the maternal death rate varies from 20 to 30 per cent., and in regard to the child the mortality is between 35 to 50 per cent. Yet, in spite of many investigations, we seem to have discovered no specific method of treating the condition once convulsions have occurred. We are not even sure that much can be done in the way of prophylaxis, for we do not know how many of the cases of toxic albuminuria of pregnancy that are carefully treated would have terminated in the eclamptic state.

I shall not discuss the methods of treatment usually adopted. I wish to consider only the question of blood transfusion in eclampsia.

Attention has lately been directed in a leading article in the BRITISH MEDICAL JOURNAL¹ to certain recent immunological investigations. In 1911 Dold² showed that saline extracts of many viscera contain a toxin, lethal to animals, which is completely neutralized by normal blood serum. To this toxin he gave the name "*Organgift*." The nature of the substance has, however, not yet been determined, although many investigations have been made. Obata,³ following the work of Dold and others, has recently made an important contribution to the subject from an obstetrical point of view. This investigator has found that, when an extract of fresh human placenta is injected into mice, symptoms resembling those of eclampsia are produced, and that there is no difference between the toxicity of the extract of placenta from a normal case and that of the extract of placenta from a case of eclampsia. Further, Obata observed that fresh serum from the blood either of a normal person or of an eclamptic patient produces similar symptoms in mice, but no increase in toxicity was noted in regard to the serum of eclamptic patients. When, however, the extract of placenta was mixed with serum from a normal person—and it was found that sex and pregnancy did not affect the issue—the toxins of the placental extract and also apparently of the serum were neutralized; but, on the other hand, the serum from the blood of an eclamptic patient failed to neutralize the toxin of the placenta.

It appears, therefore, that there is some substance in normal blood that neutralizes the toxin of the placenta, and it seems curious that this is present in the blood of males as well as females, until we remember that the fetus is the product of the male no less than of the female.

On thinking over these facts when faced recently with a serious case of eclampsia, I determined to try the effect of blood transfusion, in the hope of introducing an antitoxin into the maternal blood stream. The result was so satisfactory that I have ventured to bring forward the case, although a single one, especially as the treatment of it was based on experimental findings. I would have preferred to wait, but as it may be some time before I have a further opportunity of testing it, and as no harm can result from the treatment properly carried out, I think it only right that the method should have a proper trial at the hands of others, in order that we may know whether blood transfusion may be regarded as a reliable method of treatment.

Abstract of Notes of the Case.

Mrs. E. T., aged 24, a primigravida, in the ninth month of gestation, consulted Dr. D. R. Evans on April 15th, complaining of recurring pains in the back, and pain on micturition. Dr. Evans examined her urine and, finding a large amount of albumin, sent her home to bed. He saw her the following evening, when he found that labour pains had commenced at 5 p.m., and that she had had a "fit." He then administered hypodermically morphine gr. $\frac{1}{4}$. Other "fits" followed at hourly intervals.

She was admitted to the Liverpool Royal Infirmary at 9 p.m., and was then conscious and rational. A catheter was passed, but no urine was obtained. The eyelids were slightly oedematous. Another convulsion soon occurred, and following this she remained oblivious of her surroundings. I saw her at

10.30 p.m. She was struggling during labour pains, but, otherwise, was indifferent to what was going on. Owing to her restlessness a proper abdominal examination was impossible, but *per vaginam* a fetal head could be felt lying low in the pelvis. I hoped, therefore, that the child would soon be expelled. Another severe convulsion occurred at 11.30 p.m. After this she remained semicomatose. She was then placed under light ether anaesthesia and removed to the theatre, where I delivered with forceps, and without difficulty, twins—a boy and a girl, weighing respectively 5½ and 4½ lb. The cords were pulsating feebly when the infants, in a state of "white asphyxia," were born; but it was impossible to stimulate respiration. The patient remained semicomatose and restless all night. At 5.30 a.m. another convulsion occurred, followed by a very severe one at 6 a.m. The patient remained cyanosed; 20 c.cm. of urine loaded with albumin was obtained by catheter.

The house-surgeon now opened a vein in the arm, but was unable to bleed the patient, as directed, while saline infusion was being introduced. A quantity of saline solution was, however, run into the vein. I received a message at 8 a.m. to say that the patient appeared to be dying, and that she was more deeply comatose. I saw her as soon as possible (10.30 a.m.), and found her lying quite still, almost completely comatose; her face was of a yellow colour, and her pulse was very soft and feeble. I determined then to try the effect of blood transfusion, and was fortunate enough to obtain the assistance of my colleagues Mr. R. E. Kelly and Dr. Wallace Jones, who have had much experience in this procedure. The husband, a robust-looking young man, willingly consented to be the donor. His blood was found to be in Group IV, so 500 c.cm. were withdrawn into citrate solution from his median basilic vein. Approximately the whole of this was transfused into the median cephalic vein of the patient.

At 1.30 p.m. the patient looked better—the colour had almost immediately been improved by the transfusion; 60 c.cm. of urine, withdrawn by catheter, were found to contain acetone, and albumin to the extent of 12 per cent. The following estimate of the ammonia coefficient was made by Professor Ramsden:

Ammonia nitrogen	0.05 per cent.
Urea	0.48 "
Total nitrogen	0.23 "
Ammonia N } ratio	22.0 "
Total N					

A few hours later the patient was able to talk rationally; and when the house-surgeon made the evening round she discussed her condition, and said that she had no recollection of anything that had happened previously in regard to her confinement. In the sixteen hours subsequent to the blood transfusion 50 oz. of urine were secreted. A sample was then found by Professor Ramsden to contain "a small amount of albumin." Acetone was absent. The ammonia coefficient was estimated as follows:

Ammonia nitrogen	0.017 per cent.
Urea	0.75 "
Total nitrogen	0.35 "
Ammonia N } ratio	4.8 "
Total N					

In the next twenty-four hours 71 oz. of urine were secreted. Since then convalescence has been uninterrupted.

Should another case come under my care I shall perform blood transfusion immediately. It may be possible by so doing to save not only the life of the mother, but also that of the child. In such circumstances it would probably be necessary to repeat the transfusion at the end of parturition.

With regard to the method of transfusion employed in this case, citrated venous blood was used, and I noticed that some difficulty was experienced by the house-surgeon in shaking, and at the same time collecting, the blood from the vein, in the flask containing the citrate solution. I think that the blood might best be mixed with the citrate solution by allowing oxygen to bubble through the fluid; moreover, oxygenated blood would probably be better in all cases of transfusion than venous blood.

In conclusion, I wish again to emphasize the fact that this is only one case, and that no final judgement can be formed until many cases have been treated in the same way by competent observers and by those who have had some experience in blood transfusion and who are able to carry out the necessary procedures quickly and safely. It is unlikely that any treatment will ever be introduced which will ensure the recovery of every patient; but, if the present appalling maternal and fetal mortality can be reduced, something will have been accomplished. In those circumstances the preparation of a human antitoxic serum might be worth while in order to simplify treatment.

A Lecture

ON

PARTIAL PYLORIC OBSTRUCTION.

BEING AN ABSTRACT OF THE THIRD OF THE JAMES WATSON
LECTURES ON "SOME CHRONIC GASTRIC DISORDERS."*

BY

A. ERNEST MAYLARD, B.S.LOND., F.R.F.P.S.GLASG.,
F.R.S.EDIN.

CONSULTING SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

THE causes of pyloric obstruction may be primarily classified into anatomical and pathological; and the latter may be subclassified into (1) those dependent on inflammation and (2) those the result of new growths.

ANATOMICAL OBSTRUCTION.

Congenital Narrowness of the Pyloric Orifice.

This class has received but comparatively slight recognition, but I trust I may be able to show that it plays no inconsiderable part in the group of conditions that obstruct the gastric outlet.

At an early period of my work, when operating for obscure and intractable symptoms indicative of gastric derangements, I now and again encountered a condition of the pyloric orifice which I was at a loss to explain on any other ground than that the opening was too narrow to allow of a free and easy exit of the gastric contents; that this was the source of the chronic gastric disorder received confirmation from the fact that relief and cure followed on the operation of gastro-jejunostomy. After an experience of 7 cases I read a paper before the Clinical Society of London¹ entitled "Congenital narrowness of the pyloric orifice." Later, in another paper published in the BRITISH MEDICAL JOURNAL,² 12 other illustrative cases were given. Dr. William Russell³ of Edinburgh also contributed an exhaustive article on the subject, published in the same number of the JOURNAL, strongly supporting the view that I had promulgated, that such an anatomical condition existed, and accounted for the symptoms met with in certain classes of cases.

Before describing the particular features peculiar to this form of obstruction, I ought perhaps to state what may be considered the normal condition of the orifice as met with by the surgeon on the operating table. Under complete anaesthesia the gastric parietes are more or less flaccid. Externally the pylorus can usually be recognized by the somewhat deeper colour it presents in contrast to the neighbouring parts, and by the convergence of vessels, mostly veins, at its lower margin. Only the faintest constriction is, as a rule, visible, the duodenum often passing so imperceptibly into the stomach that it is only by the tactile sensation afforded by the sphincter and the distribution of the vessels that the exact seat of the pylorus is determined. There is no constancy in the amount of induration (if I may so express it) which the pylorus presents, a fact which seems to suggest that although the patency of the canal may be quite normal, there may be considerable differences in the developmental condition of the sphincter—differences possibly dependent on the same physical causes which may naturally affect other parts of the body. I have little doubt that this variation, when not taken into due account, has led to the difficulty experienced by some in determining whether the greater thickness met with in one case as compared with another is or is not due to some excessive hypertrophic or inflammatory cause. I am, however, convinced that the variation is quite normal, and may exist within considerable limits. Regarding the calibre of the pyloric orifice, I have always found that while the index finger passes easily, it has conveyed to it the sense of a uniformly narrow, elastic ring, which feebly embraces and rolls over the finger as it is gently pushed on into the duodenum. I should consider 12 to 15 mm. the normal calibre during life and under relaxation. If a section of the pylorus is looked at—such, for instance, as is given in *Quain's Anatomy*—a sensation such as that just described is what might be reasonably expected. A uniform ring-like projection of

mucous membrane is seen containing within its reduplicated folds bands of muscle fibre.

When, in my earlier cases, I first met with this abnormally narrowed condition of the canal, I was inclined to believe that, if not due to chronic spasm, it was the direct result of the stimulating and exciting influence evoked by the introduction of the finger into the pyloric orifice; that such an indigestible morsel as the index finger, so large, solid, and unfit to pass out of the stomach, was certainly likely to cause contraction of the pyloric sphincter whose chief function is to prevent all but the most efficiently peptonized food passing out of the stomach. However, I had on one occasion a very striking and informing illustration of what the parietes of the stomach and the pylorus are like under contraction. The stomach had been opened for inspection and partially withdrawn from the abdomen with the pylorus in view. The patient seemed somewhat suddenly to come out of the anaesthetic, when a violent contraction of the gastric parietes took place, causing a little of the clear fluid in the stomach to be forcibly spurted out. Immediately there followed contraction of the pylorus, which assumed the appearance of a rigid structure about 2 in. in length, and about the circumference of the ring finger. As the patient again came under the influence of the anaesthetic the parts relaxed; and it was under this relaxed state that I felt a narrow, uniform, ring-like constriction of the pyloric aperture incapable of admitting the apex of the index finger. It was the information gained in this particular case that led me first to doubt whether these narrowed orifices could be the result of a chronic spasmotic condition, and to suspect that they owed their existence to some abnormality in development rather than to any acquired cause.

As to the nature of this abnormality, I am inclined to regard it as due to an excess of reduplication of the pyloric fold, whereby the width of the valve is increased, but the calibre of the canal proportionately diminished; that it is, therefore, purely anatomical and congenital in origin. Such a definition entirely fits the facts revealed in the cases met with, for the obstruction was always perfectly uniform, and simply gave the impression that the orifice was abnormally small; the smaller it was the greater the resistance it offered to the introduction and passage of the finger. Further, it should be emphasized that the resistance was in no sense like that encountered as the result of cicatrization. That, as is well known, rarely gives way, except as the result of a certain amount of laceration of newly formed tissue; while, in the majority of these cases—the exception being those of a very high degree of narrowing—the ring gradually dilates, and uniformly stretches over the advancing finger.

If I have been right in the construction I have put forward regarding the nature and origin of this narrowing of the aperture, it is possible to conceive how we may have, solely as the result of development, any calibre of the pyloric orifice between that which we regard as normal and that which will admit only a small sized—say No. 6—ordinary urethral catheter.

I ought to say, before proceeding further, that, although ignorant of the fact when I first met with the condition just described, subsequent investigation has brought to my notice the description of this same appearance of the part by others. Landerer (quoted by Maier⁴) some years ago seems to have been the first to draw attention to this simple narrowing of the pylorus unaccompanied by any marked thickening or other changes connected with the part. Maier discusses this congenital abnormality; his cases, numbering twenty-one, were necropsies on patients who had died mostly from other causes than those in any way associated with the gastric condition. For some years, therefore, the possibility of chronic gastric disorders in the adult dependent on this particular kind of narrowing of the pyloric aperture has been recognized; but it is only comparatively recently, since the stomach has been explored by the surgeon, that the cause and its effects have come to be more exactly noted, and still further treated. The subject is briefly referred to by Mayo-Robson and Moynihan in their book,⁵ where a very typical case illustrative of the condition is recorded.

If further support of the opinions expressed were needed I think it is to be found in the unmistakable evidence generally acknowledged to exist in some other parts of the

* Delivered before the Royal Faculty of Physicians and Surgeons of Glasgow, March, 1920.

body possessing somewhat similar functions. Thus, there are distinct variations in the calibre of the ileo-caecal orifice; and William Mayo⁶ has reported cases he has operated upon in which an abnormal narrowing of the passage between the ileum and the caecum has been the cause of constipation. No evidences of disease of any kind were discoverable to account for the smallness of the valvular aperture; presumably, therefore, the condition had to be regarded as one due to defective development of the ileo-caecal valve. The uterine cervical canal affords yet another analogy, for the passage may be congenitally narrow and prove obstructive to the easy and unimpeded flow of the menses. It is not, perhaps, overstretching the comparison to indicate the great differences that exist in the size of the oral aperture, and in the width of the palpebral fissure, not that any undue smallness of either of these apertures is any impediment to the particular part each has to play in the human economy, only they serve to show, from the obvious natural existence of developmental variations, that any such defect at the pyloric aperture is a perfectly reasonable assumption.

Hypertrophic Stenosis of the Pyloric Orifice.

Occupying a somewhat dubious position in the matter of its cause or origin is hypertrophic stenosis of the pyloric aperture. Although a condition most frequently met with in early life, it is not entirely confined to this period, as cases are occasionally encountered in the adult; and I have myself met with two unmistakable illustrations. Maier⁴ fully established its existence in later life in some of the cases he describes. Others, too, in this country, among whom may be specially mentioned Clinton Dent and E. Cautley,⁷ have likewise confirmed the existence of this particular form of obstruction in the adult.

PATHOLOGICAL OBSTRUCTION.

1. Chronic Ulceration.

Of all the causes that give rise to obstruction none are so frequent as those which arise from chronic ulceration of the non-malignant type. The obstruction is partly due to cicatricial contraction, but more often it is the result of the inflammatory thickening associated with the active spread of the ulcer. So great sometimes is this hard, more or less oedematous mass, that it is mistaken for a malignant growth.

The variable phases of the pathological aspect of the subject all have their bearing on the multiple manifestations which the lesion may present. For, as will be pointed out, it is the capacity or incapacity of the stomach to overcome the obstruction with ease or with difficulty that leads to the many complexities in symptomatic manifestations which so frequently complicate the diagnosis of this particular class of cases.

2. New Growths.

The new growths which may cause obstruction are both malignant and innocent. The latter may be briefly dismissed with a few words. Occurring on the inner surface of the stomach close to the pylorus, they may block the aperture like a ball-valve. External pressure is another rare cause of obstruction, and may be due to a distended gall bladder or a mass of enlarged glands over the head of the pancreas. By far the commonest form of new growth is carcinoma. This may commence in the walls of the canal, or be the result of invasion from without.

SYMPTOMS.

As regards the symptoms of pyloric obstruction, it will simplify matters very materially if we first consider what are likely to be the natural physiological and pathological sequences of any hindrance to the escape of the contents of the stomach into the duodenum. I do not intend to continue the discussion into a consideration of those advanced cases in which there is no difficulty in diagnosis—where, for instance, we have all the signs of a stomach that occupies a considerable portion of the abdomen, holds several pints of fluid, and retains so much of the food taken that the patient occasionally vomits a "basinful" or a "chamberpotful" of sour, incompletely digested, porridge-like material containing fragments of food taken several hours or days before. Fortunately we rarely see these advanced cases now. It is not, then, with the symptoms of this type of case that I propose to deal, but

with those in which the stomach is still capable of overcoming the obstruction, though with variable degrees of success. For want of a better and more accurate term to apply to these cases they may be designated cases of partial pyloric obstruction. It is the variability of the amount of obstruction that constitutes the difficulty so frequently encountered in diagnosis.

If we consider the possible physiological effects of obstruction at the gastric outlet—and by this it must be understood that not only the pylorus itself, but the parts of the canal both in front of and distal to it are included—it will be clear that the organ first to be affected will be the stomach itself. Whatever be the relative importance of the different functions of the stomach, it is certain that nothing can take the place of the motor function; and the contents of the stomach—however much they may be acted upon, whether sufficiently or not, by the gastric juice—must be propelled out of the viscus by the contraction of the muscle tunics. Thus, then, it may be reasonably assumed that the primary effect of obstruction will be to place increased work upon the muscle layers; and the amount of work which they are called upon to perform will be in direct proportion to the amount of obstruction that they have to overcome. It is more than likely that the increased pressure to which the contents of the stomach are subjected, in the greater effort of the organ to rid itself of its digested ingesta, may deleteriously affect the normal secretion of the gastric juice both quantitatively and qualitatively. But, however this may be (and possibly it is only a matter of moment in cases of considerable and prolonged obstruction), it is the effect upon the muscle tunics that determines the interesting symptomatic vagaries of the condition—the factor deserving of most attention.

Consider, for a moment, the parallel illustration of any voluntary muscle of the body which is called upon to undergo prolonged exertion. If the work to be done be of an intermittent type, the periods of rest and increased requirements lead to a compensatory development, which, up to a certain pitch, succeeds in accomplishing the ends required. If, however, there be no periods of rest interposed, weariness intervenes, and an entire failure of accomplishment ensues. Introduce another factor into the scheme—failure to supply the body with proper and sufficient nourishment—and muscle inertia will be rapidly experienced.

The stomach does for a time, and in direct proportion to the amount of obstruction it has to overcome, succeed in carrying out its normal functions. Its muscle tunics hypertrophy, and, in consequence, it is enabled to drive out its contents successfully; but, as time goes on, it becomes more and more susceptible to influences which may reach it either by way of the nervous system or the blood supply. Thus, causes of various kinds, which arise from nerve exhaustion or imperfect metabolism affecting the constitution as a whole, influence the struggling stomach in particular; muscle inertia then ensues, and instead of the viscus propelling its contents through the obstructed orifice, they remain, only in part it may be, pent up in the gastric cavity, awaiting the time when the muscle parietes shall have regained sufficient energy to effect total expulsion. The sequence of events, however, may not prove so simple as thus far they may appear. For when, for the reasons given, the stomach is unable to expel its contents, it may, though sheer weariness of effort, relax its endeavour and give way to passive dilatation. To what extent this may go, and how long it may last, will again depend on the nature and degree of obstruction, and the general physical state of the patient. Herein will be seen to enter the symptomatic vagaries of the disease; for there is no telling when the symptoms will subside, exactly why they should appear, and why they are of the nature manifested. And yet, taking these considerations collectively, they furnish the best clues to the nature of the complaint.

Let me now ask for a closer investigation into some of the symptoms which the above considerations naturally lead one to expect will at one time or another manifest themselves.

I. In the first place, there is usually nothing about the general appearance of the patients to suggest constitutional disease; in other words, the gastric symptoms appear to be solely dependent on the disturbances affecting the viscus itself; indeed, there is often an appearance

of health and robustness about them, and between their "attacks" they are quite well. In those cases where the patients are thin, it is not the thinness of constitutional disease, but simply an emaciation due to lack of sufficient nourishment.

2. The earlier history of the case will sometimes indicate that the initial symptoms suggested an active ulcerative attack; but often any such sudden onset is absent, and the symptoms begin and creep on quite insidiously. This is usually the course taken by that type of obstruction dependent on congenital narrowness of the pyloric orifice.

3. Exacerbation of the symptoms is engendered by anything that has an enfeebling effect upon the constitution. If from undue exertion, mentally or bodily, from worry or anxiety, the patient is reduced to a state below par, the same diminished sense of physical and physiological fitness is experienced by the stomach and renders it less capable of overcoming the obstruction.

4. It will nearly always be noted that while, at the onset, the attacks of dyspepsia are few and far between, they gradually increase in frequency; and as they become more frequent so they become more severe. This sequence of events is most suggestive, because it indicates two probabilities—one, an increasing narrowness of the pyloric aperture; the other, the increasing failure of the stomach to overcome the obstruction.

5. Physical examination is only of value as regards dilatation. And here it may be remarked that, as a symptom, no more importance should be attached to the absence than to the presence of dilatation; for while at one time the viscus may be able to overcome the obstruction, at another it may fail; but, notwithstanding its absence, the obstruction is there. Rather, therefore, should it be taken that its presence at one time and its absence at another is an indication of partial pyloric obstruction.

As a means to diagnosis the *x* rays and opaque meal aid us considerably; but, from all that has been said about the occasional power of the stomach to empty itself completely by overcoming the obstruction, it can be well understood how that sometimes an erroneous impression may be conveyed. If, however, the meal takes an unduly long time to pass out of the stomach, and the skiagram shows, in addition, some irregularity in the shape of the parts in the neighbourhood of the obstruction, the picture presented by the *x* rays will help to confirm the opinion which the symptoms have probably already suggested.

TREATMENT.

If surgery had done nothing more in the treatment of chronic gastric disorders than deal with this particular class of cases, it would have earned for itself a reputation beyond the power of words to express. I know of few patients whose existence may be more miserable, and who, when relief is afforded, become more happy.

The condition of partial pyloric obstruction can always be temporarily relieved by rest in its broadest sense and careful attention to diet; but, as the condition is dependent essentially on mechanical causes, it is only by mechanical measures that it can adequately be dealt with. With regard to operation, we have the choice of two primary procedures. One is to deal directly with the obstruction; the other, to leave the obstruction untouched and circumvent it by uniting the stomach to the bowel. As regards the first of these two procedures, much must depend upon the nature of the obstruction. If it be due to growth, removal if possible; if it be of an innocent nature and the part can be freely mobilized, gastroduodenostomy by Finney's method would appear to be better than either the Heincko-Mikulicz operation of pyloroplasty or pylorodiosis.

As regards the second of the two procedures, short-circuiting by the "no-loop" operation of gastro-jejuno-stomy is the sole method employed. Of all the operations for obstruction none have been more frequently executed than this. In my own wards, for instance, the operation has been performed by myself and by my assistant colleagues, Mr. Grant Andrew and Mr. Farquhar Macrae—now surgeons to the institution—428 times up to the end of 1919. Perhaps the best testimony that can be borne to the permanent good effected by the operation is to be found in the fact that, to my knowledge, there lives at the present day a female patient, perfectly well and engaged

in active work, whom I operated upon seventeen years ago; and another, a male, also quite well and driving a motor car, upon whom I operated nineteen years ago.

A Lecture

ON

HEART AFFECTIONS IN RELATION TO THE LABOUR MARKET.

DELIVERED DURING THE POST-GRADUATE COURSE AT THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART.

BY

R. O. MOON, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL.

DURING the war, and particularly in connexion with recruiting, doctors were continually having to estimate the all-round efficiency of a man as a fighting unit, quite apart from having to disqualify him for such obvious disabilities as flat-foot, hammer-toe, hernia, etc.

Into such an estimate the strength and general condition of the heart necessarily entered very largely, and indeed became one of the most important and difficult factors to appraise in deciding upon a man's category. Owing to the vast complexity of modern warfare, in which whole nations are, so to speak, in arms, there came to be numerous posts which could be filled by men who were very far from being A1 men.

In the fully organized army a constant process of sorting was always going on by which those with impaired efficiency were moved downwards into lower grades, while those whose efficiency had improved were moved upwards.

There is no reason why in civil life a similar effort, doubtless on a somewhat different system, should not be made for estimating the efficiency of a man in the labour market. The problem here is in one sense easier than in the army, in another sense more complex; for clearly a man might be A1 for his particular trade, but not A1 as an infantry soldier, on whom frequent calls for excessive exertion may be made at any hour of the day or night, so that many a man, though he might only be B1 or B2 from the army standpoint, might quite well be A1 in his own particular occupation, which did not call for such sudden and strenuous forms of exertion, though it could not in any sense be classed as "light work." To quote from American experience:

Throughout the war it remained a strange paradox that the "irritable heart of soldiers," which is a functional neurosis, where the heart is known to be intrinsically normal, should give rise to such pronounced cardiac symptoms, whereas the cases of valvular heart disease were so completely free from symptoms; in the "soldier's heart" anything approaching a normal heart rate even during rest is very unusual. It was generally found that mild cases of valvular disease in the army examinations showed a cardiac response well within normal limits and were remarkably free from subjective sensations, thus offering a striking contrast to the "effort syndrome" in which such symptoms are usually pronounced.¹

We want to consider this afternoon how far cardiac lesions, whether functional or organic, affect a man's chances of getting work in the labour market and to what extent they are actually prejudicial to him when he does get it.

The progress of modern medicine has stripped heart disease of many of its terrors simply by demonstrating that there are numerous organic affections of the heart which are compatible with a life of reasonable length and of a not too restricted activity. Still, for all that, one must realize that an organic disease of the heart is a handicap in the labour market, more especially as heart disease still connotes to the employer the idea of early and sudden death, as doubtless it did to the profession in the dim and distant past, for the ideas held by doctors in one generation become the *idées fixes* of the laity in the next.

Now it is, of course, quite obvious that patients suffering from a gross structural disease of the heart, such as mitral stenosis or aortic regurgitation, cannot safely be employed on really heavy work, though almost any doctor with much experience could produce an instance of someone who had done astonishingly heavy work in spite of one or other of these lesions. Patients with aortic disease are more likely to be unconscious of their cardiac ailment than are the subjects of mitral disease, in whom shortness of breath manifests itself sooner than in cases of aortic disease. But we must not be guided by exceptional cases, which make bad rules for medicine just as legal people say that "hard cases make bad law." On the other hand, to write down every cardiac case as fit for "light work only" is equally ill advised, at least if by light work we mean something mainly sedentary. The fact is that fairly hard work can be done by many people who suffer from heart disease, provided the hours are regular and the work more or less the same from day to day and hour to hour, while there is no undue sense of hurry in the doing of it. Anything in the nature of spurts, which may be almost an essential element in some occupations, though the work itself may not be so intrinsically heavy, should be strenuously avoided; thus, dockers are a good instance of an occupation which involves periodical rushes, with, it may be, unduly slack intervals, and that kind of thing is bad for almost any form of heart disease, and particularly for the older and casual workers.

A heart which has been badly damaged in early childhood must always be a source of anxiety, and in such cases we can seldom look forward to anything but quite sedentary work under the most favourable circumstances; the important thing is to decide early as to what sort of sedentary work the boy or girl should be trained for, carefully considering their individual proclivities. The heart, however, which is damaged by rheumatic fever after puberty in early adult life, if wisely handled at the outset, is often capable of a surprising amount of work, and it is these cases, especially of aortic disease, which are often able to carry on fairly hard work for a quite considerable length of time. In the case of mitral stenosis, on the other hand, decidedly less work can be expected from the heart, and it is well to remember the dictum of Huchard that in mitral stenosis we have a heart "*réglé pour un petit travail*."

But it is quite a different matter when we come to the case of men who seem to develop heart disease in or about middle life as a result of strain or lues. Such cases are nearly always progressive, and their value in the labour market is much inferior to that of those whom we have just been considering, where the lesion is due to rheumatism.

In particular it is true that cases with a history of lues can seldom be relied upon for any seriously continuous hard work, and the special liability to sudden death in these cases should never be forgotten. Doubtless it is this kind of case which has frightened employers, and as, of course, so often when sudden death occurs, the verdict brought in is that of "heart disease," all forms of heart disease become tarred with the same brush and all seem equally likely in the eyes of the employer to give rise to sudden death, so that they not unnaturally look askance at all cases suffering from heart disease, no matter what the cause may be.

Putting aside the grosser structural lesions of the heart there are all kinds of minor cardiac affections which, for want of a better term, might be grouped under the heading of "weak heart." These cases may, in many instances, be the result of some infective process, such as influenza, malaria, or indeed any febrile condition, and are not unreasonably described as "poisoned hearts," but in addition to this there would seem to be some people who are born apparently with subnormal cardiac power; fortunately there is not, as a rule, so much difficulty about these cases as regards occupation, for they, at the outset of their career, have insensibly drifted into quasi-sedentary occupations more or less suited to them, having instinctively recognized an inaptitude for much physical exertion, and it was cases such as these which, at the beginning of the war—perhaps not unnaturally—were passed into the army as A.I., and tended to swell later on the mighty host of D.A.H. patients to such formidable proportions. Many cases of this kind in which the nervous

system plays a part are undoubtedly benefited by occupation, and also by exercise within reasonable limits. There are, of course, symptoms apparently associated with the heart which do not necessarily arise from it, though it may be difficult to disabuse a patient of the belief that a pain in the left side and perhaps some shortness of breath is a sure sign of heart disease.

In civil life the doctor, except when definitely employed by the State, an insurance company, or some similar body, has primarily to consider the interest of the individual, but in reality the wider interests of the State and the individual are not so much opposed as might at first sight appear. Clearly it is not to the interest of the State or an employer to let themselves discard an efficient workman because he happens to have some disease of the heart—all the employers and the State require is to be protected against exceptional risks; on the other hand, the individual is benefited by finding a suitable employment. "There are positions in industry, in fact, in every plant of reasonable size, that people of varying substandard conditions of health and body can fill with efficiency to the profit of their employers and themselves."

The main thing to grasp, from the point of view of the labour market, is the importance of prognosis; with regard to this the ordinary stethoscope diagnosis does not help us much—we merely learn that there is or is not some structural disease of the heart; whereas what we want to know is the man's efficiency, and how far this structural disease should affect his chances of employment. No doubt a great study of the prognosis for heart cases has been made through insurance companies and much useful information has been acquired as to the expectation of life. But here it is purely a question of "How long the proposer is likely to live." We want to consider the more profound question: "In what way can he live with greatest benefit to himself and the community?" In what work can he most effectively engage or continue? Are there some trades which are more suitable for cases with heart disease than others? It would, of course, be easy to reply that cases with heart disease are best suited by clerical and sedentary work, and no doubt this covers a fair amount of the ground. But among the vast masses of the manual labourers there are many whose whole temperamental and psychic make-up, so to speak, is entirely unsuited for sedentary work. Then, again, a man may be working well but gets an attack of rheumatism which damages his heart: is he to give up his work? If really exceptionally heavy, he clearly must do so, but when a man has been at some occupation for several years, much of it which to a tyro would be heavy and difficult has to him by long practice become comparatively easy. The whole aim of industrial or occupational medicine is to find the square hole for the square man, and as this is particularly difficult to do with regard to heart disease we want to consider rather closely the various trades which would be most suitable for any particular cardiac lesion. Obviously the first thing to be considered is the man's own natural aptitude and inclination for any particular occupation. As a general rule it might be said that all work which puts a good deal of strain on the lower extremities is less unfavourable to cardiac cases than that in which the strain falls mainly on the upper extremities. Most forms of aortic disease and undoubtedly those of the degenerative type, appear to be very unfavourably affected by any work which involves even a moderate strain upon the arms, such as carpentering; and this is particularly the case when there is any suspicion of angina. Thus I had recently under my care at the hospital a young man with an aortic lesion. He worked in a "card-glazing" factory and was given the easiest work to do which they had; it consisted in pulling with the left hand quite a light lever, which set in motion the roller beneath which the cards were passed, but this continued pulling with the left hand, though the resistance was quite moderate, proved too much for him. Then, again, I recently saw a man who had been invalided out of the army with aortic disease, whose occupation was "pile driving"; now this is not heavy work, as it is done by a machine and only requires superintending; however, such work may involve going up a ladder to the height of 40 ft., and when he had to do this he would become giddy and be in danger of falling, so that this kind of work had to be abandoned.

To take a few trades which are usually classed as light work, and which are in most cases suitable for those who have compensated valvular lesions:

1. *Tailoring*.—As a rule, we are apt to associate this occupation with bad ventilation, but of course there is no reason why the ventilation should be bad, and during the past few years all factories have been greatly improved in this respect; still, owing to the very sedentary nature of the work, men easily feel the cold and want windows shut, so, to that extent, the ventilation is not such an easy problem. The work itself is in general light enough, the only heavy part being the ironing; the iron generally used weighs from 14 to 20 lb., and may sometimes weigh even as much as 30 lb. No doubt there is a great deal of knack in the use of these irons, so that the weight may not seem much to a man accustomed to the trade.

2. *Boot repairing* is another occupation which is not unreasonably classed as "light work," but here again the ordinary boot repairing known as "botching," as opposed to finer boot repairing, involves standing upright at the bench for long hours at a stretch, which of course puts a strain upon the circulation, and I have on several occasions met with men having compensated aortic lesions who had to give up this work owing to the long hours of standing required, though they might have done intrinsically harder work which did not happen to involve so much standing.

3. *Boot-making* is also classed as a "light occupation," and so it is; but it will be found unsuitable for most forms of heart disease, as it involves much use of the arms both in the hammering and wide stitching which nearly always puts a strain upon the heart; the posture of boot makers is also bad for all kinds of chest complaints.

4. *Basket-making*.—This might seem eminently suitable for those suffering with minor affections of the heart, but this will not always be the case, for there is a great variety in basket-making, which differs much in different localities, and the making of a large basket involves a wide extension of the arms, and so puts an undue strain upon the heart.

5. *Leather Work*.—Many kinds of light leather work are well adapted for most forms of heart disease, where the patient can get about easily, but for such occupations a man should be fairly handy and intelligent. Often a trade which seems quite light, and indeed is so in a general way, may incidentally involve quite heavy work. Thus, for instance, portmanteau sewing would seem quite suitable for many cardiac cases, but unfortunately it frequently involves having to lift heavy weights, so that one has been obliged to knock off a man from such work, though superficially it might seem entirely suitable.

6. *Scavenging*.—Then, again, one has met with scavengers for a borough council who could quite well do ordinary sweeping, but the extra exertion involved by "squeegeeing" when it has been specially wet unfits them for the job and they have it give it up.

Motor Driving.—The occupation of chauffeur is suitable for many varieties of cardiac lesion, provided there is an automatic starter, otherwise the cranking of the car may be a severe strain; and quite recently I had under my care at the hospital a man whose cardiac symptoms first dated from an occasion when he was cranking his car and he felt the strain to be excessive; in his case the lesion was myocarditis of luetic origin, and for such a man the occupation of chauffeur is quite unsuitable, as there is always in a case of this kind danger of sudden death.

As a general rule, dusty occupations, at least for mitral cases, should be avoided, as they induce coughs and catarrhs, so favouring bronchial congestion, to which patients with a mitral lesion are particularly disposed. Similarly, in advising upon any occupation it is important to consider whether it will expose the patient specially to vicissitudes of weather and sudden changes of temperature.

On careful inquiry it will often be discovered, particularly in towns, that it is not so much the work which is trying the patient as the fact that he lives at the top of some model dwellings, so that at the end of a long day's work he has to ascend an interminable flight of stairs; then, again, the main trouble may be the long journey to work, the catching of omnibus or train, and not the work itself.

With a certain amount of care and trouble in the adjust-

ment of occupation much more work can be got out of quasi-derelict hearts, to the great advantage of the community and the not less benefit of the individual patient.

CIVIL LESSONS OF THE WAR FOR THE TREATMENT OF FRACTURES OF THE SKULL.*

BY

C. M. KENNEDY, M.B.E., F.R.C.S.ENG.,

ASSISTANT SURGEON, SOUTH DEVON AND EAST CORNWALL HOSPITAL;
LATE MAJOR R.A.M.C.(T.C.).

At first sight it would not seem that gunshot wounds of the head could teach us any lessons of use in dealing with the ordinary fractures of the vault in civil life. Certain points in the treatment of fractures of the vault—none of them really new—have, however, been firmly established by experience in the war. On such of these as appear to be of use in civil practice I wish to touch.

The advantages of total excision of scalp wounds before dealing with underlying fractures were so firmly established during the war that this procedure is likely to become a routine instead of an occasional step in operations upon civil compound fractures.

Early in the war Sargent introduced perforated metal tubes for dealing with the appallingly septic results of leaving head wounds to be operated on at the base. These tubes will, I think, find a really useful place in the drainage of cerebral abscesses; for it is often difficult to keep a rubber tube in position in the brain. To overcome this difficulty I successfully used a tracheotomy tube to drain a cerebellar abscess in a boy in the East London Children's Hospital. Now I should under similar circumstances use a Sargent's tube.

But I think that the most important point which has been fully established in connexion with the treatment of fractures of the vault is the efficient treatment of wounds of the great blood sinuses. Wounds of the superior longitudinal sinus are not, I fancy, very common in civil practice, but any depressed fracture in or near the middle line of the vertex may be complicated by such a wound.

In the summer of 1910 I operated on a depressed fracture in the mid-line of the vertex. The fracture, which was caused by a falling brick, had caught the upper ends of both Rolandic areas, and both legs were paralysed below the knees. On raising the depressed fragment I encountered that copious stream of haemorrhage which a large rent in the sinus produces. I controlled the bleeding by packing gauze between the sinus wall and the skull, and then sutured the rent. The case recovered and I was very pleased with myself, and decided that I knew how to deal with wounds of the superior longitudinal sinus. There my knowledge of wounds of the sinus remained until the Somme fighting. Then, having lost one case of torn sinus which I had sutured, I contented myself with packing the next one with gauze and leaving in the packing—as a matter of fact, this case recovered. But it was the last I packed, because another surgeon asked: "Why didn't you 'postage stamp' it?"

Haemostasis.

I had been familiar with Horsley's use of muscle grafts for arresting haemorrhage from cerebral vessels, but I did not know that it had been applied to torn sinuses, though this had, I understand, been done for some years before the war by Cushing, who, I believe, always uses a muscle graft cut from the calf for his "postage stamp." Short of assistance, as one often was in the war, I (and I fancy many other surgeons) tried cutting grafts from the aponeurosis of the scalp flaps. The graft should be cut about the size of a postage stamp, and as soon as cut placed over the rent and pressed over it by a gloved finger. This is better than gauze, as the graft is apt to stick to the gauze and come away with it. In twenty to thirty seconds the graft is usually securely stuck and all the haemorrhage

* Read before the South-Western Branch of the British Medical Association, Torquay, April 7th, 1920.

has ceased. These fascial grafts are quite as good as muscle for wounds of the cranial surface of the sinus, which are the only ones likely to be met with in civil practice, and they have the advantage of being cut quickly and without leaving the field of operation. That these grafts stick extremely firmly I know from the examination of two fatal cases at *post mortem*.

If, however, the rent runs round the corner on to a cerebral surface of the sinus it is difficult to get fascial grafts to stick, and they usually require a reinforcing stitch which is not always easy to apply. In such cases a "plug" of muscle is the most satisfactory method of arresting haemorrhage, for the muscle graft with its power of causing rapid clotting holds more quickly. Where the sinus has been torn almost across, it is best to divide it completely and ligature it. This I have had to do twice (both times in the frontal region). One case I was able to watch for four weeks, and he showed no ill effects. The other was operated on in the Somme fighting, and was only watched for a few days before evacuation. He was apparently well then.

I think that all surgeons who did much head work in the war have abandoned plugging for wounds of the superior longitudinal sinus as uncertain and dangerous, owing to the risk of introducing sepsis later and because it entails too much haemorrhage before haemostasis is established. Moreover, bleeding is apt to start again when the gauze is removed. Another point which we learnt was to beware of all depressed fractures near the mid-line of the vertex, and to nibble away sufficient bone around the depression fully to expose the sinus before displacing any fragments likely to have penetrated it. It is no easy matter to stop bleeding from a sinus if the rent is not fully exposed. If bleeding has started before the sinus is fully exposed it is best to place a finger of the left hand on the bleeding point and nibble away bone until the dura is exposed all round that haemostatic finger before attempting to apply a graft.

In order to get at a rough idea of the frequency of this complication I have been through such statistics as I possess. They are the total number of gunshot wounds with fractures of the vault (whether the dura was penetrated or not) operated on in No. 12 Casualty Clearing Station between November, 1916, and November, 1917, and 47 cases operated on by myself in the Somme fighting. There were 614 gunshot wound fractures of the vault, with thirty wounds of the superior longitudinal sinus, or rather less than 5 per cent. superior longitudinal sinus injuries. Of these 30 cases 18 recovered and 12 died. Included in these figures are 11 cases personally operated on (7 recoveries and 4 deaths) out of 215 gunshot wound fractures of vault, or rather over 5 per cent. Probably the incidence of this complication in civil fractures is less than 5 per cent.; 2 per cent. to 3 per cent. would probably be nearer the truth. If this be so, I think that, apart from the opportunities given by the war, few surgeons can have had sufficient experience of wounds of the superior longitudinal sinus to become at home with them. That is why I have ventured to give the results of my experience in this field. I am convinced that any one who is prepared to tackle a depressed fracture should be familiar with the "postage-stamp" method of dealing with this emergency, for it is a complication which may easily cost the patient his life if the surgeon is not prompt and sure in his method of haemostasis. Armed with the knowledge of the "postage-stamp" method, the arrest of haemorrhage from a sinus is hardly ever a matter for anxiety.

Lumbar Puncture.

Lumbar puncture was amongst the procedures which aroused considerable interest during the war. As a means of diagnosis in gunshot wounds it is seldom if ever needed. Post-operative lumbar puncture was very useful for reducing cerebral hernia. It acts slowly, producing its maximum effect in about twenty-four hours. One drachm to three drachms was withdrawn according to the pressure, and the puncture was not done oftener than every forty-eight hours. Occasionally there was a marked recession in place of the hernia after one puncture, and for this reason puncture should not be employed until the hernia is at any rate moderately clean. Our treatment crystallized out to antiseptic lotions (usually Dakin's) till sepsis was well in hand; then lumbar puncture every second or third day till

the hernia was reduced, and then a plastic operation to cover the raw surface. Covering the raw surface with Thiersch grafts is not satisfactory, as it leaves a very poor scar.

Headache with a tense wound is relieved by lumbar puncture. But headache with a lowered pressure is made worse by lumbar puncture. Also if too much fluid is removed headache is caused by lumbar puncture. We had no success in treatment of meningitis by lumbar puncture where streptococci had been demonstrated in cerebro-spinal fluid.

Fits soon after operation occurred in about 5 to 10 per cent. of cases where the dura had been perforated. They were usually associated with high cerebro-spinal pressure and a bulging wound. When this was the case lumbar puncture usually relieved. These fits unless frequently recurring were (contrary to expectation) not of serious prognostic importance.

Anaesthetic.

The war proved without doubt that local anaesthesia can be satisfactorily used in even the most severe cases of fractured vault. It is very satisfactory in patients who are fully conscious. In those quite unconscious no anaesthetic is needed. The cases which show the restlessness of cerebral irritation need a general anaesthetic. Some surgeons used omnopon or morphine for this purpose and still considered that they were operating under local anaesthesia. I preferred to use open ether for such cases. Local anaesthesia (especially novocain and adrenalin) is very satisfactory, and might be used for most of such cases in civil practice. The adrenalin greatly diminishes the bleeding from the scalp flaps, and so saves a good deal of time and irritation.

CONCLUSIONS.

I would suggest that experience during the war has established:

1. The advantages of excision of scalp wounds.
2. The value of metal tubes for draining cerebral abscesses.
3. The ease with which sinus haemorrhage can be stopped by a "postage-stamp" graft.
4. That lumbar puncture is useful in certain complications of fractures of the skull.
5. The value of local anaesthetics in cranial surgery.

THE ETIOLOGY OF DIVERTICULITIS.

BY

C. H. WILLEY, M.D., D.Sc. EDIN.

CONSULTING SURGEON, SHEFFIELD CHILDREN'S HOSPITAL.

THE very full description of diverticulitis given by Dr. Maxwell Telling in the *British Journal of Surgery* of January, 1917, called my attention at the time to what appeared to be a newly discovered disease, and the interesting discussion on the subject at a meeting of a subsection of the Royal Society of Medicine, and reported in the *BRITISH MEDICAL JOURNAL* of January 17th and 24th of this year, revived speculations as to the causes of this condition. The theories advanced on those occasions were largely based upon appearances found after death. I venture to think, however, that when we are able to collect the previous histories of a sufficient number of cases it will be found that the true causes will be more truly deduced from the living. Although the three cases which I have been able to observe ended in recovery, their clinical history and symptoms nevertheless have suggested some speculations upon the etiology of the disease. I think, in order to realize fully the causes and early stages, we have to consider the whole of the medical history before the appearance of the local lesions encountered at operation or in the *post-mortem* room; and in this history certain types of build and temperament appear to be strong predisposing elements.

In opening the discussion Dr. Telling assumed that the diverticulum is made first, congenitally or otherwise, and that, as is the case of the appendix, all inflammations are brought about by morbid septic activity developing in their

contents, and are secondary. But is it necessary to make this assumption? May there not be a primary infection of mucous follicles such as occurs in the skin in the case of an ordinary boil, or for that matter in an ischio-rectal abscess? In one of my cases ischio-rectal abscess did occur two years before diverticulitis. If such an event had occurred a little higher up the bowel and within the peritoneal cavity, should we not have had diverticulitis? In another of my cases diverticulitis occurred ten years after a severe Whitehead's operation for piles, but whether there was any association between the two I could not say.

The earliest theories regarding the sac formation seem to me to be rather too mechanical. For instance, the belief in gas pressure and constipation was started and is still handed on, although this point is not insisted upon by surgeons in regard to appendicitis; my three cases were associated with looseness of the bowels. The diagnosis in two of them was confirmed by operation by two distinguished surgeons. One of these was found to be suffering from an acute kink resulting from adhesions of the sigmoid to the parietal peritoneum, and the other from a fistulous communication between the sigmoid and bladder.

We are still somewhat uncertain as to the constitutional and local causes at work before the condition declares itself, and I feel sure it would be illuminating to note in all cases the particular type and build and temperament of the patients, as well as any temporary condition of mental worry or powerful emotional disturbance. I have no doubt of the very close connexion between depressing emotion and pathological conditions of the large intestine. We find this to be a constant contributor to the common colitis of this country, and I would suggest that this is the first stage in the creation of diverticulitis; a sensitive and impassioned temperament being the most powerful predisposing factor. In men of this build the effect of acute emotional worry tells at once in some way on the large intestine. The colitis of worry evidently results from diminished trophic innervation and tissue resistance, whilst at the same time the natural digestive ferments are faulty in quantity and quality. Food and the mucous lining become morbidly septic. The *B. coli* becomes more and more virulently active. Probably many follicles are infected, which may account for diverticuli being multiple.

So far, I believe, no one has suggested a comparison with ischio-rectal abscess. May not these abscesses and diverticulitis in their respective origins have much in common? After the fifty-seventh year of life the sigmoid would appear to be the more vulnerable locality of the two. Possibly many infected follicles of the mucous membrane undergo spontaneous cure by discharge into the bowel, whilst owing to distension and destruction of their lining the sacs thus produced may become what we have hitherto thought to be permanent or congenital diverticuli.

In my cases pain in the left lower quadrant of the abdomen led to some amount of tumour formation (fibrous hyperplasia), very apparent in the case with parietal adhesions and kinking, not so much so in the case in which the sigmoid adhered to the bladder and perforated into it. The latter case exhibited, in addition to the daily passage of flatus by the urethra, all the phenomena of intense *B. coli* toxæmia, showing in succession well marked rigors, fever, violent headaches lasting from two to four days, trinitus and toxæmic vomiting; evidently the result of leakage of toxins and bacteria into the peritoneum. Two years before these events I saw this man suffering from an acute attack of colitis with diarrhoea, severe colic, and tenesmus.

DURING the year 1918 there were 19,018 cases of diphtheria in Australia, with 607 deaths, out of a population of about five millions.

A CONFERENCE of the "Nordiske Forening mod Tuberkulose" will be held on June 28th, 29th, and 30th, in Stockholm. The subjects to be discussed are (1) tuberculosis legislation in the Scandinavian countries; (2) work therapy in sanatoriums and the organization of colonies and settlements; (3) the special measures required in tuberculosis of the larynx; and (4) the surgical treatment of pulmonary tuberculosis, including treatment by artificial pneumothorax. Representatives from Finland and Iceland, as well as from the three Scandinavian countries, are expected to attend.

