THE Medical Research Council has published a full account¹ by Professor J. Martin Beattie and Mr. F. C. Lewis of Liverpool of their experiments on the use of electricity in the sterilization of milk. The work was begun in 1914 and was assisted by the Medical Research Committee, as it was then styled. The method employed is the passage of alternating electric currents through milk which is flowing with uniform velocity through a horizontal tube. In practice it is found desirable that the temperature at the outlet should be 62° to 64° C. A higher temperature gives a slightly greater degree of sterilization, but is not advised, on the grounds that the milk undergoes chemical changes, that the process carried out under these conditions does not furnish any advantages over ordinary heat sterilization, and that wastage of electrical energy is considerable. If electrical treatment is followed by natural cooling there ensues a "favourable temperature period," during which "residual" bacteria may multiply; more rapid cooling is therefore requisite, and in large-scale practice a refrigerating plant is a necessary adjunct to the electrical apparatus. The taste of the milk is not altered, and souring is delayed to the fourth day at least. Milk prepared in this way was used at the Liverpool Corporation infant welfare centres. It was found that the average reduction of bacteria, as indicated by agar culture, was over 99.9 per cent.; *B. coli* was always absent from the treated milk, although control specimens furnished innumerable colonies growing on neutral red agar at 37° C. The effect of the process on *B. tuberculosis* was carefully tested: milk artificially infected with pure cultures of *B. tuberculosis* and also with sputum containing large quantities of this organism was rendered free, as tested by the inoculation of guinea-pigs with the centrifuged deposit of 100 c.cm. of milk. The Medical Research Committee was able to secure an independent trial of the method in Birmingham, where Professor Leith repeated and extended the Liverpool observations, and Sir Oliver Lodge superintended the study of current action. The work was much interrupted owing to the war, but the results confirm Professor Beattie's claim that the electrical is an effective method for the sterilization of infected milk. Professor Leith concludes that "both the thermal and electrical methods have a high practical value, and deserve consideration in any endeavour made to improve milk supplies. The thermal is simpler and cheaper, the electrical quicker in action." The Liverpool and Birmingham workers differ in the view they take of the manner in which these changes are brought about. The Birmingham workers found a close parallelism between the effects of heat and the electrical current respectively upon the organisms in the milk, and they concluded that the electrical method owes its results not to the direct action of the current as such on the bacilli, but to the heat generated in its passage; Professor

¹ Medical Research Committee. On the Destruction of Bacteria in Milk. London, H.M. Stationery Office, 1920. No. 49. Price 9s.

Beattie and Mr. Lewis, on the other hand, believe that the alternating current produces its destructive action on bacteria by other than thermal means. The Medical Research Council expresses the hope that this question may presently be settled by special inquiry; in the meantime it has no doubt "that the work of Beattie and Lewis has given us an elegant and practical method of purifying milk for human consumption, of which the use upon a large scale becomes now a problem for closer financial and administrative examination."

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

THE present instalment of the *Oxford or New English Dictionary*¹ passes from *visor* to *vyver* (an obsolete form of *viewer*), and contains some interesting medical terms. There is *volsella*, "the chyrurgical little tongs," so often referred to in textbooks of gynaecology, and so often wrongly written *volsellum*, as if *volsella* were a noun plural instead of the singular feminine, which it really is; now that the *Dictionary* has given *volsella* its aegis, it may be hoped that the other form will disappear; *acanthobolus* is another name for it. *Vomica*, which is simply the Latin word for a boil or ulcer, has its strictly medical significance of an ulcerous cavity or abscess in the substance of the lungs, and also that of a place at which water issues. Every medical student knows that the *vomer* is so called from its ploughshare shape, but all are not aware that the *vomic nut* or the *poison nut* is the obsolete name of *nux vomica*. *Vomiturient*, which has the meaning of "characterized by a desire to vomit," is now obsolete—why, it is hard to tell, for it has an expressive enough sound and would seem, so to say, to meet a felt want. *Vomitory*, also, in its medical sense of emetic, is likewise marked as obsolete in the *Dictionary*, although a quotation is given from a work of 1743, and it is probably to be found in books much more recent than that. *Vomito* is given as a non-naturalized word; it means the yellow fever, and the reference is, of course, to the black vomit which accompanies it in its virulent form. *Vitellus*, and the words grouped with it (for example, *vitellary*, *vitelline*, *vitello-intestinal*, *vitelligenous*, etc.), mostly embryological names, are all fully illustrated; and *vitreous* (glassy), in its medical references, such as vitreous humour, is defined, but as applied to thick and tenacious mucus it has become obsolete. The many medical or, rather, chemical meanings of *vitriol* are set forth in order; but who knows now that *vitriol of Mars* is made by digesting filings of steel in spirit of vitriol? Also, who knows that *vitta* is "that part of the Coat called Amnion, which sticks to the Infant's Head when 'tis just Born"? Under *vivisect* and its associated words the anti's are well represented in the illustrative quotations. Dr. Craigie (the Editor of the present portion) has unearthed a realistic definition of *volvulus* from a book of 1679—namely: "When the Entrals are stoppt that they cannot void, it is the Volvuli or wringing of the Guts." An interesting group of words is found in *vulnerary* (useful in healing wounds) and its associates (*vulneral*, *vulnerate*, *vulneration*). Archagathus, as described by Pliny (in Holland's translation), "was called (by report) The vulnerarie Physician or Chirurgion." So much Dr. Craigie's illustrative quotation tells us; but a reference to Holland's delightful book supplies us with the "end-result," so to say, of Archagathus: "Wonderfull much seeking and running there was after him, and none more wealthie than he at his first coming; but soone after when hee was knowne once to carry a cruell hand over his poore patients, in cutting, lancing, dismembriing, and canterizing their bodies, they quickly began to alter his name, and to terme him the bloody Butcher or Slaughterman, whereupon not only all

Physitians, but Physick also grew into a bad name and became odious." So much for "the first Physician that ever came to Rome" and his fair beginning but bad ending. It is a great virtue in a dictionary when its quotations send the reader out of curiosity to the original sources, and in this, as in so many other things, the *New English Dictionary* is "excelling."

PHYSICAL THERAPY IN THE NAVY.

IN continuation of the series of reports dealing with the naval medical history of the war, Surgeon Commander A. K. Smith-Shand, R.N., has contributed to the current number of the *Journal of the Royal Naval Medical Service* a comprehensive account of the work done in radiology and physico-therapeutics. It increased progressively throughout the war and was done chiefly at the large naval hospitals at Chatham, Haslar, and Plymouth, but the R.N. Sick Quarters at Shotley dealt with casualties following certain of the bombardments and raids on the east coast, and the R.N. Hospital at Malta bore the brunt of the work arising from the Gallipoli campaign. A new building for massage and electro-therapeutics was erected at Chatham in 1916, and similar work was carried on in 1918 and 1919 at the R.N. Auxiliary Hospital at Peebles. X-ray work was chiefly performed at the three large hospitals. Foreign bodies were usually localized by Mackenzie Davidson's cross-thread method or by Bradbury's method; for eye work Sweet's localizer was usually employed. The number of opaque meal examinations increased fourfold during the war; recently a preparation supplied by Messrs. Allen and Hanbury, containing 75 per cent. barium sulphate in a pabulum of cocoa, arrowroot, and desiccated milk, was the material preferred. In treating ringworm Adamson's 5-exposure modification of the Kienbock method was employed, and one pastille dose was usually sufficient to cure mild uncomplicated cases of sycosis. Good results were obtained in chronic eczema and psoriasis; scars, keloid and lupus also responded well to repeated exposures. Cures were obtained in six cases of rodent ulcer. Surgeon Lieut. Commander Bradbury, at Plymouth, had good results in cases of tuberculous arthritis, and expresses the opinion that "tuberculosis of the wrist, ankles, etc., and of glands should not be operated on until x-ray treatment has been given a fair trial." Promising effects were obtained in cases of hyperthyroidism by the administration thrice weekly of one-third pastille doses through a 1 mm. aluminum filter. Ultra-violet radiation was introduced into naval hospitals in 1916, a Simpson lamp being used at Chatham and a Forbes lamp at Haslar; an English-made mercury vapour lamp was employed at Plymouth. The healing of granulating wounds, ulcers, and bedsores was thus accelerated; for after-treatment, a dressing of isotonic saline solution or simple shielding was preferred. Good results were also obtained in cases of acne, sycosis, keloid, and lupus, and after the battle of Jutland treatment by ultra-violet rays, directed through a speculum, was thought to produce remarkably rapid healing of rupture of the ear-drum. In the three large hospitals the work of the physico-therapeutic departments increased fourfold during the war, and was greatly helped by a generous gift made by Johannesburg and Rand school children. Ionic medication was extensively used in the treatment of gonorrhoeal and gouty arthritis, corneal ulcers, neuritis, and fibrositis. Surgeon Lieut. Commander Bradbury had good results from the use of zinc iodide in otorrhoea, and Surgeon Commander Connell reports the employment at Haslar of ionization with mercuric chloride in many cases of primary syphilitic sores and of chancroid. The departments of mechano-therapy were equipped with Sargent's weight-and-pulley apparatus, bicycle exercisers, foot and knee machines, and many other special therapeutic appliances; radiant heat, hydrotherapy, and diathermy were also used. The staffing of the massage

¹ A *New English Dictionary on Historical Principles*. Vol. x. *Visor—Vyver*. By W. A. Craigie, M.A., LL.D. Oxford: At the Clarendon Press, London, Edinburgh, New York, etc.: Oxford University Press, Humphrey Milford, March, 1920. Price 2s. 6d. net.

departments and training in them was greatly helped by the decision, taken in 1916, to employ women during hostilities; in 1917 it was arranged to appoint in each hospital a head sister and an assistant sister for massage, together with seven temporary masseuses and three masseurs; the head sister was chiefly employed in teaching. It is the intention of the Admiralty to form a trained staff of male masseurs, and for this purpose schemes have been prepared for the instruction and examination of twenty-four sick berth ratings each year.

THE HOSPITAL SURVEY.

THE hospital survey undertaken by Sir Napier Burnett, Director of the Joint Council of the British Red Cross Society and the Order of St. John, to which reference was made in a Current Note published on May 1st, has been completed. The object in view was to give an indication of the volume of work done by each hospital during 1919, and of the present financial position. The data used were either supplied direct by the hospital secretary or abstracted from the hospital's annual report. Throughout the fifty-five counties of England and Wales 550 hospitals have been dealt with, constituting approximately 78 per cent. of the voluntary civil hospitals, excluding those dealing solely with tuberculosis and excluding also the voluntary hospitals in London which enjoy the benefit of King Edward's Hospital Fund. A table has been prepared giving details of 507 hospitals, which, taken together, provided 29,821 available beds. They are classified in four groups: Group A, containing 82 large general hospitals of 100 beds or over, provided 15,958 beds; Group B, containing 87 hospitals with 30 to 100 beds, provided 4,724 beds; Group C, containing 240 small or cottage hospitals of under 30 beds, provided 3,355 beds; Group D, consisting of 98 special hospitals, provided 5,784 beds. Statistics were not obtained of the number of cases treated during the year in all these hospitals; but 498 hospitals treated 350,459 in-patients during the year. In the case of 296 hospitals with 23,621 beds, the daily average number occupied was 18,705 (79 per cent.). The enormous volume of work done is shown by the fact that in 374 hospitals 219,196 surgical operations were performed during the year. The ratio of medical to surgical cases found in sixty-eight hospitals from which such statistics could be obtained showed that the medical cases formed 21 per cent. and the surgical 72 per cent. of the total. It is suggested that these figures do not indicate that medical diseases are disappearing, but rather that people no longer shun the hospital from the dread of an operation. On the financial side it was found that the excess of expenditure over income for the hospitals under review was £475,627; approximately 75 per cent. of this deficit arose in the large general hospitals with 100 beds or over. The Joint Council is recommended to make a special public appeal in the hope of raising a million a year, and, further, to afford the hospitals facilities for co-operative buying. It is suggested also that the hospital work in each area should be co-ordinated by bringing the smaller hospitals into relation with the appropriate large or "key" hospitals. Arrangements would be made for the transport of patients and for the receipt of severe cases from small hospitals by the central hospital, and the return of slighter cases to the cottage hospitals and convalescent homes. It is further proposed that all pathological and bacteriological work of each group of hospitals should be conducted at the central hospital. We must defer further comment upon this interesting report to a future occasion.

VOLUNTARY MOVEMENTS IN NERVE LESIONS.

THE vast number of nerve injuries produced by the war has led to a new valuation and revision of many textbook "facts" as to the innervation of muscles and their actions. The pendulum has swung probably too far in the revolu-

tionary direction, and a paper by Wood Jones,¹ in which the actions of muscles is examined in some detail, may act as a corrective to those who are apt to cover their ignorance by wilfully abandoning pre-war knowledge and setting up standards of their own. Despite recent teaching, Wood Jones figures the supinator longus and pronator radii teres as useful flexors of the elbow-joint. His brief analysis of many of the movements of the hand and fingers is lucid, and many "trick" movements, which may be mistaken for evidences of recovery in a given nerve, are exposed. One of the most interesting of these is the extension of the wrist by the interossei in case of complete musculo spiral division. This necessitates flexion at the metacarpo-phalangeal joints; the movement cannot be executed with the fingers extended. There is a discussion of the movements possible in injuries of the musculo-entaneous, musculo-spiral, ulnar, and median nerves which will repay study. The estimation of the condition of injured nerves is always a very difficult and at best an uncertain procedure. A patient told to perform a movement sets himself to accomplish the feat without a thought for the particular muscles which he will or ought to use. For this reason, in nerve lesions the subject will use any muscle which has any power whatever to move the joint in question, and therefore the analysis of such movements requires close observation.

DINNER TO SIR GEORGE MAKINS.

THE complimentary dinner to Sir George H. Makins, G.C.M.G., C.B., P.R.C.S., was held on Monday evening, May 10th, when more than 100 medical men met together at the Hotel Great Central, with Sir Cuthbert Wallace, K.C.M.G., in the chair. Those present included Sir William Arbuthnot Lane, Sir Charles and Sir Hamilton Ballance, Sir Seymour Sharkey, Sir James Porter, Sir Felix Semon, Sir Walter Fletcher, Sir Archibald Reid, Sir W. G. Macpherson, Sir James Magill, Sir Robert Fox Symons, Sir C. Gordon Watson, Professor Arthur Keith, Dr. T. D. Acland, Dr. H. P. Hawkins, Mr. W. H. Battle, Mr. Raymond Johnson, Professor F. G. Parsons, Mr. Percy Sargent, Mr. J. Sherren, Colonel G. H. Barefoot, Mr. A. H. Cheatle, Dr. J. S. Fairbairn, Sir John MacAlister, Dr. F. F. Caiger, Dr. Alfred Cox, Mr. F. G. Hallett, and Dr. H. G. Turney, with many other members of the staff and former students of St. Thomas's Hospital. Messages were received from Lord Dawson and a number of colleagues who could not be present. The Chairman, in proposing the toast of the evening, gave personal recollections of Sir George Makins at St. Thomas's in former days, during the South African war, and as the first consultant surgeon with Sir Anthony Bowlby in the Great War. Sir Cuthbert Wallace spoke of the affection and trust inspired by their guest, of his kindly tolerance, and his calm and happy nature; to himself Sir George had been surgical father and friend. The toast was supported by Lieut.-General Sir John Goodwin, D.G.A.M.S., Mr. E. F. White, F.R.C.S., Sir John Bland-Sutton, and Sir George Savage. Sir John Goodwin said that his own debt to the teaching, writing and example of Sir George Makins was shared by the army, which had paid him the compliment of piling task after task upon him. An American colleague in France had aptly described their guest and their chairman as "two of the bulkiest of surgeons." All who had worked with Sir George Makins admired his steadfastness of purpose, his rectitude, and human sympathy. Mr. White added the tribute of a general practitioner and a friend of forty-five years' standing. Makins, he said, always played the game as a consultant, and gave real help to the general practitioner, whether the patient were rich or poor or one of the doctor's own household. Sir John Bland-Sutton, speaking as a vice-president, described Sir George Makins as the most popular president of the Royal College of Surgeons within living memory. Their friendship began in 1887, when they took part in founding the Anatomical Society

¹Journ. Anat., 1919, 54, 41.

of Great Britain. A great tradition in the surgery of gunshot wounds had been carried on in direct succession by William MacCormac, George Makins, and Cuthbert Wallace; Makins's work on injuries to the blood vessels was a milestone in the progress of surgery. Sir George Savage, speaking of an unclouded friendship since the time when Sir George Makins was his pupil at Bethlehem Hospital forty years ago, said that in all the relationships of life their guest's urbanity and humanity shone forth. Sir George Makins, who was received with great enthusiasm, expressed the pride he felt in seeing so many friends gathered round to do him honour. Among them was represented every one of the activities of his career. He thanked all his friends for the tribute they had paid him. With reminiscences of the past and kindly references to many of those seated around him he touched on his long association with the Army Medical Service and its succession of director-generals, on his relations with the Naval Medical Service and its heads, on St. Thomas's Hospital and the inspiring influence of Sir William MacCormac in war surgery, and on the great services rendered to medical education by the Royal College of Surgeons of England.

AUXILIARY R.A.M.C. FUND.

From the brief report, published at p. 689, of its recent annual meeting, it will be seen that the Auxiliary Royal Army Medical Corps Fund is doing good work. Since the last annual meeting it has given help to the orphans of thirty-one officers of the Auxiliary Royal Army Medical Corps who lost their lives owing to the war. As in many instances several children of the same officer were helped, the total number assisted was considerable. The fund, which also makes grants to the orphans of the rank and file, derives the major part of its income from subscriptions, which may be sent to the honorary secretary, Sir William Hale-White, K.B.E., M.D., at 11, Chandos Street, Cavendish Square, W.1. No one can doubt that the fund is needed, and we have reason to believe that it is judiciously and economically administered. It is therefore one which makes a strong appeal for the support of the profession.

THE Croonian Lecture of the Royal Society will be given by Professor W. Bateson, F.R.S., on June 17th. The subject is genetic segregation.

SIR WILLIAM OSLER, Regius Professor of Medicine in the University of Oxford, left estate of the gross value of £15,865, with net personalty £11,650. He bequeathed his medical and scientific library, as catalogued by himself, to the medical faculty of McGill University, Montreal. The remainder of his property he left to Lady Osler, but on her decease, or earlier if she should wish, Sir William Osler directed that his residence, 13, Norham Gardens, Oxford, be given to the Dean, Canons, and Governing Body of Christchurch as the residence of the Regius Professor of Medicine. Sir William Osler's only son was killed in the war.

Medical Notes in Parliament.

Financial Position of London Hospitals.

MR. R. YOUNG, on May 6th, asked the Minister of Health whether he was aware that some of the London hospitals were in a serious financial position, and that appeals were being made in elementary schools to the children, and through them to the parents, for assistance to prevent some of the hospitals partly closing down or otherwise curtailing their very necessary and beneficent work; and whether any steps were likely to be taken by legislation or other means to place these institutions on a sound footing to carry on their activities in the interests of the nation. Dr. Addison replied: In view of the urgent representation which has recently been made to me in regard to the financial position of certain of the London hospitals, I am considering what steps can be taken to meet a difficulty

which I hope is only temporary, but I am not yet in a position to make a definite statement on this matter, which necessarily involves far-reaching issues.

Election of Direct Representative to Fill Vacancy.

Sir Henry Craik, on May 10th, introduced a bill to amend Section 8 of the Medical Council Act, 1886, under which a direct representative elected to fill a vacancy is elected for a full period of five years. The purpose of the bill is to provide that a direct representative elected to fill a vacancy shall hold office for the unexpired period of the term of the member whose place is to be filled. This course is usual, so as to avoid overlapping periods of office. The bill is backed by Captain Elliot and Dr. Nathan Raw.

Doctors and Motor Car Taxation.

Sir W. Joynson Hicks asked the Minister of Transport, on May 5th, whether it was intended under the new scheme for the taxation of motor vehicles to grant any special privileges, exemptions, or rebates in respect of motor cars used by doctors and veterinary surgeons, in accordance with the privileges enjoyed by them under the present system of taxation. Mr. Neal replied: There is no intention to give special privileges to these classes of motor car users. This question was carefully considered by the Departmental Committee on the Taxation and Regulation of Road Vehicles, and the reasons for the withdrawal of existing privileges are set out in paragraph 23 of their report. The rebates which these users now enjoy were conceded partly in order to bring them into line with commercial motor vehicles, which pay no Inland Revenue duty and are entitled to a rebate of half the duty on motor spirit. With the abolition of preferential treatment to commercial users, the case for medical practitioners and veterinary surgeons necessarily fails. There could be no justification for exempting members of two professions only. Every person using a motor car in connexion with his profession or business would be equally entitled to preferential treatment. The concession to medical practitioners and veterinary surgeons was made when motor cars were taxed as luxuries. This is now no longer the case. The proposed tax is in fact a tax upon road users for road purposes.

War Pensions Bill.

Mr. Macpherson, on May 5th, moved the Second Reading of the War Pensions Bill, the chief object of which is to provide that the administration of post-war pensions shall be undertaken by the appropriate service departments instead of by the Ministry of Pensions. For this particular purpose the end of the Great War is defined as July 31st of the present year, and from that time new awards are "post-war pensions." The Government made this proposal in the interests of economy and efficiency, so that it should not be necessary that post-war pensions should be considered by two different departments—that was, by the Ministry of Pensions as regards disability and by the Service Department as regards service recognition. The business of pruning the gigantic organization of the Ministry of Pensions had already begun. The training of disabled men had been transferred from the Pensions Ministry to the Ministry of Labour; and it had been decided not very long ago—not by the wish of the Government nor by the wish of the Ministry of Pensions, nor, he believed, by the wish of the Ministry of Health—that the medical and surgical treatment of discharged and disabled soldiers should in two years' time be given to the Ministry of Health. This was the decision of the House of Commons. Nothing in the present bill interfered with the powers of the Ministry of Pensions or the Pensions Committee, except that their operations would be confined to the circumstances and happenings of the period from August 4th, 1914, to July 31st, 1920. In speaking of the importance of economy, Mr. Macpherson said he believed the administration of the Pensions Department cost as much as five millions a year. Another feature of the bill was a clause to substitute for the present county committees local committees acting independently over wide areas within a county. The local committees at the present time had control over the expenditure of 24 million sterling. Mr. Macpherson praised the public spirit of these committees, but said that the new arrangement would tend to greater economy, and there was a further proposal for the Government to have powers to appoint a finance officer who, if need be, would take charge of the local finances in any exceptional case. In one respect the bill would give the Pensions Ministry new duties, in that it was proposed to transfer to the Ministry the award of wound pensions to officers, hitherto undertaken by the

War Office or the Admiralty. Amongst other changes intended under the bill was one to give the Minister discretionary powers for the restoration of pensions forfeited by men on conviction and imprisonment; to give the Ministry of Pensions definite power to control the children of officers or men who had died on service or were still on active service, this power to be placed in the hands of a particular representative of the Ministry.

There was some discussion, but the second reading was given without division.

New Select Committee on Pensions.—At the instance of the Government, on May 7th, the House of Commons ordered the appointment of a select committee to inquire and report upon (1) the position as to employment and training for ex-service men disabled in the war; (2) the payment of grants by the Civil Liabilities (Military Services) Department; and (3) pensions for officers and other ranks of the mercantile marine so far as they were engaged in war service. Lieut.-Colonel Allen, Mr. Betterton, Sir John Butcher, Captain Coote, Major Entwistle, Lieut.-Colonel Sir Frederick Hall, Sir Henry Harris, Captain Loseby, Lieut.-Colonel Parry, Mr. Pennefather, Captain Redmond, Mr. Roberts, Mr. J. Taylor, Mr. Stephen Walsh, and Major Mackenzie Wood were nominated members of the Select Committee.

Sale of Quinine Stores.—In reply to Mr. Glauville, on May 6th, Mr. Hope, Financial Secretary, Munitions Ministry, said that a considerable quantity of compressed tablets of quinine was recently sold by the Disposal Board to Messrs. John Bell and Croyley, Ltd. The quantity of quinine salts contained therein amounted to approximately 270,000 oz.; fifty-six invitations for tender were issued, and amongst those who offered were Messrs. Whiffen, Messrs. Howards and Messrs. T. and H. Smith, Ltd. The price paid was slightly in excess of the valuation made by the expert advisers of the Department, and was substantially larger than the next highest offer received. The official responsible for the disposal of these tablets was a civil servant of many years' standing, and was still in the service of the Disposals Board.

Milk and Dairies Bill.—Dr. Addison on May 10th introduced a Milk and Dairies Bill to amend the Milk and Dairies Act, 1915. The main objects of the bill are to provide for the licensing of milk producers and dealers, for the definition and grading of milk, and to give power to local authorities to undertake the supply of milk in their areas.

Paper Supplies.—The President of the Board of Trade said, on May 10th, in reply to questions by Sir R. Cooper, that in consequence of the great demand and the general shortage of supplies of papermaking materials throughout the world, prices had risen everywhere to a very high level. He did not see what action the Government could take to ameliorate the situation, which was entirely due to economic causes. It was true that waste paper merchants were experiencing difficulty in disposing of waste paper to paper manufacturers, which appeared to indicate that persons who wanted material for the manufacture of paper preferred new and original supplies to waste paper; this would seem to indicate that the shortage of pulp was not so great as some people had imagined. On the suggestion that steps might be taken to ensure supplies of raw materials to Austrian paper mills, which made excellent paper before the war, Sir R. Horne said that supplies of raw materials were wanted in America and Canada as badly as here.

Answers in Brief.

Mr. Bonar Law has stated that it is intended to bring the National Health Insurance Bill into operation on July 5th, 1920, and that he hoped it might be read a third time this week.

The Minister of Transport has stated that the Committee on Motor Taxation early in its investigations indicated a preference for a petrol tax. On further consideration it arrived at the conclusion that it was impracticable. He undertook to publish the interim report on the subject.

The question whether the Government shall reconsider cases of hardship owing to pensioners being refused grants by the Civil Liabilities Commissioners on the ground that their applications are too late has yet to be determined.

The question of increasing the pensions of pre-war pensioners is now being considered by a Cabinet Committee.

The Government cannot make any definite forecast as to the period during which it may be necessary to continue the work of the Ministry of Food. A bill to extend its life will shortly be introduced.

Under the Budget proposals the amount of direct taxation per head of the population of the United Kingdom will be £14 7s. in 1920-21.

Eaton Hall, Chester, is the only remaining hospital for convalescent soldiers, but steps are being taken to transfer the patients, and it is hoped that the Hall will be vacated within the next two or three weeks. The number of patients treated during the first three months of the year was—January 119, February 75, and March 113.

Sir James Craig has stated that the qualification for participation in naval prize money is service in a seagoing offensively armed ship of war. In these circumstances claims based on hospital ship service would not be admissible.

The Government hope to introduce the Dentists Bill before the end of the month.

England and Wales.

SCHOOL MEDICAL OFFICERS' SALARIES.

At a meeting of the Devon Education Committee, on May 6th, at Exeter, the secretary stated that though the salary of the school medical officers had been put at £400 a year, rising to £500, the annual increments had not been decided upon. In reply to a question, the County Medical Officer of Health (Dr. Adkins) said that the medical papers refused to accept advertisements for medical officers at a salary less than £500 to start with. He had now received the resignation of Dr. E. L. Sturdee, of Barnstaple, who wrote that he found it impossible to live on the salary paid by the committee, and he was accepting a better paid post. Advertisements were inserted in the local newspapers. Six applications were received, but five had since been withdrawn, a notice having been issued that before applying for a position under the Devon County Council doctors should communicate with the British Medical Association. The fact was that the Devon County Council was on the "black list." There was now only one applicant for the appointment. Dr. Mackenzie said he was not a member of the British Medical Association, and he was opposed to all trade unions, but he liked to look at these matters in a reasonable way, and if they wanted a good service they must pay for it. Dr. Adkins said the one remaining applicant was Dr. C. G. Mathews, who had done a good deal of work in Devon and came with strong testimonials. The appointment was for the Barnstaple district. He would have to work with the medical men in North Devon, and would be looked upon as a "blackleg"; it would be an awkward position. Dr. Adkins mentioned that the candidates who withdrew stated that they would be glad to take the position at a starting salary of £500. It was agreed to appoint Dr. Mathews, and that increments should be £25 p.a. annum.

Dr. C. P. Mathew of 12, Thornton Hill, Exeter, asks us to state that he is not the medical practitioner who has been appointed assistant school medical officer for the Barnstaple district under the Devon County Council.

We have since been informed that Dr. C. G. Mathews also withdrew his application.

ASSISTANT MEDICAL OFFICERS AT MENTAL HOSPITALS.

It has been decided to increase the establishment of assistant medical officers at each of the larger mental hospitals in the county of London (that is, with over 2,000 patients) to eight. Hitherto the number has been six, with a locumtenent during the annual leave season. The services of the locumtenent will be dispensed with under the new arrangement. Among the reasons for this increase of establishment is that under the new conditions of employment and promotion for the nursing staff a greatly increased number of lectures has to be given by the medical officers. The suggestion has been made that the higher standard of nursing now required might operate to reduce the amount of professional medical care necessary; but the Asylums Committee is advised that this is not the case, and that the patients must suffer if the previous standard of medical care is not maintained. A further factor which affects the question is that the Council has provisionally agreed to the principle of granting study leave to assistant medical officers in the mental hospitals' service, with a view to their obtaining diplomas in psychological medicine; they are being given facilities for attending the course of lectures in psychological medicine instituted at the Maudsley Hospital.

PREVENTION OF VENEREAL DISEASE.

Early this year Dr. A. Mearns Fraser, M.O.H. Portsmouth, prepared a special report on the prevention of venereal disease, in which, after alluding to the prevalence of these diseases, he expresses the opinion that there are no infectious diseases so easily guarded against as venereal diseases. The report states that application of a disinfectant to the male genital organ within an hour of exposure to infection can be relied on to prevent the acquisition of venereal disease, and quotes the names of eighteen medical men (eight of whom are members of the executive committee of the Society for the Prevention of Venereal Disease) who have allowed their names to be

used in support of the opinion that "self-disinfection, promptly and efficiently carried out, is an almost certain preventive against venereal disease." The report goes on to combat the arguments which have been put forward against self-disinfection, and to discuss the ethical aspects of the question. Dr. Fraser recommended the Portsmouth borough authorities to take such steps as may be necessary to spread a knowledge of the means of self-disinfection; the procedure advised is that advocated by the Society for the Prevention of Venereal Disease—namely, the swabbing of the male genital organ, immediately after exposure to infection, with a solution of 1 in 1,000 potassium permanganate, and the rubbing in of a 33 per cent. calomel ointment. The report was approved by the Health and Housing Committee on March 3rd, and the policy which it suggests was adopted by the borough council on April 27th.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The annual meeting of the general council of King Edward's Hospital Fund for London, to receive the accounts and the report for the year 1919, was held at St. James's Palace on April 30th, the Earl of Donoughmore, K.P., being in the chair. Among those present were Viscount Burnham, the Hon. Sir Arthur Stanley, Sir Norman Moore (President of the Royal College of Physicians), Sir George Makins (President of the Royal College of Surgeons), and Lord Somerleyton and Sir Frederick M. Fry, honorary secretaries. Lord Somerleyton alluded to the council's deep regret at the death of Sir Henry Burdett, and a resolution of regret and condolence was passed. A cablegram was read from the Prince of Wales, President of the Fund, expressing his regret that his absence in Australasia made it impossible for him to be present at the annual meeting. Lord Donoughmore, in moving the adoption of the report, compared the present annual expenditure of the London hospitals with that of 1897, when the Fund was inaugurated by the late King Edward VII. In that year the total expenditure was £700,000 and the annual deficit was £70,000. The estimated expenditure of the London hospitals for 1919 was about £2,100,000, with a deficit of £200,000. Mr. M. C. Norman, Governor of the Bank of England, seconded the adoption of the report, the most important features of which were summarized in our issue of March 27th, p. 451.

MATERNITY AND CHILD WELFARE ARRANGEMENTS IN LONDON.

The Public Health Committee of the London County Council has agreed, as an experiment for one year, that the appropriate officers of the Lewisham Borough Council should exercise the powers of infant life protection visitors and of lying-in homes inspectors. The argument in favour of the new arrangement is that it is in accord with the general principle governing local health administration that the local sanitary authority should be responsible for the internal sanitary conditions of homes. Further, as the local medical officer of health is the officer responsible for carrying out the maternity and child welfare scheme in the borough, it was felt to be desirable that he should be associated as closely as possible with the kindred work of the supervision of nurse-children and the inspection of lying-in homes.

THE 1ST AND 2ND SOUTH MIDLAND FIELD AMBULANCES, BIRMINGHAM.

A successful smoking concert was held on May 7th, at the White Horse, Birmingham, to commence the recruiting for the 1st and 2nd South Midland Field Ambulances. Lieut.-Colonel C. Howkins, C.B.E., D.S.O., T.D. (O.C. 1st S.M.F.Amb.), was in the chair. Lieut.-Colonel R. A. Broderick, D.S.O., M.C. (O.C. 2nd S.M.F.Amb.), and Majors H. Boeddicker, W. Bowater, M.C., Mandy Cox, M.C., Captain Hirst, M.C., Drs. Parsons, Teill, and many others who were interested in the re-formation of the ambulances, were present. The Chairman stated that it would be a great slur on the city of Birmingham if two ambulances could not be quickly raised up to the strength laid down for the peace establishment and carry on the traditions of those Birmingham field ambulances which did such excellent work with the 48th and 61st Divisions. Lieut.-Colonel R. A. Broderick, on behalf of the 2nd

S.M.F.Amb., stated that he was prepared to do his best to carry on the ambulance and make it the success it was in the past, and, if possible, have the transport section again at Sutton Coldfield. Speeches in aid of recruiting were also made by Majors Bowater, Cox, and Captain Hirst, and from the large numbers of old members of the units present and the enthusiasm displayed little difficulty is anticipated in raising the units. An excellent musical programme was arranged and a most enjoyable evening spent.

Scotland.

BRITISH ORTHOPAEDIC ASSOCIATION.

A SPECIAL meeting of the British Orthopaedic Association will be held in Edinburgh on June 4th and 5th under the presidency of Sir Robert Jones. At the morning session on Friday, June 4th, Mr. R. C. Elmslie will open a discussion on the principles of the correction of congenital talipes equino-varus, and particularly of inveterate and relapsed cases; Mr. John Fraser will speak on the results of tendon transplantation for paralysis of the muscles below the knee; Mr. S. Irwin on acute arthritis of the hip in infants; and Mr. Harry Platt on traumatic dislocation of the knee-joint. At the afternoon session Professor Putti of Bologna will speak on the end-results of arthroplasty of the knee-joint; Dr. Murk Jansen of Leyden on hallux valgus, rigidus and mallens; Mr. A. P. Mitchell will read some notes on bone, fascia and tendon grafting; and Miss Forrester-Brown will present a paper on the possibilities of end-to-end suture after extensive nerve injuries. Mr. John Fraser will give a demonstration of cinematographic records illustrating the various types of gaits in children. A dinner will be held in the evening. On the morning of Saturday, June 5th, Sir Harold Stiles will demonstrate cases at the Edinburgh Royal Infirmary, and will operate.

THE STILLBIRTHS RATE IN EDINBURGH.

During 1919 283 stillbirths occurred in Edinburgh, and since the birth notifications numbered 6,280, the stillbirths rate was almost exactly 45 per 1,000. The births registered numbered 6,060. Of course the notified births, if complete, ought to tally with the registered *plus* the stillbirths, and therefore the notifications ought to have been 6,343 instead of what they actually were—6,280. This would seem to show some leakage in the notification of births returns. The neo-natal deaths for 1919 showed a rate of a little over 41 per 1,000 live births. By adding the stillbirths and the neo-natal mortality rates together, it follows that in Edinburgh 86 infants out of every 1,000 brought to the last two months of ante-natal life died either soon before, during, or within a month after birth. Roughly, therefore, the population of Edinburgh lost something like 500 babies from these two causes in the year. During the previous year (1918) the number of births notified was 5,400 and the stillbirths were, 238, the stillbirths rate being therefore 44 per 1,000 notifications. This reveals a somewhat steady proportion of stillbirths. So far as 1920 has gone the stillbirths rate is 44.4. The details were as follows: January—notifications 831, stillbirths 44, rate 52.9; February—notifications 688, stillbirths 28, rate 40.7; March—notifications 941, stillbirths 40, rate 42.5; April—notifications 738, stillbirths 30, rate 40.6. So that, although there are variations in the rate from month to month, the annual rate remains fairly steadily round about 44 and 45 per 1,000 births (living and still).

SMALL-POX.

The number of cases of small-pox under treatment at the Glasgow Fever Hospital was nearly doubled during last week. The total number was 99. 17 new cases having been received during the week-end. Most of the cases have occurred in the east end of the city, but one was removed last week from a house in Langside. It was mentioned last week that one case had occurred in Edinburgh in which no connexion with Glasgow could be traced. A second case was notified on May 7th in a middle-aged man who had recently paid a visit to friends in Glasgow. The Scottish Board of Health has issued a memorandum to medical practitioners stating that there is

reason to fear wide dissemination of the disease, which is of a severe type, causing marked fatality among the unvaccinated. Medical practitioners are invited to co-operate closely with the public health department in efforts to prevent the spread of the disease and to secure early diagnosis of any suspected case. The number of unvaccinated children is known to be very high, and practitioners are asked to use their influence to induce persons to resort to vaccination. The Board has also issued a memorandum to medical superintendents of infirmaries and hospitals warning them of the danger of the introduction of the disease. The Board has notified medical officers of health and clerks to local authorities that it will keep a supply of vaccine in Edinburgh for issue to medical officers of health; it is the vaccine prepared by the Government lymph establishment, London, and will be supplied free on application to the Board, 83, Princes Street, Edinburgh. The medical officer of health for Edinburgh has issued an appeal to citizens to protect themselves by revaccination. A considerable number of cases have occurred in persons who were vaccinated in infancy but have not since been revaccinated.

Ireland.

ULSTER MEDICAL SOCIETY.

A SPECIAL meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on May 6th, to discuss the relationship of the Ulster Medical Society to questions of public health arising in Belfast and the neighbourhood. Mr. Andrew Fullerton, C.B., C.M.G., F.R.C.S.I., the president, occupied the chair, and the subject was discussed at considerable length in all its aspects, and it was finally agreed unanimously that certain meetings of the society should be held, which would devote themselves entirely to public health and kindred subjects. After full discussion, at such meetings, the society could take whatever steps they considered necessary to lay their views before the different public health authorities.

GRAYMOUNT HOSPITAL, BELFAST.

In the abstract of the report of Sir Henry Gauvain on the suitability of Graymount as a place for the treatment of non-pulmonary forms of tuberculosis amongst Belfast children, his opinion was accidentally misstated. In his full report Sir H. Gauvain said that three objections had been pointed out to him—that is, a clayey soil, the dampness of the Lagan Valley, and at times a smell from the foreshore of the Lough. In his opinion, however, these objections were not of such a grave nature as to render the house unsuitable for a surgical tuberculosis hospital.

Correspondence.

DUODENAL ULCER AND THE HYPERTONIC STOMACH.

SIR,—The quick, sure, and permanent cure of duodenal ulcer which Mr. John Morley, in his letter to the *JOURNAL* of May 8th, rightly described as following gastro-enterostomy is no doubt a triumph for the abdominal surgeon. But it is none the less a confession of failure that surgical treatment should be required at all—failure on the part of the physician who has not effected a quick, sure, and permanent cure by medical means; the practitioner who has not recognized the premonitory signs of ulcer and so prevented its development; the medical schools which have not taught their students how these signs can be recognized; the pathologists who have been too much interested in the pathology of the dead and of the lower animals to investigate the pathology of ulcer in the living man; and the Government which has not provided the money to staff and equip institutions, which would fulfil the objects described by Dr. Tyson in his letter of May 1st, in which people of every class could benefit by the modern methods of investigation in the earliest stages of disease.

Like Mr. Morley, I have seen a few exceptions to the rule that duodenal ulcer is associated with a small and

rapidly emptying stomach. But what rule is there without exceptions, and what evidence have we that these exceptional cases did not conform to the rule in their earliest stages, the dilatation and delayed evacuation being due to achalasia or spasm of the pylorus, either of which may result from an ulcer in the neighbourhood, even before the actual sphincter is involved?—I am, etc.,

May 9th.