ETIOLOGICAL FACTORS IN ABORTION:
A STUDY OF 100 CASES.*

HOSPITAL; REGISTRAR, ST. MARY'S HOSPITALS,
MANCHESTER.

INTRODUCTORY.

THE material on which this paper is based has been obtained from a clinical and pathological examination of a hundred unselected cases of abortion admitted to the maternity department of the St. Mary's Hospitals, Manchester. This is too small a number on which to base authoritative statistics, but the conclusions arrived at indicate the lines along which a more extensive investigation should be carried out.

A majority of the cases belonged to the class of incomplete abortion, and in these the whole ovum was not available for pathological examination.

Our thanks are due to Professor H. R. Dean of the pathological department, University of Manchester, who kindly arranged to carry out the work in connexion with the Wassermann reactions, and to members of the honorary medical staff of the St. Mary's Hospitals, Manchester, for allowing us to examine cases of abortion admitted under their care.

The following table shows the period of gestation at which abortion occurred:

TABLE I.—Period of Gestation at which Abortion Occurred.

	Per Cent.
4 weeks	0
6 (inc.) to 8 weeks	3
8 (inc.) to 12 "	12
12 (inc.) to 16 "	40
16 (inc.) to 20 "	15
20 (inc.) to 24 "	12
Doubtful	18

The 18 cases in which the period of gestation was doubtful were all early abortions. The great majority therefore occurred during the first half of pregnancy and 40 per cent. between the third and fourth months.

Table II gives the number of previous full term labours and abortions.

TABLE II.—Previous Full Term Labours and Abortions.

Pregnancies ...	Full Term.					Premature.						
	0	1	2	3	4 and over	0	1	2	3	4	5	9
No. of cases ...	20	15	17	11	37	60	24	8	1	5	1	1

In 17 per cent. of the cases there was no previous pregnancy; 80 per cent. had previously had full-term children. 37 per cent. more than three; 40 per cent. gave a history of previous abortions, but in more than half of these abortion had only occurred once.

THE CAUSES OF ABORTION.

(a) Clinical Investigation.

To the question what produced the abortion, the patients replied as follows:

	Cases.
Strain	7
Falls	6
Kicked abdomen	1
Shock	2
Injury to foot	1
Instruments	1
Syringing	1
Lead pills	8
Sexual excess	1
Unknown	72

Excluding the above cases, the following abnormal

* From a paper read before the North of England Obstetrical and Gynaecological Society, March 19th, 1920.

conditions were found either during the clinical examination or at the time the uterine contents were evacuated.

	Cases.
Mitral stenosis	1
Chronic bronchitis	1
Phthisis	1
Severe anaemia	1
Influenza	3
Fibroids	2
Fibroids and placenta praevia	1
Placenta praevia	2
Foreign body in vagina	1
Retroversion or flexion uteri	5
Hydatid mole	1
Previous abdominal operations	3
Total	22

Twelve patients gave a positive Wassermann reaction. In six of these no other cause could be found to account for the abortion. A possible cause could therefore be ascertained clinically in 56 per cent. of the cases.

(b) Pathological Investigation.

In 54 specimens gross pathological changes were found as follows:

	Specimens.
Fetal circulation obstructed	2
Hydatid mole	1
Extensive placental infarction with associated arterial degeneration	6
Placenta oedematous	1
Haemorrhage into placenta (including three cases with red infarction, and three associated with accidental haemorrhage or placenta praevia)	9
Haemorrhage on fetal surface of placenta under amnion	2
Haemorrhage into decidua (including two cases of fibroid polyp, one placenta praevia, and eight blood moles)	33
Total	54

In the remaining 46 specimens various conditions were met with, but were either too limited in extent to be of decisive importance or the specimens examined were too incomplete for satisfactory results to be obtained.

ANALYSIS OF THE CASES GIVING A POSITIVE WASSERMANN REACTION.

In twelve patients the Wassermann reaction was positive.

(a) Clinical Observations.

Signs of active syphilis were present in one case—a patient with specific ulcers on her legs. One patient only was aware that she had syphilis. This was a single girl whose blood had been previously examined and shown a positive Wassermann reaction.

Of the twelve patients eleven had previous full-term children, and all were born alive except in one case, where three were stillborn. One patient had nine and one seven full-term living children. Six patients had had previous abortions but in only one case more than one.

Repeated abortions therefore are not necessarily associated with a positive Wassermann reaction. In fact, of seven patients in the complete series with four or more previous abortions not one gave a positive Wassermann reaction.

TABLE III.—Details of Previous Full Term Labours and Abortions in Cases in which the Wassermann Reaction was Positive.

	Full Term.				Premature.				
	1	2	3	4 and over	0	1	2	3	4
Pregnancies	1	2	3	5	5	6	1	0	0
No. of cases	1	2	3	5	5	6	1	0	0

A patient with a positive Wassermann reaction need not necessarily abort but may go to full term. It is therefore fallacious to suppose that when abortion does occur it must be caused by the syphilitic virus. Such a woman is just as much exposed to the influence of other factors which produce abortion as one in whom the reaction is negative.

Obviously, however, secondary syphilis may lead to separation of the ovum in the same way as any other

acute infection, and tertiary lesions, if affecting the fetus, placenta, or decidua, may have a similar result, or, at any rate, act as predisposing causes.

In the twelve cases under consideration the following alternative factors were present:

	Cases.
Falls and strains	2
Previous Caesarean section and adhesions between uterus and abdominal wall	1
Fibroid polyp in uterine cavity	1
Marked retroflexion of uterus	1
Previous operation for ectopic gestation	1
Obstruction of vessels in umbilical cord	1

The two cases attributed to accident may be objected to on the ground that the only evidence is the patient's own statement. Both were married women with families and appeared to be telling the truth. In one case abortion took place a week after a fall downstairs, in the other after lifting a heavy tin box.

An adherent uterus after Caesarean section and a fibroid polyp in the uterine cavity are just as likely to be the cause of abortion as syphilis.

The case with marked retroflexion of the uterus had no symptoms of incarceration, but the congestion caused by the faulty position might easily account for the engorged decidua and haemorrhage into the placenta observed on subsequent examination.

Ectopic pregnancy is very frequently associated with lesions due to pelvic infection, and these may lead to abortion. If post-operative adhesions are also present abortion is more likely to occur.

Obstruction of the vessels in the umbilical cord undoubtedly led to fetal death in the case referred to, but this appeared to be due to an amniotic adhesion which in turn may have been produced by syphilitic disease. No obvious syphilitic lesions were to be found in the fetus or placenta, however.

(b) Pathological Observations.

No specimen presented the typical naked-eye appearances of syphilis. No osteo-chondritis of the long bones or miliary gummata of the liver were observed in the four cases in which the fetus was available for examination, nor could spirochaetes be found in the liver in these cases. The placentas showed no gross abnormalities other than infarction and blood infiltration. The microscopic appearances varied considerably, but no conditions were found which were not present in other cases in which the Wassermann reaction was negative. A careful search was made for spirochaetes but without success.

To sum up, 12 per cent. of cases gave a positive Wassermann reaction. In more than half of these other abnormal conditions were present which by themselves might produce abortion. In two cases (adherent Caesarean section scar and fibroid polyp) we feel justified in saying that syphilis was not the cause of the abortion. In two others (retroflexion of uterus and obstruction of vessels in umbilical cord) we think it extremely unlikely that syphilis was the deciding factor.

We therefore estimate at 10 per cent., and probably less, the cases in which syphilis leads to abortion.

CONCLUSIONS.

(a) The commonest period for abortion to occur is between the third and fourth months.

(b) Abortion is comparatively uncommon in primiparae, less than one-fifth belonging to this category. Most women who abort have borne previous full-term children, and in a majority of cases more than one. Frequent abortions in the same patient are uncommon, and when they do occur are not necessarily due to syphilis.

(c) As regards aetiology, accidental or reflex causes are present in 18 per cent. of cases.

General disease of the mother, disease or displacement of her genital organs, and gross abnormalities of the fetus or placenta (other than those due to haemorrhage or infarction) are found in 25 per cent.

Syphilis, as represented by a positive Wassermann reaction, accounts for 12 per cent., but its influence as the actual cause of the abortion is probably much less, and nearer 8 per cent.

From the remaining 52 per cent. has to be deducted the figure for the self-induced group, which is probably not less than 20 per cent. In the present series 8 per cent.

admitted taking lead pills, and a number of these showed clinical evidence of lead poisoning. This leaves over 30 per cent. of cases with no cause assigned. Pathological investigation throws little additional light on the subject, as most of the morbid changes found do not produce the abortion, but occur during the operation of some other cause.

It would appear, however, that the mother is primarily at fault as the result of some diseased condition, whether it be of an organic nature, or merely an increased irritability of the centres presiding over the expulsive action of the uterus.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE MYOCLONIC TYPE OF EPIDEMIC ENCEPHALITIS.

AFTER reading with great interest Dr. Piero Beveri's article in the *JOURNAL* of April 24th, p. 570, I record the following case, which occurred recently in my own practice:

On February 9th I was called to see a man, aged 62, who had been suddenly stricken with severe spasmodic pains in the limbs, chest, and face. For two days the pains persisted, but had then gradually diminished in severity, giving place to sudden painful contractions of the extensors of the legs, the abdominal muscles, sternomastoids, pectorals, intercostals, and diaphragm (as evidenced by hicough). Twitching occurred about every two seconds. The patient sweated profusely, and was slightly cyanosed. There was considerable muscular weakness and some ataxia. The superficial reflexes were in abeyance, Kernig's sign was absent, but the head was a little retracted. The deep reflexes were slightly exaggerated, but no ankle clonus was present, and the plantar response was flexor. There was no apparent disorder of sensation. The discs were slightly injected, but there was no optic neuritis. The only cranial nerve involved was the seventh, there being occasional twitches of the *alae nasi* and *occipito-frontalis*. At this stage, although there was no actual lethargy, there was a curious prolongation of the reaction time to aural stimuli—this I have observed, however, previously in patients on chloral and bromide, as was this patient—but it roused suspicion. The blood pressure was 170 mm.

In a day or two these symptoms abated *pari passu* with the advent of lethargy, passing into stupor; tremors of the right hand (only) now appeared, and the patient assumed the mask facies of paralysis agitans.

The cerebro-spinal fluid, which was quite clear and under slight pressure, was examined by Dr. Arthur Sladden, pathologist to Swansea Hospital, who reported a cell count of 5 to 6 per c.mm., a trace of albumin, and negative cultural results; the Wassermann reaction in the blood and cerebro-spinal fluid was negative.

The patient, after beginning to improve, died quite suddenly of what was evidently either (gross) cerebral haemorrhage or thrombosis. A *post-mortem* examination, even partial, was discontinued by the relatives.

The temperature varied between 100° and 99°, and the pulse rate gradually increased from 80 to 120 and diminished again to 80. There was no history of influenza, but there was some coryza with a thin watery discharge throughout. Profuse sweating was a marked feature of the whole course of the disease. This case is of interest, firstly, in that it showed the chief seat of the morbid process to be in the thalamic region, with probable involvement of the red nucleus, and secondly, in that it bridges the gulf between the more usual clinical type of the disease and that type described by Dr. Boveri, exhibiting the lethargy of the former as a late manifestation and the myoclonic spasms of the latter. Of further interest, too, may be an undoubted case seen by me eight months ago, in which the disease was ushered in by right hemiplegia with aphasia; after running a typical course for three weeks it ended in such a measure of recovery that all that can now be said of the patient is that he is not quite so methodical an accountant as he formerly was.

In both these cases there was a history of considerable and prolonged mental strain.

HAEMATOPORPHYRINURIA.

DR. WYATT-SMITH, in his article on the treatment of delirium tremens (*BRITISH MEDICAL JOURNAL*, December 6th, 1919, p. 743), says that he has never met any one who has seen a case of haematoporphyrinuria from the use of sulphonal. He and others may be interested in the following extract from my note book:

Miss A. B., aged 35, came under my care on October 22nd, 1901, suffering from a complication of ailments. Some six months before she had such constant vomiting, accompanied at one time by severe haematemesis, that the diagnosis of gastric ulcer was made, and at one time it was feared that there might be malignant trouble. There had been great loss of flesh and she suffered severely from neuralgia and insomnia, for which morphine, phenacetin, and sulphonal had been freely prescribed.

When first I saw her she had been carefully fed and had regained much of the weight she had lost, but the muscles were flabby and she was intensely weak. She had a heavy, drowsy appearance, with eyelids which seemed loth to lift; her speech was dragging; there were no superficial or deep reflexes. Sensation was normal. She complained of pain in the right renal region, where there was an enlarged tender movable kidney, and of intense pains in the legs. Constipation was very obstinate. The urine was of a dark brown-purple colour, almost like port wine, and gave in the spectrum the bands characteristic of haematoporphyrin. It contained no albumin, corpuscles, casts, or sugar. The specific gravity was 1020. The temperature was normal. I found that she was taking 30 gr. of sulphonal every night, and had done so without intermission since January, 1898, her English medical advisers having told her that it was safe to do so. For the four previous years she had taken sulphonal and phenacetin freely. She had also been in the habit of drinking a large amount of alcohol, though the exact amount I found it impossible to elicit.

I immediately stopped the sulphonal, giving bromides instead, and administering a tonic with strychnine. After this she slept well, and took her food satisfactorily, and seemed much better, though the urine still retained its abnormal colour.

After about ten days marked paresis of the lower limbs appeared, and soon increased to complete paralysis. The upper limbs followed suit. Later she had incontinence of urine and faeces, and still later all power of phonation was lost. There was no loss of sensation. Her mind became more and more clouded, and she died on November 6th, 1901. She took her food well to the last.

At the *post-mortem* examination all the tissues and organs were found very deeply stained with the same brown-purple colour. The kidneys were congested and the capsules slightly adherent. The liver was congested and enlarged. The spleen was quite disorganized, and so liquid that none could be saved for examination. The brain was normal, save for some adhesions of the arachnoid, which exhibited some cloudiness. Rigor mortis was not marked, though the examination was made six hours after death.

It is interesting to remark that in this case, as in other recorded cases, death was preceded by peripheral neuritis. The course of the symptoms is strongly suggestive of those accompanying Landry's acute ascending paralysis.

Wellington, New Zealand.

G. E. ANSON, M.D. Cantab.

SCLEREMA NEONATORUM ASSOCIATED WITH PLACENTA PRAEVI.

As the pathogeny of sclerema neonatorum is practically unknown, it may be worth while to record the following case: Mrs. N., 3-para, aged 34, was confined on December 17th, 1919. Labour was ushered in with a sharp haemorrhage at 5.30 a.m.; there was practically no pain, and the os barely admitted one finger. At 8.30 a.m. the os admitted two fingers, and there had been no more bleeding to speak of; I detached the placenta round the rim of the os as far as I could reach—the anterior edge of the placenta was just at the rim of the os at this stage—and gave pituitrin 1 c.cm. No further bleeding occurred. At 2.15 p.m. I ruptured the membranes and gave another injection of pituitrin; pains rapidly improved, and the child was born at 3.15 p.m. At birth the boy was blue and limp, and it was some minutes before respiration was satisfactorily established. The placenta was delivered normally at 3.40 p.m., and was of the type usual in these cases; the area I had detached was clearly distinguishable, and measured approximately six square inches. When bathing the child a little later, the nurse commented on the hardness—"like frozen meat"—of many of the muscle

masses, particularly the muscles of thighs and buttocks, and the hard swelling on the backs of the hands and feet; the skin appeared as if tightly bound down to the underlying muscle. Difficulty was experienced from the beginning in getting the child to swallow, and at first it refused to suck. Constipation was a trouble throughout. The child died on December 26th, death being ushered in by a sudden drop of body temperature and by an escape of pink-tinged fluid from mouth and nose.

On November 15th, 1919, Mrs. N. had had a single large haemorrhage which was sufficient to blanch temporarily the conjunctivae; and though she was taking iron in full doses from that time she was still markedly anaemic when the haemorrhage occurred which heralded the onset of labour thirty-two days later. The puerperium was uneventful except that the milk which came plentifully on the fourth day vanished on the eighth, perhaps because of the lack of stimulus as the infant was unable to suck.

Stafford.

A. E. HODDER, M.B., B.Ch.Cantab.

Reports of Societies.

APPENDICULAR CONCRETIONS.

At a meeting of the Section of Pathology of the Royal Society of Medicine, held on April 20th, with Dr. BULLOCH, F.R.S., in the chair, Dr. MURRAY demonstrated preparations and charts from three cases of malignant tumours in rabbits, in which autologous grafting had been carried out. The bearing of the results on the possibility of increasing or diminishing resistance to spontaneous cancer was discussed. Dr. LYON SMITH read a paper on direct haemolysis, a test for bacterial toxins, and for the quantitative estimation of doses of bacterial vaccines.

Professor S. G. SHATTOCK, F.R.S., made a communication giving the results of the systematic examination of twenty-five appendicular concretions, the examination being carried out by delamination under water; the concretions had at no time been allowed to dry. When an arbitrary centre of the size of a hempseed was reached, this was crushed in glycerin between a slide and cover-glass, and studied microscopically. In no instance was any nucleus present, the centre being of the same kind as the rest, and consisting of the undigested residues of plant tissues. In two or three the number of stiff pericarpal hairs present in flour and oatmeal was notable, but in no instance were they sufficient to constitute a nucleus after the manner of the oat hair concretions sometimes met with in the colon. In no example were any particles of steel, or of the enamel flakes from cooking utensils, present. The absence of these was opposed, therefore, to the suggestions that had been put forward in regard to the etiology of appendicitis in general—namely, that its increase was due to the introduction of enamelled ironware, or of the milling of flour by means of the cylindrical steel rollers now almost universally used. An examination of the contents of 100 appendices taken from subjects over 40 years of age, and of twenty-five from those between the ages of 15 and 25, dying from causes unconnected with the appendix, gave equally negative results in this respect. In a few of these, small faecal pellets were met with, which might be regarded as appendicular scybala; such appeared at times to furnish the starting point of concretions. The etiology of concretionary formation, the author thought, resolved itself into neuro-muscular faults of the appendix, a matter of much interest in regard to ectasias and constrictions of the oesophagus, stomach, and intestine. The entry of faecal material into the appendix was presumably helped by the contraction of the caecum upon its contents, whereas the exit depended upon the appendix alone.

The factor of mechanical kink might be viewed as an exceptional one, since in concretionary forms of appendicitis the organ retained its usual curvatures. As to roller-milled flour itself, the finest passed between as many as thirteen pairs of revolving steel cylinders. Yet the author had found that no inorganic iron could be chemically demonstrated in it. The skiagraphy of concretions, after being taken out of the excised appendix (and not allowed to dry), or whilst still in the excised organ, the author found, gave results too variable to prove a negative in clinical application. If the deposition of

calcium carbonate and phosphate in the stercolith was well pronounced, a laminated picture was equally so; but if little, the picture was so faint that such a concretion would certainly escape observation in the living body. If the appendix, again, happened to lie behind the caecum, the picture would be obscured by the contents of the latter.

ANAESTHESIA FOR THYROID OPERATIONS.

At a meeting, held on April 9th, of the Section of Anaesthetics of the Royal Society of Medicine, with Dr. HAROLD LOW, Vice-President, in the chair,

Mrs. DICKINSON BERRY read a paper on anaesthesia for operations on the thyroid gland. Her remarks were based upon an experience of 700 cases of operations for removal of goitre. In the past chloroform and its mixtures had been used either throughout or for induction, but since 1912 Mrs. Berry had relied entirely upon open ether, and had met with no fatality and little anxiety. She advocated an anaesthesia as light as was compatible with the requirements of the operator.

Atropine is used beforehand but not morphine; a slow induction is practised. The operation begins when regular breathing is established, even if the conjunctival reflex still persists. When the gland is reached ether is withheld if the patient is absolutely quiet. The eyes may open spontaneously or talking occur, the patient remaining quite motionless. Dislocation of the tumour is a dangerous process in cases of severe dyspnoea; the anaesthesia is kept specially light at this stage. Straining should occur when the last ligatures have been tied, in order to show any points which might lead to post-operative haemorrhage. Notes of cases illustrating the above and other points were read.

Two groups of cases were described as offering special dangers—those with much tracheal obstruction and those with cardiac trouble. For the former it was often necessary to use oxygen with the ether. The cardiac cases included those in which the heart was affected by long-standing dyspnoea, true exophthalmic cases, and cases of goitre not typically exophthalmic, but associated with cardiac symptoms.

Dr. J. F. W. SILK maintained that "team work" and a light form of anaesthesia were most important. He had found rectal oil-ether of great value, particularly in exophthalmic cases.

Mr. JAMES BERRY said that the anaesthetist should never begin the administration for a goitre operation until the surgeon had on gloves, gown, etc., and was quite ready to begin. It was sometimes necessary to perform the earlier stage of the operation very suddenly and rapidly on account of dyspnoea. In cases of dyspnoea it was well to ascertain to what extent the head could be extended without causing serious interference with breathing, and during the operation never to let it be extended beyond this amount. It was his custom to have the head held firmly throughout and turned only under special directions. In cases of dyspnoea the anaesthetist should acquaint himself before operation with the exact position and shape of the trachea. A unilateral goitre displaced the trachea to the opposite side, curved it, and flattened it on the side of the tumour. The point of maximum compression was nearly always $1\frac{1}{2}$ in. below the cricoid. The dyspnoea was always due to direct pressure on the trachea and had nothing to do with irritation of recurrent laryngeal nerves. In cases where the heart was seriously affected its condition should be ascertained by x-ray and electro-cardiographic examination. Mr. Berry said that he was using local anaesthetics less and less for goitre operations and relying more and more upon light ether anaesthesia.

Dr. J. S. GOODALL thought the performance of any thyroid operation, except simple ligation, under local anaesthesia undesirable on psychic grounds. Any local anaesthetic containing adrenalin might induce auricular, and even ventricular, fibrillation. He had examined the hearts of many patients before, during, and after thyroid operations, paying particular attention to (1) degree of myocardial exhaustion, (2) amount of dilatation, (3) presence of definite myocardial degeneration, (4) height of systolic blood pressure. Electrocardiographic and x-ray examination, together with mapping out of the field of cardiac response, were essential in estimating the condition of the myocardium.

Dr. J. BLONFIELD said that he used open ether for these cases, but relied more than the reader of the paper upon

preliminary injection of omnopon, scopolamine, and atropine. Many surgeons were uncomfortable if as light a degree of narcosis as that described by Mrs. Berry were employed. He related a case showing the necessity for the surgeon's being ready to operate from the first moment of induction of anaesthesia.

Dr. F. E. SHIPWAY preferred intratracheal ether in all goitre operations except the exophthalmic cases. All difficulties were removed by this method, particularly those due to pressure of the tumours upon the trachea, and a very light narcosis could be accurately maintained, permitting straining or coughing at the surgeon's desire. For exophthalmic cases he favoured oil-ether per rectum, preceded by large doses of morphine and scopolamine; the direct laryngoscope and catheter should be at hand.

Dr. HAROLD LOW said that the cases requiring special treatment were those in which the trachea was pressed upon and those with constitutional symptoms. He considered the ideal anaesthetic to be either intratracheal or rectal ether: next to these he placed open ether used to maintain a light degree of narcosis. Only skilled anaesthetists should undertake goitre cases.

Dr. F. S. ROOD divided goitre cases into three groups. (1) Simple tumours or cysts with no respiratory obstruction and no toxæmia; (2) patients with stridor and possibly definite respiratory obstruction and heart failure; (3) cases of exophthalmic goitre. In the first group the choice of anaesthetic was not specially important. In the second group he preferred chloroform to ether; in the exophthalmic cases he thought it most important to guard against the element of fear, and a preliminary injection of morphine and scopolamine was most useful.

ISCHAEMIC CONTRACTURE.

At a meeting of the Royal Medico-Chirurgical Society of Glasgow, held on April 16th, the President, Mr. A. ERNEST MAYLARD, being in the chair, Dr. J. SCULER BUCHANAN and Dr. WALTER W. GALBRAITH showed two cases of effusion into both knee-joints due to congenital syphilis. In the first case, that of a boy aged 11 years, previously healthy according to his parents' account, the only symptoms had been a feeling of tiredness in the legs, with little or no pain, and swelling of the knees without tenderness or restriction of movement. He showed, however, some keratitis, fissures about the mouth, and pegged teeth; both he and his father gave a positive Wassermann reaction. In the second case, a boy aged 13 years, stiffness and swelling of the knee-joints were first complained of after a fall from a height on to his knees. Except a slight degree of "sabre-blade tibiae," the boy showed no evidence of congenital syphilis, but both he and his father gave a positive and his mother gave a "suspicious" Wassermann reaction.

Mr. ARCH. YOUNG showed a case of Volkmann's ischaemic contracture of the forearm, treated by manipulation and splinting.

The patient, a boy aged 11 years, was admitted to hospital in March, 1918, for simple fracture of both bones of the forearm slightly above the middle. Under an anaesthetic the arm and forearm were put up on an anterior (flexor) splint of moulded metal bent at right angles at the elbow (the forearm being fully supinated), supplemented by a corresponding moulded poplastic splint applied to the extensor aspect of the forearm only. Six days later, on account of pain at the elbow and disability in finger movements, the splints were removed and put up less firmly, there having evidently been excessive pressure by the anterior splint at the bend of the elbow. By March 22nd there was well marked tendency to contracture of the fingers, and the patient, when dismissed on May 14th, was ordered to attend the outdoor department for massage and passive movement. On October 26th he was readmitted to hospital with well marked ischaemic contracture and atrophy of all the muscles of forearm and hand; the fingers were constantly flexed when the wrist was dorsiflexed, but extended slightly when the wrist was palmar flexed. The treatment adopted was on the lines of that described by Jones of Liverpool, but differed from it in detail. Under an anaesthetic the four fingers were separately stretched and fixed, fully—or almost fully—extended, in individual moulded sheet-iron splints, previously sized and fitted on the other hand, and covered in advance with lint. These being secured, maintenance of the palmar flexion of the wrist was obtained by applying a long metal splint duly padded and fixed on the extensor aspect of forearm and hand. At the end of a fortnight the splints were readjusted, flexion at the wrist being reduced and extension at the metacarpophalangeal joints increased. A fortnight later the fingers and wrist were further manipulated, and fixed again with the wrist still flexed and the metacarpophalangeal joints more extended. Twenty

days later the fingers and wrist were freely manipulated and splints reapplied with the contracture almost fully corrected. Sixteen days later, after manipulation of the joints, a moulded and padded splint was applied on the palmar aspect of the forearm and hand from beyond the finger-tips to two-thirds of the way up the forearm, this splint being considerably dorsiflexed at the wrist; at the same time the special finger splints were discontinued. On the occasion of each readjustment of splints a general anaesthetic was given. Less than a week later the long splint was removed; massage was instituted and continued for some time, together with electrical treatment.

When the boy was shown to the society more than a year later the function of the limb was very good, but there was still disparity in muscular development of the two forearms, particularly in the flexor pronator groups. There had been slight recurrence of the contracture, especially of the middle finger, but not such as substantially to impair function, nor to be readily obvious. Sensation to touch was good, and all the muscles acted. Such contracture as existed was mainly of the flexor profundus. It might yet be desirable to renew the splinting in order completely to restore freedom of extension to fingers and wrist.

Mr. MAYLARD showed a specimen of hypertrophic stenosis of the pyloric orifice removed by operation from an adult. When admitted to hospital, the patient, a woman aged 36, was of poor build, very thin, with abdomen somewhat distended, and a firm, movable mass, rather tender, palpable in the right iliac region. She gave a history of rapidly increasing emaciation, of constipation, and latterly of pain in the right hypochondrium (followed by vomiting) shortly after taking food. The abdomen was opened by a transverse incision just above the umbilicus, when a freely movable pyloric tumour was found, associated with a greatly dilated stomach. In the belief that this was a growth, the pylorus, with half the stomach, was excised, and the continuity of the canal re-established by performing a "no-loop" posterior gastro-jejunostomy. The patient did well for three days, taking nourishment without any discomfort, but on the morning of the fourth day the temperature suddenly rose, and she died a few days later from double pneumonia. The pathologist reported on the specimen that there was stenosis of the pylorus, with marked hypertrophy of the muscular ring, but no evidence of tumour tissue suggestive of new growth, and no indication of recent or healed ulcers. Microscopical examination showed regularly arranged tubular glands which passed deeply, no new formed tissue round the glands, and hypertrophy and diffuse interstitial fibrosis of the muscular tissue.

EXPECTANT TREATMENT IN ECLAMPSIA.

At a meeting of the North of England Obstetrical and Gynaecological Society, held at Leeds on April 16th, the President, Mr. MILES H. PHILLIPS, being in the chair, Mr. W. GOUEN (Leeds) presented an analysis of 61 cases of eclampsia treated at the Leeds Maternity Hospital during the last ten years; 47 were primiparae and 14 multiparae. The average age was about 26 years; multiple pregnancies occurred three times and hydatid mole once; in one case only was there a history of previous eclampsia.

The speaker brought this subject before the society with a view to advocating the expectant method of treatment. In 5 cases in which pregnancy was artificially terminated 2 died—a mortality of 40 per cent. In the remaining 56 cases the only treatment adopted was expectant, and followed closely the lines of that advocated by the Dublin and Glasgow schools; in a few cases delivery was hastened by forceps late in the second stage, but this was the only operative treatment. In 9 cases, the fits commenced post-partum, and of these one died. Of the remaining 47 cases 5 died, excluding 1 death caused by a perforated gastric ulcer. The maternal mortality for this group of cases was therefore 8.5 per cent. As regards the children, in the cases where labour was induced one child was born alive and 4 were stillborn. Where no operative interference was carried out, 24 were born alive and 21 were stillborn; in one the pregnancy was a hydatid mole, and the remaining patient recovered from her eclampsia and went home undelivered. He was convinced, therefore, that much better results were obtained for both mother and child if labour was allowed to come on spontaneously.

The President congratulated the Leeds Maternity Hospital on their excellent results. The maternal

mortality was much lower than any figure he had seen published hitherto. At the Jessop Hospital, Sheffield, the mortality over a similar period was nearly 25 per cent. in 177 cases; it varied very much from year to year, however. He thought Caesarean section good treatment in carefully selected cases, and had obtained several very satisfactory results from it.

Dr. BRIDE (Manchester) had analysed the cases treated at the St. Mary's Hospitals, Manchester. During the last ten years 220 cases were admitted, and the mortality was nearly 33 per cent. The figure varied much from year to year, in one year being as low as 12 per cent.; it was of interest that in that particular year the pregnancy was generally terminated by rapid dilatation of the cervix and immediate extraction.

Dr. HELIER thought that Caesarean section was sound treatment if carried out by competent operators and in suitable surroundings. Where this was not possible the expectant method was much safer.

Dr. DOUGAL (Manchester) was of the opinion that cases varied so much in type that one method of treatment was not always the best. He had tried Caesarean section with disappointing results, but the cases were chosen because of their severity. He thought it possible that this mode of treatment might give the best results if carried out in every case at an early stage of the disease.

At a meeting of the Pathological Section of Liverpool Medical Institution, held on April 15th, with the President, Dr. J. E. GEMMEL, in the chair, Mr. F. C. LEWIS read a note on the standardization of the blood-cell suspension in complement-fixation tests, and demonstrated his thesis *in vitro*. He laid emphasis on the fact that different workers used suspensions of different strengths, and further, that the method generally adopted for making the suspension led to irregularities in the strength. It was suggested that variations in the result of Wassermann tests applied to the same serum could, other factors being equal, be explained on the assumption of a variable minimum haemolytic dose of complement. A plea was made for the use of a uniform and gravimetric suspension in order to ensure that the term "minimum haemolytic dose of complement" was common to all laboratories. Mr. JOHN T. MORRISON contributed a short paper on diseases of the male breast, with special reference to chronic mastitis. The general similarity to diseases of the female breast was pointed out, and a brief description given of the malformations, acute inflammations, granulomata and neoplasms affecting the gland. The condition, unsatisfactorily termed "gynecomastia," was discussed in detail. Histological reports were very few in number, but none confirmed the suggestion that the condition was a true hypertrophy of mammary tissue. On the other hand, there was evidence that a slow, quiet inflammatory process was at work in most instances. In cases of frankly chronic inflammation the breast, or a nodule within it, felt as a firm well-defined tender mass; axillary adenitis might be present, but suppuration was rare. Histologically there was an increased formation of fibrous tissue, with sometimes, in addition, an increase in the number of ducts; inflammatory reaction was noted at this latter site. It was recommended that cases which did not react to rest and the application of heat should be excised and examined microscopically. The suggestion was made that the lactiferous ducts, or their accompanying lymphatics, were the path of entry of the causal factor. The paper was freely illustrated by lantern slides.

H. LECLERC (*Bull. Soc. de Thérap. de Paris*, February 10th, 1920) reports several cases, including that of himself, in which consumption of large quantities of cress gave rise to dysuria, vesical spasm, and (in one instance) priapism. Examination of the urine showed no characteristic changes, and in only one case did the sediment reveal an abnormal amount of epithelial desquamation. The symptoms, moreover, were of such short duration that they were apparently due to a transient irritation of the vesical mucous membrane, and not to actual cystitis. Chemical analysis of the cress showed the presence of iron, iodine, and a sulpho-nitrogenous essence, to the irritating properties of which it was thought probable the symptoms were due, since, after being cooked (whereby the essence was destroyed) the cress did not produce any toxic symptoms. Leclerc had not been able to find any description of these effects of cress in medical literature, but a passage in the *Thesmophoriazusae* of Aristophanes showed that they were well known to the ancient Greeks.

Rebicus.

THE NAVY IN THE WAR.

THE first volume of Sir JULIAN CORBETT'S account of the *Naval Operations*¹ which began on August 4th, 1914, brings the story down to the battle of the Falklands in December of that year. It is the beginning of a history of the Great War prepared by direction of the Historical Section of the Committee of Imperial Defence. The Admiralty has given the author access to official documents, but declares itself "in no way responsible for his reading or presentation of the facts as stated." Among the official papers used are depositions of prisoners and captured documents, and recourse has been had also to unofficial publications—British, allied, and enemy. The author's main difficulty must have been the choice of material from the enormous mass available; the success with which he has surmounted it is remarkable. There are places where the mass of detail becomes oppressive, but in his handling of the larger incidents Sir Julian Corbett shows that he can be fired by a story and tell it well. He is judicious in commenting on British failures in judgement or enterprise, and generous in his tribute to any display of gallantry by the Germans, as when von Spee turned back to fight at almost hopeless odds at the Falklands. The narrative is kept well on the move; the reader is carried easily from incident to incident, and gradually obtains not only a general view of the course of the operations but a comprehension of the strategical principles by which they were guided. The volume contains some silhouettes of ships and a series of maps and plans which will probably suffice for most readers. The serious student will find eighteen large maps in a case supplied with the volume. All the maps are drawn by the Historical Section of the Committee of National Defence.

The period covered is comparatively short—barely five months—but it was a time when active operations were being carried out on many seas. The navy did its work so thoroughly that the area to be dealt with in later volumes will be narrower, and the story, therefore, in that respect less complicated. To the civilian the most interesting chapters will probably be those which deal with the "British War Book," and those describing the procedures during the time of "Strained Relations" and the "Precautionary Period," the vexed question of the escape of the German cruisers *Goeben* and *Breslau* to the Bosphorus, and the combined naval and military operations during the attempted relief of Antwerp and the fighting along the Belgian coast. The accounts of the important actions at Heligoland and the Falkland Islands probably contain little which has not already been published to some extent elsewhere, but the movements of von Spee's squadron in the Pacific are related in great detail, and the motives which may have led Admiral Cradock to accept action at Coronel against almost hopeless odds and in the absence of the vessels which had been specially detailed "to ensure his safety" are fully discussed.

The volume contains few references to medical affairs; the intention appears to be to publish the medical history by instalments in the *Journal of the R.N. Medical Service*; if so, it is to be hoped that the articles will eventually be published in a connected form. The story of Coronel and the Falklands confirms the belief that in a general action the defeated side loses so heavily in ships that the work of the medical service is wiped out. There were no survivors of *Good Hope* and *Momouth* sunk at Coronel. Of the crew of *Scharnhorst* (11,420 tons), sunk at the Falklands, not one was saved. Of her sister ship, *Gneisenau*, it is said that out of a complement of 850 she had 600 killed and wounded; as 200 were picked up, this may be an over-estimate, but it gives some idea of the condition to which the crew of a beaten ship that fights to the last is reduced. These two ships were sunk by *Invincible* and *Inflexible*, and on neither ship was there a single casualty, though the former was hit a score of times. The *Emden* (3,592 tons), which also fought to the last, was beached; she had, apparently, a complement of 316, of whom 115 were killed; the prisoners numbered 211, of whom 56 were wounded.

¹ *Naval Operations*, Vol. i. By Sir Julian S. Corbett. London: Longmans, Green, and Co. 1920. (Demy 8vo. pp. xiv + 470; case of maps. 17s. 6d. net.)

To the reader who is interested in the Naval Medical Service and desires to understand the difficulties which, under modern conditions, it has to surmount, no part of the volume will be more informing than the Introduction, in which Sir Julian Corbett briefly relates the changes in strategical plans which had to be made during the ten or twelve years before the war. They were rendered necessary in part by the increase in the size and range of guns and in the efficiency of torpedoes and submarines. But the change of fundamental importance was that our principal enemy in any future war based its growing navy on North Sea ports.

For the easily defended English Channel, in which the old enemy had no naval base of any importance, there was the expanse of the North Sea, with its broad and stormy outlet between Scotland and Norway, and the new enemy was so placed as to have entries to it at two widely separated points which are linked together by a perfectly protected inland waterway. Finally, instead of our southern seaboard, rich in well-disposed naval ports, we had, facing the enemy, a long stretch of coast dotted with vulnerable commercial ports, but without a single fleet base of the first order, except Chatham, which, owing to navigational difficulties, was incapable of being adapted to modern war conditions.

It was therefore decided in 1903 to make Rosyth in the Firth of Forth a first-class base, but within five years it was seen that it would not contain such a fleet as we needed; consequently plans were extended to Cromarty Firth and Scapa, and it was to Scapa that the Grand Fleet went on August 1st, 1914. The changes in the strategical plans affected every branch of the Navy, the medical with the rest. It had to adapt itself as best it might to the new conditions. Scapa, without defences, was equally without the buildings and equipment required for the medical services of the largest fleet ever assembled. The principal naval hospitals were in the south of England—at Plymouth, Portsmouth (Haslar), and Chatham, the last and nearest being some 600 miles from Scapa. How the situation was being met in 1917 was told in our columns by Sir James Porter and Staff Surgeon Vavasour Elder in that year. Nobody would be more competent to complete the story than the present Medical Director-General R.N., Sir Robert Hill, who was Principal Medical Officer of the Grand Fleet.

The interest of the story Sir Julian Corbett tells in this first volume is absorbing; it ought to be widely read, and we are glad to note that its price is moderate considering the high cost of producing so large a volume and eighteen large maps under existing conditions.

THE ENGINES OF THE BODY.

In *The Engines of the Human Body*² Professor KEITH has reproduced the substance of his Christmas Lectures delivered at the Royal Institution in the winter of 1916-17, elaborated and extended.

The purpose of the book, as it was of the lectures, is to present to a lay audience the human body as an engine, or rather as a combination of many engines of varied structure and action. The book deals primarily with the muscular system of the body, and may be conveniently divided into two parts, according to whether it is the voluntary or involuntary muscular system which is under consideration. The first portion has not, perhaps, for a medical public the same interest as the second portion, and the homology between a muscle and the internal combustion engine of a motor cycle strikes us, despite the highly ingenious arguments of the author, as rather strained. No attempt is, indeed, made to establish a strict parallelism between the two, and such fundamental differences as the multiplicity of the muscle engines, and the associated action of antagonistic muscles eliminating the characteristic jerkiness which is the feature of mechanical movements are well and clearly emphasized. Due insistence is also laid on the fact that the muscles as living tissue can respond to additional calls made upon them in a way no mechanical engine can rival, although, on the other hand, they are subject to a sense of weariness of which an engine can have no experience.

The second portion of the book, to adopt our own method of division, is concerned with the action of the involuntary muscular system, and here the chapters dealing with the

heart and the circulation, with respiration and digestion, are of special interest. It is particularly in these chapters that Professor Keith shows Nature and the engineer contending, if we may say so, with each other to obtain desired results. Although Nature is often, consciously or unconsciously, closely imitated, the superiority of her methods, her efficiency and economy, is never really in question. The instance which the author mentions in which he states that man seems to have stolen a march on Nature—namely, in the matter of wireless waves—is not, we venture to think, above dispute. "There is no evidence," he says, "which leads us to believe that Nature has ever used her wireless waves to provide a communicating system for linking living units together." That Nature does not habitually use this method of communication does not necessarily imply that she has not in the past and could not in the present supply such a system. She may have found the system unnecessary and inconvenient.

From the mechanical point of view everything is said, and said well, regarding the admirable pumping qualities of the heart, the perfect and economic piston-like action of the diaphragm, and the ingenious propelling power of the intestines. In connexion with this last matter Professor Keith compares and suggests that the comparison is close between the movements of the intestines and the movements of an earthworm. He does not, however, remark upon the important help which the worm obtains from its chaetae, and thus loses an opportunity of homologizing the chaetae with the fibres of the involuntary muscular tissue in the mesentery. The important part also which the mesentery plays not merely in supporting the intestines, but in preventing the intestines from forming those tangled coils in which the "resting" earthworm is frequently found, might have been mentioned.

The important parts played by chemical and psychological stimuli are adequately described, and much recent physiological knowledge on these matters is incorporated in the book, which is thereby made of very considerably greater interest and value. The work has the further and special merit of demonstrating more clearly than ever before the universal application of anatomy and physiology to other branches of human knowledge, and more than suggests that the chemist, physicist, engineer, and architect will find in the study of these subjects the solution of many of their problems, although no doubt there will always remain some residuum only to be resolved when, if ever, the secret of life has been disclosed.

Finally, no reference to the book would be complete which failed to express appreciation of the personal and historical passages which here and there lighten up its pages. If any criticism were passed upon these it would be that Professor Keith is somewhat inconsiderate in ignoring the work of Harvey's predecessors and contemporaries in connexion with the discovery of the circulation of the blood. Did, again, Sir Charles Bell find no warmth of welcome in London?³ Bell's account of his reception at the home of Sir William Blizard for some reason or other remains in our memory, and suggests that here and there at any rate he had as warm a welcome as could reasonably be expected.

These are, however, very minor matters. What is of real importance is that Professor Keith has managed, in a characteristically interesting and suggestive manner, and within the small compass of 280 pages, to convey much of our present-day knowledge regarding the principles upon which the human body is constructed, and the way in which its several parts perform their allotted tasks. The book is one which deals with these matters from a particular point of view—namely, that of the engineer; it is a point of view which was well worth stating, and we believe that there is no one in our profession who could have expressed it as adequately or as effectively as Professor Keith.

VENEREAL DISEASES.

COLONEL L. W. HARRISON'S *Manual of Venereal Diseases for Students*⁴ resembles very closely the author's previous publication, *The Diagnosis and Treatment of Venereal Diseases in General Practice*. It is, however, as its

² *The Engines of the Human Body*. By Professor Arthur Keith, M.B., LL.D., F.R.S. London: Williams and Norgate, 1919. 1 Henry 8vo, pp. xii + 284; 47 figures, 2 plates. 12s. 6d. net.

³ *A Manual of Venereal Diseases for Students*. By L. W. Harrison, D.S.O., M.B., Ch.B., M.R.C.P.E., Brevet Colonel R.A.M.C., and K.H.P. (ret.). London: H. Frowde and Holder and Stoughton, Ltd. 1 20. (Cr. 8vo, pp. 375; 19 plates; 63 figures. 16s. net.)

name implies, written for the medical student rather than for the qualified practitioner, and has been in certain directions condensed and simplified. But at the end of this process, and with all unnecessary details eliminated, venereal disease remains a formidably large subject in the curriculum of the medical student. Whether Colonel Harrison's estimate of the amount of knowledge of venereal disease that a student should be expected to obtain is excessive or not does not alter the fact that his *Manual* is an excellent work. Within its three hundred odd pages is condensed an immense amount of useful information—that is to say, information which is useful in the treatment of disease as well as in satisfying examiners. We believe, indeed, that the book will prove as useful to the general practitioner as to the student. It contains all that is essential of its forerunner, and some valuable additions—for example, a short description of the urethroscope and of its use in diagnosis and treatment has been added, and greater precision has been given to the chapter on the treatment of gonorrhoea in women. Where it has been necessary to make sacrifices in order to keep the book within the necessary bounds, points of theory rather than of practice have been cut out. In several places the blue pencil has been used to advantage, and chapters that were overloaded and guilty of repetition in the earlier work have gained in conciseness and vigour. As a result of this it is easier to seek out a particular point on which information is required. Where space is an all-important consideration a writer is compelled *malgré lui* to be dogmatic. This, though it may seem a disadvantage to the expert, is a boon to the beginner. Indeed, we feel that in many ways the *Manual* is an even better work for practitioners and students alike than its predecessor. In a chapter on the prevention of venereal disease the subject is regarded from the public health standpoint, and statistics are given of the results of prophylactic measures during the war. At the end of the book are four useful appendices. The first gives a clear sketch of the principles underlying complement fixation tests, and the second an account of staining methods employed in the detection of micro-organisms. The third and fourth appendices contain some formulae useful in the treatment of gonorrhoea and syphilis respectively. We have no hesitation in saying that *A Manual of Venereal Diseases for Students* is the best work on the subject that we have seen. It should have many editions.

DR. WANSEY BAYLY'S book on *Venereal Disease: its Prevention, Symptoms, and Treatment*,⁴ adds another to the list of useful small volumes dealing with these maladies in the light of modern knowledge. The author is a well known writer on this question, and his position as honorary secretary to the Society for the Prevention of Venereal Disease gives additional interest to the views expressed. The book opens with a chapter on prevention, in which the many-sided aspects of this complicated problem are indicated under various heads. Nevertheless, until some working agreement is reached between the two existing camps, all that is here written cannot be regarded as final. The part dealing with the clinical side of the subject is clear and informing, and shows in a practical manner how diagnosis and cure can best be effected in the different sorts and degrees of infection. Particularly striking are the clinical illustrations, the novel method employed conveying a clear suggestion of the diseased condition. The volume contains in short form the more important facts, and will be found a useful textbook for those embarking upon a study of these maladies. The concluding chapter discusses the organization, administration, and routine work of a venereal clinic.

UROLOGY OF TROPICAL DISEASES.

DR. JOSEPH KHOURI, in the preface to his essay on the pathological urology of hot countries,⁵ has pointed to the important place that tropical disease now occupies amongst medical studies. The world war has brought very many European medical men into contact with

tropical diseases that in former years had been to them merely unfamiliar names in medical textbooks. But whilst many excellent textbooks on tropical complaints are in existence, no author has previously attempted to treat the subject purely from the standpoint of the urologist. It is therefore with the idea of supplying a complete synopsis of the urology of tropical diseases that Dr. Khouri has written his book.

Under the headings of the various tropical diseases known to medicine are given concise accounts of the changes that occur in the urine. But although the careful examination of the urine is undoubtedly an important step in arriving at a diagnosis, it is to the research worker rather than to the ordinary practitioner in tropical diseases that Dr. Khouri's monograph will primarily appeal. The author writes as a pure scientist, and as a chemist rather than as a clinician. He has collected a large number of scientific facts and placed them at the service of all who may be disposed to undertake research along similar lines; and to each chapter he has appended a very complete bibliography. The book is the result of twenty years' work in Egypt, and undoubtedly contains much that is of value.

The second part deals with the elimination of drugs by the kidneys and with methods of detection and estimation. Much of it is the result of the author's original observation. Altogether the subject has been treated with great completeness and accuracy. It is a book to which future research workers in tropical medicine will certainly appeal.

NOTES ON BOOKS.

REMARKING that there are already far too many medical periodicals that the overworked medical man is expected to read in Germany, Professor BRUGSCH of Berlin prefaces a new one, the *Ergebnisse der gesamten Medizin*,⁶ with the pious hope that it may give a true and complete picture of current medical practice and progress; and no doubt the corollary is that all other medical periodicals will become superfluous now that this compendious summary is available. The first number contains five-and-twenty articles on the symptoms and treatment of disease, speaking generally. With regard to the subjects dealt with in these articles, it may be pointed out that eczema, diphtheria, gonorrhoea, and the like are subjects the general practitioner of medicine will be glad to read about in these pages; but will he have much use for the article on "Dysbasia angiosclerotica"? The various authors of these reviews give numerous references to the literature of their subjects, almost entirely excluding work done outside the borders of the Central Powers; we notice, however, that the important paper on "Trench Fever," by McNee, Renshaw, and Brant, that appeared four years ago in the BRITISH MEDICAL JOURNAL is quoted under the title "Frühfieber," and under the names "Mc. Nee, Reuschen, and Brand," in these *Ergebnisse*. How often the periodical is to appear does not seem to be stated; its price—180 marks in paper, 240 marks bound—may be taken as an index of financial stringency rather than intrinsic merit. Broadly speaking, it appears too abstract a periodical for practical men, too loosely written and second-hand for men of science.

DR. ROCKWELL'S *Rambling Recollections*⁷ afford the reader an admirable picture of the happy insouciance of high class medical practice in America during the last third of last century, and give an attractive and entertaining description of the author's intercourse with countless Americans of note and notoriety. During the course of a long professional career Dr. Rockwell has been brought into contact with all sorts and conditions of men, and the story of his experiences as an army surgeon in the civil war, and as one of the first to introduce electrical treatment, interspersed with human touches at every point, should appeal to readers of all classes.

IN *Domus Doloris*,⁸ Mr. COMPTON LEITH offers an etherealized and philosophic picture of hospital life and hospital work during the war, purged of gross detail,

⁴ *Venereal Disease: its Prevention, Symptoms, and Treatment*. By Hugh Wansley Bayly, M.C., late Surgeon R.N. (temporary) and Acting Major R.A.M.C.T.F. London: J. and A. Churchill. 1920. (Med. 8vo, pp. viii + 152; 5 figures, 10s. 6d. net.)

⁵ *Essai d'Urologie Pathologique des Pays Chauds*. Par Joseph Khouri, Docteur de l'Université de Paris (Pharmacie). Paris: J. B. Baillière et Fils. 1919. (Med. 8vo, pp. v + 183. Fr. 6.)

⁶ *Ergebnisse der gesamten Medizin*. Unter Mitwirkung hervorragender Fachgelehrter herausgegeben von Professor Dr. Th. Brugsch, Oberarzt der II med. Klinik der Königlichen Charité in Berlin. Erster Band. Berlin and Vienna: Urban and Schwarzenberg. 1920. (Imp. 8vo, pp. 653; 160 figures, 14 plates. M. 130 in paper; M. 240 bound.)

⁷ *Rambling Recollections*. An Autobiography. By A. D. Rockwell, M.D. New York: Paul B. Hoeber. 1920. (Roy. 8vo, pp. 332; 7 illustrations. 4 dols. net.)

⁸ *Domus Doloris*. By W. Compton Leith. New York: John Lane Co. London: John Lane. 1919. (Cr. 8vo, pp. 222. 7s. 6d. net.)

analytical, redolent of the classics, in touch with humanity and the larger soul through all the avenues of feeling. Such literature as this, with its graceful cadence and dreamy sentences, falls pleasantly on ears deafened by the din of the market place, and should serve to bring home to its readers the deeper meanings and moral lessons that may be drawn from the war and all the sufferings it entailed. We commend this book to the attention of the many readers of all classes who welcome poetic prose and the distraction from the commonplace it offers.

Three lectures on various aspects of *Education in War and Peace*,⁹ by Dr. STEWART PATON of Princeton, deal out to the patient reader a series of generalities on the aims and methods of education, the relations of the mind to the body, the interest of psychiatry and the study of social misfits, from the point of view of an American university lecturer in neurobiology and psychiatry. He urges the importance of studying the genesis of the social unrest and emotional disorders now so prevalent throughout the world.

Miss BARBARA LOW's *Psycho-Analysis*¹⁰ gives the general reader and teacher some insight into a subject that has suffered as much from its defenders as its critics. The book is short, generalized, and written in a highly appreciative manner; it is perhaps stronger on the theoretical side than the practical.

⁹ *Education in War and Peace*. By Stewart Paton, M.D., Lecturer in Neurobiology, Princeton University, etc. New York: Paul B. Hoeber, 1920. (Cr. 8vo, pp. ix + 105. 1.50 dols. net.)

¹⁰ *Psycho-Analysis*. A Brief Account of the Freudian Theory. By Barbara Low, B.A. Introduction by Ernest Jones, M.D., M.R.C.P. Lond. London: George Allen and Unwin, Limited. 1920. (Cr. 8vo, pp. 191. 5s. net.)

THE LONDON RADIUM INSTITUTE.

ANNUAL REPORT OF THE MEDICAL SUPERINTENDENT,
MR. HAYWARD PINCH, F.R.C.S., FOR 1919.

The Radium Institute in Riding House Street, Portland Place, London, was opened in August, 1911. In his annual report for 1919, Mr. Hayward Pinch, F.R.C.S., the medical superintendent, who expresses his acknowledgements to Dr. J. E. A. Lynham (assistant), has taken the opportunity of summarizing some of the conclusions he has reached with regard to the method of using radium. Special attention is directed to the construction of apparatus, to application in various situations and for various purposes, to variations in the reactions, local and general, to the sequelae occasionally met with, and to the measures taken for the protection of radium workers from the local and general effects of the rays. Prognosis is discussed at some length in order to indicate what benefit may reasonably be expected from radium therapy. These sections are founded on Mr. Pinch's twelve years' experience, and on the administration of over 70,000 treatments.

APPARATUS.

The rays emitted by radium salt and radium emanation are identical, and both are used at the Institute. The therapeutic power of alpha rays, which consist of positively charged atoms of helium, with a velocity of one-fifteenth that of light, is negligible, as they are stopped by thin metal, glass, paper, rubber, or a few centimetres of air. The velocity with which the beta rays—consisting of negatively-charged bodies—are projected is of the same order as that of light, but varies so that three types are distinguished—soft, medium, and hard—the velocity of the first being least and of the last greatest. They are of the same type as the cathode rays produced in a vacuum tube. Gamma rays are considered to be analogous to very penetrating Roentgen rays; their passage through metals produces "secondary" or "excited" rays, which may cause considerable surface irritation.

When radium salt is used the strength of the apparatus is expressed in terms of hydrated radium bromide, which contains 55.6 per cent. of radium, but as it is a deliquescent salt, it is converted into the insoluble sulphate and is used either in capillary glass tubing or on applicators of various sizes and three strengths, containing in the square centimetre—full strength 1 eg., half strength 0.5 eg., and quarter strength 0.25 eg., corresponding roughly to the

French classification of 2,000,000, 1,000,000, and 500,000 activities. An advantage of the applicators is that the emitted radio-activity is always constant, and the apparatus if carefully handled needs little attention beyond an occasional renewal of its varnish. Radium emanation is used either in tubes or in hollow applicators of thin german silver or glass. The loss of value of radium emanation, due to decay of the emanation, can be provided against. During the first twenty-four hours the emanation loses exactly 16 per cent. of its activity; it is therefore possible to make an apparatus the mean activity of which for twenty-four hours shall be practically the same as that of a radium salt applicator of known strength. For example, to obtain the effect of an exposure of twenty-four hours with emanation equal to that emitted by 100 mg. of radium bromide, an emanation tube is used possessing an initial activity of between 109 mg. and 110 mg.; at the end of twenty-four hours it will have fallen to between 92 mg. and 93 mg., so that its mean activity for the whole period will be as nearly as possible that of 100 mg. of radium salt.

Clinical experience has rendered it possible to reduce the number of screens to four types:

Aluminium, 0.01 to 0.2 mm. in thickness.
Silver, 0.2, 0.5, and 1 mm. in thickness.
Lead, 0.1, 1.0, 1.5, and 2 mm. in thickness.
Platinum, 0.3 mm. in thickness.

The best screen for general use, whether for tubes or applicators, is 1 mm. of silver, which reduces the percentage of beta rays to 1.18, but of gamma rays to 95.5 only. Aluminium screens are used in the treatment of superficial and non-malignant cutaneous lesions, and platinum for small but powerful tubes to be buried in small malignant growths in the neighbourhood of the mouth, fauces, and air passages. Lead screens 2 mm. thick cut off nearly all the beta rays, but allow the gamma rays to pass to the extent of 92.8 per cent. Screens of various forms are used to suit the situation and purpose in view. Investigations have been made in the Research Laboratory of the Institute to ascertain the best method of absorbing secondary rays excited in thick screens of heavy metal, which, as has been said, cause considerable surface irritation. It has been found that the emergent secondary rays from a lead screen 2 mm. thick can be completely absorbed for all practical purposes by a layer of aluminium 2 mm. thick; the lead screens now used have an aluminium sheath of this thickness.

A flat applicator should be somewhat larger than the lesion to be treated. Healthy skin and tissues surrounding the lesions should be protected by a layer of lead rubber; the lesions should be cleansed and dried, and the applicator, if used unscreened, covered with a thin layer of rubber sheeting to protect it from moisture or discharge. The method of burying tubes in growths varies according to the situation. Whenever it is possible to bury a tube this is done, because the radiation from it is centrifugal and the whole of its activity is made effective; if merely laid upon the surface, little more than 30 per cent. of the rays come into action. Details of the method of application in various positions are given.

REACTION.

All tissues when treated with radium respond by a reaction, the nature and extent of which is determined by a number of different factors.

Mucous surfaces are much more responsive than dry skin, and moist skin or surfaces more than dry. Carcinomatous or sarcomatous tissue does not show the same resistance to radium rays as normal cells, and it is upon the appreciation of this fact that successful radium therapy largely depends. Tissues which have previously been treated much with x rays or ionization, or by CO₂ snow, or cauterization, require special care, as slight overdosage may be followed by breaking down of old scar tissue far beyond the area it is desired to affect. The extensive dissection required in the performance of Wertheim's hysterectomy seriously impairs the vitality of the pelvic tissues for some time, so that the propriety of giving radium treatment within three or even six months must be carefully considered. The reactions in persons suffering from locomotor ataxy, syringomyelia, paralysis, or other diseases affecting the functions of the trophic nerves, are often extensive.

The reaction is influenced not only by the strength of the applicator but by the size of the area to which it is applied. Further, marked personal idiosyncrasies are observed; in neurotic persons both the local and systemic reactions are likely to be greater than in the phlegmatic. In the treatment of some uterine conditions it is desirable to use only half strength in persons of neurotic temperament.

Four degrees of local reaction are distinguished:

1. Simple erythema.
2. Erythema followed by desquamation.
3. Vesication with superficial ulceration.
4. Deep ulceration, generally followed by the formation of a definite "limpet-shell" crust, beneath which repair takes place.

The interval before reaction takes place varies. Sometimes it is short; this is particularly noticeable in capillary naevi. On the other hand, in treatment for rectal disease the reaction may not come on for three weeks or more, and may then persist for a month or six weeks, not disappearing entirely for about three months.

Systemic reaction may occur when a large quantity of radium has been employed and long exposures given; on or about the fourth day after the termination of the treatment the patient suffers from languor, nausea, sometimes vomiting, and a rise of temperature to 100 or 101°. These symptoms, no doubt due to auto-intoxication, may be ameliorated by the judicious employment of laxatives and diuretics. In exophthalmic goitre the first effect of the treatment is often an exacerbation of the symptoms, due probably to an increased influx of thyroid secretion into the blood stream.

SEQUELAE.

Certain late effects must be guarded against: among them are pigmentation and telangiectasis, noticed especially after treatment of cutaneous naevi; the risk cannot be altogether avoided, but it may be diminished by taking care to avoid vesication. Patients should be seen every three months for at least two years, and any telangiectasis destroyed with a fine electric cautery. Pigmentation may be kept in check by the application of a weak lotion of mercury bichloride and glycerin. Superficial ulceration sometimes follows prolonged treatment of naevoid growths; the treatment must then be suspended for at least six months, and resumed with care.

In the vagina or rectum frequent exposures with heavily screened applicators may be followed by a considerable degree of progressive annular fibrosis, which will require dilatation with the finger or bougie.

EXPOSURES.

The length of exposure varies according to the object it is sought to attain; exposures of three to fifteen minutes, using half-strength applicators unscreened, are generally used in the treatment of superficial cutaneous lesions, such as chronic eczema, lichenification, and psoriasis; exposures of thirty to ninety minutes, with half or full strength applicators, are used for very superficial small capillary naevi, keratomata, warts, corns, papillomata, and the early stages of rodent ulcer. Exposures of from ninety to 120 minutes are used, with full-strength applicators, when it is desired to produce a definitely destructive reaction, as in the treatment of hypertrophic or deeply ulcerated rodent ulcers, small localized epitheliomata, and pigmented moles. Cavennous naevi, keloids, vicious cicatrices, flat superficial epitheliomata, indolent ulcers, and inflammatory induration of recent origin are treated by half-strength applicators, screened with 0.1 mm. lead, or 0.5 or 1 mm. silver, for thirty to ninety minutes. When it is desired to obtain only the gamma radiation a screen of 2 mm. lead is employed, and the length of the exposure is usually from twenty to forty hours, or even longer.

When tubes of salt or emanation are buried in a tumour a screen of 1 mm. of silver is usually employed, and the length of the exposure is twenty-four hours. A tube should not be buried in a rapidly growing carcinomatous nodule, as it merely increases the necrosis; it should be directed to the periphery of the growth and prolonged screen exposures given, in the hope of limiting spread by stimulating fibrous tissue formation. Mr. Hayward Pinch states that "There appears to be some difference in the response of growths of epiblastic as opposed to those of

hypoblastic origin; the former appear to be more favourably influenced by a longer exposure with a weaker dose, the latter by a shorter exposure with a larger dose—for example, 100 mg. for twenty-four hours in the one case, 200 mg. for twelve hours in the other."

RADIUM WORKERS.

A person who habitually handles radium or is constantly in contact with radium rays suffers local and systemic effects. After working for a few months with radium apparatus the skin of the fingers becomes roughened and inelastic, and the tactile sense is diminished, but sensation to heat and cold is exaggerated. Later the skin becomes fissured, small corns or warts develop, and the nails become thick and brittle. As the clinical workers are more affected than laboratory workers it is thought probable that the majority of the local effects are due to the "secondary excited" rays. The general symptoms are said to be disproportionate fatigue after a day's work, and after a time a fall in the number of white corpuscles; there is also a diminution in the number of red corpuscles, but at first this is to some extent compensated by an increase in the colour index. Many female workers, it is said, "show a peculiar susceptibility in respect of their menstrual functions. Menorrhagia is first noted, the periods then become irregular, and amenorrhoea results, and remains permanent so long as the worker continues at her employment, though the functions return to normal after a holiday of four or six months' duration."

To prevent local effects workers are required to wear thick leather gloves, and to handle apparatus as far as possible with forceps a foot long. Screens are also used, but it has been found that no nurse or attendant should be allowed to make up or habitually apply apparatus for more than three months; there should then be an interval of rest at least as long. As emanation does not produce secondary radiation for at least half an hour after its preparation it is easier to handle. For the prevention of the general effects care should be taken to keep all radium apparatus in closed leaden boxes 4 to 5 cm. thick. In making up the apparatus a leaden breastplate or screen should be used. Each worker should be given two clear days' holiday a week, to be spent as much as possible in the open air.

CARCINOMA.

With the exception of rodent ulcer, to which separate reference is made, no operable cases of malignant disease are treated at the Radium Institute, save in the few instances in which the patient positively refuses operation. In at least 70 per cent. of the cases treated the disease was far advanced, and extensive dissemination was present, so that arrest of the progress of the disease and relief of the attendant symptoms are the utmost that can be expected.

Breast.

Cases of carcinoma of the breast constitute 25 per cent. of all those treated. In the rapidly growing encephaloid type with extensive lymphatic involvement prognosis is invariably bad, but very prolonged screen exposures to the periphery of the growth may occasionally retard the progress of the disease to some slight extent. On the other hand, the atrophic type usually responds favourably to prolonged screened exposures, which have the effect of reinforcing the natural tendency to the production of a curative fibrosis. The prognosis in the various types of cases between these two extremes depends to a great extent upon the history and clinical features; the object of treatment should be to increase the development of fibrous tissue in the hope of constricting the carcinomatous alveoli, causing degeneration of their contents and arresting dissemination by the lymphatics. Half-strength applicators, screened with 1 mm. of silver and applied for twelve to eighteen hours, may induce healing of ulcerated skin over the growth. Small isolated subcutaneous nodules attached to muscles, ribs, clavicle, or sternum, are treated by the insertion of an emanation tube for eighteen to twenty-four hours. Metastatic lesions of the viscera, scalp, or long bones, are treated by prolonged screened exposures which may arrest the progress of the disease, and sometimes cause an actual decrease in the size of the secondary foci.

Uterus.

In the patients with cancer of the uterus received at the Institute the disease has, as a rule, existed for so long and dissemination is so far advanced that little hope of effecting even "apparent cure" can be entertained. In a few border-line cases radium irradiation has been used in the hope of diminishing the amount of existing induration and the fixation of the uterus, so that its removal can be more completely and satisfactorily accomplished. We quote in full the remainder of this section of the report:

It has hitherto been the practice at the Radium Institute strongly to urge immediate operation in cases where such a measure is practicable, but radium treatment appears to exert such a very beneficial effect upon early cases of carcinoma of the cervix that if the patient exhibit any great reluctance to operative interference the latter method of treatment may be adopted.

In cases which are manifestly inoperable the systematic improvement which almost invariably follows upon radium treatment is most striking, and far exceeds that of any other therapeutic measures. Arrest of haemorrhage, lessening of discharge, healing of ulceration, reduction of surrounding infiltration, diminution of the rate of growth, and amelioration of pain are constantly observed, and though the susceptibility of patients varies within very wide limits, some responding much more speedily and completely than others, yet in nearly every instance definite benefit results, and the progress of the disease is greatly retarded.

Several factors must be taken into account when attempting to form a prognosis in the radium treatment of uterine cancer. The disease usually runs a slower course, and dissemination into the pelvic glands is much less active in patients who have passed the climacteric than in those in whom the menopause has not been established. Very young and very corpulent patients also do badly, though this rule is not without its exceptions.

The cases in which the best results may be anticipated are those in which the patients are of 50 years of age and upwards, where there is but little fungation, the vesico-vaginal and recto-vaginal septa are not much involved, and there is no very great amount of peri-uterine induration present. In these instances definite arrest of the progress of the disease is sometimes obtained, the patient remaining apparently well for three, four, or more years. It is not, however, correct to speak of these cases as "cured," as there is always the probability that sooner or later evidence of dissemination will occur, and the disease will be found to be affecting regions far beyond the effective range of radium. Recurrences in the vaginal wall after the operation of hysterectomy, if taken at an early date, often do surprisingly well, their complete disappearance is occasionally brought about, and no recurrences take place.

When the uterus is very firmly fixed, the patient complaining of sacral and pelvic pain radiating into both thighs, infection of the pelvic glands and deep parametric tissues may be regarded as certain, and radium is able to do but little for these patients beyond possibly arresting the disease and slightly diminishing the pain.

When treating cases of cervical carcinoma, if the growth be of the cauliflower or fungating type the removal of as much of the mass as possible by excision or cauterizing before the treatment is commenced is to be advocated. A tube containing not less than 100 mg. of radium should be employed, the screening should be either 1 mm. of silver or 2 mm. of lead, according to whether the apparatus can be inserted actually within the cervical canal or has to be placed in the vagina in contact with the diseased surface.

The uterine tissues appear to have a greater power of resistance to the radium rays than have the vaginal ones, and the employment of a silver screen in contact with the vaginal wall for a period of more than eighteen hours may quite possibly lead to the formation of a fistula, but with the tube inserted within the cervical canal this contingency does not arise. The exposure should be between twenty and twenty-four hours' duration, and may advantageously be supplemented by the use of a plate containing 100 or more mg. of radium screened with 2 mm. of lead, and applied externally over the fundus. By this means a thorough radiation of the whole diseased area is obtained. The exposures should be repeated at intervals of not less than six weeks.

Circumscribed and indurated nodules of small size in the substance of the cervix may receive, in addition, treatment by the insertion into their substance of thin emanation tubes of 20 to 30 mg. initial activity, screened

with 0.3 mm. of platinum, for from twelve to eighteen hours.

Carcinoma of the body of the uterus is of much less frequent occurrence than cancer of the cervix, and since the prognosis as regards recurrence after hysterectomy is very favourable, operation should always be resorted to if practicable.

If radium treatment be determined upon, a tube of not less than 160 mg., screened with 1 mm. of silver, should be inserted into the uterine cavity, supplemented if possible with a plate of equal strength, screened with 2 mm. of lead, and applied over the fundus. Great caution must be observed in making the intrauterine application, the uterine walls being extremely friable when infiltrated with carcinoma, and readily perforated if undue force be used.

Tongue, Fauces, and Oesophagus.

Cases of carcinoma of the tongue, palate, and buccal mucous membranes only come under treatment when all surgical measures have been exhausted and recurrence is widespread, producing constant and severe pain. The results of treatment in such cases are unsatisfactory. Upon those in which acute ulceration predominates radium has very little effect, although occasionally exposures of one to two hours' duration to tube apparatus in contact with the ulcerated surface on four or five successive days tends to arrest the ulceration and sometimes to induce very transient repair. Cases in which induration predominates are more amenable; when the induration is circumscribed, or in the form of small non-ulcerated nodules in the tongue, the floor of the mouth, the palate or jaws, the insertion of a small powerful emanation tube, screened with 0.3 mm. of platinum, for five to six hours, will bring about their disappearance. The probability of lymphatic infection may be diminished by the prophylactic radiation of the cervical and submental glands. Exuberant papillated epitheliomatous growths of the mucous membrane of the mouth, with little submucous invasion, if treated at an early stage by brying powerful emanation tubes, often clear up completely and then seldom recur. With old lymphatic infection and masses of indurated glands prolonged exposures, with heavily screened apparatus, are often of considerable use in diminishing the size of the glands and preventing implication of the skin covering them. In some cases the neuralgic pains are distinctly relieved after prolonged irradiation, but this result cannot be assured in any particular cases. Definite but only temporary relief may sometimes be obtained in cancer of the oesophagus by the use of radium. It must be applied by a laryngologist skilled in oesophagoscopy.

Rectum.

The form of carcinoma of the rectum which does best is the annular, vascular exuberant type at the upper half of the rectal ampulla. If much ulceration be present colostomy should be performed before radium treatment is undertaken, as the passage of faeces over an ulcerated surface, made more tender by a radium reaction, produces very severe pain. As the healthy rectal mucous membrane is very susceptible to radium rays great care must be taken to protect it during the treatment. During the year some cases received injections of cuprase between the radium exposures: 5 c.cm. of the solution was injected intramuscularly every fourth day until 60 c.cm. had been injected. Mr. Pinch expresses no positive opinion, but the results have, he says, been such as to justify a continuation of the combined treatment.

Bladder and Prostate.

The treatment of inoperable carcinoma of the bladder by radium sometimes gives extremely good results, especially in women in whom, in addition to the radium tube in the bladder, a screened tube is placed in the vagina. Carcinoma of the prostate, limited to one lobe, the enlargement of the gland not being very great, is treated by burying a silver screened emanation tube within the carcinomatous mass. If the patient objects to this, the method of cross radiation with a tube in the urethra and a plate over the perineum has sometimes been found to produce definite improvement and prolongation of life for perhaps two or three years.

Stomach and Intestines.

In inoperable cases of carcinoma of the stomach and intestines prolonged exposures with heavily screened

powerful applicators sometimes diminish the pain and arrest the progress of the disease.

RODENT ULCER.

This is the only form of malignant disease in which it is at present justifiable to use radium therapy in preference to any other method. The results are, of course, more satisfactory in early cases. Rodent ulcers previously treated repeatedly with caustics, scraping, CO₂ snow, or x rays, must be very carefully handled, or a destructive reaction far exceeding what is desired may occur. If rodent ulcer has invaded the bony tissues radium has no power to cure; therefore the affected portion of bone should be excised before radium treatment is commenced.

SARCOMA.

The response of sarcomata to radium treatment varies; the periosteal variety usually responds better than the endosteal, and if it does respond, the tendency to recurrence or dissemination is greatly inhibited, so that the patient may remain "apparently cured" for many years. Prognosis is better in a spindle-celled sarcoma than in the small round-celled variety; the large round-celled type appears to occupy an intermediate position. The result in cases of myeloid sarcoma (now named "myeloma") is uncertain; in about half the cases radium produces no effect, but in the other half the result is gratifying. Of sarcomata affecting the nasopharynx Mr. Pinch says:

These are extremely susceptible to radium, and often completely disappear within a month of the treatment. The lympho-sarcomata attacking the cervical and mediastinal glands usually show a very rapid and pronounced improvement, the improvement persisting for four or six months. In most cases some recrudescence of the condition is then noted, necessitating further exposures, which may have to be repeated at prolonged intervals for three or four years. A time is, however, ultimately reached when the response to radium treatment becomes negligible, and the disease then rapidly assumes the mastery.

For the treatment of sarcomata massive doses must be given, and whenever practicable silver-screened tubes should be buried in the centre of the mass.

NON-MALIGNANT CONDITIONS.

Uterine Fibroids.

The relief which follows the treatment of uterine fibroids with radium is stated to be definite and striking. The reduction in the size of the tumour may not be very great, but the flow is gradually checked and may return to normal or may cease altogether for three or four months, or longer. It may be necessary to repeat the treatment after three or four months, and if it is given on three or four occasions the probability of premature menopause must be made clear to the patient. Chronic metritis also responds to radium therapy.

Naevi.

The best results in cavernous naevi are obtained if the infant is seen before other treatment has been adopted. Radium treatment requires great patience on the part both of the operator and parents. When a cure has been effected there appears to be no tendency to recurrence. The results in capillary naevi vary very greatly. If complete blanching can be obtained by a moderate degree of pressure the result will probably be good; if not, no more than a diminution in the intensity of the colour is to be expected. Owing to liability at a later stage to telangiectasis or pigmentation the child should be seen at fairly frequent intervals for some time.

Warts, Papillomata, and Keloids.

The majority of corns, warts, papillomata, and keratomata can be removed by short exposures. With a correct dose exfoliation of the growth, with little accompanying inflammation, occurs three to four weeks after the application. Radium treatment of keloids and vicious cicatrices generally brings about great improvement, if not complete disappearance.

Lupus Erythematosus.

This obstinate and disfiguring disease is frequently very greatly improved by radium therapy, though recurrences tend to take place after varying intervals.

Tuberculosis.

In the treatment of lupus vulgaris the Finson light is usually to be preferred to radium, but it will, not infrequently, give excellent results in cases that prove refractory to the light. Lupus in a position inaccessible to Finson light, as in the mucous membrane of the nose, is suitable for radium therapy; cross radiation is employed. Lupus of the palate and fauces may often be very greatly improved by radium. Radium treatment of tuberculous adenitis, if adopted at an early stage before numerous glands are affected and caseation has occurred, may with some confidence be expected to give favourable results.

Skin Diseases.

Many chronic forms of superficial skin diseases, such as lichenification, chronic eczema, leucoplakia of the first degree, and pruritus, are favourably influenced; so also is psoriasis, though it shows a strong tendency to recur.

ARTHRITIS DEFORMANS.

Infective arthritis of comparatively recent origin in patients under 40, accompanied by peri-articular rather than intra-articular changes, is often greatly benefited by the internal administration daily of 500 c.cm. of a solution of radium emanation of a strength of 1.5 millicuries to the litre. When one joint only is affected and the changes are intra-articular, with osteophytic growths or pathological changes in the bones or cartilages, little good is to be expected.

CHEMICO-PHYSICAL LABORATORY.

Mr. W. L. S. Alton, F.I.C., director of the laboratory, has had the help of Mr. J. F. Clarke, M.Sc., who was appointed in June. The number of emanation tubes and applicators prepared was 771, giving an activity in terms of radium bromide equal to 66.04 grams. A large quantity of the radio-active water, referred to in connexion with arthritis deformans, was prepared. The number of radium applicators made included a set for a hospital at Reykjavik; others were made for a medical man in New Zealand, and a complete installation for making emanation applicators was supplied to a clinic in Paris. Mr. Clarke carried out measurements of the amount of secondary radiation emitted by compound lead-aluminium screens. Mr. Austin refers to the precautions that must be taken to protect the workers with radium; they include powerful fans for ventilation, as it is inadvisable to breathe air containing emanation, and accidents to emanation tubes occasionally occur.

RESEARCH DEPARTMENT.

Dr. J. C. Mottram, director of this department, reports that it was opened in May, 1919, but that considerable delay occurred in fitting up the laboratory. He reported to the Electro-Therapeutic Section of the Royal Society of Medicine an investigation into the leucopenia produced by radiation; he had also made a report to the same section on the examination of patients in ultra-violet radiation, after the manner devised by Professor R. W. Wood (Baltimore). Dr. Mottram describes it as follows:

Dr. Wood produced a glass which, whilst allowing ultra-violet radiation to pass, is opaque to light. Using an arc lamp, such as a mercury vapour lamp, one is thus able to obtain a beam of ultra-violet radiation. On examining patients in the beam a number of striking appearances are seen. Briefly, the skin is seen to glow with a violet light; but certain areas, especially on the face, are not fluorescent, and appear as black spots. This spotty appearance varies much, some individuals are almost free from spots, whilst others are thickly covered. Similar differences are to be seen in photographs taken in a particular manner with an arc lamp, and it has been observed at the institute that patients showing a spotty appearance in these photographs are more susceptible to radium radiation than the relatively unspotted. As the spots in the two cases (that is, photographically obtained and seen in ultra-violet illumination) are almost certainly the same, it follows that examination in ultra-violet radiation will probably give the radiologist a means of at once estimating the susceptibility of his patient. Other striking appearances are seen besides the dark spots. Scattered over the face are numerous minute brightly fluorescent spots, having the appearance of stars. The teeth are very brilliantly fluorescent, less so the nails. The eyes may be likened to the eyes of a boiled fish—this being due to fluorescence of the lens. Whether these and other appearances will be of value in radium treatment remains to be seen.

British Medical Journal.

SATURDAY, MAY 8TH, 1920.

ENDOCRINOLOGY AS AN EXACT SCIENCE.

THE speculative philosopher is always with us, and during the last few years has found his chief medical field of activity in the ductless glands and their secretions. Here he has been extremely busy, with the result that the number of such "glands" has grown almost equal to the number of different tissues in the body: while the number of internal secretions and hormones postulated has become no less enormous. Indeed, it may be said, not unfairly, that with many writers who deal with the subject the only proof of the existence of a hormone nowadays required is that it should seem to be demanded by theory. As an example may be quoted the "libidogenous hormone," to which Higier attributes the existence of libido, libido being the term to indicate the instincts of self-preservation and race propagation. The libidogenous hormone, we read, is secreted "in all probability" by the interstitial substance of the testicle; the plain man may perhaps be excused if he prefers to regard it as a typical secretion of balderdash. Such loose fancies as those leading to the invention of "libidogenous hormones" and the like do nothing to aid in the advancement of science.

Professor Gley has recently collected four lectures,¹ delivered at the end of the year 1917 at Barcelona, and they form a useful corrective of the tendency. The whole subject is one which Professor Gley may be said to have made peculiarly his own during the last thirty years, and in these brief, masterly, and well-poised deliverances will be found a summary of present knowledge of the internal secretions. He would distinguish two classes—hormones proper, and harmozones, a word formed from ἁρμόζω (to regulate or direct); the word is intended to be non-committal, for the nature of the substances is unknown, though they must be presumed to exist in order to account for the known action of certain organs on the growth and nutrition of certain others at a distance. The most striking example is afforded by the thyroid, which influences the formation of the skeleton, the growth of the genital glands, and the development of the higher cerebral functions. Another instance is afforded by the interstitial substance of the testicle, a gland producing an internal secretion which determines the development of the special characters of the skeleton, and of the skin and cutaneous appendages proper to the male; further, it would appear that there are formed by the interstitial gland and the pituitary body not only substances which stimulate growth—harmozones—but others, called chalones² by Sir E. Sharpey Schafer, which control growth and limit its extent. Professor Gley traces the whole idea of internal secretions back to Claude Bernard's discovery of hepatic glycogenesis in 1855. In the second lecture Professor Gley shows that three criteria—histological, chemical, and physiological—must be satisfied before a gland can be passed as endocrine; and that a hormone cannot be recognized as such until it has been proved to have

a definite physiological action and has been found both in the venous blood leaving the gland that secretes it and in the general arterial blood. The method of looking for hormones or internal secretions by the injection of glandular extracts is, he holds, inadequate, and he advances evidence to prove that it has often proved fallacious. Thus recent work on the suprarenal glands tends to prove that the suprarenal cortex and its secretion, adrenalin, have not the physiological importance usually attributed to them. The medulla of the gland may be the essential part: the cortex may be concerned mainly in the elaboration of lipid substances and cholesterolin. Professor Gley maintains that in the past experimental physiologists have often, for want of clear thinking and the neglect of suitable experimental methods, fallen into the error of assuming that the constant physiological action of an organ of internal secretion is identical with that of a large quantity of the extract of an organ suddenly thrown into the circulation. A line of argument often employed here is one that would lead an experimenter using cascara and observing its customary effects to conclude that constipation is an expression of hypocoascarism.

Professor Gley admits that the experiments of Bayliss and Starling on secretin fulfil all the conditions he requires; they show conclusively that this substance is produced by the mucous membrane of the duodenum when acted upon by hydrochloric acid, and is carried by the blood to the pancreas, which is stimulated to activity; he recognizes also that the existence of a galactogenic hormone producing lactation and of a testicular harmozone may be taken as proved, though their existence cannot yet be regarded as certain. Much more uncertain is the secretion of hormones and harmozones by the hypophysis, the pancreas, the liver, the thyroid, the thymus, the testis, or the corpus luteum. Here is a fruitful country for further study, and Professor Gley points out the road that experimental physiologists must follow and the pitfalls into which so many of their predecessors have fallen. In his fourth lecture he describes the revolution in biological science produced by the notion and investigation of internal secretions.

The study of these lectures may be warmly recommended to medical men and others interested (as indeed we all are) in the progress of knowledge of the endocrine glands. It is a matter of great practical importance; it is also of great theoretical interest, but has here the weakness of lending itself too readily to hasty and speculative misinterpretation. Professor Gley may be accepted as an authoritative guide in all these matters both of fact and fancy, and his lectures will help to raise endocrinology from the slough of guesswork and hypothesis into which it has been precipitated by the enthusiasm of some—by no means all—of its exponents.

RADIUM THERAPY.

THE report for 1919, by Mr. Hayward Pinch, on the London Radium Institute, is a document of more than ordinary interest and well worthy of study, not only by those directly concerned with the administration of radium, but by members of the profession generally, since in it an attempt is made to define some basis for prognosis. Many difficulties in this respect remain, but Mr. Pinch has succeeded in indicating some of the factors, and we think that anyone who will read the full account published elsewhere in this issue (p. 640) will be convinced that he is actuated by a desire to give an impartial opinion.

² ἁλόνες—lo check. *The Endocrine Organs.* London, 1916.

He is to be congratulated upon the facility he shows in conveying to readers so much in words so few and so well chosen. Whilst on the whole the record of the year's work only emphasizes the results of previous years, three points appear worthy of special attention. In the first place, and speaking somewhat generally, there appears to be a tendency to emphasize the importance of using larger quantities of radium for the treatment of definitely malignant conditions. A second point of importance relates to the results he has obtained in the treatment of cancer of the uterus, and it is evident that increasing experience is suggesting that radium treatment of this condition should no longer be confined to so-called inoperable cases. For many years past radium therapy has been held to be justifiable only in cases in which operation was considered to be contraindicated; and although many results were obtained, surprising, perhaps, not so much from the point of view of cure as from that of amelioration of symptoms and the prolongation of life, it was not thought reasonable to apply radium to operable cases. More modern methods of dosage, together with a better appreciation of dosage and its effects, are undoubtedly pointing in the direction of radium therapy in earlier cases—even in those which are operable. A careful consideration of the part of this report dealing with uterine cases should be recommended to those whose special work brings them in contact with numbers of these unfortunates.

The third point to which special attention should be given is the effects of radium on those who have to prepare the various applicators, and who spend their lives, so to speak, in an atmosphere of radium. There is a warning as to the extreme care it is necessary to exercise. Apart altogether from the direct effects upon fingers and hands due to handling emanation tubes and applicators, there are the constitutional effects, due no doubt to prolonged radiation by gamma rays. It is found that after a certain time definite blood changes make their appearance, the white corpuscles falling well below 4,000 in the cubic millimetre, and at the same time the red corpuscles diminish in number. The same thing has been noticed amongst workers in *x*-ray departments, and it can hardly be doubted that the more general use of Coolidge tubes has increased these dangers. It is laid down in the report of the Radium Institute that no nurse or attendant habitually applying apparatus should work continuously for more than three months, and that this period should be followed by a change of occupation or a rest for an equal period of time; and, moreover, that all these workers should have at least two clear holidays a week to be spent in the open air. In the past not sufficient attention has been paid to the constitutional effects produced in workers with radium and *x* rays; in the case of the latter especially, who very often have to work for long hours in small, badly ventilated rooms, with inadequately protected apparatus, some drastic changes in the conditions of work will have to be made. Hospital authorities in the future must be prepared to deal more generously with the staffs of these special departments in regard to hours of work, holidays, and times for out-of-door life.

THE ROYAL ACADEMY.

THE one hundred and fifty-second exhibition of the Royal Academy of Arts, which opened to the public on Monday last, provides the usual medley of colour and gives the art critic his usual opportunity for blaming the academicians for their neglect of certain modern schools of painting. The ordinary sightseer, however, bent more upon enjoyment than criticism, will find much to interest him and

a good deal to admire. The old bad practice of filling the walls with pictures from floor to ceiling seems to have been abandoned finally; almost every picture is now, so to speak, hung on the line and can be studied without fatigue. The first thing to attract notice in Gallery I is the presentation portrait of Sir Clifford Allbutt, painted last November by Sir William Orpen, R.A. The strength and dignity of the portraiture, the fine feeling for character, and the masterly handling of form and colour, make this picture worthy of the artist and of his subject. The first glance shows that it has been painted with real enjoyment. The expression is a little stern, but not severe, and all who know the doyen of our profession will say that the hands are as true to life as is the countenance. The inscription runs: "Sir Clifford Allbutt, K.C.B., M.D., F.R.S., Regius Professor of Physic in the University of Cambridge; President of the British Medical Association. Presented to him by his Profession, 1920." In the room set apart for drawings, engravings and etchings, is hung an unfinished proof of Mr. H. Macbeth-Raeburn's striking and sympathetic mezzotint engraving of the portrait; to be seen at its best it should be studied at not too great a distance. Other medical pictures in this year's Academy are an unmistakable profile in oils of Sir Charles Ballance, by W. W. Oules, R.A.; a small but decorative painting of Dr. William Hunter in doctor's robes, by Eleanor Fortescue-Briekdale; Hugh Riviere's open-air study of Mr. and Mrs. Eardley Holland; and a spirited portrait of Surgeon Captain P. W. Bassett-Smith, R.N., by C. Ross Burnett, whose eye may perhaps have resented the magenta facings of the F.R.C.S. gown against the scarlet and gold of the naval rank badges. This is not the place to discuss the features of the exhibition in general, but we may note the curious effect upon one artist of painting the portrait of a gentleman with jaundice—a fine but distressing picture that speaks eloquently of the later stages of disease. Another portrait by the same painter has a slight icteric tinge, and a fainter echo of xanthoeroic vision may be perceived in the nude figure dominating his third exhibit. If for nothing else, the 1920 Academy would be noteworthy for Walter Bayes' "Oratio Obliva" and for Orpen's pictures; but in many respects it is well above the average of recent years.

THE ANNUAL DINNER AT CAMBRIDGE.

THE Master and Fellows of St. John's College, Cambridge, have very kindly invited members of the Association to dine in the College Hall at 8 p.m. on Thursday, July 1st, as guests of the College. As the seating accommodation is limited to 200 it will be necessary to ballot for tickets. Members who would wish to accept this invitation should therefore send in their names to the Local Secretaries, British Medical Association, The Medical Schools, Cambridge, before June 25th.

SECTIONS AT THE CAMBRIDGE MEETING.

THE following programme has been arranged for the Section of Surgery, which will meet under the presidency of Sir George Makins, during the annual meeting at Cambridge next month. On Wednesday, June 30th, a discussion on the surgical treatment of gastric ulcer will be opened by Sir Berkeley Moynihan and Dr. Charles H. Mayo. On July 1st a discussion on the surgical treatment of cancer of the rectum will be opened by Mr. W. Ernest Miles and Mr. Grey Turner. On July 2nd a discussion on the end-results of injuries of the peripheral nerves treated by operation will be opened by Sir William Thorburn and Mr. Percy Sargent. The discussions will begin at 10 a.m. each day and will end at noon. The following papers will be read at 12 o'clock: June 30th, Mr. Frank Kidd, treatment of calculi in the lower third of the ureter; July 1st, Lieut.-Colonel R. H. Elliot, diagnosis of glaucoma; July 2nd, Mr. Herbert Tilley, inflammatory lesions of the nasal accessory sinuses from the standpoint of the general

physician and surgeon. Demonstrations will be given in the afternoons by Major Maurice Sinclair on the treatment of fractures; by Mr. H. D. Gillies and Mr. Percival Cole on the plastic surgery of the face; by Mr. Tilley on endoscopy of the lower air passages and gullet; and by Mr. Arthur Cooke and Mr. Adrian Stokes, on the technique of blood transfusion. The Medical Education Section will meet on Thursday, July 1st, from 10 a.m. to 1 p.m., under the presidency of Sir George Newman, who will give an address. A discussion on Preliminary Scientific Education in the Medical Curriculum, will be opened by Professors S. J. Hickson, Arthur Keith, Ernest Rutherford, J. Lorrain Smith, and A. Smithells, who will deal respectively with the subject from the standpoints of biology, anatomy, physics, pathology, and chemistry. The Naval and Military Section will meet on Wednesday, June 30th, at 10 o'clock, under the presidency of Colonel Joseph Griffiths, who will introduce a discussion on the Army Medical Service in its relation to the education and training of newly qualified medical men. It is hoped that the importance of this subject to the profession generally will secure an adequate discussion; those desirous of taking part are requested to communicate with the president. At 2.30 p.m. Sir G. Sims Woodhead will give a demonstration on the purification of drinking water in the field. Further demonstrations for the afternoon are invited; early notice should be given.

PUBLIC OPINION AND PREVENTIVE MEDICINE.

THE annual Lady Priestley Memorial lecture of the National Health Society was delivered at the house of the Royal Society of Medicine by Sir George Newman, K.C.B., Chief Medical Officer of the Ministry of Health, on April 22nd. Sir James Crichton-Browne, F.R.S., Chairman of the National Health Society, presided, and H.R.H. Princess Christian, the president, attended the lecture and presented diplomas to the Society's students. The subject of the lecture was "The place of public opinion in preventive medicine." Sir George Newman said that the increase of physiological and pathological knowledge which had occurred during the last fifty years showed that disease resulted from definite causes which in a large and increasing measure were controllable. Public and personal health had become purchasable, and the business of preventive medicine was to make human life better, larger, and more useful, and to prolong our days. In spite of the improvement in national health shown in the mortality tables, three important sources of evidence proved that the English people suffered from very defective physique. Ten years of medical inspection in elementary schools had shown that one million children were so defective as to be unable to derive reasonable benefit from their schooling; the insurance returns for 1914-16 showed that more than half the insured persons in England and Wales received medical treatment every year; and in 1917-18, of the 2,000,000 recruits examined, only 36 per cent. were in full health and strength. The coming of the Ministry of Health would lead to new attacks on the strongholds of disease, but "as the science of Government becomes more representative of the aspirations of the people as a whole, so also its practice becomes more dependent upon their education and equipment; only an educated people is an effective and healthy people." Not only technical instruction in hygiene was required, but also an informed humanism which welcomed and understood the growth of medicine and accepted its results boldly and gladly on behalf of all mankind. Much of the impaired health of the country was due to public ignorance and neglect of the proper way in which to secure adequate nutrition, fresh air, and exercise. Economic conditions permitted, as a rule, the purchase of sufficient food, but among the great mass of workers there was ignorance of the right food to buy and how to cook it. Lack of knowledge and dominance of bad habit prevented also the use

of the means for adequate ventilation in houses, schools, and factories. A complete national scheme for the provision of facilities for all forms of healthy physical recreation was necessary. The need for exercise was common to both sexes, and if music and dancing, golf, hockey, and tennis were good for any young woman, they were good for all. By maintaining a clean mouth and clear breathing passages, and by abstinence from spitting, sneezing, coughing, or shouting at others, people might go a long way towards the prevention of pulmonary tuberculosis, influenza, poliomyelitis, and cerebro-spinal fever; infantile mortality, as well as the incidence of dyspepsia, septic wounds, and other groups of diseased conditions, could be lessened by the diffusion of some simple knowledge of their causation. The whole child and adolescent population of all social grades and classes should be given a knowledge of personal health and an experience of the practice of hygiene—the habit of healthy living. A new opportunity for such teaching occurred in the continuation schools, attendance at which was now compulsory. All doctors, nurses, midwives, health visitors, sanitary inspectors, and welfare workers should be missionaries of hygiene. It was impossible to over-estimate the value of the admirable work done by voluntary health societies, or the significance of the newspaper press as an educative agency. Lastly, the Government itself could not be absolved from its share of responsibility in begetting a wise public opinion in health matters.

THE VIRUS OF EPIDEMIC ENCEPHALITIS.

STRAUSS, HIRSHELD, and LOEWE just a year ago published a report¹ of some experiments in the pathological laboratory of Mount Sinai Hospital, New York City. They stated that the intracerebral injection of an emulsion of brain tissue in salt solution from a fatal case of epidemic encephalitis produced in monkeys lesions resembling closely those in man; that the inoculation of washings from the nasopharynx in a case of epidemic encephalitis filtered through a Berkefeld N filter produced the disease, and that it could be conveyed to another monkey. Another series of experiments published later² showed that the filtrable virus obtained from the nasopharyngeal mucous membrane of fatal cases of epidemic encephalitis produced lesions similar to those found in the human brain; it had been carried through four generations of rabbits, transmitted to monkeys in the fifth generation, and then brought back to rabbits. They stated that the virus could be recovered from the nasopharynx of animals inoculated intracranially. About half their rabbits showed natural immunity, and one monkey afforded evidence of acquired immunity. They also stated that the cerebro-spinal fluid from a fatal case of encephalitis caused the disease in rabbits. Mackintosh and Turnbull³ throw doubt on the results of the experiments in New York; they suggest that some other virus must have been present, partly on the ground that gross haemorrhages which have not occurred in cases of human lethargic encephalitis were observed. The New York observers, however, in their second paper rejected this suggestion in anticipation, stating that they had found typical microscopic lesions at a distance from the haemorrhage, and also that one of their strains, which at the earlier inoculations manifested a tendency to produce haemorrhage, at subsequent inoculations yielded the more varied lesions found in human brains. The New York observations have been confirmed by Levaditi and Harvier⁴; they state that the virus is easily transmitted from rabbit to rabbit, that it can be preserved in glycerin, that it passes easily through Chamberland filters (1 and 3), and that by a certain number of passages through the rabbit its virulence for the monkey appears

¹ *New York Medical Journal*, May 3rd, 1919.

² *Journal of Infectious Diseases*, 1919, p. 378.

³ *British Journal of Experimental Pathology*, April, 1920.

⁴ *Bulletin de l'Académie de Médecine*, T. 85, p. 365 (April 20th).

to be increased, and it becomes virulent also for the guinea-pig. They consider that its behaviour towards animals shows that it is quite distinct from the virus of epidemic poliomyelitis. In a note on the organism published last October⁵ Loewe and Strauss stated that cultivation, whether aerobic or anaerobic, of the material on ordinary laboratory media gave negative results, but by using the Noguchi method they obtained a growth which was manifested on the fifth to the seventh day by clouding of the medium in certain tubes; when recultivated on ordinary laboratory media it was proved to be free from contamination. The growth in the solid medium appeared as minute colonies. In smears from them stained with Giemsa solution or methylene blue after preliminary fixation, small globular purplish or bluish objects were seen, sometimes singly, sometimes in pairs, sometimes in chains or clumps. This organism resembled that described by Flexner and Noguchi in poliomyelitis, remained virulent in cultures for a period of at least six weeks, and had been carried to the twelfth generation.

GOVERNMENT POLICY AS TO HOSPITALS.