ARTHUR F. HURST.

AORTITIS AND AORTIC REGURGITATION.

SIR,—In commenting upon Dr. J. E. MacIlwaine's paper I desired to draw attention to a feature of the morbid anatomy of aortic regurgitation associated with syphilitic aortitis, and perhaps in doing so appeared to criticize Dr. MacIlwaine. While this was not my intention, I feel that he lays too much stress on the situation of the pain. The most common position of cardiac pain arising from any cause is near the inner end of the third left intercostal space. I am not aware that there is evidence of aortitis causing pain in this situation, except indirectly by interfering with the nutrition of the cardiac muscle.

"The fact that the syphilitic virus gives rise to arteritis, aortitis, endocarditis, and myocarditis is known" is the opinion of Dr. MacIlwaine. Having made 2,500 autopsies, and also having been a careful student of various details connected with the heart, I feel that I am in a position to comment upon such a belief. It may be mentioned that I have never met with a case of syphilitic endocarditis, but, as was stated in a former letter to the *BRITISH MEDICAL JOURNAL*, the inflammation of a syphilitic aortitis commonly spreads to the aortic valve, causing a fibroid contraction of the cusps. With regard to myocarditis, if gummata of the heart come under the heading of myocarditis, then there is, of course, a syphilitic myocarditis; but apart from that I do not see how the term can be used unless applied to localized patches of disease associated with arteritis of the vessels in the cardiac wall. Such an arteritis of the cardiac vessels, definitely syphilitic, seems to me to be rare. I have only met with one clear example, and that, curiously enough, was after I had given up routine *post-mortem* work.

Degeneration of the cardiac muscle, due to syphilitic disease of the intrapericardial portion of the arch of the aorta, stands in a different category. It is probably the most common cause of sudden death in men between the ages of 45 and 55 or possibly 60.—I am, etc.,

Norwich, May 8th.

THEODORE FISHER.

THE EARLY DIAGNOSIS OF SYPHILIS.

SIR,—In reply to the letters under this heading in the *JOURNAL* of May 1st, we wish it to be understood that we do not for a moment depreciate the value of laboratory methods of diagnosis when properly interpreted; and if the *Practitioner* of May, 1916, is referred to, an article by one of us (Ffrench) will be found which lays great stress on the use and value of laboratory diagnosis. Nevertheless, in cases in which the laboratory findings are negative, it is better practice to rely upon one's clinical experience and put the patient under treatment if the clinical signs are suggestive of syphilis, than to lose valuable time by keeping such cases under indefinitely prolonged observation. It is impossible to make an accurate time limit for such observation, for patients vary so greatly in developing secondary manifestations, and it is well recognized by experienced syphilologists that the first month after infection is the most important regarding the commencement of treatment. It has been our experience that obvious cases of syphilitic chancre have given negative laboratory results from day to day, and we know that in many such cases medical officers have hesitated to make a diagnosis of syphilis on account of the negative laboratory findings. We feel justified, therefore, in laying the greatest stress on the cultivation of clinical experience.—We are, etc.,

London, W., May 8th.

C. F. MARSHALL,
E. G. FFRENCH.

TUBERCULOSIS SANATORIUMS.

SIR,—In your issue of May 1st, p. 619, Dr. F. W. Inman makes the alarming, and in my opinion very ill advised, statement that "In sanatoriums a very malignant form is always present in the wards, and those who are admitted

with a mild form probably contract there a severer form and convey it to their family."

During twenty years' experience of tuberculosis in sanatoriums and outside I have never met with a single case which would support such a theory.—I am, etc.,

LEONARD CROSSLEY, M.D.,
County Tuberculosis Officer for Wilts.

May 6th.

EARLY MENTAL TREATMENT AND THE RIGHTS OF THE SUBJECT.

SIR,—In the speech in which the Right Hon. Dr. Addison introduced the Health Ministry Bill, he made explicit reference to "the inadvisability of including under the Health Ministry many judicial questions which are not in any sense medical, such as those that concern the rights of the subject, etc." In face of this declaration from such a high authority, it would seem a little curious to notice in the sketch communicated to your issue of April 10th (p. 515) the remark "that the Lunacy Board of Control will no doubt before long be transferred to that Ministry." In a preceding sentence the function of that Board is stated as "having to do with restraint of the liberty of the patient, with safeguards, etc., and with the protection of the hopelessly confirmed insane."

If so transferred, the Board will doubtless have to leave behind it at the Home Office a large proportion of its duties, for its legal half, at any rate, is intimately concerned with the rights of the subject, and must consequently (in accord with the dictum of the Health Minister) be excluded from the purview of his department.

In a memorial presented in July, 1914, to the Local Government Board, and supported by half the House of Commons, it was expressly urged that to promote the recovery of early uncertifiable mental cases it was both inexpedient and inappropriate that the recuperative hostels or sanatoriums designed for them should have any connexion with the Lunacy Board. The Lunacy Act, 1890, confers on the Commissioners no jurisdiction over any but the certified—that is, the incarcerated—and the protection of the helpless (if properly attended to) will give abundant scope for their energies. It is a sacred trust, involving serious responsibility.

In the communication of April 10th it is noted that the Lunacy Board desires "permissive legislation enabling early mental cases to receive treatment for six months in general or special hospitals or homes without the necessity for certification." I fail to see where any need for legislation to this end arises. General or special hospitals or borough hostels can, under the present law, receive and treat uncertifiable cases at any time, and for any length of time, where no detention is intended. That is the crux. A patient under the Lunacy Act, S. 74, can only be justifiably detained if he is proved to be "dangerous and unfit to be at large." It is somewhat difficult, on p. 516, to disentangle the meaning of one or two sentences dealing with the "detention of patients as voluntary boarders"—apparently a contradiction in terms.

It is, no doubt, a very convenient arrangement for the proprietors of mental homes to have patients consigned to them for detention on the sole recommendation of one doctor (p. 515), without any judicial investigation or appeal. But the ordinary outlook of the public (as the said article sagely comments) has also to be reckoned with, displaying as it sometimes does "a meticulous care for the liberty of the individual." As an instance, recall the defeat of the "Mental Treatment Bill," proposed by the Lunacy Board in 1915.

In devising expedients to evade certification (on the plea of evading "stigma") it is overlooked that the legal procedure of certification constitutes the main bulwark against false imprisonment; and it is highly dangerous to tamper with such safeguards. Better the risk of an evanescent stigma than the peril of a lifelong submersion in helpless misery. It is not the safeguarding procedure of certification that stigmatizes, but the degrading element entailed in detention, coupled with unnecessary indignity, and the loss of all personal and civil rights.

The one hope of an effective check to the constant increase of insanity is the natural and reasonable provision of untainted homes (kept carefully apart from any link with lunacy) which shall afford hope, encouragement, and freedom from apprehension, with bodily care and attractive surroundings, appropriate to the restoration of those highest faculties often tem-

porarily unhinged from quite natural and sufficient causes. Such is the path of common sense. It is a pity that legislation should be invoked to destroy the usefulness of these health-giving methods. Mental homes for uncertifiable cases, free from detention, should immediately be started by the Health Ministry under suitable local committees, on a purely hospital footing. Patients would be controlled during their stay by the rules of the place, but be free to leave on giving a specified notice.

Ex-service men cannot be said to be specially enamoured of the so much admired regimen of military mental hospitals. Cases of acute transient mania—for example, influenzal, puerperal, etc.—ought to be treated in hospitals as delirious cases.

Money spent on half-way houses to asylums will be simply thrown away; whereas mental sanatoriums as above described would prove not only an immense boon to the community and a benefit to doctors, but by their adaptation to the needs of early cases would intercept them on the downward track, and tend eventually to a material reduction in our present huge and unproductive asylum expenditure.—I am, etc.,

London, W., April 17th.

S. E. WHITE, M.B., B.Sc.

THE DEATH OF DR. A. P. SPELMAN: A MOVING APPEAL.

SIR,—I take the liberty of appealing to you on behalf of the widow and children of the late Dr. A. P. Spelman of Dunmore, co. Galway. Last week, when returning from a call, his motor car skidded at a badly protected part of the road, and overturning killed him instantly. The deceased was only 26 years of age, and had not his life insured in any way.

Mrs. Spelman and two young children are now left absolutely destitute and totally unprovided for, and in these circumstances I would appeal to your readers for their help.—I am, etc.,

P. J. DELANEY, M.B., B.Ch.

Claremorris, co. Mayo, May 4th.

P.S.—We are circularizing all the local doctors. Subscriptions, which will be duly acknowledged, may be sent to myself or Dr. Heneghan, Ballindine, co. Mayo.

The Services.

HONOURS.

TERRITORIAL DECORATION.

The Territorial Decoration has been conferred upon the following officers of the R.A.M.C., T.F., under the terms of the Royal Warrant of August 17th, 1908, as modified by the Royal Warrant of November 11th, 1918: Lieut.-Colonel Alexander G. Hamilton, O.B.E., and Major Douglas C. L. Orton, attached Welsh Mounted Brigade Field Ambulance; Major Vyner Graham, attached 5th Battalion Yorkshire Light Infantry; and Major George P. Chappel, attached 7th Battalion Middlesex Regiment.

FOREIGN DECORATIONS.

The following decorations have been conferred by the Allied Powers in recognition of distinguished services rendered during the course of the campaign:

By the King of Italy.

Order of the Crown of Italy (Cavaliere).—Br.-vet Major Arthur D. Griffith, R.A.M.C., T.F.

By the King of Serbia.

Order of St. Sava.—1st Class: Colonel Sir Almoth Wright, K.B.E., C.B., F.R.S., late A.M.S. 4th Class: Major Cuthbert Lindsay Dunn, I.M.S.; Surgeon Lieut.-Colonel Basil Pares, Royal Horse Guards. 5th Class: Captain (acting Major) Robert Patrick Starkie and Captain Gilbert Wolridge Rose, R.A.M.C., S.B.; temporary Captains Edward William Archer, George Herbert Brown, John William Grice, Ernest Eugene Herga, M.C., Orme Stirling Kellett, Frank Harold Looney, Edward Holmes Rainey and William Johnston Sykes, R.A.M.C., Gerald Spencer Coghlan, M.B.E., S.A.M.C., and the late temporary Captain Arthur Maxwell Fisher, R.A.M.C.

AUXILIARY ROYAL ARMY MEDICAL CORPS FUND.

THE annual meeting of the Auxiliary R.A.M.C. Fund was held on April 30th, when Lieut.-General Sir John Goodwin, D.G.A.M.S., was in the chair.

Since the last annual meeting the sum of £1,974 has been granted to help in the maintenance of the orphans of 31 officers in the Auxiliary Royal Army Medical Corps who lost their lives as a result of the war; and £2,620 has been granted in the same way to the orphans of 83 of the rank and file, making a total of £4,594 granted and 114 cases relieved in a single year. As frequently several children in a single case were relieved, it will be seen that the total number of persons relieved was considerable.

The major part of the income of the fund is derived from subscriptions, and the committee earnestly hopes that these will continue to be sent to the Honorary Secretary, 11, Chandos Street, Cavendish Square, London, W.1.

DEATHS IN THE SERVICES.

MAJOR LLEWELLYN LANCELOT GRAEME THORPE, R.A.M.C., died at Whitstable on April 23rd last, aged 46. He was the younger son of the late Captain Edward Thorpe, of the 43rd Foot and 27th Madras Infantry, and was educated at University College, London. He entered the R.A.M.C. on June 21st, 1900, and became major after twelve years' service.

Captain Robert Gordon Ball, R.A.M.C., died in Dublin on February 3rd. He was educated at Trinity College, Dublin, where he graduated M.B. and B.Ch. in 1911, and was a member of the West African Medical Staff till he took a temporary commission in the R.A.M.C. as lieutenant on August 14th, 1917, becoming captain after a year's service.

Major Satis Bose, I.M.S., died at Barrackpore, where he was in command of the Indian Station Hospital, on January 5th. He was educated at Edinburgh, where he graduated M.B. and C.M. in 1897, and entered the I.M.S. as lieutenant on June 27th, 1901, becoming major in December, 1912.

Brevet Major Gwilym Gregory James, I.M.S., died on December 19th, aged 35. He was born on June 24th, 1884, and educated at Westminster Hospital, graduating M.B. and B.S. Lond. in 1907. After filling the posts of demonstrator of histology and house-surgeon at Westminster, and of second assistant medical officer at St. Marylebone Infirmary he entered the I.M.S. on January 30th, 1909, and was promoted to captain after three years' service. He was medical officer of the 127th Baluch Infantry, and served in that capacity during the war, being mentioned in despatches in the *London Gazette* of August 15th, 1917, and receiving a brevet as major on January 1st, 1918.

Universities and Colleges.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

D.P.H.—Margaret H. Grant, G. H. Gunn, R. F. Lund, A. B. MacDougall, J. M. Ritchie, J. M. Young.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examinations indicated:

SURGERY.—*G. S. Ashby, *C. C. Bennett, *A. G. L. Brown, *A. Furniss, *M. Ibrahim, *A. L. Urquhart.

MEDICINE.—R. E. Laurent, *M. Pigott, *A. L. Urquhart.

FORENSIC MEDICINE.—E. Brazao, J. A. Cohen, M. Pigott, A. L. Urquhart.

MIDWIFERY.—E. Brazao, J. A. Cohen, A. McKenzie, M. Pigott, R. M. Rodriguez, W. H. Summerskill, A. L. Urquhart.

* Section I. † Section II.

The diploma of the Society has been granted to Messrs. M. Ibrahim, M. Pigott, and A. L. Urquhart.

Obituary.

CROYDON has sustained a great loss by the death on April 12th of its late coroner, Dr. THOMAS JACKSON. Advancing years and ill health caused him, in July, 1919, to resign this office, in which he was succeeded by his son, Dr. Becher Jackson. Thomas Jackson was born at Torrington, North Devon, in 1846, and took the B.A. Lond. at the age of 21. In 1870 he was Congregational minister at Launceston, but his views on theological questions being in advance of those times he gave up the ministry. He obtained a scholarship at the Middlesex Hospital Medical School, and took the diplomas of L.R.C.P. Ed. and L.S.A. in 1877. He became M.R.C.S. in 1878, and was appointed resident obstetric officer at the Middlesex Hospital. He settled in practice at Thornton Heath. He was appointed coroner in 1889. A strong Liberal, he took a keen interest in local and other politics, and did much to improve the social condition of his neighbourhood, being largely instrumental in the opening of Thornton Heath recreation ground, the polytechnic, and the free library. He was one of the first aldermen of the borough of Croydon, and a justice of the peace. Much beloved, his death will be deeply regretted by all who came in contact with him. As a coroner he was always sympathetic, tactful, and kind, as a public man—although a keen fighter—always good-tempered, stimulating both friends and foes, and he lived long enough to see some of his ideals universally adopted. From all deepest sympathy will be with his widow and four children, two of whom are members of the medical profession.

WE regret to record the death of Dr. CHARLES AUGUSTUS THORNE, M.B.E., the senior medical practitioner in Dero and Totley, Derbyshire, which occurred on April 24th, in

his 63rd year. The cause of death was heart disease, brought on by continued overstrain during the war. For five years he served as M.O. to the Dore V.A.D. Auxiliary Hospital, and his kindness to the wounded will long be remembered by them. He devoted all his spare time to the wellbeing of the "Boys in Blue"; and two or three were generally to be seen accompanying him on his long country rounds. He also served on the Recruiting Board in Sheffield. In civil practice he was beloved by rich and poor alike, and served the district for long faithfully for about thirty years. He took the L.R.C.P., L.R.C.S. Edin. in 1885, previously he had served as a cadet in the Royal Navy. In later years he became a county magistrate, and was also medical officer to the Ecclesall Union and Cherry Tree Orphanage. He was laid to rest in Ecclesall on April 26th, large numbers of his old friends and patients attending the funeral.

THE death of Dr. HENRI TRIBOULET calls for a few words of tribute to his memory, if only because he was the honorary secretary of the committee in Paris which arranged the visit of French doctors to London in October, 1904, the first evidence of the growing sympathy between the two countries, which came to fruition in the *entente cordiale*. Those British doctors who shared in the return visit to Paris in the following spring will recall that the perfection of the arrangements in Paris was largely due to his organizing powers. Dr. Triboulet was born in 1864 and began practice in Paris in 1893. He became *médecin des hôpitaux* and devoted himself specially to the study of diseases of children, a subject to which he made many important contributions. He was joint author also of a *Traité de l'alcoolisme*, published in 1905, in which that difficult subject was treated with scientific impartiality. It was, however, as a practising physician, and more especially as a teacher, that Dr. Triboulet attained distinction. His enthusiasm, his high standard of conduct, and his conscientious devotion to duty, endeared him to all his pupils. He died, after a long and painful illness, last February.

DR. JOHN KERR BUTTER of Cannock passed away on April 29th after an illness of ten days, in which erysipelas and kidney trouble played a leading part. He received his medical education in the University of Aberdeen and graduated M.B., C.M. in 1879 and M.D. in 1881. He settled at Cannock, Staffordshire, in 1887; as police surgeon he established a wide reputation, and was considered an excellent witness in medico-legal cases. He also did much useful work for the St. John Ambulance Association both as lecturer and examiner. He was a man of fine physique; he possessed in a marked manner a racy Scottish humour, and was well versed in Burns literature and song. He established a fine collection of animals and birds. The funeral service was in Cannock Parish Church on May 4th, and the thousands who thronged the streets of Cannock testified to his popularity in the district. The body was taken to Glasgow for cremation.

WE regret to record the death, which took place very suddenly on April 24th, at the age of 53, of Dr. RICHARD LUMLEY ROBERTS, of Bethesda, North Wales. He was born in London in 1867, and afterwards lived at Plas Hwfa, Talybont; he was educated at Guy's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. in 1896. He was greatly respected in Bethesda, where he enjoyed a large practice. Dr. Lumley Roberts, who was a member of the North Carnarvon and Anglesey Division of the British Medical Association, leaves a widow and one child.

LIEUT.-COLONEL WILLIAM KINGTON FYFFE, New Zealand Medical Corps, died at Wellington, New Zealand, after an operation, on April 23rd. He was the eldest son of the late Deputy Surgeon-General William Johnston Fyffe, R.A.M.C., and was educated at Cambridge and St. George's Hospital, graduating B.A. in 1885, and M.B. and B.C. in 1890, also taking the L.S.A. in 1890, and the M.R.C.P. Lond. in 1893. After serving as house-physician and medical registrar at St. George's, and assistant physician and pathologist at the Victoria Park Hospital for Diseases of the Chest, he went to New Zealand, where he settled in practice at Wellington. He served at Gallipoli as medical officer with the 4th New Zealand contingent.

Medical News.

SIR ST. CLAIR THOMSON, M.D., has been awarded the Médaille de la Reconnaissance Française in silver for valuable services as a specialist in laryngology.

DR. JAS. SCARTH SPENCE LOGIE of Kirkwall, who took the diploma of L.R.C.P. Edin. in 1841 and graduated M.D. in 1842, celebrated his 100th birthday on May 11th. Among the congratulatory messages received was one from the King.

THE annual general meeting of the Chelsea Clinical Society will be held at St. George's Hospital Medical School on Tuesday, May 18th, at 8.30 p.m., when the retiring president, Dr. T. B. Hyslop, will deliver an address.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Tuesday, June 8th, at 7.45 p.m., Major-General G. F. A. Harris, C.S.I., in the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 63, Addison Road, Kensington, W.14.

SIR ROBERT ARMSTRONG-JONES will begin a course of four Gresham Lectures on physic, at Gresham College, Basinghall Street, E.C., on Tuesday, May 18th, at 6 p.m. The subject of the course is "The vegetable parasites affecting man, and the diseases caused by them." Admission is free.

AT the Congress of Dermatology and Syphiligraphy, held at Rome last December, a proposal was made to found a biennial prize named after the well-known specialist, Professor Tommaso de Amicis, for the best Italian work on dermatology. Professor Ducrey, of the University of Rome, was elected President for the forthcoming session.

THE final arrangements for the Congress of the Royal Institute of Public Health in Brussels have now been made. The inaugural meeting on Thursday, May 20th, will be attended by the King of the Belgians. On the previous evening the delegates and members will be received at the Palais des Académies by the Brussels Organization Committee. There will be seven sections, in all of which papers will be read and discussions held. Full particulars can be obtained from the honorary secretary, 27, Russell Square, London, W.C.1.

THE programme for the fourteenth French Medical Congress, which will be opened in Brussels on May 19th, is now complete. The chief subjects for discussion are syphilis of the cardio-vascular system, the importance of lipoids in pathology, and the value of artificial pneumothorax. Further particulars can be obtained on application to the Secrétaire-Général, 22, rue Joseph II, Brussels. An excursion to Yser and the Flanders battlefields will be made on the Sunday and Monday following the meeting.

IN a circular letter, dated April 23rd, addressed to local and port sanitary authorities, the Ministry of Health expresses its anxiety to obtain appointments for discharged and disabled officers and men who have been trained by the Ministry of Labour as sanitary inspectors and inspectors of nuisances. It is not suggested that preference should be given to these men over sanitary inspectors who during the war joined the Services or were on public grounds retained in civil employment; where, however, no such suitable candidates offer themselves, the local authorities are asked, in filling vacancies, to appoint men trained under the scheme of the Ministry of Labour.

SIR ARTHUR STANLEY, chairman of the Joint Council of the British Red Cross Society and the Order of St. John, in speaking to the Incorporated Association of Hospital Officers last week, said that there were two alternatives for the hospitals at the present time. The first was that they should be taken over by the State or the municipalities; the Minister of Health had given the most explicit assurances that the Government did not contemplate this course, and would regard the disappearance of the voluntary system as a calamity. The municipalization of hospitals, which meant that they would be supported by the rates, was an unsatisfactory proposal, especially when regard was had to the heavy municipal rates already imposed. The alternative to State or municipal support was the development of the voluntary system. He estimated that at present only 10 per cent. of the population of the country contributed in any way to the hospitals; that 10 per cent. was finding about two-thirds of the total hospital expenditure, and he was sanguine that the deficiency of one-third could be made up from 10 to 20 per cent. of those who did not now subscribe.

THE house of the Royal Society of Medicine will be closed from Saturday, May 22nd, to Tuesday, May 25th, both days inclusive.

DR. A. G. WILKINSON, who this year has completed his eighty-fifth birthday and his fiftieth anniversary as a medical practitioner in Northampton, was presented on May 3rd with a cheque for £150 and an illuminated address as a mark of esteem by his many friends and patients in the district.

DR. J. S. FRASER (Edinburgh) will give a lantern demonstration of microphotographic slides illustrating diseases of the internal ear, at the Central London Throat and Ear Hospital, Gray's Inn Road, on Thursday, May 20th, at 5 p.m.

TUBERCULOSIS officers are invited to attend a meeting at 1, Upper Montague Street, Russell Square, W.C.1, on Friday, May 28th, at 3 p.m., when a proposal to form a Tubercle Group within the Society of Medical Officers of Health will be discussed.

THE Publication Committee of the Zoological Society has issued a notice calling the attention of those who propose to offer papers to the great increase in the cost of paper and printing. This, it is stated, will render it necessary for the present that papers should be condensed, and be limited so far as possible to the description of new results.

M. LLE. SENTIS and M. Rimband reported to a recent meeting of the Montpellier Medical Society a case of poisoning by veronal in a hysterical person who presented symptoms—somnia and paralysis of the ocular muscles—suggestive of lethargic encephalitis.

AT an inquest held at Southport it was found that a man had died from poisoning by potassium bichromate. A friend had recommended him to take "bi-something of potash" for neuritis, and in mistake he purchased from the chemist bichromate instead of bicarbonate.

A DEPUTATION from the London and Counties Medical Protection Society, Ltd., was received by Dr. Addison at the Ministry of Health on May 6th. The deputation was introduced to the Minister of Health by Lieut.-Colonel F. E. Fremantle, M.P. The chairman of the society, Dr. C. M. Fegen, on behalf of the deputation, urged upon the Minister the necessity for early legislation to protect the medical officers of venereal disease clinics from being compelled in the witness box to violate the established principles of professional secrecy and to give information of the nature of their patients' ailments and of anything else which came to their knowledge in their professional capacity. These medical officers were being compelled in the law courts, under penalty of imprisonment for contempt of court, to reveal what their patients had communicated to them believing that the information would be treated as absolutely confidential. The effect of this, it was urged, would be disastrous to the working of the clinics, and would militate against the efforts at present being made to cure and eliminate venereal disease. Dr. Addison expressed his cordial agreement with the views of the deputation, and promised to do what he could to promote legislation as suggested by the deputation. He said that he felt sure that public opinion would support the maintenance of professional secrecy in connexion with venereal disease clinics.

TO celebrate the centenary of the birth of Florence Nightingale, who was born on May 12th, 1820, an appeal has been issued to complete the fund for the National Tribute to the Nurses. The appeal is signed by the three matrons-in-chief of the Army, of the Territorial Force, and of the Expeditionary Force during the war, and by the head of the Nightingale School at St. Thomas's Hospital, which was endowed with the proceeds of another fund established by Florence Nightingale after the Crimean war. The object of the appeal is to raise £20,000 to complete the endowment of the College of Nursing, and to create a benevolent fund for the relief of nurses in old age, sickness, or unavoidable pecuniary trouble. "In no way," the matrons-in-chief say, "could the hundred years be more fittingly commemorated than by completing the Nation's Tribute to Nurses, and as the biography of this leader of nurses shows, she was ever mindful of the well-being of those engaged in nursing. We would appeal to all those who realize the value of the gentle ministrations of the trained nurse, to honour the memory of one of England's greatest daughters by sending a contribution of one shilling or more to Miss C. May Beaman, 10, West Bolton Gardens, S.W.5 (Honorary Organizer); or Miss Lloyd Still, Nightingale School, St. Thomas's Hospital, S.E."

Letters, Notes, and Answers.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bocallus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

G. B. E. asks for references to recent literature on the treatment of psoriasis, and whether salvarsan has been used with success.

"BACK NUMBER" asks for opinions as to the prognosis and treatment of pseudo-hypertrophic muscular paralysis. The case, a boy aged 12, is in the early stage, without any sign of hypertrophy.

G. P. Lances., asks for suggestions for treating a lady of 25 who suffers periodically from a "clicking in the ear," after which "her voice seems peculiar," and as she breathes she "hears the passage of the air." To put the ear right she has to hold her nose and "draw in"; she is only free from these symptoms when she has a cold. There is no deafness, and the nose and throat are normal except for slight pharyngeal catarrh; she has no hysterical tendency.

INCOME TAX.

A. R. has been informed by the local inspector of taxes that he cannot be allowed as a deduction from his gross receipts more than one-third of his rent or of the wages and maintenance of the extra maid who attends to the surgery. Is there a chance of successful appeal?

* A. R. is entitled to deduct a reasonable proportion of the expenses—provided that in the case of the rent it does not exceed two-thirds. So far as our experience goes, one-half is generally allowed in provincial practices, and unless there are special circumstances in the case we consider that A. R. would have a reasonable prospect of success if he presses for that proportion.

A. B. X.—When husband and wife both practise as doctors, what allowances can each claim for rent, rates, servants, etc.; also for repairs to the house? Is it any advantage for them to keep separate books, and make separate claims?

* Assuming that there is a certain amount of connexion between the two practices, separate claims could not be made, and there would be no advantage gained by keeping the accounts of the two practices apart. The proportion of the general expenses applicable to the practices would depend upon the facts, but of course the same expenditure could not be deducted by each—for example, each could not deduct half the rent. Probably the most that would be allowed would be from one-half to two-thirds the rent; the cost of one servant, and the estimated cost of lighting and heating the waiting-room and surgery. The proportion for repairs would be the same as for rent, subject to any special facts—for example, if the bedrooms were papered and not the surgery, or vice versa, the result is obvious.

R. A. M. was in the forces of the Crown during the financial years 1917-18 and 1918-19, and in 1919-20 has been doing work as an assistant, and later was employed on a sessional basis by the Ministry of Pensions on Medical Boards. What is the proper basis of liability for 1919-20 and the future?

* We have been informed that where a person was in a definite "employment" and after service in the forces has returned to similar work even under a different "employer," he is allowed to average the army or navy emoluments with his civil earnings; if, therefore, E. R. A. M. was acting as an assistant in 1916-17 and had continued to act in that capacity during 1919-20, he could properly have returned his earnings at £516—on the average basis. We agree, however, with him, that his employment is casual and therefore akin to private practice—for example, there is no continuity of engagement even for part time—and on that construction of his agreement with the Ministry of Pensions a different result follows; he is assessable for 1919-20 on the basis of that year's earnings, for 1920-21 on the same amount, for 1921-22 on the basis of the

average of 1919-20 and 1920-21, and thereafter on the ordinary three years' average. This assumes, of course, that he does not change the nature of his work—for example, by taking a share in a partnership. E. R. A. M. points out that undue effect may be given under such an arrangement to an unusually high level of earnings in 1919-20, but this is met by a provision in the Income Tax Acts which gives him the right to discard the statutory basis in favour of the earnings of the actual year if they should prove less; that right exists until the year 1919-20—that is, the first year—has disappeared from the basis of the assessment.

LETTERS, NOTES, ETC.

ASPHYXIA FROM INHALATION OF TOBACCO SMOKE.

MR. SOMERTON CLARK, F.R.C.S.E. (formerly C.M.S., Dera Ismail Khan, N.W.F.P., India), writes: During five years' work in Dera Ismail Khan I observed a few cases of a condition which, I believe, has not previously been described. These cases only come for the treatment of burns in the Ramzān (Mohammedan Lent). The patients are men in the prime of life who have ridden long distances across the desert in the later part of the Fast and arrive at their destination exhausted. As they are prohibited from eating or drinking between sunrise and sunset they seek comfort by smoking. They light their hubble-bubbles at a fire and fill their lungs with smoke, till they become asphyxiated and tumble into the fire, burning the left arm and the left side of the face. These cases are not epileptic.

A RECORD TRAMP?

COLONEL FRED. E. BURNHAM, M.D., President of the Canadian War Hospital Fund, writes from Field Head Quarters at Dulcigno, Montenegro, as follows: On April 23rd I had occasion to travel from Dulcigno to Antivari. The usual means of conveyance having for the moment failed, to walk was the only alternative. Accordingly I set out at 4 a.m. and reached Antivari at 8.40 a.m., having traversed twenty-three miles in 4 hr. 40 min. Even among these hardy mountaineers this is looked upon as an achievement. After twenty-six years in the practice of medicine and surgery this may be considered a fairly good demonstration of physical fitness. I am curious to hear of similar efforts by any who have been a quarter of a century in the practice of medicine. In the many journeys which I have made through the Balkans both by day and by night since the beginning of the war, as a rule the mind has not been allowed to rest on time or distance. In the instance above there was no thought of making a record.

READING BY EAR.

DR. FOURNIER D'ALBE published in *Nature* of May 6th a description of the instrument for reading by ear, to which the name optophone has been applied. By means of an ingenious optical system a line of luminous dots is thrown on the print, each dot having a different musical frequency. The light constituting these dots is reflected back on to a tablet of selenium. Those dots of light which fall on white paper produce a note of their own musical frequency in the telephone, while those which fall on black are extinguished. A "white-sounding" optophone is thus obtained, in which the black letters are read by the notes omitted from the scale. With this a blind girl was able to read habitually at a speed of about twenty-five words a minute. By a modification of the instrument it had been found possible to obtain a "black-sounding" optophone, which would probably make it easier to learn the alphabetical sounds.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 37, 38, 39, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 35, 36, and 37.

The following appointments of certifying factory surgeons are vacant: Blackford (Perth, Campbeltown (Argyll), Gravesend (Kent).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	7	6
Each additional line	0	1	3
Whole single column	6	0	0
Whole page	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

A Clinical Lecture ON CHRONIC PAROXYSMAL TRIGEMINAL NEURALGIA AND ITS TREATMENT.*

BY

WILFRED HARRIS, M.D. CANTAB., F.R.C.P.,

SENIOR PHYSICIAN, ST. MARY'S HOSPITAL; PHYSICIAN, HOSPITAL FOR
EPILEPSY AND PARALYSIS, MAIDA VALE.

THE subject of these lectures has been revised and brought up to date in order to present results of my experience of the treatment of this disease during the last twelve years.

Trifacial neuralgia, chronic trigeminal neuralgia, tic douloureux, or neuralgia major of the fifth nerve, as it has been variously described, is an inveterate and violently painful paroxysmal neuralgia, affecting, in the majority of sufferers, one side of the face only. In by far the larger number of sufferers the pain is referred to the territory of the second or the third division of the fifth nerve—that is to say, roughly, the upper jaw and cheek, upper lip and side of the nose for the second division, and the lower jaw, lower lip, and perhaps the side of the tongue for the third division. In a considerable proportion of cases the second and third divisions of the nerve are both affected, and the pain will not cease, or ceases only for a time, if one of the divisions alone is treated. In a small proportion of cases the supra-orbital branch of the first division is involved, scarcely ever alone, but in addition to neuralgia affecting the second division or the second and third divisions. Supraorbital neuralgia alone is usually due to temporarily acting causes, such as influenza, malaria, or other fevers, or to such causes as errors of refraction, frontal sinusitis, migrainous neuralgia, and many others, and it must be distinguished from the chronic paroxysmal and inveterate disease known as trigeminal neuralgia. The pathology of this disease is somewhat obscure. What is certain is that there is no disease to be detected by hitherto known methods, either in the nerve centres of the brain, Gasserian ganglion, or main branches of the fifth nerve. The undoubted fact that efficient interruption of the conduction of afferent sensations along these branches of the fifth nerve gives instant relief to the neuralgia appears to me sufficient proof that such neuralgia is dependent upon stimuli affecting the nerve endings at their periphery.

The results of destruction of the ganglion as compared with neurectomies or alcohol injections below the ganglion differ only in the degree of their permanence—that is to say, operations on the nerve trunks, however complete at the time, are always followed by some re-establishment, sooner or later, of nerve conduction through downgrowth of nerve fibrils from the ganglion cells above. If, on the other hand, the ganglion is thoroughly destroyed by any means, the anaesthesia of the fifth nerve territory is permanent, and the cure of the neuralgia is correspondingly complete.

The nature of these stimuli from the periphery in this neuralgia is a matter of speculation, but it seems highly probable that they are due to septic neuritis of dental nerve filaments, the result of previous dental caries, pyorrhoea, or abscess around the roots; and recently in a case of this chronic neuralgia a piece of the maxilla was removed for me by Mr. Warwick James under the most careful aseptic precautions, and a pure growth of streptococci was obtained.

I have been impressed, in taking the histories of cases, by the number in which the pain has definitely started immediately after dental operations or antral abscess. No other nerve in the body, except the second and third divisions of the fifth nerve, is so liable to chronic infection of its branches, and although in some cases even many years have elapsed between the loss of a tooth and the onset of the neuralgia, yet this does not exclude septic neuritis from dental infection as the cause, and when the infection has thus spread backwards into the dental filaments within the jaw it is easily understandable that removal of the tooth does not cure the neuralgia; indeed, it often makes it worse.

* The substance of two lectures given for the Fellowship of Medicine at the Royal Society of Medicine (June, 1919).

Causes.

During the last twelve years I have seen a large number of cases of chronic trigeminal neuralgia, and I have analysed my records of over 312 cases, 230 in private practice and 82 hospital cases. I have, in addition, seen and operated upon a considerable number of hospital cases whose records are not available or are inadequate. Some curious points come out in my analysis which I have never seen referred to in other writings on the subject. The proportion of women affected to men is 62 per cent. to 38 per cent., or about three women to two men, while of the unilateral cases of neuralgia, which of course form a very large majority, the right side is affected in correspondingly greater frequency—namely, 62 per cent. to 38 per cent. This excess of right-sided cases over left-sided obtains in each group of men and of women, both in private cases and in hospital cases, and, moreover, in each separate year of the eleven years I have analysed a somewhat similar excess of right-sided cases over left is seen. I cannot therefore look upon this difference in frequency of incidence on the two sides as accidental; what its cause can be it is not easy to say.

I do not know whether any statistics are available of the relative frequency of dental caries on the two sides. Other factors, too, have to be taken into account which may act as the exciting cause for the origin of trigeminal neuralgia. I have already spoken of dental operations originating the pain in a certain number of cases, such as fracture of teeth and difficult stump extractions. In ten of my cases severe *chill* to the face, as by motoring in a cold wind, was the immediate precursor of the original spasms of pain; in five cases intense *emotion* immediately preceded the first attack. A woman was shocked by being told that her child, who was playing in the roadway, had been run over by a motor car and taken to the hospital. She immediately hurried off to the hospital, and on reaching there three-quarters of an hour later heard that her child was dead; at the same time a spasm of violent neuralgia struck her in the right lower jaw, the pain continuing at intervals until I saw her two years later, and was able to arrest it by injecting the third division of the fifth nerve with alcohol.

Still another cause of onset of this terrible neuralgia is a *blow* upon the jaw or face; this occurred in six of my cases. For example, a young woman, aged 27, was stooping to pick something off the floor when another girl's head struck her violently on the lower jaw, making her teeth clash and rattle, as she said. About three hours later, when she had just mounted on to the top of an omnibus, she was suddenly seized with the most excruciating pain in the face, which made her behave so wildly that she said she was like a mad woman, and had to be taken off the bus. The paroxysm lasted altogether some ten minutes, but recurred again and again in the manner characteristic of trigeminal neuralgia until I saw her and injected the third division of the nerve some years later.

Such suddenness and violence of onset of the spasms of pain are extremely characteristic of this peculiar form of neuralgia, and I have notes of some forty-six cases in which this was the case. One of apparently the most severe cases of pain I have ever seen began in this way. She was a cook, aged 45, who in her spasms of neuralgia lost all control, and screamed and threw herself about. Six years previously her first attack occurred, without any warning one night at 3 a.m., when she was awakened with the most awful agony in her face. Her screams awoke the whole household; a doctor had to be sent for, and she was kept under morphine almost continually for three weeks. She got no relief from any drugs until I injected the second and third divisions of the fifth nerve with alcohol; this gave her complete relief for two years. Recurrence and reinjection with alcohol again gave her two years' freedom from pain, when I injected her Gasserian ganglion with alcohol, since when she has been completely free for several years.

In other patients the pain may at first be mistaken for dental neuralgia, but the spasms of pain gradually increase in severity, in spite of the removal of teeth, until at last it is realized that the neuralgia is of the graver inveterate type.

Age.

The age of onset of the disease varies very widely in my experience, the oldest being 85 when the disease

commenced. In two cases, both females, the severe neuralgia began at the age of 17; one of them had suffered from neuralgia of the third division for twenty years when I saw her, temporary relief only having been obtained by a division of the inferior dental nerve. Alcohol injection of the third division ten and a half years ago gave her complete relief, which still persists. The other patient was a lady aged 70 when I saw her for the pain; she had suffered almost constantly for fifty-three years; in her case injection of the ganglion was done under chloroform two and a half years ago, causing total anaesthesia of the fifth nerve and complete relief of all pain, which should be permanent.

The onset of the neuralgia is rare under the age of 30, though I have seen eleven other cases commence before the age of 30, at the ages of 20, 21, 22, etc. The average age of onset in 205 of my cases is almost exactly 50. Once the disease has started it is practically certain that permanent cure can only be obtained by destruction of the nerve trunks involved, or of the ganglion itself. In only two instances have I known the neuralgia disappear spontaneously, after existing a number of years. One was the father of a lady whom I injected for typical neuralgia, and she told me that her father suffered from the same spasmodic pains from the age of 65 until he was 90, when the pains gradually left him, so that he was free from the neuralgia during the last twelve years of his life, for he died at the age of 103.

In a number of cases a considerable interval may elapse between the first onset of the neuralgia and its subsequent establishment. A lady had severe spasmodic pain in her left lower jaw at the age of 45, lasting for nearly two years, when it left her for thirty years, recurring severely after exposure to a cold wind when driving. After the pain had continued for nine weeks I injected the left Gasserian ganglion. I have notes of similar intervals of twenty years, seventeen years, nine years, seven years, and so on.

Heredity.