OUR Lobby Correspondent writes: Statements of a somewhat sensational character in London daily papers have created some misapprehension as to the attitude of the Government in regard to the problem of securing adequate hospital accommodation for the community. When the Ministry of Health Bill was introduced it was stated officially that after it came into operation there would be further legislation to reform the Poor Law system, and since then Dr. Addison has intimated that he would in the course of time introduce a Health Services Bill. This announcement and statements as to the lack of sufficient hospital accommodation in some areas led to questions as to the Government's intentions in regard to hospital services. Dr. Addison replied at various times that he could not put forward any general policy until he had before him the report of the Medical Consultative Council, which on its formation last autumn was instructed "to consider and make recommendations as to the schemes requisite for the systematized provision of such form of medical and allied services as should in the opinion of the Council be made available for the inhabitants of a given area." This report, it appears, has been completed and is in the hands of the Minister of Health, who meanwhile had received an application from Bradford for sanction to carry out an agreement between the corporation of that city and the board of guardians for the utilization of St. Luke's Poor Law Hospital as a municipal general hospital to supply the deficiency in existing accommodation. The proposal was sanctioned by the Ministry of Health, and on April 14th, in reply to a question as to whether this was indicative of a new policy, Dr. Addison said that, pending further legislation which was being prepared, he would deal on its merits with each application for sanction for a hospital to be provided by a local authority. That is really where the matter stands. There is good ground for saying that the Minister of Health does not intend to introduce a bill specially to deal with the provision of hospitals. But he does propose to include in a general bill provision to enable counties and county boroughs to establish hospitals if they think fit, and if they are able to satisfy the Ministry in various respects. The legislation will be optional, not compulsory. The idea probably will be to make or take units of area and to sanction the setting up of such additional accommodation as may be needed to make good deficiencies. Some hope has been expressed by Dr. Addison that a certain amount of progress might be made this session with the measure he proposes to introduce, but the expectation that time will allow such a bill to have the attention of Parliament within the present year is faint. It is even doubtful

whether there will be an autumn session, and unless there is it can hardly be in contemplation to proceed with a Health Services Bill.

OPHTHALMOLOGY AND THE PUBLIC.

THE report of the Council of British Ophthalmologists on the work it has done since it was founded two years ago shows that it has rendered very useful services. The Council has met on nineteen occasions to consider subjects thrashed out for it by committees consisting of London and provincial ophthalmologists with, when it seemed desirable, the help of others possessing special knowledge and experience. Two reports dealt with education; the recommendations of the one, on the need for improved training of medical students in the subject, was not accepted by the General Medical Council; but the other, on the need for a higher qualification in ophthalmology, has been fruitful; Oxford instituted such a diploma some time ago, and we publish elsewhere particulars of the regulations for the diploma in ophthalmic medicine and surgery to be granted by the Royal Colleges in England. The conclusions of a report on the vision of men engaged in motor road transport was accepted by the leaders of the men concerned, and has been adopted by the police authorities in London and elsewhere. Members of the council have served on the London County Council Committee dealing with the lighting of cinemas and eye strain. Committees have been appointed to consider the standardization of test types and the notation of cylinder axes, and a report has been issued on the standard illumination of tests of visual acuity. A committee has also been appointed to consider the question of sight testing by opticians. Two representatives of the council have been appointed to serve on the Visual Optics Subcommittee of the Advisory Committee on Technical Optics. The council is prepared to advise on any questions of ophthalmological interest arising in connexion with national industries or public services, and the spirit in which its work is done is evidenced by the fact that its expenses have been defrayed by its members.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE annual dinner of the West London Medico-Chirurgical Society was held at the Hotel Great Central on April 29th, with the President, Dr. Herbert Chambers, in the chair. After the loyal toasts has been honoured, Sir Robert Armstrong-Jones, C.B.E., proposed the Imperial Forces, paying a warm tribute to all those who had given their services on behalf of country and the Empire. In their replies, Surgeon Rear Admiral Sir Robert Hill, K.C.M.G., Medical Director-General R.N., and Lieut.-General Sir John Goodwin, K.C.B., D.G., A.M.S., expressed the gratitude and appreciation of all ranks of the regular forces for the invaluable aid given to them by the civilian medical profession. Each Director-General spoke also of the debt owed by very many of his officers to the excellent post-graduate courses at the West London Hospital. The toast of prosperity to the West London Medico-Chirurgical Society was proposed by Sir William Hale-White, K.B.E., who in an interesting speech mentioned some of the leaders of the medical profession who had served as presidents of the Society or as Cavendish Lecturers; and he ended, as he began, by complimenting the Society upon the vigour and enthusiasm with which it maintained its activities. The President, in acknowledging the toast gave an outline of the year's work and foreshadowed an early increase in the very modest subscription of 5s. a year. He then announced that the Society's Triennial Gold Medals, founded by Dr. Phineas Abrahams, had been awarded to Mr. G. E. Gask, C.M.G., D.S.O., and Dr. T. R. Elliott, C.B.E., D.S.O., in recognition of their signal services during the war in connexion with penetrating wounds of the thorax. He then handed one medal to Mr. Gask, explaining that the presentation to Dr. Elliott must be deferred until his return from abroad. Mr. Gask

⁵ *Journal of the American Medical Association*, vol. lxxiii, p. 1056.

was very warmly cheered on rising to acknowledge the award. On behalf of his colleague and himself he said that they wished it to be clearly understood that they claimed only a share in the great advances made during the war in thoracic surgery; their fellow worker, Pierre Duval of the French Army, by working along parallel lines, had reached similar conclusions with regard to the indications for operating and the method to be followed. He preferred to regard the award as including recognition of many colleagues whose work had helped to bring about success, including the administrative heads of the regular R.A.M.C. for their constant and open-handed support. The health of Kindred Societies and Guests was proposed by the Mayor of Kensington, Dr. A. J. Rice-Oxley, C.B.E., and responded to by Mr. V. Warren Low, C.B., President of the Medical Society of London, and Dr. Leonard Williams. A successful evening was brought to a close with the toast of The Chairman, proposed by Sir D'Arcy Power, K.B.E., and briefly acknowledged by Dr. Chambers.

DR. WILLIAM RUSSELL will give the George Alexander Gibson Memorial Lectures before the Royal College of Physicians of Edinburgh on Monday and Wednesday next, May 10th and 12th, at 5 p.m. The subject of the lectures is the sphygmometer in practical medicine.

Medical Notes in Parliament.

Medical Men and the Motor Car Tax.

IN the course of the debate in Committee of Ways and Means on the Budget, on April 27th, Sir Eric Geddes (Minister of Transport) said that the effect of the proposed change in the taxation of motors would be that the more a man used his car the less would the tax hit him. The car owner who used his car only for week ends and who did not use it regularly like the doctor was the man who was worse hit; but he was not badly hit. In the letters which the Ministry had received from two large central selling corporations it was stated that they were giving 7d. reduction in petrol, as soon as the 6d. tax came off; and thus those two very deserving users of motor cars—the doctor and the veterinary surgeon—would get an advantage which was not shown in the statement at all.

Dr. McDonald made a strong appeal on behalf of medical men throughout the country. He said that the Medical Committee of members of that House had met a strong deputation of the British Medical Association, which had urged them to point out that medical men had hitherto enjoyed a rebate. With the increase in taxation of motor cars now taking place many medical men in the country districts would be very hardly hit indeed. Those who had hitherto paid £3 3s. would be called on for £20. He asked that medical men should be allowed a rebate of half the tax as in the past.

Dr. Murray said that under the present regulations medical men were allowed a rebate on the petrol tax—not as a special favour to the profession, but for the reason that the medical man had to use his car for very necessary work. He believed that medical men generally would have preferred that the duty on petrol should have been retained, because they had some justification for feeling that if abolished, the advantage would go ultimately into the pockets of petrol proprietors. If the Minister of Transport stuck to the tax on power rather than on petrol, he ought to apply to medical men under the new regulations the same principle as applied to them formerly. Otherwise they would be very hardly hit. They would also suffer, because in some parts of the country they had to keep two cars, as they could not afford to wait if their ordinary car broke down until it could be repaired. He suggested, therefore, that the tax should apply to one car only, provided there was reasonable ground for thinking that only one car was used at a time. He asked the Minister to bear in mind also that in hilly districts very high power cars must be employed. He had seen many so-called hills in his part of the country which in Scotland would be termed gentle undulations, suited probably for exercise by people suffering from heart disease.

Sir Eric Geddes did not reply, and the resolution was agreed to. The matter will come up again at a later stage. The deputation from the British Medical Association to the Ministry of Transport is described in the

Departmental Inquiry on "Shell Shock."

Lord Southborough in the House of Lords, on April 28th, called attention to the different types of hysteria and traumatic neuroses, commonly called "shell shock," and to move for an inquiry, either by select or departmental committee, into the expert knowledge derived by the army medical authorities and the medical profession, with the object of recording for use in time to come the experiences of the war, and to advise whether, by military education or otherwise, some scientific methods of dealing with such cases could be devised.

Lord Southborough said that he was inclined to think that what in this war had commonly been called "shell shock" had occurred in previous wars, and that amongst its victims were many whose conditions were never properly understood and who suffered the death penalty. There was a fairly general consensus of opinion here, in France, and in America, that varying and differing types of hysteria or traumatic neurosis were common in civil life, well understood by medical practitioners and frequently met with after railway and other violent accidents.

If it was a fact that a true identification of the disorder was wanting in the early months of the war, then he feared that through inadvertence and want of knowledge dreadful things might have happened to unfortunate men who had, in fact, become irresponsible for their actions. It was clearly not long, however, before our army medical authorities, in common with the French, fully realized the gravity of the disorder. They appreciated that any one who understood hysteria would be well on his way to understand shell shock. The wonder was that the vast number of boys taken from civil life stood firm and sound in mind and body to the end. There was evidence, however, that shell shock or hysteria was not confined to the untrained soldier. Seasoned soldiers, marked for bravery, were often attacked. This meant, no doubt, that in some cases, after wear and tear, the nervous system refused to do more. It also probably meant that the seasoned soldier had already suffered from shell shock, had been invalided home, and then returned to the front. It was worth while to inquire whether, when a man had been badly damaged by shell shock, it was safe, either for himself or his comrades, to allow him to return to the fighting line. Other questions also deserved consideration. There were many thousands of cases of shell-shocked men discharged to pension or invalided out of the service; and some investigation, not of individuals, but of classes, might be expedient. Were there not a very large number of men doing nothing but drawing their pensions whose health might be greatly improved by an organization designed to give them a little work at the beginning? Again, as regards the cases which did not offer hope of recovery, was the treatment given to them the most desirable? Was it wise that various classes of the disorder should be mingled together? Coming to the cases in which dereliction of duty was followed by court-martial, and in some instances by the death penalty, Lord Southborough expressed the hope that if a committee were appointed the War Office would keep back the names of the unfortunate men even from the committee itself, using a number for a name. But the committee might privately consider the evidence to see whether any other course could have been taken in regard to some, at any rate, of the men—not with the object of revising a verdict as to any particular man, but for guidance. The real question in these cases was whether there was a loss of will power. He gathered that where a plea of insanity was entered at a court-martial the medical officer was not allowed to report generally on a prisoner's state of mind. Was it not a fact that a prisoner before a court-martial on a charge of malingering was in a worse position than he was before a civil court? Judges in recent years had approached the position that responsibility might be abrogated by loss of control, if arising from mental disease and infirmity, and not from the accused person's own conduct. Lord Southborough asked whether it would not be possible to prepare the minds of the soldiers against the disasters of hysteria and neurosis. Dr. Morton Prince, a distinguished physician of Boston (Massachusetts), held that it might be driven into the soldier's mind as part of his ordinary training that shell shock was a form of hysteria due to his own thoughts and fears, and external suggestion arising from the conditions of the modern battlefield, and that so long as he received no physical injury there was little danger to be apprehended from the disaster. Those familiarized with the risks of their employment were less liable to neurosis as the result of a violent accident. But, however this might be, soldiers after recent experiences naturally had a dread of disaster. He submitted it was worth considering whether some method of giving confidence might not be

devised. In conclusion Lord Southborough expressed his preference for a Departmental Committee of Inquiry.

Lord Horne, as a general officer who had had the honour of commanding large forces in the field, supported the motion, holding that there was a tremendous field for research open. Referring to the courts-martial, Lord Horne said that when a death sentence or long term of penal servitude was involved, or when there was any case open to doubt, the matter came before a higher commander, who was advised by officers with unrivalled knowledge of military law, and if there was any suspicion that the crime was caused by shell shock the sentence was not confirmed until the accused had been under observation by medical authorities. He thought it extremely probable that some method of training soldiers to endure the strain of war better might be devised; but he suggested that the term "shell shock" should not occupy people's minds too much lest it should affect their nervous tension. Courage was merely a form of nerve control, and bravery as exemplified by some highly organized people was on a much higher scale than it was on the part of a man of lower mentality.

Lord Haldane, who said that he had reviewed probably more courts-martial than had any other man in this country, expressed agreement with the grounds of Lord Southborough's motion. His own opinion was based not on his experience of courts-martial, but on close conversations with eminent experts on shell shock and analogous conditions. People might have received the impression that shell shock and its results were something peculiar to persons of a nervous temperament. If so, that would not be very easy to distinguish from what shaded into want of physical courage, but in reality a great deal of shell shock and its consequences were due to quite different causes. He had had before him privately cases of persons who thought themselves very much aggrieved by their convictions by courts-martial, principally in the early stages of the war. They said they did not know what they were doing. The tribunal could not find them insane in view of what had happened, and put it down to an affection of the nerves very difficult to distinguish from physical cowardice. But now it was known that want of mental control was in a great many cases the result of an actual physical cause. For instance, the shock of an explosion might physically inhibit the action of the nerves which controlled breathing; the supply of oxygen to the blood, and therefore to the brain, might be impaired. The result was that the individual was for the time being, and perhaps for some time after, a different personality. He might be permanently in the position of having his reason impaired. The inquiry would be much more than a question for the ordinary experts. Even the most careful inquiry in the present state of knowledge would encounter difficulties in reaching definite results. All that could be done, he thought, was to collect the very valuable body of evidence which had been got together lately: its value, however, could only be appreciated by expert investigation. It had too often been the custom, because a man was a very eminent medical man, to ask him to investigate a branch of a very great science which had ramifications with which he was not familiar. A small body of picked men of the highest eminence in this particular branch of investigation should be got together who could roughly, at all events, lay down certain standards.

Lord Peel (Under Secretary for War) said that no doubt cases of "shell shock" had occurred in former wars, but were not recognized as such, and of course the number of troops engaged had vastly increased this particular form of damage. Whether before the information now accumulated had been obtained cases of injustice had occurred it was impossible to say, but immense trouble was taken that no person should be condemned to death unless for very grave and most serious reasons, and unless all the different causes of mistake had been eliminated. The instructions issued for courts-martial were that where the soldier in his defence, or in mitigation of punishment, made a substantial plea on medical grounds, a medical witness was invariably to be called, either to substantiate or rebut the case before the finding, if it was in defence, and afterwards if it were urged in mitigation of punishment. What happened in practice was that the court adjourned and a medical board was held. On the adjourned hearing one or more members of the board would be called as witnesses, to give evidence as to the facts observed and the conclusion from these facts. A mental specialist was always included if there were any suggestion of shell shock or any other kind of mental or nervous derangement. If no such board was held, and if by reason of something which transpired afterwards there was the slightest

ground for further inquiry, the army authorities or general head quarters would order a medical board to examine and report before any action was taken to confirm the proceedings or to carry out the death sentence. No death sentence was carried out in any theatre of war unless it was confirmed by the Commander-in-Chief of the force. Each force was accompanied by a Judge Advocate-General, who was consulted by the Commander-in-Chief before the proceedings were confirmed. The number of cases in which the death penalty was carried out was small. For cases of cowardice 18 death sentences were carried out, and 266 for desertion. The total number of sentences carried out was 343, which showed that the two particular offences mentioned embraced much the larger proportion of the whole 343. The total number of death sentences actually passed on officers and men was 3,076—a percentage of 11.15 of the whole. These figures covered every theatre of hostilities, and the whole period from August 4th, 1914, to December 31st, 1919. The Government felt that great advantages might be obtained from the inquiry suggested by Lord Southborough. Many of the nervous and mental conditions encountered were entirely new to many of the medical officers concerned, and there had been a great many expressions in different medical journals of their individual views. Such investigation as was suggested would be of value in co-ordinating all the opinions and experience gained during the war, and it would be of great value also for the purposes of discipline. It would, however, be very wrong if such a committee were to investigate cases already settled, and he was glad the motion had been so drafted as not to involve this. The composition of the committee must be a matter for consideration. There would have to be upon it men of expert knowledge, but it must also be considered whether perhaps from the discipline side some lawyers should not be included, and perhaps some soldier also, who though he had not the medical experience of the experts was familiar with the conditions under which these cases arose. It might be wiser to have a mixed committee of that kind than one consisting wholly of experts, but that could be discussed later. The suggestion for a departmental committee was accepted by the War Office.

Hospitals for Mental Cases.—Replying to Major Entwistle, on April 27th, Mr. Churchill said that the number of mental cases which had passed through Warrington Hospital since August 4th, 1914, up to March 31st, the date of the last report of the present year, was 8,410. The statistics up to the end of 1919 were as follows: Number of cases treated, 8,127; discharged to their homes recovered, 3,657; discharged to asylums, 1,026; transferred to other military mental hospitals or repatriated overseas, 2,433; died, 108; remaining in hospital, 905. The statistics for Whitechurch Hospital from the date of opening to October 31st, 1919, were as follows: Number of cases treated, 1,862; discharged to their homes recovered, 1,102; discharged to asylums, 446; died, 33; remaining in hospital, 281. The hospital was closed on January 2nd of the present year.

Midwives.—Asked by Mr. Briant, on April 28th, what steps, if any, the Ministry proposed to take to secure that an adequate supply of midwives should be available, Dr. Addison said that according to the last report of the Central Midwives Board, the number of women entitled to practise as midwives on March 31st, 1919, was 44,166; but the number who gave notice of their intention to practise in 1918 was only 11,293. No useful estimate could be made of the total number of midwives required. The shortage which existed in some districts was due to the fact that the number of cases within reach was too small to enable a midwife practising independently to make a living. The Ministry of Health had continued the policy of the Local Government Board of urging local authorities and nursing associations to subsidize midwifery in the more scattered districts, and of paying grants in respect of such subsidies. By this means the proportion of the rural population served by trained midwives had increased since 1917 from 51 per cent. to 65 per cent., and steady progress was being made. Nearly all the County Councils and County Nursing Associations had framed schemes for extending the midwifery service of their county. A number of local authorities in urban areas had also, with the assistance of the Ministry, subsidized the provision of trained midwives in parts of their districts in need of this service. A grant in aid of the training of women as midwives was administered by the President of the Board of Education.

Expenses of the Ministry of Health.—The total estimate for the expenditure of the Ministry of Health in the year ending March 31st, 1921, is £27,572,797. Out of this total £21,859,000 is for housing. The grants for maternity and child welfare amount to £300,000, for the treatment of tuberculosis £700,000, in respect of venereal diseases £300,000, for the welfare of the blind £109,000. The grant promised to port and riparian sanitary authorities is estimated at £67,000. The estimate

for contributions, benefits, etc., in England under the National Insurance Acts amounts to £9,095,800; this includes special grants for medical referees of £155,000 and for sanatorium benefit £45,000. The estimate for the Welsh Board of Health, including grants amounting to £54,000 for the treatment of tuberculosis, is £129,220. To this is to be added statutory contributions and special grants totalling £604,000. The estimate for the expenses of the National Insurance Joint Committee is £402,330—almost the same as last year. The total amount of the estimate for the Scottish Board of Health is £3,949,279; this includes £2,910,664 for housing grants. The estimate for the Local Government Board, Ireland, is £1,729,441, an increase over the previous year of £1,493,121, mainly accounted for by grants for housing. The expenses of the National Insurance Commission, Ireland, are estimated to be £442,380, an increase of £5,435, the chief item under which the increase has taken place being salaries, wages, and allowances.

Medical Degrees in East Africa Protectorate.—Mr. Waterson, on April 14th, again raised the question whether persons holding Indian University medical and law degrees, such as L.M. and S. and B.A.B.L., who are eligible to practise medicine and law in India, were allowed to so practise in British East Africa. Lieut.-Colonel Amery (Under Secretary for the Colonies) said that Indian medical degrees or diplomas were recognized in the East Africa Protectorate, provided that they entitled the holder to registration in the United Kingdom. The general question of the position of Indians in East Africa was under consideration between the Secretary of State and the Governor of the Protectorate.

Dangerous Drugs.—On May 4th the Home Secretary introduced a bill to regulate the importation, exportation, manufacture, sale, and use of opium and other dangerous drugs.

Answers in Brief.

Mr. Chamberlain states that the corporation tax is not devised as a tax on the individual, but as an impersonal tax on the profits of a company prior to distribution. No question of recovery by an individual shareholder therefore could arise. A person whose entire income of £100 a year is derived from company dividends must suffer with the rest.

A Member was advised on April 27th that he should supply any information in his possession as to the conduct of massage establishments in London to the London County Council, the responsible body.

The ventilation of the House of Commons is again being considered by the First Commissioner of Works with the assistance of officials of the National Physical Laboratory.

There are now 20 homes of recovery under the control of the Ministry of Pensions, and 2,383 men are under treatment.

Mr. Montagu is still awaiting the views of the Government of India as to what increases are to be made in the pensions of the widows, children, and dependants of deceased officers of the Indian Army, the Indian Medical Service, and the Royal Indian Marine. He has marked the matter "Very Urgent."

Mr. Montagu is in communication with the Government of India as to whether any assistance can be given to officers who were invalided from the service on comparatively small pensions.

The sick berth branch of the navy has now been nearly reduced to peace numbers, and promotions will therefore shortly be resumed. A report has been called for as to the alleged shortage in sick berth ratings in the Royal Naval Hospital at Haslar.

The number of ex-service disabled men in training on April 18th was approximately 21,000, of whom 8,000 began their training during the present year.

Mr. Law has promised to bring under the notice of the appropriate Government Department the allegation that unwholesome foreign manufactured whisky is now being imported into this country, and that even in Scotland there is being dumped cheap American whisky.

An After-care Committee established in Hull to deal with persons who have received sanatorium treatment has produced a striking improvement in the condition of the patients discharged. Asked whether "after-care" may be made an integral part of the scheme for combating tuberculosis and receive liberal financial encouragement from the Treasury, Dr. Addison said, on April 28th, that the financial arrangements were under consideration.

The Minister of Pensions hopes to be able to announce within the next fortnight his decision regarding the provision of half-rate vouchers to ex-service men undergoing treatment away from home.

Of the large number of British prisoners of war taken by the Germans 222 were still unaccounted for when the British Military Mission closed its inquiry. No similar inquiry had been made in Turkey, as any information obtained would be of small value.

Dr. Addison stated, on April 27th, that the financial arrangements which will be necessary on the termination of sanatorium benefits was under consideration, and he hoped to make an announcement at an early date.

It is estimated that an "all trading profit tax" of 5s. 6d. in the pound would be required to yield the equivalent of the Excess Profits Duty and Corporation Profits tax.

The number of Poor Law children in receipt of institutional relief on January 1st of this year was 59,283; the number in receipt of outdoor relief (including children boarded out) was 138,380. There were in the sick wards of workhouses 2,496

over 3 years of age and 2,326 under; in other wards the numbers were 3,084 and 2,914 respectively.

Asked on May 3rd whether the Discharged Soldiers Committee of the Citizens Committee of Birmingham was finding difficulty in dealing with orthopaedic cases in consequence of the masseuse staff being too small, Major Tryon said that the necessary additions to the staff would be made as soon as possible.

Two cases of small-pox have recently occurred in Bolton, one ending fatally. The medical officer of health has reported that the first case was that of a woman employed at a cotton mill, and that it is possible she contracted the disease from infected cotton.

The Minister of Health has given instructions that wherever practicable vacancies occurring on local Advisory Blind Committees shall be filled by blind persons, until at least one-third of the Committee (excluding representatives from local authorities) consists of blind persons.

The number of retired regular naval and military medical officers employed by the Ministry of Pensions on a sessional basis who are drawing pensions is 152, being 5 per cent. of the total number of medical men so employed. The maximum number of sessions is eleven a week, but owing to the number of medical men available for the work the average number of sessions a week which can be given to each officer is less.

AN AMERICAN HOSPITAL IN LONDON.

CONSIDERABLE progress has recently been made, both in England and the United States, with the organization of the American hospital for London; as we announced at the time, the hospital was founded at a meeting of the Royal Society of Medicine on July 17th, 1919, when Lord Reading was in the chair. A governing council was appointed, with Mr. Franklin, F.R.C.S., as honorary secretary. The American committee has now received a cablegram from ex-President Taft accepting the presidency of the institution in the United States; Lord Reading has accepted a similar position in Great Britain, and Lord Bryce is vice-president.

The plans have been carefully considered by an influential committee of American citizens resident in London, and steps are now being taken to incorporate the institution according to the laws of the State of New York, and a campaign will then be opened to raise an endowment fund of several million dollars. Under present conditions a large building scheme is hardly desirable, but the committee hopes to open a temporary building for the accommodation of patients early in the coming autumn.

The resolution by which the American Hospital was founded laid down that one of its most important aims was "to act as a link in binding together the two nations for the advancement of medical science as affecting the welfare of humanity." For many years past American graduates who desired to continue their medical education in Europe settled almost as a matter of course in Berlin or Vienna, where special opportunities were freely placed at their command by the German and Austrian authorities. Since 1914 conditions have changed, and the leading members of the American colony in London have determined that American graduates who come to Europe shall find in London all the facilities they were formerly offered on the Continent. This decision has received the fullest support of the British medical profession. The Medical Committee in Great Britain includes Sir Arbutnot Lane, Bt., Sir Humphry Rolleston, Sir John Bland-Sutton, Sir John Y. W. MacAlister, and Mr. Philip Franklin, whilst the similar committee in the United States consists of such well known physicians and surgeons as Dr. George W. Crile (nominated by the American Academy of Science on International Relations), Dr. W. J. Mayo and Dr. Charles H. Mayo of Rochester, Dr. A. H. Ochsner of Chicago, Dr. Rudolph Matas of New Orleans, and Dr. Franklin Martin of Chicago.

The organization of the American Hospital is thus becoming of considerable international value, whilst in medicine it presents great possibilities.

The American Committee in London is proceeding steadily with its plans for the future. The social side is not being neglected, and in July the authorities of the hospital will entertain at dinner in London one of its American colleagues, Dr. Charles Mayo of Rochester, Minn., who is coming to this country to attend the Annual Meeting of the British Medical Association in Cambridge, where he will take part in the proceedings of the Surgical Section.

EIGHTY-EIGHTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION, CAMBRIDGE, 1920.

EVOLUTION OF THE MEDICAL SCHOOL (continued).

As mentioned in the previous article (BRITISH MEDICAL JOURNAL, April 10th, p. 505) Humphry succeeded to the Professorship of Human Anatomy in 1866, and George Paget to the Regius Professorship of Physic in 1872. Neither of them was young when appointed, Humphry being 46 years of age and Paget as much as 62; but their work and influence had begun many years before.

Paget succeeded, as early as 1842, in persuading the University to institute bedside examinations for its medical degrees, and these were the first regular clinical examinations held in the United Kingdom. His other innovations may seem less radical, but were not less real. His service to the school consisted largely of a strenuous advocacy of everything that made for its advancement, such as the creation of Departments of Physiology and Pathology and the encouragement of all branches of Natural Science. His courteous and tactful manner succeeded where more aggressive methods might have failed. He spent the whole of his professional life in Cambridge, was Linaere Lecturer on Medicine at St. John's College from 1851 till 1872, and Representative of the University on the General Medical Council from 1863 till 1869.

Humphry came to Cambridge as a general practitioner, and in 1842, at the age of 22, was appointed surgeon to Addenbrooke's Hospital.

"He at once began to give clinical lectures and systematic teaching in surgery. In 1847 he was invited to act as deputy to the professor of anatomy (Clark), and he gave the lectures and demonstrations upon human anatomy from 1847 to 1865. . . . The Museum of Anatomy and Surgical Pathology engrossed much of his attention, and many of his holidays were spent in journeys designed expressly to secure specimens to fill its shelves. As an anatomist he was one of the earliest workers who attempted to bring human anatomy into line with the growing science of morphology."¹

He entered Downing College as a fellow commoner in 1847, graduated M.B. in 1852, M.D. in 1859. In 1869 he succeeded Paget as representative of the University on the General Medical Council.

When Humphry began the teaching of anatomy the accommodation for dissection was only a small room adjoining the Anatomical Museum or Rotunda in Downing Street; and the lecture theatre in the same building was

a mean room which would admit but a small class. Under his management the number of students increased until it became necessary, in 1879, to build a considerably larger dissecting room, and to hold the lectures in the larger theatre which had been built for zoology and comparative anatomy.

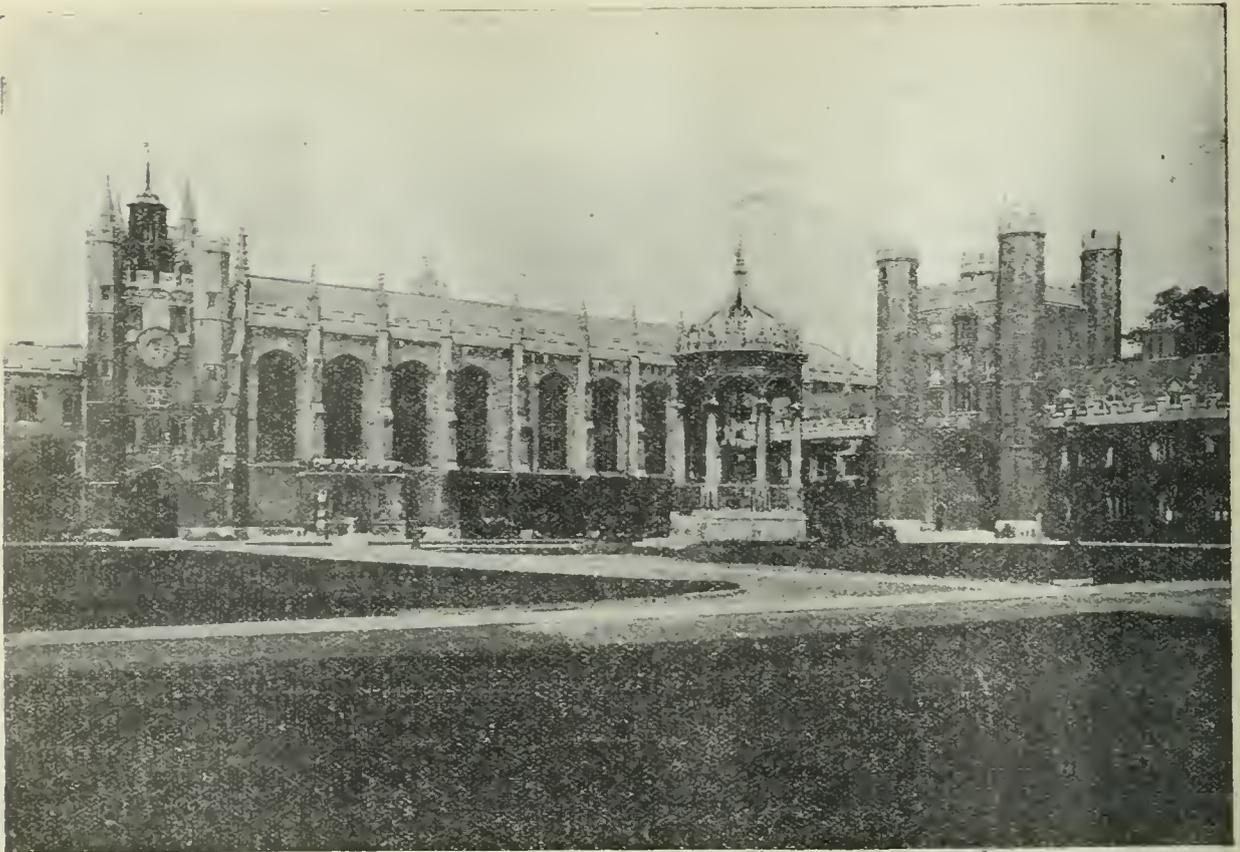

In the Natural Science Tripos Human Anatomy was at first admitted only as a branch of Comparative Anatomy. But Humphry's teaching invested the subject with so much more of the scientific spirit than was usual at the time, that he succeeded in getting Human Anatomy admitted as a separate subject in the Tripos from 1876 onwards.

At the appointment of Humphry the Professorship of Anatomy was subdivided, the comparative side being transferred to a new Professorship of Zoology and Comparative Anatomy, of which the first tenant was Alfred Newton of Magdalene College. Three years before his appointment new buildings had been commenced, including a museum which for its time was large and convenient. Under Newton's administration the department was greatly advanced, and the comparative collections received large additions, to which Humphry as well as Newton contributed.

The organization both of the museum and of the teaching was carried out chiefly by John Willis Clark of Trinity College, son of William Clark, the Professor of Anatomy, and nephew of Robert Willis, the Jacksonian Professor and eminent antiquary. He was appointed Superintendent of the Museum of Zoology when the professorship was instituted. A man of very versatile talents, he served the cause of science at Cambridge in many ways, but attained more distinction as an antiquary than as a zoologist. Sir Arthur Shipley, in his *Memoir of John Willis Clark*, tells us that an entirely new era in the teaching of zoology in the University was begun in 1871, when J. W. Clark, with the assistance of his friend T. W. Bridge (afterwards Professor at Birmingham), began for the first time to give courses of practical work, in which the students actually dissected the animals instead of watching a dissection by the professor, and were encouraged to make permanent preparations for their future use.

Humphry desired that the University should appoint a professor of surgery, and offered to accept the appointment without stipend and to resign the professorship of

¹ Sir D'Arcy Power, in the *Dictionary of National Biography*.

anatomy. This change was carried out in 1883, and Humphry held the new professorship until his death in 1896. The professorship of surgery was a move towards the ideal, which Humphry always cherished, of making a complete medical school in Cambridge; but in this matter very few persons shared his views, for it was obvious that the town and neighbourhood of Cambridge were not populous enough to supply the necessary clinical material. Addenbrooke's Hospital is admirable for the first few months of clinical work, but after that the student should proceed to one of the great cities.

Through the influence of Paget and Humphry, and on the recommendation of Huxley, Michael Foster was brought to Cambridge to create the School of Physiology. He came in 1870 as Praelector in Physiology at Trinity College; the University did not give him a professorship until 1883. At first a couple of rooms in the zoology building were assigned to his department; these were not convenient, and the supply of apparatus was meagre; but Foster soon gathered around him many enthusiastic students, and from these he selected a number of demonstrators. His first demonstrator was H. Newell Martin, whom he brought from University College, London. Subsequent demonstrators trained in his Cambridge school were Gaskell, Sheridan Lea, and the present Professor of Physiology. For the growing department new quarters were provided in an extension of the zoology block of buildings in 1879; and eleven years later additional rooms were built, including a large lecture theatre for the joint use of the Professors of Human Anatomy and of Physiology. These buildings were used by the Physiological Department until the opening of the handsome Physiological Laboratory presented by the Worshipful Company of Drapers.

Paget, Humphry, Foster.

The writer had the privilege of working for several years under these three pioneers—Sir George Paget, Sir George Murray Humphry, and Sir Michael Foster—and on that ground he ventures to record his personal impressions of them, speaking in the first person, as his views may be influenced by personal bias.

In Paget the most striking characteristic was his extreme courtesy under all circumstances. His manner to patients was gentle and sympathetic, but authoritative, inspiring them with confidence to an unusual degree. His discussion of cases in hospital was critical and interesting, but (in later years at all events) he did not enter into commonplace details; he left these to be discussed between the students and the house-physician. He was already old when I first met him; and though he was still agile and keen, his more strenuous work for the School was finished.

Humphry was the most inspiring teacher I have ever known. He delivered his expositions not merely with earnestness but with enthusiasm, and in lecturing he seemed to speak to his pupils individually rather than as a class. His language in lecturing was informal, even colloquial. He never stooped to be funny; but his lectures, like his conversation, were often illumined with boyish gaiety and laughter. He often tested the success of an exposition by asking questions upon it, and if anyone happened to fall asleep at lecture, he was sure to be aroused by a question. Humphry always lectured sitting, and surrounded with abundant means of practical demonstration—real specimens, diagrams, and blackboard; and he enhanced the objectivity of his lectures by frequent reference to instances which had come under his own observation. He paid great attention to the functional aspect of all features and to their evolution. His enthusiasm was most pronounced over the mechanism of the joints, in many cases so exquisite, though he was not blind to the shortcomings of Nature, the failures of evolution, as for instance in the inadequacy of the external ligaments of the ankle. But he paid no attention to trilling details, such as are learnt only for examination, to be soon forgotten, or if remembered, to occupy room in the memory which is needed for more useful things. It was customary to call his anatomy "Humphryology," and to say that it was of no use for any examination but his own. It might not have sufficed for the "First Fellowship," but some of his pupils can testify that it did not fail them in other examinations.

Foster's mode of lecturing was in diametric contrast to

that of Humphry. His language was literary, carefully weighed, almost without a superfluous word. His method was strictly critical, and I cannot remember his ever betraying enthusiasm; he seemed to fear the possibility of over-statement, or the suspicion of advocacy. He never used any demonstration or objective illustration at lectures, not even a diagram, except such as he rapidly and skilfully drew on the blackboard—and wiped off immediately, so that his pupils had not time to copy it, or could only copy it incorrectly. All this was intentional. He said to me in after-years: "I don't wish my pupils to have anything to divert their attention from *what I have to say*." He objected especially to the optical lantern in teaching, saying that it was a method of obscuring one's exposition.

I was too much interested to criticize his lectures unfavourably, and no doubt many of his students were as satisfied as I was—but not all; a few complained that the lectures were intolerably dull and uninforming. As I look back on these lectures I think that, though brilliant expositions, they were a survival of the lecturing method of the Middle Ages, and not suitable for natural science, the teaching of which should be objective and practical.

His forte was organization: his department worked with remarkable regularity. He had the faculty of getting a number of men to carry out his arrangements thoroughly and willingly. In this way he delegated not only the practical demonstrations, but the lectures on special branches of the subject, to his lecturers and demonstrators. I do not remember to have seen him handle any apparatus but the microscope, and that to examine preparations made by others. He seemed to absent himself a good deal from his laboratory, but kept in touch with everything. If in spite of best intentions anything went wrong, he would remind the responsible person, not by a reprimand, but by a kindly hint that he depended upon him to prevent a recurrence.

If a student came to him with some new idea or a proposal for original investigation, Foster's intensely critical reception of it was liable to act as a wet blanket. This critical attitude probably deterred Foster from carrying out any important original work after his student days; he would probably not have trusted his own results. He had a particular objection to speculation, and did a good service in checking the publication of speculative ideas as if they were discoveries. Of course, speculation is useless except as an incentive to investigation, but without a speculative mind the scientist can hardly advance. The explorer must always imagine something beyond the visible horizon.

CORRIGENDUM.

In the last article, published on April 10th, it was implied that the Macartney collection was moved from the old to the new anatomical museum. This is incorrect, the Macartney collection not having been purchased until 1836, four years after the building of the Rotunda.

England and Wales.

THE CARLISLE EXPERIMENT IN LIQUOR CONTROL.

DR. HENRY BARNES, O.B.E. (Carlisle), has forwarded the following brief account of the fourth annual report of the General Manager.

Sir Edgar Sanders, the General Manager for the Central Control Board (Liquor Traffic) of the Carlisle and District Direct Control Area, in his report for the year 1919 (which has been issued as a Parliamentary White Paper [Cmd. 666], price 2d. net), briefly summarizes the measures which the special position of the Board at Carlisle has enabled it to take. The summary does not pretend to be exhaustive; it is a catalogue of facts only, and not of results:

1. The reduction of the number of licences in the City of Carlisle from 119 to 69.
2. The suppression of all grocers' licences.
3. The limitation to a reasonable number of the places where "off" sales of spirits are conducted.
4. The abolition of advertisements of intoxicants.
5. The limitation of the sale of intoxicants to young persons.
6. The appointment of salaried managers in all the Board's houses having no pecuniary interest in the sale of intoxicants.
7. The provision of food at public-houses.

8. The improvement of the structure and arrangements of many of the public-houses.

9. The provision of tea-rooms in country inns.

10. The permanent closing of two out of the four breweries in Carlisle.

11. The bottling of beer at one centre instead of a dozen, with its resulting economy.

12. The establishment of one up-to-date spirit store, instead of the wholesale trade being carried on at thirteen different places.

13. The organization of the whole trade in intoxicants on an economical and co-ordinated business footing, and the consequent prevention of overlapping.

In dealing with the supply of food on licensed premises it is noted that in addition to the Gretna Tavern six public-houses have been reconstructed as "food taverns"; the plan was described in the account of the report for 1918, published on April 19th, 1919, p. 487. The houses chosen were situated in different parts of the city, and were designed to cater for all classes of the community. The reconstruction in each case includes up-to-date kitchen accommodation and a dining-room, separate from the bar, where cooked meals are served and where in most instances cooked food can be purchased and taken away for home consumption. That these houses are appreciated is shown by the fact that their trade in food in 1919 amounted to £18,648, and the number of meals supplied for "on" and "off" consumption was about half a million in the year. Intoxicants can be obtained with the meals if desired, but it is a much more usual custom for a man to have his meal in the dining-room and then go through to the bar for a drink and a smoke afterwards. The popularity of these reconstructed houses is evident from the large numbers who frequent them. In Carlisle, where the distances are not great and most people live near their work, the food taverns, which have been well placed, go far to meet what demand there is for food and light refreshments.

The accounts of the undertaking for the year ending March 31st, 1919, which were published last October and appear as an appendix to this report, show that the capital involved at that date was £853,550, and that the total trading profits for the year were £137,985. After providing for interest on the money supplied by the Exchequer and for all the ordinary trading charges, the net surplus accruing to the State for the year was £96,518. This sum gives a return of nearly 12 per cent. on the average capital involved, in addition to the interest already provided for. In other words, there was for that period a full return of 17 per cent. on the whole capital employed. The accounts for the year ending March 31st, 1920, have not yet been completed, but interim accounts were prepared for the half-year to September 30th, 1919, and sufficient is known of the results for the year to state that the surplus which will accrue to the Exchequer in replacement of the capital cost of the undertaking will not be less than during the previous year. Assuming this to be the case, the accumulated surplus at March 31st, 1920, will amount to not less than £300,000. Taking into account the gradual accumulation of the capital, there will have been paid off up to March 31st, 1920, on that basis, upwards of one-half of the average capital employed from July, 1916. These facts indicate that, so far as the financial aspect of the scheme is concerned, it has been a success.

The number of convictions for drunkenness at Carlisle was actually smaller by two in 1919 than 1918; in the country generally the number was almost doubled. The Chief Constable of Carlisle, in his report to the justices for the year 1919, said:

The continuance of sobriety I attribute almost entirely to the system under which intoxicants are sold in Carlisle, where none of the managers have any interest in the amount of liquor sold, and all are given strict instructions not to serve customers who appear to have had enough. I am unable to account for it in any other way, for while Carlisle is unique in its licensing system, it is subject to all the causes just mentioned, which in the country generally have contributed to a very decided increase in drunkenness. There can be no question in the minds of careful and impartial observers that the direct management of the licensed trade by the Control Board has been of great benefit to the city.

The general manager mentions various facts which throw light on the feeling of the public, which is one that cannot be estimated with any degree of accuracy. As to the customers, all that can be said is that if there were any real signs of discontent they would soon be apparent. Very few complaints of substance are made, notwithstanding that interested parties may try to persuade the public that

they are being badly treated. The managers assert that whereas there was loud grumbling when it was necessary to curtail the supplies drastically under the Food Controller's orders, now that the supplies are adequate the amount of grumbling is negligible. On the other hand, the customers appreciate what has been done for them in the way of improved conditions. It appears to be incontrovertible that any proposal to hand back the licensed trade to private interests would be received with dismay by the great majority of the inhabitants. At Carlisle the system of direct control has greatly improved the conditions under which the liquor trade is carried on. There have been put into operation most of the generally accepted temperance proposals made during the last half-century. This has been done without any sacrifice of the reasonable rights and privileges of the community, and without undue interference with the liberty, tastes, and preferences of the great mass of the adult population.

WHOLE-TIME MEDICAL APPOINTMENTS UNDER THE WORCESTERSHIRE COUNTY COUNCIL.

At a meeting of the Worcestershire County Council, on April 24th, the Chairman stated that difficulty had arisen in securing applicants for the ten whole-time appointments authorized by the council in connexion with the medical service scheme for the county. Two doctors had applied, but when the council endeavoured to insert the advertisement in the *BRITISH MEDICAL JOURNAL* and the *Lancet* it was informed that advertisements could not be accepted offering a lower salary than £500 per annum for such posts. A letter had also been received from the Ministry of Health expressing doubt whether tuberculosis officers, who should have special qualifications and experience, could be secured for the salary offered—namely, £450. The chairman objected to this sort of pressure, and to "allowing the medical press to dictate to the council."

Dr. H. E. Dixey said that when the price of living was considered, £500 was not an extravagant sum to be paid to a whole-time medical officer, and reminded the council that the doubts expressed by the Ministry of Health had found confirmation in the report of the medical officer of health on the scheme. He proposed that the committee should be authorized to advertise for eight assistant medical officers at a commencing salary of £500, rising to £600 per annum by annual instalments of £25; that the two medical officers already appointed should be placed on the same footing; and that the two senior assistants should have special advisory functions and should receive a salary of £600 per annum, rising to £700. The council was aware of the necessity of the scheme, and would, he hoped, agree to these proposals; of the increases, amounting to £650 a year, which were contemplated, half would be paid by the Board of Education. Dr. F. W. J. Coaker seconded the motion.

Other members protested that the county council should not submit to the treatment accorded them by the medical press. One member was not satisfied that the officers could not be obtained for £450 a year, and proposed first to try to do so; it would then be time enough to discuss an increase. Dr. Dixey recalled a somewhat similar situation which arose some years ago when the council decided to advertise in the lay press, and the chairman said he thought that although they got some applicants in this way they did not appoint any of them. Mr. G. E. Wilson said that this was not a new policy on the part of the medical press, and recalled certain advertisements for asylum medical officers issued some time ago by the council. Mr. C. Dalley thought that £500 a year for a trained medical man was not an extravagant sum; the council would be unwise to play with this matter. Dr. Broughton alluded to the serious shortage of doctors, which would be felt more in three or four years' time than to-day. In the end an amendment was carried by 34 votes to 23 that the appointments should be advertised at £450 a year in the London daily papers.

In March, 1915, the Worcestershire County Council authorized the appointment of an assistant school medical officer at a salary of £350 a year, inclusive of travelling expenses. The net salary offered was less than the minimum approved by the British Medical Association, and for some months, the county council's advertisement having been refused, a notice was printed in our columns. In October, 1915, the county council decided to abandon

the proposed appointment, probably for the duration of the war. Possibly these are the events to which the members of the council allude; it seems clear in any case that the Worcestershire County Council in the past has not been unacquainted with the difficulties which it makes for itself by its unwillingness to pay reasonable salaries.

Scotland.

VILLAGE SETTLEMENTS FOR TUBERCULOUS EX-SERVICE MEN.

THE Scottish Board of Health has issued to local authorities a circular letter¹ summarizing those sections of the Departmental Committee's Report² of August, 1919, which deal with village settlements. Such settlements, which are intended primarily for discharged soldiers or sailors, should, it is said, adjoin and be closely related to a sanatorium and training colony; they should provide permanent employment, with housing accommodation for the patients and their families. The Committee suggested the provision of ten village settlements in Great Britain; on this basis, in Scotland one, or perhaps two, should be set up. The Treasury has not yet decided to make available the capital grant of one million pounds which, according to the suggestion of the Departmental Committee, should be provided for the erection and financing of settlements; nor is it expected that it will until constructive proposals are made by the Ministry of Health and the Scottish Board. The immediate purpose of the latter body is to invite local authorities responsible for administration of tuberculosis schemes to devote attention to the best methods for the foundation of village settlements; the full bearings of this question will be discussed at a conference shortly to be summoned.

MALARIA IN SCOTLAND.

The Scottish Board of Health has issued to local authorities a memorandum³ pointing out that there are in Scotland many men who had malaria when serving with His Majesty's forces, and that among them may be persons carrying the parasites in their blood. The presence of the anopheline mosquito has been recorded in Aberdeen, Dumbarton, Fife, Inverness, Lanark, Midlothian, Perth, and Sutherland; climatic conditions are likely to limit its activities to the months of May to September, inclusive. The attention of medical men is drawn to the possibilities of the occurrence of indigenous cases of malaria among the civil population; children, especially such as are ill-clad or ill-nourished, are said to be particularly susceptible. To facilitate diagnosis the Board has made an arrangement whereby blood specimens sent by local authorities will be examined at the laboratory of the Royal College of Physicians for a fee of 10s. 6d. Malaria has been notifiable in Scotland since August 1st, 1919.

INFLUENZA-STRIKEN ST. KILDA.

The life of St. Kilda, a small island some seven miles in circumference far out in the Atlantic, to the west of North Uist, has been suspended by an epidemic of influenza and pneumonia. The news was brought by the trawler *Active*, which sailed again for the island from Aberdeen on May 2nd with supplies of medicine and comforts. The inhabitants support themselves chiefly on the myriads of sea-fowl that frequent the cliffs of the island; the eggs are collected and the birds are killed for the feathers and for the oil which some species yield. Fishing is perilous, and the care of the few sheep on the island has become impossible, because, of the eighty inhabitants, sixty are or have been ill. The nurse and the parish minister have done their best to cope with the conditions, but the scale of the calamity has been too much for their resources.

SMALL-POX IN SCOTLAND.

Cases of small-pox continue to occur in Glasgow; altogether 49 persons are known to have been affected in

¹ Circular I.D.B., No. IX, 1920.

² H.M. Stationery Office, Cmd. 317, *BRITISH MEDICAL JOURNAL*, August 30th, 1919, p. 275.

³ Memorandum on Indigenous Cases of Malaria in Scotland. Edinburgh: H.M. Stationery Office. (Price 1d. net.)

Glasgow or its immediate neighbourhood; 41 were under treatment at the beginning of this week. Among the earlier cases two groups could be traced to infection brought by sea from India and Alexandria respectively, but the source of the infection of the more recent cases has not been ascertained. The proportion of cases occurring in unvaccinated children remains high, but there is evidence that the public is recognizing the importance of having children vaccinated, as a considerable number are now being brought to the vaccination stations. Over 8,000 persons in the immediate neighbourhoods of the different cases have been vaccinated. A case of small-pox in a young man was notified in Edinburgh at the end of last week; no connexion with the Glasgow cases has been established.

Ireland.

GRAYMOUNT HOSPITAL, BELFAST: SIR H. GAUVAIN'S REPORT.

THE report of Sir Henry Gauvain, M.D., as to the suitability of Graymount as a place for the treatment of non-pulmonary forms of tuberculosis amongst Belfast children was presented to a meeting of the Tuberculosis Committee of the Corporation on April 26th.

Sir Henry Gauvain reported that the objections founded on the clayey soil and the site in the Lagan valley, said to be damp and foggy, were sufficient to render the place unsuitable as a hospital for surgical tuberculosis. The house itself was exceptionally well constructed, but it was costly and generally unsatisfactory to adapt houses built as private residences for the purposes of a surgical hospital, and the levels at Graymount did not lend themselves well to suitable additions. He advised the selection of a suitable site of some 20 acres and the construction of a specially designed hospital, with Graymount as part of the scheme. A hospital at Graymount in the existing buildings, with additional wards, would be expensive and would never be more than a makeshift. He recommended that the hospital should be on the sea front, with abundant sunshine and a considerable foreshore; the soil should be sandy, the rainfall moderate, the country relatively treeless, and the atmosphere pure; hills should protect the site from the north, and rivers should be remote. The patients should have freedom of access to the beach, and the spot chosen should not be overcrowded by holiday makers. There should be no cliffs, and there should be a maximum of reflected light, an ample supply of pure water, facilities for adequate drainage, and easy access to the nearest town. Graymount should be used only as a temporary hospital until a suitable building could be erected, when it might be used as an open-air school for surgical cases, thus relieving the pressure in the hospital itself. The new hospital should accommodate 100 cases, with facilities for extension; the work done should be of the very highest order.

MEDICAL FEES FOR PUBLIC WORK.

At recent meetings of the City of Limerick Medical Association, consisting of practitioners in that town, various important medical questions were considered with regard to (1) medical fees for life insurance examination, (2) the salary of the medical officer attached to the Limerick post-office, (3) surgeon to the Admiralty, (4) fees paid to certifying factory surgeons. The following resolutions were unanimously adopted, and are now in force:

1. That the scale of fees for life insurance examination shall be as follows:

INDUSTRIAL ASSURANCE (WEEKLY PAYMENT SYSTEM).

Under £100	£0	10	6
£100 to £500 (inclusive)	1	1	0
Above £500 and less than £1,000	1	11	6
(£1,000, or any higher sum	2	2	0

2. That owing to the inadequacy of the salary and the multitudinous duties of the medical officer to the G.P.O. the position, which has been vacant for some years past, shall not be applied for; and that the fees shall be 10s. per visit (including certificate) within the borough boundary.
3. That the position of surgeon and agent to the Admiralty be not applied for under existing terms. Fees shall be 10s. per visit (including certificate) within borough boundary, and no duties other than purely medical duties be rendered.
4. Re position of certifying factory surgeon: The above association cannot recommend any medical man to apply, owing to extreme inadequacy of fees.

The following resolution has also been passed:

That the rate for contract practice be increased 25 per cent. Same to come into operation from beginning of next quarter.

Correspondence.

DUODENAL ULCER AND THE HYPERTONIC STOMACH.

Sir,—The very interesting lecture by Dr. A. F. Hurst on gastric and duodenal ulcer, published in your issue of April 24th, demands brief comment. Dr. Hurst's observation that duodenal ulcer is associated with a hypertonic stomach, emptying with unusual rapidity, is undoubtedly true in a large majority of cases. But the rule is by no means absolute, for I have recently operated on two cases in which x-ray examination showed a low-lying, hypotonic stomach, with considerable delay in emptying, but operation disclosed a definite chronic ulcer in the first part of the duodenum, unassociated with any organic stenosis. In each case the stomach was carefully examined, but there was no trace of gastric ulceration. In neither case had the radiologist been able to obtain satisfactory filling of the first part of the duodenum, so that the characteristic deformity of the duodenal bulb was not seen. The radiographic evidence, according to accepted ideas, pointed to gastric ulcer or simple gastropnoia. The clinical histories pointed to duodenal ulcer and proved to be right.

May I add a mild protest against Dr. Hurst's *obiter dictum*: "Everyone must agree that the surgical treatment of gastric and duodenal ulcer is a confession of failure?" There is a sense in which any operation, as, for instance, partial gastrectomy for cancer of the pylorus, is a confession of the failure of purely medical treatment. But the crux of the matter lies in this test: Does surgery offer the patient the prospect of a quicker, surer, and more permanent cure than medical treatment can give? From surgeons who are regularly dealing with gastric and duodenal ulcers there can be only one answer.

Dr. Hurst's convincing remarks on the relation of hyperchlorhydria to ulcer should remind us of the fact, long recognized but never more conclusively proved than by Mr. Sherren in his recent Hunterian Lecture, that gastroenterostomy is followed by a constant slight regurgitation of alkaline bile into the stomach and a permanent reduction of gastric acidity. It is an undoubted fact that the great majority of patients with chronic ulcer show, after appropriate operative treatment, a permanent tolerance to all foods and freedom from their old periodic dyspeptic crises.—I am, etc.,

Manchester, May 1st.

JOHN MORLEY.

ARSENIC IN LETHARGIC ENCEPHALITIS.

Sir,—In the leading article of April 24th on "Types and Treatment of Encephalitis" I was interested to see that the use of arsenic and neo-salvarsan is strongly condemned, as I have recently used neo-kharsivan in a case with markedly beneficial results.

On April 3rd I was called to see a woman aged 55, who complained chiefly of intense headache. There was a history of occasional diplopia recently and dizziness; respiration was rapid (55), pulse 65, temperature subnormal. There were frequent involuntary movements of the lips. During the following days lethargy developed; it was with effort that the eyelids were opened, and they very soon closed again. As I had not previously seen a case of lethargic encephalitis, I requested Dr. J. R. Monro of Spalding, who had some experience, to see the case with me, and he confirmed the diagnosis. On April 9th, symptoms having developed steadily, I gave 0.25 gram of neo-kharsivan intravenously. The next day the patient had obviously improved. On April 11th she did not seem so well; I therefore gave a further injection of 0.3 gram intravenously. She felt very ill some three or four hours later, but next day was much better. This improvement lasted several days, but as her condition did not seem so favourable on April 17th I gave 0.3 gram again. This was again followed by a feeling of serious illness a few hours later—not, however, sufficient for me to be sent for—and the next day the patient was cheery and feeling pretty well. She is still doing well.

My object in sending this brief note is to encourage others who might be disposed to try this drug, but who, in face of the very definite pronouncement of Netter, might refrain from its use.—I am, etc.,

Long Sutton, May 2nd.

W. A. WILSON-SMITH, M.D.

PUBLIC HEALTH VERSUS THE STATE.

SIR,—Dr. Freer "reminds" me of the war-limited hospital accommodation for civil patients. It was a work of supererogation. The Fabian report to which I referred is dated March, 1914; Mrs. Nevinson's paper which first drew my attention to the run on workhouse beds was early in the war, and of course dealt with the past; and I had limited myself to the end of 1915.

In answer to him, I pleaded the injustice of taxing the thrifty, in need and out, for the sake of the shiftless. His rejoinder, that it is not only the shiftless who have times of stress, seems to lack relevancy, unless it is meant as corroboration of my point.

May I say a few more words to wind up this correspondence? There is a terrible discrepancy between the tuberculous death rate as it is to-day and as it should have been had the rate of fall persisted which obtained under a policy opposite to that of to-day, and the tale of deaths which we had a right to look on as avoidable from 1896 to 1915, already exceeds the deaths in any war previous to the great war. Seeing that the change of policy has aimed at social amelioration, especially of the lives and health of the poor, it is incumbent on the advocates of this change to explain the discrepancy. This duty they disregard, except that now and again they will assign an obvious cause for a rise in any given year or two, a method which leaves much to be desired in explanation of an eighty-years' record or a world record.

I think any fair-minded man will acknowledge that in these columns there has been no satisfactory answer to the explanation I have submitted; indeed, I believe he would admit that my position has been strengthened by the opposition it has met. This much is certain, that while not contradicted by any facts as yet shown, it does explain all the startling facts, and on the world scale. For example, the three countries which in the last forty years of last century showed a rise in tuberculous mortality were exceptional not less in that than in the failure of wages to rise. It explains not only many fluctuations, but the rapid fall, the slackened fall, and the final rise in Great Britain. And it has stood the supreme test of successful prophecy, in that it foresaw a rise after the Insurance Act, and a check to the rise in the later years of the war. As Sir R. W. Philip shows for Scotland, the later years probably reduced the tuberculous mortality which otherwise would have obtained; and the obvious explanation is the complete temporary abolition of poverty among the classes which used to be called, and will shortly again be called, "the poor."

If you take, say, Mr. Harold Cox's letters to *The Times* in 1911 on the Insurance Bill, and compare them with, say, Mr. George's speeches at the time, you will find all the large prophecies of the one have come true and all those of the other falsified. Why should we pursue with unshaken confidence the principles of the false prophet and contemptuously disregard those of the true?—I am, etc.,

Rayleigh, Essex, May 3rd.

B. G. M. BASKETT.

TREATMENT OF SEPTIC PERITONITIS.

SIR,—Mr. Steward, in his lecture on septic peritonitis (April 17th, p. 527) says: "A large amount of fluid is poured out, partly as free fluid into the peritoneal cavity. . . . This fluid is highly toxic; consequently the patient suffers from an acute toxæmia." Surely the fluid that is poured out by the peritoneum in response to attack is anti-toxic and bactericidal; it only becomes toxic when its defensive powers are exhausted and the resistance of the peritoneum overcome by the invading sepsis. This fluid is Nature's first line of defence against septic infection, and is thrown out at once in order to gain time for the preparation of adhesions, which form her second line of defence.

That this fluid is non-toxic is demonstrated by every-day experience. A child will come in with a temperature of 102 and pulse 120; an acutely inflamed appendix is found, and an abdomen full of turbid fluid; unless this fluid is quite purulent and has the characteristic smell of *Bacillus coli*, the wound is closed without any attempt at drainage. In the morning the temperature and pulse will be normal, or nearly so. If this fluid were toxic the result of this closure would be disastrous, and if it were responsible for the toxæmia previous to operation the symptoms of

toxæmia would continue until all the fluid had been absorbed.

Drainage is a difficult and at present a very confused subject in abdominal work. An intra-abdominal abscess cavity may be drained, but in the great majority of cases as soon as the contents are evacuated the walls of the cavity fall in.

When we put a tube into the abdominal cavity it is isolated in a marvellously short time by adhesions between viscera, and viscera and parietes. So certain in its action is this property of the peritoneum that we frequently depend upon it in operations such as those of gastrostomy and cholecystostomy. We know also that adjacent peritoneal surfaces when irritated will be strongly adherent in less than twelve hours. It seems certain, then, that so long as the peritoneum retains its power of forming adhesions it will isolate a tube or tubes in twenty-four hours. When the peritoneum has lost this power to form limiting adhesions, it means that Nature's resistance is at an end, and though in this case the tube may function as a drain, it will be quite useless in face of the unlimited spread of septic infection.

Certainly at the end of forty-eight hours, probably at the end of twenty-four hours, the great majority of tubes are draining nothing but their own track, and while they are doing this they are also helping on secondary infection, stimulating irregular intestinal movements, and so assisting in the spread of the infecting organisms, and are probably scrubbing a hole in the intestinal wall, with the possible production of a faecal fistula.

Surely, in face of the facts, we should recognize that the function of a drain is simply to facilitate the escape of deleterious matter to the surface of the body. A drainage apparatus should only be retained until it is reasonably sure that exit to the surface is freer than penetration in any other direction.

Mr. Steward omits to mention the two places where a drain is really seen at most advantage: these are those cases of pelvic abscess which can be drained into the vagina or rectum; even here it is not good to leave a drain in for more than a few hours. In the first case quoted by Mr. Steward it seems most probable that the paralysis of the ileum was due to trauma from the tube.

I cannot see that Carrel tubes will act in any way different to the usual; they will be more numerous, and constant irrigation may to a certain extent militate against the formation of adhesions, though this is not altogether to the good. The constant stream of saline may be useful in retarding a secondary infection, but it may be equally effective in aiding the spread of the primary infection, especially if it hinders the formation of adhesions. Case I would, I think, have done quite as well with dependent drainage through the vagina. Case II does not convey any conviction of the superiority of the method, in view of its subphrenic abscess and empyema. Case III is just an ordinary one, with nothing very remarkable about its recovery. Case IV would have done equally well with vaginal drainage.

With regard to pituitrin, it has seemed to me on several occasions rather to favour the development of cardiac weakness, and that its action is in no way better than that of eserine or strychnine.

I have written at length because Mr. Steward's lecture appeared to me to tend to encourage the undue retention of tubes—a practice which is too prevalent already.—I am, etc.,

Watford, April 29th.

J. C. BARKER.

AORTITIS AND AORTIC REGURGITATION.

SIR,—Dr. Fisher (April 24th, p. 536) expresses the opinion that in my remarks I have not laid sufficient stress upon the associated myocarditis. The fact that the syphilitic virus gives rise to arteritis, aortitis, endocarditis, and myocarditis is known, but how to apportion the signs and symptoms to the separate lesions is difficult. The cases of aortic regurgitation in which myocarditis is the most dangerous lesion are probably the most numerous. On the other hand, in cases in which retro-sternal pain and dyspnoea on effort—or even at rest—are the most prominent symptoms, I would consider the aortitis to be the more important factor.—I am, etc.,

Belfast, April 26th.

JOHN E. MACILWAINE.

Obituary.

SIR HENRY BURDETT, K.C.B., K.C.V.O.

WE regret to record the death of Sir Henry C. Burdett on April 29th, at his house in Porchester Square. His services in the cause of the voluntary hospitals, and his knowledge of hospital administration and finance during more than fifty years had earned for him a unique position in the hospital world.

Henry Charles Burdett was born in March, 1847; his father was the rector of Gilmorton, Leicestershire, a living which had been held by members of the Burdett family for several centuries. He began life in a Birmingham bank, but at the age of 21 was appointed secretary to the Queen's Hospital in that city. His great ability and enterprise soon became evident in that post, and he had a large share in linking up under one management the two medical schools which then existed in Birmingham. There also began his life-long concern for the training and welfare of nurses. In the early seventies his interest in medicine induced him to enter as a medical student at Guy's Hospital. It may be doubted whether he seriously thought of going on to qualification, but his period of medical study gave him an insight into hospital matters from a new angle, and in after-life he always took pride in speaking of himself as an old Guy's man. In the autumn of 1874 he was elected superintendent of the Seamen's Hospital at Greenwich. In 1883, when he was appointed secretary of the Share and Loan Department of the London Stock Exchange, he was elected to the Committee of Management of the Seamen's Hospital Society; in 1896 he was elected a vice-president and so remained until his death. Despite the responsibilities of the new work in the City he maintained his keen personal interest in the voluntary hospitals and showed it in many ways. Thirty years ago he published the first edition of *Burdett's Hospitals and Charities*, an indispensable yearbook of reference on matters relating to hospitals and other philanthropic institutions. In introducing the last edition to the public, Sir Henry Burdett spoke of the happiness he had derived from "fifty busy years in the cause of the sick, their treatment, nursing, and progressive welfare," and added that this might be the last preface that he would address to the readers of "Burdett." During his Stock Exchange days, which ended in 1897, and afterwards, his eloquent appeals on behalf of charitable objects charmed many thousands of pounds out of the pockets of rich men. He did a great service to the nursing profession by organizing, thirty years ago, the National Pension Fund for Trained Nurses and Hospital Officials. In this he had the active support of King Edward and Queen Alexandra (then Prince and Princess of Wales), who entertained for him a high regard and showed it often. In the year of the Diamond Jubilee his public services were rewarded by the K.C.B., and in 1908 King Edward created him a K.C.V.O. Sir Henry Burdett was the active spirit in starting what is now the King's Hospital Fund for London; he never missed a meeting of the council from the foundation of the Fund in 1897 until last year. He had an important share also in the foundation of the League of Mercy. Again, he was the acknowledged originator of the uniform system of hospital accounts; others improved and extended it, but the idea was his.

Sir Henry Burdett was a voluminous writer on hospital and nursing topics, on finance, and on various aspects of politics and public life. He was the founder and editor of the *Hospital*, a weekly organ of administrative medicine and institutional life, while the *Nursing Mirror*, which began as a supplement to that paper but has long been issued separately, gained great popularity under his guidance. He paid many visits of inspection to the hospitals of the United Kingdom, and during his foreign tours he studied the work and organization of medical charities in the United States and on the Continent. The outcome of these inquiries was his large work *The Hospitals and Asylums of the World*, in four volumes, with a comprehensive portfolio of plans. He had an almost fatherly feeling towards medical matters and the work of the medical profession. He missed no opportunity to use his influence in the advancement of medical science and practice, and showed warm interest in post-graduate education. At the annual meeting of the British Medical Association at

Brighton in 1913 he took part by invitation in a discussion on "Hospitals in Relation to the State, the Public, and the Medical Profession" in the Section of Medical Sociology. He there expressed the view that, but for the services the hospitals were rendering, the Insurance Act would be a dead letter. He argued, too, that if only for financial reasons a whole-time salaried state medical service would never come to pass. Lady Burdett, whom he married in 1875, was a daughter of the late Mr. Gay Shute, F.R.C.S.; she died last year.

A former colleague writes: Those who at any time worked in close association with Sir Henry Burdett and visited him at The Lodge, Porchester Square, knew him as a kindly, hospitable, home-loving man. Until quite recent years, when death took one after another from the home circle, he was singularly happy in his family life. He was always to be found in the large library on the ground-floor, everlooking the lawn, where he spent a large part of the day, and did most of his work. Even through a personal talk he never could quite subdue the instinct for oratorical effect, for the dramatic pause with glittering eye and wide-armed gesture. His books and articles were dictated to an invisible audience, and as a result his literary work had often something of the diffuseness and floridity of platform speech, with the characteristic personal touch caricatured a little by cold print. Nevertheless he was an accomplished and alert journalist, eager for the success of his papers and well versed in the various branches of editing and publishing. His mind in general moved along large lines towards large objectives; but, while he much preferred to depute the working out of details to others, he could if need be get down to the smallest parts of a big scheme and handle them with bold dexterity. He was a man of strong and commanding personality, by no means an "intellectual" but with very great mental powers. The qualities that especially stand out in the memory of Sir Henry Burdett are his unquenchable enthusiasm, the bigness of his ideas and projects, and his persuasive eloquence. As a colleague he was most kind, courteous, loyal, and considerate; he could not be shaken from his opinions, but when he said he would do a thing he kept his word.

A. J. CHALMERS, M.D., F.R.C.S.,
Khartoum.

WE announced some time ago the death in Calcutta from pneumonia of Dr. A. J. Chalmers, who was best known to the profession as the author, with Dr. Castellani, of the large *Manual of Tropical Medicine*, which is the most comprehensive and detailed work on the subject in existence. Albert John Chalmers was born in Manchester in 1870, and received his medical education in the University Colleges of Liverpool and London. As a student his career was brilliant; he graduated M.B., Ch.B. Victoria in 1890, and in the same year was appointed Holt Fellow of the Liverpool College, a position he held for two years. When he graduated M.D. Vict. in 1893 he took the Gold Medal. He became F.R.C.S. Eng. in 1895. In 1897, probably more from a desire to become acquainted with tropical life than from any intention to follow it as a career, he joined the West African Medical Service; he served in the Ashanti war of 1900, was a member of the garrison that fought its way out of Coomassie, was mentioned in dispatches, and received the medal with clasp.

He was appointed registrar of the Ceylon Medical College in 1901 and did much to improve its organization and raise the standard of teaching, which is now at a high level. When he resigned in 1902 he gave full bent to his inclination to devote himself to the parasitology, bacteriology, and general pathology of tropical diseases. One outcome of this period was his share in the *Manual*, the first edition of which appeared in 1910, and the third last year. He afterwards gave much attention to pellagra and travelled widely, some of his journeys being made with Dr. Sambon to study the distribution of the disease, the occasional occurrence of which in England he was one of the first to recognize. He became Director of the Wellcome Tropical Research Laboratory at Khartoum in 1913, and since then has been responsible in whole or in part for a long series of papers on a large variety of subjects in tropical medicine. He was a member of the Sanitary Board,

of the Sleeping Sickness Commission and of the Archaeological Committee of the Sudan. Dr. Chalmers was industrious and accurate in research, and had a wide and intimate acquaintance with the rapidly growing literature of the department to which he had devoted himself. His premature death while on a holiday journey eastward round the world is a loss to tropical medicine.

DR. JOHN LIDDLE CROMBIE, who died at North Berwick on May 1st, aged 77, was for many years associated with the health offices of that well known and popular watering place at the entrance to the Firth of Forth. He graduated M.D. at Edinburgh University in 1863, having taken the diplomas of L.R.C.S. and L.R.C.P. Edin. in the previous year. After acting as house-surgeon to Perth Infirmary his lot was cast in North Berwick, where he quickly gathered together a large private practice. He became parochial medical officer and medical officer of health, as well as certifying factory surgeon. For a time he was Surgeon-Colonel (V.D.) 7th V.B. Royal Scots, and he was also surgeon and agent for the coastguard. He was honoured by his professional brethren by being elected a member of the Harveian Society, and his interests outside medicine were shown by his connexion with the Berwickshire Naturalists' Club.

To all who knew Dr. JOSEPH WILLIAM HUNT, who practised so long in Hackney, the news of his death on April 17th, after a long and trying illness, will come as a sense of loss, for though a man of retiring disposition, contented quietly to do his daily round of duty, he was endowed with abilities out of the ordinary, and a character of no common elevation. He was born in 1851 in Canada, where his father was a missionary. He came to England when 12 years old and entered University College Hospital Medical School with an exhibition at an early age. He took the degree of B.Sc. Lond. in 1876 and in the same year at the M.B. won a gold medal in medicine; in the following year he won the gold medal at the M.D. examination. After holding the appointment of house-physician to University College Hospital he became resident medical officer; he then went to Wolverhampton, where for four years he was physician to the General Hospital. In 1881 he settled in practice at Hackney in partnership with the late Dr. Daly, and soon won the affection and respect of his fellows. He had held the office of vice-president of the Metropolitan Counties Branch and chairman of the City Division of the British Medical Association; he was also at various times president of the East London Clinical Society and the Aesculapian Society. He was an earnest churchman, and lived a self-denying, consistent, and useful life. For many years he was the local secretary to Epsom College, and his work as one of the trustees of the Spinstowe Charity, and for the deaf and dumb at the Asylum at Clapton, was much valued.

Universities and Colleges.

UNIVERSITY OF OXFORD.

MR. EDWARD WHITLEY has offered to the University the sum of £10,000 towards the endowment of a professorship of biochemistry, and the British Dye-Stuffs Corporation has made a donation of £5,000 towards the cost of extending the laboratory of organic chemistry. Decrees accepting these munificent and timely gifts are being proposed in Convocation this week.

UNIVERSITY OF CAMBRIDGE.

At a congregation on April 30th the following medical degrees were conferred:

M.D.—R. N. Chopra (admitted by proxy) and C. Worster-Drought.
M.B. and B.Ch.—A. W. Uloth, C. M. Billington, M. L. Young, G. L. Smith.
M.B.—C. R. Wright.

UNIVERSITY OF LONDON.

Advanced Lectures in Physiology.

PROFESSOR E. MELLANBY, M.D., began a course of lectures on nutrition, at King's College for Women (household and social science department), Campden Hill Road, Kensington, on May 3rd, at 5 p.m. The remaining lectures of the series will be given on May 10th, 11th, 17th, 18th, and 31st, and June 1st. A course of eight lectures on the biochemistry of sterols will be given by Mr. J. A. Gardner, M.A., F.I.C., University Reader in Physiological Chemistry, in the physio-

logical laboratory of the University (South Kensington), at 5 p.m. on Tuesdays from May 18th to July 6th. The lectures are addressed to advanced students of the University and to others interested in the subject. Admission is free.

UNIVERSITY OF GLASGOW. MEDICAL CURRICULUM.

At a meeting of the General Council on April 28th a sub-committee reported that the summer term was the most advantageous time for the commencement of studies in the medical school. Members of the medical faculty were unanimous on the point, but the co-operation of the schools and of the education department would be needed. The matter will be further considered at a meeting of the University Court.

UNIVERSITY OF ST. ANDREWS.

At the meeting of the University Court, on May 1st, Dr. John Taylor was appointed to the lectureship in regional anatomy, Dundee, and Dr. L. T. Price, surgeon to the Dundee Royal Infirmary, to that in diseases of children.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary comitia of the Royal College of Physicians was held on Thursday, April 29th, when the President, Sir Norman Moore, was in the chair. The President announced that Professor C. S. Sherrington had been appointed the representative of the College on the Committee to consider a memorial of the late Professor Sir William Osler.

MEMBERS.

The following candidates, having passed the required examination, were admitted as Members:

Robert Allen Bennett, M.D. Lond., L.R.C.P.; Francis Bernard Chavasse, M.D. Oxf., L.R.C.P.; Thomas Forrest Cotton, M.D. McGill; John Alexander Drake, M.B. Lond., L.R.C.P.; Arthur Wm. Mickle Ellis, M.B. Toronto; Francis Richard Fraser, M.B. Edin.; Joseph Gatt, M.D. Malta, L.R.C.P.; Mary Esler Harding, M.D. Lond.; Harold William Hills, M.B. Lond., L.R.C.P.; George Johnson Langley, M.D. Lond.; Elias Leopold Woolf Mandel, M.D. Lond., L.R.C.P.; Edward Maother, M.D. Lond.; Henry Bret Russell, M.B. Lond., L.R.C.P.; Evelyn Dennis Scott, M.B. Lond., L.R.C.P.; Hugh Stannus Stannus, M.D. Lond., L.R.C.P.; Margaret Grace Thackrah, M.D. Lond.; Robert Heywood Wilshaw, M.D. Lond.

FELLOWS.

The following were elected Fellows on the nomination of the Council:

William Francis Menzies, M.D. Edin.; James Graham Forbes, M.D. Camb.; William Morton Robson, M.D. Lond.; Samuel Ernest Dore, M.D. Camb.; George Basil Price, M.D. Lond.; Eardley Lancelot Holland, M.D. Lond.; Albert Ramsbottom, M.D. Vict.; Arthur Stanley Woodwork, M.D. Lond.; Francis Graham Crookshank, M.D. Lond.; Arthur Charles Douglas Firth, M.D. Camb.; Nathan Mutch, M.D. Camb.; Francis Martyn Rouse Walshe, M.D. Lond.; George Graham, M.D. Camb.; George Ernest Beaumont, M.B. Oxf.

UNIVERSITY OF LONDON.

Dr. Fawcett and Sir Wilmot Herringham were appointed representatives of the College on the Senate of the University of London in place of Dr. Sidney Martin and Sir Seymour Sharkey. The thanks of the College were awarded to the retiring members for their services.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

A report was approved from the Committee of Management containing regulations for the Diploma in Psychological Medicine (D.P.M., R.C.P. and S. Eng.) drawn up after a conference with teachers in the various subjects. The examination will be held in two parts, in June and December. A candidate may enter for Part I at any time after obtaining a registrable medical qualification, and the two divisions may be taken separately or together. The subjects of examination will be (a) anatomy and physiology of the nervous system, (b) psychology. After passing Part I a candidate may enter for Part II of the examination on the completion of a year of special study subsequent to obtaining a registrable medical qualification. Candidates will be required to produce certificates (a) of having attended clinical instruction for at least two months at a recognized hospital for nervous diseases, or in the department for nervous diseases at a recognized hospital; (b) of having held a resident appointment at a recognized institution for mental diseases where clinical instruction is given, for at least six months, or of having attended clinical instruction in psychological medicine at a recognized institution during twelve months. The subjects for examination for Part II are (a) neurology, including clinical and pathological neurology, and (b) psychological medicine, including its legal relations. The conditions of study may be modified by the Committee in the case of a candidate (a) who has carried out original investigations or has written a thesis on psychology or neurology in relation to psychological medicine, or (b) whose studies have extended over a prolonged period without fulfilling the exact conditions, but exemption will not be granted for any part of the examination. Graduates in medicine or surgery of Indian, colonial, or foreign universities recognized by the Examining Board in England, but whose degrees are not registrable in this country, may enter for the examination by fulfilling the same conditions in regard to study. The fee for admission or readmission to each part of the examination is six guineas.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.

A similar report embodying regulations for the Diploma in Ophthalmic Medicine and Surgery (D.O.M.S., R.C.P. and S.Eng.) was also adopted. The examination will be held in two parts, in January and July. A candidate may enter for Part I at any time after obtaining a registrable medical qualification. He must present himself for the whole of Part I, but if he fail in one division only will be allowed to present himself for re-examination in that division. The subjects of examination will be (a) anatomy and embryology of the visual apparatus (including the contents of the orbit, the bones in the neighbourhood thereof, and the central nervous system so far as it relates to vision); (b) the physiology of vision; (c) elementary optics. After passing Part I a candidate may enter for Part II on completion of one year of special study of ophthalmology subsequent to obtaining a registrable medical qualification. Candidates will be required to produce certificates of having (a) specially studied ophthalmic medicine and surgery and general medicine in its relation to ophthalmology for a period of twelve months; (b) engaged in the investigation and correction of errors of refraction; (c) attended the clinical practice of a recognized ophthalmic hospital or ophthalmic department of a recognized general hospital for twelve months; (the conditions may be fulfilled by holding the appointment of house-surgeon or house-physician or clinical assistant at one of the above hospitals or departments, provided that in the case of a clinical assistant the certificate shows that he has attended for at least three hours a day on two days a week); of having (d) attended a practical course of operative ophthalmic surgery, and (e) attended a course of pathology and bacteriology with special reference to ophthalmic medicine and surgery. The subjects of the examination for Part II are (a) optical defects of the eye; (b) ophthalmic medicine and surgery; (c) pathology, with special reference to medical and surgical ophthalmology. These conditions may be modified in the case of a candidate (a) who has carried out original investigations in any branch of the examination; (b) who has written a thesis on the pathology of the eye; (c) whose studies have extended over a prolonged period without fulfilling the exact conditions, but exemptions may not be granted from any part of the examination. Graduates in medicine or surgery of Indian, colonial, or foreign universities recognized by the Examining Board in England, but whose degrees are not registrable in this country, may enter for the examination for the Diploma in Ophthalmic Medicine and Surgery on fulfilling the same conditions in regard to study. The fee for admission or readmission to each part of the examination is six guineas.

LONDON SCHOOL OF TROPICAL MEDICINE.

THE following candidates have passed the examination of the school at the termination of the sixty-second session, February-April, 1920:

* H. E. Whittingham (Duncan medal). * A. K. Cosgrave. * A. Kbalik. E. J. Wood. * E. Forrester-Paton. J. Fanstone. E. G. Mack. W. P. Hogg. J. S. Armstrong. J. R. C. Stephens. M. Wong. G. A. S. Madgwick. G. A. Frendo. C. Basile. M. Jackson. E. C. MacWilliam. N. Nedergaard. H. R. Dive. J. R. Crollius. J. Gray. A. Y. Cantin. D. Schokman. C. H. Brangwin.

* With distinction.

Medical News.

THE University of London announces that M. Pierre Janet, Professeur de Psychologie au Collège de France, Paris, will next week give a course of three lectures on "La Tension Psychologique, ses Degrés et ses Oscillations." The first lecture will be given at the house of the Royal Society of Medicine, 1, Wimpole Street, W., at 5 p.m. on Tuesday, May 11th. The two other lectures will be given at the same hour on Wednesday and Thursday. The lectures, which will be delivered in French and will deal in part with the medical aspect of the subject, are addressed to advanced students of the university, but others interested are invited to attend. Dr. Henry Head, F.R.S., will take the chair at each lecture.

THE Ministry of Health has issued a Statutory Order, which came into operation on May 1st. It requires the M.O.H. of a city or borough council to send a copy of each certificate or notification of a case of acute primary pneumonia, acute influenzal pneumonia, malaria, dysentery, trench fever, acute encephalitis lethargica, and of ophthalmia neonatorum—whether notified by a medical practitioner or by a certified midwife—within twelve hours of its receipt, to the Metropolitan Asylums Board, who will repay to the borough council or to the common council the fee paid in respect of such notification.

AT the Leigh (Lancashire) Borough Police Court, on April 22nd, the Lancashire County Council took legal proceedings against Charles C. Abbott, "herbal specialist," of 56, Railway Road, Leigh, for treating a person for venereal disease and prescribing a remedy therefore contrary to Section 1 of the Venereal Disease Act, 1917. A fine of £10 was inflicted.

DR. J. F. MACDONALD, D.P.H., of the Middle Temple, and Dr. G. D. H. Wallace, of Gray's Inn, were called to the bar on April 28th.

THE Congrès Français d'Oto-Rhino-Laryngologie, which will be held in Paris next week (May 10th to 13th), will be attended by a number of British specialists.

NOTIFICATION of lethargic encephalitis was made compulsory in Denmark at the beginning of this year. By the end of January 29 cases had been notified, some of them dating back to July and August, 1919. Among them four deaths had been recorded, but in two the diagnosis was uncertain. The Pathological Institute of the University of Copenhagen has undertaken to examine *post-mortem* specimens.

CASES of lethargic encephalitis have recently appeared in various parts of Spain.

THE University of Birmingham has arranged for a post-graduate course of instruction to be given in the Medical Faculty, Edmund Street, Birmingham, and at associated hospitals, from Monday, July 5th, to Saturday, July 17th, both dates inclusive. The course will comprise sections of medicine, surgery, pathology and bacteriology, obstetrics and gynaecology, diseases of children, ophthalmology, diseases of the ear and throat, radiology, electrical treatment, and anatomy and physiology. The fee for admission to the lectures and clinical demonstrations in each section is one guinea. Further particulars can be obtained on application to the Clerk to the Clinical Board, University, Edmund Street, Birmingham.

IT has already been announced that the eleventh session of the Australasian Medical Congress (the first since 1914) will be held at Brisbane under the presidency of the Hon. W. F. Taylor, M.D., from August 23rd to August 28th, a season in which the climate of Queensland is usually agreeable, the maximum temperature being on the average 72.4° and the minimum 50.7°. The Executive Committee of the congress invites any member of the Association who may be visiting Queensland at the time to attend as an honorary member. Any one who thinks of accepting should communicate with Dr. Wilton Love, the honorary general secretary in Brisbane, at once, as the accommodation is limited. The principal subject for discussion will be the question of the permanent settlement of a healthy white race in tropical Australia. It is expected also that the contributions to the sections of naval and military medicine and surgery will be of unusual interest.

THE half-yearly dinner of the London Aberdeen University Club will be held at the Criterion Restaurant on Thursday, May 20th, at 7.30 p.m. The annual general meeting will take place at 6.30 p.m. Further particulars can be obtained from Dr. W. A. Milligan, 11, Upper Brook Street, W. 1.

SIR EDWARD SHARPEY SCHAPER has thoroughly revised his *Essentials of Histology*, and the new (eleventh) edition will shortly be published by Messrs. Longmans.

THE shortage of the supply of paper is becoming an even more serious problem to periodical publications than the rise of price, great as that has been. Newspaper proprietors have been giving evidence before a Subcommittee of the Senate of the United States; one of them asserted that if consumption proceeds at the present rate there will be no paper-pulp producing forests left in twenty-five years. The only remedy so far suggested is to decrease the size of papers and periodicals and increase advertising rates.

WE are asked to state that the subscription (35 francs), to be paid by those who propose to attend the Congress of Physiology which will be held under the presidency of Professor Charles Richet in Paris from July 16th to July 20th, should be sent as soon as possible to M. Lucien Bull, Secrétaire du Congrès, Sorbonne, 1, Rue Victor Cousin, Paris, V, from whom a list of hotels with which special arrangements have been made can be obtained. The titles and summaries, not exceeding twenty-five lines, should be received by the secretary of the congress not later than June 1st. There will be an exhibition of apparatus and instruments. The last Congress of Physiology was held at Groningen in September, 1913.

SIR ARTHUR SHIPLEY prefaced his lecture to the Child-Study Society on April 29th on "Biting insects and children" (to which title *Punch* has alluded) with the remark that as a bachelor he knew less about children than he did about insects; accordingly his lecture was devoted to an entomological description (with literary and historical digressions) of lice, bugs, and fleas, with no particular reference to the special susceptibilities of children or to preventive measures which may be taken on their behalf. In the course of discussion the

question arose whether it was possible to secure personal immunity from fleas. Sir Arthur said that the essential oils, especially the oil of cedarwood, were supposed to keep fleas away, but the personal factor was so large in these cases that no means could be absolutely relied upon. Dr. C. E. Wallis said that in some correspondence on the subject which appeared in the *BRITISH MEDICAL JOURNAL* about eight years ago it was stated that the taking of two or three sulphur lozenges would render a person unpalatable to fleas. He had found that procedure of no use whatever, but he had discovered one preventive measure which in his personal experience had proved most successful. When he was a student doing midwifery he had to take lodgings in Clare Market, and found himself attacked the first night by a host of fleas. He decided that drastic counter-measures were necessary, and therefore applied with a sponge a 1 in 20 carbolic solution to his neck, wrists, and ankles, believing that these must be the means of entrance whereby the insects invaded the person. As a result he was immune from flea-bite during the remainder of his month's stay. Sir John Cockburn, the chairman of the meeting, remarked that in Australia there were such things as flea storms, whirlwinds of fleas, which covered the verandahs of the houses. Stock breeders in Australia paid a good deal of attention to the question of susceptibility to insect bite, and animals much subject to the bites of fleas and flies were not allowed to breed.

THE honour of O.B.E. has been conferred upon Mr. Edmond Thomas Gann, M.B.E., Secretary Army Medical Advisory Board and Army Sanitary Committee.

As cases of small-pox have occurred in and around London during the past few weeks, and some of these have remained undiscovered for a considerable time after the first appearance of the disease, the London County Council draws attention to the arrangements under which in doubtful cases the practitioner confers with the M.O.H. of the borough, and to the fact that, should a further opinion be required, on application to the Public Health Department, the services of Dr. W. McC. Wanklyn will be available.

Letters, Notes, and Answers.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

THE postal address of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Ailology*, *Westrand*, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, *Westrand*, London; telephone, 2650, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, *Westrand*, London; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bacillus*, *Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate*, *Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

"L. C." writes: A patient, aged 52 years, suffers from a continuous saline taste in the mouth; the taste is like saltpetre. The patient is in good health and apparently quite sound; he has had some pyorrhoea, and is subject to lumbago and sciatica. He smokes about twenty cigarettes a day. The taste is worst in the morning, and improves as the day goes on.

INCOME TAX.

J. I. H. explains that in 1918 the local inspector of taxes asked that his figures should be verified by a chartered accountant, and that it was found that the sums returned for assessment had been insufficient. The inspector now asks that the years subsequent to 1918 should be dealt with on the basis of figures prepared by a chartered accountant. Is he justified in this demand and in maintaining the assessment on a basis of a three years' average?

* The three years' average is the statutory basis of assessment and is binding. The inspector has no legal right to require audited accounts; his statutory function extends only to the bringing of the case to the attention of the Assessing Commissioners, who may in their discretion ignore the return made by the taxpayer and make an estimated assessment in excess of that amount. In that event our correspondent would presumably lodge a notice of appeal, and the

Commissioners to whom the appeal was directed would have the right of requiring full accounts of the receipts and expenses of the practice; non-compliance with that requirement would result in confirmation of the assessment. It will be seen that there is some ultimate claim for accounts on the part of the authorities, and, as our correspondent was not at one time able to make a correct return without professional assistance, we hardly like to advise him to refuse the inspector's request. Possibly he might arrange a compromise by offering to prepare the detailed statements himself—on the lines followed by his accountant in 1918—and to show his books to the inspector if necessary.

SPIRITUALISM AND MENTAL DISEASE.

DR. GERARD SMITH (31, Greville Road, N.W.6) writes: In order to support the contention that in the pursuit of "spiritualism" persons of a certain temperament are exposed to grave dangers, I am anxious to secure evidence—especially recent evidence—of cases of mental derangement brought about in this way. I should, therefore, be glad to receive notes or short statements of such cases. I have no concern with the truth or error of "spiritualism."

LETTERS, NOTES, ETC.

PROPOSED TAXATION OF MOTOR CARS.

DR. W. BERNARD SECRETAN (Reading) writes with reference to the Government's intention to allow no rebate on the taxation of doctors' cars. Unless the profession makes its voice heard it will receive the usual official treatment meted out to those who are not too importunate or dangerous. I suggest that every medical man make a point of writing at once to his Member of Parliament, pointing out the harshness of the no-rebate proposal. Points might be made of (1) the falsity of the argument that doctors stand to gain more than the average motorist by the abolition of the petrol tax on account of their large mileage, since doctors have only paid in the past half this tax; (2) the unfairness of taxing two cars kept by one doctor, only one being used at a time, at the full rate; (3) the bad policy of a scheme which tends to hinder instead of increase the efficiency of the medical service of the country. No doubt other arguments will occur to many.

* * Accounts of the action taken by the *British Medical Association* have been published in the *BRITISH MEDICAL JOURNAL* during the last three weeks. An account of the proceedings at the deputation to the Ministry of Transport will be found in the *Current Notes of the SUPPLEMENT* for this week.

OPHTHALMIC OPERATIONS.

LIEUT.-COLONEL F. P. MAYNARD, M.B., F.R.C.S., I.M.S. (retired), writes: In your issue of May 1st it is stated that Grimsdale and Brewerton's *Textbook of Ophthalmic Operations* "is the only one of its kind on this special subject in our language." May I be permitted to point out that this is incorrect? In your columns for 1908 (vol. ii, p. 200) there is a review of my *Manual of Ophthalmic Operations*, a second edition of which will be published in a few weeks.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 30, 33, 34, 35, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 31, 32, and 33.

THE post of specialist medical referee under the Workmen's Compensation Act, 1906, for ophthalmic cases in County Court Circuit No. 6, is vacant. Applications should be made to the Private Secretary, Home Office, by May 26th.

THE following appointments of certifying factory surgeons are vacant: Ballindalloch (Banff), Cardenden (Fife), Ellesmere (Salop), Leicester, West (Leicester).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

Observations

ON

THE NUTRITION OF ARTICULAR
CARTILAGE.*

BY

T. S. P. STRANGEWAYS,

LECTURER IN SPECIAL PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE.

(From the Laboratories of the Cambridge Research
Hospital.)

[With Special Plate.]

THE structure of articular cartilage has been the subject of numerous papers, but the study of its nutrition appears to have been neglected. The generally accepted explanation of the nutrition of this avascular tissue is that the nutritive fluid is derived from the vessels of the adjoining structures, chiefly from the vessels of the marrow and bone, but also to some extent from the *circulus articulari vasculosus* formed by the narrow border of vessels which lie underneath the synovial membrane and surround the circumference of the articular cartilage. The fluid from these vessels is supposed to reach the cartilage cells by imbibition. Some observers have described lymph channels in the hyaline matrix, but the existence of these is very doubtful.

Microscopic examination of a section through the articular cartilage prepared and stained by the ordinary methods reveals a characteristic, well defined structure. The cartilaginous tissue rests upon a thin, practically continuous layer of bone. In the deeper parts of the matrix are seen columns of cartilage cells which run perpendicularly towards the free surface; as these become more superficial the columns contain fewer cells and are distributed in an irregular manner, and the uppermost groups lie parallel to the free surface. The free surface is covered by a layer of cells with thin, elongated nuclei (perichondrium). In the deeper layers of the cartilage, where it lies in contact with the bone, a deposit of calcium salts is seen; this may be called the zone of calcified cartilage. A study of such a section shows that the cells of the superficial layers appear more active than those of the deeper layers, and it is difficult to understand how the nutritive fluid can pass from the vessels of the bone through the bone matrix and through the avascular layer of calcified cartilage towards the surface in sufficient quantity to cause the obviously greater vitality of the superficial layers. It is equally difficult to explain how the fluid from the vessels of the *circulus articulari vasculosus* can reach the cells forming the large area of cartilage on the articular surface.

If, as I believe, the present view of the nutrition of articular cartilage is incorrect, there is yet another source from which it may derive nourishment, namely, the synovial fluid. It is strange that this source of nourishment should not have been more widely discussed. The supply of synovial fluid in a normal joint is sufficient, and granting that it contains material suitable for the nourishment of the cartilage, the cells can obtain by imbibition all the nutriment required by this type of tissue.

In support of this view I offer the following description of the naked eye and microscopic changes seen in certain free bodies which are found occasionally in a joint cavity.

The origin of these free bodies has been discussed by several writers (Klein,¹ Weichselbaum,² Poulet and Vaillard,³ Real,⁴ König,⁵ Rimann,⁶ Ludloff,⁷ and others). The question whether they arise from local changes within the joints, or whether they are of traumatic origin, need not be discussed here, but it seems probable that the majority, if not all, of the type referred to in this paper are due to traumatic detachment of a portion of the articular cartilage. Whichever explanation is the true one, the microscopic changes which take place are of considerable interest.

* Four free bodies of this kind have been examined: they were obtained from the joints of three patients. The first was found accidentally in the knee-joint of a youth; the

other three were very kindly presented to me by Major D. W. Hume, and were removed by him at the operation table.

The first specimen is from the knee-joint of a youth, aged 16, whose left lower limb was amputated for sarcoma of the thigh. On opening the joint there fell out a smooth shining lenticular body, 2.3 cm. long and 1.5 cm. broad, with rounded edges. To the naked eye its structure resembles cartilage. On the centre of the outer condyle of the femur there is a slightly depressed area of a shape similar to the free body, but somewhat smaller. The surface of this area is somewhat irregular and is covered with a thin smooth shining tissue, through which the yellowish texture of the underlying bone can be seen. Evidently the free body had been detached some time previously from this area. The articular cartilage of the joint is otherwise quite normal. One surface of the free body is white, smooth, and shining, and exactly resembles cartilage to the naked eye. This smooth surface is present on the rounded edges of the body, and is continued on to the other surface for a distance of 0.3 cm., forming a white ring around it. The other surface is slightly irregular and yellowish, but examination shows that this area is also covered with a thin smooth shining membrane. The smooth white cartilaginous surface evidently represents the free surface of the cartilage and the irregular surface the deeper portion where it was attached to the condyle. Small bony fragments were probably adherent to this side of the free body after its separation from the condyle.

Microscopic examination of the free body shows that both surfaces as well as the edges are covered by several layers of cells with elongated nuclei. On the side which forms the free surface of the cartilage they exactly resemble the cells of the normal perichondrium, and shade off into hyaline cartilage (Fig. 1). At the edges these cells form a definite layer of cells with elongated nuclei which shade off into young atypical cells (Fig. 2). The under surface is covered by several layers of cells of connective tissue type. This tissue varies in thickness; it is thicker towards the edges and becomes thin where it covers the irregular yellowish tissue seen on the deeper surface of the fragment. There are in this layer of connective tissue cells a few small areas which show signs of proliferation; these appear to be replacing the atypical tissue described below. At the edges of these proliferating cells, where they are in contact with the atypical tissue, a few well-formed giant cells are seen (Fig. 3). These resemble osteoclasts. The greater part of the section is composed of typical hyaline cartilage, which shows no signs of degeneration or of fibrillation. The nuclei stain well and the cells are arranged as in normal cartilage. They represent the free surface of the articular cartilage. There is in the deeper layers of this cartilage a definite deposit of calcium salts, but these are scattered irregularly and are for the most part grouped round cartilage capsules (Fig. 4). They do not show the normal appearance of calcified cartilage, but seem to represent calcium salts which have been set free from the layer of calcified cartilage as well as from bony fragments previously adherent to the cartilage and have then accumulated around the cells and in the matrix of the central part of the specimen where the proliferative processes are least marked. A thin layer of atypical tissue is seen on the under surface between the layer of connective tissue cells and the hyaline cartilage. This layer seems to be derived from and to replace the detached fragment of bone and the zone of calcified cartilage. Two distinct forms of cell are seen; one resembles young hyaline cartilage in the course of regeneration such as is sometimes seen in sections from joints of chronic arthritis. The young cartilage cells are of a hyaline type, but consist of closely set single cells lying in a hyaline matrix. These areas are found lying in and apparently replacing the other form of tissue, which consists of single cells fairly regularly scattered lying in a matrix somewhat hyaline in appearance when seen in sections stained with haematoxylin and picocarmine. Stained by Schmorl's method, the cells present the appearance of typical bone cells with long processes. This tissue passes over in some places into the atypical cartilage tissue just described, and in other places into the layers of cells with elongated nuclei which form a capsule on the under surface of the free body. In no part of the section, however, is the structure of normal bone observed. Some parts of the matrix in which the bone cells lie show in those sections which are

* The expenses in connexion with this study were met by a grant from the Medical Research Committee.

stained with haematoxylin distinct blue granules apparently due to a deposit of lime salts.