I have noticed heredity as a factor of trigeminal neuralgia in five cases. I have already referred to one patient, a lady of over 60, whose father suffered for over twenty-five years from this form of neuralgia, and then outlived it. In another instance I have treated a mother over 70 years of age, who suffered for many years with bilateral neuralgia, mostly of the third division. Injection of the nerve at the foramen ovale gives her about two years' freedom from pain. One of her daughters at the age of 36 began to suffer in a similar manner with spasmodic neuralgia of the right third division. I saw her for this soon after the pain began, and recommended drug treatment and rest; this, however, failed entirely. I did not see her for three years, the pain having continued all that time, and she told me she had been twice injected by another physician without any relief, as the nerve could not be found. I then injected the third division at the foramen ovale, causing complete anaesthesia of its distribution and immediate cessation of the pain, from which she has now been quite free for three and a half years. In my other three patients—two men and one woman—it was the mother in each case who was said to have suffered from typical trigeminal neuralgia for many years. In investigating such histories one must be careful to distinguish between migraine and the true trigeminal neuralgia.

Chill.

I have already referred to chill as being the exciting cause of the first spasms of the neuralgia in ten cases. One illustration will suffice. A woman, aged 50, drove twenty-five miles in an open dogcart through a blizzard, snow, and icy cold wind to Exeter. The same evening, about 9 o'clock, while she was having supper, intense neuralgia struck her lower jaw, the pain being on the same side as had been exposed to the wind. This was the beginning of a severe case of trigeminal neuralgia which continued for several years until I saw her. In numerous other instances exposure to a cold wind or draught will restart the paroxysms of a neuralgia which has become dormant, and, indeed, cold wind or draught may be said to be the worst enemy of these subjects of neuralgia.

Although chill has such a bad effect upon trigeminal neuralgia it is surprising that subjects of this disease have

not special immunity during hot weather, and it is extremely common for patients to say that the time of year makes no difference to their pain, and it is waste of time and money to send such patients for treatment to a hot climate.

"Warnings."

I have referred to the absolutely sudden onset of the disease in numerous cases. Three of my cases have described a warning by which they recognize the imminence of a period of severe attacks. A lady, aged 64, had suffered from right lower jaw neuralgia for ten years, made worse by extraction of the teeth. Alcohol injections by Horsley gave no relief. As she says no numbness of the face was produced, the nerves were no doubt not injected. She says she has always noticed a burning sensation on the top of the head for some days before the neuralgia attacks commence. Alcohol injection, in May, 1916, of the second and third divisions relieved her pain entirely, the relief still persisting. In another case, a man whom I injected at the age of 39, with neuralgia of the left second and third divisions, seven years ago, used to get a warning, for a day or two before the neuralgia attack, of constipation and sensation of swelling in the gums.

Another patient, a lady aged 54, says she always gets a shivering sensation along the right cheek before the pain starts. She had lost all her teeth twenty-seven years before the pain began.

Character of the Pain.

The suddenness of onset of neuralgia is often likened to an electric shock; one patient thought she had bitten on to a needle, another that she had broken a tooth. Some speak of a stinging pain at the commencement. Very many describe the pain as hot, "like a lot of red hot bradawls being pushed up," "flickering," "hot," "like daggers," "like a hot knife or needles being run into the forehead." In others the pain starts with a tacking sensation or tapping, scarcely painful at first, but rapidly getting worse, until the pain "explodes along the nerve like fireworks or hot electric wires." The severity of the attacks must be witnessed to be appreciated, and patients get little sympathy or credit for their suffering, except from others who have seen them in it. Some patients lose all control of themselves in the attacks, screaming out, fighting, and struggling. In others the jaw becomes fixed, perhaps wide open, and saliva may trickle from the mouth.

One patient described the commencement of her attack as having suffered for two days with severe agony in a tooth; she thought such pain was impossible, had two teeth out, but was no better for a week; since then she has been subject to repeated attacks in which the pain stings into the right side of her tongue. She calls it a "hellish pain," and says it has destroyed her nerve, and she feels during the attacks as if she could smash everything, or commit suicide. Indeed, before the remedy was devised for this pain in the operation of gasserectomy, and later by alcohol injection of the nerve trunks, suicide was not a very uncommon ending for sufferers from this dreadful disease.

So long as patients are able to take food they do not lose weight or suffer notably in health, but as soon as the neuralgic spasms are sufficiently frequent and severe to prevent the taking of food there is danger of rapid loss of strength from starvation, and it may be necessary for the patient to suck liquid nourishment through a straw or tube on the other side of the mouth, and to write instead of speak, because the spasms of pain are started by attempts at eating and talking.

Treatment.

Only a comparatively small number of sufferers from trigeminal neuralgia get relief from drugs. In a few gelsemium gives relief, though with the majority even morphine in large doses fails. Practically the only two methods are gasserectomy and alcohol injection. In my opinion the former operation should never be undertaken until alcohol injection has been thoroughly tried. During the last ten years I have injected the Gasserian ganglion with alcohol through the foramen ovale in 63 cases; in 31 the anaesthesia has remained total and no recurrence of pain has taken place. In many of the remainder partial

ganglion anaesthesia has persisted though pressure could be felt, yet the relief from pain appears to be equally good.

In many cases, though total ganglion anaesthesia is produced at the time of injection, yet the anaesthesia of the first and second divisions wears off, perhaps completely, in from ten minutes to an hour, though the third division remains totally anaesthetic. This is no doubt due to the ganglion cells having been shocked, and not destroyed, by a partial infiltration only. In such a case pain is liable to recur after twelve months or two years, as in a case of ordinary injection of the nerve. With total destruction of the ganglion there is the same liability to keratitis as with the operation of gasserectomy, but if the lids are kept carefully closed by strapping for the first week and the conjunctival sac washed out with boracic lotion twice a day, I have found little or no trouble with my later cases. The lids, however, should be kept closed from the beginning, and it is unwise to wait and see whether keratitis develops, as then it will be necessary to keep them closed for a much longer time.

Hutchinson's partial gasserectomy avoids the danger of keratitis, but is not a certain permanent cure, as I have seen three such cases relapse with neuralgia.

Bilateral Neuralgia.

Bilateral trigeminal neuralgia is comparatively rare, though I have seen and injected 25 bilateral cases, usually at different dates, but on several occasions I have injected both sides, one after the other.

Gasserectomy is an impossible operation for bilateral cases of trigeminal neuralgia, owing to the necessary destruction of the motor branch of the fifth nerve on each side and consequent jaw-drop. Alcohol injection has the advantage that the nerve injury is less complete, and the motor nerve fibres regenerate. In one case I produced jaw-drop for two and a half months, which recovered completely later. On December 10th, 1919, I injected the left Gasserian ganglion in a woman of 49, for neuralgia of the left upper jaw, whose right Gasserian ganglion I had previously destroyed by alcohol injection seven years previously. She was still totally anaesthetic over the whole right fifth distribution, just as much as in any case of gasserectomy, though in her case the motor branch had recovered well, and she had quite good right temporal, masseter, and pterygoid muscles. Injection of the left Gasserian has now produced in her case total anaesthesia of the whole of the face and front half of her head, though she can chew fairly well by means of the muscles on the right side, and those on the left side will doubtless recover also later. So far as I know, bilateral destruction of the Gasserian ganglia has never previously been done.

Method of Injecting Alcohol.

As regards the methods of practising alcohol injection, details have already been published and need not here be repeated, though I would like to insist on the advisability of using the method of trial and test. That is to say, when the needle is thought to have struck the nerve inject a few drops of 2 per cent. novocain, and, after waiting half a minute, test the skin distribution of the nerve for anaesthesia. If none has developed do not inject alcohol, but try again to find the nerve. As soon as anaesthesia appears to novocain injection, then complete by injecting about 1 c.cm. of 90 per cent. alcohol, when total anaesthesia to touch, pin, and pressure will develop almost instantaneously if the nerve at the foramen ovale or foramen rotundum has been correctly hit.

Results.

In almost every case, as soon as anaesthesia develops from the injection, the neuralgic spasms cease, and they can no longer be started by any chewing movements or rubbing the face.

The duration of the cure rarely lasts less than twelve months, if good anaesthesia has been obtained, and in the majority the relief from pain lasts from two to three years. Very many of my cases have been quite free for four or five years, one six and a half years, another seven years, another nine years after nerve injection only, while I expect my cases of ganglion injection to be permanent cures, just as if gasserectomy had been done. No trophic

effects on the skin are ever seen. Keratitis is a risk if the cornea is anaesthetic after injection of the ganglion, but this may always be avoided by proper precautions.

THE SIGNIFICANCE OF ACIDOSIS IN CERTAIN NERVOUS DISORDERS.*

BY

B. H. SHAW, M.D.,

MEDICAL SUPERINTENDENT, COUNTY MENTAL HOSPITAL, STAFFORD.

ACIDOSIS, as evidenced by the presence of acetone bodies in urine, is frequent in cases of acute delirium, confusional and stuporose states, certain melancholic conditions, and in epilepsy.

The following notes are taken from two recent deaths resulting from extreme acidosis:

1. E. J., a mischievous, weak-minded boy of impulsive tendencies, aged 15, admitted in September, 1917. He was well nourished, and took his food very well indeed. He had had no fits previously. During the night of December 30th, 1919, he had a severe typical epileptic fit, and lapsed into a condition of cerebral irritation, with paresis of his legs and conjunctival injection. Specific gravity of urine 1024; no albumin or sugar, but strongly positive to acetone. He was put on alkaline treatment and improved, the acetoneuria disappearing, and he continued to take his food well. On January 10th he again developed strong acetoneuria, which did not yield to alkaline treatment, and he died at 9.40 a.m. on the 16th.

Post-mortem Examination.—Intense minute injection of the pia arachnoid in a patchy fashion, especially marked over sulci and along veins, one large patch extending over the vertex of the left hemisphere; numerous puncta cruenta on section of the cerebral tissue; strong acetone reaction in cerebro-spinal fluid and blood. Microscopic examination showed minute vascular engorgement, diffuse and central chromatolysis of the neurone body, and degenerative changes in nuclei—in other words, primary degeneration of the nerve cell. The suprarenal glands showed some congestion and fat deficiency; other organs apparently normal.

2. J. H., a well developed man, aged 49, admitted on February 4th in a state of acute confusion; had been ill for six weeks prior to admission. He was, on admission, in a state of restless noisy excitement, continually wet and dirty, rendering it impossible to collect his urine for examination. He was put on milk and other extra diet, which he took satisfactorily. He was extremely feeble when admitted, became gradually weaker, and died at 2.30 a.m. on the 10th.

Post-mortem Examination.—Cadaver in good condition, marked opacity and thickening of the pia arachnoid, with much recent minute injection and patchy ecchymotic areas. Brain tissue showed numerous puncta cruenta on section. Acetone reaction strongly marked in cerebro-spinal fluid, which was in excess in pericardial fluid and in the blood. Microscopic examination showed engorgement of vessels, with some minute extravasations, diffuse and central chromatolysis of cells, nuclear changes, and absence of pigment. Suprarenal glands softened, scanty fat; liver somewhat fatty; other organs normal.

In mental cases it is the exception to find *post mortem* a normal transparent pia arachnoid. Secondly, in long-standing cases of epilepsy almost the only change met with may be a thickening and opacity or milkiness of the pia arachnoid; this thickening and opacity I regard now as most probably due to congestive attacks resulting from acid intoxication. These congested areas are most pronounced over the vertex where the membrane is thickest and the underlying neurones mainly motor.

Thirdly, after death in status epilepticus there is intense congestion of the membranes and the cells show the profound structural changes of primary degeneration—structural changes which I have shown to be also present in the cases mentioned. It is of interest to note here that the meningeal appearances in these cases are very similar to many I have seen in the Balkans as a result of malignant malaria, and in which the symptoms indicated intense toxæmia, no doubt due to deficient oxidation as a result of the destruction of vast numbers of erythrocytes and also to the haemoglobin and oxyhaemoglobin set free in the plasma behaving as weak acids. Addison, Lusk, and Graham consider that the rise in heat production in severe anaemias is due to the pathological production of lactic acid from carbohydrates in consequence of an inadequate supply of oxygen to the cells. Recently I have had two cases of confusion following malignant malaria contracted at Salonica, one of whom had definite acidosis periodically while here.

* Abstract of paper read at a Staffordshire Branch meeting of the British Medical Association, February 26th, 1920.

Notes on twelve cases were quoted, in which the acidosis was associated mostly with delirium, confusion, mild melancholia, stupor, epilepsy and masked epilepsy, and it was pointed out that in cases which recover improvement synchronized with diminishing acidosis. Haemolysis of erythrocytes by acetone bodies and bile acids simply means cellular disintegration. Taking into account the other still more destructive ferments present in acidosis, it is obvious that these substances in the blood and body fluids must have a most irritative and disastrous effect on tissue cells. This is already evidenced by the degenerative cell changes noted in the *post-mortem* examinations alluded to. If the acidosis is intense or continued for a length of time, or if the patient gets frequent recurrences, permanent damage to the neurones must ensue.

It was next pointed out that the adult human brain contained practically 2 per cent. of cholesterol, while children's brain tissue contained much less—a child 3 months old only 0.69 per cent. This substance can be shown *in vitro* to exercise a protective function on erythrocytes with regard to the action of haemolytic agents such as autolytic ferments and acids, and it is therefore suggested that the more serious cerebral effects of acidosis in young children may be traceable to this deficiency of cholesterol as compared with adults.

Referring to ferment action, it was mentioned that the diastatic content of urine in cases of acetonuria was somewhat higher than normal, and also it was pointed out that pancreatic lipase which is normally present in blood became haemolytic when activated by fat. In reference to this, serums from different types of mental disorder were investigated as regards the effect on them of tryptic digestion. The serums were drawn at the same time of day in every case, primarily for syphilitic sero-diagnosis, and in the results the serum in cases of chronic alcoholism, chronic melancholia, and epilepsy, showed a higher acid content as compared with others. Charon and Briche's observation that fits are most frequent at night time, when the reaction of the blood tends most towards acidity, was confirmed. The relationship between tuberculosis and epilepsy and the influence of acidosis in favouring microbial infection was pointed out. It was suggested that Biedl's glycosuria resulting from throwing the thoracic duct out of circulation was due to the absence of a ferment derived from lymphocytes, and that the lymphocytosis present in such diseases as tuberculosis, typhoid fever, malaria, and epilepsy, is an evidence of increased ferment action and acidosis. It was pointed out that the adrenals, as well as being concerned with sugar elaboration, have antidotal properties as regards autolytic agents; in sympathetic disturbances serious interference with cell metabolism and consequent acidosis may result. Thus:

Fright or anxiety produces hyperglycaemia; this is probably due to stimuli emanating from the brain passing over the splanchnic nerves, in part to the liver, inducing acetone formation and the splitting up of glycogen, and also to the suprarenals, causing a discharge of adrenalin. Constant action of this nature may lead to exhaustion of the adrenal tissue, with resulting loss to the organism of the protection normally afforded against agents producing cell autolysis. Further, adrenalin is *in vitro* readily precipitated by acetone, consequently the presence of acetone in the body fluids directly inhibits the action of adrenalin. . . . Degenerative suprarenal changes are very constantly met with at necropsies on the insane. In epilepsy, Prior states that out of twenty suprarenal glands examined by him degenerative changes were present in fifteen; also, in addition to adrenalin being readily precipitated by acetone in solution, its normal destruction in the blood is inhibited by any tendency towards acidosis.

The production of acid from glucose by the streptococci responsible for pyorrhoea alveolaris was referred to, and the frequency of this affection in cases of mental confusion instanced.

After reference to previous experimental work on animals, the following evidence of the toxic effects of acetone-containing urine was mentioned:

Two rabbits were taken, both bucks from the same litter and each weighing 3 lb. Into the first rabbit 2 c.cm. of urine from a patient suffering from marked acetonuria was injected intravenously, with the following result:

In a few minutes he became drowsy and lethargic, taking no notice of food though previously feeding with avidity. Inco-ordination of hind legs set in and paresis; breathing, at first, rapid, became appreciably slower. In half an hour he looked

very ill, hunched up, fur ruffled, movement of nostrils spasmodic and slow; remained in one place; resistive to stimuli; shut eyes occasionally; half an hour later hind leg paresis had passed off, although still lethargic and disinclined to move.

Into the second rabbit the same amount of the same urine, but one-third saturated with anhydrous sodium carbonate, was injected intravenously. This injection has no apparent effect on the animal. It had previously been ascertained that 2 c.cm. of normal urine had no effect on a rabbit when injected intravenously.

Treatment.

In mild cases the indications are rest, warm clothing—in view of the fact that acidosis is nearly always associated with low blood pressure; sleep, nutritious diet—avoiding fat and including plenty of carbohydrates, by-nogen. Allenbry's diet and such artificial foods; free purgation and alkaline medication. Potassium citrate is very useful, as in addition to the fact that it changes into carbonate in the blood it provides citric acid, which has the effect of restoring fat metabolism to normal, thereby reducing directly the acetonaemia. This, combined with the carbonates of calcium and lithium and the bicarbonate of soda, makes a very useful prescription. The more bases given the better. Free ventilation is necessary to secure an adequate supply of oxygen.

In a case showing more serious symptoms, complete rest in bed and, in addition to the above, enemata of 20 per cent. glucose solutions; while in a severe attack it may be necessary to give glucose or sodium bicarbonate intravenously. It might indeed be advantageous to consider gum saline intravenously, as Bayliss suggested in wound shock. Glucose, it must be recollected, may behave as a weak acid in the blood.

Unless absolutely necessary for the provision of sleep, as little drugging as possible and as little disturbance in the way of chatter and interference—the exhausted and damaged neurone has quite enough to put up with. Be firm and make the patient realize that his is a serious bodily disorder. In all but the mildest cases send the patient to hospital as soon as possible. The acetonuria having disappeared, continue a full dose of the alkali towards evening and give a mixture of iron and arsenic. The experiments of Crile show that in these conditions strychnine is contraindicated, as it caused cell changes precisely similar to those resulting from the emotions, toxins, and foreign bodies—namely, hyperchromatism succeeded by chromatolysis. With regard to means of control of the kinetic drive, Crile also states:

Whatever the activation, whether infection, emotion, injury, or Graves's disease, morphine measurably controls the outward phenomena such as pulse rate, respiratory exchange, sweating, thirst, restlessness, acid excretion, fever, muscular action, and pain. . . .

And it is interesting to note that so far back as 1822 De Quincey, in his *Confessions*, states opium to be

. . . under an argument undeniably plausible alleged by myself, the sole known agent, not for curing when formed but for intercepting whilst likely to be formed, the great English scourge of pulmonary consumption. . . .

He considers that he himself was cured of phthisis between the ages of 22 and 24 by the regular and continued use of opium. There is at present here a patient, at one time a confirmed epileptic, who was given, many years ago, continuous and gradually increasing doses of opium for a number of years. During this period the fits disappeared, nor have they ever returned, though for a good many years now the opium habit has been broken off.

In conclusion, attention was drawn to:

1. The profound structural alteration in the neurone caused by acidosis, and the extreme danger of permanent injury to it by continuance of the condition or by frequent attacks.
2. The urgent need of early diagnosis, and the recognition that such cases are very ill indeed, and need complete rest and proper treatment, or they may become invalids for life and a burden on the community.
3. The simplicity of the diagnosis.
4. The fact that, as a rule, acidosis can be readily counteracted by efficient treatment.

5. The need—in view of acidosis being a probable etiological factor in epileptic states—for careful investigation, and the probability that, if such is the case, efficient alkaline treatment may cure the condition if recognized at the onset of the fits. The giving of bromides would seem to be dangerous in such a state, as it only tends to dull cellular activities; later on it may be of use in treating nerve cells which have acquired vicious habits.

6. The danger to the patient in not adopting a firm attitude. If such cases are at once sent to hospital before serious mental symptoms come on there would soon be marked diminution in the admission rate at asylums.

7. The predisposition to microbial diseases afforded by acidosis, above all to tuberculosis. As regards children, there are questions which can best be answered by the general practitioner; for instance:

What is the relationship between "biliousness" in children and subsequent tuberculosis? Are the sexes equally subject to acidosis? Does it throw any light on the greater mortality of male children?

With regard to tuberculosis:

Is it a question of the optimum reaction of the medium necessary for the growth of the tubercle bacillus? In other words, do certain individuals, as a result of errors of nutrition or faulty cell metabolism, offer a more favourable pulmonary or lymphatic culture medium for the growth of the tubercle bacillus than do others?

Finally, is this whole question of acidosis, within limits, at the bottom of what we understand by heredity in respect to disease processes? Is it an effort on the part of the organism to autolyse itself? All these questions are of extraordinary interest, and the whole subject may bring us vastly nearer a proper comprehension of certain processes which up to the present have been shrouded in mystery.

THE CARE OF CRIPPLED CHILDREN.

BY

G. R. GIRDLESTONE, M.B., F.R.C.S.,

VISITING SURGEON, HEADINGTON ORTHOPAEDIC HOSPITAL; HONORARY SURGEON, SHROPSHIRE SURGICAL HOME; HONORARY ASSISTANT ORTHOPAEDIC SURGEON, RADCLIFFE INFIRMARY, OXFORD.

Crippled children need both treatment and education; only thus can they be restored to active citizenship, healthy-minded and, so far as may be, healthy-bodied.

In a former paper, published in the *BRITISH MEDICAL JOURNAL*, October 11th, 1919, attention was called to the crying need for effective treatment for crippled children, and a system of orthopaedic hospital-schools and out-patient clinics designed to carry out the work was outlined. It was estimated that about 10,000 beds would be required for the whole of England and Wales, but it was pointed out that new construction was not involved to this extent, both because in some places hospitals carrying out this work already existed, and in other places there were hospitals in use by the War Office or Ministry of Pensions which would be suitable, and could eventually be made available for this civil orthopaedic work.

Those who have studied the problem feel very strongly that provision for the treatment and all-round education of crippled children is the reverse of an extravagance, even in the present financial straits. The following figures are taken from the report on "An inquiry concerning physically defective adults and children" carried out by the City of Birmingham Education Committee in 1911. Their capacity for work was a subject specially noted, and it was found that among 1,001 cripples over the age of 16 only 111 were "able to do remunerative work at home," and 531 were "unable to do any remunerative work." Now it is the experience of those who work at hospitals for cripples that 90 per cent. can be cured or improved sufficiently to enable them to take a share in industry if the disability is tackled early and efficiently and training given.

It is true that there must be expenditure, perhaps for six months, during the active treatment of a crippled child, and that in some cases his education expenses afterwards may be high, but from the financial point of view alone it is a clear economy, for he is thus enabled to become a pro-

ducer instead of a dependant for the many years that follow. Further, these crippled children are already being maintained somewhere and by somebody. Many are in workhouses, infirmaries, or industrial homes, and quite out of touch with expert treatment. A large number have to be admitted to general hospitals on account of the severity of their condition; this is especially true of cases of tuberculosis of the spine, hip, and knee—the very cases that need many months or several years of unremitting treatment in open-air wards in the country with plenty of good food. These are the children above all others for whom the hospital-school and continued supervision are needed. On all these children money is now being spent, but with very imperfect results. On the other hand, a certain number of orthopaedic hospitals, orthopaedic departments of general hospitals, and hospital-schools for crippled children are already doing most excellent work; they can only deal with a minority of the cases, yet their very existence means that so much of the capital cost has already been faced, and so much of the maintenance expense is already being found.

In some places new hospital-schools for crippled children are needed, but almost everywhere there is waste and inefficiency due to lack of the combination of education and treatment, of the fellow-working of all the forces that have hitherto worked apart, and of continuity of orthopaedic supervision. The recognition of this is neither new nor singular, as the following quotations will show.

1. Report of the City of Birmingham Education Committee March 29th, 1912:

"More systematic co-operation and definite co-ordination between the local education authority and the hospital and medical charities, especially those which deal with orthopaedic cases, (are needed). In England, speaking generally, the divorce between these two organizations and their respective attitudes towards the children under their supervision is complete. The success which has attended the joint work of education and cure of cripples in America and on the Continent is in no small degree due to their close co-operation and identity of outlook."

2. Report of Census of Cleveland, Ohio, 1916:

"The need does not arise from failure to recognize separately the medical and educational requirements, but the failure to co-ordinate these and other forces affecting the life of each crippled child."

On the completion of their treatment most of the children would be able to go to ordinary schools. In towns some "special schools" would be advisable, but certainly far fewer than are called for now, when many children are allowed to remain crippled needlessly. As the cases are sent in progressively earlier the reduction of the number of children too crippled to attend ordinary schools will become greater in the same degree.

For a few children, either very severely crippled or living too far from a school, a "residential school" would be needed in each district, and this should be in the same grounds as the hospital-school. On their discharge from the hospital these children would then remain under the supervision of the orthopaedic surgeon and continue to attend the school and workshops. The advantages would be many, including administrative, educational, and workshop economy, and facility of orthopaedic supervision.

The publication of the paper already mentioned brought some of those whose work lay specially in the treatment of crippled children into touch with others who had done much for their education and training. These mutual interests have combined, and the "Central Committee for the Care of Cripples" has been formed. Its purpose is to represent and help voluntary associations devoted to the welfare of cripples, and to push forward the work in every possible way. This committee has become associated with the "Central Council for Infant and Child Welfare," and has an office at 20, Berkeley Street, W.

Whenever schemes are put forward or new associations formed there is alarm amongst existing organizations, for they naturally feel anxious lest their proved work is to be set on one side. In this case probably the feeling has been—"Is some new and theoretical system of State Service to start afresh with the slate wiped clean, and then perhaps never to work with the same sympathy and enthusiasm?" That is the last thing desired. Rather is the aim to unite and help the present efforts, to combine the workers and put better tools into their hands, and to make the attainment of results easier and quicker.

There is no need for new administrative machinery. The organization of this work must be moulded so that it will fit into its place in the health work of the nation—that system composed of central government (by the State), local authority (locally elected), and the ultimate network of health and social services, official and unofficial. Of this network the hospitals form nodal points; voluntary in origin, they are becoming more and more linked up with State mechanism by the system of capitation grants for the treatment of various types of disability.

The Hospital-Schools for Crippled Children will, it is hoped, be worked in close touch with the medical officers of health in their districts, and in affiliation to the general hospitals. For the costs of maintenance each hospital-school will be largely dependent on capitation grants from the local authorities, who will pay only if they are satisfied with the work that is being done, and if the institution has been approved by the Ministry of Health and Board of Education, for with this approval 50 per cent. of the maintenance fees paid out can be recovered. In some districts several counties will be served by one hospital-school; these arrangements will be made to accord with the geographical conditions in various parts of England and Wales. On the other hand, in London and other big cities a fitting plan would be that each orthopaedic hospital, or general hospital with an orthopaedic department, should have its section of the town, and its beds for crippled children in the country. This would make towards simplicity of working, and continuity of treatment and supervision of the patients present and past throughout hospitals, special schools, and their homes.

Guidance and help from the Ministry of Health and Board of Education would be welcome, for an organization for the care of cripples, planned to give them all that they need, must at the same time be moulded to fit into its place exactly, and be linked up accurately with the existing health and education machinery, for only thus will efficiency be quickly realized and permanently maintained. It will be a small part of the whole structure, yet essential, for it is to deal with children to whom effective care alone can give lives active, happy, and self-supporting.

A HOSPITAL-SCHOOL FOR CRIPPLED CHILDREN.

An attempt has been made to represent diagrammatically a hospital-school of 200 beds, with its various parts indicated and grouped on a definite plan, and an associated "residential school." The plan is intended to serve as a means of illustrating some of the many points to be thought of in planning such a hospital and as a stimulus towards further consideration of the subject. No doors or windows are indicated.

Types of Cases.

The conditions for which these hospitals are needed can quickly be grasped from such a table as that given in the article on the Care of Cripples, in the BRITISH MEDICAL JOURNAL of October 11th, 1919. It is now repeated—corrected in one particular—in the next column. It will be seen that the cases are grouped into three main categories:

1. Deformities.
2. Paralyses.
3. Surgical tuberculosis and other affections of bones and joints.

Desiderata.

1. *Open Air Wards in the Country.*—Probably only those who have worked in a hospital where the children are in open air night and day can realize its marvellous effect on their vitality and powers of recovery.

2. *A site on dry subsoil*, fairly high, with southern aspect, and a low rainfall. A low local rainfall can sometimes be found in a district which as a whole has a comparatively high rainfall.

3. *A position in the neighbourhood of a main town*, with good radiating railways and roads, and if possible near enough to the town to share in the advantages of its electricity and gas and the transport, water, and drainage systems.

4. *Affiliation with a good General Hospital.*—Hospital organization is tending towards the co-ordination of the special hospitals in each neighbourhood with a "mother" general hospital. This should give many advantages—

Table of Cases under Treatment.

	Shropshire.	Stoke.	Total.
Approximate population of area served...	425,000	246,307	671,307
Approximate proportion of cases under treatment to population	1 to 538	1 to 722	1 to 594
A. Deformities, congenital or acquired:			
Rickets	177	51	228
Deformities of the foot	71	51	122
Scoliosis	8	14	22
Congenital dislocation of hip... ..	16	8	24
Fractures, non-union and mal-union	15	10	25
Other deformities... ..	43		43
Total	330	134	464
B. Paralyses:			
Infantile paralysis	211	72	283
Infantile hemiplegia	43	11	65
Spastic paraplegia		11	
Total	254	94	348
C. Surgical tuberculosis:			
Spine	55	75	230
Hip	57		
Knee	26		
Other joints, etc.	17		
Total	155	75	230
D. Other conditions:			
Osteomyelitis	33	11	44
Varicos	16	28	44
Total	49	39	88
Grand total	783	342	1,130

for instance, the special hospitals would share in the benefits of a first class pathological laboratory, and it should bring the spirit of team work into hospital relationships.

5. *Sufficient beds* to meet the demand from the area which the hospital serves. It is particularly important to avoid the results of bed pressure: (1) Undue curtailment of treatment, and (2) a heavy waiting list.

6. *A Unit of Manageable Size.*—The hospital shown is planned for 200 patients. This is recommended as the best size. Sufficiently large to justify the necessary expense of an expert staff, it is yet not too large to be dealt with effectively by a clinical team consisting of orthopaedic surgeon, assistant orthopaedic surgeon, two house-surgeons, physiotherapist, and masseuses.

7. *Administration Offices.*—Where these hospitals are to be managed by a committee, offices will be required for a secretary-accountant and his clerk or clerks; for the matron and her clerk; and for a housekeeper or steward.

8. *Construction and Design.*—The hospital as shown might well be of semi-permanent construction and of "bungalow" type. Wood should not be used externally, owing to the great cost of maintenance involved. Beside the general principle of placing all wards and living rooms on the southern side of the hospital the following points illustrated in the plan may be mentioned:

(a) *Ward units*—each main ward complete with its two accessory blocks.

(b) The concentration of departments specially concerning the surgeon (west end of centre block); the conjunction of clinical rooms of surgeon and physiotherapist (49, 50).

(c) The aggregation of the departments requiring heating or hot water supplies into a small number of groups. In each of the three main groups the heating plant can be situated under or close to a department requiring special heat—namely, (1) theatres in the surgical group, (2) the hydrotherapy room, and (3) the kitchen.

(d) The economy of service, heating, and hot water supplies obtained by the grouping together of all the dining-rooms and the resident quarters of the matron and the three medical officers.

(e) The advantage of locating entrance, kitchen, etc., on the northern side of the hospital, so that the southern may be clear.

(f) An arrangement of drive, short, but serving the principal points of supply.

(g) The provision of covered walks between the various buildings of as short a total length as possible, yet so arranged that nurses or children can get from any one part of the institution to any other without getting wet.

(h) A convenient position should be found for the nurses' quarters. This building should stand in its own garden. Each nurse should have a separate small bedroom. A reading room and a recreation and lecture room should be provided.

9. *Departments and Wards well equipped for Orthopaedic Work.*—Points that may be mentioned have regard to:

A. *Examination Room.*

This should be long, so that patients may be seen walking, warm, and with good light. There should be a waiting-room for patients. Even if the main clinical laboratory work is done at the general hospital, simple equipment for the examination of smears, etc., should be provided.

B. *Theatres.*

Two are indicated with the anaesthetic room between. Each should be complete with its whole outfit and one reserved exclusively for clean cases. There should be ample space and light. The plan does not show separate rooms for washing-up. The writer works in accordance with a plan worked out by Mr. A. P. Dodds-Parker which is recommended as very simple and extremely safe. It involves merely a rather elongated theatre with one end reserved for washing-up and the sterilizing of instruments, the other for operating. The ends are partially separated by a central transverse baffle coming down from the ceiling to within 7 ft. of the floor. Fresh air is admitted to the operating area through ample inlets protected by a single layer of muslin: at the same time the steamy air is prevented from spreading into this half of the theatre (and there condensing) by the baffle and by an exhaust fan at the southern end.

A room for aspirations and minor operations in the south block is shown.

C. *Plaster Rooms.*

Plaster-of-Paris plays a great part in the work of these hospitals. The actual treatment of cases in plaster, the preparation of casts on which to make spinal jackets or other appliances, and record casts, together necessitate good provision of plaster rooms. Two are shown in the surgical block, and a third in the south block for the treatment of the cases there. They should be well heated and ventilated, and equipped with an Abbott's frame, a good vertical suspension frame, and a strong table with arrangements for pelvic rests, etc.

D. *The Splint and Appliance Workshops.*

These workshops are mentioned later.

E. *The Wards.*

The four main wards shown on our plan can be partitioned further if thought desirable. They face directly south, and on this side are open right up to the ceiling level, which should be about 9 ft., the place of the south wall being taken by pillars.

The beds would usually be ranged in a double row. When driving rain beats into the ward the front row of beds could be pushed back. Further protection can be given by stout canvas roller blinds which can be pulled down between each pair of pillars.

All main wards should be lit and ventilated by windows on the north side, in addition to being open to the south.

The floor of the wards should slope slightly outwards.

In these open-air wards the children need plenty of food, plenty of blankets, and, in cold weather, a supply of artificial heat. Whether hot bottles which have to be reheated or refilled several times a day or electrically-warmed mattresses will prove more economical is not yet clear. Possibly the latter system will gain on the score of economy due to the saving of hot water, labour, and breakages; it is certainly a more efficient source of controlled and steady heat. Information on this point should soon be available from the Hayling Island annexe of Sir William Treloar's Alton Hospital.

The southern block of the hospital could be specially devoted to cases of surgical tuberculosis. Diseases of the spine and hip account for the majority of such cases in hospital and mean treatment in bed for very long periods.

Each main ward has attached to it:

1. *Ward Annexe, containing—*

A. Sister's room, 15 ft. by 9 ft., from which there is a good view of the ward.

B. Nurses' duty room, 15 ft. by 19 ft.; this is available for dressings and the massage of certain bed cases.

C. Bathing room, 15 ft. by 12 ft., with tables on which cases on frames or in plaster can be washed.

D. Ward kitchen, 15 ft. by 5 ft., with gas stove.

E. Bathroom, 15 ft. by 7 ft., with washing basins and baths.

F. Drying room, 15 ft. by 7 ft., for damp clothes or bedclothes.

G. Kit and linen store, 20 ft. by 10 ft. south, 15 ft. by 10 ft. centre.

Rooms B, C, D, and E should be fitted with hot and cold water. For B and C warmth combined with thorough ventilation is most important, for it is dangerous to take the more delicate children into a stuffy room for washing or dressing, although they remain free from bronchitis if treated continuously in the open ward. It is exceedingly difficult to keep these two rooms warm and airy without windows which can be opened on either side and open fires. Further, the nurses on duty must be remembered as well as the patients.

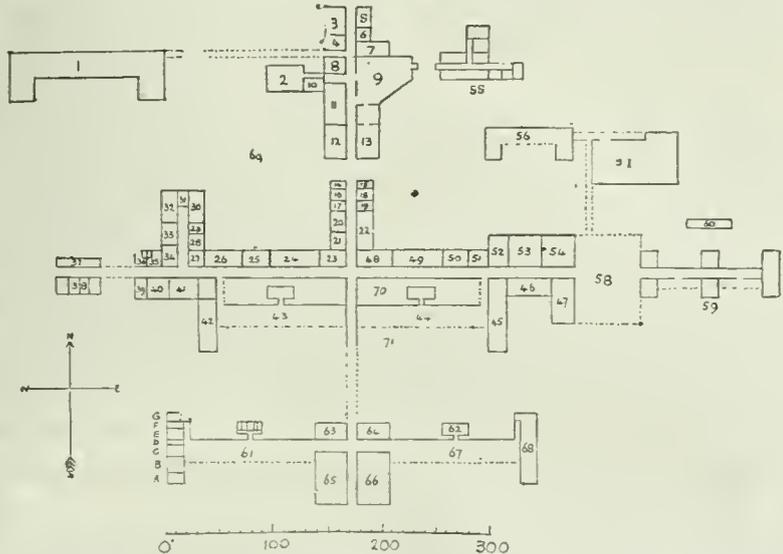

The projection of this annexe in front of the ward gives some shelter from cross winds, and adds to the stability of the structure.

2. *Sanitary Block*, connected to the centre of each main ward by a short cross-ventilated passage, and containing a slop sink, etc.

Wards for Isolation and Acclimatization.—The plan indicates three small wards (15 ft. by 10 ft.), with partially glazed partitions, and a nurse's room from which the wards can be overlooked. The south side of these wards consists of double doors which can be opened inwards. The wards can be used for infectious cases or for the acclimatization of specially delicate children to living in the open air. Observation of newly admitted cases in special wards is not found necessary in open-air hospitals.

Babies' Wards.—On the south side of the west end of the central block are two wards—one for babies, the other for the admission of both mother and baby when necessary; both can be completely opened to the south.

Recovery Ward.—In a children's hospital especially it is a very great advantage to have a ward set aside for the reception

- 1. Nurses' quarters.
- 2. Matron's bungalow.
- 3. Kitchen offices.
- 4. Cooks' room.
- 5. Housekeeper's office.
- 6. Stores.
- 7. Larder.
- 8. Servants' room.
- 9. Kitchen.
- 10. Matron's dining-room.
- 11. Nurses' dining-room.
- 12. Girls' dining-room.
- 13. Boys' dining-room.
- 14. Porter's room.
- 15. Telephone room.
- 16. Matron's office.
- 17. Matron's clerk.
- 18. Secretary's office.
- 19. Secretary's clerk.
- 20. Waiting room (parents).
- 21. Stores.
- 22. Ditto.
- 23. Dispensary.
- 24. Sewing room.
- 25. Photography.
- 26. Radiology.
- 27. Developing.
- 28. Plaster casts and records.
- 29. Sterilizing.
- 30. Theatre for septic cases.
- 31. Anaesthetic room.
- 32. Theatre for clean cases.
- 33. Plaster.
- 34. Splint store.
- 35. Surgeon's changing room.
- 36. Nurses' changing room.
- 37. Isolation annexe and sanitary.
- 38. Isolation ward.
- 39. Mother and baby.
- 40. Babies.
- 41. Recovery ward.
- 42. Ward annexe.
- 43. Centre ward, girls.
- 44. Centre ward, boys.
- 45. Ward annexe.
- 46. Reading room.
- 47. Play room.
- 48. Waiting room.
- 49. Clinical room, surgeon and clerk.
- 50. Clinical room, physio-therapist.
- 51. Massages' duty room.
- 52. Hydrotherapy.
- 53. Electricity and massage.
- 54. Gymnasium.
- 55. Medical officer's quarters.
- 56. Residential school quarters.
- 57. School.
- 58. Covered playground.
- 59. Workshops.
- 60. Sanitary block (workshops, etc.).
- 61. South ward, girls.
- 62. Ward sanitary block.
- 63. Plaster.
- 64. Minor operations.
- 65 and 66. Schoolrooms.
- 67. South ward, boys.
- 68. Ward annexe.
- 69. Drive.
- 70. Asphalt or concrete area.
- 71. Asphalt or concrete slope. Garage, laundry, chapel not indicated.

N.B.—Pathological laboratories and an out-patient department, though not shown, will be required if the hospital is not working in touch with a general hospital.

of cases for the first twelve or twenty-four hours after operations. It must be most harrowing for children to watch others go through the process of "coming round" from an anaesthetic, and a most undesirable preliminary to a subsequent operation on themselves.

Adolescents and Adults.—No special wards are indicated for these. The girls and boys are in distinct sides of the hospital, so that adults could be accommodated in one end of the ordinary wards.

Paying Patients.—Similarly no wards are indicated. Small bungalows in suitable positions could be provided.

Education.