From the above histological examination it seems clear that a portion of the articular cartilage was detached from the condyle of the femur, and small fragments of bone remained attached to the articular cartilage at the time of separation. Definite changes have occurred in these structures; the cells have proliferated, and the matrix has undergone changes. Thus the free surface of the hyaline cartilage shows an increase in thickness of the perichondrium, while the fragments of bone adherent to the cartilage show considerable modification. On the under surface the bone cells have proliferated and rearranged themselves so that they form a definite layer of cells of a connective tissue type which blend with the layer of thickened perichondrium, and thus a continuous capsule of connective tissue has been formed around the free body. The bone cells in the deeper parts have also rearranged themselves in an atypical matrix as described. These atypical tissues seem to have been formed partly by proliferation of the bone cells and partly by proliferation of the cells of the hyaline cartilage. In areas where the proliferation is most active new atypical hyaline cartilage has been formed.

The origin of the giant cells mentioned is not clear, but they are found in areas where the connective cells are undergoing proliferation and replacing the atypical bone and cartilage cells. These giant cells have presumably been formed from the proliferating connective tissue cells, and seem to be a form of osteoclast.

Microscopic examination of the depressed area on the condyle, from which the fragment was obviously detached, shows that the free surface is covered with a layer of tissue, which appears to be formed of connective tissue cells somewhat stellate in appearance with branching processes. This layer, which is avascular, is about the same thickness as the hyaline cartilage, which it unites on both sides around the edges of the depression. These connective tissue cells form a fairly sharp zone where they join the normal articular cartilage, the cells of which at the edge of the zone show obvious signs of proliferation. The bone trabeculae upon which the tissue rests show obvious signs of previous fracture and have a very irregular arrangement; they are also somewhat increased in thickness and density. In other respects there is little change in the structure of the articular tissue in this situation.

The second specimen of free body was removed at operation from the knee-joint by Major Hume. This free body had caused repeated attacks of pain in the joint for several years. The patient made a good recovery, but the attacks of pain continued, and a few months afterwards Major Hume fully exposed the joint, and found lying towards the posterior portion of the joint cavity behind the crucial ligaments a second free body. The larger specimen (which was removed first) is lenticular in shape, 3 cm. long, 1.5 cm. broad, and 0.75 cm. in its thickest part. One surface is smooth and shining and resembles articular cartilage. The other surface is nodular and shows depressions, but is also covered with a smooth, shining tissue.

On naked-eye examination of a section through the specimen two definite types of structure are seen. There is a thin white capsule surrounding the whole specimen. The tissue beneath the surface, which is smooth and cartilaginous in appearance, extends for a depth of 0.3 cm.; it occupies about a third of the area of the section, and resembles hyaline cartilage. The rest of the tissue is yellow and more granular in appearance, but on closer examination it is found to consist of a superficial whitish-yellow portion and a deeper central zone which has a brownish-yellow colour.

The smaller specimen, which was removed at the second operation, is 1.75 cm. long, 2 cm. wide, and 0.75 cm. thick, and shows a similar external structure to the other specimen, one surface being smooth and the other nodular, but on section the larger portion of the cut surface resembles hyaline cartilage. There is a thin layer on the nodular surface which has the same yellow granular appearance as that seen in the larger specimen.

Microscopic examination of the larger specimen shows on the smooth surface, which represents the free surface of the articular cartilage, a somewhat thickened layer of perichondrium; this is continued over the edge on to the

nodular surface, where it is continuous with a tissue formed by several layers of connective tissue cells. These layers form a membrane of some thickness. The hyaline cartilage on the free surface is not much altered, though there is some evidence of proliferation of the cartilage cells, together with an irregular deposit of calcium salts, probably derived from the calcified cartilage and fragments of bone. Near the rounded edge of the specimen there is a formation of a new atypical hyaline cartilage, the cartilage cells being more numerous and the hyaline material less abundant than in normal cartilage. As in the previous specimen, an atypical tissue has replaced the bone which was adherent to the cartilage at the time of separation, and this can again be divided into two forms of tissue—one resembling atypical cartilage and the other atypical young bone. When stained by Schmorl's method well formed bone cells are seen lying in a granular matrix. In places this tissue shades off into a degenerated tissue lying in the centre of the mass, which appears to be made up partly of degenerating, but not necrotic, cartilage, and partly of a degenerate tissue which seems to result from an arrested attempt at the formation of hyaline cartilage. Towards the free surface the bone cells at the rounded edge of the specimen appear to have been transformed into the young hyaline cartilage previously mentioned, and on the under surface they blend with the cells of the connective tissue capsule previously described. Many of the cells in this layer, when stained by Schmorl's method, resemble typical bone cells.

One part of the specimen shows an interesting structure. The connective cells of the capsule, the bone cells in the atypical bone, and those of the young hyaline cartilage meet, and the impression is given that the connective tissue and young cartilage cells arise from the modified bone cells, which in their turn must have originated from the normal bone cells of the bone detached from the condyle.

In one section a small oval area is seen which consists of branching stellate cells with long processes somewhat myxomatous in appearance, resembling the cells seen in the early stages of the formation of fat (Fig. 5). This may be considered a form of avascular atypical marrow tissue.

A few giant cells are also seen in these sections; these appear to be formed from the connective tissue cells forming the capsule, and appear to be taking part in the tissue changes which are taking place at the edges of the atypical bone and cartilaginous tissue. These seem to be acting as osteoclasts.

Microscopic examination of the smaller specimen shows similar changes. The central portion of the section is composed of typical hyaline cartilage, the cells of which form groups owing to proliferative changes. On the free surface of this hyaline cartilage there is a zone of tissue which contains cells resembling atypical hyaline cartilage with single nuclei. Their structure is somewhat like the cartilage found in the ear of a mouse, but it shows more matrix. In some places a definite layer of cells is seen. These cells resemble bone cells when stained by Schmorl's method, and appear to be replacing the perichondrial layer.

The opposite surface of the specimen shows that the deeper layers of the hyaline cartilage are infiltrated with lime salts, and beneath this a layer of cells is seen resembling bone cells, which stain characteristically by Schmorl's method. In this region also there are areas of atypical cartilage tissue composed of single cells surrounded by a hyaline capsule. The free surface is covered with a distinct layer of connective tissue cells. As in the previous specimen areas of myxomatous cells are replacing the atypical cartilage and bone cells from which they seem to originate.

Groups of proliferating connective tissue cells are also seen in these sections. In some of these groups, where the cells are in contact with the atypical bone or cartilage, a few giant cells are found.

The changes seen in the two specimens above described resemble closely those seen in the first examined. In this again there is evidence that the cartilage, when it became detached, carried with it fragments of bone, and that proliferative changes have occurred after its separation both in the bone and cartilage cells. In spite of the long history there is evidence that these changes are still progressing, for otherwise it would be difficult to explain the presence of the well-formed giant cells and the young

M. J. STEWART: USE OF POLARIZED LIGHT IN DETECTION AND INVESTIGATION OF SUTURE MATERIALS EMBEDDED IN TISSUES.

In each instance Figure A represents the ordinary microscopic appearances, Figure B the same field viewed between crossed Nicol's prisms, (Drawings by Miss Ethel Wright.)

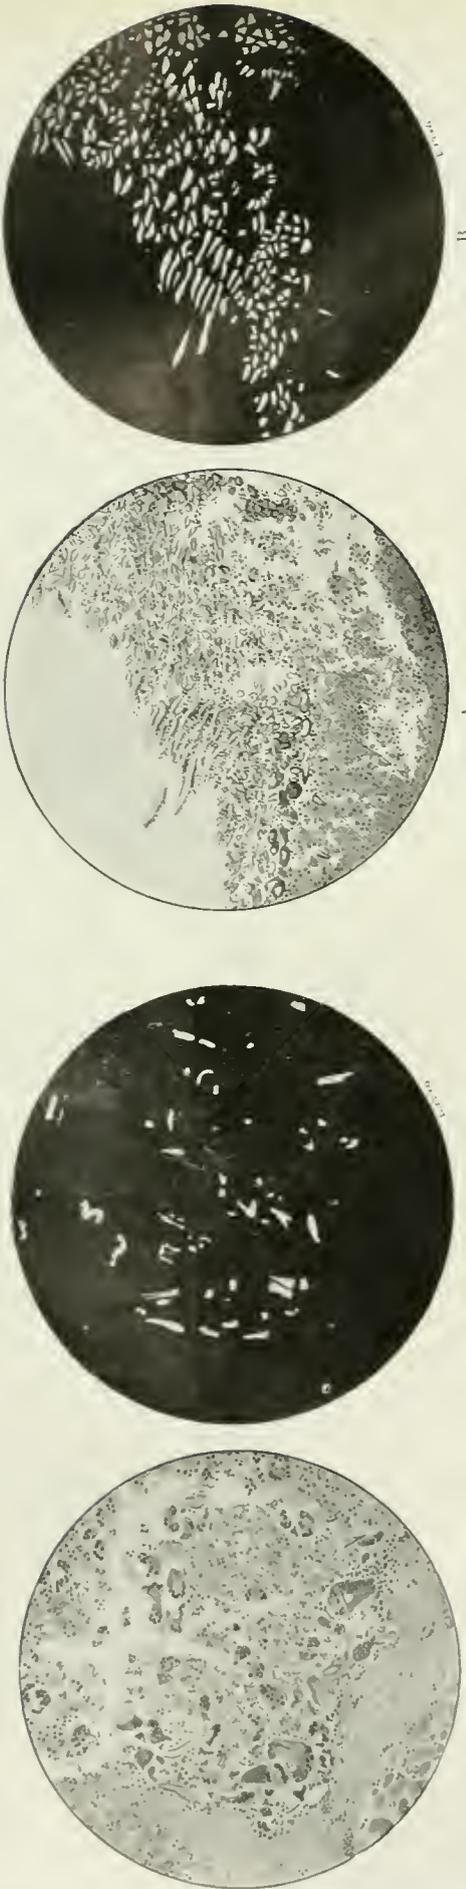

FIG. 1.—Low power. Case 2; duration six years; silkworm gut. The patient had been operated on six years before for appendicitis. The tissue containing the suture ridges was removed from the wall of a sinus which had persisted ever since. Note numerous small portions of silkworm gut, many of them ingested by foreign body giant cells. The lesion is bounded by a layer of dense fibrous tissue (seen here on two sides) separating it from the surrounding striated muscle.

FIG. 3.—Low power. Case 6; duration three years; silk. From an old case of ventrifixation. At the second operation a small painful tumour was excised from the depths of the seat. To show numerous silk fibres cut transversely or obliquely, lying in the midst of necrotic debris and pus. Some of the fibres to the left hand side of the field show the pre-absorptive changes mentioned in the text.

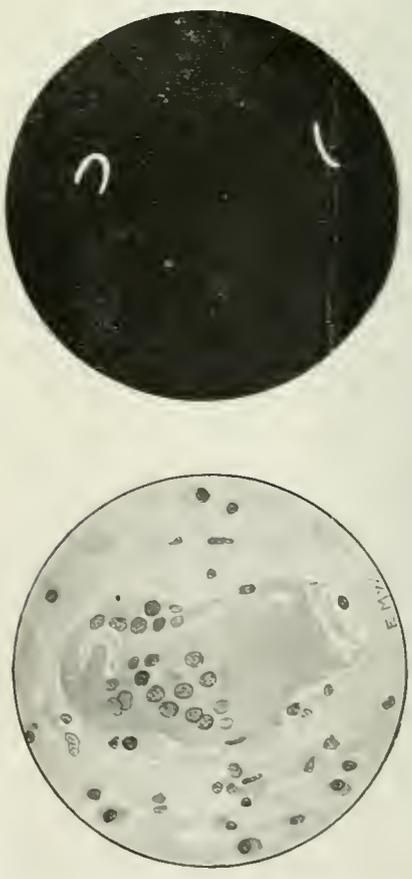

FIG. 2.—High power. Case 8; duration six years; silkworm gut. From a case of recurrent renal calculus in which a portion of the old scar was excised at the second operation. To show a large foreign body giant cell containing two small portions of silkworm gut.

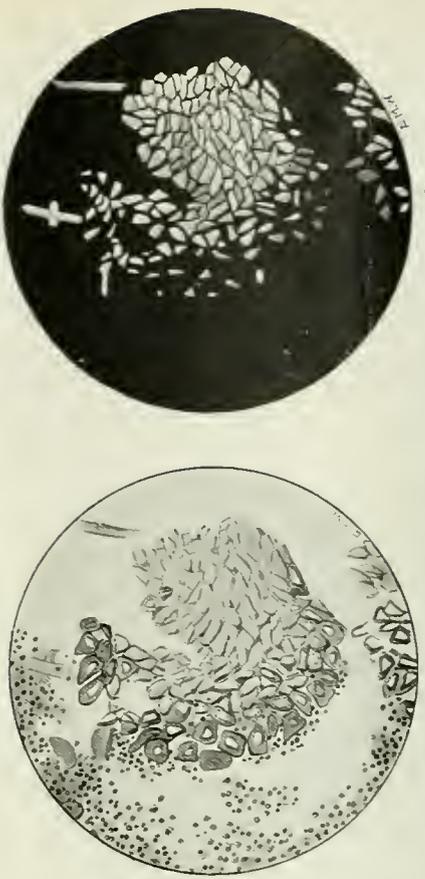

FIG. 4.—High power. Case 19; duration three months; silk. Old gastro-enterostomy case. To show pre-absorptive changes in silk fibres. The marginal portion first and ultimately the whole fibre swells up and becomes granular and strongly eosinophilic, at the same time losing its optically active cores in the left half of the field.

fibroblastic cells which are found in certain areas. The presence of stellate cells of pre-adipose tissue type is also of interest.

The fourth specimen of a free body was removed by Major Hume from the knee-joint of a patient who gave a history of recurrent attacks of pain in the joint for many years. The specimen is an irregular round flat body, 4 cm. in its largest diameter, 3.5 in the smallest, and about 0.5 cm. thick. The edges are rounded, and the surfaces are nodular and fissured but covered with a layer of shining, membranous-like tissue. On section the structure resembles modified hyaline cartilage. There can be little doubt that this specimen altered in shape and increased in size after separation.

Microscopic examination of this specimen shows changes which differ somewhat from those described in the previous specimen. No typical articular cartilage is seen. Part of the specimen is composed of a form of young hyaline cartilage mixed with which are areas of atypical fibrocartilage. In some parts of this tissue a deposit of calcium salts is found (Fig. 6). Scattered throughout the section, especially towards the surface, are groups of cells which, on staining by Schmorl's method, are found to be typical bone cells. These do not, however, show the structure of true bone when stained with haematoxylin and eosin, or with picrocarmine. In the centre of the specimen there is an area of degenerating tissue in which lies a small mass of true bone; this appears to be a portion of a fragment of the original bone showing typical bone trabeculae, with Haversian canals surrounded by their system of concentric lamellae. The fat cells of the bone marrow and the blood vessels of the marrow and bone are necrotic. The bone cells do not stain well.

In this specimen again there is evidence of proliferative change both in the cartilage and bone after separation, but this change is more advanced and the resulting structures are more atypical than in the other specimens described.

It seems fair to assume that the changes in structure found in the detached cartilage and bone of the four specimens described occurred after separation from the articular surface; even if this is not admitted, the long history of pain and inconvenience—which ceased in two of the patients after removal of the free body—is evidence that these free bodies had been present in the joint for some years. The staining properties and the appearance of the cells on section show that they were alive at the time of their removal from the joint cavity.

CONCLUSIONS.

It may thus be assumed that nutritive processes were being carried on after separation. That these processes were of an active type is shown by the proliferative changes described.

There are two possible sources from which this nutritive material might have been derived:

1. From the death of cells in the fragment. From these dead cells the surviving cells might have obtained their food supply. Nutrition of this type has been described by Burrows and Neymann⁸ as occurring during the growth of cells in isotonic salt solution. This explanation, however, cannot be accepted, as there is evidence that such fragments increase in size after separation while they are lying free in the joint cavity.

2. The other explanation is that the nutritive material is derived from the synovial fluid. If this is so, then the possibility of cartilage cells and of bone cells also being nourished by the synovial fluid must be allowed.

It follows, therefore, that the articular cartilage of the joints may derive some, if not the greater part, of its nourishment from the synovial fluid.

If this hypothesis is true, then the changes which are found in the degenerative types of arthritis can also be explained. The primary cause of these degenerative types will be found not in the cartilage or bone, but in changes in the nutritive value of the synovial fluid. There is evidence, which I hope to produce later, that changes in the nutritive value of the synovial fluid may be due to changes in the vessels of the capsule of the affected joints.

ON THE USE OF POLARIZED LIGHT IN THE DETECTION AND INVESTIGATION OF SUTURE MATERIALS EMBEDDED IN THE TISSUES.

BY

M. J. STEWART, M.B. GLAS., M.R.C.P. LOND.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LEEDS.

[With Special Plate.]

THE use of the polarizing microscope in pathology has hitherto been mainly confined to the study of the doubly refracting lipoids, "myelin," cholesterol, cholesterol esters, and the like. Such investigations have been made by Adami and Aschoff (1906,¹ 1910²), Powell White (1908,³ 1909⁴), Stewart (1915⁵), and others. Its use as a means of detecting microscopic foreign bodies (fragments and threads of clothing, particles of wood, etc.) in the depths of wounds has been pointed out by Polieard and Desplas (1917⁶). Slattock (1917⁷) has shown its value in the elucidation of a unique case of foreign body tumour formed round crystals of silica which had been forcibly intruded into the tissues of the lip eleven years before.

The present communication will show that many of the suture materials in common use by the surgeon are optically active, and that the polarizing microscope affords a ready means for their detection in the tissues as well as for their subsequent investigation. Since the optical activity of these substances is unaffected by treatment with the usual dehydrating and clearing agents, paraffin sections are all that is required for the demonstration of the phenomenon. If such a section be viewed microscopically between crossed Nicol's prisms, the particles of suture material present will, in certain instances, show up brilliantly illuminated on a dark background, and in this way they can often be picked out with great readiness, even when their presence has not previously been suspected.

It is important to notice that certain tissues are normally optically active, even in paraffin sections. Thus, the collagen-fibril bundles of dense fibrous tissue show various degrees of luminosity, at least when they are cut longitudinally or obliquely, and the same is true of the stratum corneum of squamous epithelium and of the hairs in their root follicles. The muscle bundles of striped muscle are also doubly refracting under certain conditions (? of internal strain), and even the stratum lucidum and rete Malpighii may show the phenomenon to a slight extent. In these situations it is sometimes noticeable that luminous and non-luminous segments alternate. Elastic tissue, on the other hand, would appear to be optically inactive.

THE OPTICAL ACTIVITY OF SUTURES.

The suture materials used in surgery fall into two main categories, (1) absorbable (the various kinds of catgut), and (2) unabsorbable (silk worm gut, silk, linen and "celluloid" thread, and horsehair). Kangaroo tendon occupies an intermediate position. These substances have all been examined with the polarizing microscope in the freshly prepared state, before use, and it has been found that silk worm gut, silk, linen and "celluloid" thread show intense optical activity, whereas catgut, horsehair and kangaroo tendon show the phenomenon only to a very slight degree or even not at all. This difference is accentuated by residence in the tissues. Catgut tends to lose very speedily what little optical activity it possesses, whereas that of silk and silk worm gut persists for months and years.

Before discussing the morphological appearances of the more common suture materials as seen in paraffin sections it is necessary to indicate briefly the different purposes for which they are employed.

1. Silk worm gut is now used almost exclusively for skin sutures, whose function is temporary and which are removed by the surgeon after a certain number of days.

2. Catgut is used where absorbable sutures are required, but these must be able to hold the parts in apposition

¹ Communicated to the Pathological Society of Great Britain and Ireland, January, 1920. The expenses of this research were in part defrayed by a grant from the British Medical Association, for which I beg to express my thanks.

sufficiently long to allow natural union to take place; for example, in stitching the deeper layers of the anterior abdominal wall after laparotomy.

3. Silk, linen, and "celluloid" thread are used under two conditions, in both of which it is necessary that the mechanical action should be exerted over a considerable period of time, namely, (a) where the suture will ultimately cut out spontaneously and escape from a free surface, as in closing off the duodenum after partial gastrectomy, and (b) where it will probably remain permanently in the tissues, as in arterio-venous anastomotic operations and in ventrifixation.

MATERIAL STUDIED.

The material on which this study is based consists of twenty-six specimens containing suture relics. Most of them are from portions of tissue which had been excised during life by the surgeon; a few were obtained *post mortem*. Eighteen specimens were found to contain silkworm gut, five catgut, and six silk. The age of the various specimens, that is, the length of time the sutures had been in the tissues, varied between wide limits. The silkworm gut periods varied from three weeks to six years, the catgut from four days to five months, and the silk from three weeks to three years.

1. *Catgut*.—This is met with in the form of irregular masses, homogeneous or very slightly fibrillated, and occasionally broken up into a few irregular pieces, never into definite discrete fibres. If the stitch has become infected it will be found embedded in pus, otherwise it is shut off by a fibrous wall which is lined internally by cellular tissue containing many endothelial cells and foreign body giant cells. None of the latter show small portions of suture material in their cytoplasm such as occurs in the case of silkworm gut. The catgut takes the acid dye, and it may or may not show a slight degree of luminosity when viewed between crossed Nicol's prisms. The rate of absorption varies greatly in different cases, and is accelerated by the presence of sepsis.

2. *Silkworm Gut*.—This is the common variety of suture relic met with in connexion with old operation scars, and the one which provokes the most characteristic and striking foreign body giant-cell reaction. The appearances in these cases suggest that small fragments of the gut become detached and remain behind in the track of the suture when the latter is removed.* They are seen as small highly refractile bodies of various shapes and sizes, often acicular or rod shaped, sometimes unstained, sometimes taking the basic dye, and always showing intense optical activity when viewed with polarized light (Figs. 1A and 1B). The smaller particles are frequently contained within the cytoplasm of giant cells (Figs. 2A and 2B); the larger have usually a number of giant cells in close relation to them. They tend to occur in small foci, with many giant cells, endothelial cells, fibroblasts, and lymphocytes, the whole often surrounded by a wall of dense fibrous tissue. In this way they may lie locked up in the tissues for years. I have never been able to convince myself that there is much evidence that foreign body giant cells absorb these silkworm gut relics. They seem rather to protect the tissues by simply enveloping or rounding off the corners of mechanically irritating particles. In some of the cases the particles of silkworm gut are both few in number and minute in size, and might readily escape detection if looked for in the ordinary way. The use of the polarizing microscope may then greatly facilitate the search for such relics or confirm their presence (Figs. 2A and 2B).

3. *Silk*.—Silk and linen thread (including Pagenstecher's celluloid thread) are somewhat similar morphologically, and all show intense optical activity. They can be distinguished by the fact that linen fibres possess transverse cracks or striae, whereas silk fibres do not. The specimens which I have examined—six in number—all contain silk sutures. They are composed of fibres, usually tightly packed, which are triangular or polygonal in transverse section, and which, when they are cut obliquely or lie longitudinally, have often a prismatic as well as a doubly

refracting action on polarized light (Figs. 3A and 3B). In haemalum and eosin sections the fibres remain unstained except for a narrow rim at the margin, which stains a purplish hue. The whole fibre is stained bright yellow by picric acid, as in van Gieson's stain. In two of the six cases examined the suture is embedded in pus, doubtless as a result of bacterial infection; in two it is surrounded by a zone of fibroblasts, endothelial cells, and foreign body giant cells, and in one it is simply encased round with dense fibrous tissue. In the two purulent cases, the marginal fibres of the suture, which are becoming separated from one another by pus cells, show a very definite and peculiar morphological change, associated with loss of optical activity (Figs. 4A and 4B). The change affects first the peripheral part of the fibre, which becomes swollen, granular, and intensely eosinophilic. The outline changes from triangular or polygonal to spheroidal, and there is a definite increase in size. The central zone, at first unaffected and still optically active, steadily diminishes in size until finally the whole fibre becomes changed in the manner indicated, and optical activity entirely disappears. It would appear to be a preliminary process to absorption, since such fibres may sometimes be seen in course of disintegration, and it is clearly related to the presence of pus, being perhaps due to a digestive action on the part of the leucocytic enzymes.

Apart from this physico-chemical change in silk, it is very striking how both silkworm gut and silk retain for long periods the property of optical activity when embedded in the tissues. In some of the cases which I have examined the suture materials have persisted in an optically active form for three years (silk) and six years (silkworm gut), the latter even after it has been broken up into tiny fragments and ingested by foreign body giant cells.

FALLACIES.

1. The only serious source of fallacy is the presence of small, air-borne particles of cotton-wool and the like on the surface of the section, since many of these—for example, cotton-wool itself—are optically active. It is usually easy to differentiate. Suture fibres are obviously embedded in the substance of the tissue; extraneous materials lie in a plane above (or below) that of the section, and are seen to be overlapping the cellular structure of the part. Sutures tend to be focally distributed more or less in relation to scar or granulation tissue, possibly with giant cells in their immediate neighbourhood; air-borne fluff may be found on any part of the slide.

2. As already mentioned, very dense fibrous tissue, striped muscle, and the stratum corneum of squamous epithelium, all possess slight optical activity, but the degree of luminosity is so slight and the anatomical arrangements are so obvious that no difficulty should arise.

SUMMARY.

1. Sutures or ligatures of silkworm gut, silk and linen thread—that is, all the ordinary suture materials except catgut—are intensely optically active, and the polarizing microscope affords a ready means of determining their presence in tissue sections.

2. These various materials may retain their optical activity in the tissues for years, and in the case of silkworm gut even after the fibres have been broken down into tiny pieces and ingested by foreign body giant cells.

3. Catgut is much less optically active than the other substances named, and the property tends to be speedily lost in the tissues. For this material, therefore, the method may be inapplicable.

4. Ordinary paraffin sections are all that is required for the demonstration of the phenomenon.

Addendum.—Since this paper was written Dr. J. G. Greenfield has very kindly lent me the histological preparations relating to the experimental investigation of nerve suture materials carried out by him in conjunction with Mr. Percy Sargent.⁴ The experiments were made on the great sciatic nerve of rabbits, and extended over periods of from twenty-one to eighty-one days. Suture relics were visible microscopically in 13 cases, and in these the materials used were catgut of various kinds (6 cases), silk (3 cases), linen thread (3 cases), and Japanese silkworm gut (one case). The last three show very intense optical activity in every instance. Catgut is variable: some specimens are optically quite inactive;

* I am informed that this is quite in keeping with clinically observed fact—namely, that silkworm gut sutures are often rough and eroded at the time of removal. Sutures which have been repeatedly sterilized by boiling are much more liable to undergo this change, and are, indeed, sometimes frayed when inserted.

¹ Some were in fact so missed and only discovered when the sections were re-examined with polarized light.

most show fairly definite luminosity with crossed Nicol's prisms, at least in parts—even a specimen which had been eighty-one days in the tissues.

I beg to express my great indebtedness to Professor J. H. Teacher and Dr. J. G. Greenfield for the loan of valuable material, and to Mr. E. R. Flint for useful criticism and suggestions.

A Clinical Lecture
ON
GALL STONES.

DELIVERED AT GUY'S HOSPITAL

BY

R. P. ROWLANDS, M.S., F.R.C.S.,

SURGEON TO THE HOSPITAL.

I PROPOSE to make some general remarks upon gall stones and to illustrate my lecture by three interesting cases.

Nearly all gall stones form in the gall bladder, and are due to:

- (a) Infection of the gall bladder.
- (b) Over-concentration of the bile.

(a) The infection may occur through the blood stream, through the lymphatics, or ascend along the ducts from the duodenum. The researches of Rosenow indicate that infection by the blood stream is by far the most important, and cultivations obtained from infected human gall bladders often produce similar lesions in animals. It is very probable also that infection spreads to the gall bladder along the lymphatics from diseases of neighbouring organs, as, for instance, the appendix, duodenum, and stomach. The most common organisms to be found are the streptococcus, *B. typhosus* and *B. coli*. These have been cultivated from the centres of gall stones, from the bile, and from the wall of the gall bladder. It is well known that infection of the gall bladder often occurs in enterica and that gall stones frequently follow it.

(b) That concentration of the bile, leading to the deposition of mucus and crystals, is an important factor is clear, for nearly four-fifths of the patients suffering from gall stones are women who have had children, and in them symptoms often date from the time of pregnancy, when the bile is very concentrated. Stasis of the bile in the gall bladder is an important additional factor, therefore in a pendulous weak gall bladder, or in one the duct of which is kinked or obstructed in any way, gall stones are likely to form.

The cystic duct is very narrow and tortuous and its mucous membrane is raised into valvular folds, so that it is very difficult for any but very small stones to pass through it (Fig. 1). Moreover, it is much narrower than any part of the common bile duct, except the termination of the latter at the duodenal papilla, therefore the large majority of sufferers from gall stones never develop jaundice.

It is also important to remember that the part of the common bile duct traversing the pancreas is not as easily distended as the first part of the duct; hence it often happens that the common bile duct is shaped like a funnel, and stones become impacted in the upper part of the pancreatic portion of the duct. The duodenal papilla is very narrow, and minute stones which will pass freely through the other parts of the ducts become arrested here. A stone smaller than a pea may thus lead to death; when it is impacted at this point it dams up both the bile and the pancreatic juice.

SYMPTOMS.

1. *Stones in the gall bladder* may cause (a) recurrent attacks of pain in the right hypochondrium associated with vomiting and local tenderness. These attacks are often mistaken for gastritis. It may be possible to feel the gall bladder during the colic, or on deep inspiration there may be "a catch" or pain in the gall-bladder region, and local tenderness on palpation. Or (b) a dull aching pain in the right hypochondrium and right shoulder, with a distaste for food and flatulent dyspepsia. It may not be possible to feel any swelling unless the cystic duct be obstructed or cholecystitis with local peritonitis develop. There is no jaundice unless the common duct also is obstructed.

2. *A stone in the cystic duct* may cause colic at intervals, with a swelling having the characteristics of a distended gall bladder. Usually this is in the right hypochondrium, but it may reach the right iliac fossa. Jaundice is absent unless the stone is junctional and presses upon or otherwise obstructs the common or hepatic duct. The stone usually falls back and the colic abates after a few hours, but it may remain impacted and cause inflammation with suppuration, or even sloughing of the gall bladder. Grey patches appear at the fundus of the gall bladder or below the stone in the duct. Perforation may take place and local or general peritonitis ensue, or adhesion to the duodenum, colon, or stomach may take place, with the formation of a fistula. It is still a common error to believe that gall stones are unlikely without a history of jaundice, but it should be remembered that as the cystic duct is narrower than the common duct, except at the papilla, more stones get impacted in the cystic duct than elsewhere, and that jaundice is really an exceptional and late sign of gall stones. This error has condemned many patients to years of unnecessary suffering, a diagnosis of gastritis or hysteria being commonly made.

3. *A stone in the common bile duct* usually causes colic and jaundice sooner or later, and fever due to an ascending infective cholangitis is sometimes present during the attack of jaundice. Sometimes stones impacted in the common duct do not cause colic but only nausea. There is often tenderness on deep palpation over the common duct above and to the right of the umbilicus. Small stones in a dilated common bile duct, although they may cause frequent colic, may not obstruct long enough to produce jaundice. It is imperative, therefore, to examine the common duct carefully at the operation in every case, even when there is no history of jaundice. The gall bladder is usually contracted, shrunken, and matted

down by adhesions in these late cases, so that no gall bladder swelling is evident. In fact, if the gall bladder can be felt in a jaundiced patient, the obstruction is probably due to other causes, such as growth of the head of the pancreas or chronic pancreatitis.

DIAGNOSIS.

- (i) *Stones in the Gall Bladder.*

The diagnosis of gall stones in the gall bladder when there is no history of definite biliary colic may be very difficult, for the symptoms may closely resemble those of

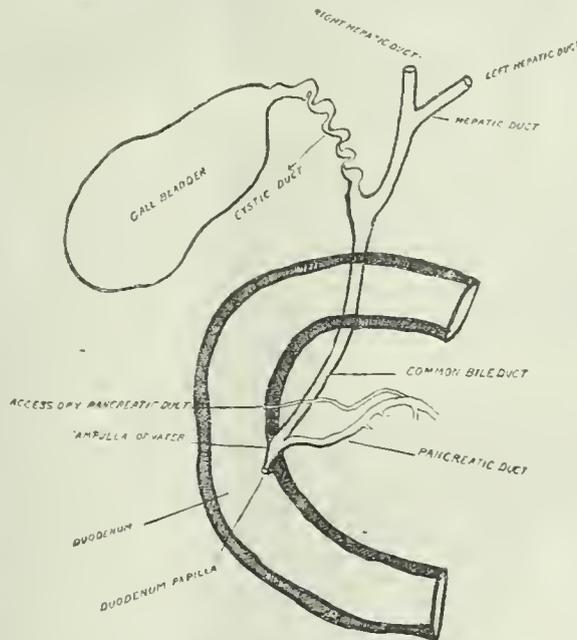

FIG. 1.—Anatomy of the biliary apparatus.

gastric or especially duodenal ulcer or chronic appendicitis. Gall stones may give rise to reflex disturbances in the stomach and duodenum, altering the secretion and the movements of the stomach, and thus adding to the difficulties. The absence of hyperacidity on repeated examination is against peptic ulcers and in favour of gall stones. The researches now going on at Guy's by the analysis of the gastric juices every quarter of an hour may throw some additional light on this subject. The repeated presence of even minute quantities of blood in the vomit, gastric juice, or faeces is much in favour of peptic ulcer and against gall stones. I have, however, seen profuse melæna due to the erosion of the cystic artery by a gall stone impacted at the neck of the gall bladder. I have also known the same sign to be due to ulceration of the gall bladder and the formation of a fistula into the bowel. Anaemia and wasting are more commonly associated with peptic ulcers than with gall stones.

The time relationship of the pain to food is not so constant and striking with gall stones as with duodenal ulcer. Marked local tenderness on palpation below the ninth right costal cartilage on deep inspiration is much in favour of gall stones. Radiography may help by giving evidence of pyloric or duodenal obstruction or distortion of the shadow due to gastric or duodenal ulcer. It is unfortunate, however, that it does not often show gall stones; even with the greatest care in the examination and a good apparatus, only large gall stones or large collections of small stones are shown by the *x* rays. This fact is rather important, as many people are led to believe that they have no gall stones if the *x* rays do not show any. It is sometimes practically impossible to distinguish cholecystitis due to gall stones from chronic appendicitis, especially when the appendix is unusually high and near the gall bladder. If one is fortunate enough to see the patient in an acute attack the difficulties are less, for a local fixed swelling may be palpable over the appendix or the enlarged gall bladder may be felt moving on respiration.

(b) Biliary Colic without Jaundice.

This has to be distinguished from other colics, especially right renal colic. Here the distribution of the pain is of the greatest importance, renal colic shooting from the loin along the course of the ureter and causing pain and retraction of the testicle with urinary symptoms, and biliary colic being confined to the front and upper part of the abdomen and associated with local tenderness in the right hypochondrium. Pancreatic colic due to stones impacted in the pancreatic duct is very rare; the pain is mesial and lower down. Intestinal colic is a far more common source of error, but it is rarely so very violent as biliary colic. I have several times been temporarily misled by colic due to obstruction by a growth at the hepatic flexure, but on watching the abdomen carefully peristalsis may be noticed in the distended caecum and ascending colon. Appendical colic is rarely so severe and the pain is lower, generally referred to the navel. There is marked local tenderness over the appendix during the attack.

(c) Biliary Colic with Jaundice.

Jaundice due to gall stones has to be distinguished from that due to other causes, such as cirrhosis, or growth, or hydatid cysts of the liver, or obstruction of the main bile ducts by growth in their walls or pressing upon them from the head of the pancreas or lymphatic glands. To these conditions chronic pancreatitis and catarrhal jaundice must be added. The absence of severe pain is against gall stones and in favour of catarrhal jaundice or chronic pancreatitis. Jaundice due to cancer may cause severe pain, but rarely so acute and abrupt a colic as that due to gall stones. Moreover, the jaundice is gradual in its onset, progressive and severe, and not sudden, remittent or intermittent and moderate as it generally is with gall stones. Long continued and black jaundice is very rarely due to gall stones. The age, sex, and especially the general condition of the patient, assist in the diagnosis, for with pancreatitis, and especially with malignant disease, the patient looks more ill and wastes more rapidly than with gall stones.

Small hydatid cysts may become impacted in the common bile duct, and give rise to jaundice and colic simulating that due to gall stones. Under these conditions the absence of a palpable stone in the common bile duct at the

operation may be very disconcerting; but on examining the liver carefully the parent hydatid cyst may be felt. In a case of this kind I enucleated the cyst from the upper surface of the liver five years ago, and the man is quite well now.

With secondary cancer of the liver there is usually some indication of the primary growth, and definite local swellings may be felt in the liver; but with primary cancer of the liver jaundice may appear early. In one case I found a diffused primary endothelioma of the liver. Hypertrophic cirrhosis of the liver may also mislead, for the patient often denies the essential history. The peculiar congestion of the face, and the marked wasting associated with the enlargement of the liver, may help.

INDICATIONS FOR OPERATION.

For obstruction of the cystic duct or neck of the gall bladder with distension of the gall bladder which is unrelieved within forty-eight hours, it is imperative to operate in order to avoid suppuration and its complications, such as sloughing of the gall bladder, localized or even general peritonitis, pyelophlebitis, and pulmonary complications, and such late complications as intestinal obstruction secondary to perforation of the gall bladder into the duodenum or colon. In the former case the stone is generally impacted in the lower part of the ileum. In the latter case it generally gets impacted in the narrow part of the pelvic colon. This complication is generally very grave, because it is not often recognized in time for a hopeful operation.

It is of the greatest importance to realize that jaundice which is neither slight nor transient, and is therefore not catarrhal, calls for early exploration and treatment. In this way only can such dangerous complications as infective cholangitis and post-operative haemorrhage be avoided with certainty. Sometimes it is advisable to wait for a few days when there is fever due to an exacerbation of existing cholangitis, for it is safer to operate in a quiet period.

When gall stones in the gall bladder give rise to symptoms, such as repeated attacks of colic or localized pain with flatulent dyspepsia, it is wise to advise operation unless there are grave contraindications to the anaesthetic. It is wise to do this in order to avoid the complications already mentioned, and also carcinoma of the gall bladder, which is apt to follow the chronic irritation of gall stones and to involve the liver early and to become irremovable by the time it is recognized.

OPERATION.

In operating it is of the greatest importance to obtain the best possible access to the bile apparatus, for the operation, although sometimes easy, may be one of the most difficult in surgery. After trying many incisions, I have come to the conclusion that that of Kocher is the best (Fig. 2).

I have used this almost exclusively now for some years because it gives such a wonderfully good view, and also because it is so rarely followed by hernia, even after drainage. The incision begins above and to the left of the tip of the ensiform cartilage, and runs downwards and outwards nearly parallel to the costal margin and an inch below it across all the fibres of the rectus muscle. Occasionally it is necessary to prolong it into some of the fibres of the oblique muscles. It is not necessary to divide any intercostal nerves and thus weaken the abdominal wall. The muscular fibres join well. I make no apology for describing this incision, for several writers on operative surgery figure and describe it as being placed much further out where it would not give anything like as good access. In addition to this, the fatty coverings, which are often abundant, are divided for one or two inches more than the deep part of the wound, and a lumbar cushion is invaluable to bring the biliary apparatus prominently forward into the wound. If necessary, the falciform ligament also can be divided without detriment. In every case the operation should begin as an exploration of the whole abdomen, special attention being paid to the stomach, pancreas, and

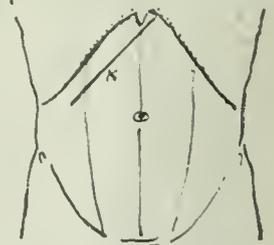

FIG. 2.—Kocher's incision. K. All the fibres of the right rectus but no nerves are divided, although the incision may be prolonged across the linea alba and outwards into some of the external oblique muscle.

appendix. Then the whole bile apparatus, including the liver, are carefully examined before any operation is decided upon. When the stones are limited to the gall bladder and cystic duct I always remove the gall bladder if the condition of the patient and the mobility of the parts allow it to be done without undue risk.

I believe that under these conditions cholecystectomy is not only more radical in that it removes the source of gall stones but also that it is safer, there being less risk of infecting the wound. In this way the considerable risk of recurrence of gall stones or the occasional occurrence of a biliary or mucous fistula and the danger of cancer of the gall bladder are avoided. The need and duration of drainage are lessened, a firmer wound is obtained, as well as a more comfortable and rapid recovery. It would, of course, be foolish to adopt cholecystectomy in old, feeble, or jaundiced patients, or when adhesions clearly add to the risk of the operation. A stone impacted in the cystic duct may be extremely difficult to remove by backing it into the gall bladder, and its impaction in the duct for some time may be followed by stricture with mucous fistula or mucocele. It is generally much easier and safer to remove the whole gall bladder and duct without opening them. Recurrence of symptoms is much rarer after cholecystectomy than after cholecystostomy.

Stones in the Common Bile Duct.

Whenever possible stones in the common bile duct should be removed through an incision in the anterior wall of the first part of the duct well above the duodenum. When a stone is impacted in the lower reaches of the duct it may be very difficult to press it back into the first part. It is much easier to do this before the bile is allowed to escape; therefore the stone should always be pushed back before the duct or gall bladder is opened. The incision is made well above the duodenum in order to avoid a branch of the hepatic artery which often runs down to the upper border of the duodenum, and in every case the left index finger is passed into the foramen of Winslow, and the stone is held up and fixed before an incision is made into the duct. When the stone cannot be dislodged from the lower part of the common bile duct it may be removed by displacing the second part of the duodenum forward and incising the duct as it runs through or grooves the pancreas. To allow this to be done the posterior peritoneum has to be incised vertically a little to the right of the duodenum. It is also of the greatest assistance to pass a blunt-pointed probe downwards from the first part of the duct. This serves to tilt the duct to the right and forward into the wound. When a stone is firmly impacted at or near the papilla and cannot be dislodged, the trans-duodenal route has to be adopted and the mucous membrane covering the stone incised, either at or above the papilla, and the stone thus removed. The wound in the anterior wall of the duodenum is closed with the greatest care, and sealed over by displacing and fixing some of the omentum over it. Without this care the trans-duodenal route does undoubtedly add considerably to the risk of the patient. In all cases the common bile duct must be proved to be clear by the insertion of the finger whenever possible, or by the passage of a blunt-pointed probe down the duct into the duodenum. The probe should also be passed up into the hepatic ducts, for a stone may have become displaced upwards into one of them. Whenever I have to open the common bile duct for stone, I drain it by inserting and fixing a small tube in it. I believe this is much safer than sewing up the duct and placing a tube near the incision. In one of my cases in which I did not fix a tube in the duct, bile escaped into the lesser sac, distended it enormously, and had to be evacuated ten days later. The patient had been very collapsed when the sac became over-distended, and she was then thought to be suffering from acute cardiac failure. She made a good recovery after the second operation. In another instance, which I published in the *Guy's Hospital Reports* (vol. lxvi, p. 219), a large clot formed in the sutured common bile duct, and gave rise to colic and collapse. At the second operation the healed duct was incised, the clot evacuated, and the patient made a rapid recovery.

MORTALITY.

The mortality of operations for gall stones has greatly diminished in recent years owing to improvements in technique.

D

Cholecystectomy and Cholecystostomy.—For the three years 1913–15 inclusive the Mayos¹ had a mortality of 1.2 per cent. in 1,767 cholecystectomies and 3.4 per cent. in 435 cholecystostomies. From 1907–15 inclusive they had a mortality of 1.3 per cent. in 2,493 cholecystectomies and of 1.5 per cent. in 2,854 cholecystostomies. It is very interesting that during the last three years of the period given the mortality of cholecystectomy should have been reduced below that of cholecystostomy. This is doubtless due chiefly to the fact that with increasing experience the Mayos have become more radical, doing cholecystectomy as an operation of choice and reserving cholecystostomy for the graver cases unsuitable for cholecystectomy.

Choledochotomy.—The mortality of simple choledochotomy in the absence of serious symptoms of infection or jaundice of long duration is about 2.5 per cent., but when infection of the bile ducts has occurred with remittent fever and deep jaundice and infective cholangitis has occurred, the mortality is about 15 per cent. The operation should, whenever possible, be done before the onset of this grave condition, or, failing this, it should, if possible, be performed during a remission of the fever and jaundice.

Duodeno-choledochotomy has a mortality of about 8 per cent. It is done for the removal of stones impacted at or near the ampulla of Vater, is often deferred until too late, and is in itself a severer operation, apt to be followed by duodenal fistula. Whenever possible the stone should be backed into the first part of the duct, whence its removal is much safer.

CASE I.—*Stone Impacted at Duodenal Papilla: Cholecystectomy; Pancreatic Growth: Biliary Fistula: Cholecystectomy: Choledochotomy: Recovery.*

The patient, a man aged 67, kindly wrote the following account of his symptoms:

Family History.

"Father never ill until age of 65, when he had a severe illness, at first thought malignant, but was no doubt due to gall bladder. He was not jaundiced. I, a student at the time, examined faeces for gall stones, but found none. He completely recovered for seven years, and then after a long walk died of haemorrhage from the stomach in twelve hours. I was then abroad. Father's brother, a healthy man, was treated for gall stones at the age of 45. Recovered and died at 74. Mother died at 85.

Personal History.

"Born 1852, never robust, but seldom laid up. Had typhoid badly in Argentina at the age of 20 and malaria badly in Persian Gulf at age of 24. Came home and malaria disappeared. Always lived a moderate life.

History of Present Illness.

"About five and a half years ago, after about twenty-four hours' dull pain in the back, I became slightly jaundiced, which lasted a few days. I had about two similar attacks in four years up to March, 1918. During this night (March 21st, 1918) I awoke at 1.30 with a strong rigor lasting twenty minutes. No pain; resembled malaria but without subsequent sweating. The day before this I had felt some malaria and discomfort in the back. Slightly jaundiced next day, which went off in four days' time. Day after attack motored twenty-one miles and sat on Recruiting Board. Got home very weak in afternoon. Went again next day, but could scarcely eat my lunch. Kept on the same for five days, but then awoke in the night with severe rigor and high temperature (104° or 105°). Stayed in bed three days, and symptoms, including jaundice, gradually subsided, but felt very weak. For some months before this attack was conscious of tenderness over gall bladder, which was always improved by doses of castor oil, even before bowels responded. Weight (stripped) after attack, 8 st.; about three or four years before, about 10 st. Went into a nursing home July, 1918. Had a rigor the first night there and about every six days; was operated on after about three weeks and three small gall stones removed. I noticed that the first two motions after operation contained bile, but no bile in the subsequent motions. Came home about a month after the operation. Nearly all bile came, through sinus in wound, and I was slow in picking up strength. Had three or four loose motions every day, with ravenous appetite for the six months until the second operation. There was occasionally a streak of darker colour in the almost uniformly pale motions."

Second Operation.

I saw the patient for the first time in January, 1919. At the first operation the pancreas had been hard, and malignant disease was feared, but the patient's general condition improved, and he put on some weight during the next six months, but his biliary fistula became very irksome. When I saw him all the bile escaped at the biliary fistula, and the patient was still thin and in a bad state of nutrition. He was willing to undertake any risk in order to get rid of the fistula.

The lips of the fistula were separated and clamped to avoid spilling of bile infecting the wound, and also to maintain the

pressure inside the ducts. Kocher's incision was adopted; a vertical incision had been used at the first operation. The gall bladder was very large, the common bile duct was distended, no stone could be felt at first, but later, on feeling the third part of the duodenum, a large stone was felt evidently at the end of a very much elongated bile duct or pedunculated papilla. With some difficulty the pedunculated part of the duct was steadied with one hand while the stone was squeezed back into the duct with the other. In this way the need of opening the duodenum was avoided, and the stone then extracted from the first part of the common duct. In order to avoid recurrence, the ducts having been proved to be clear, the gall bladder was removed, and the common bile duct drained. The stone was the size of a filbert. The patient wrote on March 1st, 1920, stating that:

"Since my second operation there has been no looseness of bowels, and the appetite became very moderate. The motions are always uniformly stained dark-brown with bile. Unless the gall bladder has some beneficial secretion of its own—I have only heard of mucus—I think we should be better without it."

CASE II.—Cholecystostomy; Cholecystectomy; Choledochotomy.

Mrs. J., aged 52 years, was a patient of Dr. Talford Jones. After suffering some twenty years from symptoms of gall stones with intermittent attacks of jaundice and colic, she had been operated upon by a woman surgeon in March, 1916. Cholecystostomy was then performed and several stones removed from the gall bladder. The attacks continued. The second operation was performed in January, 1917, by the same surgeon, who then removed the gall bladder. The attacks continued. The patient had a slight attack of jaundice while she was still in the hospital. On several occasions she has been deeply jaundiced, and has suffered very severe colic. She has been very reluctant to consider another operation, but she found life intolerable, and at last consented to see me. A vertical incision had been adopted at the former operation.

She was admitted into Guy's Hospital in November, 1919. Kocher's incision. Six stones removed from the common bile duct, the stones serving as excellent guides to the dilated common bile duct, although the gall bladder had been previously removed. The patient made a good recovery, and has remained well since. It is probable that a larger and more suitable incision would have enabled the surgeon to find and remove the stones from the common bile-duct at the first or second operation.

CASE III.—Gall Stone in Neck of Gall Bladder; Cholecystectomy.

Mrs. A., aged 45, patient of Dr. Phillips, Croydon. She had had three children, and is a very active woman who eats very little owing to indigestion. She has never had a bilious attack, but often has slight attacks of diarrhoea. On the evening of November 7th, 1915, she ate a piece of urripe pear. At 1 a.m. on November 8th she was seized with violent abdominal pain, and did not sleep again. She got up and went into another room and lay on a bed there, but could not sleep. She was sick a good many times. She then went downstairs and lay before the gas fire, as she was so very cold and in much pain. She did not bring up anything but watery fluid, and later bile. Dr. Phillips saw her in the early morning, and thought she had intestinal colic due to the pear. The pulse and temperature were subnormal and she was cold. As she was very tender in the epigastrium, he wondered whether she had a perforated gastric ulcer, and got Dr. Male to see her. Dr. Male found that the tenderness and pain were then lower down towards the appendix, and he suggested an operation for (?) acute appendicitis. I saw her at 4 p.m. on November 8th, and felt two swellings, which Dr. Male and Dr. Phillips had also felt, in the right flank. Dr. Phillips thought that they might be scybala or a piece of pear, and found that they were movable. After getting the abdomen thoroughly relaxed, I was able to make out that the swelling was of the same size, shape, and attachments as the gall bladder, but it was lying very far back and a little lower down and farther out than usual. As I felt it the patient was seized with nausea and vomiting, and the consistency of the swelling seemed to vary. Once it seemed to consist of one lump, and another time of two. At the operation this was explained, for I clearly felt the fundus and at times also the bend of the neck of the gall bladder. I diagnosed gall stones impacted in the cystic duct, and advised an immediate operation, as the patient was so ill and would probably get worse. After some delay she was moved to a nursing home.

Operation.

Dr. Male gave the anaesthetic (November 8th, 1915). The gall bladder having been more definitely made out under the anaesthetic, a Kocher incision was made. The gall bladder was found. It was considerably enlarged, uniform in shape, and very oedematous. There was also some bloody fluid in the kidney pouch. A stone was felt impacted in the neck of the gall bladder. This was backed a good deal, but in view of the absence of stones in the common bile duct and the pendulous nature of the gall bladder, it was clearly safer to remove the latter, and this was done in the usual way, the raw area on the under surface of the liver being covered over with peritoneal flaps sewn with catgut. The abdominal wall was closed as usual, but a small tube was left at the inner and upper angle of the wound. She made a good, rapid, and complete recovery, and is now well, four and a half years later.

AIR-WAY INFECTIONS.

BY

T. H. C. BENIANS, F.R.C.S.ENG.,

PATHOLOGIST TO THE PRINCE OF WALES'S GENERAL HOSPITAL,
TOTTENHAM, N.

It is probable that in considering the mode of infection of the trachea and bronchial tubes sufficient attention is not paid to the normal protective mechanisms of these regions. At present methods of prophylaxis are directed mainly towards an internal immunity designed to lessen the severity of an infection when once it has taken place. It seems not improbable that an attempt to turn the natural mechanisms of prevention to account might be worth considering with the intention of actually preventing infection from occurring.

The respiratory passages from the anterior nares to the infundibula are so constructed by their plications and subdivisions and by their moist and sticky surface to take up the particles of dirt and bacterial organisms that may enter in the inspired air. Such foreign matter as may get right through into the alveoli is carried away into the body by the lymphatic system; but for dealing with that which settles in the air-ways—and this is the enormous bulk—we have, in all except the very smallest tubes, two essential mechanisms: they are the mucous secretion and the ciliary action of the mucous membrane.

The value of the mechanical self-cleansing process due to the sweeping action of the cilia is self-evident. Whilst the cilia are acting effectively any bacterial organisms deposited on the surface will be swept along and not allowed time to affect the underlying cells, for a stationary state would be necessary before invasion of the epithelium could occur. The sweeping-up function culminates in cough and expectoration of the offending matter.

As regards the protective functions of the mucoid matter lining the mucosa of the air tubes, apart from its capacity for maintaining an even supply of moisture so essential for ciliary action, there is experimental evidence that this type of substance protects the tissues in various parts of the body against the action of ferments. For instance, in the alimentary tract, Bayliss,¹ quoting Klug, states that it is the mucin which protects the alimentary canal from the action of its own digestive juices; this it apparently does by adsorbing the excess of enzymes. Now it is probable that the damage to the wall of the air passages that may follow the implantation on it of pathogenic organisms is in part effected by ferment action, the ferments being derived from the infecting organisms, either from their living or dead bodies. Apart from a direct breach in the epithelial wall from ferment action, there is also the probability of the absorption of toxic bodies if these lie directly on the epithelial surface. With the exception quoted below, I do not know of any experimental evidence on this latter point, although the same probabilities exist as in the case of ferment action, but it can be shown by staining experiments that large molecular bodies do not easily pass through a layer of mucilage. It follows that the action of bacterial ferments and toxins on the epithelial cells is likely to be inhibited by a free supply of mucus.

In the various examples of the "carrier" state we find the body protected from the action of pathogenic organisms, not by a true immunity of the internal type—for these patients are often not immune and may suffer reinfection—but apparently by the mucous environment of the bacteria. In these "carrier" conditions, if we except urinary tract infections, which are not properly to be considered in this class, we find the bacteria bedded in a mass of mucus: The typhoid bacillus in the gall bladder, the dysentery bacillus in the mucous crypts of the large bowel, the gonococcus in the prostate, the meningococcus in the nasopharynx, and the diphtheria bacillus in the mucopurulent discharge of chronic rhinitis. All these instances suggest that the body obtains protection from bacterial invasion in this manner.

I have shown elsewhere,² using bacteria embedded in mucilage of tragacanth, that the animal organism could be protected against the highly toxic Shiga's bacillus. The organism remained alive in the body for months, leading neither to the production of toxic symptoms nor to the production in the host of antibodies directed against the infecting bacillus.

This point of view of course is not new, but it seems probable that more might be done, both prophylactically and therapeutically, if closer attention were paid to the normal mechanisms of body protection.

LOEWI'S ADRENALIN MYDRIASIS AS A SIGN OF PANCREATIC INSUFFICIENCY.

BY

W. L. COCKCROFT, M.R.C.S., L.R.C.P.,
LATE ACTING MAJOR R.A.M.C.(T.F.)

SERVICE in the army has hitherto prevented me from publishing these notes, which were made in 1914. The cases, which were under the care of Dr. Murray in the Manchester Royal Infirmary, were, clinically, almost identical.

CASE I.

A man, aged 63, was admitted on October 26th, 1914, complaining of jaundice and intense pruritus all over the body. He stated that he had had dyspepsia for several years, had been a heavy beer and whisky drinker, and was very constipated. He first noticed jaundice and pruritus five weeks previous to admission, and for some months his stools had been gradually becoming lighter in colour. He had had no pain whatever over the liver or gall bladder.

Condition on Examination.

The skin, mucous membranes, and sclerotics were all extremely yellow. Emaciation was not marked until later, but the patient said that he had become weaker. The abdomen was distended and there was some ascites. No peristalsis was visible and no distended superficial veins were seen. The right lower border of the liver could be felt 3½ in. below the costal margin. The gall bladder was distended, tense, and tender; it extended down to the level of the umbilicus. The patient vomited once or twice soon after admission. The stools were soft, unformed, almost pure white in colour. The urine showed bile present, no albumin, no sugar, reaction neutral, specific gravity 1008.

After-History.

On November 2nd, 1914, two drops of adrenalin chloride solution (1 in 1,000) were dropped into one eye. After one hour there was no reaction, the pupils remaining exactly equal. The reaction was again negative on November 6th and on November 9th. The patient had free hæmorrhage from the bowels and died on November 10th.

Post-mortem Examination.

The jaundice was found to be due to carcinoma of the bile ducts with secondary growths in the liver. Suppurative cholangitis was also present. The gall bladder was greatly distended with serous fluid, but it contained no gall stones. The pancreas was nowhere invaded by the new growth, nor were there any secondary deposits in it, the gland itself being quite healthy.

CASE II.

A man, aged 42, was readmitted to the infirmary about October 1st, 1914, complaining of jaundice. He had had "dyspepsia" during September and October, 1913, and influenza during the early part of that year. At Easter, 1914, he first noticed jaundice, accompanied by severe pruritus. His stools had been clay-coloured for some time. He was admitted on May 26th, 1914, refused operation, and was discharged June 23rd, 1914, "condition unchanged."

Condition on Examination.

The skin, mucous membranes, and sclerotics were very deeply pigmented with bile; he was worn and emaciated, the pruritus was much less than formerly, but there was great tenderness over the gall bladder and attacks of pain round the region of the umbilicus. The gall bladder was distended, and could be felt 3 to 4 inches below the right costal margin. The liver was not enlarged. There was a history of several attacks of epistaxis. No ascites was present, and no distended superficial veins were visible.

After-History.

On October 10th, 1914, two drops of adrenalin chloride solution (1 in 1,000) were dropped into one eye. After one hour there was marked dilatation of the pupil of that eye. On October 28th, and also on November 1st, the test was repeated, with marked positive reaction (dilatation of pupil) on each occasion.

A few days before his death exaggerated peristalsis of the walls of the stomach became visible through the abdominal wall. At the same time, owing to the progressive emaciation, a hard mass became palpable in the region of the head of the pancreas. The stools were clay-coloured; the urine

mahogany-coloured, neutral, specific gravity 1009; bile was present, but no albumin nor sugar. X-ray examination on June 16th, 1914, and also later, had shown no gall stones nor other evidence of disease of the gall bladder. The patient began to vomit everything he took by mouth, became very depressed and stuporous, and died on November 4th.

Post-mortem Examination.

There was found to be malignant disease of the head of the pancreas, which invaded the duodenum and common bile duct. There were metastases in the liver, and obstruction and dilatation of the common bile duct and bile passages. The growth in the pancreas caused stenosis of the duodenum, with secondary dilatation and hypertrophy of the stomach and upper part of the duodenum.

It will be noted that in Case I, in which the pancreas was completely free from disease and quite efficient, Loewi's reaction was completely negative on three separate occasions, whereas in Case II, in which the pancreas was almost completely disorganized, the reaction was markedly positive, also on three separate occasions.

VAGASTHENIA.

BY

JAMES A. W. WATTS, M.B., B.S. DURH.,
MAJOR R.A.M.C.(R.)

ALL medical practitioners who, as officers or civilians, have been occupied with troops during the war, and those who are still engaged in treating returned soldiers or as members of Pensions Medical Boards, have been, and still are, constantly confronted with the letters D.A.H. My observation leads me to believe that the ideas held as to the meaning of these letters are not very distinct or informative. Broadly and literally, they indicate a condition of increased frequency, slowing or irregularity of the heart beat, or a combination of any two of these. Since these alterations of rhythm occur in many pathological and physiological states, which may depend on disordered function arising outside the heart itself or in the intrinsic structure of that organ, it seems to me that it is desirable to find a phraseology which will not only be less cumbersome but which will bear also some relation to the particular condition that is met with. It is a reflection on the medical profession that its members should so readily follow the Army fashion—neither dignified nor scientific—of labelling things by initial letters. The letters P.U.O., however useful a purpose they may have served until the discovery of a definite disease, which we now know as trench fever, are gradually falling into disuse, and I suggest that their brothers, D.A.H. and V.D.H., should accompany them into the war museum, not again to emerge.

Clinical Characters.

Although the term "D.A.H." may be applied to any of the conditions enumerated above, it is used in the vast majority of cases to signify a symptom group which has been described for many years past as irritable heart or soldier's heart, and it would have been as well to retain these names until we could decide upon a more scientific one. Notwithstanding the divergent views as to the cause of this malady, it has come to be recognized as a definite clinical entity, presenting a well defined and easily determined syndrome, marked by increased frequency of the heart's action, early exhaustion, shortness of breath, dizziness, and frequently precordial pain; less often there is precordial hyperæsthesia. These symptoms are common to all cases of myocardial exhaustion, and it is necessary that we should be able to exclude all forms of structural heart disease before arriving at a definite diagnosis. Murmurs may be and often are present to increase the difficulty of deciding. What are the points, then, which will help us? First and foremost, in my opinion, is the absence of cardiac enlargement; secondly, the rhythm, although much increased in rate, is always regular; the inception of a new rhythm, such as auricular flutter, auricular fibrillation, or extra systoles, never occurs. Murmurs are always systolic in time and soft in character, and are variable—that is to say, they are not always present and alter with the position of the patient, sometimes being audible when he is standing, at others when

he is recumbent. In making this somewhat dogmatic statement I would exclude cases due to rheumatism, for it is probable that these really belong to the class of structural disease, either the endocardium or myocardium being affected. In these cases the inception of a new rhythm is frequently met with, as also some cardiac enlargement.

The Origin of the Disorder.

Many circumstances have been assigned as the cause of the condition; foremost amongst them is the presence in the blood of the toxins of acute infections, especially influenza, but shock, the absence of basic salts in the blood, and other causes have also been suggested. Reflection on the characteristic features of this disorder leads us to believe that it is not due to any affection of the heart itself, interfering with its power of generating stimuli within itself, its faculty of conducting them or its power of contraction, but to something which affects its nervous control. In affections of the myocardium or the conducting paths in the heart we always find some increase in size of the organ, and the inception sooner or later of a new rhythm such as auricular fibrillation, followed eventually by "back pressure symptoms"; these features, in my experience, never occur in cases of irritable heart.

If, then, we conclude that the condition is due to interference with the nervous control of the heart, it must be due either to weakness of vagus action or over-stimulation of the sympathetic. Every medical officer who has served during the war has had cases in which the history could leave no possible doubt that the tachycardia was noticed for the first time after some severe shock, such as a shell explosion in close proximity to the patient, who, before it, was perfectly well. It is the same condition as that which supervenes on fright or shock in all stages of life, more especially in children. It has always been supposed that this latter condition is due to suppression of vagus control, and it is reasonable to suppose that the condition of irritable heart in soldiers is due to the same complex, which, instead of being temporary, persists.

If this view is accepted, I suggest that a more accurately applicable and more scientific name for this symptom-group would be "vagasthenia." A condition of vagotonia in which we get hyperactivity of the vagus mechanism has been described, more especially by Continental writers; why should we not use a name which describes an affection in which an opposite set of factors is at work?

Treatment.

The recognition of this malady as a neurosis gives us an important guide to its treatment. It may be that the methods of the psycho-therapist may meet with the same good results which have attended them in the other forms of neurosis. So far the only method of treatment giving good results has been the employment of graduated exercises, and I believe that these results are due to suggestion, or rather persuasion, as practised by the psycho-therapist, rather than to the effect of exercises on the heart muscle itself. Is it not irrational on any other ground to increase the work of the heart muscle, which is already doing a double amount of work in contracting constantly at almost double its normal rate? May we not hope that a further stage of this treatment—namely, psycho-analysis—may reveal some forgotten shock or emergency in early life which is at the bottom of the trouble, as in so many cases of neurosis which exhibit paralyses, phobias, etc.? My experience in the early stages of the war, when men joined voluntarily and so had not the terror of conscription before them, was that very great numbers suffered from irritable heart from the beginning of their training. Probably they had had it for years previously; it was only when they were called upon for the extra effort entailed in training that they found themselves unfit—that is to say, training did not cause but revealed it.

It is because I feel that ideas generally concerning D.A.H. are so confused, and that the retention of the name D.A.H. tends to perpetuate that confusion, that I put forward the suggested name vagasthenia, in the hope that it may elicit an expression of views from others better qualified than myself to speak on the subject.

ACUTE SUFFOCATIVE CATARRH.

BY

J. A. SMYTH, M.B.,

MELTON MOWBRAY.

HAVING read the reports of cases of this condition in recent numbers of the BRITISH MEDICAL JOURNAL, I think it may be useful to publish summaries of similar cases which I have attended since 1914.*

Case 1 occurred in a male of 63, who suffers from Bright's disease, and whose blood pressure is 200 mm. Hg.

He partook of a heavy meal at 6 p.m., and shortly after stood for ten minutes in a cold wind. Having gone in he felt distressed; he was almost immediately seized with urgent dyspnoea, and began to cough up copious brownish frothy expectoration, which flowed from the nose and mouth. His complexion was dusky. He was relieved in ten minutes by hypodermic injection of morphine and atropine and by amyl nitrite inhalations.

Case 2 was that of a woman of 82, suffering from mitral regurgitation.

In November, 1915 two hours after taking a heavy supper, she awoke with intense dyspnoea, rattling in chest, feeble rapid irregular pulse, intense pallor and sweating, and constant cough without expectoration. Râles were audible in the upper part of the chest. She was relieved by injection of morphine and atropine, and digitalin given by the mouth; the chest was clear next day. On February 24th, 1916, a similar attack occurred, and was relieved as before. The patient died in 1917.

Cases 3 and 4 occurred in patients of about 65, who were hearty eaters.

In both there was a sudden attack of dyspnoea with cough and rattling in the chest, but no expectoration; râles were audible, chiefly over the upper portions of the lungs. Relief was obtained by injections of strychnine and by inhalation of amyl nitrite. *Case 4* died seven months afterwards of heart failure with dropsy.

In *Case 5* the patient had suffered from angina pectoris for five years.

From January, 1917, to 1919, his anginal attacks were frequently accompanied by rattling in the chest and oedema of the lungs, with constant dry cough; râles were limited to the upper part of the chest. The attacks usually lasted about an hour, and were relieved by chloral and nitroglycerin, together with amyl nitrite inhalations. He died early this year after an attack of pericarditis.

Case 6, a male of 69, had suffered from bronchitis.

Two hours after retiring he woke suddenly and exhibited cyanosis, dyspnoea, and copious secretion of a brownish-red frothy fluid, which filled the nose and mouth. He was relieved by strychnine and amyl nitrite, and remained fairly well until his sudden death a month afterwards.

Case 7, a man of 54, suffered from aortic regurgitation.

Urgent dyspnoea, with cyanosis, constant cough, and expectoration of a small amount of stained frothy fluid, appeared suddenly at 5 a.m., and were relieved in half an hour by amyl nitrite, nitroglycerin, and brandy. Five hours afterwards the chest, in which continuous "rattlings" had been audible, was clear. He had many subsequent attacks of dyspnoea, in none of which was pulmonary oedema detected. He died five months afterwards (heart failure accelerated by pulmonary embolism).

I have also met with two similar cases in consultation. In both of them the blood pressure was greatly raised; one was relieved by venesection.

In many of the milder cases of this condition the oedema was noted to be limited to the upper part of the chest, and not the basal region, as one would have expected if heart failure were the sole cause. The combination of the three factors—high blood pressure, cold winds, and indiscretions in diet—appears in some cases to act as an exciting cause. If one includes under the heading of "acute suffocative catarrh" the milder forms of this pulmonary oedema the condition is not uncommon.

* The clinical notes have been condensed.

ACCORDING to the official directory for 1920, Luxembourg possesses 129 doctors, 24 dentists, 40 chemists owning a shop and 54 without a shop, 2 druggists, 42 veterinary surgeons, and 199 midwives. At the frontier 19 doctors, 4 veterinary surgeons, and 25 midwives of Luxembourg nationality are allowed to practise in France, and 7 doctors and 25 midwives resident in France have similar permission to practise in adjacent Belgian territory.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ENCEPHALITIS LETHARGICA.

The following case, diagnosed as encephalitis lethargica, is of interest partly because of the bacteriological findings and partly on account of the treatment by sodium salicylate given intravenously in fairly large doses.

Abstract of Clinical Notes.

The patient, an adult Indian follower, was admitted without notes or history to a stationary hospital on January 17th, 1920. His pulse was 96, his temperature was 100.4°; the respirations were 26. His general condition was stuporose; he lay still, with expressionless face and closed eyes.

The ocular conjunctiva was congested; no strabismus was present; the pupils were medium sized and equal, contracting to light. There was a considerable degree of general muscular tension and irritability, the arms and legs being flexed. Rigidity of the neck and Kernig's sign were absent. Subsequent records are given below.

Fourth day: Slight improvement. Can be roused, when for a time he is intelligent and talkative, but suddenly reverts to lethargy. Photophobia; knee-jerks increased, Babinski's sign absent.

Sixth day: Not so well, cannot be roused. Constant muscle twitchings, general, but best seen in pectorals and hand and finger muscles. Bouts of hiccough. Extreme myoedema. General rigidity increased; sphincters not under control. Blood examination: 9,000 leucocytes per cubic millimetre, no malarial parasites. Sod. salicyl. gr. 3 in 20 c.cm. saline given intravenously; gr. 10 t.d.s. by the mouth.

Seventh day: Patient pulseless, pituitrin given in two injections.

Seventh to seventeenth day: The stupor persisted in varying intensity. Ptosis of the eyelids, lagophthalmos, slight external strabismus on the right and deviation of the tongue to the left were noticed, and attacks of muscular twitching continued to occur; between them the position of tetany was sometimes noticed. Complaint was made of pain in the eyes, mouth, and throat, and of failing vision. Cultures were made from a nasopharyngeal swab; influenza bacilli were found, together with a few pneumococci. The cerebro-spinal fluid, clear and not showing increased tension, contained a few lymphocytes but no organisms. The injections of sod. salicylate (gr. 13 to gr. 4) were repeated on the seventh, eleventh, and fifteenth days.

On the seventh day a blood culture was made on broth; the report showed the presence of Gram-negative bacilli a little larger than *B. influenzae*, inclined to lie in pairs. A second culture, made on the fifteenth day, contained no organism; possibly the first finding was due to contamination.

Seventeenth day: There was very noticeable improvement; he was less stuporose, and sat up; the rigidity began to disappear, and the ptosis and strabismus to diminish. His appetite returned.

On the thirty-fourth day he was almost well, except for incessant loquacity. The temperature had never risen above 100.4°.

It is noteworthy that in December, 1919, another patient in this hospital who was convalescent after what seemed a typical attack of influenza and had had a normal temperature for nine days, suddenly complained of inability to open his eyes. In the course of a few days this became worse, and gradually there set in a train of symptoms similar to the above. One intravenous injection of sod. salicyl. (gr. iij in 20 c.cm. saline) was given, and some slight improvement followed. Unfortunately this patient passed out of observation soon afterwards. I have since heard that he made a good recovery.

It has been generally noticed here that many patients convalescing after an attack of influenza have complained of heaviness in their eyelids, and have shown a great tendency to drowsiness.

I have to thank Captain Adler, R.A.M.C. (S.R.), who did the bacteriological work, and Colonel Kennedy, R.A.M.C., who verified the findings; also Colonel Mackelvie, I.M.S., for permission to publish these notes.

A. SMITH GOUDIE, M.B., Ch.B. Glasg.,
Captain R.A.M.C. (S.R.),
61st Indian Stationary Hospital, Baghdad.

GONORRHOEAL VULVO-VAGINITIS IN A NEWBORN INFANT.

An infant, 14 days old, was brought to me for examination. The history was of a vaginal discharge beginning a few days after birth, very slight in amount, but increasing steadily and becoming more purulent. There was no evidence of the child having dysuria or being in any way upset by the local condition. She was otherwise healthy, but inflammation of the vulva was seen, and after the

child's straining a little on micturition a rush of green pus from the vagina occurred. A film from the vagina was taken at once, and the pathological report was: "Pus and numerous gonococci present."

The child was born in a Poor Law institution, and details of labour, chart, etc., were easily procured. The mother's genital tract had appeared normal before, during, and after labour. Delivery was easy, though the presentation was breech. The mother's recovery was uneventful, not the slightest pyrexia appearing on the chart. She herself looked normal locally, but gonococci were found in films from the cervix.

The infant's infection was undoubtedly contracted during labour, and the interesting points are:

1. The infection of the child's presenting part.
2. Total absence of ophthalmia.
3. Child's general good condition and lack of malaise, though the local infection was severe.

There was no possibility of infection having taken place after birth, as the case was still in the maternity wards, where the child's toilet was wholly performed by pupil midwives.

In charge Female V.D. Clinics, Royal Free Hospital
and Blackfriars Skin Hospital.
London, W.

Reports of Societies.

OPHTHALMOLOGICAL TEACHING.

THE annual congress of the Ophthalmological Society of the United Kingdom was held at the house of the Royal Society of Medicine on April 29th. The President, Mr. J. B. STOKY, P.R.C.S.I., took as the subject of his presidential address the teaching and examination of medical students in ophthalmology. He said:

The Council of British Ophthalmologists have already urged the General Medical Council to adopt two reforms—first, to make three months' attendance at an ophthalmic clinic obligatory and secondly, to have an examination by ophthalmic surgeons as part of the final pass examination. The General Medical Council accepted the first and rejected the second, a most astonishing thing to those who know well that medical students have no time to waste on subjects that are not necessary and in which examination is not compulsory. There are two reasons why a certain knowledge of ophthalmology is necessary for every person permitted to practise—(1) because the vast majority of practitioners cannot escape from having to diagnose and treat diseases of and injuries to the eyes when no specialist can be obtained, and (2) because in many serious diseases the evidence afforded by ocular conditions is most important, and often the ocular symptoms are those which induce the sufferer to seek medical advice. For instance, interstitial keratitis may be the first evidence of infantile syphilis, even before the eruption of the teeth described by Jonathan Hutchinson; and acquired syphilis may show itself in the choroid, iris, or retina long after the patient has forgotten the primary disease completely. Ocular tuberculosis may be the first visible manifestation of that disease, and the ocular signs are important in tabes, disseminated sclerosis, meningitis, and other intracranial lesions, diabetes, nephritis, arterio-sclerosis, to mention only a few serious and not uncommon affections. In many of these the ocular signs may be mainly naked-eye appearances or fairly easily observed ophthalmoscopic lesions. The final decision of the General Medical Council is said to be that the hospitals should, or may, refuse certificates to students who do not acquire sufficient knowledge—thus shuffling off the responsibility thrown on it by Act of Parliament and placing it, not on the licensing bodies over whom it has control, but on the medical staffs of hospitals. It has been objected that if an examination in ophthalmology is instituted at the Final, it will overload the curriculum, and that other special branches of surgery will claim a similar privilege. As regards the first objection, the special clinical examination has been the rule in every one of the Irish licensing bodies for some thirty years, and has not caused overloading. As regards the second, it has been already pointed out how great is the importance of ocular signs and symptoms in serious constitutional diseases, an importance much greater than can be assigned to any of the other organs usually taken up as specialties. Ophthalmic surgeons are not narrow-minded, and would certainly urge that every medical man should be able to

recognize anomalies of ear, nose, and throat which can be seen with such simple instruments as the common head mirror and aural speculum.

The President, in conclusion, insisted upon the necessity of a practical clinical examination, because, in his experience of thirty years as an examiner, he had found students whose book knowledge was perfect unable to diagnose quite simple ocular anomalies in the patients before them. The General Medical Council, he said, should be urged by the Society to consider its recommendation and institute the following reforms: (1) That each candidate for a licence to practise should be compelled to attend an ophthalmic clinic for a period of three months; (2) that the final examination should include as a separate pass subject a clinical examination by ophthalmic specialists. If the Ophthalmological Society were unsuccessful he hoped the general practitioners throughout Great Britain would take the matter up.

TREATMENT OF ANTE-PARTUM HAEMORRHAGE.

A CONJOINT meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine with the North of England and Midland Obstetrical and Gynaecological Societies was held in London on May 6th. In the morning a discussion on "The treatment of ante-partum haemorrhage" was introduced by Dr. HASTINGS TWEEDY, of Dublin, and in the afternoon Dr. EARDLEY HOLLAND read a paper on "Rupture of Caesarean section scar in subsequent pregnancy or labour." The chair was occupied in the morning by Mr. J. E. GEMMELL, of the North of England Society, and in the afternoon by Mr. CHRISTOPHER MARTIN, of the Midland Society.

Dr. HASTINGS TWEEDY said that it was an error to consider all ante-partum haemorrhages, other than those arising from placenta praevia, as accidental, yet this was a mistake commonly made by nurses and students. It was of great importance to determine the amount of loss which brought the condition within the category of accidental haemorrhage. At present various standards were used in the compilation of different statistics, and the comparison of results, therefore, was rendered difficult. In the Rotunda Hospital at Dublin the term was now not used unless the bleeding was sufficient to necessitate the presence of an assistant master, who was not summoned unless his presence was required in the interest of the patient; many insignificant bleedings thus escaped being recorded. During the speaker's entire mastership he reported but 49 cases of accidental and 45 of unavoidable haemorrhage in 13,524 deliveries, and in the extern maternity 47 haemorrhage cases in 15,543 deliveries. Sir William Smyly, in his first hospital report, adopting a different standard, recorded 44 cases in 3,600 deliveries, most of the cases being of little consequence. Amongst his own 49 patients who had accidental haemorrhage, Dr. Hastings Tweedy said that 22 were in serious danger, and were treated by the vaginal plug. He lost two of his hospital patients, the deaths probably arising from intraperitoneal haemorrhage, and seven of the extern maternity patients died, in five of whom the plug had been employed. In 1915 he returned to the Rotunda, and, in conjunction with Sir William Smyly and Dr. Purefoy, carried on the work of the institution for three years, when 23 cases of accidental haemorrhage were encountered. They were then in possession of the knowledge that accidental haemorrhage might arise as a result of pregnancy toxæmia, and this permitted them to perform Caesarean section when the double complication existed in a severe form. Altogether, his hospital experience comprised 72 cases of accidental haemorrhage in over 18,000 deliveries, with only two deaths; 30 of these cases were plugged. Berkeley and Bonney had expressed a doubt whether plugging could have any directly useful effect in concealed accidental haemorrhage, with the accompanying uterine inertia. A plug applied in the manner recommended by these authors, said Dr. Tweedy, would not compress the vessels, for they applied the plug with the aid of a speculum and a forceps, and used for this purpose rolls of cotton, each tied round with a string to facilitate removal. Dr. Tweedy strongly maintained that com-

pression was accomplished with the plug which he applied, and that he had demonstrated this principle during the performance of several Caesarean sections.

To plug efficiently the left hand should be passed into the vagina, the tips of the fingers lying behind the cervix. Small pieces of cotton-wool, squeezed out with lysol solution, and each the size of the thumb knuckle, were then taken and inserted by means of the right hand around the cervix. The fingers of the left hand were kept busy squeezing the pellets into a compact mass and forcing the spaces between them to permit the insertion of still another plug. This process was continued in a systematic manner from above downwards until the vulva was reached and the vagina could hold no more. A T-bandage was applied to keep the plug in position and an abdominal binder was fastened tightly from above downwards to press the side walls of the uterus against the vaginal dam, and this completed the operation. To what extent intraperitoneal haemorrhage could be controlled by a vaginal plug was still a matter of doubt. In the vicinity of the internal os the control was complete; on the other hand, it would fail entirely to stop a leakage from the ovarian artery. The latter supplied a relatively small amount of blood to the placenta, chiefly flowing to its upper portion where detachment was rare. When the main supply was cut off the loss on blood pressure promoted coagulation in the sinus.

Dr. Tweedy added that hysterectomy had no place in the treatment of accidental haemorrhage, and finally it might be stated that rupture of the membrane did not contraindicate plugging the vagina.

The CHAIRMAN (Mr. Gemmell) said that he had only carried out this method of treatment in one case some years ago, and the procedure was eminently successful. The old surgical axiom, "Put your finger on the bleeding spot," should be remembered; to put the finger on the bleeding spot in accidental and unavoidable haemorrhage was difficult, but there were means towards that end. In severe cases of accidental haemorrhage where blood clot remained behind the placenta a certain amount of inertia of the uterus always resulted, and played an important part in allowing the haemorrhage to go on. To plug the vagina successfully it was necessary to have hands accustomed to vaginal work; it could hardly be expected of the ordinary practitioner.

Dr. FLETCHER SHAW congratulated Dr. Tweedy upon the results of the Dublin method. It was an extremely good treatment for accidental haemorrhage, but in Manchester they adopted another method—rupturing the membranes, putting on a tight binder, and probably giving ergot, and he thought the results quite as good by this method as by the other. It must be remembered that in a large maternity hospital, while, of course, the treatment of the patients had primarily to be considered, the teaching of students had to be considered too. These men and women were going into practice, where they would get occasional cases of accidental haemorrhage, probably occurring in the very worst possible surroundings. There was nothing more alarming to the practitioner than to have haemorrhage. It seemed so essential that it must be stopped; every other consideration went by the board, and the treatment which had been taught to that practitioner in his student days presented itself naturally as the method to be carried out. The practitioner found a case of accidental haemorrhage; possibly he had not had a case for years, and was not prepared with sterilized material. If he had been taught to pack he used what he had at hand. Those who worked in maternity hospitals received cases in which the sepsis was appalling, the result of unfortunate packing. He had seen strips torn from bed sheets and just dipped in some antiseptic solution; one case was packed with a dish-cloth. With packing in this careless manner a large number of septic cases were bound to arise. He himself, however, did not use packing, and did not teach students to use it; the other method was quite as efficacious, and could be carried out without anything like the same amount of risk. There were but few cases in which haemorrhage could not be stopped by either of these methods. In 1916 he described six cases requiring abdominal section and hysterectomy, but he had not had a single case since. In the case of unavoidable haemorrhage, Caesarean section was used nowadays very much more frequently than formerly; there were undoubtedly a number of cases in which it ought to be used for placenta praevia and other conditions. If the patient had a fair amount of haemorrhage and the child was alive, and there was not much dilatation of the cervix, Caesarean section was the treatment to be generally adopted.

Dr. HERBERT WILLIAMSON gave some statistics gathered from the maternity ward of St. Bartholomew's Hospital.

The ward was opened in February, 1911. Between that date and the end of July, 1919, 2,600 patients were admitted. Among these were 98 cases of ante-partum haemorrhage; these figures were of no value in determining frequency, because the great majority were sent in on account of the bleeding, and but for the haemorrhage would have been delivered elsewhere. Fifty of these cases were accidental haemorrhage and 48 placenta praevia. Of the mothers with accidental haemorrhage, 47 recovered and 3 died, and of the children 27 were born alive and 23 dead. Of the cases of unavoidable haemorrhage 12 were central, 27 lateral, and 9 marginal placenta praevia. Of these mothers 45 recovered and 3 died, and of the children 16 were born alive and 32 were stillborn. Amongst the accidental haemorrhage cases 17 were suffering from albuminuria, and amongst the placenta praevia cases 3. Local infection in the puerperium was manifested in 12 per cent. of the accidental haemorrhage cases and in 25 per cent. of the placenta praevia. Of the whole 98 cases 37 were delivered without interference, the procedure being rest in bed, injections of morphine, etc.; these patients, of course, remaining under exceptionally favourable circumstances. This same treatment, with ruptured membranes in addition, was carried out in 8 cases; bipolar inversion and bringing down a leg in 11 cases; manual dilatation of cervix and forceps delivery in 3 cases; Champetier de Ribes's bag in 18 cases; Caesarean section in 3 cases; and plugging of vagina and application of abdominal binder in 18 cases, of which 11 were cases of accidental haemorrhage and 7 were cases of placenta praevia. The cases selected for plugging were those in which uterine contractions were not present and the cervix was not sufficiently dilated for bipolar version or the introduction of the Champetier de Ribes bag. Plugging was done under an anaesthetic, and instead of using little pledgets as Dr. Tweedy did, narrow strips of gauze were employed. The result of the plugging was that in 8 cases—of which 3 were placenta praevia, 2 external accidental haemorrhage, 1 concealed accidental haemorrhage, and 2 mixed accidental haemorrhage—the bleeding was arrested, labour pains excited, and no further treatment required; in 3—1 of placenta praevia, and 1 of external and 1 of mixed accidental haemorrhage—the bleeding was arrested but no labour pains were excited; in 3—2 of placenta praevia and 1 of external haemorrhage—the bleeding was arrested for a time but recurred after an interval; in 4—2 of placenta praevia, 1 of concealed and 1 of mixed accidental haemorrhage—the haemorrhage was not arrested and the treatment was abandoned in favour of other methods. Amongst these 18 cases there were 2 deaths, but he did not believe the lives of these women could have been saved had any other line of treatment been adopted. Of the children, 13 were stillborn, 4 were born alive, and in 1 case the patient died undelivered.

He regarded the plugging of the vagina as a valuable method. By its application the bleeding would be arrested in the majority of cases. It was by no means infallible, however, and those who employed it must be prepared to meet with disappointments. He now taught that, excluding cases of concealed haemorrhage of the toxæmic variety (which, in his opinion, should be treated by Caesarean section), where uterine contractions were not present and there was no dilatation of the cervix, if simple measures had failed to arrest the bleeding plugging should be employed. Where the cervix was sufficiently dilated to admit two fingers it was better either to practise bipolar version or to introduce the Champetier de Ribes bag. Dr. Williamson added that the method of blood transfusion in severe ante-partum and post-partum haemorrhage was important, and suggested that those working in hospital maternity departments should have their blood tested to determine their suitability as emergency donors.

Dr. BLAIR BELL believed that plugging was valuable, but he could not agree as to the action attributed to it by Dr. Tweedy. The speaker was positive that with fairly high blood pressure it was a physical impossibility to compress the artery, and many believed that even if they were to tie the uterine arteries in these cases it would not stop the haemorrhage. It was unfortunate that there was no animal on which the experiment could be made except the pregnant chimpanzee; and the ape did not breed in this country, so that the experiment would have to take place in Africa. He suggested another explanation: When a woman was in labour the mere introduction of the fingers into the vagina would stimulate a uterine contraction; in the same way it was possible that contraction was stimulated by plugging. He believed that the plug as used by Dr. Tweedy combined with the binder above would compress the fundus uteri, apart from causing strong uterine contraction. In severe accidental haemorrhage pituitary extract in not too big a dose seemed worthy of trial. In placenta praevia he believed that Caesarean section was the only satisfactory treatment.

Dr. HERBERT SPENCER insisted that many cases of

so-called accidental haemorrhage were of very slight significance indeed. Those who had not a large experience might think it necessary to do Caesarean section in large numbers of accidental haemorrhage cases, but he believed that Caesarean section was rarely required for accidental haemorrhage or for placenta praevia. By tradition and practice he was not quite in favour of Dr. Tweedy's method of vaginal plugging, but in Dr. Tweedy's hands there was no doubt it had had good results. He felt with Dr. Shaw, however, that there was a certain danger in teaching students to do the plugging. Long ago in the maternity ward he saw more than 100 cases of ante-partum haemorrhage in six years, but very few were really grave cases of accidental haemorrhage or needed any treatment beyond ordinary mild measures. It was a very grave thing indeed to do hysterectomy for an accidental haemorrhage, though there might be occasions when this was required. In a very large experience of placenta praevia the only cases in which he thought Caesarean section was indicated were those in which the child was alive, a large quantity of blood had been lost, the os was not dilated, and the placenta was central.

Dr. W. E. FOTHERGILL was perfectly sure that most obstetricians, if they had seen what he personally had seen, would not teach students to pack at all for any condition of obstetric haemorrhage. The constant occurrence of sepsis after packing was quite enough to restrain him from saying anything about packing to students. The tragedies he had seen through the packing done by practitioners outside, before the cases came into the hospital, had impressed him very greatly, and he believed the practice would gradually die out of use; he considered it obsolescent, if not already obsolete. What they taught midwives to do was very much more important than what they did themselves, and he suggested certain respects in which the examination of the midwife was not as satisfactorily conducted as it might be.

Dr. GORDON FITZGERALD, referring to the obvious division of schools with regard to the proper treatment of accidental haemorrhage, thought there was too marked a tendency to stamp this or that school as the champion of this or that line of treatment without any reference to the different behaviour of the uterus at the time when the haemorrhage occurred. If the uterus was contracting—that is, if the patient was in labour—when the haemorrhage occurred, he did not think they were on contentious ground at all; those were the cases which might be classed as slight, and the uterus would do all that was necessary apart from plugging or similar treatment. As for concealed accidental haemorrhage, there were very few obstetricians who had seen a large enough number of true cases to have gained any reliable basis of opinion as to a proper course of treatment. The extirpation of the uterus might be necessary and justifiable. In all cases of concealed accidental haemorrhage he would do Caesarean section, and if the retraction of the uterus was not satisfactory he would go on to extirpation. The extreme rarity of the condition, however, made it out of the question to be dogmatic.

Dr. T. W. EDEN said that he had seen few cases of ante-partum haemorrhage. It was very important that the methods of treating accidental haemorrhage which students were told to adopt in practice should be taught to those students in hospital. The thing that mattered from the general point of view was, as Dr. Fothergill had said, not what was done in the hospital but what was done by practitioners, and the teaching that plugging was the best line of treatment for accidental haemorrhage must involve the demonstration to the students of how to do it. He had never yet seen a case sent into the hospital plugged which was in the least efficiently plugged. He hoped that there would be some outcome of this discussion with regard to the relation of Caesarean section to placenta praevia. If some conclusions could be formulated as to the class of case which could be treated by Caesarean section it would be a great help to teachers and to general practitioners.

Dr. SYDNEY RUMBOLL said that in the hospital where he worked the plugging method was followed. In every case of accidental haemorrhage which he thought required plugging the patient was put under an anaesthetic, and after a most thorough cleansing of the vagina the plugs were carefully introduced. He would never teach nurses to plug. Plugging, he believed, ought only to be carried

out in a special institution—either a surgical home or a hospital. In the majority of cases of placenta praevia plugging was the best treatment; in other cases Caesarean section might be employed.

Dr. GORDON LEY said that at the City of London Maternity Hospital during the war in the majority of cases of placenta praevia the practice of external version and bringing down the leg was effective. The mortality of the mothers was infinitesimal, and about two-thirds of the babies were born alive. Caesarean section, he thought, should only be done in placenta praevia when the cervix was not dilated, the patient was at full term, and the baby was alive.

Dr. R. G. McKERRON was convinced that plugging was the best method of dealing with severe external accidental haemorrhage. He always taught his students to use the plug as the most effective method they could employ.

Dr. MENRO KERR said that the advantage of external version in placenta praevia was not only that the manipulations inside were less, but also that the placental site was less disturbed, and therefore the chances of infection were diminished. The great argument in favour of Caesarean section for placenta praevia was the improvement of infant mortality. He did not think that by Caesarean section it was possible to improve the maternal mortality save in exceptional cases. He was sure that Caesarean section would be employed in placenta praevia more frequently in future. Why were so many children born dead after placenta praevia? If that question were investigated in the light of hospital records it would be found that a considerable number of children were lost after version in placenta praevia cases because the delivery of the child had been hurried. It was swinging between life and death, and it was very undesirable to hurry the delivery. To drag on the child too early might be a fatal interference. With regard to accidental haemorrhage, he had employed plugging very extensively. He agreed that in very few cases was Caesarean section necessary in accidental haemorrhage. But there were a few such cases. He thought it possible, as Dr. Gordon Ley had suggested, that the use of pituitary extract and rupturing of the membranes might be an alternative to plugging.

The CHAIRMAN, in summing up the discussion, remarked that it might now almost be said that Caesarean section could be done with as little chance of mortality as ordinary labour. In dealing with placenta praevia where they had a closed surface, and particularly when they were dealing with a primipara, Caesarean section ought to be the treatment of choice. At all events that treatment should be borne in mind, granted that there were good nursing homes and hospitals available.

Dr. HASTINGS TWEEDY, in a brief reply, said that the danger of sepsis in plugging the vagina was a real one, and this was one of the reasons why he emphasized the methods of plugging. Every nurse and student should be taught to plug. It was the one treatment that was available to nurses in bad cases of haemorrhage where a doctor was not at hand. In dozens of cases, in outlying parts of Ireland and Scotland, a nurse was left to herself while her patient was almost dying. The difficulty about aseptic material was not so great as had been suggested. A sheet could be torn in small pellets, and these boiled in a saucepan. It was extraordinarily easy to get aseptic materials. Even in a hovel, attending a midwifery case, the first thing to be done was to get the pot boiling on the fire, and there was no excuse for a man with this resource plugging unaseptically. If he did, it showed that his teachers had not done their duty. As for midwifery, his experience was that the midwives knew their work a great deal better than the students. The majority of practitioners were not able to send their cases into the hospitals, and this plugging offered them an extraordinarily efficient method. Several speakers in the discussion had said that plugging could not control the uterine artery. But they spoke on theoretical grounds. They had not put the thing to the test. It was a pious belief repeated at every meeting he attended. But he had found that it did control the uterine artery, and this was not the result of his own observation only, but also that of Sir William Smyly and Dr. Purefoy, who had been with him in Caesarean sections for haemorrhage. In Dublin at all events there was now a general belief that the plugging actually did stop the pulsation of the uterine artery.

(To be concluded)

THE PEPYS OF MEDICINE.

THE annual oration before the Medical Society of London was delivered on May 10th by Sir D'Arcy Power, K.B.E., who took for his subject "The Rev. John Ward and Medicine."

Ward, who was vicar of Stratford-on-Avon in the reign of Charles II, was versatile and curious, and loved experiment. While in London he had attended the lectures of Sir Charles Scarborough at the Barber-Surgeons' Hall, had visited the hospitals of St. Thomas and St. Bartholomew, and had made inquiries about the cost of foreign medical degrees. He treated gratuitously his parishioners of the humbler ranks, although there was an apothecary and at least one physician in Stratford during his incumbency. From time to time he did a little minor surgery, and he followed the surgical aphorism, "Always lay a wound open, whether it be fresh or ulcerated." He seemed to have some idea of the metastasis of cancer, for he spoke of glandules arising in other parts among people who thus suffered. On pleurisy and effusion he wrote: "When an incision is to be made into ye breast open it betwixt ye 3rd and 4th ribb reckoning upwards, yt is just above ye diaphragm, and to yt perhaps apply a Caustick wch is very strong and will eat through ye muscle: yu make an Incision and keep itt open with Tents."

Among the epidemics from which Stratford people suffered during Ward's incumbency were small-pox, measles, and plague. The difficulty of distinguishing between small-pox and chicken-pox did not escape him. On plague he made several observations—one that "it was observed yt fat people catch itt sooner but lean people died 2 for 1." Some interesting facts about Greatrakes, the "stroker," or faith healer as he would be called to-day, were given in Ward's diaries. This man tried his cure on Lady Anne Conway, without success in her case, though he relieved many persons in the neighbourhood, so that Dr. Stubbs, the physician at Stratford, wrote a volume in favour of his cure.

From the details given by Ward of the illnesses of his neighbours and parishioners, it was sometimes possible to make a diagnosis, as, for instance, in the case of Dr. Gordon, Bishop of Exeter, and later of Worcester, who died of a stoppage of the urine which was supposed to be stone, but no stone appeared, only "two pieces of flesh growing one against another in ye neck of the bladder yt ye urine could not pass"—doubtless a case of enlarged prostate. Ward occasionally made an effort to generalize from the particular; thus he said: "Whether a great desire to live which some persons manifest upon their sick beds, as also a willingness to take anything wch before they refused is not a sign they are tending to their long home." In Ward's own opinion, and probably that of his neighbours as well, he was very skilful in urinoscopy, and made many entries on that subject. He distinguished clearly between syphilis and gonorrhoea, which were rife at Stratford during his incumbency. Death did not end the interest which Ward took in the bodies of his parishioners. He gave many details of embalming.