Regulations as to education in hospital-schools are laid down by the Board of Education. In this plan no design of the schoolrooms is indicated, but positions are suggested. The main school lies to the east of the site and is surrounded by the workshops, residential school quarters, covered playground, reading and play rooms. The main school block would be attended by walkers and chair cases from the central block of the hospital, as well as by the children in the residential school quarters. The schoolrooms in the centre of the south block are so placed that the children confined to bed in this ward can be pushed to school easily, bed and all.

The residential school quarters are for children who, though they no longer require hospital treatment, would get no education if sent home, owing to the relation of the degree of their disability to the distance of the school from their home. Here, again, no internal structure is indicated, but as some of the children in these quarters will probably be convalescent from tuberculous conditions, one or two open-air dormitories might well be provided. No cubicles or dormitories should be on the north side. The size of this particular building should not be regarded as a reliable guide as to the residential school needs of an area requiring a hospital of 200 beds. A group of small cottages would be an alternative method of housing the older children. The children in hospital and in residential school need reading rooms, play rooms, covered and open playgrounds.

The *Workshops* should supply training in various handicrafts. Besides those of general application, such as carpentry, cobbling, leather and basket work, in each district the local trades should be specially considered.

Splint Shop.—It is an immense gain to an orthopaedic hospital that all the splints and appliances needed in the hospital should be prepared in its own workshops. The instrument makers can then work in constant touch with the orthopaedic surgeon, and so carry out his ideas exactly. Further, in urgent cases special splints can be made immediately.

It is recommended that part of the workshops should be of the open-sided hut type, and that all should be specially well ventilated, for they will be used in the training of children in the hospital and residential school. It will sometimes be possible to give permanent work as instrument makers or instructors to children who have passed through the residential school and shown special aptitude.

Maintenance.

Complete fulfilment of the conditions laid down by the Ministry of Health and the Board of Education, which include arrangements for dental and refractive work, is necessary so that the "approval" of these departments may be obtained for work under (a) the Maternity and Child Welfare Act, (b) the Education Act (1918), and (c) the tuberculosis clauses of the Insurance Act.

Great benefits will be derived from close association with the medical officers of health and tuberculosis officers of the group of local authorities served by each hospital-school.

Definite working arrangements should be made with the local authorities by which the costs of maintenance, worked out to an average for each child and approved by the Board of Education, are paid on a capitation basis by the local authority concerned in accordance with the Acts mentioned above.

Expenditure.

The following is an analysis of the weekly expenditure per child at Baschurch for the quarter ending December 31st, 1919:

	£	s.	d.
Food	0	19	1
Drugs and chemicals	0	1	9
Instruments and appliances	0	4	4
X-ray apparatus	0	11	2
Boots and leather	0	5	0
Repairs and renewals	0	2	11
Buildings and machinery	0	1	0
Hardware and crockery	0	2	11
Furniture and bedding	0	1	0
Oil and fuel	0	2	11
Laundry	0	1	0
Printing	0	2	10
Stationery	0	2	10
Postage, telegrams	0	2	10
Rent, rates	0	2	10
Carriage	0	2	10
Railway fares	0	2	10
Miscellaneous	0	2	10
Total	2	7	3½

The total weekly cost is seen to be greater than the estimate of £2 given in the paper published in October. This is due to the rise of prices, which unfortunately has not yet stopped.

Beyond all these material advantages, there is needed in the staff enthusiasm for the work, orthopaedic experience, with a balanced judgement of the values of various methods of treatment, the highest degree of skill, and well arranged clinical team work. Further, the efficacy and permanence of the work of such a hospital depends on early recognition and treatment and on thorough after-care. The use of all the health services of the district, official and voluntary, especially the work for infant and child welfare, should lead to the early discovery of crippling conditions, and avail to bring them into touch with orthopaedic treatment without delay. Similarly, each patient on discharge from hospital should be attached to one or other of the orthopaedic clinics scattered through the district. Careful after-treatment and supervision will then make for the attainment of the best result possible for every child.

THE X-RAY TREATMENT OF ACNE VULGARIS.

BY

H. C. SEMON, M.A., M.D., M.R.C.P.,

DERMATOLOGIST TO THE GREAT NORTHERN HOSPITAL, LONDON, N.

INTRODUCTORY.

IN spite of the general advance in dermato-therapy during the last decade, it is discouraging that few of the commoner skin diseases can be permanently cured. It is now established that acne vulgaris—perhaps the most widespread minor skin ailment in this country—no matter how extensive, or in what stage it presents itself, can be permanently cured by judicious x-ray treatment. I am well aware that, in making this statement, I lay myself open to the retort that radiotherapy for so trivial a complaint is a dangerous and quite unjustifiable remedy. The comedo and pustular stages of the condition are, however, very objectionable, and women especially cannot afford to regard the prospect of permanent disfigurement by pitted or keloidal scars with equanimity. It is surprising to find that most of the larger textbooks incline to the opinion that x-ray treatment should be reserved for the most intractable cases. In these, however, irremediable cicatrization will already have occurred, and the final appearance when cure has been brought about may resemble the after-effects of small-pox or lupus. It would seem to be an axiom of therapeutics that nearly all its most effective weapons are dangerous in unskilled or injudicious hands; but no reasonable member of the profession would therefore limit the administration of salvarsan in syphilis, of emetine in dysentery, or of chloroform in the major operations of surgery. To relegate an invaluable and approved remedy to the position of a last resource because there have been disasters among the earlier cases, is to assume an attitude for which there is now no justification, and which it is the main purpose of this article to repudiate.

Pathology.

Acne vulgaris is mainly attributable to the activities of a particular microbacillus first grown by Sabouraud. Every comedo contains it in more or less pure culture, as can be proved histologically by suitable staining reagents. The acne pustule is the result of contamination of the

comedo with various other organisms, among which the staphylococcus predominates. The deep-lying acne nodules also contain the acne bacillus, but in reduced numbers; and cultivations from these, as from many other types of very chronic abscesses, are not infrequently sterile.

The acne bacillus flourishes only in the presence of sebum, and is found more or less profusely wherever sebaceous glands are situated. As it can be recovered from the normal gland, it follows that it is not necessarily pathogenic, a circumstance of which there are other instances—for example, (1) *B. coli* in the large intestine is physiological, but in an appendix abscess it is pathological; (2) Vincent's spirillum is a normal parasite in the saliva, but a dangerous factor in certain types of buccal and pharyngeal ulceration; and so with the pneumococcus, *Streptococcus faecalis*, and *Staphylococcus albus*, all facultative pathogenic organisms.

The sebaceous glands share the increased activity of all glandular structures at puberty; and it is, perhaps, to their superficial position and liability to fortuitous secondary infection that the appearance of acne at this time of life may be due. The comedo is nothing but a sebaceous gland the duct of which is choked with inspissated sebum, cellular detritus from the corneous layer, and colonies of the acne bacillus.

We are still unable to explain why this "inspissation" should occur; but, as with other secreting organs of the human body—as, for example, the appendix, gall bladder, and kidney—once it has taken place, secondary infection is only a matter of time and opportunity. Streptococci, staphylococci, the bottle bacillus, and various yeasts are frequent contaminations; and the symbiosis thus established appears to increase the proliferative and irritant characters of each. Whilst infected and blocked glands become pustules or spread deeply into the cutis and become nodular abscesses, those in the immediate neighbourhood react to the irritation by an increased output of sebum, which in its turn favours extension of the condition by the rich pabulum it provides for new generations of the causative organisms. We are thus confronted with a very simple example of a vicious circle.

The morbid histology, so far as it concerns our thesis, may be considered under three headings: (1) Involution of the comedo to a condition of normal sebaceous activity; (2) secondary infection and acute suppuration, with destruction of the sebaceous gland, and eventual scarring or pitting; (3) chronic suppuration which may result in the production of (a) deep nodular abscess formation, or (b) cicatrization, or hypertrophic and true keloidal tissue.

The structure of a comedo has already been alluded to. In addition to inspissation of sebum and cell detritus in the duct, there is usually a small round-celled infiltration about the duct and neck of the affected gland. This infiltration is excessive in the second stage, that of acute suppuration; being usually extraglandular, it explains why it is that such an abscess is difficult to express, an easy procedure in the case of a comedo. It is with the results of the third stage, the chronic suppurative condition, that our discussion is mainly concerned.

Histological sections reveal the well known cells common to all the granulomata—for example, chronic sepsis, tubercle, syphilis, etc. Fibroblasts, mast cells, giant connective tissue cells, leucocytes of various kinds, and strands of fibrous tissue are present in all such sections in varying degree—the fibrous element predominating in direct proportion to the chronicity of the lesion. The periglandular fibrosis is often exceedingly dense, a fact which may have some bearing on the frequent failure of vaccines and topical application to reach the micro-organisms in the ducts, where they lie secure, and in a state of latent or potential virulence, which only needs such factors as constipation, dyspepsia, menstruation, or the abuse of alcohol or tobacco, to call them into activity.

Treatment by X Rays.

If the preceding pathological sketch is correct in essentials, the causes of failure to cure by internal and external medication or by vaccines become apparent, and can be ascribed in the main to the presence of young connective tissue cells and their fibrous derivatives, which bar the access of all remedial agents to the seat of the disease. The action of x rays is selective on fibroblasts and on any unorganized and rapidly proliferating

cellular structure. It is this selective affinity which is responsible for the favourable destructive effects on certain types of cancer, more especially in sarcoma, which is a connective tissue cell derivative.

Its relatively superficial position in the epidermal or subepidermal plane renders the acne lesion peculiarly accessible to the penetration and direct action of x rays. But the rays possess a still more valuable characteristic: they are inhibitory to the physiological action of the secreting cells of sebaceous glands—as well, as sweat glands, thyroid and ovarian glands, etc. If, therefore, the fibrous capsule of the infected comedo is "dissolved," and at the same time the secretory activity of the gland itself diminished or altogether inhibited, two favourable conditions for the growth of the acne bacillus will have been removed and the vicious circle broken. Whether the explanation offered is correct or faulty is of academic importance only. The incontrovertible fact is that x rays will cause involution both of the comedo and the deep nodular abscess, and reduce to a minimum the still greater disfigurement already caused by hypertrophic scars and keloidal tissue.

Dose of X Rays.

The dosage of x rays required to effect a cure in any particular case depends in the first place on the stage of the infection. For the sake of convenience, and in conformity with the pathological data, three such stages can be clearly distinguished: (1) Comedo formation; (2) comedo and pustulation; (3) nodulation, or deep infection, with concomitant fibrotic or keloidal changes.

In stage (1) local applications of sulphur, resorcin, mercury, or salicylic acid, are almost invariably prescribed either in a lotion or in an ointment. Soft soap is frequently incorporated in the ointment base, or directed to be used antecedently in the form of a shampoo with hot water. Stock or autogenous acne and staphylococcal vaccines are administered periodically; and the results, as long as treatment is continued, are satisfactory, the comedones disappear, and the case is apparently cured. It must be admitted that in the great majority of cases, and in spite of the most punctilious attention to detail on the part of the patient, relapse is exceedingly common. I am of opinion that in some cases treated by this method the energetic friction and application of local remedies has actually favoured secondary infection with staphylococci and the development of pustules. Be that as it may, it will be generally conceded that the process is tedious and causes considerable discomfort to sensitive skins. The x-ray treatment of the comedo stage is entirely free from both these objections.

Method.

In stage (1), in which only mild surface action of x rays is required, a filter is not used. A tube of medium hardness, working at a spark gap of between four and five inches, is the best for the purpose. A visible erythema—the so-called "reaction"—should not be aimed at; nor is it necessary to produce subjective sensations of itching or heat. The dose must be controlled in every case by the change of colour of a reliable make of the Sabouraud-Noirée pastille, which should be accurately placed at a point exactly equal to half the distance between the anticathode of the tube and the surface irradiated. It is also of the utmost importance that the trajectory of the rays should make a right angle with the plane on which they fall. As the areas usually affected by acne (except in the case of the back and chest) are relatively curved, and not plane surfaces, this direction can only be approximately followed in most cases. The summit of the curve will obviously be the nearest point to the anticathode; and it follows that the measurement of the distance from the anticathode, which should not be less than 6 in., must be made from the centre of this area. For a case of uncomplicated comedo formation a dose approximating to four-fifths of the full epilation dose (or B tint) is generally sufficient to effect a marked improvement. The administration is usually given in two sessions, with an interval of five days between them. In some cases the activity of the sebaceous glands is not effectively damped down by four-fifths of the pastille, and another two-fifths* or

* I use a recent modification of Corbet's radiotintometer (made by the Cox-Cavendish Electrical Company) for accurate estimation of slight colour changes.

three-fifths of the full dose may be required. In all cases ten days must be allowed to elapse after the primary four-fifths B dose has been administered. If this precaution is rigorously adhered to there is no risk of overdosage. The appearance of an erythema is the signal for cessation of x-ray application to that particular area; the final effect of the treatment cannot be accurately gauged until all reaction has passed away. A cure can be anticipated in the majority of the cases in which it has occurred; for slight and invisible cutaneous atrophy, in which the sebaceous glands particularly are implicated, will ensue. It is again emphasized that the atrophy of the sebaceous gland is neither physiologically desirable nor a factor in the treatment. Inhibition of an excessive activity is all that is required to cause involution of the comedo. In every case of facial acne treated by x rays the eyebrows, eyelashes, and mucous membranes must be effectively protected by strips of malleable lead foil, which can be fixed *in situ* by rubber strapping.

In stage (2), when pustulation and dermatitis are marked, an effort should first be made to allay them by the application of mild antiseptic and detergent lotions of lead, calamine, or mercury oxycyanide (1 in 4,000). A few days later the areas can be treated by x rays. Two-fifths of the B tint can be given at intervals of ten days, and repeated as found necessary. "Erythema reaction" should be carefully avoided in the pustular stage.

While there are conceivable alternatives to radiotherapy in (1) and (2), the presence of intradermic and subdermic nodules and cold abscesses, periglandular fibrosis, and keloidal tissue (stage 3) is a direct indication for x-ray treatment, for by no other agency can their involution be permanently achieved. The deeper situation of all these lesions calls naturally for the use of harder or more penetrating rays. These can be obtained in two ways: either (a) by the use of a "hard" tube with a spark-gap working at a distance of 5 to 6 in., or by (b) interposing a screen of sheet aluminium, which cuts out the soft erythema-producing rays altogether. The filter should have a thickness of 0.5 mm., and with this in position a full pastille dose (tint B) may be given at the first session without risk. (The pastille holder must be used on the proximal side of the screen.) Considerable improvement will usually be noticed in ten days or a fortnight, and filtered half-pastille doses may be repeated at this interval until involution is complete. The use of a filter will prevent or delay the development of erythema reaction, and in most cases a satisfactory result will have been obtained before this develops.

Local relapse after efficient treatment by x rays has, in my experience, rarely occurred. A case I treated in 1913 will suffice to illustrate the contention. The patient, an unmarried lady of 26, had suffered from the deep nodular variety with recurrent suppuration and hypertrophic cicatrization for many years in spite of vaccine treatment, local applications, ultra-violet rays, and yearly visits to a sulphur spa. The case was undertaken with considerable trepidation, as at that time my experience was not extensive. During the seven years which have since elapsed there has been no recurrence, nor is there now the slightest suggestion of cutaneous atrophy, although, as a result of treatment, the patient developed temporary erythema at the time.

X-ray Stigmata.

The ill effects produced by overdosage of x rays are well known, and may be either permanent or temporary.

An x-ray burn is a serious disability; it can be caused only by massive or repeated and uncontrolled doses of x rays. In the most intractable cases painful ulcers may develop. More usually there is parchment-like atrophy of the skin, pigmentation, and minute vascular stigmata (telangiectases), with permanent, partial, or total destruction of hair follicles. Such appearances are still occasionally the result of inaccurate dosage in opilation treatment of tinea of the scalp and chronic sycosis barbae, and more excusably after massive doses for lupus vulgaris and epithelioma. Modern refinements, however, have rendered the accident relatively uncommon, even in cases in which massive doses are essential. If the rules insisted on for acne cases are rigorously followed such accidents will not occur in the treatment of this disease. It is therefore with

the results of mild irradiation only that we are concerned. These are temporary, as a rule, and consist, as far as evident at all, of disturbances in the physiological distribution of pigment. As might be expected, blonde individuals are more susceptible in this respect than dark, and these should always be warned in advance of the possibility of the temporary appearance of "freckles" as a result of the x rays. In no case do they result in anything approaching the acne nodule or pustule in degree of disfigurement, and in a few weeks they vanish. The only treatment called for is the occasional application of calamine lotion, which is also useful in cases which develop erythema reaction. Grease in any form is never well tolerated, and ointments should therefore not be prescribed for patients undergoing radiotherapy.

CONCLUSIONS.

1. Acne vulgaris in its early stages can be relieved by vaccines and the application of lotions and ointments containing sulphur, resorcin, or mercury.
2. As far as the author knows, cure can only be attained by the judicious application of x rays.
3. The nodular and keloidal varieties of the disease are not amenable to relief or cure by any other method.
4. Relapse after apparent cure by x rays is rare. Should it arise it can be dealt with by further irradiation.
5. There are no permanent contraindications to the treatment by x rays.
6. Temporary cosmetic stigmata are sometimes met with, especially in blonde subjects; but permanent disfigurement of any kind is the result of faulty technique.

TREATMENT OF SLEEPING SICKNESS BY SALVARSANIZED SERUM.

BY

CLAUDE H. MARSHALL,

MEDICAL OFFICER, UGANDA PROTECTORATE.

THE history of the treatment of sleeping sickness in the past has been one of optimistic hopes resulting in failure, as each new method tried has been found to be nearly the cure, yet to have just fallen short of success. This applies more especially to African patients, for while certain Europeans and Asiatics have been undoubtedly cured of the disease, no such success has followed the treatment of natives. The reason may be that the African native is seldom seen in the very early stages, and being also more susceptible to the poisonous effects of the arsenic preparations used, is unable to stand the large doses employed to kill the trypanosome in the cases of non-natives.

For nearly a year after its introduction atelyl was hailed as a definite remedy, only to prove not quite successful, while more recently Drs. Rodhain and Broden in the Congo have shown that salvarsan produces great improvement in early cases, although they do not claim it to be a cure, and definitely state that it is of little value if the trypanosome can be found in the cerebro-spinal fluid (Manson).

Quite early in the disease the trypanosome appears to gain an impregnable position in the central nervous system, and when attacked by drugs which drive it from the blood stream, remains undefeated in the spinal cord, in the same way as syphilis, which in the early stages is easily cured, but once it has established itself in the central nervous system complete cure is more problematical.

It would appear therefore that if sleeping sickness is to be cured, except in the earliest stages, the trypanosome must be attacked in the spinal cord, as well as in the blood stream. With this idea I commenced treating cases by intraspinal injections of neo-kharsivan; unfortunately the first case so treated died as a result of the injection.

Case 1.—W., a man aged about 40 years, was examined on September 26th, 1918. The glands were small, but typical. Trypanosomes were present in the gland juice. An intravenous injection of 0.6 gram neo-kharsivan was given on September 27th, and on October 1st an intraspinal injection of 0.025 gram neo-kharsivan, after 10 c.cm. of cerebro spinal fluid had been drawn off. The patient died on the following day.

Though doubtless this method will not necessarily cause death, I decided to employ neo-kharsivanized serum for future injections into the spinal cord instead of the drug itself.

The patients treated were divided roughly into five classes according to the stage of the disease, as follows:

CLASS A.—Early cases with distinct glands, the juice of which contains scanty trypanosomes, but with no other signs. The patients consider themselves quite well, and are only discovered by systematic examination of a large number of natives.

CLASS AB.—The glands are well marked and contain numerous trypanosomes. The patients do not feel well, and complain of pains and sleeplessness.

CLASS B.—In addition to above signs there are finger and tongue tremors, increased knee-jerks, headache, and pain in the limbs. Impotent.

CLASS BB.—Advanced cases, unintelligent, spastic, and uncertain gait.

CLASS C.—Almost comatose. Unable to walk or reply to questions.

With this classification it is suggested that the central nervous system has been invaded in the AB class, though it is possible that this may occur even earlier.

Method.

1. An intravenous injection of neo-kharsivan is given, and after one to two hours 10 c.cm. to 40 c.cm. of blood are drawn off from a vein into a sterile vessel.

2. The vessel containing the blood is kept cool by being placed in a beaker of cold water for from twelve to sixteen hours, by which time the clear serum has separated from the blood clot.

3. A lumbar puncture is performed, and 15 c.cm. to 20 c.cm. of cerebro-spinal fluid drawn off, and a corresponding quantity of the serum, obtained as above, slowly injected into the spinal cord through the lumbar puncture needle by means of a large all-glass syringe.

This method has been used in a series of 12 selected cases, with the results tabulated below. Several patients have only been observed a short time since the treatment; the longest period of observation has been sixteen months.

While no absolutely definite results can be looked for till several years have elapsed after the patient has been treated, it must be borne in mind that these cases have only had one injection of the serum and were then sent back to their homes without further treatment of any kind, except in one case, No. 9, to whom two injections of serum were given.

Two cases are recorded in detail, and the others are shown in the table.

Case 2.—A woman, aged about 30, Class AB, was examined on September 9th, 1918. There was a large typical chain of glands in the neck and trypanosomes were present in the gland juice. On October 1st an intravenous injection of 0.6 gram of neo-kharsivan was given; 2 oz. of blood were drawn off after three hours. Twenty minims of serum were injected into the spinal cord next day. On December 14th, 1918, the glands at re-examination were found to be few and pea-like. One cubic centimetre of the patient's blood was injected into a monkey, which on December 24th escaped and was not recaptured. On the 30th the glands were as before and another monkey was inoculated. On February 8th, 1919, this animal was well; as I left the station on tour it was not seen again, but I understand it remained perfectly well until it escaped some time later. The patient was re-examined on May 29th and September 2nd, 1919, when she was quite well and the glands were very small. A monkey inoculated on the latter date was quite well at three subsequent examinations (the last on January 7th, 1920). The patient was last seen on November 29th, 1919, when she was quite well; two pea-like glands were present, the juice of which contained no trypanosomes.

Case 4.—A woman, aged 27, Class AB, had one large soft gland in the neck on January 9th, 1919; trypanosomes were present in the juice. On January 10th, 1919, 0.6 gram of neo-kharsivan was injected into a vein, 40 c.cm. of blood being drawn off. Intraspinal injection of 20 c.cm. of serum was performed next day. At her next examination, on September 2nd, 1919, no glands were palpable, and inoculation of 2 c.cm. of blood was made into a sheep, which was found quite well on October 30th, 1919, and January 7th, 1920. At subsequent re-examinations on November 12th, 1919, and January 7th, 1920, the patient was well and her glands were not palpable.

Note.—This woman disappeared during the severe famine in the early part of 1919, and was not seen for nearly nine months.

These two cases had only one injection and no other treatment. After sixteen and twelve months respectively they show no signs of relapse, declare themselves to be perfectly well, and are certainly in better health than when they first came under treatment.

Table showing Twelve Cases Treated.

No. of Case.	Sex.	Class.	Dose of Serum.	Months since Treatment.	Result.
2	F.	A B	20 min.	16	Well.
3	M.	A	3 c.cm.	1	Disappeared.
4	F.	A B	20 c.cm.	12	Well.
5	F.	A B	8 c.cm.	1	Died (cause unknown).
7	M.	B	15 c.cm.	6	Well.
8	F.	B	15 c.cm.	4	Well.
9	M.	C	20 c.cm.	1½	Died.
10	M.	B B	15 c.cm.	2½	Improved.
11	M.	B	21 c.cm.	1½	Well.
12	F.	A B	7 c.cm.	1½	Well.
13	F.	B	20 c.cm.	1½	Well.
15	F.	A B	24 c.cm.	1½	Well.

Of the cases quoted above, Case 3 showed no signs of relapse when last seen, but he was lost trace of during the famine, and is said to have died of hunger and dysentery in April or May.

Case 5 was treated on July 11th, 1919, and showed considerable improvement. She died suddenly on August 18th, 1919, from some unknown cause. I did not see her as I was away on tour, but I understand that she was well and working on the cultivation in the morning, but was found dead in her hut next day. There appears to be no reason to suppose that her death was due either to sleeping sickness or to the serum injection.

Case 9 was very advanced; on admission he could not give his name and was unable to walk, and could only stand with difficulty. This patient was a man, aged about 22, Class C; he was examined on September 25th, 1919. A very large chain of typical glands was found on both sides of the neck, and the gland juice contained numerous trypanosomes. Trypanosomes were also found in the blood but not in the cerebro-spinal fluid. Next day 0.6 gram of neo-kharsivan were injected intravenously. On the 27th an intraspinal injection was made of 20 c.cm. of serum, and on the 29th he appeared better. On October 12th he was much improved and more intelligent; the glands were harder and smaller and their juice contained no trypanosomes. The same observation was made two days later. On October 16th 0.6 gram of neo-kharsivan were given; this was repeated on November 1st, on which date no trypanosomes were found in either the blood or the gland juice. Next day 22 c.cm. of serum were injected intraspinally, and no trypanosomes were found in the cerebro-spinal fluid, of which 3 c.cm. were injected into a dog. The patient died on November 3rd; on January 7th, 1920, the dog was well.

It appears quite possible that this man died from the effects of treatment, but at the same time the disease was so far advanced that even supposing the trypanosomes in his system had been killed their effect prior to treatment might still have caused death. It is interesting to note that there was no rise in temperature above normal after the first injection.

In order to confirm the experiments of Drs. Rodhain and Broden, as well as the one or two similar cases which have occurred in Uganda, I quote the following cases to show that the improvement noted in the patients tabulated above is not due to the injections of neo-kharsivan alone:

Case 6.—A large dog was brought to me suffering from keratitis, and on examination its blood was found to be swarming with trypanosomes of the *gambiense-brucei* type (Duke). On July 11th, 1919, it received an intravenous injection of 0.3 gram of neo-kharsivan; on the 13th it was much improved, the eye symptoms being better and the dog eating well. On the 22nd the trypanosomes returned to the blood, and on August 1st the animal was very ill, and refused all food; 0.4 gram of arsenophenylglycin was given intravenously, and three days afterwards no trypanosomes could be found in the blood. They returned, however, on the 14th, and on the 25th the animal, which was blind and refused food, was shot.

Case 7.—M., a man of about 30, Class B, had a few small glands with trypanosomes in the juice when first examined on June 1st, 1919. He disappeared for a month, but when he returned similar findings were observed (July 1st). On the 10th, 0.6 gram of neo-kharsivan was injected intravenously, but no serum was given. On the 27th the glands were small and hard, and trypanosomes could not be found in the juice; 20 minims of cerebro spinal fluid, containing no trypanosomes, were withdrawn by lumbar puncture on September 29th, and injected into a monkey. On October 25th the patient was greatly improved, and stated he could do work of which he was not previously capable. All glands but one (very small and hard) had disappeared. The monkey was quite well. Three days later trypanosomes were found after prolonged search in the

centrifuged deposit from the man's cerebro-spinal fluid, 3 c.cm. of which were injected into a sheep. Next day 0.6 gram of neo-kharsivan was injected intravenously, and 15 c.cm. of serum were given intraspinally. On January 7th, 1920, the patient, the monkey, and the sheep were found to be quite well.

In these cases the patients made undoubted progress under neo-kharsivan alone, but in neither case was the disease cured.

The fact that the cerebro-spinal fluid in Case 7 showed no trypanosomes on first examination, and that both the sub-inoculated animals remain well, I am unable to explain except as due to faulty technique.

In conclusion, I would suggest that these experiments tend to show:

1. That intra-spinal medication causes improvement in the patient, and may prove to be a complete cure.

2. That it has a greater beneficial effect than intravenous injections alone.

3. That in advanced cases, even if the actual disease is arrested, the damage already done to the central nervous system is probably beyond repair.

I wish to express my thanks to Dr. C. A. Wiggins, Principal Medical Officer, Uganda Protectorate, for permission to publish these notes.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF ENCEPHALITIS: LETHARGY AND MYOCLONUS.

A STEEL dresser in a shipyard was admitted to the Royal Victoria Hospital, Belfast, under the care of Dr. William Calwell, on April 26th.

He had been a soldier for eleven years (one year in Africa, no illness; six years in India, enteric; four years in France, influenza, 1916). On April 2nd he felt ill, complaining of headache and double vision and pain and stiffness of the neck and right shoulder; the following day his right eyelid dropped and he developed a double internal squint. About a week later the muscles of the neck and right side of the face were twitching.

He was admitted in a drowsy condition; temperature 99.4°, pulse 84, systolic blood pressure 130; urine, heart, and lungs normal. He lay indifferent to his surroundings, and would only answer questions if vigorously roused, when he was, however, quite intelligent, though slow of cerebration. When the stimulus of the raised voice was withdrawn he sank back into lethargy. Although lethargic he did not sleep at night.

There were striking myoclonic movements of the face and neck; the twitchings, rhythmic, at the rate of 60 a minute, involved the levator anguli oris, the masseter, the temporalis, the sterno-mastoid, and the upper part of the trapezius of the left side. The diaphragm was not involved. The sphincters were normal; the knee-jerks were brisk; there was no ankle clonus; the abdominal and epigastric reflexes were absent. The pupils responded to light, but not to accommodation. There was ptosis of the right eyelid (N.3), double internal strabismus (N.6), and inability to close the left eyelid (N.7). The discs were normal.

The cerebro-spinal fluid was clear under pressure, and the cell count under 10. The Wassermann reaction, blood and cerebro-spinal fluid, was negative.

On May 14th the patient's condition was unchanged except that there was a slight decrease in the lethargy and abatement of the ocular symptoms.

The case is therefore hybrid between lethargic and myoclonic encephalitis. It conforms to the lethargic syndrome with the dominant exception of the myoclonus.

JAMES CAMAC, M.B., B.Ch.,

Royal Victoria Hospital, Belfast.

House-Physician.

A BUST has recently been erected by the Faculty of Medicine and Pharmacy of Lille to commemorate Joseph Willot, a Roubaix chemist, who by the publication of a journal known as *L'Oiseau de France* did much to keep up the courage of the population of Northern France during the German occupation, and subsequently died during imprisonment in Germany.

Reports of Societies.

TREATMENT OF TUBERCULOSIS.

At a meeting of the Medico-Chirurgical Society of Edinburgh, held on May 5th, with Emeritus Professor F. M. CAIRD in the chair, Professor Sir ROBERT PHILIP opened a discussion on the treatment of tuberculosis. He showed how the Hippocratic conception of the disease was a terminal phenomenon, and explained the modern outlook on the subject by which all efforts were directed to the early recognition of bacillary infection. He outlined the essential facts as to invasion of the organism, tissue reaction and systemic intoxication, drawing an analogy between tuberculosis and syphilis. He urged a broad outlook in dealing with a general disease with local manifestations. In the past too much had been made of the local phenomena in the various organs without taking sufficient notice of the systemic disturbances, these latter being very frequently in advance of the local signs. The value of the various special diagnostic tests was briefly reviewed. He then dealt with the advances that had been made in the recognition of the tractability of the disease if taken in hand sufficiently early and sufficiently firmly. He urged strongly the importance of keeping the patient under surveillance once the disease had been definitely determined. Tuberculosis took a long time to come and a long time to go, even with the best results. Once the patient was tuberculinized there was always the risk of further spread in acute or chronic form. So-called "fresh outbreaks" were simply caused by further spread in an already infected individual. He showed from the Registrar-General's returns the very steady decline in the mortality, although there was an increase in the cases coming for diagnosis and advice. He also reminded his audience how the age of death had gradually been postponed, as shown by the mortality tables. Finally, he urged the need for continuous intensive observations, both clinical and experimental, with a fuller training of men on the modern lines. There was ample reason for sound optimism.

Sir HENRY J. GAUVAIN dealt with the conservative as opposed to the radical treatment of non-pulmonary tuberculosis. He pointed out that tuberculosis was a general disease with local manifestations, and the aim of conservative treatment was to make use of every means in our power to assist in the formation of Nature's fibrous barriers. Conservative treatment was not to be confounded with convalescent treatment. He considered his lines of treatment under four main headings:

1. General treatment, which included (a) climate; (b) hygiene; (c) occupation, on which he laid considerable stress, and told how he had five educational establishments at Alton, beginning with a nursery school and going on in stages to continuation classes for cripples; (d) dietetic; (e) specific, including drugs.

2. Local treatment. This included orthopaedic and other measures designed to secure local rest and prevention and correction of deformity. He explained the vital importance of minute attention to detail in carrying out these procedures.

3. Adjuvant methods of treatment, including (a) heliotherapy, which was used by gradual increasing exposure to the sun—he found those who did not take on pigment readily did badly; (b) x rays; (c) vaccine-therapy; (d) chemio-therapy; and (e) surgery.

4. Treatment of complications. He gave in detail the gradual change which had taken place in our views as to the treatment of tuberculous abscesses.

Finally, figures were given to show the results obtained by the conservative method as practised at Alton, and he explained how a considerable length of time was required to attain satisfactory results.

Professor GULLAND, in thanking Sir Robert Philip and Sir Henry Gauvain, mentioned the importance of the time factor and good will of the patient in treatment.

Mr. JOHN FRASER, from his study of the pathology of bone and joint tuberculosis, declared himself a strong believer in conservative methods of treatment, but urged that certain conditions made operation necessary—namely, (1) social conditions, (2) age of the patient, (3) in bone tubercle, when the disease was near a joint, removal of disease would save the joint.

Dr. IAN STRUTHERS STEWART spoke of sanatorium difficulties. He found the question of occupation of his patients of vital importance, as the tendency to staleness

was great. His experience of pigmentation in heliotherapy agreed with Sir Henry Gauvain's. He considered there had been no definite general advance in sanatorium treatment during the last twenty years, and thought the cause was due to a failure to develop sufficiently broad lines of research.

Sir DAVID WALLACE confined his remarks to renal tuberculosis, and classified such cases into three groups—namely, (1) early cases with renal symptoms but no cystitis, (2) cases with vesical symptoms and no special renal symptoms, (3) cases showing a palpable tumour, with no urinary symptoms because of total destruction of the kidney. He quoted cases showing the value of removal of the affected organ, and so removing the source of infection and toxæmia; this also had the result of diminishing bladder symptoms. He urged on his audience the necessity of excluding or verifying tuberculosis as a cause of any chronic cystitis. Tuberculin he considered of some value, but general lines of treatment were, in his opinion, much more valuable.

Dr. LOGAN TURNER gave a series of statistics showing the frequency of tuberculous disease in nasal and laryngeal regions; there was a large excess percentage of lupus in the female. He considered enforced silence and general treatment the essential factors in treatment.

Dr. FERUS HEWAT spoke of D.A.H. as at times a symptom of latent or undiscovered tuberculosis, and quoted a case in which tubercle bacilli were found in the sputum on the twenty-eighth consecutive examination. He urged a more careful consideration of toxæmic symptoms.

Dr. W. G. SYM referred to cases of pseudo-glioma and prolonged inflammation of the ciliary body. He was not satisfied that tuberculin was of much avail in the latter type of cases. His experience of children with chronic infected corneæ—not blindness—was that they took in consequence a lower place in the world. He noted, however, that even three days in the ward made a vast difference to them, but economic conditions of the present day were against these children.

Dr. CHALMERS WATSON spoke of the importance of secondary infections in tuberculosis, and urged that a more complete investigation should be made along these lines. He also referred to latent tuberculosis in childhood.

Dr. GEORGE MACKAY referred to a paper he had published in the BRITISH MEDICAL JOURNAL of October 19th, 1912, in relation to tuberculosis in ophthalmic work. He thought the value of tuberculin was enhanced by the addition of a vaccine from a secondary infection organism—for example, staphylococci. He referred to tuberculous deposits as a cause of ocular paresis.

Mr. CATHCART spoke of the conservative treatment of chronic abscesses, and referred to Lister's method of treatment in such cases. Mr. Cathcart obtained good results from the use of iodoform emulsion.

The CHAIRMAN referred to the length of time required for treatment, the importance of rest and fixation, and considered the site of the disease was an important factor in determining operative or conservative treatment. He had had good results by operation in advanced cases, as he found the removal of advanced disease assisted the natural tendency to recovery. He said some of his results had been most surprising.

RUPTURE OF CAESAREAN SECTION SCAR.

(Concluded from 671.)

At the afternoon session of the conjoint meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine and the North of England and Midland Obstetrical and Gynaecological Societies,* Mr. CHRISTOPHER MARTIN presiding, Dr. EARDLEY HOLLAND read in abstract a paper on "Rupture of the Caesarean section scar in subsequent pregnancy or labour," and this was followed by statistical reports from various hospitals. Dr. Holland said that he supposed no accident in the whole of obstetrics was so disturbing to the surgeon as the one which formed the subject of his paper. It had seemed desirable to him to get at the truth of the matter by a series of investigations in which various hospital staffs and others had willingly co-operated. This investigation had been an unqualified success.

* The first part of the report appeared in the BRITISH MEDICAL JOURNAL of May 15th, p. 672.

In the first part of his paper he reported 5 new cases; in the second part he reviewed the literature and entered into a general discussion of the etiology of ruptured scar; and in the third part he compressed the results of his follow-up inquiry. The cases of ruptured scar after the classical operation which he had been able to find in literature in the shape of the original report numbered 92; two-thirds of these had occurred between 1910 and the present time, corresponding with the period during which the indication for the operation had been very much extended.

He touched upon the anatomy of the completely healed scar, thin scar, and ruptured scar. There was no doubt that perfect healing led to complete muscular regeneration, with the result that under the microscope not a trace of scar tissue could be seen. The essential point in all the badly united scars was failure of the muscle fibres. During pregnancy the scar became thin, and ultimately might come to consist of peritoneum outside and decidua inside, and between the two a layer of thin fibrous tissue. As to the frequency of rupture, no information had hitherto been available. There was a tradition in obstetric literature that rupture occurred in 2 per cent. of cases after Caesarean section, but that tradition could be traced to its source and there was no truth in it. Dr. Holland then gave the results of the collective investigation.

Some twenty-four hospitals and private obstetricians had contributed, and the totals were as follows:

Caesarean sections	1,582
Followed up	1,089
No subsequent pregnancy	610
Subsequent pregnancy	473
Delivered by natural passages	70
Repeated Caesarean section	325
Abortions	42
Pregnant now	91
Ruptured scar	18

An investigation was also made as to the suture material employed, and it was found that this was catgut in 713 cases and silk in 293.

The Glasgow Royal Maternity Hospital, for example, had been able to trace the subsequent obstetric history of 94 patients. Of these, 40 patients had not since become pregnant; 54 patients had become pregnant since operation, and 8 of them had conceived for a second time. There had thus been an opportunity of investigating the strength of the scar in 62 pregnancies. In 7 cases the pregnancy was not sufficiently far advanced to produce an appreciable strain on the scar. Of the remaining 55 cases, 2 patients were at present bearing the strain of eight months' gestation; 39 were delivered by abdominal Caesarean section after the onset of labour, and 7 similarly delivered before labour had set in; 3 cases terminated by normal labour, 1 by a breech labour, 1 as a forceps delivery, and 2 as craniotomies. In this series of 55 scars one rupture was to be recorded, one scar was on the point of rupture, and one dangerously thin. The conclusions from this one hospital report were that there was relative sterility following Caesarean section to the extent of 42.6 per cent., that abortion was relatively uncommon, only occurring in 5.3 per cent., that liability to rupture was present in 5.5 per cent., and that rupture actually occurred in 1.8 per cent.

Professor MUNRO KERR (Glasgow) discussed the subject under the following heads:

1. The evidence that the uterine scar in conservative Caesarean section was often unsatisfactory.
2. The reasons why the uterine scar was so often defective.
3. The means by which a better scar could be secured with an ordinary longitudinal incision.
4. An alternative incision which he considered preferable to the old longitudinal incision.

He believed that the scar was unsatisfactory because of the difficulty of securing complete asepsis; the autolysis which occurred in the uterine muscle fibres, during involution; the great difficulty in adjusting accurately the edges of the wound; the state of unrest of the uterus subsequent to operation; the difficulty of complete hæmostasis; the spongy and friable condition of the tissues on the placental site when this was on the anterior wall of the uterus. He believed that a better scar would be secured if the patients could be properly prepared for the operation beforehand, and that the risk of infection would be less if the placenta were expressed through the vagina instead of being brought out through the uterine wound. He advocated suture in layers; personally he employed catgut for the deepest layers, linen thread or fine silk for the bulk of the muscle tissue, and catgut for the peritoneal surface. He thought it important to suture the uterus whilst it was in a state of retraction, not of contraction. He suggested an alternative incision—namely, a transverse incision in the lower uterine segment, and gave details of the procedure. The advantages he claimed for it were: (1) The comparatively slight bleeding incurred; (2) the uterine wall

was here thin and the edges of the wound therefore more easily adjusted; (3) this area of the uterine wall was at rest during the earlier days of the puerperium; (4) owing to the fact that the lower uterine segment was not fully stretched until labour was well advanced, the risk in subsequent pregnancies and labours was less than with the ordinary incision.

Dr. J. D. BARRIS said the subject under discussion was a vital one. If it could be proved that the scar was liable to rupture they must modify their attitude with regard to the classical conservative operation. The cases had been collected at St. Bartholomew's Hospital so as to include all these recorded up to July, 1919. The results were:

Total number of Caesarean sections (excluding sterilized cases), 81.

Number of cases traced, 43 (59 per cent.).

Number of cases in whom no subsequent pregnancy occurred, 20 (41 per cent.).

Number of cases who subsequently became pregnant, 28 (59 per cent.).

Results of pregnancies: Delivery by natural passages, 4; by repeated Caesarean section, 21; abortion, 1; non-pregnant, 1; rupture of scar, 0.

The method of suture employed was a buried interrupted silkworm gut. Caesarean section had been performed several times upon the same patient without untoward result.

He pointed out that the common factors in the 18 cases of rupture reported by Dr. Holland were the use of catgut in 15 cases and sepsis which occurred in about half. He considered there was justification for preferring the classical operation.

Dr. L. G. PHILLIPS said that, excluding sterilized and fatal cases, sixty Caesarean sections had been performed since 1912 at the Middlesex Hospital.

Of these 60 cases, 39 had remained sterile and 21 had subsequently become pregnant, of whom 14 had had repeated sections, 3 had had subsequent natural labours, 2 had had miscarriages, and 1 was pregnant at the present time. There had been 1 case of rupture of the scar. With regard to the condition of the scar in repeated sections, 4 cases had had three and 11 cases had had two repeated sections, making in all nineteen repeated sections. In 1 case only was the scar seen as a thin line; in the other 18 cases the scar was invisible and impalpable, and healing was apparently perfect.

An interesting feature was the anterior placental implantation in every case of repeated sections, though in the first sections the placenta was often posterior, and it had been maintained that implantation on the scar was harmful, through the trophoblastic action of the placenta or the liability to retro-placental haemorrhage. Dr. Phillips suggested that the reverse might be true, for a thick placenta might act as an internal splint to the scar, and tend to prevent thinning of the scar region in labour. Moreover, the uterine musculature of the scar region because of its apposition with the placenta would not be subjected to the same muscular strain in labour as the rest of the uterus. If this were not so, uterine retractions and contractions would lead to premature separation of the placenta, which was not common.

Of the 60 cases, 39 had remained sterile for from two to seven years, mostly three years or over, and, excluding cases where precautions had been taken, the percentage still worked out at 52. There was no indication that pyrexia in the puerperium was a causative factor, for 68.4 per cent. of the sterile cases had afebrile puerperium, while 27 per cent. of those subsequently pregnant had pyrexia in the puerperium. Age and parity appeared to have no influence, as half of the sterile cases were primiparae in the twenties. The frequency of recurring pregnancies with repeated Caesarean section indicated that the operation itself was not to blame; latent gonorrhoeal infection might play a part. Perhaps this sterility and delayed pregnancy represented Nature's attempt to allow time for consolidation of the scar.

Dr. AMAND ROUTH said that when, in 1910, he collected 1,282 cases of Caesarean section performed by over 100 obstetricians and gynaecologists then living, beginning with a Caesarean section performed by Dr. Lloyd Roberts in 1867, the risk of repeated Caesarean section in anticipated cases was briefly discussed, more particularly from the point of view of whether sterilization of the patient was justifiable or desirable.

In 1910 the mortality of Caesarean section for contracted pelvis in clean cases was under 3 per cent., and the risk of repeated Caesarean section in anticipated cases was even less, but fourteen out of the 100 operators advised sterilization to

avoid the danger of rupture of the scar in subsequent pregnancies. In this century "not sterilized" operations had increased considerably, leading to more subsequent pregnancies and repeated Caesarean sections. Of 669 "not sterilized" cases of Caesarean section for contracted pelvis 112 cases had become pregnant. Of these 112 pregnancies 103 ended in repeated Caesarean sections (some more than once), and three had a subsequent rupture through the scar, a percentage of 2.6.

Dr. ROUTH thought, however, that there must have been many pregnancies and probably some more ruptures amongst the 354 "not sterilized" cases included in the last three and a half years of his series. To encourage perfect union, if the position of the placenta could be determined or surmised, the incision should be made elsewhere, especially in "unclean" cases. It seemed clear that transverse fundal incisions were not advisable, partly because the placenta often spread on to the fundus. Caesarean section should be performed at full term or at the earliest indication of labour, so as to secure perfect uterine retraction. Intrauterine sepsis was doubtless a cause of imperfect union of the incised muscles, especially if the incision had been made through the placental site. Sepsis, even with suppuration of the wound, did not necessarily prevent further pregnancies or repeated Caesarean section. As to sutures, in 1910 catgut was used for both deep and superficial sutures by twenty-seven operators, whilst forty-one used silk and eight silkworm gut.

Dr. CARLTON OLDFIELD said that he had been able to follow up 39 out of 41 cases operated upon by himself. Twenty-one had had no further pregnancies; this fact he believed was due mainly to dread of a subsequent operation. Nineteen had afterwards become pregnant; 3 were delivered through the natural passages; 11 had Caesarean section performed twice, and 1 three times.

Dr. HERBERT SPENCER, after expressing appreciation of the valuable papers by Dr. Holland and Professor Munro Kerr, regretted that the work had not been carried out on the same scale and general plan as that adopted by Dr. ROUTH. It was a pity that the series was not made continuous with Dr. ROUTH's, and that the cases in which the first operation was performed before 1912 were excluded. He (Dr. Spencer) had performed 66 Caesarean sections and 13 repeated Caesarean sections, and had never met with a case of ruptured scar; it ought not to occur in an aseptic case properly sutured. He regarded adhesions in an aseptic case as due to faulty technique.

Dr. BLAIR BELL held that failure of the uterine scar to heal firmly was due to sepsis. He believed that in the most definitely "suspect" cases an afebrile puerperium could be obtained by sterilization of the uterus and vagina with hypochlorite solution. A large gauze pack, saturated with this solution, undiluted, should be left in the uterus protruding through the cervix into the vagina, and removed when the patient had been put back to bed. The question of technique, however, was important. He preferred to make the incision as high up as possible in the uterus. He had operated in the way described by Professor Munro Kerr. This situation, however, might be unsuitable owing to the presence of a large venous plexus running across the utero-vesical pouch. For the closure of the wound he preferred mattress sutures of chronic catgut for the deeper part of the uterine muscle, the same stitch being carried over to bring together the superficial part of the muscle of the peritonium.

Dr. FORMERGILL said that investigations conducted by American obstetricians in recent years led to the conclusion that in the absence of obstruction, and when the recovery from the previous Caesarean section had been afebrile, the patient under skilled observation might be left to deliver herself. He thought the present discussion did not warrant any advance from this position. Too much stress seemed to have been laid upon the suture material. He had had equally good results with silk and various kinds of catgut, and now sewed up with anything the nurse gave him. Adhesions were avoided by making the abdominal incisions high up, so that when the uterus was emptied and sewn up, the two incisions should not lie opposite one another. He had always avoided cutting into the lower uterine segment owing to the proximity of the vagina and bladder, and because of the large venous structures around it; before adopting the procedure advocated by Dr. Munro Kerr he would like to have the results of a few hundred cases.

The discussion was continued by Dr. GOUGH, Dr. FLETCHER SHAW, Dr. BRIDE, Dr. CLIFFORD WHITE, and Dr. LAPHORNE SMITH.

In reply, Dr. EARDLEY HOLLAND said that the most important point revealed in this collective investigation was the danger of eatgut, and he hoped that those who used this material would renounce this dangerous practice. Professor MUNRO KERR said that time only would show which incision gave the soundest cicatrix. Perhaps in five or ten years' time he would be convinced that the incision in the lower uterine segment did not possess the advantages he now believed it to have. He was at present a little uncertain whether infection in the wound would be more likely to occur with this incision than with the classical longitudinal one.

ANNUAL OPHTHALMOLOGICAL CONGRESS.

THE annual congress of the Ophthalmological Society of the United Kingdom was held from April 29th to May 1st at the house of the Royal Society of Medicine, London. The president, Mr. J. B. STORV, of Belfast, in his opening address, of which an abstract was printed last week at p. 671, dealt with the position of ophthalmology in the curriculum of the medical student and in the final examinations.

The first morning of the meeting was devoted to the reading of papers. Amongst these were papers by Mr. Usher on "Enlarged cornea in fish with indications for the cause of the overgrowth"; a companion paper by Mr. Treacher Collins on "Megalocornea and microcornea." A paper by Mr. John Rowan, entitled, "Are not some cases of glaucoma better treated without operation, and, if so, what are the indications?" gave rise to a keen discussion, which showed that there is much room for critical observation of the progress of chronic glaucoma and the advisability of operating, and of the results of the various modes of operating. Other papers were read by Mr. Harrison Butler on "Infection after operations for cataract," by Mr. G. H. Pooley on "Abnormalities of the lacrymal apparatus," by Mr. Harvey Goldsmith on "Double traumatic dislocation of the lens," and by Mr. G. F. Alexander on "Operation for cataract and for squint."

In the afternoon a clinical meeting was held at the Royal London Ophthalmic Hospital (Moorfields), the features of which were an exhibition of "artificial daylight" and a most interesting oretiological disquisition on the neighbourhood of old Moorfields by Mr. Percy Flemming, illustrated with lantern slides and maps.

Friday morning was occupied by a discussion on "Diabetes in relation to diseases of the eye," opened by Sir Archibald Garrod and Mr. Foster Moore, followed by Dr. Leyton, Mr. G. Mackay, Dr. Poynton, Mr. P. H. Adams, Dr. Cammidge, Mr. Gray Clegg, Dr. C. O. Hawthorne, and others. The most striking point arising from the various papers was the difference in view of the ophthalmic surgeon and the physician. To the former the association of eye diseases with diabetes was a fairly frequent finding. To the physician, with his much greater number of cases of the general disease under observation, the connexion was a comparatively rare one.

The evening of the day was taken up by the reading of papers: Mr. H. M. Traquair on "Anatomically separate anterior commissure at the chiasma in a case of pituitary tumour with acromegaly"; Dr. Gordon Holmes on "Tumours involving the optic nerves and chiasma"; Mr. M. L. Hine on "Primary epithelioma of the ciliary body"; Mr. Ernest Clarke, "A further note on the accommodation of the eye"; Mr. Humphrey Neame, "Cysts of the retina"; Mr. William Wallace, "A glyptic method for the representation of certain conditions of the fundus in disease."

Saturday morning was occupied by a visit to St. Margaret's Hospital, Kentish Town, which has recently been established by the Metropolitan Asylums Board for the reception of infants infected with ophthalmia neonatorum and their mothers. A discussion on "The prevention and treatment of ophthalmia neonatorum" was opened by Dr. Gibbon FitzGibbon, Master of the Rotunda Hospital, and Mr. M. S. Mayou. A number of members of the Congress took part in the discussion.

Reviews.

MEDICAL ENTOMOLOGY.

THE first edition of Colonel ALCOCK'S *Entomology for Medical Officers*¹ was published in 1911, and immediately established its position as an excellent introduction to the entomological borderland of medicine. A second edition has now appeared; it has been written and illustrated anew, but its aim has not been altered. Colonel Alcock has been guided by his experience as lecturer on entomology, etc., at the London School of Tropical Medicine, but the easy style in which it is written shows that he understands how much the usefulness of a book dealing even with a technical subject can be increased by attention to literary form. It is aptly said that ever since the days when Aaron stretched forth his rod and smote the land of Egypt with lice and flies Arthropoda have had an evil reputation as the source of some of the sharpest and readiest scourges of mankind. "A series of discoveries brilliantly initiated by Manson in 1879" have replaced vague surmise by precise knowledge, and the object of the handbook is to outline the range of the activities of the Arthropoda in the domain of human pathology, as parasites, as agents in spreading infection, and as aggressively or defensively venomous. This object is well fulfilled, and though many pages of the book are necessarily filled with details, the author does not hesitate when occasion offers to discuss the general principles of administration and to express his own opinion. As an illustration we may refer to what is said on p. 191 with regard to schemes for dealing with the tsetse flies. The sweeping extermination of wild animals upon which these flies naturally feed is declared to be not only insecure in its particular foundations, but "almost impious in its disregard of all the lessons of Nature." "We ought," the author writes, "now to have learned that though, after long experience and by gradual reconstruction of his whole environment, man may subdue organic Nature, yet any isolated blind strokes that merely 'deal damnation round the land' will not be overlooked by Nemesis." The book is addressed to medical officers whose circumstances or inclination take them to hot countries, but from the manner of its composition it will appeal to many others, who will find in the introduction to the book and to the several chapters much matter of absorbing interest.

THE ORTHOPAEDIC TREATMENT OF GUNSHOT INJURIES.

ORTHOPAEDICS is perhaps the branch of surgery which has received the biggest impetus as the outcome of the war. Civilian surgery is certain to benefit proportionately, for there can be no doubt that many surgeons have had their thoughts turned to the possibilities of orthopaedics in conditions hitherto regarded as outside their province, and have realized as never before the need for preventive surgery in deformities. It is therefore very proper that surgeons to whom the opportunities for orthopaedic work came should bring their opinions and experiences before their colleagues.

Dr. MAYER'S book, *The Orthopaedic Treatment of Gunshot Injuries*,² is in no wise a treatise on the subject. He claims only that it is an attempt to help those (in the words of his dedication) striving to aid the cause of the crippled soldier, by presenting principles and rules of guidance that have been of value to himself. It is divided into two parts, according to the stage of treatment: at the front, and at the base hospital. Naturally, the second is the important one now.

In the treatment of bone injuries the author lays stress on the advantage of powerful extension, preferably with "bone-tongs" and heavy weights, on the prevention of joint stiffness in prolonged immobilization (pictures and description of mobilizing the knee while extension of the femur is maintained are shown), and on bone implantation in non-union of fractures. The operative skill demanded

¹ *Entomology for Medical Officers*. By A. Alcock, C.I.E., M.B., LL.D., F.R.S. Second edition, revised. London: Gurney and Jackson, 1920. (Demy 8vo, pp. xv+380; 197 figures, 18s. net.)

² *The Orthopaedic Treatment of Gunshot Injuries*. By Leo Mayer, A.M., M.D., Instructor in Orthopaedic Surgery, New York Post-Graduate Medical School and Hospital, Philadelphia and London: W. B. Saunders Co. 1918. (Post 8vo, pp. 250; 184 figures, 12s. net.)

for implanting bone grafts is very considerable, and no surgeon should attempt these procedures without possessing practical ability as well as theoretical knowledge of the best kind of graft, its object and its fate. The author in this chapter goes a little out of his way to describe experiments, illustrated with some very beautiful pictures, to controvert the Macewen theory of the function of the periosteum.

In the chapter on treatment of nerve injuries the various methods of suturing nerve ends and bridging gaps are mentioned with sufficient detail to guide the reader. The author is exceedingly open-minded on the whole question and frankly says that "in nerve suture no one dare speak with authority." While not unmindful of the great value of posturing and transplanting methods, he claims sufficient success in a few cases for nerve grafting to justify its use. One cannot avoid comparing the conclusion of Sir Robert Jones on the matter, that only end-to-end suture, however brought about, should be attempted.

The best chapters in the book are the two last, dealing with tendon operations and the treatment of the amputated. Mayer argues strongly for a more thorough knowledge of the intimate anatomy of tendons and their sheath relations. Minute details are given for most of the commonly employed transplantations; as these are the result of the author's experience, they will be found of great value to the surgeon. The secret of a non-adhesive transplantation is to follow Biesalski's suggestion and draw the transplanted tendon through the sheath of the paralysed one. In the treatment of the amputated, personal sympathy and tactful encouragement play a great part, for here is a social as well as a surgical question. These qualities are plainly the possession of Dr. Meyer to a marked degree, for this whole section is most happily written and beautifully and plentifully illustrated. Indeed we would be glad if the public could have their eyes and minds opened through such a chapter to the possibilities of usefulness and pleasure in the lives of the maimed with practised management of artificial limbs.

We have sufficiently indicated the scope of this very commendable book; it is a valuable contribution to war surgical literature, and will amply repay the surgeon who looks to it for help and guidance.

GYNAECOLOGICAL SURGERY.

THE appearance of the second edition of BERKELEY and BONNEY'S *Gynaecological Surgery*³ has been delayed for several years by the claims of the war upon the time of the writers. In the eight years that have elapsed since its first publication, however, gynaecological surgery has made several advances, and this new volume was needed. The text of the original has been revised and in many parts rewritten, and some hundred new figures have been added, which, we are particularly glad to note, retain the simplicity of those of the first edition and are each content to demonstrate one point. Only too often are figures of operations obscured by an attempt to illustrate two or more steps at once—a false economy.

The section on the plastic surgery of the vagina has been rewritten, and that on the treatment of displacements has been strengthened quite legitimately by the inclusion of a chapter on the normal supports of the genital canal, and on the various factors involved in different forms of displacement. Although more strictly pertaining to a text-book of gynaecology, this is so obviously and closely related to the selection of the proper method of operating in different cases that there will be no cavil at its inclusion in this book. Both the section in which myomectomy is discussed and that on radical abdominal hysterectomy for cancer of the cervix have been brought up to date in the light of the authors' further experience. The latter is a most interesting record, of which they may well be proud, though never satisfied. The discussion of the place and risks of this operation is still the best short consideration of the subject familiar to us.

A description of abdomino-perineal excision of the rectum has been included, in view of the possibility of gynaecologists having to deal with a carcinoma of the

rectum or pelvic colon which has been mistaken for a tumour of the uterus or its appendages.

In every respect this book reflects the very highest credit upon its authors, and it will long continue to rank as the standard guide to gynaecological operative methods in this country and in the British Empire.

NOTES ON BOOKS.

A CORDIAL welcome is assured to the fifth edition of Dr. FERGUSON'S handy little *Aids to the Mathematics of Hygiene*.⁴ Anyone who has had to struggle with the formulæ, etc., encountered in the course of preparation for any D.P.H. examination will find here all the help he needs clearly and concisely set forth. This work has been thoroughly revised, and the new method of recording barometrical observations is introduced, and also an estimation of the calorific values of foods. Examples and illustrations taken from papers set by the various examining bodies are included, and will prove a valuable guide to candidates preparing for such examinations. Considerable service is rendered by the author in thus collecting and explaining with admirable clearness and brevity the many formulæ and mathematical processes employed in public health work, too often found scattered at large throughout the textbooks and lightly dismissed as presenting no difficulties to the advanced student, who may, however, have ceased to have any facility in mathematics.

No better book than Dr. BARDSWELL'S *Advice to Consumptives*⁵ could be offered to convalescent patients with pulmonary tuberculosis in this country. Beginning with a short account of the disease itself, it goes on with chapters devoted to such subjects as fresh air, food, rest and exercise, occupation, emigration, and the like. It gives plenty of sound and sensible advice; perhaps its most useful section is that dealing with emigration to various parts of Africa, North America, and Australia, in which the general advantages and limitations imposed by nature and humanity on the emigrant are discussed at length and with much special knowledge. The book is well written, and may be warmly commended.

The small book on the *Change of Life: its Difficulties and Dangers*,⁶ by Mrs. SCHARLIEB, M.D., is a practical guide that should be of great use to women confronted with the problems with which it deals, and may be warmly recommended to the attention of middle-aged laywomen. A more ambitious work, dealing with the same subject for the most part, but also touching on other analogous problems that have to be solved by men and women of other ages, is Mr. GALLICHAN'S *The Critical Age of Woman*.⁷ Both volumes contain a quantity of common-sense instruction and advice.

⁴ *Aids to the Mathematics of Hygiene*. Fifth edition. By R. Bruce Ferguson, M.A., M.D., B.C. Cantab., D.P.H. Eng. London: Baillière, Tindall, and Cox. 1919. (Fcap. 8vo, pp. xii + 185. 3s. 6d. net.)

⁵ *Advice to Consumptives. Home Treatment, After-Care, and Prevention*. By Noel Dean Bardswell, M.V.O., M.D., F.R.C.P. Second edition. London: A. and C. Black, Ltd. 1920. (Cr. 8vo, pp. xvi + 153. 5s. 6d. net.)

⁶ *Change of Life: its Difficulties and Dangers*. By Dr. Mary Scharlieb. London: The Scientific Press, Ltd. 1919. (3½ × 5½, pp. 126. 1s. 3d. net.)

⁷ *The Critical Age of Woman*. By Walter M. Gallichan. London: T. Werner Laurie, Ltd. 1920. (Cr. 8vo, pp. 160. 6s. net.)

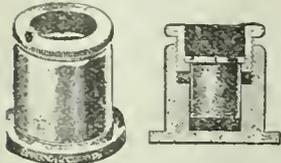

APPLIANCES AND PREPARATIONS.

Sedimenting Cell for Microscopical Examination of Cerebro-spinal and other Fluids.

DR. FRANK C. EVE (Hull) has devised a mechanical cell, shown in the accompanying illustrations, to render it possible to scrutinize every bacillus contained in a column of cerebro-spinal fluid 1 cm. in depth. A cover-glass (not too fragile) is placed at the bottom of the cell, which is then filled to the brim with cerebro-spinal fluid. If tuberculous meningitis is suspected the fluid must be fresh, because a fine clot may quickly form in that disease. After an hour or two the cells and cocci will have sunk through the 1 cm. of fluid and will be lying on the cover-glass. The supernatant fluid is got rid of without disturbing them or the clot by gently unscrewing the milled head. This causes the floor of the cell to rise, creating a vacuum beneath it. Hence, provided the screw is airtight (a trace of vaseline on the thread ensures this), the fluid must retire through the little channels provided into the well below the cell. This leaves the cover-glass free of fluid. A few more turns of the screw and the cell becomes detached from the base. The cell is placed in front of the

³ *A Text-book of Gynaecological Surgery*. By Comyns Berkeley M.D., F.R.C.P., and Victor Bonney, M.S., M.D., F.R.C.S. Second edition. London: Cassell and Co., Ltd. 1920. (Med. 8vo, pp. xii + 829; 489 figures, 16 coloured plates, 42s. net.)

fire and its wall will drop by its own weight, leaving the cover-glass on a little altar of brass, where it quickly dries. The ordinary routine is then followed of fixing by gentle heat in a flame and then briefly in absolute alcohol. In staining no heat should be applied to the stains, lest some cells be washed off. In collecting the fluid the first blood-stained portion should be rejected. If the cerebro-spinal pressure exceeds 12 in. by my cerebro-spinal manometer (Messrs. Allen and Hanburys), meningitis, or tumour, or abscess is almost certainly present. If a quantitative measure of the number of cells is required a one-sixth objective is used, a Thoma-Zeiss counting chamber placed beneath it, and the tube of the microscope moved till the

Half scale.

Section.

circular field coincides in breadth with four of the smallest squares—that is, 4.20 mm. Then the area of the microscope field will be $\pi \times 2.20 \times 2.20$ —that is, 3.100 square millimetre, and the volume of fluid will be 3.10 cubic millimetre, which originally contained the cells now visible in each field of the microscope.

Even if the cells are not counted, by the regular use of this apparatus a quantitative impression of the number of cells is obtained and they are quite evenly spread. In tuberculous meningitis a spider-web clot often forms which entangles the tubercle bacilli, and any one who has tried knows that when an attempt is made to spread out this clot thinly it inevitably ravel into a tangled mass which cannot be scrutinized microscopically. If this apparatus be used, a tubercle bacillus cannot hide. If the whole of a cover-glass 1 cm. square was systematically searched with a mechanical stage, the report, instead of the usual "No T.B.s present," would read: "Absence of tubercle bacilli can be guaranteed in the thousand cubic millimetres of fluid searched." If the cerebro-spinal fluid looks turbid to the naked eye, it will need dilution before using the instrument. For microscoping urines this apparatus is better than the centrifuge if two hours' delay does not matter. Messrs. Allen and Hanburys supply the instrument as here described; also the earlier model shown at the Neurological Society, the design and action of which is more self-evident. My thanks are due to my engineering friend, Mr. F. M. C. Lewis, for the excellent design.

Nujol.

A sample of nujol, made by the Standard Oil Company, New Jersey, U.S.A., has been examined; it is found to be a pure liquid paraffin, having a specific gravity of 0.883 at 15.5° C., and complying with all the requirements of the *British Pharmacopoeia*, 1914, for liquid paraffin.

THE LISTER INSTITUTE.

THE Report of the Governing Body presented to the annual general meeting of the Lister Institute of Preventive Medicine, Chelsea, on May 12th, showed that in many directions the Institute was resuming its civil work, which had been interrupted by the war. Upwards of thirty original papers have been published during the year from the laboratories of the Institute. The output of scientific work would no doubt have been still greater but for three circumstances: first, the diminished regular staff, especially in the bacteriological department; secondly, the various readjustments necessary; and thirdly and chiefly, the scarcity of research workers. For the five years of the war the supply of young men suitably trained and willing to devote a few years to medical research work was seriously curtailed, and those who have worked in the Institute have gone there rather to learn methods of investigation than to engage in research. In this way the Institute has given much useful post-graduate instruction, particularly to Colonial officers who have served in the war, but the actual return for this labour is not yet. Amongst the subjects investigated were the following:

Rickettsia Bodies in Trench Fever and Typhus.

Dr. Arkwright and Mr. Bacot have continued their observations on the small micro-organisms found in the intestines and faeces of lice some time after feeding upon a patient suffering from trench fever; the organisms conformed to the description given by Ricketts of those found by him in ticks fed upon Rocky Mountain fever and by

Ricketts and Wilder in lice fed upon typhus patients. Mr. Bacot has confirmed the opinion that in the case of trench fever the Rickettsia bodies do not occur in lice unless they have had a meal of blood from a patient suffering from the disease. In eight to twelve days after the meal, the time varying with the temperature at which the lice are kept but falling within the period at which the lice are known to become infective, immense numbers of the bodies are found in the stomach, but not in sections of any other part of the insect. Dr. Ledingham, on his return from war service, was invited to assist the War Office Trench Fever Committee, and gave attention chiefly to the transmissibility of the virus to laboratory animals; some indications that this occurred were obtained, but actual proof was not reached. In the course of his work Dr. Ledingham established the fact that the Rickettsia bodies are agglutinated in a manner similar to bacteria in general by the serums of immunized animals. The reaction would be of great assistance in further studies should opportunity occur. Trench fever, however, has virtually disappeared, but Mr. Bacot has gone to Poland to make use of the knowledge acquired about trench fever in an investigation into the etiology of typhus fever under the auspices of the League of Red Cross Societies.

Bacterial Variation.

Dr. Arkwright has also been studying problems in bacterial variation, and has found that cultures of dysentery bacilli, and probably other organisms of the great colityphoid group which agglutinate quite uniformly with the respective immune serum when tested in the mass, may as the result of examination of individual colonies be found to consist of two types of organisms, the one reacting like the parent mass, the other possessing little or no serological affinity. This observation will have to be reckoned with in connexion with modern attempts to classify bacteria on serological grounds.

Accessory Food Factors.

Much of the work in the department of biochemistry was a continuation of the programme of experiments on accessory food factors. Reasons have been found for supposing that rickets and scrophthalmia in children and osteomalacia in adults may be due to deficiency of the "fat-soluble A" factor in the diet. Experiments with the fat-soluble factor have hitherto been rendered somewhat indecisive owing to the necessity of administering it with the fat in which it occurs. Dr. Zilva proposes to avoid this source of uncertainty by employing an alcoholic extract of green leaves and carrot, both of which contain the factor in considerable amount. Endeavours are also being made to isolate the active principles responsible for the actions of both the fat-soluble and the antiscorbutic substance. An estimate has been made of the antiscorbutic requirements of the monkey, and it has been found that that animal requires the same absolute amount of orange juice to prevent the onset of scurvy as the guinea-pig, an animal about one-eighth its weight; the time of onset of the disease is, however, very different, being about three weeks in the guinea-pig and two months in the monkey. It is added that clinical experience as to the amount of orange juice that must be administered daily to a child to obviate scurvy, when the diet is otherwise devoid of antiscorbutic power, tends to show that the requirements of the human organism in this respect are probably much nearer to those of the monkey than those of the guinea-pig. Dr. Robison has found that orange juice can be reduced to a dry residue by rapid evaporation at a low temperature without suffering appreciable loss of its antiscorbutic power, and that the residue still contains a considerable degree of potency after storage for two years in the dry condition. It is considered that the preparation on a commercial scale of dried fruit juices of high antiscorbutic power is quite practicable. Dr. Zilva is making some experiments to test the general belief that a deficiency of diet renders the subject more liable to disease; animals are being kept on diets deficient in definite constituents and their susceptibility tested by their capacity to produce agglutinins and other antibodies in response to immunization, as well as by direct infection.

Diseases due to deficiency of accessory food factors have been studied also in the Department of Experimental

Pathology. Experiments have been made to ascertain the amount of antiscorbutic substance in various foodstuffs; they have involved hundreds of observations, each extending from three to six months; the results are expressed in the following table, in which the average value of one gram of lemon juice is taken as 100:

Fresh lemon juice	100	Carrot juice	7
Fresh orange juice	100	Beet juice	7
Fresh cabbage juice	100	Potato, boiled 30 mins. ...	7
Ripe onion	100	Tamarind	7
Fresh swede juice	60	Cocum	7
Fresh turnip juice	60	Mango	7
Green French beans, un-		Grape juice	5
cooked	30	Fresh cow's milk	1 to 1.5
Germinated peas	30	Dried cow's milk	less than 0.5

The influence of heating and drying was tested in the same way in the case of cabbage, fresh juices, and milk. The drying of vegetables even at a low temperature reduced their antiscorbutic value to 10 per cent. or less of the original. The factor is much more stable in acid fruit juices. It will be noticed from the table that dried milk was found to possess less than half the antiscorbutic value of fresh milk; a monkey on a maximum diet of dried milk developed acute scurvy, and was cured by the same quantity of fresh milk—a result of obvious import for infant feeding.

An experiment on the etiology of pellagra was made by Dr. Harriette Chick and Miss Ilume. Monkeys were fed on a diet complete in every respect, save that the protein, which was derived from maize, was not of good biologic value. All the animals gradually lost in weight and became very weak. One of them developed cutaneous lesions strikingly like those of pellagra in the human subject, and two others patches of dermatitis of the same nature. The loss of weight was stayed by the daily addition of tryptophane and diamino acids, but otherwise no improvement was noticed. In the case with the severe skin lesions a dramatic cure was brought about directly casein was added to the diet.

Antitoxic Serums.

Experiments to ascertain whether antitoxic serum saturated with sodium chloride would prove sufficiently stable to be used as a standard antitoxin have given encouraging results. Diphtheria and tetanus antitoxins so treated have retained their original potency during twelve months, and proved as stable as the standard serums sent out by the Hygienic Laboratory, U.S. Public Health Service, Washington. Samples of the brined serums have been sent to that laboratory with a request that they may be compared with the standard serums. Brined antidyenteric serum is being studied from the same point of view, and the possibility of using the method for vaccines is also being tested. Large quantities of various antitoxins and serums were supplied to the military and naval authorities during the year ending March 31st, 1920, and over one million and a half cubic centimetres of influenza vaccine have been supplied to the Ministry of Health.

Antivariolous Vaccine.

Some progress has been made in the study of the cultivation and identification of the specific organism of vaccinia. The experiments indicate that that organism can be propagated, although when cultivated under artificial conditions it ceases to be capable of producing its specific effect. Observations showing that certain animal products are specially congenial to the virus will encourage further research in this direction. The bulk of the antivariolous lymph produced is supplied to Crown colonies, mostly to tropical Africa. The satisfactory reports received from medical officers in Africa prove that the Institute has been successful in producing a vaccine which, even after transport and retention in a tropical climate, retains sufficient potency for successful vaccination.

Research Hospital.

Last year the members of the Institute decided that its constitution should be extended so as to make it possible to establish and maintain a residential hospital. The legal advisers were not satisfied that the resolution then adopted was correctly drawn; consequently at the meeting on May 12th a resolution embodying the principle in terms drafted by the lawyers was presented and adopted by the annual meeting and by an extraordinary general meeting. It will be submitted to a second extraordinary general

meeting on May 26th. In taking this step the Institute is following the precedent of the Pasteur Institute in Paris and the Rockefeller Institute in New York. The progress of medical research has proved that the divorce of the laboratory from clinical work is disadvantageous. The ordinary funds of the Institute cannot be used for the establishment of a hospital, but a site is available, and we do not doubt that the appeal which the Institute will issue for a special fund will be generously supported.

VOLUNTARY HOSPITALS:

RESULTS OF A PRELIMINARY SURVEY.

BY

SIR E. NAPIER BURNETT, K.B.E., M.D.,

DIRECTOR OF HOSPITAL SERVICES, JOINT COUNCIL OF THE BRITISH RED CROSS SOCIETY AND THE ORDER OF ST. JOHN.

LAST week a summary of the principal results of the survey recently carried out by the Joint Council of the British Red Cross Society and the Order of St. John was published in the BRITISH MEDICAL JOURNAL. It will, I believe, be interesting to the medical profession to set out some of these results again and to point to some of the conclusions which may be drawn from them. The object of the survey was to obtain some indications, first, of the volume of work done by the hospitals during the year 1919, and secondly, of their present financial position. The voluntary hospitals in London were not included in the survey, but 550 hospitals (approximately 78 per cent. of the voluntary civil hospitals) throughout England and Wales were included. The hospitals dealt with included: (a) 82 general hospitals of 100 beds or over, providing together 15,958 beds; (b) 87 hospitals of 30 to 100 beds, providing 4,724 beds; (c) 240 small or cottage hospitals, providing 3,355 beds; and (d) 98 special hospitals, providing 5,784 beds. The special hospitals included twelve maternity hospitals.

SUMMARY OF RESULTS.

A. Volume of Work Done.

Of the 550 hospitals reviewed—

507 hospitals have 23,821 available beds.
498 hospitals treated 359,459 in-patients during the year.
376 hospitals treated 1,600,859 out-patients during the year.
276 hospitals with 23,621 beds had a daily average occupation of 18,705.36 beds—79 per cent.
374 hospitals show 219,195 surgical operations during the year.
68 hospitals give figures showing the nature of cases treated—namely:
Medical cases ... 7,034 = 21 per cent. of total.
Surgical cases ... 26,466 = 79

B. Financial Position.

543 hospitals show ordinary income	£2,835,269
543 hospitals show ordinary expenditure	£3,310,896
Excess of expenditure over income	£475,627

Some Details of Ordinary Income.

316 hospitals show as workmen's contributions, direct or through Saturday Fund	£451,426
464 hospitals show as patients' contributions	£214,570
248 hospitals show as public services (for example, War Office, Pensions Ministry, Borough or County Councils)	£517,890
512 hospitals show as interest from investments	£423,044
The total from these four sources	£1,606,930
(56.67 per cent. of ordinary income).	

Of these 543 hospital accounts analysed—

449 hospitals show invested capital amounting to	£9,585,855
Yielding annual interest	£340,529
65 hospitals show £33,706 as annual interest, but show no capital.	
28 hospitals show no capital or interest.	

Depreciation of Invested Funds.

9 hospitals show invested capital amounting to	£306,976
Market value at end of 1919	£248,199
Depreciation in value	£58,777

This last item is given in answer to a criticism that the hospitals in their present financial difficulty should realize some of their capital. Some few hospitals have actually been obliged to take this course, but only very few. The figures indicate that the hospitals cannot afford to unload their stock in the present state of the market.

Owing to differences in the manner of recording their results it has not been found possible to make an estimate of the average annual cost of each occupied bed, nor of the average length of stay in hospital of each in-patient. The figures from 296 hospitals show that 79 per cent. of

the beds were occupied daily; the difference (21 per cent.) of beds not in actual occupation daily is not high. It will be noted that returns from 374 hospitals show that over 200,000 surgical operations were performed during the year. An examination of the returns of 68 hospitals shows that the medical cases constitute 21 per cent. and surgical cases 79 per cent. of the total. While admitting that medical cases on the average remain probably twice as long, yet this ratio appears to indicate that medical cases are gradually being squeezed out of the hospitals. This conclusion is supported by remarks made in the annual report of several hospitals. Looking at the figures in a general way, and making an allowance for hospitals not included in the survey, it would appear that the voluntary hospitals are supplying beds in the proportion of about 1 to 1,000 of population. In my opinion this is inadequate, and the provision ought to be, in industrial areas, 3 to 1,000 of population, and in rural areas 1 or 1.5 to 1,000.

From the financial particulars given it will be seen that the deficit was about one-seventh of the total ordinary expenditure. The financial difficulties from which many of the voluntary hospitals throughout the country are known to be suffering are due to increased expenditure and diminished income.

The expenditure of hospitals is increased by the higher cost of foodstuffs, drugs, surgical dressings, and hospital furnishings; by the increased cost of labour and of materials for cleaning, repairs, and alterations; and by the increase in salaries and wages, including the larger staff needed to meet the requirements of nurses and other employees for shorter hours. In addition to these causes, common to almost all undertakings at the present time, there is the fact that the number of patients treated has largely increased; many more people are now using the hospitals than formerly; they no longer look upon them with dread as places to die in, but as healing houses where the best nursing and medical skill can be obtained to restore them to life and activity.

The diminished income is due, first, to diminished subscriptions; secondly, to depreciation in invested funds; and thirdly, to the fact that the hospitals no longer receive the capitation grant from the War Office for the military patients they did so much for during the war. The beds which were occupied by the paying military patients are to-day occupied by non-paying patients, so that some hospital committees are considering whether they must not restrict the usefulness to the public of their institutions by closing certain wards.

To prevent such a catastrophe the Joint Council of the British Red Cross Society and the Order of St. John desires to offer voluntary hospitals assistance, financial or other.

The Survey figures show that for 543 hospitals the excess of ordinary expenditure over ordinary income during 1919 was £475,627—that is to say, that for all the provincial voluntary hospitals the deficit on the year's working was approximately £600,000, a sum probably much below what had generally been supposed.

These figures, however, do not fully represent the true situation. In view of the extra cost of labour and materials many hospitals have refrained from carrying out the necessary repairs, alterations, and improvements that have fallen into arrears since the beginning of the war. Further, many have been "carrying on" with plant much of which is out of date. For instance, in some cases new laboratory provision is needed, and new x-ray plant, fresh operating theatre and appliances are necessary to bring them up to the standard of modern requirements. Especially the larger hospitals—groups (a) and (b)—are faced with increased expenditure in providing additional accommodation for an enlarged nursing staff. In fact, this is one of the most pressing problems confronting many of these hospitals. Again, there is the necessary expenditure for increasing the accommodation for patients.

It has become of late almost impossible for one to speak on this question of hospital finance without being confronted with the question, Are you in favour of the hospitals being nationalized, or do you favour the voluntary principle? I do not regard it as altogether unfortunate that this important subject of hospital service has become a matter of discussion between those holding opposite views, for both are seeking doubtless for a more efficient service in the healing of the people and the general welfare

of the State. My own impression is that the controversy is likely to end in the old-fashioned British way of compromise. There is room and need for both State aid and voluntary service. From the standpoint of finance I suggest that the voluntary principle has failed to meet the needs of the present situation, owing not to any fault in the principle as such but to the methods of its application. The voluntary principle of finance operating in many of our hospitals belongs to the nineteenth century, and has failed to adapt itself to the situation of to-day. If the voluntary methods are brought up to date, I have no doubt they will go a long way in the maintenance of our hospital system. Illustrative of the former methods, one hospital secretary informs me despairingly that his committee recently issued through the post 25,000 copies of an appeal for funds in support of the large hospital in the town, with the result that the annual subscriptions were increased by £50 and some £500 was received in donations. Now let me give two instances of more recent methods. One secretary writes:

You may be interested to hear that considerable progress has been made by the committee in connexion with their appeal for funds. With only two exceptions up to the present, all the men in the large works in the town have agreed to contribute for a period of three years the sum of 1d. in the £ earned per week, and an effort is now being made to induce the employers of labour of all kinds to contribute £1 per man over the same period, and I am glad to say there is good prospect of many of them doing so.