Perhaps the most interesting observations in Ward's notebooks were his references to Willis, Lower, Robert Boyle, and others of his contemporaries, who were personally known to him as graduates at Oxford. Lower's classical experiments on transfusion, suggested by Christopher Wren's injection of various drugs into veins, were recorded by Ward. Of Sydenham, Ward wrote: "Dr. Sydenham advises a vomit two hours after a gentle dinner; after vomiting hee gives a narcotick potion or Bolus to allay ye tumult yt ye vomit hath made." Other entries related to Sir Charles Scarborough, Sir Francis Prunjean, and Sir Alexander Prazier, of whom "the King hath a high opinion . . . and says all ye physicians are fools to him." The properties of opium, laudanum, and antimony were the subject of much inquiry at this time, and Ward made several allusions to these drugs. "Starkey told me that ye sleeping properties of opium may be separated so as to make itt a hinderer of sleep, but ye sudorific and anodyne qualities cannot."

His observations showed Ward to be a man of great versatility at a time when the prevailing type of mind was versatile. In many respects he was a true disciple of Boyle. He would have made a good practitioner had he given himself entirely to medicine, and he would have advanced the science of physiology. Boyle interested him in the new chemistry, and his restless curiosity led him into metallurgy and the more dangerous quest of the philosopher's stone. But with all this he was a dilettante, spoiled, probably, by the possession of a competency, hampered perhaps by ill health, for he was certainly ruptured, and died at the age of 52, probably of phthisis.

Reviews.

THE SURGERY OF THE BREAST.

Absorption in the war held up the progress of European surgery in every direction but that immediately concerned with it. The investigations of civilian surgery ceased for the time, and any advance made has been due to the implanting of the ideas of war surgery on the surgery of civil life. On the other side of the Atlantic for a long period of the war civil surgery progressed unimpeded. Some of the fruit of that progress we find in the monumental work before us, the review of which, we regret, has been unavoidably delayed. This volume on the *Breast: Its Anomalies, its Diseases, and their Treatment*,¹ is the joint production of Professor JOHN B. DEEVER and Professor J. McFARLAND, with the assistance of Dr. J. LEON HERMAN. The result of the collaboration of a surgeon and a pathologist with an anatomist is that the subject is treated with infinite elaboration, meticulous care, and overflowing wealth of detail.

We may pass lightly over the chapter dealing with the anatomy, and its intricate description of the lymphatics of the breast, and also over those concerned with polymastia, amastia, gynemastia, polythelia, hypertrophy, actinomycosis, and sporotrichosis. Sufficient is it to say that they are each most copiously illustrated with pictures and statistical tables, that each contains not only references but short abstracts of cases recorded in literature. The inquiring surgeon will find in them all the available information possible to collect into one volume. We may here say that the work is not intended to meet the wants of the practitioner, into whose range breast cases come only once in a while; its appeal is to the operating surgeon, called upon, as he is, to decide as to the nature of the condition of the breast, to advise for or against operation, and to plan any requisite operative procedure.

It is a notable feature of the book that a serious attempt is made to simplify the nomenclature of many of the diseases of the breast. This need for simplification is nowhere more apparent than in the big section of these diseases classed as "cystic disease of the breast." Apart from the cystic conditions recognized by all writers, such as galactocoele, serous cysts, hydatid cysts, there is a large class which, in this country, we have been inclined to regard as more or less connected with chronic mastitis. The complete nomenclature discovers at least twenty different names for this condition. The authors of this work advocate strongly that the suggestions made by Warren should be followed, and these cystic changes all placed together as changes brought about through abnormal involution. They go on to present the argument:

The breast tissue is restless; it is acted upon by a variety of agencies, is stimulated to grow or its growth inhibited according to circumstances known or unknown. The result is disturbance of structure and function whose extreme departures from the normal constitute abnormal involution and are supposed to prepare the way for, if not directly lead into, the epithelial invasion of the malignant character that we know as cancer. There is no inflammation; or, any coexisting inflammation is incidental and accidental. There is no tumour, or if there be, it is either incidental, papillary formations in the cysts, or consequential, cancer.

It is these cases which present the greatest difficulty in diagnosis. Probably every surgeon has had experience of removing a breast for "early scirrhus" which proved on microscopic examination to be simply cystic disease. Clinically some of these cases are not distinguishable from early cancer. Even if the expedient of making a microscopic examination within the operating theatre at the time of operation is followed, a mistake may be made—unless the whole tumour mass removed is submitted to examination—for we learn that cystic disease from abnormal involution and a small cancerous nodule may coexist in the same breast and this nodule may be missed. Further, "abnormal involution" may possibly be a process secondary to "squamous-cell carcinoma,

tuberculosis, and other chronic diseases." As "abnormal involution" may be accompanied or followed by carcinoma in one case in every ten, the importance of making a correct decision in any individual case is very obvious. The treatment will consist in subcutaneous excision of the breast or in conservative amputation of the breast with the axillary contents.

The most important of all breast diseases—carcinoma—is discussed as fully as any of the others. Indeed, the chapters are themselves a complete treatise on the subject. The authors ask for a simpler classification, and suggest that all the names of cancer of the breast be reduced in number from the fifty-four varieties which they give as having been found in literature to six: scirrhus or hard cancer; encephaloid medullary or soft cancer; carcinoma simplex (something between the two preceding forms); adeno-carcinoma (not derived from gland tissue but gland-like in structure); gelatinous carcinoma (formerly colloid); squamous-cell carcinoma. It may be argued that even these six might be simplified still more, and simpler names will occur to most surgeons. It may be noted that the manner in which the term "cell nests" is used by these authors differs from our usage. Cell nests to them are simply the collections or masses of cancer cells within the surrounding stroma. To us the cell nest is a distinctive formation seen in the terminal portion of the epithelial projections of epithelioma. Sampson Handley's permeation theory of the spread of cancer is accepted without reservation, and very complete descriptions of his operation for removal of the breast and lymphangioplasty, as well as the details of the theory are given. The only operative procedure in which the authors believe is properly one which will involve complete removal of both pectoral muscles and a complete dissection of the axilla *en masse* with the breast. Several of the methods of carrying out this procedure are described and lavishly illustrated. The chapter on the treatment of inoperable cancer is as inconclusive as the subject itself. The special author is Dr. Pfahler, and he seems to have had a considerable amount of experience in the treatment of such cases by x rays. He advises that every case operated on or inoperable should have a course of treatment by x rays. The details of the treatment and its success and failure are very fully placed before the reader.

The book is certain to meet with the highest approbation from surgeons for its large statistical collections and its pathological records, as well as for the even-minded discussions its chapters present of the problems of breast diseases. It is unnecessary to say that it is a handsome volume with few blemishes, and these of minor importance. Misspellings are observed on pp. 235, 282, 485, a singular substantive with a plural verb on p. 273, and the American verbs "to disadvise," "to metastasize," jar on the British reader. But the meaning of the authors is never obscure.

ENTOZOA IN MAN.

MEDICAL science sometimes shows a tendency to proceed from the pathological to the normal. Medical students are taught to recognize a number of malevolent bacteria, but the neutrals, the saprophytes, the inoffensive of the mouth or skin which rarely or never produce lesions, are omitted from the crowded curriculum. Reports of investigations on this or that pathogenic protozoön are many, but few indeed are the papers or books written on these animals unless they produce hurt to man. We do not even know what is the normal fauna in the human intestine in most parts of the world.

We therefore welcome Dr. ANNIE PORTER'S *Survey of Entozoa observed among Natives in Johannesburg*,² and trust that workers the world over will devote some time to informing us what the normal fauna is. It is obvious that such an inquiry would throw a flood of light on epidemiology; at present "the natives" are rather vaguely regarded as a source of danger to the cantonment or barrack. In the few places in which such investigations have been made it has frequently been a source of surprise to find some particularly "deadly" organism occurring in a large percentage of the population and apparently causing no harm. A man (or a monkey) may carry *Entamoeba histolytica* for a very

¹ *The Breast: Its Anomalies, its Diseases, and their Treatment*, by John B. Deever, M.D., LL.D., Sc.D., Professor of the Practice of Surgery, University of Pennsylvania, etc., and Joseph McFarland, M.D., Sc.D., Professor of Pathology and Bacteriology in the Medical Department of the University of Pennsylvania, etc., assisted by J. Leon Herman, B.S., M.D., Assistant Surgeon to the Methodist Hospital of Philadelphia, etc. London: Wm. Heinemann (Medical Books), Ltd. 1913. (Sup. roy. 8vo, pp. 724; 277 figures, 8 coloured plates. 42 net.)

² *A Survey of the Intestinal Entozoa, both Protozoal and Helminthic, observed among Natives in Johannesburg from June to November, 1917*. By Annie Porter, D.Sc. Johannesburg: S. African Institute for Medical Research. 1918. (Sup. roy. 8vo, pp. 58; 2 plates, 25 tables. 5s.)

long period and not be one jot the worse. Dr. Porter very definitely ranges herself with those who regard *Giardia* (*Lamblia*), *Trichomonas*, and *Chilomastix* as causers of diarrhoea. Until some worker can produce a series of cases of "flagellate diarrhoea," the stools of which were proved by repeated platings not to contain pathogenic bacteria, we shall maintain an attitude of doubt. If we may be pardoned for saying so, the protozoologist's attitude is not a sound one: we grant that various flagellates are often numerous in persons suffering from diarrhoea; we are very much interested to hear that these infections were found to be associated *post mortem* with points of inflammatory oedema, sometimes with definite ulceration; we can, however, never forget seeing a stool consisting almost entirely of *Giardia* and mucus, which was regarded as an undoubted case of flagellate diarrhoea, until a methodical bacteriologist isolated from it the *Vibrio cholerae*.

Dr. Porter gives statistical evidence of the infection of various native tribes with the prevalent protozoa and worms; 56 per cent. of the men examined were passing entozoa in their stools; multiple infections were not common, and were usually due to infection with *Entamoeba coli* or *Spirochaeta eurygyrata*, in company with some other organism. The discovery that cockroaches feed on human excrement, and pass the cysts it may contain unharmed through their own alimentary canal, is of very great importance. Cockroaches are world-wide in their distribution and closely associated with man, and in warm climates, where intestinal disease is so rife, they have, owing to the habits of the people, much easier access to human faeces than in this country.

STARLING'S "PHYSIOLOGY."

At every stage in his career the student of medicine is admirably provided nowadays with numerous textbooks from which he can choose whichever best suits his style of mind or special aptitudes in reading. This is, perhaps, most of all the case when he comes to study physiology, a science provided with a greater number of varied but first-class textbooks than any other at the present time. In the third edition of Professor STARLING'S *Principles of Human Physiology*³ the student and medical practitioner will find a full and up-to-date account of the whole subject, clearly written, excellently illustrated, and summarized for his benefit by a practical physiologist of great knowledge and well-known originality.

The first part of the volume deals with general physiology, or the structural, material, and energetic bases of the body. In the second part the mechanisms of movement and sensation are described; a new feature in this edition is the introduction of chapters on vision by Dr. Hartridge, extending to over a hundred pages, in which the whole subject is very lucidly put before the reader. The third part describes the mechanisms of nutrition, including metabolism and the physiology of digestion, the part played by the circulating blood and lymph, respiration, renal excretion, and other such subjects. The last part of the book is devoted to the subject of reproduction.

Everywhere Professor Starling writes as a man of science interested primarily in the mechanics and chemistry of physiology, the concrete rather than the abstract, the practical reactions of the living body rather than the metaphysical conceptions or interpretations to which they may give rise. The book is admirably arranged, the text sufficiently dogmatic to form thoroughly instructive reading that is at the same time thoroughly interesting. The issue of three editions of the volume within nine years shows that it has attained the success it so fully deserves.

A PRACTITIONER'S CYCLOPAEDIA OF MEDICINE.

The fifth edition of the large textbook of *Internal Medicine*⁴ by Professor WILSON of the Jefferson Medical College, Philadelphia, and a number of collaborators, including Dr. C. H. Turner, is issued in four volumes.

³ *Principles of Human Physiology*. By Ernest H. Starling, C.M.G., F.R.S., M.D., Hon. Sc.D. (Cambridge and Dublin), F.R.C.P. Third edition. London: J. and A. Churchill, 1920. (Roy. 8vo, pp. xiv + 1315; 579 figures, 10 in colour, 25s. net.)

⁴ *Internal Medicine: A Work for the Practising Physician on Diagnosis and Treatment*. With a complete Desk Index. By Nathaniel B. Potter, M.D., and James C. Wilson, M.D. Fifth edition, in four volumes. With 441 illustrations. Philadelphia and London: J. B. Lippincott Co. 1919. 43 15s. net.

The first two of these have as sub-title the term "Medical Diagnosis"; the third volume is the fourth edition of Orther's book on treatment, translated by Dr. Bartlett, and edited by Professor N. B. POTTER; and the fourth volume is described as a "complete desk index." The whole is intended for the use of the medical practitioner. Volume I deals with clinical methods or medical diagnosis in general, giving the various methods that may be used in examining the patient and their immediate results, the symptoms and signs of disease exhibited by the different systems of the body, and the modes of applying a number of tests. Volume II, erroneously described on its title page in the copy now before us, deals with the clinical applications of the results revealed by the methods and tests detailed in the first volume, and is described as a "Natural History of Disease." It is, in fact, a textbook of descriptive medicine in eighteen chapters, clearly written, and paying great attention to the differential diagnosis of the various morbid conditions described.

The third volume is given to the treatment of disease, and reflects current practice in Germany, enlarged by the addition of many notes by the editor; the prescriptions have been rewritten in conformity with the American *Pharmacopoeia*, both the English and the metric scales of measurement being given. The fourth volume is a general index to the other three, and appears to be perhaps less complete than the rest of the work: thus it contains no mention of *Filaria loa*, for example, or of "saltatory spasm," "palms," "jumpers," "latah," "myriachit," and "Bamberger's static reflex spasm"—disorders all described in the second volume.

In general, the volumes of *Internal Medicine* may be described as well written and comprehensive, up to date, adequately illustrated, and therefore to be recommended to medical men in search of textbooks of clinical diagnosis and the principles of treatment. The general practitioner who acquires these volumes should consult the first of them as often as the second, and the second as often as the third.

A HANDBOOK OF SKIN DISEASES.

DR. FREDERICK GARDINER has succeeded well in describing the more common skin affections, in his small *Handbook of Skin Diseases*.⁵ In present times, when the medical curriculum demands every spare moment from the hard-worked medical student, such a handbook will prove useful to those who have no opportunity for fuller reading. From a dermatologist so well known correctness of description and treatment are to be expected, and this is found in the book.

The reader will seek in vain for a chapter on eczema. Since the author says that new dermatitis is but old eczema "writ large," it is to be assumed that he includes the condition under this heading. But such a terminology seems to us to have many disadvantages and few merits, for the substitution of another name does not prevent the abuse of it. As understood by dermatologists, "eczema" has a definite meaning, and the proper employment of this term is both useful and accurate. For this reason alone its omission seems regrettable.

Apart from this criticism the book will be found to give in clear language a good short account of the diagnosis and management of the diseases of which it treats, and will prove a useful aid to those consulting it.

NOTES ON BOOKS.

AS an interesting study in modern sociology Miss ARABELLA KENEALY'S book on *Feminism and Sex-Extinction*⁶ sets out to show the harmful side of feminism in the past, the present, and the future. It begins with a study of the part played by women in human evolution, and it is argued that human decadence and the fall of ancient civilizations have largely been due to feminist movements and doctrines; the last chapter of the book, entitled "The impending subjection of Man," foretells the coming downfall of the human race should feminist aims be realized. Miss Kenealy writes with conviction, and her pages should confirm, if not console, those who see nought but harm in votes for women.

⁵ *Handbook of Skin Diseases*. By Frederick Gardiner, M.D., B.Sc., F.R.C.S.E. Edinburgh: E. and S. Livingstone, 1919. (Cr. 8vo, pp. xix + 160; 46 figures, 6s. net.)

⁶ *Feminism and Sex-Extinction*. By Arabella Kenealy, L.R.C.P. Publ. London: T. Fisher Unwin, Ltd. 1920. (Demy 8vo, pp. x + 313, 2s. 6d. net.)

THE FINANCE BILL.

THE activities of the tax collector entail such serious consequences in the present day that we feel impelled to turn again to the subject of national finance, to deal with the further information that has been made available by the recent publication of the Finance Bill, 1920—the Chancellor's proposals in statute form.

On the important question of motor-car taxation very little further light is thrown, as the Government White Paper, issued when the Budget was introduced, apparently contained an almost verbatim copy of the detailed proposals: the bill, however, contains a specific exemption in favour of "ambulances," a privilege which they share with road-rollers and the fire brigades of local authorities. Since Mr. Chamberlain's speech, however, the deputation from the British Medical Association to the Ministry of Transport and the Budget debate of April 27th have materially elucidated the questions in issue. The argument put forward in Parliament by Sir Eric Geddes was, in brief, that a system of taxation by "licence," instead of by fuel consumption, favoured the constant user at the expense of the occasional user, and in consequence automatically conferred a preference on the owner of a car kept for professional and therefore frequent use. To that argument the medical profession has two answers—first, that a frequent use often implies a virtual necessity to maintain a second or reserve car, which under the proposals would increase the licence duty by 30 per cent. for the quarter in which resort was had to the reserve car; and secondly, that even if the medical man has any such automatic preferential treatment, so has the owner of a commercial car, and equity demands that any advantage which the commercial car has by assessment of the licence duty on the basis of weight should be extended to cover both, seeing that the purposes served are essentially similar. The report of the recent Royal Commission on Income Tax unanimously recommended that the two classes of car should, for the first time, receive identical treatment as regards the income tax depreciation allowance, and the recommendation will presumably receive statutory effect before long; it seems strange to find one Government department deliberately setting up a distinction which another department has just been advised to abolish. We are clear that the same rules for licence duty should apply both to commercial and to professional cars; others may consistently take another view, but the point as to which there can surely be no difference of opinion is that at least a "reserve" car should be officially recognized and exempted from licence duty so long as it is not used simultaneously with the ordinary car. Any other course of action would put a very heavy penalty on any practitioner who keeps a reserve car. Seeing that when a sudden breakdown occurs the patient is the chief sufferer, the public as well as the profession are directly concerned in this question, and may even yet make their voice effectively heard.

On the proposals for reconstructing the income tax system so far as the graduating of the effective rate and the relief to earned incomes are concerned the bill throws some further light. To the taxpayer whose income is entirely unearned—or, in the newer phraseology of the statute, is "investment income"—the increase in the allowances is not quite so marked as might appear at first sight; for instance, in such a case the wife allowance is extended from £50 to £90 not from £50 to £100, and so on.

The position with regard to a married woman doing professional work has been somewhat improved. Under the old Act an allowance for separate "abatement" was given only where the total joint income of husband and wife did not exceed £500. In present circumstances that limit was sufficiently low to debar the great majority of married women working professionally from the advantage of any such allowance. The position under the new bill is that in any case the married man has a deduction of £90 from his "assessable income," and there is also to be deducted nine-tenths of the earned income of the wife, provided that that deduction does not exceed £45. When it is remembered that £225 of the taxable income is to be charged at 3s. and the remainder at 6s., it will be realized

that the value of an allowance has in most cases to be reckoned at 6s. in the £, so that though the allowance seems insufficient, it will at any rate affect the actual tax payable to a maximum extent of £13 10s., which is better than no allowance at all.

The deduction to be made in respect of a child now applies irrespective of what may be the total income of the parents—the old Act limited the allowance to cases in which that total did not exceed £1,000 per annum—but a new proviso makes its appearance, that the child must not be "entitled in his own right to an income exceeding £40 a year." Having regard to the purposes for which the allowance is presumed to be required, it is difficult perhaps to find fault with the proviso, but it may disappoint some who had expected to find themselves entitled to the deduction, and are affected by the limit of £40. It should be added that scholarships and similar educational endowments are not reckoned in computing the £40 income.

The provisions in respect of Colonial income tax and the relief to be given to persons paying a "double" tax, because they reside in one fiscal jurisdiction and draw their income from another, strike us as being complicated and likely to be rather difficult to work; the basis of the allowance is, however, fairly simple. Briefly, the idea is for the British Exchequer to give up either one-half the effective rate of British tax or the rate of the Colonial tax, whichever is the less. Unfortunately, owing to the system of allowances, neither of these rates can be readily computed, and the reparation of claims for repayment under these provisions is likely to be a long and intricate task. In the result, however, the relief should be not ungenerous from the point of view of the other British taxpayers.

The stamp duties invite no further comment; they are unwelcome, but have been generally accepted in a spirit of somewhat mournful resignation. The excitement and feeling of resentment engendered in financial and commercial circles by the unexpected increase in the excess profits duty has probably diverted into another channel the antagonism which the increase in stamp duties would otherwise have attracted.

The opposition to the excess profits duty has to some extent concentrated on what is certainly the most objectionable feature of that universally disliked but very lucrative tax, and that is the unfortunate position of new concerns possessing no "pre-war standard" measured by pre-war profits. It is true that a "standard" is given by allowing a certain percentage on capital to be taken in lieu of a "profits" standard, but it is urged that this does not leave the founders of a new concern sufficient financial inducement to take the necessary risks, particularly in view of the high rate of the income tax levied on the residuum of the profits left after payment of income tax, and thereby is checking the organization of increased production. The Chancellor held out some hope that special consideration would be given to such cases, but the bill is silent on the point. No doubt he is reserving his decision in order that it may be dealt with when the bill is in a later stage. A levy of 60 per cent. is provided for, and as Sir William Pearce's committee does not seem likely to advocate a practicable scheme for a capital levy on war fortunes with any approach to unanimity, its reduction to 40 per cent., which was to be contingent on the adoption of such a scheme, does not appear very probable.

The corporation tax has only an indirect interest for members of the medical profession; it is, perhaps, sufficient to say that the bill provides for an allowance of £500 a year, the tax being imposed at 1s. in the £ on the excess over that sum, and contains provisions intended to prevent the artificial reduction of the profits by payment of high salaries to managers who are virtual proprietors, or in other ways.

The repeal of the land values duties is coupled with the grant of a right of repayment of past duties, such claims to be lodged within six months after the commencement of the Act. The Chancellor of the Exchequer suggested that it would be a graceful act to refrain from making such a claim. Time will show somewhat interestingly to what extent the British taxpayer is open to so altruistic an appeal.

The Finance Bill contains no reference to the new postal rates, but when it comes into force on June 1st the increase

in the letter rate from 1½d. to 2d. will make letter writing a tax on the pocket as well as on the time of doctors, and will seriously increase the expenditure of an Association such as ours.

WEIGHT, HEIGHT, AND LONGEVITY.

A PAPER read by Mr. Lewis P. Orr, manager of the Scottish Life Assurance Company, to the Faculty of Actuaries of Edinburgh last December, has now been published as part of the *Transactions* of the Faculty. We propose to direct attention here chiefly to one point in Mr. Orr's paper—namely, the matter of weight in relation to height and age.

Among the proposers for life assurance, he said, were some who, though they had no adverse points in their family or personal history, and showed no signs of disease, were light in weight and poor in chest development; their chance of living long depended upon their consenting to take a course of physical exercises and recreation in the open air. The best course was to give them this advice and either defer the proposal for a considerable time or impose a substantial extra premium, with a promise of reconsideration in the course of a year or two.

Tuberculosis.

The relation of weight to height appeared to be an important point in the consideration of lives giving a family history of tuberculosis. He suggested that the facts justified general recommendations on the following lines:

Lives up to age 25.—Up to age 25 lives with a tuberculous family history should not be accepted without an extra premium. Particular attention should be paid to weight and to the development of chest. In many cases the physical development will be found to be under average and to be associated with an under-average weight; it is desirable to defer such cases for some years unless the condition is so unsatisfactory as to lead to the harsher verdict of declinature.

Lives aged 25 to 35.—In this section of lives those under 30 should be subject to rigid scrutiny, and, generally speaking, should be regarded as requiring an extra premium dependent upon the incidence of the family history and the physical condition (particularly the weight) of the proposer. Those between 30 and 35 may be looked upon more favourably; where the family record is tainted by consumption to a very limited

extent (say, one isolated case) and the personal history, physique, weight, and environment are good, then the life might be regarded as assurable at ordinary rates.

Lives above 35.—Unless the tuberculous family history be well marked (say, two cases) or the weight below the average, it is not necessary to load the premium for these lives, provided they are thoroughly satisfactory in all other ways. From and after the age of 40 a family record of tubercle loses much of its significance.

Personal Condition.—In assessing all such lives particular attention must always be paid to personal history and physical condition (including particularly the development of the chest and the weight in relation to height and age), and also to occupation and environment, for their importance as favourable or unfavourable factors is exceedingly great.

In the discussion which followed the paper both Dr. Byrom Bramwell and Professor Gulland expressed the opinion that Mr. Orr had taken too favourable a view with regard to a history of tuberculosis in persons over 35.

Weight in Relation to Height and Age.

As a contribution to an estimate of the importance of weight in relation to height and age in insurance practice Mr. Orr presented a table (printed at foot of page), based on the experience of male lives accepted as first class under 18,306 assurances; the actual number of lives was less, as cases in which the same life had been insured at intervals were included. The investigation comprised the period 1881–1915 inclusive, and the lives were of a good healthy class, as was shown by the satisfactory rate of mortality. The error introduced by the fact that the persons were weighed in their clothes—the weight of which would vary in summer and winter—was of little consequence from the insurance point of view, as in selection a margin was allowed on either side of the standard weight. The measurements were taken for the most part with the proposer's boots off.

Comparison of these statistics with those of the American medico-actuarial investigation showed close correspondence. The weights for the principal heights were very consistently about two pounds less than the American experience, except at ages over 50; the British weights above that age were two to four pounds more, but owing to the smallness of the British numbers no importance could be attached to this. From what was known

Average Weights in Relation to Height and Age. ("Scottish Life" Experience—1881–1915.)

52	10 3	10 7	10 11	11 1	11 6	11 10	12 1	12 6	12 11	13 3	13 10	14 2	52
53	10 3	10 7	10 11	11 2	11 6	11 11	12 1	12 6	12 12	13 3	13 11	14 3	53
54	10 4	10 8	10 12	11 2	11 7	11 11	12 2	12 7	12 12	13 4	13 11	14 3	54

The age given is the age next birthday. At age 55 and upwards the average weight might be regarded as that applicable to age 51.

of German and Austrian insurance statistics, it appeared that the Anglo-Saxon, as represented by Great Britain and the United States and Canada, was lighter than the German and Austrian to the extent of, roughly speaking, one stone.

Opinions differ as to the extent to which over-weight and under-weight might prevail without making it necessary to require an extra premium. Mr. Orr suggested that 16.66 per cent., or one-sixth of the total normal weight, might serve as a general guide, but the facts in each case must be taken into consideration. Thus light weight combined with a family history of consumption or a personal history of chest disease was unfavourable, particularly in the younger lives. In normal persons light weight was favourable in middle age and among elderly lives. It might, indeed, be that among lives otherwise satisfactory it was only at young ages that light weight was adverse; it was adverse because at these ages there was apt to be in persons under weight a greater tendency towards lung trouble than among those of average build. Mr. Orr, after quoting Hippocrates to the effect that "corpulence is not only a disease in itself, but the harbinger of other diseases," went on to say that in life insurance heavy weights showed a heavy mortality and that among heavy weights those with a protuberant abdomen were the least desirable. Regret was expressed during the discussion that Mr. Orr was not able to give a table of weights of women to elucidate the general statement that females were lighter than males to the extent of some five or six pounds at the chief insuring ages and heights. He said, however, that the best type of female life for assurance companies was the spinster earning her own living; the least, the married woman not earning her own living. He thought it probable that in the latter case there was a selection against the companies, the wife's life being insured because it was believed not to be so good as the husband's.

SOME MANUSCRIPT NOTES BY FLORENCE NIGHTINGALE.

MAY 12TH was the centenary of the birth of Florence Nightingale, who was born in Florence on May 12th, 1820. The anniversary is touched with a peculiar glory in view of all that the nursing profession has achieved in the Great War. The Leader of Nurses died only a year or two before this supreme test of her ideals and achievements on a vast scale. But we seem to hear her voice once more, when, as now, there comes to hand in a medical library a scrap of writing from her prophetic pen. It is typical of a whole branch of her many activities, which were yet all concerned with nursing.

Long after she had won fame by her heroic labours in the Crimean campaign Florence Nightingale acquired quite another reputation—by which alone she would deserve to be remembered—as a commentator of official reports on the health and sick-nursing of soldiers. In 1863 was issued the Report of the Commission on the Sanitary Condition of the Army in India. It is contained in two folio volumes amounting to nearly 1000 pages, and in Volume II are the reports from every station in India occupied by British or native troops. This immense mass of evidence had been sent in manuscript to Miss Nightingale for her criticism and report. Her observations at p. 347 of Volume I bring together the facts "in an order and with an incisive force of statement," says one of her early anonymous biographers, "which render it one of the most remarkable public papers ever penned." The report was regarded as likely to inaugurate a new era in India, for her views extended to towns as well as cantonments.

During the American Civil War, and again during the European War of 1870, Miss Nightingale was officially consulted on several occasions as an authority on questions of military hygiene and assistance to the wounded in the field. Later, private persons appealed to her. In the early days of the movement for the fuller employment of women she was eagerly referred to. In the year 1881 an article entitled "Notes on Sick Nursing," by Nurse Enderby, was forwarded to Miss Nightingale by the editor of *Every Girl's Magazine*, with a polite request for comment and suggestion. Miss Nightingale's reply is in pencil. The handwriting is clear and more modern than might have been expected. The date is November 19th, 1881. She apologizes for a long delay in sending her reply

"I am always," she writes, "under the severe pressure of overwork and illness. . . . Some short remarks I will make by way of suggestion."

"The article rightly professes to take the form of notes and to afford only hints to those for whom systematic teaching and practice is not available. But it is to be feared that some portions of the Article would tend to induce a belief in the readers that mere lectures and classes, unconnected with Hospital *ward training*, mere reading, mere good will and intentions would enable them to do many things for which only a trained nurse is competent—

"—such, for instance, as the otherwise useful instructions relating to the authority of the nurse over her patient and those about the patient—

"—to the observation of symptoms and reporting thereon to the Medical Men—

"—to the giving of food and to some extent also to the proper carrying out of ventilation.

"The tendency to over-confidence is usually far greater in those possessing a superficial knowledge than in the well trained. The power both of observation and of safely exercising any discretion in executing the Doctor's orders can only be acquired by training and long practice; and in any serious illness outside a Hospital there must necessarily be always frequent occasions in which the Doctor's instructions cannot be precisely adapted to the varying circumstances of the Patient during his absence.

"Words of warning and caution seem to me, therefore, to be desirable with regard to the application of these portions of the Notes."

"I need hardly say that it is a matter of rejoicing that the attention and interest of all classes of women should be aroused to the subject by periodicals specially addressed to them, and that it would be a matter of intense thankfulness if more of *first-rate* women could be brought in to fill, after a good Hospital training, the places which are eagerly waiting for them of heads, etc., of Hospital Nursing and of departments of Hospital and Workhouse and District Nursing. People scarcely realize how few the real labourers are to the harvest. I therefore hail beyond anything your interest in the subject.

"P.S. Since I wrote this, I have Miss Enderby's second note. I can only bid you 'God speed' with all my heart and might, and repeat my apology. It is very many years since I have been obliged to decline, however unwillingly, any work of this kind, such as revising ladies' articles, much as it may concern the subject on which I spend my life.

"Excuse a pencil scrawl.

F. N."

"*Had I time and strength I could give you instances where the Patient's life has been jeopardized by the Nurse exerting her 'authority' with insufficient knowledge—in each of the applications cited."

The foregoing is a fragment and, though marked by much of her characteristic common sense, belongs to that latter period in the long and illustrious career of Florence Nightingale when she had retired into the seclusion of her sick room in her house in South Street, Mayfair, and had become somewhat of a myth—a voice, as it were, behind a veil. Her seclusion lasted some forty-five years, until her death some ten years ago. "The dying woman," says Mr. Lytton Strachey in his witty *Eminent Victorians*, "reached her 91st year," and he proceeds to paint a somewhat severe picture of the last phase of the once masterful heroine. The few phrases sent to the editor of the magazine, which are quoted above, are certainly in great contrast with the well known *Notes on Nursing* of 1860. The author of that "Classical compendium of the besetting sins of the sisterhood, drawn up with the detailed acrimony, the vindictive relish of a Swift, now"—in Miss Nightingale's last period, that is—"spent long hours in composing sympathetic addresses to probationers, whom she petted and wept over in turn." This is picturesque exaggeration: the *Notes on Nursing*, taking into consideration their epoch, are neither acrimonious nor vindictive. Their satire is in their very truth. They are pungent, as truth alone can be, in their references to "amateur females" and their "physicking" propensities, nurses who "rustle," nurses in crinolines, who expose themselves as much as opera dancers when they have to pick something up, "female ink-bottles" (delightful phrase), and "missionariness." In her last epoch Florence Nightingale had already begun to be mollified by the results of her teaching. Surrounding her had grown up a new generation of nurses, one trained in her passion for fresh air, long since discriminated, actuated according to her fine ideals. There was, therefore, no further need for her satire. And it is this consideration which will account for her later style as it appears in her annual addresses to the nurses at the Florence Nightingale Institute at St. Thomas's Hospital. These addresses, begun in 1872, the year when she ceased her connexion with the War Office, and continued to the year 1900, are doubtless those of which Mr. Lytton Strachey does not approve.

VICTOR G. PLARR.

SATURDAY, MAY 15TH, 1920.

EXPERIMENTAL INDUCTION OF CANCER.

ABOUT seven years ago¹ we called attention to a brilliant study by Fibiger of Copenhagen, in which he claimed to have produced *de novo* in the stomach of rats a squamous-cell carcinoma. This represented then, and probably still represents, the only indisputable instance of the experimental production of cancer. It may be recalled that he was struck with the high incidence of gastric cancer in a certain breed of rats, and after most painstaking investigations discovered that these rats all came from a certain sugar factory infested with cockroaches. The latter were carriers of a nematode of unknown species now recognized to be new, and named *Spiroptera neoplastica*. Fibiger stated that the female nematode was 4 to 5 em. long by about 0.2 mm. in diameter. The male is less than half the size. The eggs are oval and clear; they measure about 0.06 mm. or less in diameter, and contain curled-up embryos. They were seen both in the body of the female nematode and lying free between the upper layers of the epithelium. The nematode, which was found only in that part of the stomach lined by squamous epithelium, lay, as an almost invariable rule, between the stratum corneum and the stratum granulosum. By feeding rats on the infected cockroaches, or by causing them to ingest the ova of the nematode, Fibiger was able to produce in a fair proportion chronic inflammation, papillomatosis, or even carcinoma of the stomach.

Since that time little more has been heard of his experiments, but recently² he has published some further interesting researches on the subject. He has found that the transmission of the nematode *Spiroptera neoplastica* (*Gongylonema neoplasticum*) to rats produced carcinoma in the cul-de-sac of the stomach with such frequency that it provides a method applicable to the systematic study of the origin of cancer. He undertook a series of experiments on several species of rodents, especially a strain of rats which had been preserved for a long time in the Copenhagen University Institute of Pathological Anatomy. Here the transmission of the nematodes was accomplished either, as in his former experiments, by feeding the rats on cockroaches (*Periplaneta americana* or *P. orientalis*) infested with the spiroptera, or by the ingestion of the nematode larvae obtained from the muscles of the cockroach, or by injecting the larvae directly into the stomach. The gastric lesions thereby produced were studied in 116 rats which had survived for periods of 30 to 298 days and the stomach of each was examined by serial sections. None of the rats dying from 30 to 44 days after the transmission of the spiroptera presented any indications of malignant growth, but of 102 rats which survived for 45 to 298 days no fewer than 54 showed quite typical carcinoma of the squamous-cell type in the gastric cul-de-sac. In the remaining 48 rats no carcinomata were found but only benign epithelial proliferations and signs of inflammation which are almost invariably provoked by the

spiroptera; the absence of carcinoma was verified by serial sections. Of the rats that died with gastric carcinoma in from one and a half to three months after ingestion of the infected material 20 had tumours of more or less microscopical dimensions, and 5 had multiple carcinomata: of 26 which lived for three to ten months 18 had tumours of fairly large size and 8 had minute nodules, whilst 15 had multiple cancers. Finally 8 rats which lived for the prolonged period had tumours of considerable size. The fact that the great majority of carcinomata were more voluminous in the rats which survived for a relatively long time than in those whose period of survival was short would indicate that the majority of the tumours were produced in from one and a half to three months after the transmission of the nematode. The metastases of this experimental cancer have a marked tendency to localization in the lungs. Generally these metastases were so small that serial sections were necessary to demonstrate their presence. In 33 rats the lungs of which were thus examined, pulmonary metastases were observed in 6 cases. In the absence of the actual sections the evidence for pulmonary metastases may not be convincing, for any observer who has studied the histology of the lungs of rats or mice must have been struck with the frequency with which he encountered microscopic nodules of epithelial tissue difficult to interpret. But Fibiger, who is reputed to be an authority on the pathological anatomy of rats, may be credited with the ability to interpret the findings aright. At any rate, he has been able to demonstrate in one case metastases from the gastric epithelioma in a retro-peritoneal lymph gland.

Up to the present he has produced carcinoma of the stomach in 89 rats and carcinoma of the tongue in 5, the particulars of which are to be given in another article. Whilst admitting that other strains of rats may be less susceptible to nematode cancer than those brought up in his institute, he states that the other strains of tame rats with which he has experimented are equally prone. But other species of rats—grey rats or black rats—would seem to be much less often affected. It would seem to be established that nematode cancer of rats can be produced readily in more than half of the experiments after a period of six weeks, and it provides a means for studying the mode of origin and conditions of development of cancer—problems which, so far, have been impossible of systematic experimental investigation.

VENEREAL DISEASE IN THE PORTSMOUTH AREA.

THE incidence of venereal disease in the Portsmouth area has acquired some importance in the unfortunate controversy which exists between those who do and those who do not advocate that soldiers and other males should be taught that self-disinfection immediately after sexual intercourse lessens very greatly the risk of acquiring venereal disease. On December 10th, 1919, in the House of Lords, Lord Willoughby de Broke, who is president of the Society for the Prevention of Venereal Disease, raised a debate on venereal disease. Lord Sandhurst, replying to a question regarding the prevalence of such disease in the "Portsmouth area," said that in 1914 the incidence of such cases was one and a half times as great, from 1916-18 about twice as great, and in 1919 two and a half times as great in this area as among the military population throughout the United Kingdom.

¹ BRITISH MEDICAL JOURNAL, 1913, vol. 1, p. 400.

² Comptes rendus de la Société de Biologie, vol. lxxxiii, No. 10.

Sir Archdall Reid, in letters to *The Times* of December 16th and December 19th, said that Lord Willoughby de Broke, in framing his question in the House of Lords, "desired to ascertain in what proportion troops dwelling in a certain definite area under the medical care of a certain medical authority acquired venereal disease as compared to troops in other areas." Sir Archdall Reid expressed his belief that the true incidence in this area was under 25 per 1,000 per annum, and suggested that the figures given by Lord Sandhurst included not only cases of diseases contracted in the area, but also cases appearing among men not under the authority—as, for example, among drafts from other military areas and from overseas. He remarked also that if Lord Sandhurst still believed his reply to Lord Willoughby de Broke to be correct, it was easy for him to establish his position by publishing in full the figures on which the reply was based. These figures are set out in detail in the nine closely printed foolscap pages of a statement recently presented to Parliament by the Ministry of Health, with the concurrence of the War Office, on the incidence of venereal disease amongst soldiers in the Portsmouth area and in the rest of the country.¹

Sir Archdall Reid has stated his belief that Portsmouth is the "model area for the whole country"; it appears from his letters published in this JOURNAL on January 24th (p. 128) and in *The Times* (December 16th) that by the Portsmouth area he meant "a certain definite area under the medical care of a certain medical authority," where the troops were infected at a rate of less than 25 per 1,000 per annum; this area included the greater part of Hampshire and Dorsetshire. From the Ministry of Health's statement it appears that Lord Sandhurst's comparison was based on notes of cases supposed to have come from "the two contiguous military stations of Portsmouth and Gosport, which practically form one compact urban area." This confusion of name is the first factor in the explanation of the difference between Sir Archdall Reid's figure of less than 25 per 1,000 on the one hand and the figure (163 per 1,000 in the Portsmouth area, compared with 64 per 1,000 elsewhere in the United Kingdom) on which Lord Sandhurst's statement to the House of Lords was based.

Two other factors contributing to this discrepancy would appear to be, first, a lack of uniform practice in classification of entrants to military hospitals, so that cases of venereal disease occurring among other troops were counted against the strength of the Portsmouth and Gosport areas; and secondly, the inclusion of certain admissions from colonial and R.A.F. troops. Lord Sandhurst's statement rested on a comparison of rates of 163 and 64 per 1,000 respectively in the Portsmouth area and the United Kingdom during 1919. In the White Paper these figures are admitted to be erroneous; the rate for the whole of the Portsmouth area should be 47.3 per cent., and for the garrison area 54.4 (not 163). In fairness it should be stated that the incidence rate of 64 per 1,000 for the United Kingdom, if calculated like the other rates on amended lines, would show some diminution.

It is difficult profitably to compare the incidence of infection among sections which differ from time to time in number and composition, and in which the duration of stay of the various elements varies widely at different periods. To obtain a basis for estimating the value of self-disinfection after intercourse it would be necessary to know (1) how many men were exposed to infection and afterwards made efforts at disinfection; (2) how many were exposed and subsequently made no such efforts; (3) how many of the

first group became infected; (4) how many of the second group became infected. It is admitted that no information as to these ratios can be derived from the statistics given in sections B and C of the statement regarding the proportions of hospital patients who had practised immediate or late disinfection or none at all. These sections indicate that of 3,000 admissions to military hospitals in the Southern Command, 1,100 in round numbers had used antiseptics, 550 on the same day; a detailed investigation at two other hospitals showed that out of 385 patients questioned by the medical officers in charge of wards 7.3 per cent. said they had swabbed with permanent solution within ten minutes after exposure; 3.6 said they had used calomel ointment within ten minutes; and 1.5 said they had used both preparations within that time. While these figures have little value for purposes of comparison, and have been challenged by the Society for the Prevention of Venereal Disease, they justify Lord Sandhurst's statement that, even among soldiers who had received instruction, immediate self-disinfection by no means invariably conferred immunity from infection. The statistics do not seem to justify any more general conclusion.

SECTIONS AT THE CAMBRIDGE MEETING.

At the Annual Meeting of the British Medical Association at Cambridge, which begins at the close of next month, the Section of Medicine will meet on Wednesday, Thursday, and Friday, June 30th, July 1st and 2nd, under the presidency of Sir Humphry Rolleston. The morning session on June 30th, with the president in the chair, will be devoted to a discussion on the diagnosis of nervous disorders of the stomach and intestines, to be opened by Dr. A. F. Hurst. The other speakers will include Sir Clifford Allbutt, President of the Association, Dr. Charles Bolton, Dr. Langdon Brown, Dr. Maurice Craig, Dr. R. G. Gordon (Bath), Mr. H. Tyrrell Gray, Dr. Robert Hutchison, Dr. Craven Moore (Manchester), Dr. R. J. Buchanan (Liverpool), Dr. E. Hobhouse (Brighton), and Dr. W. J. Tyson (Folkestone). In the afternoon Mr. J. Barcroft, F.R.S., will demonstrate methods of analysing the gases of the blood and alveolar air. On the morning of July 1st, with Professor J. B. Bradbury in the chair, Professor F. G. Hopkins will open a discussion on the present position of vitamins in clinical medicine, which will be continued by Sir James Barr, Dr. S. M. Copeman, Dr. Corry-Mann, Dr. A. Croft Hill, Professor C. J. Martin, Dr. Eric Pritchard, and Dr. Leonard Williams. On the morning of July 2nd, with Dr. Thomas Lewis in the chair, a discussion on the clinical significance and course of subacute bacterial endocarditis will be opened by Sir Thomas Horder, who will be followed by Dr. Carey Coombs (Bristol), Dr. J. M. Cowan (Glasgow), Dr. H. S. French, Dr. A. G. Gibson (Oxford), Dr. A. E. Gow, Dr. A. J. Hall (Sheffield), Dr. J. Hay (Liverpool), Dr. F. J. Poynton, Dr. H. J. Starling (Norwich), and Dr. W. E. Hume (Newcastle). An exhibition of specimens illustrating the subject of this discussion will be held in the Pathological Museum. The Tropical Diseases Section will meet under the presidency of Professor G. H. F. Nuttall, on Wednesday, June 30th. During the morning session papers will be read on problems of filariasis, by Drs. Stephens and Yorke; on the part played by *F. bancrofti* in the production of lymphatic obstruction, and a consideration of elephantiasis from the pathological standpoint, by Dr. G. C. Low and Dr. Manson-Bahr; and on the effects of vitaminic deprivation on the endocrine organs, with special reference to wet beri-beri and epidemic dropsy, by Lieut.-Colonel R. McCarrison, I.M.S. During the afternoon Dr. R. T. Leiper will demonstrate parasitic worms; a collection of all known

¹ Cmd. 505. H.M. Stationery Office. 2d. net.

species of tsetse flies will be exhibited by Professor Newstead, who will give a demonstration dealing with their morphology and bionomics. Lieut.-Colonel S. P. James will demonstrate the use of the mobile laboratory for malarial inquiries in England; and paintings illustrating the treatment of leprosy will be shown by Sir Leonard Rogers. The Section of Medical Sociology will meet on Friday, July 2nd, at 10 a.m., under the presidency of Dr. G. E. Haslip. Sir George Newman, K.C.B., M.D., will open a discussion on the Future of Medical Practice, dealing with the subject from the point of view of the State. The discussion will be continued by Sir Wilmot Herringham, K.C.M.G., M.D., from the standpoint of the Consultant; by Dr. Alfred Linnell, from that of the General Practitioner; by Professor F. Gowland Hopkins, F.R.S., from that of Medical Research; and by Mr. E. W. Morris, C.B.E., House Governor of the London Hospital, from that of the Hospitals.

NATIONAL COLLECTION OF TYPE CULTURES.

THE Medical Research Council has made arrangements with the Lister Institute to maintain a national collection of type cultures at the Institute, where all the necessary facilities have been provided. The object of the collection is to enable biologists in general and bacteriologists in particular to obtain from a trustworthy source authentic strains of recognized bacteria and protozoa for scientific work. The need of an available supply of this kind has long been felt in many directions and particularly in medical research work, for the study of principles and methods in bacteriological technique, and for the systematic classification of bacteria and protozoa in their various species and strains. In this country the Lister Institute of Preventive Medicine has for many years assisted bacteriologists both at home and abroad, so far as the resources of its own private collection have permitted, but British workers have been dependent in great part upon the courtesy of scientific colleagues or upon the collections of institutes in other countries. Before the war the collection at the Pasteur Institute in Paris, maintained by M. Binot, was very helpful to workers here. A collection of type cultures was formerly maintained on a commercial basis by Král at Prague, and this was subsequently transferred to the sero-physiological institute of Vienna. This source of supply was never completely satisfactory. In America the Museum of Natural History in New York has maintained a Culture Bureau during the last eight years, and it is believed that the facilities afforded by the bureau have been of the greatest benefit to workers there, not only by the provision of authentic cultures, but also through the studies in classification made by its staff. The Medical Research Council expresses its great indebtedness to the governing body of the Lister Institute for affording an opportunity of establishing a central collection upon a proper footing without further delay. The present arrangement is made for a short term of years, and the future location of the collection will be considered before the term expires. The scheme will be under the direction, on behalf of the Council, of Dr. J. C. G. Ledingham, bacteriologist in chief to the Lister Institute, whose part-time services have been lent for the purpose. Dr. R. St. John Brooks has been appointed by the Council to the full time post of curator, and Miss M. Rhodes to that of assistant curator. It is proposed to collect and maintain bacterial and protozoal strains of medical, veterinary, and economic importance, but in the immediate future the efforts of the staff will be directed more particularly to obtaining fully authenticated strains of pathogenic organisms. Subsidiary researches on the viability of bacteria in artificial media will be undertaken with a view to the discovery of economical and labour-saving methods of subculture. The staff will also be prepared to give help in the identification and classification of strains received from workers at home or abroad.

The co-operation of bacteriologists is earnestly invited; cultures that may be sent, either for identification or for maintenance in the collection, should be accompanied by the fullest particulars as to source and date of isolation and by clinical and epidemiological notes. The Director will determine what kinds of cultures are of sufficient importance to be maintained in the collection, but workers are asked to forward strains of even the commonest types as they will be of value at least for the representation of strains of recent origin, and studies in classification will be aided if large series of authentic specimens of different but closely similar or cognate species are available. Cultures will as far as possible be supplied on demand for a small charge to workers at home or abroad. Strains of the commoner types of human infection can already be supplied, and it is intended to prepare a catalogue for publication.

STERILIZATION OF MILK BY ELECTRICITY.