At another hospital the report is:

The Workpeople's Hospital Fund, which is entirely organized by the workpeople of the city, have made great efforts to induce their members to double their subscriptions at least, and to subscribe twopence per week instead of a penny, and although the scheme has only been in work for a small portion of the year, it has resulted in an increase of the funds at their disposal for the benefit of the medical charities making their grant to this one hospital of £11,500 for the year. Following on these lines a scheme is also being launched to give the employers of the city the opportunity of bearing their share in the expense of this hospital and the other charities. Under this scheme the employers make a voluntary levy upon themselves of 2s. per annum per employee (less than one halfpenny a week). So far the scheme has met with universal support, and this hospital's share will amount to £10,000 or £12,000 a year.

One well-known business firm has made an interesting offer to the local hospital—namely, to defray the actual cost of inpatient treatment of any of their employees and dependants, based on the cost of the previous hospital year.

In these examples I suggest that we have a more satisfactory basis of hospital support than has hitherto obtained.

Paying Patients.

A number of the provincial hospitals now provide private wards for the treatment of paying patients, more particularly the small or cottage hospital group. Comparatively few of group (a)—the largest type of hospital—have yet adopted this idea, but many admit that they are now considering the advisability of doing so. As soon as the public knows that in the general hospital there is accommodation for those who can afford to pay modified fees, in addition to the free beds, then I suggest that to the patients themselves may be left the choice between free and paying bed. The basis of money distribution has altered considerably since pre-war days, and hospital provision might quite well accommodate itself to the altered circumstances.

State Aid.

One of the chief functions of the Ministry of Health is to endeavour to co-ordinate the various agencies at work in the country seeking for the prevention and cure of disease. In no branch is this co-ordination more needed than in the voluntary hospital system. Each hospital to-day is an isolated unit working on its own, with comparatively little knowledge of what other hospitals are doing; and whatever be the extent of State assistance to the voluntary hospitals, I suggest that it might be accompanied by some attempt at co-ordinating the work of these institutions, leaving the management in the hands of those voluntary committees who have rendered such excellent service in the cause of the sick and suffering, and who know the local needs of their districts.

Hospitals Associated with Medical Schools.

Of the five groups of hospitals set out in the survey it will be seen that group (a)—the largest hospitals—show an

excess of ordinary expenditure over ordinary income for the year of £355,685. In that group of eighty-two hospitals are included fifteen hospitals attached to medical schools. The figures are as follows:

Number of school hospitals	15
Number of beds	4,791
Average number of beds to each hospital	319.46
Total ordinary income	£490,934
Total ordinary expenditure	£688,174
Excess of expenditure over income	£197,240

In London the medical schools and their hospitals are under the same management or authority, whereas in the provinces the medical school and the hospital are separate institutions, and administered by entirely different authorities. The Board of Education gives annual grants to the medical schools, but not to the associated hospitals, which provide the facilities for the clinical training of the medical student. These hospitals, I suggest, are important national outposts, and in the interests of the training of the future medical practitioners of the country merit some special consideration from the State.

The Demand for More Beds.

The statements made by so many voluntary hospitals as to the crowded condition of the available accommodation, and the number of patients waiting for admission, taken in conjunction with the fact that 296 hospitals, with 23,621 beds, had an average daily occupation of 18,705 (79 per cent.), indicate that the present available accommodation in the voluntary civil hospitals is not adequately meeting the needs of the people.

The pressure is undoubtedly greater in some localities than in others, and I suggest that it is sufficiently widespread and acute as to justify the need for an official inquiry on a broader and more detailed basis than that of the present survey. Such an inquiry should be undertaken by some commission visiting the more important areas and ascertaining on the spot the actual requirements, and how best they could be met. This should be undertaken before the hospitals launch the new building schemes they now have in contemplation, and also before the Government finally decides on its hospital policy.

Apart altogether from the unalleviated personal suffering, I suggest that these waiting lists have an economic importance to the State in that so many men and women have idleness and unemployment compulsorily thrust upon them.

How is the Demand to be Met?

Two questions arise with regard to the demand for more hospital beds:

First, are the present hospital beds being put to their best use? I suggest that the voluntary hospitals, instead of seeking continually to enlarge their capacity, might seriously consider the problem from another angle—namely, how to accelerate the discharge of their patients and thus make room for those on the "waiting list." I admit that to-day many patients are discharged too soon, to return to their homes, with the result that sometimes the cure begun in hospital remains uncompleted in the home and the patient's name reappears on the "waiting list." They should return to their homes by way of the convalescent hospital. Undoubtedly additional hospital provision is needed in many localities, but the suggestion is worthy of consideration before large and expensive building schemes are entered upon. Throughout the country there are to-day some 12,000 convalescent beds under the control of a large number of private associations. Of these beds, only some 2,200 are directly affiliated to the voluntary hospitals.

Further, in many hospitals there is quite a number of chronic patients never again likely to be fit for active duty who are occupying beds. They might be transferred to other institutions specially reserved for this class of case.

The second question is, Are we as a nation to continue for all time building more and more hospitals? Is there to be no attempt made to lessen the demand for and the need of these expensive institutions? There are thousands of people who might be prevented from graduating as in-patients of hospitals if in the early stages of their illnesses they were prescribed a fortnight's residence in a convalescent home in the country. Every doctor practising in industrial and manufacturing communities realizes how true that statement is. How often he is at a loss to know what to do for a patient not responding to medicine and

yet not sufficiently ill to be admitted to hospital. These are patients showing the beginnings of disease; and instead of allowing them to continue their work in the factory or shop, for which they are temporarily unfitted, they ought to be sent to the convalescent home for a short period, and thus short-circuit them from becoming hospital patients.

Our policy in dealing with disease is so often "too late," that I put forward a plea for the establishment of pre-hospital convalescent homes for the arrest of these early phases of disease, and thus lessen the ever-growing demand for more and more hospitals. Birmingham has this idea already in operation for pensioners in the form of a chain of convalescent institutions scattered along the Welsh coast.

These homes might be associated with the local municipalities, under the guidance and direction of the public health committees, whose main function is prevention rather than the cure of disease. Such institutions should operate in close association with the out-patient departments of the local hospitals. If the medical officers in attendance could be provided with a wider outlet for their treatments in the direction of convalescent homes, the pressure on the hospital beds would be relieved.

Scarcity of Nurses.

I was somewhat surprised to find how widespread was the shortage of nurses at the hospitals, both large and small. Among the larger hospitals comparatively few stated that they had a sufficient number to select their probationers from. The greater number of hospitals indicate not only a deficient supply, but also that the general standard of the applicants was not of a high order, whereas both quality and quantity were complained of in the smaller hospitals.

There is a shortage of probationer nurses, and this is a question of some national concern, for the great majority of the nurses trained in our hospitals in due course pass into the service of the general community, so that the diminished supply of probationer nurses in the hospitals to-day will, in three years' time, reveal itself in a shortage of nurses for the private household.

I submit the following reasons in explanation of the present falling off in the supply of hospital nurses—namely:

1. The inducements offered in other professions. For example, a woman may become a trained masseuse in about a third of the time required to qualify as a nurse, and receive about double the salary. A stenographer can earn from £150 to £200 per annum after twelve months' training.

2. Health visitors and the school medical service, and even the medical profession itself, are now absorbing a considerable number of women who have either trained as nurses or who would have been eligible for the nursing profession.

3. A spirit of revolt against the long hours of drudgery in ward work and the low rates of pay that have hitherto obtained in this profession.

4. A neglect on the part of the hospital authorities or of the community in which the hospital is located to offer facilities for the social welfare and general training of the nurses. Plenty of time and energy as a rule are expended on the professional side of her training, but far too little has been attempted in the way of providing opportunities for the more general development of the nurse's life.

Further, in view of the national aspect of this question, I suggest that the Ministry of Health or Board of Education might supply money grants to hospitals for the training of nurses, as is now done in the case of lying-in institutions. Such grants might be apportioned in part to the hospital and in part supplementing the nurse's salary. In this way it would be possible for the central authority to exercise some control over the general standard of training, which varies greatly in different institutions.

The nursing difficulty in the case of the small hospitals is in large measure due to the number of beds being below the standard required for a hospital to be recognized as a training school for nurses granting the requisite certificates. Obviously a probationer will select a hospital for her training that is in a position to grant her the authorized certificates.

In order to overcome this difficulty some of the smaller hospitals are making arrangements with the nearest large hospital to share in the training of probationer nurses. Further, the local Red Cross associations are prepared to recommend V.A.D. members for part-time service in these smaller hospitals.

SATURDAY, MAY 22ND, 1920.

THE HOSPITAL SURVEY.

THE account which Sir Napier Burnett gives in this issue (p. 710) of the preliminary results of the survey of voluntary hospitals which he has carried out for the Joint Council of the British Red Cross Society and the Order of St. John will be read with much interest, and may serve as a prelude to the account which we expect to be able to give in our next issue of the interim report on the organization of the medical services of the country which the Medical Consultative Council of the Ministry of Health has prepared. The survey is concerned with the work done by the voluntary hospitals throughout England and Wales, excluding London, and with their financial position. The survey extended to 550 voluntary hospitals in the fifty-five counties of England and Wales; this is 78 per cent. of the whole number. The information obtained was not uniform, being far more complete in the case of some hospitals than of others. On most of the main points, however, the figures are sufficiently complete to justify certain conclusions.

The first point that emerges is that 507 hospitals provided nearly 30,000 beds, so that the total number of beds in voluntary hospitals must be well over this amount. The return as to hospital accommodation in England and Wales, prepared by the Local Government Board¹ and published in June, 1915, showed, in round numbers, 33,500 beds in the general and special hospitals, excluding London. The results of the two investigations are therefore concordant, and would appear to indicate that the provision of beds in voluntary hospitals is in the proportion of rather over one bed to 1,000 of population. The Local Government Board return showed that there were in the Poor Law infirmaries, including sick wards at workhouses, 94,000 beds (74,000 outside London) and 39,121 in fever and small-pox hospitals (30,367 outside London). The total number of beds in hospitals of all sorts and in Poor Law infirmaries in the whole country was 178,525, or 4.9 beds to 1,000 population; but the beds in fever and small-pox hospitals should be omitted in order to obtain a correct view of the situation; when this is done the proportion of beds to population is reduced to about 3.5 to 1,000 population. Sir Napier Burnett expresses the opinion that the proportion ought to be, in industrial areas 3 beds to 1,000 of population, and in rural areas 1 or 1.5 to 1,000 of population.

The results of his survey, taken together with the facts given in the Local Government Board return, show how important a part Poor Law infirmaries can be made to play in the provision of hospital accommodation and how nearly, to a rough estimate, the total number of beds which would be made available by their inclusion approaches the proportion which he considers necessary. A deduction must, however, be made in respect of the sick wards at workhouses, which, in many instances, do not come up to hospital standard. The reform of the Poor Law is promised and cannot be long delayed;

the London County Council last year expressed the view that the health functions of the Poor Law authorities should be divided between the council and the borough councils, and proposed that a central council of London hospitals should be formed, having a large voluntary representation but containing members nominated by the County Council and the Ministry of Health. It laid down also the principle that, except for public services dealing with environmental conditions, public authorities in providing medical treatment should recognize the principle that the cost of such treatment should be borne to the extent of his ability by the person treated or by a fund like the insurance fund, made up mainly by the contributions of employers and employed. In replying to a deputation from the London County Council on April 23rd the Minister of Health said that it would not be possible to split up hospital supervision and that the main principles governing the Council's recommendations were unassailable.

The results of the survey on the financial side are, as its author indicates, rather surprising; the deficit on the year's working (1919) of the provincial voluntary hospitals is estimated at approximately £600,000, an amount equal to about one-seventh of the total ordinary expenditure, a proportion probably, as he says, much below what had been generally supposed. The facts, however, are not so satisfactory as might be concluded from this generalization, for repairs, alterations, and improvements which have been accumulating since the beginning of the war will now have to be carried out, new apparatus must be provided, and increased expenditure will be incurred by the employment of a larger nursing staff and in providing additional accommodation for it. The Joint Council intends to make an attempt to raise a sum of £1,000,000 a year by public appeal, not only to the classes who have hitherto been the largest contributors to voluntary hospitals, but also for an increase in the workmen's contributions, which already constitute about 16 per cent. of the ordinary income of voluntary hospitals outside London.

From the point of view of public policy the most instructive part of Sir Napier Burnett's comments on his survey is contained in the paragraphs discussing the demand for more beds and the manner in which it should be met. He asks the pertinent question whether the only way in which the demand can be met is by building more hospitals or adding to those already in existence; would it not, he asks, be possible to relieve the general hospitals, which are necessarily expensive to erect and maintain, by providing auxiliary institutions? Such auxiliary institutions, he suggests, would include not only convalescent homes, but similar institutions for the reception of persons not sufficiently ill to be admitted to hospital, but needing rest and change of air for their restoration to normal health. In this way he thinks that part of the stream of persons who now eventually become hospital patients might be short-circuited. Another illustration of the same principle is afforded by the paper of Mr. Girdlestone on the care of crippled children, published at p. 697; it illustrates the need for special methods and modes of institutional treatment for a special class of case, for whom the best treatment is to be obtained, not through the elaborate and necessarily expensive equipment of a large general hospital, but through the good fresh air and food and the kindly nursing, under skilled medical supervision, in a country institution where they can also have the advantage of elementary education, and eventually, perhaps, of early training for a skilled occupation.

THE DANGEROUS DRUGS BILL.

ON May 4th the Home Secretary, in redemption of promises repeatedly given, introduced a bill—the Dangerous Drugs Bill—"to regulate the importation, exportation, manufacture, sale, and use of opium and other dangerous drugs." A brief memorandum attached to the bill explains that it has been prepared to give effect to the International Opium Convention signed at the Hague more than eight years ago. In an article which appeared in the *JOURNAL* of March 6th last we adumbrated the presentation of this bill, and added that we looked to the Government to lose no time in handling this question effectively.

There is no doubt that, as pointed out by Sir William Collins in these columns on September 20th, 1919, the Treaty of Versailles has given a fresh impetus to the effectuation of the International Opium Convention of 1912. As explained in an answer given by the Foreign Office to a question in the House on December 2nd, 1919, and as is repeated in the memorandum to the bill, Great Britain, although, unlike some of the Powers which are contracting parties to the Treaty of Versailles, she had prior to the war ratified the Opium Convention, yet holds herself bound, by Article 295 of the Peace Treaty, to enforce the Convention forthwith and to enact the necessary legislation within a year from the coming into force of the Treaty.

The Dangerous Drugs Bill consists of fifteen clauses and is in four parts, dealing respectively with raw opium, prepared opium, morphine, cocaine, etc., and certain general administrative questions. The bill as drafted appears, broadly speaking, to follow the provisions of the Hague Opium Convention. As regards "prepared opium"—that is, opium prepared for smoking—its import, export, manufacture, use, and possession are absolutely forbidden, as far as the United Kingdom is concerned, under penalty of a fine not exceeding £200, or imprisonment, with or without hard labour, not exceeding six months. As regards raw opium, morphine, cocaine, ecgonine, heroin, and their salts, and medicinal opium, their import and export are forbidden, except under licence, under similar penalty. No raw opium may be exported to any foreign country prohibiting its import nor, except under appropriate restriction, to any country restricting such import. Regulations, which must be laid before Parliament, may be made for preventing the improper use of the alkaloids already mentioned or of medicinal opium, whereby the manufacture, sale, possession, and distribution will be controlled. To this end the manufacture of these drugs will be restricted to licensed premises, and the traffic in them to authorized persons; the prescription and dispensing of such drugs will also be regulated. The premises, books, and stocks of persons producing or dealing in these drugs will be liable to inspection. Preparations containing less than one-fifth per cent. of morphine or less than one-tenth per cent. of cocaine, ecgonine, or heroin fall outside the purview of Part III of the Bill. There is power by Order in Council to add any new derivative of the aforementioned alkaloids or "any other drug of whatever kind (which) is or is likely to be productive, if improperly used, of ill effects substantially of the same character or nature as or analogous to those produced by morphine or cocaine," to those enumerated in the Bill.

Much will depend on the nature of the regulations which will be drafted under the powers conferred, presumably on the Home Secretary, and almost everything will depend on the vigilance of administration by the Customs officers and inspectors charged with

the new duties. The smallness of bulk of the dangerous alkaloids must inevitably make their supervision, from manufacture to distribution, a matter of considerable difficulty, and the misuse of prescriptions will require to be carefully guarded against. It must nevertheless be conceded that the Bill now introduced represents a bona fide attempt to give effect to the requirements of the Opium Convention, especially in the case of the alkaloids of addiction, whose inclusion was so strongly pressed at the Hague by the British delegates on behalf of their Government. If all those Powers which, by their ratification of the Convention or by their signature of the Special Protocol or by adhesion to the Peace Treaty, are similarly bound will proceed forthwith to enact and enforce similar legislation, the appalling over-production of these drugs, in excess of legitimate requirement, should be checked, where alone it can be effectually checked, at the source.

It will be remembered that the general supervision of the international execution of the Opium Convention is entrusted to the League of Nations. As it is understood that the Dutch Government, which has played so courteous and successful a part hitherto in promoting the effectuation of the Convention, is desirous that further steps in this direction should now rest with the League, there should be no difficulty in that body urging the universal adoption of legislation similar to that which is now before the Commons of the United Kingdom.

SECTIONS AT THE CAMBRIDGE MEETING.

THE following programme has been arranged for the Section of Electro-Therapeutics at the forthcoming Annual Meeting of the British Medical Association at Cambridge. On Friday, July 2nd, the President of the Section, Dr. A. E. Barclay, will give his address on the place of the radiologist in medicine. Mr. H. S. Souttar will open a discussion on diagnosis and treatment of paralysis caused by nerve injury. Papers will be read by Dr. Robert Knox on tumours of the chest; by Dr. Howard Humphris on the use of the melted paraffin wax bath, and the tungsten arc-light; by Dr. E. P. Cumberbatch, on the treatment by diathermy of intravesical growths and ulcers of the urinary bladder; by Professor J. Goodwin Tomkinson on x-ray therapy in oriental sore; and by Dr. S. Gilbert Scott on the diagnostic value of the renal outlines and the method of determining the relation of abnormal shadows to them. A joint discussion with the Section of Obstetrics and Gynaecology on the treatment of uterine fibroids by x rays will be opened by Dr. Robert Knox. The Naval and Military Section will meet on Wednesday, June 30th. In the morning a discussion on the Army Medical Service and its relation to the education and training of newly qualified medical men will be opened by the President, Colonel Joseph Griffiths, at 10 o'clock. The discussion will be followed by papers on the evolution of protective measures against gas warfare; on the relation of the condition of the teeth to the physical fitness of the soldier, and on the incidence of water-borne disease in the Gallipoli campaign. In the afternoon there will be a demonstration by officers of the Naval, Military and Air Force Medical Services, who will exhibit the various improvements and inventions that arose during the war. Details of the arrangements for all the Sections are given in the SUPPLEMENT, p. 161.

THE ASSOCIATION OF SURGEONS.

THE newly formed Association of Surgeons of Great Britain and Ireland held its first meeting in London at the end of last week. The proceedings opened on Thursday afternoon, when the president, Sir John Bland-Sutton, gave an address, in which he sketched the early history

of surgery. It will be published in full in the *British Journal of Surgery*, which has now become the property of the Association of Surgeons; those who know the author will not be surprised should it turn out that he followed the Horatian maxim that a lesson may sometimes be best enforced by quips of wit and sallies of humour. On Friday morning, May 14th, a discussion on the ritual of the surgical operation was opened by Sir Berkeley Moynihan and Mr. Raymond Johnson. Saturday morning was devoted to the study of the specimens in the war collection in the museum of the Royal College of Surgeons; Professor Keith related the history of the collection, Sir George Makins spoke on specimens of wounds and blood vessels, and Sir Cuthbert Wallace on gunshot injuries of the abdomen. The afternoons of Friday and Saturday were spent at various London hospitals, where operations were witnessed. On Thursday evening Sir John Bland-Sutton entertained members of the Association to the number of over one hundred at Claridge's Hotel. Speeches after dinner were few and happy. The host spoke of the birth of the Association, and Sir Berkeley Moynihan, who may, perhaps, be called its father, said that surgical thought in Great Britain and Ireland had been deep, but it was hoped through the new Association to lead it into wider channels. Mr. Herbert Pendlebury, the honorary secretary, also responded, and Mr. Thomas Sinclair, C.B., of Belfast, proposed the health of Sir John Bland-Sutton, which was received with enthusiasm and acknowledged in a few characteristic phrases. The menu was adorned with a reproduction from a Pompeian mural painting showing the surgeon Iapix extracting the head of the dart from the wound in the thigh of Aeneas. (*Aeneid*, Lib. XII.) Among those present at the dinner were the Earl of Athlone, chairman of the Board of Management of the Middlesex Hospital, Sir Robert Hill, Medical Director R.N., Sir John Goodwin, Director-General A.M.S., Sir George Makins, President of the Royal College of Surgeons, Sir William Macewen of Glasgow, Professor Marnoch of Aberdeen, Sir Harold Stiles and Professor Alexis Thomson of Edinburgh, Sir Robert Jones and Mr. Thelwall Thomas of Liverpool, Sir William Thorburn of Manchester, Sir W. de C. Wheeler of Dublin, Sir Rickman Godlee, Sir Gilbert Barling, Sir Anthony Bowlby, Sir Charles Ballance and Sir Hamilton Ballance. Among the guests were the Editors of the *Lancet* and the *BRITISH MEDICAL JOURNAL*, and it may be concluded that though the Association will not permit its discussions to be reported, it bears no ill-will to the medical press. The rule prohibiting the reporting of discussions is, we believe, in the case of a meeting of experts where free discussion and criticism is desired, altogether sound.

POST-GRADUATE COURSES.

THERE are many signs of a growing desire on the part of a large number of medical men, both at home and in the Dominions, to make use of opportunities for attending post-graduate courses in Great Britain. We publish elsewhere particulars of the scheme which is being evolved in Glasgow, and some time ago gave information as to the plans at Edinburgh. The courses in Manchester are regularly noted in our columns, and a little time ago we gave an account of a special course in spa treatment to be held in Bath during next month; a great deal of trouble has been taken by the profession in Bath to arrange a useful and comprehensive course extending over a fortnight. An introductory lecture will be given by Dr. Cave on June 7th, and among the subjects to be treated during the course will be those bugbears of practice—gout, fibrositis, and arthritis of various forms, including rheumatoid arthritis and osteo-arthritis. Ample opportunities will be afforded for clinical observation in the wards of the hospitals and the method of using the waters of spas will be illustrated. The Fellowship of Medicine is receiving from all parts of

Canada and the United States a steady flow of inquiries about opportunities for graduate study in London. Last year the graduates, who crowded the courses arranged by the Fellowship, were chiefly army medical officers brought together under exceptional circumstances, and in most instances still in military employment. This season the graduates are coming upon their own initiative and at their own personal expense. Their number is a matter of speculation, but each week adds names to the register, and day by day arrive reports of those who are contemplating the journey. The future of London as a post-graduate centre will be largely determined by the opportunities offered to overseas visitors during the immediate future. The call is for clinical work, and particularly for short intensive courses in special subjects. Additional courses should be arranged without delay, and with as long a preliminary notice as possible. A time-table should also be drawn up to cover the holiday season; work naturally slackens in London from the middle of July to the end of September, but it is during this vacation period that many men will fit in a course of study, and these dates are specifically mentioned in many letters of inquiry. As London is not wholly a desert during the summer months there should be more than one way of surmounting the difficulty. The Fellowship of Medicine is conducting a propaganda which reaches the entire English-speaking medical world, and the more energetically this young organization is supported the better the hope that its efforts will be fully successful. The argument that because London has not been a post-graduate centre in the past the present campaign must necessarily fail is threadbare. It is clear that the English-speaking graduates from overseas want to come to the home country and that many of them desire to attend courses in London, if the capital city of their race will give them what they need.

LEICESTER UNIVERSITY COLLEGE.

DR. ASTLEY CLARKE, in his presidential address to the Leicester Literary and Philosophical Society in 1912, suggested the establishment of a university college for Leicester; his address led to much discussion, and matters were in train when the outbreak of war arrested the scheme. Its consideration was resumed in March, 1918, when a provisional committee was formed and a fund established, to which Dr. Finch bequeathed £5,000. A public meeting to discuss the position was then held, and the site of the Fifth Northern General Hospital was presented, with the buildings thereon, which are of considerable size, to the city of Leicester for educational purposes; it was resolved to establish the Leicestershire and Rutland University College. The fund now, before any appeal has been made, amounts to £100,000. The appeal, which is just being issued, states that the purpose of University College is to provide advanced education in the pure sciences, in arts and economics, in the fine arts, and in those branches of technology that are vital to Leicester. It is felt that Leicester, which is largely concerned in the manufacture of boots and shoes and hosiery, and in engineering, ought to play a great part in meeting the need for that increased and more enlightened production which alone can bring national and international stability. Classes will be started in the autumn. The trust deed has been completed, and the domestic science college will be removed to the new building at an early date. The provision of hostel accommodation is contemplated. The local Division of the British Medical Association was one of the first bodies to pass a resolution in favour of the college, and is represented on the Committee, of which Sir Jonathan North is chairman and Dr. Astley V. Clarke vice-chairman. Among the other members are Dr. Wallace Henry (at whose instance the local Division adopted the resolution mentioned), Dr. L. K. Harrison, and Dr. R. Sevestre (Leicester Medical Society). One of the principles adopted is that no university college or university should

managed by the educational authorities of the city or county council alone; it is held that the governing body should represent a wider constituency. We have already on several occasions mentioned the movement in Nottingham for the establishment of an East Midland University. Conferences have been held between the Nottingham body and the Leicester committee, at which Leicester has expressed its willingness to join Nottingham on equal terms as a federal college. While Leicester feels itself strong enough to stand on its own feet it recognizes that a university of federal colleges would be stronger, and there is reason to believe that this view will prevail with Nottingham also.

WHAT THE SOLDIER SAID.

WE regret to observe, from accounts printed in *The Times* and *Daily Mail* of May 12th, that the Westminster Coroner does not always remember what is due to his office. He held an inquest last week on the body of an engineer's fitter, aged 28, who threw himself into the Thames and was drowned. The father stated that his son, David Carey, joined the army in 1914, and was discharged in 1916 for valvular disease of the heart: "An army doctor told him that he only had three or four years to live." In reply to the Coroner, who asked "Did your son sometimes refer to the fact that he was sentenced to death, so to speak?" the witness said: "Yes, he often said so, and worried about it." A police surgeon who made the necropsy said that he found all the organs normal and the heart one of the healthiest he had ever seen; there was no trace of valvular disease. The Coroner then sought to lead this medical witness on to express an opinion about what a professional colleague was stated to have said four years ago. The police surgeon agreed that it would be very silly, very unkind and very wicked of a doctor to profess dogmatically that a man could not live beyond a certain number of years, and to tell the man so. The Coroner is reported to have then made the following fatuous remark: "I read of a case of a man who had been in the Royal Hospital for Incurables for fifty years and died aged 90. That shows that mistakes are made by doctors who are dogmatic." In his summing up the Coroner, we fear, must have had more than a side glance at the reporters. Taking as his text the commonplace that for a doctor to tell a patient that he has only a limited time to live is generally wrong, he aired his ideas on dogmatism in prognosis, and declared that in this case a perfectly healthy young man had been condemned to death by a doctor, with the result that he came out of the army broken-hearted and drowned himself. "Carey might have lived for many years, but some ignorant fool of a doctor, who did not know his work, diagnosed heart disease and doomed him to death." After this a verdict of "Suicide while of unsound mind" was recorded. Now the Westminster Coroner is a medical man, and he must know that even educated people cannot be trusted to report accurately what a doctor said ten minutes before. The Westminster Coroner is also a barrister-at-law, and knows the worth of hearsay evidence. He may even be familiar with Mr. Justice Stareleigh's dictum about "what the soldier said" in the leading case of "Bardell v. Pickwick." Nevertheless, it seems that the Coroner in this case accepted without hesitation the third-hand story of what an army doctor was said to have told a soldier in 1916, and that he used this unverified tale as a stick wherewith to beat an absent colleague. The circumstances of the man's discharge from the army must be on record, but the Coroner does not appear to have called for any evidence, documentary or otherwise, from the military and pensions authorities. The medical profession has had much to put up with from lay coroners; it looks to the medical coroner to set an example of fairness towards medical practitioners, absent as well as present.

HOME AMBULANCE SERVICE.

THE Motor Ambulance Service for England, Ireland, and Wales, instituted by the British Red Cross Society and the Order of St. John, has now completed its first year's work, and the report shows that the service had already proved itself very useful. The scheme was initiated shortly after the armistice, when the Red Cross had a very large fleet of motor ambulances for the transport of the sick and wounded. It was decided that a selection should be made from the best of these ambulances, which—after the cars had been thoroughly overhauled and equipped—should be distributed on loan throughout the country for the benefit of civilian and pensioner patients. Arrangements as to their distribution in the counties were made by head quarters working in close co-operation with county directors; the ambulances are placed in charge of Red Cross detachments, special committees, or local authorities, as local circumstances dictate. Over 300 ambulances have been allotted under the scheme, and already 256 of these are at work. It is intended that, as far as possible, the service shall be self-supporting, and a charge is made for the use of the ambulances, which is, however, remitted in necessitous cases. The provision of these ambulances has met a want that had become very urgent by supplying transport for the removal of the sick to hospitals and convalescent homes. In rural areas particularly—towards which special consideration has been given in the distribution of cars—there existed a great lack of means of transport for the sick. This want the Home Ambulance Service is filling with complete success. Although the greater number of the ambulances distributed have been working for only a few months, the number of cases carried already exceeds 7,000. Every county has now its ambulance stations, and the number will be increased as the remaining ambulances allotted become available for distribution. The service has been adopted by the Ministry of Pensions for the transport of all pensioner patients, a very considerable number of whom are periodically taken to hospitals for treatment. In addition to the ambulance stations in the counties, a central unit is being organized in London to meet a need found to exist for cars to link up the work of the counties and to provide for the transport of cases between the railway termini. This unit, it is hoped, will also be of service in supplying ambulances for patients entering and leaving nursing homes in London. It has been wisely determined to maintain central control of all the ambulances, and thus any which are not found to be serving a useful purpose can be transferred. This provision will enable the committee to adapt the scheme to the changing conditions affecting health administration. As schemes for hospital co-ordination develop, the service can be so adjusted that the ambulances may be placed wherever it is found that they will most efficiently supply the needs of the public.

PLANT RESPONSE.

IT will be remembered that last March Sir J. C. Bose gave a demonstration at the Royal Society of Medicine of plant growth as demonstrated by his instrument, the magnetic crescograph, and that after the demonstration Dr. Waller raised the question whether the movements might not be due to heating effects, and invited the lecturer to repeat his experiments under laboratory conditions here. This invitation was accepted, and on April 23rd Sir J. C. Bose gave a demonstration in the physiological laboratory of University College, London, in the presence of Professor Bayliss, Lord Rayleigh, and other authorities on physiology and physics, who reported that they were satisfied that the growth of plant tissues was correctly recorded by the instrument at a magnification of from one to ten million times, and continued as follows: "We saw in particular that a flower-bud in active growth,

if treated by immersion in a solution of potassium cyanide for some hours, no longer gave a movement of the recording spot of light. We conclude that such movement, when shown by a similar bud in the active state, is not due to accidental stretching or to undetected effects of currents of air, radiant heat, etc. We agree that the instrument correctly records changes of length in the growing tissue, or, indeed, of any substance attached to the lever of the instrument, however such changes may be produced. Naturally, under the conditions of the experiments, it was impossible for us to analyse completely the complex effects produced by the passage of an electrical current." At the meeting of the Royal Society on May 13th Dr. Waller gave a demonstration, using an apparatus of his own which magnified only one thousand times, but would yet enable a record to be obtained on a photographic plate of the effect of electric stimulation on living plants, on plants killed by boiling, and on fiddle strings as had previously been shown by Engelmann. He adhered to the view he had previously expressed that Sir J. C. Bose had not established his point. A somewhat animated discussion followed, and Sir J. C. Bose replied. The President, Sir J. J. Thomson, said that the instrument devised by Sir J. C. Bose was very ingeniously adapted to register very small movements, and might be of use in physics.

THORACOPLASTY IN PULMONARY TUBERCULOSIS.

PROFESSOR SAUGMAN has recently published¹ an account of the 40 patients on whom he has performed thoracoplastic operations at Vejleford Sanatorium. In all these cases the pulmonary disease was advanced, and owing to extensive pleural adhesions collapse of the lung by artificial pneumothorax was not feasible. The position, then, of these patients was, under ordinary circumstances, practically hopeless. Yet, by adequate collapse of the most diseased lung by extensive extrapleural resection of ribs, Professor Saugman was able to restore 13 out of the 40 patients not only to comparative health, but to a certain capacity for work. Another paper on this subject deals with the results achieved by Professor Bull in Christiania. In his first series of 11 cases the operation was fatal in 3; in his second series of 26 cases there was only one death from the operation. He attributes this great improvement in his immediate results to various changes in method, the most important being the performance of the operation in two stages instead of one. Of the 33 patients who survived the operation 7 died later from tuberculosis and one of influenza pneumonia; 11 of the remaining 25 were at work, were always free from fever, and their sputum no longer contained tubercle bacilli. They had also ceased to cough, except when they caught "colds." In 7 other patients the final result could not be stated, as less than a year had passed since the operation was performed; in several, however, tubercle bacilli had disappeared from the sputum, and other signs of improvement had been noted. Professor Bull believes, therefore, that several of them may ultimately be included among his "cures." It is an instructive fact that, though these two writers have worked independently, their results are strikingly concordant. They show that, roughly speaking, a third of the patients who undergo extrapleural thoracoplastic operations may expect complete arrest of the disease, in spite of being in the last stages of pulmonary tuberculosis.

CENTENARY OF DR. LOGIE OF KIRKWALL.

As we briefly announced, Dr. James Searth Spence Logie, the doyen of the medical profession in the British Isles, celebrated his centenary last week. He was born in Kirkwall, Orkney, on May 11th, 1820, and received his early education at the Kirkwall Grammar School. He took the diploma of L.R.C.P. Edin. in 1841, and graduated M.D. of the University of Edinburgh in 1842, at the early age

of 22. His diploma is signed by Sir Robert Christison, Professor James Syme, Sir James Young Simpson, and Dr. Thomas Stewart Traill. He was one of the first to make use of chloroform anaesthesia after its discovery by his teacher, Sir James Simpson. For many years he conducted his practice with zeal and self-sacrificing devotion among the specially difficult conditions existing in the Orkney Islands. In the early days of his professional life there were no made roads in Orkney and no wheeled vehicles except farm carts. Dr. Logie has received a telegram from the King, an illuminated address signed by all the members of the medical profession in Orkney, a resolution of congratulation from the Senatus Academicus of the University of Edinburgh, and congratulatory telegrams from the President of the Royal College of Surgeons of England, and Sir Watson Cheyne, Lord Lieutenant of the County of Orkney. At his meeting on Wednesday, May 19th, the Council of the British Medical Association resolved to send to Dr. Logie a congratulatory message.

THE LONDON SCHOOL OF TROPICAL MEDICINE.

THE London School of Tropical Medicine has arranged, in addition to its ordinary course designed for candidates for a diploma in tropical medicine, short courses of lectures and clinical and laboratory demonstrations on tropical diseases for those who cannot devote the whole three months to the full course. The lectures and demonstrations will be given on Mondays, Wednesdays, and Fridays, from 2 to 4 p.m. The first course will begin on Monday, May 31st, and end on Friday, June 25th. The lectures have been specially arranged for medical men engaged in pension work, who will be certain to meet with many cases of malaria and dysentery, but others who wish to acquire some practical experience in tropical medicine will find the means of doing so in this special course. The school and hospital are in Endsleigh Gardens, close to Euston Station, and can be reached easily from any part of London.

SIR ARCHIBALD E. GARROD, K.C.M.G., F.R.S., Regius Professor of Medicine in the University of Oxford, has been elected to a studentship of Christ Church.

Medical Notes in Parliament.

National Health Insurance Bill.

The Right of Appeal.

ON report on the National Health Insurance Bill, which was taken near midnight on May 13th, Captain Elliot submitted a new clause to enable a medical practitioner to appeal to the High Court (without further appeal) against the decision by the Minister of Health, or any special body acting for the Minister of Health, to remove the name of the practitioner from the list of panel doctors. Captain Elliot said this was a right granted in the 1911 Act, which was apparently being withdrawn under the present bill. If practitioners were struck off the panel under the 1911 Act they had a right to appeal under subsection 15 (b). The only right of appeal practitioners had under the bill was to the Minister of Health. They had no right of appeal to any legal body. If a medical practitioner who came on the panel by statutory right was considered to be conducting himself improperly his case was brought before a small subcommittee of doctors, then before the Insurance Committee, and from that the appeal was made to the Minister of Health; if these authorities were against him his name was struck off the panel. It was not fair that the bureaucracy should have this tremendous power over a medical practitioner. No one would risk embarking on some individual line of treatment if he knew that any failure of this treatment would be brought before a committee of what were, after all, his competitors. If they disapproved of his action the case went before the Insurance Committee, who would probably decide against him, and then the Minister of Health would find that he had to back up the Committee. Thus a man's career might be wrecked. It was all very well for the Minister to say that nobody asked a man to come on the panel, and

¹ *Tubercle*, April, 1920, which also contains an abstract of Professor Bull's paper.

that he should not object if the Minister threw him off it; but the panel covered an enormous majority of the people of these islands. A man removed from it was faced with the ruin of his whole professional career, and should in the last resort have the chance of placing his case before an unbiased and non-technical court. What was asked for was an ultimate court of appeal, and unless the medical practitioner considered that he had a very good case he would not run the risk of bringing it before a court of law.

Lieut.-Colonel Fremantle, seconding the motion, said Captain Elliot had spoken of the panel practitioner's work as practically becoming coterminous with the whole of the medical profession. But that was not so. There was another tendency which was rather dangerous. This was for certain members of the profession to say, "We will not practise under these conditions." If they were able to carry on private practice at higher fees they would have nothing to do with panel practice. That would be a bad condition for any Government service to get into. He had a very high opinion of his own profession and of Dr. Addison, but it was quite wrong that medical men should be judged like this by such means as was proposed. He could conceive of many mistakes that might happen and hasty judgements given. The Minister of Health, if busy in other directions, might be largely governed by the judgement submitted from below, and there would be a feeling of grievance. Therefore a doctor should be given a feeling of security in his practice.

Dr. Addison said that the speech of Captain Elliot was one of the most inaccurate he had ever heard. It had no real relation whatever to the facts. He had described the bill as an extension of the power of the bureaucracy; there was no alteration whatever; there was no fresh purpose in the bill from first to last. There was no word in the bill which related to the conditions of the removal of the medical man from the panel. The fact was that when a complaint was made under the original Act, if a medical man was to be removed from a panel, it had to be proved that he was doing something which was prejudicial to the efficiency of the service, and it was a very grave matter. In the next place the case had to go before the Insurance Committee, which was a lay body—not a professional body at all, not a body of jealous fellow medical men.

Lieut.-Colonel Fremantle, interposing, asked whether the following words were not true: "This will apply only after an inquiry by his own professional brethren in the first place."

Dr. Addison, continuing, said that the Insurance Committee, before stating a case, referred the matter to the Medical Committee to see if there was a case to be stated. But the Medical Committee did not judge the matter in any way. If there were a case at all—which of course it required professional examination to see—it went to the tribunal which was set up under the original Act, and which had not been changed in any way in the present bill. That tribunal had to consist of two medical men who were experts, not in the man's own area, and it was presided over by a barrister or a solicitor. Formerly this body reported to the Insurance Commissioners, but with the establishment of the Ministry of Health the Insurance Commissioners disappeared and became absorbed in the Ministry. There was no change in the machinery. The Minister of Health was responsible for the efficiency of the service. There was nothing to compel a medical man to go off the panel; he could go on or go off if he liked. Moreover, Parliament never intended to create a statutory vested interest. What applied to a medical man under the Insurance Act applied equally to any other man in any other department of the Ministry. It was the business of the Ministry to see that the service was well and truly rendered, and this machinery was set up to secure that in a fair way. It was a complicated machinery, but although he had been Minister of Health for more than a year, no case came up to him. It was unthinkable that a man in any section of the Government service should have an appeal to the High Court on the finding that he was not doing his duty properly.

Mr. Dennis Herbert submitted that Dr. Addison's was the most convincing speech in favour of the amendment. The object of the amendment was to get rid of a gross piece of bad management under previous Acts and sustained by the bill. If cases only of a very grave character would arise, surely the very last thing that the House ought to allow was that a man under such accusation should be deprived of the ordinary remedies of the law. Dr. Addison had said that if this amendment were carried, it would be impossible to dismiss people from other branches of the service. If he dismissed one of his clerks on an allegation of a grave offence which made him unfit to carry on the practice of the profession or business in

which he was engaged, Dr. Addison would find that he would not escape the law courts. These people all had the right of appeal to the courts. The mover and seconder of the amendment put their case from the professional view-point which made it weaker.

Dr. Murray regretted very much that Dr. Addison would not agree to the amendment. He accepted the statements that the proceedings of Insurance Committees were public, but when a man chose to go before a judge and have the evidence examined, it showed that he had a very considerable belief in it, and the elementary right of such reference should not be denied to doctors on the panel. The panel practice to the majority of members of the profession was the most important part, and if they were dismissed from it their professional career was absolutely ruined. There was no desire to protect any man doing his work inefficiently or improperly, but the doctor (like any other citizen in the land) should have the security of the courts set up to protect the interests of every individual in this country.

Captain Loseby thought that there was a misapprehension in this matter. If a medical practitioner was aggrieved under common law, like any other contractor, he could have recourse to that law, and he should not have a greater right than any one else. If he were wrongly dismissed, or if the tribunal had in any way misbehaved, he had his remedy under common law in the courts.

Replying to Lieut.-Colonel Murray, Dr. Addison again defined the position. A case, he said, came up on the complaint of an insured person, and the complaint went to the Insurance Committee. The Insurance Committee then referred it to the Panel Committee, which reported their findings to the Insurance Committee.

Major Barnes said he could not believe that an amendment like this would have been supported by three medical men unless there had been some real grievance. What was asked for was that in the very rare case—a grave case as it must be—coming up there should be an appeal to the courts. That did not appear a very great thing, and he wondered why it should be denied. In the old days it was said that the King could do no wrong. In these days the Executive seemed to wish to usurp the divine right. He could understand a Minister not wishing to have an appeal against his decision, but after all, they had to consider something more important than the position or the dignity of a Minister. They had to consider the rights of individuals, and the disposition seemed to be to block the way to the courts. That had appeared over and over again during the session, but the doctrine that the Executive could do no wrong had received a nasty knock during the last few days on an appeal to the House of Lords.

Dr. Addison: There is no denial of any appeal to the courts. A doctor can appeal to the courts on the same ground as any other citizen.

Major Barnes inquired why, if there was no denial of the right, it should be resisted. It was intolerable that it should be within the power of any man, however important the department over which he presided, to block the avenues to justice.

Mr. George Roberts, in opposing the amendment, reiterated that no change whatever in the law was contemplated in the bill. He thought they might rely upon the Insurance Committees to do full justice. During the last twenty-five years he had been connected with friendly societies, and did not yet know of a complaint against a doctor under the Insurance Act. The encouragement of litigation, unless it was absolutely necessary, was objectionable. In his opinion it was unnecessary here. The medical profession was quite capable of looking after itself. It was one of the most powerfully organized professions in the land, and quite capable of seeing that no Insurance Committee, or even a Minister himself, was able to do injustice. It was not a bureaucratic body that determined this matter, but a thoroughly democratic and representative body—the Insurance Committee, acting on the advice of other medical men.

Major Farquharson said the question of the initial determination of the doctor's fault lay in the hands of a body of doctors—the Medical Service Subcommittee of the Insurance Committee of the county or county borough. This body of doctors was democratically elected by the whole body of the medical profession in the area. It very rarely happened in practice, but if it should happen that a competitor were serving upon that committee when a doctor was appearing to answer a charge, he (Major Farquharson) had sufficient faith in his profession to feel sure that such a person would withdraw from the inquiry. With regard to the Ministry of Health, it was now plausibly suggested that there should be an appeal from the Minister to a judicial tribunal. It was suggested that in a case of a breach of contract or dismissal an

action would lie. He was not prepared to advise the House on that point, but he suggested that if the Minister in the exercise of his ministerial capacity ever did a thing or caused a condition to arise as to which a doctor would be aggrieved—in the technical sense of the word—the proper place for dealing with the Minister of Health would be the House of Commons. Let the members make the Minister toe the mark and answer for his misconduct.

At this stage Captain Elliot asked permission to withdraw his amendment. He thought it was useless to go on at that hour (after one o'clock in the morning). Before this application was taken Captain Benn quoted the terms of the original Act to maintain that vested interest was created for the medical man, and that therefore Dr. Addison was wrong in contradicting Captain Elliot. If the Government was pressing conditions which the best class of men on the panel did not think fair, the best class of men would not be got to go on the panel. Mr. Myers inquired whether the delinquents amongst the members of the profession were so numerous as to make this machinery necessary.

Dr. Addison replied that he did not know of any delinquents.

Major Entwistle thought the amendment was reasonable and one that ought to be supported by the House.

Mr. Briant said the main difficulty in the Act had been to get any doctor removed at all. It was not a case of more or less exaggerated statements against the doctor, but to shift one doctor from the panel was a herculean task. No medical man need think that his reputation would be blasted by any panel of a few other medical men. The Minister of Health had been somewhat misleading the House and talking round the subject without apparently having grasped the real facts of it.

Mr. Bromfield sought to raise the question of the inadequate supply of drugs and surgical appliances to assist the doctors in their treatment, but the Deputy Speaker ruled this out of order, and the proposed clause was then negatived.

Tuberculosis Sanatoriums.

Clause 4, to discontinue sanatorium benefits under the Act of 1911 (except for Ireland) in order that separate provision might be made by the Ministry of Health, was afterwards discussed in the early hours of the morning.

Commander Kenworthy wished to leave out the discontinuing clause. In Hull it was felt that the necessary work could be done better by the existing Insurance Committee than by the Health Committee, which was overburdened with other duties.

Captain Wedgwood Benn recalled Mr. Lloyd George's confident declaration that after three or four months in a sanatorium tuberculous patients would be discharged cured.

Dr. Addison replied that a good deal had been learnt about tuberculosis since the Prime Minister's utterance ten years ago. As for what Commander Kenworthy had said, he reminded the House that such institutions as that for Hull were not provided by Insurance Committees, but by county councils. What was proposed was that one authority should be made competent to deal with all stages of tuberculosis, and it was for the benefit of the insured that the enlarged scheme was being devised.

Mr. Myers said that the defects in administration with regard to tuberculosis had been largely due to lack of funds on the part of the Insurance Committees, and lack of accommodation available from the local authorities. Domiciliary treatment had been altogether inadequate and unsatisfactory. As soon as the diagnosis of tuberculosis was made the patient should be put into the hands of the specific expert authority. He objected to practitioners of "ordinary professional skill dabbling in the tuberculin treatment."

Dr. Murray thought that the new proposals of the Government offered a very great improvement, but regretted that the discussion of so important a subject was being taken at 2.30 a.m. He disagreed with what Mr. Myers had said about the general practitioner. Early diagnosis of the disease was very difficult sometimes, but in his opinion for the most part the general practitioner was just as able to deal with tuberculosis as any of the so-called tuberculosis officers appointed under the Act.

Sir R. Thomas said Wales possessed one of the most up-to-date organizations, which had been brought into existence by voluntary contributions as a memorial to the late King Edward. From three sources—from the insured person, from the employer, and from the State—this institution had been receiving £25,000 annually, and the concern of the Insurance Committees was where the money was to come from in future. There was nothing sufficiently definite, in his opinion, to warrant a change of system.

Lieut.-Colonel Murray and Major Entwistle said that considerable apprehension existed with regard to the intended transfer.

Dr. Addison, dealing first with a question why Ireland was not included in the scheme, pointed out that there was no medical benefit in Ireland such as obtained in England. There was a Poor Law service which worked differently, but Ireland had to be left out until an alternative system of medical services had been applied to that country. In Great Britain, in connexion with the scheme now being developed for post-sanatorium training for disabled soldiers, it was proposed to make the arrangements generally applicable. It was intended

to develop the village settlement system as far as practicable, and to link the whole system up with the after-care at the end and the dispensing services at the beginning, as far as could be done, under one composite authority. The Ministry was now making a survey of village settlements as part of one comprehensive scheme, instead of dealing with it in two sections as at present.

Commander Kenworthy's amendment was then negatived.

On the motion for the third reading of the bill, Dr. Addison said the additional benefits which were the principal features were to come into operation on July 5th, and the measure had to be brought on to the Statute Book immediately. Between now and July 5th the Department had to distribute to sixteen million persons various forms, etc., and the stamps required, and the societies had to prepare their cards and do other work.

The bill was afterwards read a third time.

The bill was read a second time in the Lords on May 17th, and it was taken in Committee and read a third time in that Chamber on May 18th.

Direct Representatives of the General Medical Council Bill.

This bill was introduced in the House of Commons on May 10th by Sir Henry Craik, with the support of Captain Elliot and Lieut.-Colonel Raw.

MEMORANDUM.

Under the Medical Act, 1885, the term of office of the direct representatives on the General Medical Council is five years; but as the Act does not contain any provision by which a person elected to fill a casual vacancy should continue in office only for the residue of the term of office of his predecessor, the result has been that, instead of one general election of direct representatives being held once in five years, elections of individuals as direct representatives are continually occurring at irregular intervals. As the expenses of the election of a single representative amount almost to as much as elections of several, the burden on the General Council of expenditure on elections has been largely increased. The object of this bill is to remove this defect.

The bill also removes the obligation to fill a casual vacancy which occurs less than twelve months from the date of the next general election, and extends the time for holding an election. In many cases only one candidate is actually nominated, but the shortness of time allowed after the precept has been received from the returning officer makes it necessary to prepare for a contested election immediately, whereby a considerable expenditure is often unnecessarily incurred.

A Bill to amend section eight of the Medical Act, 1885.

BE it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. *Term of office and elections of direct representatives on the General Council.*—Notwithstanding anything in section eight of the Medical Act, 1885—

- (a) Any registered medical practitioner who, after the passing of this Act, is elected as a direct representative to fill a casual vacancy caused by the death or resignation of a direct representative shall hold office so long as the person in whose place he was elected would have held office, and no longer.
- (b) Where a casual vacancy is caused by the death or resignation of a direct representative within twelve months from the time when his term of office would have expired, it shall not be necessary to fill the vacancy.
- (c) The time within which elections to fill vacancies amongst the direct representatives on the General Council, whether caused by expiry of term of office, death, or resignation, are to be held shall be forty days after the receipt of the precept of the returning officer, and accordingly "forty days" shall be substituted for "twenty-one days" in subsection (3) of section eight of the Medical Act, 1885.

2. *Short Title.*—This Act may be cited as the Medical Act, 1920, and may be cited with the Medical Acts.

Naval Medical Establishments and Services.

In Committee of Supply on the Naval Estimates on May 17th, the vote was taken for a sum of £677,300 to defray medical services, including establishments at home and abroad, for year ending March 31st, 1921.

Sir Donald Maclean pointed out that while the number of officers and men of the Royal Navy had fallen from 225,000 to 126,000 there had been no corresponding reduction in the medical establishment. With a great reduction in fighting units, how was it that 3 surgeon rear admirals, 8 surgeon captains, 17 surgeon commanders, and 43 surgeon lieutenants were still required? He noticed that there was some reduction in the nursing staff—its cost had gone down from £34,300 last year to £30,700 this year; but there was a greater charge for the rear admirals whose numbers were undiminished. There was a slight increase in the charge for surgeon captains, while that for surgeon commanders had risen from £16,900 to £18,400.

Sir Thomas Bransdon asked questions with regard to promotion for sick berth ratings, and Commander Kenworthy asked information as to the employment of hospital ships.

Sir James Craig, in reply, said that it was impossible suddenly to drop from war to peace conditions. Two

hospital ships were on hire, one attached to the Atlantic Fleet, the other to the Mediterranean; they would be replaced probably by purchase.

Viscount Curzon, who said he had noticed that in certain naval depôts and establishments the medical staff at times had very little to do, suggested naval medical officers should be allowed to attend on the wives and children of the men.

On a further question by Sir Donald Maclean, Sir James Craig intimated that he would endeavour to clear up the particulars of the votes on report, and Mr. Long added that the figures given under Vote 3 did not constitute the total medical service vote.

Sir F. Banbury said it appeared to cost more to treat 136,000 men than to treat 280,000; it could not be said that that was owing to the increased cost of material and wages, because the comparison was with last year. For hospitals' and infirmaries' provisions and stores, medicines and instruments, the sum was £278,000 as against £232,000.

Dr. McDonald greatly regretted the opposition to the vote. He was especially sorry to hear Viscount Curzon suggest that naval medical officers should be asked to attend families and children. Other officers in the navy as well as medical men had spare time. As for the increased cost, members did not realize the enormous increase in the cost of medical and surgical appliances. Medical salaries had been increased, but not unreasonably so. Dr. Murray referred to the item "medical sustenance of seamen at sick quarters," and said that before the war surgeons had to find accommodation for seamen on land with considerable difficulty. The allowance of 2s. a day, including cost of lodging, food, and nursing, was sweating.

Mr. Acland said that when he held a responsible position at the War Office he found that there was no department in which it was more difficult to reduce expenses than the medical, except the nursing department, because doctors always had such a strong position in pointing out the fine work they did, and how essential it was they should have proper material and apparatus. That applied also to the navy.

The vote was then agreed to.

Health Conditions of Recruits.—Captain Elliot asked, on May 11th, if the War Secretary was aware that many men re-enlisted for general service were drawing pensions for wounds received in the war, and whether a man suffering from a physical disability so great that he was receiving a pension on this account should be selected to fight for his life. Mr. Churchill replied that a few men of the kind named had been re-enlisted. The majority of these were not serving in combatant units, but in specialist corps, and had not been found unfit for their duties. The regulations provided that in the case of men discharged on medical grounds applying for re-enlistment, the medical officer should consult the former discharge documents before certifying the man for re-enlistment. During the rush of recruiting last year, a few men were enlisted and subsequently found unfit for service, but steps had been taken to obviate such mistakes in the future. In view of the present position of recruiting, orders had been given that ex-soldiers receiving disability pensions were not to be re-enlisted. Captain Elliot asked if Mr. Churchill would on information look into the cases of men actually in combatant units and cavalry regiments who were in receipt of disability pensions. Mr. Churchill responded he would wish to deal with each case separately. If a man had been wounded and wished to go on to the service, and his military superiors thought he could do useful work, he should not be subjected to the same rigid examination for health as an absolutely new man. Captain Elliot inquired whether this was a question for a man's "military superiors"—was it not rather for the medical authorities, who could say whether or not a man would ultimately break down from the strain of service, though he might be perfectly fit for peace soldiering? Mr. Churchill said he did not altogether agree. In regard to recruiting for the Territorial Army, he had directed that men who had disability pensions were not for that reason—if there were no other—to be refused. There were many officers in the Army who liked the idea of continuing service with their old comrades—men who served in the Boer War and in the Great War. Dr. Murray asked if it were not the fact that pensions were granted for slight disability that did not interfere with a man's usual work. Mr. Churchill said that in some cases the pension was on account of the amount of disablement, in others the amount of suffering and injury that an individual had incurred. Replying to Mr. Houston, who alleged that new men who were physically unfit were being recruited, Mr. Churchill answered he was doing his best to stiffen the standard of recruiting. In the first instance the War Office had to take anybody that could be got. It was intended by a refining process to get rid of the men who were not physically fit.

The Value of Vaccination.—Mr. W. Thorne asked, on May 11th, whether during the past ten years fewer children had been vaccinated in England and Wales than in any previous decade; whether, during this period, there had been fewer small-pox deaths recorded than in any previous decade; and if so, whether the Minister of Health would instruct his department to publish the facts, "so that the misapprehensions of the position which were widespread in official medical circles might be removed." Dr. Addison replied that the figures were as Mr. Thorne indicated; the statistics regarding vaccination were published annually, and he was not aware of any misapprehension in official medical circles. He might point out that a consideration of these statistics without regard to other

relevant facts might result in a misapprehension of the protective value of vaccination against small-pox. The matter was referred to in the 43rd Annual Report of the Local Government Board (Medical Supplement), 1918-19.

Medical Service Pay.—Mr. Dennis Herbert asked, on May 11th, if the War Secretary was aware that great hardship and much discontent was being caused among members of the medical service of the Royal Air Force by the delay in payment of back pay now many months overdue. Mr. Churchill replied that the arrangements for remustering Royal Air Force medical personnel to the new rates of pay had been under preparation for some time, and the necessary order was issued last week.

The Demobilization of Medical Students.—Major Glyn, referring to a telegram issued by the War Office on March 19th, to the effect that all non-regular officers were liable to retention beyond April 30th, 1920, irrespective of whether they did or did not volunteer, asked whether this was not a reversal of the policy laid down by Mr. Churchill on February 23rd, when he said that all such officers would be demobilized by the end of April. Major Glyn said he raised the matter especially in the interests of medical students retained in Mesopotamia who wanted to continue their studies at home. Mr. Churchill regretted that he was unable to take any exceptional action in the case of medical students. Officers held their commissions during His Majesty's pleasure, and they were liable to be retained in the following circumstances: when they filled an appointment within an authorized establishment; when no regular officers were available to replace them; and when it was impossible to dispense with their services without relief. Every effort, however, was being made to replace temporary officers.

Medical Conditions of Service in India.—Replying to Sir W. Joynson-Hicks, Mr. Montagu stated, on May 12th, that in 1914 the number of officers in the Indian Medical Service was 706 Europeans and 63 Indians. In December, 1919, excluding officers holding temporary commissions, there were 650 Europeans and 80 Indians. During 1919 twenty-five Europeans and twenty-one Indians were appointed to permanent commissions. In amplification of improvements already sanctioned he hoped to announce at an early date increased rates of pay and pension for the Indian Medical Service. He recognized also that it was essential to improve the facilities for leave and study, but no decision on these points could be effective until recruiting had brought the service nearer to its normal strength. Mr. Montagu added that he hoped to be able to state decisions within a few weeks.

Travelling Facilities for Men under Treatment.—Major Tryon announced, on May 11th, new regulations for travelling facilities for ex-service men under medical treatment away from home. Under the present regulations a man under treatment away from home may be provided with a free railway ticket after six months, and a further free ticket for each subsequent six months' treatment. In future, four half-fare vouchers may be substituted for two free tickets, and the man under treatment for less than six months will thus be able to visit his home at half fare after three months. Men under treatment in the convalescent centres will be allowed three free tickets or six half-fare vouchers instead of four and two respectively.

British Soldiers in France and Germany.—Replying to Captain Elliot, on May 11th, Mr. Churchill said he was aware that there had been a rise in the incidence of venereal disease amongst the troops in France and Germany since the armistice. The subject had been receiving anxious consideration for some months, and he was satisfied that the authorities on the spot were taking all possible steps to combat it.

The Treatment of Tuberculous Soldiers.—Dr. Addison, on May 12th, announced that the Ministry of Health had come to decisions on the report of the Interdepartmental Committee on tuberculous soldiers. The capital grant in-aid for the provision of additional sanatorium and hospital accommodation had been increased to £180 a bed, and considerable extensions of the existing accommodation were being made. Facilities for the training in suitable occupations of ex-service men suffering from tuberculosis were being provided at existing sanatoriums at an estimated cost of £250,000; and a scheme for the provision of village settlements for these men and their families had been worked out, and was now under consideration by the departments concerned.

Answers in Brief.

The total number of persons employed by the Ministry of Health on May 1st, including the staff of the Welsh Board of Health, was 5,825, of whom 3,452 were on a temporary basis.

Mr. Bridgeman, on May 12th, stated that any person who could obtain a medical certificate that coal was needed in a case of illness could get from a merchant a supply forthwith.

Sir Archibald Williamson has stated that R.A.M.C. officers are detailed for service overseas in accordance with a foreign service roster, except in the case of an officer who, on account of special qualification, is required in the United Kingdom. When an officer who had completed a tour of service in India became due for foreign service every endeavour was made to post him to a colony. Due consideration was given to service in theatres of war other than France and Italy.

Sir Robert Horne has stated that he is aware of only three factories in Great Britain producing morphine. When the Dangerous Drugs Bill is passed into law, control over such factories will be exercised in accordance with the provisions of the Opium Convention. Licences are at present granted by the Board of Trade for exports of morphine on the basis of the legitimate requirements of the country of destination.

Sir Robert Horne has promised a statistical statement as to the quantity and quality of condensed milk imported into this country.

Scotland.

POST-GRADUATE MEDICAL TEACHING IN GLASGOW.

For many years before the war post-graduate courses in medicine had been conducted at several of the Glasgow hospitals, but there was no organized scheme whereby the teaching in the different hospitals might be correlated. Early in 1914, at the request of the medical faculty of the university, a meeting of the medical staffs of the university and other medical schools and of the general and special hospitals of Glasgow was convened, and a committee was appointed to promote co-operation between the various bodies concerned with the purpose of instituting a general scheme of post-graduate medical teaching. The scheme, however, fell into abeyance on the outbreak of war in August, 1914, and nothing further was done until February, 1919, when an emergency course for the ensuing summer session was instituted, partly to meet the needs of graduates who had been on service. This course was repeated in the autumn, and comprised clinical classes in medicine, surgery, tuberculosis, and other special subjects, as well as evening demonstrations in diseases of the nose, throat, and ear. Eighty-six graduates attended; the majority were officers or ex-officers of the navy or army, but a number of local practitioners also availed themselves of the opportunity of refreshing their knowledge in the classes.

In December, 1919, a conjoint meeting of the medical faculty of the University and the general committee was held, in order to consider the results of the emergency classes, and to discuss the further organization of post-graduate teaching in Glasgow; as a result a special sub-committee was appointed to formulate a permanent scheme. This scheme was unanimously approved at a conjoint meeting held in the University, on March 2nd, under the chairmanship of Principal Sir Donald MacAlister, K.C.B. It is recommended that for the purpose of arranging, co-ordinating, and administering post-graduate medical teaching in Glasgow and the West of Scotland a central body shall be formed under the title of the Glasgow Post-Graduate Medical Association. The governing board is to consist of ten representatives of those institutions granting facilities for post-graduate teaching, and eight representatives of the teachers who have taken part in the post-graduate teaching in either of the two years preceding the year of election. It is recommended that the following courses be arranged: (1) "Refresher" courses for the general practitioner, to be held twice a year, and to last four to six weeks; (2) weekly demonstrations for local practitioners, to be held one afternoon a week, the summer months excluded; demonstrations of an hour and a half's duration are to be given by different members of the teaching staff; (3) advanced and comprehensive courses intended particularly for those desirous of qualifying specially in one or more subjects. These courses are to occupy the full time of the practitioner, and to be of not less than six months' duration. The committee consider that medical practitioners who attend such courses and show proficiency in the subjects studied should be able to obtain suitable recognition of their work, in the form either of a diploma conferred by the university or of a special certificate granted by the Post-Graduate Association. Courses in venereal diseases, tuberculosis, obstetrics and child welfare, and school medical inspection and hygiene, should be instituted as soon as possible. It is suggested also that the Post-Graduate Association should make known the facilities offered for research workers in medical subjects, and be the means of introducing suitable workers from other parts. Fees should be charged for all teaching, and the practicability of obtaining direct or indirect financial assistance from the Government should be considered.

SMALL-POX IN SCOTLAND.

Cases of small-pox continue to occur in Glasgow, and at the end of last week 116 were under treatment in Belvidere Hospital. A case has occurred also at Paisley and another at Dundee. The Glasgow Health Committee has approved the arrangement for the offer of free vaccination to all persons, has invited insured persons to go to their panel doctors (the cost of vaccination being borne by the corporation), and has agreed to pay a fee of 2s. 6d. to doctors in respect of non-insured persons. Dr. A. K. Chalmers, M.O.H. Glasgow, held a conference

with representatives of the medical profession at which a proposal to institute a house-to-house visitation in the east end of Glasgow was discussed. Dr. Glen, Secretary of the Glasgow Division of the British Medical Association, said that medical practitioners had undertaken to note the names and addresses of the insured persons they vaccinated. As regards others, doctors were asked to inform the medical officer of health of all vaccinations.

The Royal Faculty of Physicians and Surgeons of Glasgow has issued a memorandum to the public on the value of vaccination in which the opinion of the Royal Commission of 1889 is set out. That Commission found that vaccination diminishes liability to attack and renders the disease if contracted less fatal and of milder type, but that its effect gradually diminishes, so that revaccination is required to restore the protection after a period of nine or ten years. The memorandum goes on to recall that the value of effective recent vaccination was amply illustrated during the prevalence of the disease in Glasgow, which began in 1900. Early in the following year the Health Committee offered free vaccination; ultimately over 4,000 persons made use of the offer, and not one case of small-pox occurred among them; 1,800 cases which did occur were all in persons who did not accept the offer. The experience of the small-pox hospital is quoted also. The medical and surgical staff numbered eighty; all were efficiently vaccinated and none contracted the disease, and the same was true of fifty hospital servants. Further, over 150 practitioners and students of medicine visited the hospital; all were vaccinated beforehand and none contracted the infection. During the outbreak it became necessary to extend the hospital, and 230 workmen were employed; 217 accepted revaccination and none contracted the disease. Of the 13 who refused or for some reason were not recently revaccinated, 5 contracted the disease and 1 died.

Ireland.

THE LATE DR. SPELMAN, OF DUNMORE, CO. GALWAY.

It was stated in a letter which we printed last week that a fund has been opened for the relief of the widow and two young children of Dr. A. P. Spelman, who was killed by the skidding of his motor car as he returned from a professional call. Subscriptions may be sent to Dr. P. J. Delaney, Claremorris, co. Mayo, or to Dr. Heneghan, Ballinadine, co. Mayo. Dr. Spelman was only 26 years of age, and his widow and two young children are left totally unprovided for. It is a case that should make special appeal to the generosity of the medical profession.

England and Wales.

THE BLACK SMOKE TAX.

THE Manchester City Council has for years been seriously concerned about the excessive smokiness of the air in that town, and in our issue of July 11th, 1914, we described the appointment of an air pollution advisory board. The conclusions reached by the statistical subcommittee of the board have been published in a pamphlet with the title of *The Black Smoke Tax*. One of the chief endeavours of the committee was to estimate as precisely as possible the actual monetary loss caused to the town by undue smokiness of the air. A member of the staff of the Public Health Department who made a comparative investigation of the cost of the weekly washing in similar working-class households in Manchester and Harrogate respectively found that in Manchester the average cost of soap, starch, and other materials was 50 per cent. greater, and the average cost of fuel 30 per cent. greater; material and fuel together cost 7½d. a week per household more in Manchester. This difference amounts to £183,000 per annum in working-class houses where the washing is done at home. In middle-class homes where the washing is partially or wholly sent out the additional cost is larger, and includes expenditure on collection, labour, and laundry profits; but if these costs are ignored, and the outlay for the material and fuel is calculated at the same rate as in poorer households, the total expenditure in Manchester is £242,702 per annum

greater than it would be in a city of the same size as Manchester but of the same degree of atmospheric cleanliness as Harrogate. These calculations have been verified by a firm of auditors. The committee's estimates of other sources of loss through smokiness have of necessity been made with less precision; but as a result of careful inquiries from hospital superintendents, architects, property owners, hotel proprietors, and manufacturers, they conclude that excessive smoke pollution costs Manchester at least three-quarters of a million a year. To expend much thought and money on measures that would reduce this "smoke tax" is regarded by the committee as a sound business expedient. It appears from the Manchester figures that the estimate of £1 per head made by the Hon. Hollo Russell for the London area was well within the mark; comparison may also be made with the Industrial Research Department's inquiry at Pittsburg, where the estimated loss through smoke pollution was £4 a head. These economic conclusions should be collated with the well known work of Professor Cohen and Mr. Ruston¹ (who studied from the scientific side the effects of excessive smoke production); together they deserve the serious attention of urban authorities. An abortive Smoke Abatement Bill was introduced into the House of Lords in 1914; since that time the matter received little national notice until the appointment, recorded in our issue of February 28th of this year, by the Ministry of Health of a Smoke Abatement Committee, with Lord Newton as chairman.

OPENING OF DEPARTMENT OF PATHOLOGY AT SWANSEA.

On May 7th the Beck Laboratory at the Swansea General and Eye Hospital, founded mainly through the generosity of Mr. Roger Beck, was formally opened by Sir George Makins, G.C.M.G., C.B., President of the Royal College of Surgeons. Mr. Beck's name is a household word in the town of Swansea wherever wise beneficence is concerned; the medical profession at large is also indebted to him as founder of the Marcus Beck Laboratory at the Royal Society of Medicine. The two principal working rooms of the Beck Laboratory have been named respectively the Brook Room and the Lancaster Room, in acknowledgement of the practical aid given by Mr. W. F. Brook and Dr. Lancaster, of the hospital staff, towards the establishing of the new department. The laboratory consists of four rooms placed on the first floor, and is equipped for all types of clinical pathological work, including chemical pathology. When necessary the department can readily be expanded by taking over rooms on the ground floor of the present building. The animal house is conveniently placed within a few yards, and the *post-mortem* room is also in close proximity.

The department has been in working order for a year, and clinical pathological work is being done for the Swansea Hospital, various public health authorities, and for practitioners of the district. It is intended to develop the laboratory as a centre of inquiry and research as soon as the necessary expansion of the working staff has been effected. The department has been under the direction of Dr. A. F. Sladden from its initiation.

At the opening ceremony, at which there was a large attendance, Sir George Makins gave an address on the growth of clinical laboratories during the past fifty years. He instanced some of the advantages derived during the war from the close association of clinicians with laboratory workers, and emphasized the importance of the clinical laboratory as the link uniting the science with the art of medicine. Sir George Makins was followed by Professor Hepburn, Dean of the Welsh National School of Medicine, who with subsequent speakers expressed appreciation of the generous and far-seeing spirit which has actuated Mr. Beck. Mr. Beck, in reply, happily described the department he has founded as a "first aid" to the profession of Swansea and the district.

In the evening the honorary medical staff of the hospital gave a complimentary dinner to Sir George Makins and Mr. Roger Beck; it was very well attended by medical men and their friends, and was presided over by Dr. A. W. Cameron. The Laboratory, the two guests of the evening, and the Swansea General Hospital were all heartily toasted, the gathering being especially delighted by the toast of the staff's two guests, proposed with felicitous phrasing and dignity by Dr. Lancaster.

Correspondence.

STERILIZATION OF MILK BY ELECTRICITY.

SIR.—In the extremely fair note on "The Sterilization of Milk by Electricity," which appeared in your issue of May 15th, p. 632, it is stated that the work was started in 1914. This is not correct, as the work was in progress when I came to Liverpool at the end of 1912. A certain degree of success had been obtained, and when, at the request of the Health Committee of the city, I presented a report on the work, I was able to state that it gave "promise of success." There was at this period definite evidence that, without obvious change in its constitution, the milk had been freed from *B. coli*, but there was no satisfactory evidence that *B. tuberculosis* had been destroyed. The control and other experiments were, in my opinion, far too limited and the conditions under which the work had been done too unsatisfactory to justify any conclusions as to success or failure. As a result of my report a plant was erected in my department, and I was asked to carry on further investigations. This was my first connexion with the actual experimental stage, and I was fortunate in having Mr. F. C. Lewis, who had been in close association with the previous work, attached to my laboratory staff. Thus we were able to avoid the repetition of methods of experimentation which had given unsatisfactory results and to concentrate on those which had given promise of success.

Work on sterilization of fluids by electrical action had been recorded many years before this work was started, but the credit of initiating the work along the special lines recorded in the monograph by the Medical Research Committee must be given not to me but to the earlier workers in 1911 and 1912.—I am, etc.,

Liverpool, May 15th.

J. M. BEATTIE.

EXPERIMENTAL INDUCTION OF CANCER.

SIR.—Apropos the leading article in your issue of May 15th, page 680, concerning Professor Fibiger's work on carcinoma in rats, the late Professor H. G. Plimmer told me in 1917 that five wallabies at the London Zoological Gardens, confined in the same pen, had died of this disease. In four of these, all affected in the same year, it was primary in the stomach. These animals, so I was informed by the keeper, are fed on oats, cabbages, and a little bran. If I am not mistaken, Professor Plimmer said that the primary growth was by far most commonly gastric, in his experience of the animals in this collection which died of carcinoma. I found other curious cases among his records, but was unable to pursue the matter further. In view, however, of the strong suspicion entertained by many besides Sir John Bland-Sutton, that carcinoma in man is the result of an infection in most cases via the alimentary tract, I would suggest that the incidence of carcinoma among animals kept in captivity is a subject which might well reward a searching inquiry.—I am, etc.,

Liverpool, May 17th.

EDMUND HUGHES.

EPIDEMIC ENCEPHALITIS.

SIR.—I have read with much interest Dr. Hubert Phillips's admirable note in the *BRITISH MEDICAL JOURNAL* of May 8th on his case of encephalitis with myelococcus. I am sure, however, that he will accept a correction from me on one point of some small importance. My examination of the cerebro-spinal fluid showed 40 cells per c.mm., these being almost exclusively small lymphocytes.

In the earlier cases of this disease which were published a normal cell count was, I believe, generally recorded; several reporters of late, however, have found a slight lymphocytic increase. A blood count made on Dr. Phillips's patient at the same time showed nearly normal proportions—namely, 5 million red cells and 8,100 leucocytes, of which 80 per cent. were polymorphs, and only 15.25 per cent. lymphocytes.—I am, etc.,

Swansea, May 12th.

ARTHUR F. SLADDEN, D.M.Oxon.

"A PLEA FOR THE TONSILS."

SIR.—It might occur to your readers, after perusing Professor Berry's letter in your issue of February 7th, that his work on the subject had been overlooked in my

book *Immunity in Health*. Professor Berry had not seen the book when he wrote. As a matter of fact, his very valuable researches on the lymphoid tissue of the caecal apex are referred to in a number of places in the text, and indeed serve as a basis of some of the conclusions arrived at.—I am, etc.,

KENELM H. DIGBY,
Professor of Clinical Surgery.

University of Hong Kong,
March 30th.

WAR REWARDS.

SIR,—It seems to me that some alteration should be made in the rewards given out by the War Office. I know a medical man who had first of all served in the Royal Naval Artillery Volunteers and then in the Royal Engineers (Submarine Miners), and who enrolled at once as an *à la suite* officer when Lord Haldane's scheme was formulated. This man on August 6th, 1914, in reply to urgent requests for enrolments, sent a letter to the War Office to say that he was anxious to undertake any service abroad that he could possibly get. He has a good knowledge both of French and German. The usual reply came that a note of the offer had been made, and there the matter rested till he was called up for *à la suite* service in May, 1915. He was classed C1, and consequently kept at his *à la suite* post all through the war, although he made every effort to get away; not only so, but in addition to these duties he gave assistance voluntarily and without any remuneration for a whole year at the examination of recruits. He began his work in the morning with recruits, went to the military hospital about 1 o'clock, and returned to his house about 7 at night, and during that whole year he had not a single day's leave of absence except three days for a trifling operation. The strenuous times caused him to resign a teaching post of some considerable value, and also a post which he held under the corporation of the town in which he lived. The monetary losses in that respect might be put down at a couple of hundred pounds per annum, and these losses are permanent.

When he resigned his teaching appointment it was advertised, and a young practitioner in the same line of specialism applied for it and got it. This man was of medical military age. I am not aware that he had ever done any military service. Ultimately, however, when conscription came in he was compelled to join up, and thus a man who apparently had never the slightest intention of crossing his own doorstep for military service now goes about as one of the patriots entitled to the Overseas medal. The man who gave up these appointments, who saw something like 1,700 recruits in a year without a penny of payment, and who in his early days did some volunteer service, gets nothing, while a young man who did not join up till he was compelled to gets a reward. Is there any sense in such arrangements? Surely it is more patriotic to use every effort to get abroad in the service of your country than to remain at your own fireside till the recruiting officer compels you to join up. Not only did the man above mentioned get nothing for his examination of recruits, but as he was in a home station all his allowances were cut off. The hospital in which he served was situated some three miles from his dwelling, and these allowances came in handy as they helped to pay the taxis. Surely it would have been only fair to have given full allowances to a man who was doing, at any rate, nine or ten hours' work every day in a double capacity, first as an *à la suite* officer, for which he got his ordinary pay; secondly, as one of the staff of the Recruiting Boards, for which he got nothing, but which involved him in considerable expense for the hire of taxis,—I am, etc.,

Glasgow, April 30th.

X. Y. Z.

THE salaries of the professors of the Paris Faculty of Medicine have been raised retrospectively from July 1st, 1919. The professors have been placed in two classes according to their seniority, those in the first class receiving a salary of 25,000 francs and those in the second class a salary of 23,000 francs. By a recent Ministerial decree Professors Richet, Pouchet, Hutinel, De Lapersonne, Gilbert, Roger, Nicolas, Ribemont-Dessaignes, Quénu, Prénant, Vidal, Chanfard, and Weiss have been put in the first class, and Professors Delbet, Marfan, Hartmann, Bar, Marie, Broca, Teissier, Desgrès, Lejars, Achar, Robin, Leguen, Letulle, Couvelaire, Carnot, Besançon, Vaquez, Dupré, and Jéanselme in the second class.

Obituary.

SIR KENDAL FRANKS, C.B., M.D., F.R.C.S.I.

THE death of Sir Kendal Franks at Johannesburg, which has been announced in the public press, will cause much sorrow and regret amongst his many—and he had very many—friends both in the United Kingdom and in South Africa.

Kendal Mathew St. John Franks was born on February 8th, 1851, at Jerpoint Hill, co. Kilkenny, and was the fourth son of Robert F. Franks Kendal and Henrietta, daughter of the Right Hon. Charles Kendal Bushe, Lord Chief Justice of Ireland. He was a distinguished graduate of the University of Dublin, in which he obtained first-class honours in mathematics and a scholarship. As a medical undergraduate he was also awarded a gold medal by the Dublin Pathological Society for an essay on "Injuries and diseases of articular cartilage." He graduated A.B. in 1872, M.B. 1873, and M.D. in 1876. He took out the licence of the Royal College of Surgeons, Ireland, in 1875, and the Fellowship in 1879, and held the position of senior demonstrator of anatomy in the school attached to the College for some years. Shortly after graduation he was appointed surgeon to the Throat and Ear Hospital, and subsequently to the Adelaide Hospital, of which he was for some years the senior surgeon. He was also an examiner in surgery in the University of Dublin, and consulting medical officer to the London and North-Western Railway in Dublin. He was an able surgeon and brilliant operator as well as a popular teacher, and soon gained a large and profitable private practice. During the vicereignty of the Marquis of Zetland he was appointed surgeon-in-ordinary to the Lord Lieutenant.

He was a fellow of many medical and other learned societies, including the Royal Medico-Chirurgical Society, and was a member of the Surgical Council of the Royal Academy of Medicine in Ireland. He was the author of many valuable contributions to medical literature, including an article on "Movable kidney" in the *Twentieth Century Practice of Medicine*, vol. ix; on "Cholecystotomy" and on "Cases of enterectomy and enterorrhaphy" in the *Transactions of the Royal Academy of Medicine, Ireland* (1889-1893).

He married in 1879 Charlotte Selina, daughter of Richard Greene, Esq.; she died in 1881. In 1885 he married Gertrude Jane, daughter of Lieut.-Colonel Bromhead Butt, 79th Regiment; she died in 1896, leaving three sons and one daughter. In 1906 he was elected vice-president of the Royal College of Surgeons in Ireland, but in the same year, and before he had been long in office, he determined, in consequence of the serious ill health of his wife, to emigrate to South Africa. There he rapidly developed a large consulting practice and was appointed honorary consulting surgeon to the Johannesburg Hospital. During the South African war he was appointed consulting surgeon to H.M. Forces, and for his conspicuous services was thrice mentioned in dispatches and in 1900 received the C.B. He was knighted in 1904.

Sir Kendal Franks was remarkable not only for his professional attainments but also for his broad mental culture and artistic taste; his skill as an artist in water-colour, which he inherited from his mother, was of no mean order. But he especially excelled in those social qualities which endeared him to so many devoted friends—a genial optimism and extraordinary enthusiasm even in trifling matters, and never-failing sympathy. He was indeed a man.

W. J. S.

THE announcement of the sudden death of Dr. J. H. FULLARTON will cause much regret in many quarters. Glasgow graduates who can recall the early eighties will remember him as a brilliant student of biological science and the winner of prizes and scholarships. He graduated B.Sc. in 1880 and D.Sc. in 1891. For some years he was assistant to the late Professor John Young, and afterwards was appointed as examiner in biology in the university. During a number of years he devoted himself to scientific and practical zoological studies, and was zoologist and superintendent of the Fisheries Marine Laboratory, H.M. Fishery Board for Scotland. In this department his published work gained general recognition, and he was

elected an honorary member of many foreign biological societies. Later he decided to enter on the practice of medicine, and he qualified at the Scottish colleges in 1906. In the West End of London he gained a considerable measure of success, although he came somewhat late in life to the anxieties and strain of practice. Nor could science and medicine wholly content him. Always a man of decided views, he in recent years became active in political work, and only a few weeks before his death was engaged in an active campaign in a Scottish by-election. To all his work, as well as to his leisure, he brought heartiness, energy, and comradeship, and many who knew nothing of his scientific attainments will always remember him as a man and a brother. At his own request his remains are to be interred in the Island of Arran, his native home, to which he was dearly attached.

SURGEON-MAJOR-GENERAL HENRY FOLJAMBE PATERSON, Army Medical Service (retired), died in London on May 11th, aged 83. He was born at Ballater, Aberdeenshire, on July 9th, 1836, and educated at Marischal College, Aberdeen, where he graduated M.D. in 1858; he took the M.R.C.S.Ed. in 1857 and the F.R.C.S.Ed. in 1866. Entering the army as assistant surgeon on October 19th, 1857, he became deputy surgeon-general in 1888, and S.M.G. in 1893, retiring on July 9th, 1896. In the regimental days he spent the first sixteen years of his service in the Royal Artillery. He had held the post of P.M.O. at Hong Kong, Malta, and Aldershot. He took great interest in the work of the British Medical Association, and assisted in the formation of the Hong Kong and China Branch in 1891, and was appointed its first president. In his address on retiring from that office he referred to the British Medical Association as "the grandest medical brotherhood the world had ever seen."

We regret to report the death of **Dr. WILLIAM STEWART**, M.O.H. Gourcock, which occurred from pneumonia, on April 8th, at the age of 53. Dr. Stewart was educated at Glasgow University, where he graduated M.B., C.M. in 1889; some years later he took the D.P.H. He began practice in the Dennistoun district of Glasgow, but after two years removed to Gourcock, where he soon acquired an extensive practice. He was medical officer of health for over twenty years, and took a leading part in the many public health improvements of the burgh. He was also police surgeon and ambulance instructor to the Caledonian Railway Company. During the war Dr. Stewart was called upon greatly to exceed the limits of his strength. Deeply conscientious and of a retiring nature, his services were always available. When the end came he was mourned by the whole community. He leaves a widow and one daughter; his only son was killed on active service in Gallipoli.

We regret to record the death of **Dr. PETER BUREOWES KELLY**, D.S.O. Dr. Kelly was born in Ireland and received his medical education first in Dublin, where he obtained a medal for chemistry, histology, and medicine, and later at St. Bartholomew's and Charing Cross Hospitals. He obtained the diplomas L.R.C.P.I., L.R.C.S.I., and L.M. in 1911. He joined the Royal Navy on August 4th, 1914, and served first at Antwerp. He volunteered for service on H.M. transport *River Clyde*, the ship which was run ashore at Gallipoli to facilitate the landing of troops, and although wounded in the foot continued to attend the injured; for this and other gallant services he was awarded the D.S.O. He served in Gallipoli until the army was withdrawn. His last appointment was at the Royal Naval College at Osborne, and worked very hard during a severe epidemic which prevailed there. Immediately after leaving, and without any interval of rest, he commenced civil practice in London, but his health rapidly declined, and he died on April 6th at the residence of his brother, Dr. J. Kelly, of Ballymore, co. Kildare. He leaves a widow and one child.

ONE hundred and forty-one cases of gonorrhoea (sixteen in females) and thirty-one of syphilis (eleven in females) were notified to the Public Health Department of Western Australia during the last quarter of 1919.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 8th the following medical degrees were conferred:

M.D.—W. B. G. Angus.
M.B., B.Ch.—W. E. H. Bull.
M.B.—B. Haigh, R. T. Raine.

UNIVERSITY OF GLASGOW.

THE Senate of the University of Glasgow has resolved to confer the honorary degree of Doctor of Laws upon Sir Robert W. Philip, Professor of Tuberculosis, Edinburgh University, and President of the Royal College of Physicians of Edinburgh; and on Dr. John Macintyre, F.R.S.Edin., Surgeon for Diseases of the Throat and Nose, Glasgow Royal Infirmary, and lecturer on this subject in the University of Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary comitia of the Royal College of Physicians of London was held on May 13th.

The President, Sir Norman Moore, nominated Dr. James Taylor to be the representative of the College on a committee being formed by the Minister of Health to investigate the causes of blindness and defective vision.

The following gentlemen elected to the Fellowship at the last meeting were admitted Fellows of the College:

William Francis Menzies, M.D.Edin.; James Graham Forbes, M.D.Camb.; William Morton Robson, M.D.Lond.; Samuel Ernest Dore, M.D.Camb.; George Basil Price, M.D.Lond.; Albert Ramsbottom, M.D.Vict.; Arthur Stanley Woodwark, M.D.Lond.; Francis Graham Crookshank, M.D.Lond.; Arthur Charles Douglas Firth, M.D.Camb.; Natban Mutch, M.D.Camb.; Francis Martin Rouse Walshe, M.D.Lond.; George Graham, M.D.Camb.; George Ernest Beaumont, M.B.Oxford.

Diplomas in Public Health were granted to the following candidates, jointly with the Royal College of Surgeons:

Eleanor E. Bourne, M. A. C. Buckell, J. N. Dobbie, H. Evans, G. A. D. Harvey, G. D. Jameson, W. Simpson, J. G. Wallis, G. S. Wilson.

Diplomas in Tropical Medicine and Hygiene were granted to the following candidates, jointly with the Royal College of Surgeons:

M. K. Abdel-Khalik, J. S. Armstrong, C. Fasile, A. K. Cosgrave, E. Porrester-Paton, J. A. Frendo, W. P. Hogg, T. S. Keith, A. W. M. Harvey, N. Nedergaard, H. E. Whittingham, Mau Wong, E. J. Wood.

The President then dissolved the Comitia.

The Services.

R.A.M.C. COMMISSIONS.

THE War Office announces that a limited number of commissions in the Regular Royal Army Medical Corps will be given at an early date to officers who are at present serving in the army or who have held commissioned rank during the war. Intending candidates, who will be required to fulfil the undermentioned conditions, should write for forms of application and further particulars to the Secretary, War Office (A.M.D.I), Cornwall House, Stamford Street, London, S.E.1. Officers who are still serving should submit their applications through the usual official channels.

Conditions.

1. Candidates must be registered under the Medical Acts now in force in the United Kingdom.

2. They must be under 29 years of age. Previous commissioned service, if as a medical officer of the Royal Army Medical Corps, will count towards seniority promotion and retired pay. Commissioned service other than as a medical officer will count only towards retired pay. The period of any such service may be deducted from an applicant's age if this is over 28 years.

3. They must be pronounced fit for general service by a military medical board.

The rates of pay are as laid down in Army Order 324, an extract from which is appended:

Army Medical Service.

	Per day.	
	£	s. d.
Major-General	4	10 0
Colonel	3	5 0
Lieut.-Colonel	2	10 0
Lieut.-Colonel, after 20 years' total service	2	12 6
Lieut.-Colonel, after 25 years' total service	2	15 0
Major	1	15 0
Major, after 15 years' total service	2	0 0
Captain	1	5 0
Captain, after 5 years' total service	1	7 6
Captain, after 10 years' total service	1	10 0
Captain, holding higher rank by brevet, in addition	0	2 0
Lieutenant	1	0 0

The rates of allowances, gratuity, retired pay, etc., will be communicated to intending candidates.

AMERICAN SURGEONS MENTIONED IN DISPATCHES.

The *Journal of the American Medical Association* announces that King George has ordered certificates to be awarded to Colonels Christopher C. Collins; George W. Crile, Cleveland; Harvey Cushing, Boston; Mathew A. Delaney; Robert V. Patterson; Harry L. Gilchrist; James D. Fife; Richard H. Harte, Philadelphia; and Lient. Colonel Lucius L. Hopwood, M.C., U.S. Army; and to Miss Julia Stimson, Superintendent of the Nurses of the Medical Department, U.S. Army. The certificate is as follows:

The war of 1914-1918. U.S. Army Medical Corps (name of recipient) was mentioned in a dispatch from Field Marshal Sir Douglas Haig, Kt., G.C.B., G.C.V.O., K.C.B.E., dated November 7th, 1917, for gallant and distinguished services in the field. I have it in command from the King to record His Majesty's high appreciation of the services rendered.

WINSTON S. CHURCHILL, Secretary of State for War.

War Office, Whitehall, S.W., March 1st, 1919.

Medical News.

The next session of the General Medical Council will commence at 2 p.m. on Tuesday, June 1st, when the President, Sir Donald MacAlister, K.C.B., M.D., will take the chair and give an address.

DR. J. STRICKLAND GOODALL, on his retirement from the lectureship in physiology and biology at Middlesex Hospital, held by him for seventeen years, has received a presentation subscribed for by past and present students.

THE President of the French Republic has conferred the honour of Officer of the Legion of Honour on Dr. Aldo Castellani, C.M.G., of the London School of Tropical Medicine, for his method of combined typhoid-paratyphoid and enteric-cholera vaccination, the early descriptions of which were published in our columns, and other work found of utility to the allied armies during the war.

At the meeting of the Medico-Legal Society to be held at 11, Chandos Street, Cavendish Square, on Friday, May 28th, at 8.30 p.m., Dr. T. H. G. Shore will read a paper on sudden deaths on active service.

DR. DAVID J. GIBBS WISHART has been elected president of the Aesculapian Club, Toronto; Dr. Alexander Primrose, C.B., vice-president; Dr. Edmund E. King, treasurer (re-elected); and Dr. Frederick C. Harrison, secretary.

THE Glasgow University Club, London, will dine at the Holborn Restaurant on Friday, June 4th, at 7.30 p.m., when the Right Hon. A. Bonar Law, M.P., Lord Privy Seal, Lord Rector of the University, will be in the chair.

DR. LATARJET has been appointed professor of anatomy in the University of Lyons to replace Dr. Testut, who has retired.

At a recent meeting the council of the Chicago Medical Society adopted a new scale of fees, increased by 50 per cent.

THE village of Athens (New York) has embodied in its sanitary code a regulation providing that no corporation, association, firm, or individual other than licensed pharmacists and physicians shall sell or offer for sale in the village any medicine or so-called medical appliances without a permit from the local health officer.

THE ninth annual general meeting and conference of the British Waterworks Association will be held at Nottingham on July 1st, when the manager of the Sheffield Waterworks will describe the scheme of pumping water from the River Don in substitution for the statutory compensation water, and the interim report of the Water Power Resources Committee will be discussed.

IN response to the appeal of the University of Liverpool, Mr. T. Harrison Hughes, of Liverpool, has contributed £50,000, and Messrs. Alfred Holt and Co. (Liverpool) £15,000. The Association of West African Merchants and the African Section of the Chamber of Commerce, Liverpool, have asked members of the section to subscribe voluntarily at least £12,000 on the condition that the contribution shall be earmarked for some object which bears a relation to the West African trade.

THE second edition of the *Oxford University Press General Catalogue*, complete up to the end of 1919, gives an account of each of the books published and on sale, arranged in six sections according to the nature of their contents, and occurring again in an alphabetical list at the end of the general list. Many excellent textbooks of medicine, surgery, and allied subjects are published by the press.

More than 6,000 cases of small-pox have recently occurred in the north-east of Bohemia.

THE Genoese medical journal, *Liguria Medica*, which suspended publication in May, 1915, has reappeared.

It is proposed to establish a course of stomatology at the University of Liège and a course of psychiatry at the University of Ghent.

THE chairman of the Board of Licence Commissioners of Ontario has informed a committee of the legislature that 80 per cent. of Ontario physicians write less than ten prescriptions for liquor in a month.

A RIOT recently occurred at the University of La Plata (Argentina) between the professors and the students. A medical student, who was taking his examination, was killed by a revolver shot.

THERE are a few vacancies for the third post-graduate course of instruction in the diagnosis and treatment of venereal diseases by Mr. K. M. Walker at the St. Bartholomew's Hospital Clinic, Golden Lane, E.C., established by the Corporation of London. The course will be held on Thursday afternoons at 5.30 p.m. Medical men wishing to attend should write to the Secretary, National Council for Combating Venereal Diseases, 80, Avenue Chambers, Vernon Place, Southampton Row, W.C.1.

A DEPUTATION from the Society for the Prevention of Venereal Disease laid the views of the society before members of Parliament interested in the subject in Committee Room No. 7 of the House of Commons on May 12th. The policy of the society that venereal disease can be easily prevented by immediate self-disinfection within an hour of exposure to risk, was presented by Lord Willoughby de Broke (President), Sir James Crichton-Browne, Sir William Arbuthnot Lane, Miss Norah March, and Dr. Mearns Fraser. At the conclusion of the meeting the members of Parliament present resolved unanimously to form themselves into a Parliamentary Committee with the object of furthering the aims of the society, more particularly in endeavouring to obtain the support, both official and financial, of the Ministry of Health for the society's work; and of obtaining the repeal of the clause in the Venereal Disease Act, 1917, which forbids a chemist to recommend to the public or to expose for sale approved disinfectants for the prevention of venereal disease.

THE third annual report of the Conjoint Board of Scientific Societies shows that the total number of constituent bodies is now 57. Among them are the Royal College of Physicians of London and the Royal College of Surgeons of England, the Royal Society of Medicine, the Physiological Society, the Biochemical Society, and the Pharmaceutical Society of Great Britain; the Röntgen Society, the Society of Public Analysts, the Psychological Society, the Royal Anthropological Institute, and the Institute of Chemistry and the Chemical Society are also represented. The Board has a large number of committees; one of these, the Watching Committee on Education, has not been reappointed, as it is considered to have accomplished its purpose in the presentation of a joint report with the Council for Humanistic Studies, which was published under the title *Education: Secondary and University*. Its chief recommendation was that the first school examination intended by the Board of Education to be taken at about 16½ years of age should be a test of general knowledge, and should always include English language and literature, and four other groups of subjects—languages and literature other than English, history and geography, mathematics, and natural science. At the same time it was recommended that excellence in two of these groups, combined with evidence of adequate school training in all four, should be allowed to compensate for weakness in one group. It was recommended that in order to avoid premature and excessive specialization at schools, the scope of scholarship examinations should be enlarged so as to allow credit to be given for general ability, and not alone for excellence in one special department, whether literary or scientific. One of the effects of the disturbances of commerce due to the war was difficulty in obtaining glue and other adhesives; a committee was appointed which instituted researches under the direction of Professor S. B. Schryver. Investigations on the methods of preparing gelatines and glues from various tissues were carried out and results obtained which it is thought will be of value not only in the manufacture of gelatines, but in the production of gelatine for use in photography and for making foodstuffs. Investigations were also made into the preparation of adhesives from casein and from the residue of castor beans after expression of the oil.

Letters, Notes, and Answers.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

THE postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecro, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

M. C. wishes to hear of a natural sulphur water for internal consumption, containing little or no calcium.

C. S. invites suggestions as to the preventive treatment of nocturnal cramps in the legs; the patient is an extremely healthy old lady.

D. J. M. asks (1) whether any of the typhoid group is known to be louse-borne, and (2) whether milch cows which have access to contaminated water for drinking communicate typhoid through their milk.

INCOME TAX.

V. P. has in the past included an honorarium received as visiting physician to an institution in the income tax return for his general practice under Schedule D. He understands that some of his colleagues are not charged on similar honorariums on the strength of a recent "legal opinion."

* The principle involved seems to us to be covered by the decision of the House of Lords that Easter offerings are assessable on the clergy, which implies that a fee or honorarium received for services rendered is liable to tax apart from any question of *quantum meruit*. If our correspondent can throw a little more light on the source and foundation of the "legal opinion," we should be pleased to consider the question further.

"Bomo" came to the United Kingdom from the Malay Peninsula, arriving on February 21st, 1920. At what date does he become liable to income tax—on August 21st, 1920, or October 5th, 1920?

* Our correspondent is not liable to tax if he leaves the country before October 5th. That is as the law stands. There has been some discussion of the question before the Royal Commission, as a result of which the law may possibly be altered in the future, and this may perhaps account for the conflicting opinions which "Bomo" has gathered. We assume that he has not retained a residence for his family in this country during his absence abroad.

LETTERS, NOTES, ETC.

ACUTE PULMONARY OEDEMA.

DR. JOHN BROWN (Bearpark, Durham) writes: The following case of acute pulmonary oedema occurred in my practice a few years ago: M. P., aged 27, a 2-para, was delivered of a full-term healthy male child. Labour was absolutely normal. Neither ergot nor help of any kind was given. About a quarter of an hour after delivery the patient began to cough. She coughed so incessantly that the binder could not be pinned. At first the cough was dry, but in a few minutes was accompanied with expectoration of white, frothy fluid. A hasty examination discovered the chest full of râles. The expectoration soon became very abundant and the patient rapidly cyanosed; she died in less than half an hour from the commencement of the cough. She was given strychnine hypodermically and mustard was applied back and front, but without any effect. She was a strong, healthy woman, but I was informed that during her pregnancy she had been troubled more or less with a cough, but not bad enough to seek advice about. Occurring so soon after delivery, one at first thought of pulmonary embolism, but from the abundant white and frothy expectoration and rapid course it was clearly a case of acute pulmonary oedema.

DR. D. W. SAMWAYS (Mentone) writes: Some years ago I was asked to see a lady in consultation in England. I recognized the malady as acute oedema of the lungs from the excessive frothy expectoration, and suggested that atropin should be given subcutaneously at suitable intervals. The oedema disappeared rapidly, and had practically cleared up within a day or two. I had never seen another case, and I advised

atropin chiefly on theoretical grounds, though in acute nasal catarrh I have seen complete relief, at least temporarily, after a single injection, and a similar result seemed not unlikely with the pulmonary tissue involved. Judging from the letters lately published on this subject atropin seems almost a specific in acute pulmonary oedema.

THE VALUE OF CALCIUM LACTATE.

DR. GARRY SIMPSON (Lancaster Gate, W.) writes: I feel sure many practitioners must have been disappointed with calcium lactate as a haemostatic. This is due to the fact that its therapeutic value is greatly diminished by keeping, the compressed form being practically useless. I have of late been in the habit of using freshly prepared calcium lactate, with the most gratifying results. In a recent case a child 3 years old in which I removed tonsils and adenoids, the blood lost would hardly fill an egg-cup.

The following is the method for preparing the drug:

R. Acid. lactic. 75 per cent.	gr. 110
Aq. d. st.	3 iv

To which add in successive portions

Calc. carb. praecip.	gr. 58
-----------------------------	--------

After effervescence subsides add

Tr. capsici	℥ xij
Syr. limonis	ʒ ij
Aq. chloroformi	ad ʒvj

Each half-ounce contains calc. lact. recentis gr. 10.

The dose for a child should be from ten to fifteen grains three times a day for not more than three days before operation. Continued administration is said to diminish the coagulability of the blood.

THE ANTISPIRITUALISTIC VACCINE.

An editorial article in the *Journal of the American Medical Association* of March 27th, commenting on spiritualism and the spokesmen of the cult, refers to the propaganda of two well-known English exponents, the one a physicist and the other a physician who "has long left the medical field for more interesting adventures." "We should assume," says the article, "that a mind adjusted to the thought-habits of to-day would have set up a resistance to any such beliefs so completely adequate as to reject them without effort. Education is the vaccination that confers immunity; but it does not always take."

A RECORD TRAMP?

DR. H. T. BARTON (Blackpool) writes: Colonel Burnham's walk of twenty-three miles at the rate of five miles an hour is under the circumstances an excellent performance. As he wishes to hear of similar efforts of veteran walkers, I give details of some performances accomplished during the past winter by a general practitioner whose qualification dates back thirty-two years: 1 mile covered in 7 min. 40 sec., 4 miles in 35 min. 50 sec., 6 miles in 55 min. 45 sec., 4½ miles in 43 min. 15 sec.

VENEREAL DISEASE IN THE PORTSMOUTH AREA.

By an obvious error in our article on p. 681, column 1, third paragraph, line 58 (May 15th, 1920), we are made to say that according to White Paper Cmd. 505 the rate of incidence of venereal disease in the Portsmouth area was 47.3 per cent. It is clear from the context that this should read "per 1,000."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 35, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 33, 34, and 35.

AN appointment of medical referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Lanark is vacant. Applications to the Private Secretary, Scottish Office, Whitehall, S.W.1, by June 5th.

The appointment of certifying factory surgeon at Bollington (Chester) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	7	6
Each additional line... ..	0	1	3
Whole single column	6	0	0
Whole page	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

A Lecture ON THE TOXAEMIAS OF PREGNANCY.

BY
ALECK W. BOURNE, M.B., B.Ch., F.R.C.S. Eng.,
OBSTETRIC SURGEON TO OUT-PATIENTS, ST. MARY'S AND
QUEEN CHARLOTTE'S HOSPITALS.

THE exact relation of the mother to her unborn child has been debated since Bar¹ first suggested that both lived for the mutual advantage of each other. He believed that in return for the protection and nourishment of the growing fetus afforded by the mother, the fetus conferred certain nutritional advantages, as shown by an accelerated and intensified metabolism, which make for her improved general health, lasting not only during pregnancy but for long after the birth of the child.

But welcome as such a theory may be to our sentiment, the recent immunological investigations on pregnant women, notably by Leith Murray,² afford strong evidence that the fetus *in utero* is not only not a symbiotic partner but rather a foreign element, always a source of potential danger to its host. Such laboratory findings only support common clinical evidence. Though the pregnant woman may be in what she calls good health from the beginning to the end of gestation, yet we know that departures from the normal, sometimes very serious, are only too common, and in general it is undeniable that pregnant women are in a less stable and robust condition than when not carrying.

It is necessary to realize that a state of poisoning exists throughout pregnancy, the toxin produced almost certainly by the growing ovum being absorbed by the maternal circulation. Whether the pregnant woman be well or ill depends not upon the formation and absorption of some unusual poison, but on the capacity or failure on the part of the mother to develop an adequate antipoinson, by which she is rendered immune. We may almost say that the ovum is always poisoning its mother, but that in all healthy women, fortunately the majority, the poison is effectively countered by her own immunizing efforts. Where these fail, then can the toxin effect its work unhindered.

The actual source and nature of the toxin of pregnancy have been the reason of years of search and controversy, but it would be unprofitable to-day to devote any time to discussion of all the various theories. I will simply consider the later views in so far as they may help us in understanding more fully the clinical features of the toxæmia of pregnancy and act as a guide to its rational treatment.

The most recent and important work bearing on this question began with Schmoll's discovery that small pieces of syncytial protoplasm could be found in the maternal circulation. The importance of this observation was the definite proof it affords that the foreign fetal protoplasm is conveyed into the maternal circulation. The next question which naturally arose was whether there was any biochemical defence against this invasion, set up by the mother's tissues, comparable with that which the organism makes against invasion by any other foreign protein or bacterial products. The answer was probably given by Abderhalden in 1911, when he demonstrated that the maternal blood during nearly the whole of pregnancy and for ten days afterwards contains a specific ferment capable of digesting placental protein. An enormous amount of experimental work has been done in order to confirm or disprove Abderhalden's claim, and, though there is still some controversy as to the exact meaning of the reaction, the general thesis that the mother's blood contains an anti-enzyme (or other form of antibody) capable of rendering innocuous the foreign proteins from the placenta, is probably true.

Further evidence of a biochemical response on the part of the mother was furnished by Theis and Lockemann,³ who showed clearly that the maternal serum is sensitized to some bodies in the fetal serum and placenta; by Murray⁴ and Fieux and Mauriac,⁵ who showed by the complement-fixation reaction a definite antibody for an antigen existing specially in young chorionic villi; and by many others.

A modification of this theory has been put forward by Young,⁶ who suggests that the poisoning is due to the absorption of auto-digestion products from a portion of prematurely separated—and presumably necrosing—placenta. But his view is apparently not applicable to all cases of toxæmia, though it goes far to explain the association of eclampsia with accidental hæmorrhage.

Finally, I may refer to the view of Tweedy, who believes that the toxins arise from the maternal gut. He argues that in the non-pregnant condition the neutralizing and excretory mechanism of the body is capable of dealing with any noxious products absorbed from the bowel, but that in pregnancy this mechanism can be overwhelmed by the strain due to the excess of such products caused by the metabolism of the fetus *in utero*. His conclusions are based largely on the good results he has observed after starvation and purgation, with thorough lavage of the stomach and colon. But in spite of this observation a general survey of clinical and laboratory knowledge leads irresistibly to the view that the toxin is supplied by the placenta, that ordinarily this toxin is neutralized by maternal antibodies, and that failure to develop these in sufficient quantity causes symptoms of pregnancy toxæmia.

Biochemical Examination.

Turning now from theories, we find that the investigations of laboratory workers have been chiefly in the direction of blood and urine analysis, immunological reactions of the serum, and experimental attempts to isolate a toxin and cause the disease of eclampsia by injecting it into animals. In 1914 Young⁶ described experimental toxæmia in animals caused by the injection of placental extracts. In many respects the animals showed symptoms almost indistinguishable from eclampsia, and, still more significant, the *post-mortem* appearances were almost identical with those in patients dead of eclampsia.

The broad results of urine analysis are the finding of albumin, a tendency for the urea output to be diminished, a variable increase in the percentage of nitrogen excreted as ammonia, and the presence of acetone. Further, the amount of urine may be diminished even to complete suppression, and a deposit of renal casts and red blood cells is frequently observed. The general results of urine analysis point to (1) degeneration or necrosis of the specific excretory cells of the kidney, shown by diminished quantity and the presence of albumin and casts; (2) degeneration or necrosis of the liver cells, causing the disturbance of the urea and ammonia coefficients.

Let us consider the hepatic derangement and its consequences first.

We know that in health the amino-acid cleavage products of the digested proteins are absorbed and transported to the liver, where they are largely transformed, the nitrogenous moiety being converted chiefly into urea. In experimental occlusion of the hepatic portal circulation no urea is produced, and if ammonium carbonate or amino-acids are perfused through the living isolated liver, urea is formed. An intermediate product, however, in the formation of urea is ammonia (or ammonium carbonate).

It follows, therefore, that a diminished urea output indicates some degree of hepatic insufficiency; an increased ammonia coefficient in the urine may similarly indicate a stage of hepatic degeneration, short of a complete functional breakdown, but enough to prevent the final stage of urea formation from the ammonia.

One indication, then, of high ammonia and low urea excretion is hepatic degeneration, short of massive necrosis, for in this condition neither ammonia nor urea could be formed. But, as Leith Murray⁷ points out, a high ammonia output has a second significance in pregnancy toxæmia, as in other conditions. It may indicate an excessive acid formation in the system, for ammonia production is the body's natural mechanism for the neutralization of that amount of acid formed above the quantity which can be neutralized by the fixed bases (sodium, etc.).

The ammonia of the urine may therefore be divisible into two moieties, the first being an intermediate product of the liver in the course of a conversion of the amino acid into urea, and the second being that which is purposely produced by the liver, as such, for the work of neutralizing fatty acids due to an abnormal fat metabolism. The first indicates partial hepatic insufficiency in that the final urea

* Delivered to the Hampstead Division of the British Medical Association, April 15th, 1920.

stage is not reached; the second that the patient is in a condition of acidosis—of which more anon.

These different fractions of ammonia may be separated by giving large doses of sodium bicarbonate, for should the body be producing ammonia in order to neutralize excess of acid, it will be relieved of this work if the required alkali be supplied by the mouth, and the ammonia excretion in the urine will fall. In short, the fall of the ammonia, after giving sodium bicarbonate, will be a measure of the acidosis present.

The ammonia remaining, if much above the normal in pregnancy (and it tends ordinarily to be higher in pregnancy), will be a measure of how far the liver is failing to convert its nitrogen to the final stage of urea, and therefore of hepatic degeneration, but not of massive hepatic necrosis.

In spite, however, of the importance of the liver changes, it is obvious that the results of analysis of the urine may depend very greatly on the condition of the kidneys. The liver may be working well, and yet the waste products it has produced may be unable to pass through the damaged renal epithelium. How, therefore, may we obtain an index of the efficiency of the kidney? First, the quantity of urine excreted. If with an ordinary or excessive fluid intake the urine is scanty, it is reasonable to suppose that the kidney is either damaged or that, owing to congestion, the urine is unable to escape. White⁸ has shown that the kidney in eclampsia may be so intensely congested that the urine cannot flow down its collecting tubules.

Secondly, the microscopic examination of the deposit will give valuable information. Few or no casts or red blood cells with a fair secretion will indicate only slight kidney changes, while a heavy deposit of casts with much blood will be a sign of more extensive damage.

Unfortunately, the quantity of albumin gives very little information, for we find some cases of serious toxæmia with little albumin, and the contrary condition is often present.

Acetone is found in the urine in some cases. It is derived from a disordered fat metabolism, and indicates an abnormal production of acid in the system. It is commonly seen in starvation and is constantly present in those cases of toxæmia associated with intractable vomiting. In eclampsia it may indicate acidosis, and its presence is of great diagnostic value.

Symptoms in the Prodromal Stage.

During the prodromal stage the patient usually comes to her doctor on account of headache and malaise or oedema of legs and face, less commonly for a failing of sight, and more rarely still for epigastric pain and vomiting.

A headache in late pregnancy is common, not always due to toxæmia; frequently it is a symptom of a low tension debility, often complained of by multiparæ. By itself, without changes in the urine, or a high blood pressure, it usually means nothing; but it is a fairly constant warning symptom, which is of value in showing the need for a complete examination of the patient. Similarly, oedema of the legs is often non-specific in its indication, but if combined with oedema of the face and other parts its presence should call for full investigation. Failing or altered vision is an important and dangerous symptom, and warrants an immediate ophthalmoscopic examination of the fundus oculi. Miller¹⁰ states in a recent paper that early eye changes are usually significant of chronic nephritis rather than of pregnancy toxæmia. The differentiation is important for prognosis and for treatment. Of itself, retinitis is one of the more serious symptoms of albuminuria, and if, as has been pointed out, this condition indicates a pre-existing kidney disease rather than an albuminuria of pregnancy origin, then the safest course is to end pregnancy as soon as possible. If treated expectantly such patients may develop uræmia or permanent increased damage to the kidney and lasting changes in the retina.

Epigastric pain and vomiting coming on in late pregnancy, when simple dyspeptic causes can be safely excluded, may be for a few days the only symptoms of impending eclampsia. In fact it is not uncommon for a patient's friends to state that the attack of eclampsia was preceded by a few hours or days by vomiting. As a pregnant woman has probably suffered vomiting during the early weeks,

the recurrence of the symptoms does not excite her apprehension, and therein, perhaps, lies danger. Vomiting and pain coming on suddenly in late pregnancy should always be regarded very seriously, and an exhaustive examination made. In a minority of cases, as already stated, little or nothing else can be found, and the absence of albuminuria fortifies one in the belief that whatever may be the cause it is not toxæmia. Should the cause be simple, sickness rapidly yields to simple treatment, such as rest and starvation, but if in spite of careful dieting or starvation, combined with enemata and diaphoresis, the patient continues to vomit, then she is in the gravest danger, and pregnancy should be terminated with all speed. But most patients suffering from toxæmia who begin with vomiting as the first and only symptom, rapidly develop the other familiar signs, and the diagnosis is easy.

Perhaps of greater value than the symptoms are the signs discovered by examination, and of these I regard an elevated blood pressure as the most important single sign. It is the most important because it is one of the earliest and also most constant. Albuminuria may vary from 3 per cent. to the slightest trace, which is often found in normal pregnancy, but the blood pressure is nearly, if not always, definitely raised early in the prodromal stage.

Further, unlike albuminuria, the height of the blood pressure is some measure of the gravity of the toxæmia, and an indication of the likelihood of fits supervening; for instance, Irving⁹ has shown that with blood pressure—

Between 130 and 140 mm. Hg	...	1 in 32	developed toxæmia
" 140 and 150 "	...	1 in 11	" "
" 150 and 160 "	...	1 in 3	" "
" 160 and 170 "	...	1 in 2	" "
Above 180			all developed toxæmia.

Therefore, in any patient complaining of any one of the prodromal symptoms, or during the routine ante-natal examination of pregnant patients, the blood pressure should invariably be taken and noted. During antitoxæmic treatment the blood pressure movements are amongst the best indications of the reaction of the patient. In bed, on a low or starvation diet, and freely purged and sweated, the blood pressure should be low—in the region of 100 to 110—and if it quickly falls from its original high figure to this low level the other symptoms usually clear up with it, and an expectant attitude may be continued. But if, in spite of depletion, the tension maintains its height, as it not uncommonly does, then eclampsia is still just as likely to develop, and further expectant treatment is dangerous. During pre-eclampsia the blood pressure should be determined at least twice a day, and the results plotted on the chart.

The second sign in the early stage is the quantity of urine excreted. The total for the twenty-four hours on an ordinary diet should be collected and measured. A definite diminution is significant, and the urine always shows other signs of abnormal renal activity in the shape of casts, albumin, or diminished urea output. Diminution in quantity is not an early sign, however, and therefore its chief value is as an indication of the progress of the case under treatment. The most reliable method of obtaining the quantity is by regular catheterization, as otherwise some urine may be lost during a movement of the bowels. But inasmuch as the total quantity of urine is variable in normal health, depending upon the amount of fluid taken, diarrhoea and sweating, it will be readily understood that figures of the total quantity of urine have not the quality of exactness, as an indication of progress, that is possessed, for example, by the blood pressure determinations. However, gross variations from the normal are easily observed, and are indications of serious renal insufficiency.

The third sign is albuminuria. In the great majority of all cases of toxæmia in pregnancy there is some albumin, and therefore its presence has definite value for diagnosis. Only in a small minority is albumin absent until fits occur, when it may suddenly appear in large amount. The percentage of albumin (Esbach) is very variable and cannot be taken as a guide to the severity of the case, nor is it of much value in prognosis. Some patients may suffer many fits with little more than a trace of albumin, while others with as much as 3 per cent. or 4 per cent. may never develop fits or other serious symptoms.

The chief value of albuminuria as a sign may be summarized as follows:

1. Its mere presence, very easily tested for, is the strongest evidence of some degree of toxæmia.

2. If there is a sudden increase in the amount while the patient is under treatment during the prodromal period, we have a definite sign that the patient is not under control, and is passing into a dangerous condition.

3. After an attack of eclampsia the rapidity or slowness of its disappearance has some significance. Broadly speaking, if it disappears rapidly and completely the disease has been due purely to pregnancy toxæmia and the prognosis is good, both immediately and for future pregnancies, while if the amount of albumin remains high and persists for some weeks during the puerperium there is evidence either that the disease was really chronic nephritis, and not true pregnancy toxæmia, or that if it were really toxæmia the kidney has suffered some permanent damage. The prognosis for the next pregnancy is not so good. It is therefore important to have the amount of albumin determined each day by the Esbach tube.

The Convulsive Stage.

Eclampsia proper differs from the prodromal stage in that there is added a fresh symptom—convulsions and often coma—while the other conditions, such as oedema and urine changes, may be more marked.

The fits vary in onset, number, and degree, and are of the utmost importance in their effect on the patient's chances of recovery. In general, a few slight fits without coma are associated with recovery, while the prognostic outlook worsens as the fits increase in number or severity, or if coma be superadded. To this there are exceptions—for example, a patient who has only had one fit may die, while occasionally another, who has had forty or more fits, recovers; but such cases are unusual, and it remains true that the patient's life is gravely prejudiced by a large number of fits. Every fit is a fresh threat to the patient, especially because of the great danger of cerebral hæmorrhage, which is often the cause of death; moreover, every fit renders a living child still more doubtful.

The time of onset of fits is also of importance, inasmuch as the earlier in pregnancy they occur the more severe is the disease, and, further, ante-partum fits are more dangerous than intra-partum or post-partum fits.

While it is difficult to be sure as to other factors, the occurrence of convulsions has a definite relation to three conditions—the blood pressure, delivery, and external stimuli. First, the blood pressure usually mounts after fits have been established, and, in the absence of treatment, remains high. So long as it is elevated, especially while the patient is undelivered, fits are so liable to occur that a sequence of them may be expected. They may also occur in the later moribund stages, when the blood pressure is falling from exhaustion and cardiac failure, but should the tension be reduced by means of treatment there is every prospect of a diminution or cessation of fits. Further, if during treatment the blood pressure again rises to a dangerous height, fits will be likely to reappear.

Delivery of the child has such a marked influence in stopping fits that it has led many to believe that the only rational treatment of the disease is the earliest possible delivery. In about 8 or 10 per cent. of cases, however, the fits first occur after delivery, within the first twelve hours, so that though delivery is one of the surest methods of stopping fits it is not quite certain.

It is important to remember that, apart from the severity of the toxæmia, the number of convulsions may be increased by external stimuli, such as light, noise, manipulation, and passing a catheter; in fact, almost any interference with the patient may start a fit.

A second sign of fundamental importance is suppression of urine. For this reason a close watch should be kept on the amount of urine in the bladder at definite intervals. With the large amounts of fluid usually administered in the treatment of eclampsia, scanty urine or its suppression is a serious sign; on the other hand, an increase in the amount is of favourable import. Complete suppression of urine is so dangerous a symptom that it demands active and rapid surgical interference—nephrotomy or capsulotomy—as almost the only chance of saving the patient.

The qualitative examination of the urine in ordinary clinical work should be chiefly directed towards the search for casts and red blood cells in the deposit, as a large number of cellular casts is strong evidence of serious kidney mischief, and thus influences the prognosis. Further,

the amount of albumin should be estimated in each specimen of urine obtained. The determination of urea and ammonia, though of great scientific interest, has probably not the same clinical importance as the other estimations.

A third point, sometimes overlooked, is the condition of the heart. Throughout the whole of the first or prodromal stage while the tension has been high, and particularly during the convulsive stage, the heart has been subjected to a great strain; not uncommonly dangerous dilatation, leading to sudden heart failure and death, occur. Further, I have recently seen a case which furnished strong evidence that the toxins of pregnancy exercise a specially deleterious action on the heart muscle, apart from the extra strain imposed upon it by the occurrence of fits. It is no uncommon result for a patient who has been successfully shepherded through the actual attack of eclampsia to die suddenly during following days from heart failure. Where there has been pre-existing chronic nephritis compensatory hypertrophy of the heart will probably have developed, but in pregnancy toxæmia there is a sudden very great effort required of a heart which is already suffering from the additional handicap of a specific myocardial poisoning. A study of the cardiac condition is of importance when deciding upon the various measures of treatment, such as massive saline injections, or doses of veratrine, or venesection, and we should be guided in the adoption of such measures by a knowledge of the state of the heart. After delivery also the heart should be carefully watched and treated if it has suffered dilatation.

Treatment.

It is not here possible to do justice to the very numerous methods of treatment which have been advocated for eclampsia. There has been endless controversy around the most fundamental principles of treatment. Broadly, there are two main schools—the "active" and the "conservative." The first maintains that as the child or placenta are the source of the poison, the sooner they are removed the better, and to this end it is prepared to deliver as soon as possible by Caesarean section or accouchement forcé; while the second group holds that the main line of attack should be towards elimination of toxin already in the system and prevention of the fits, combined with a more deliberate obstetric treatment.

Each side upholds its method by statistics more or less favourable, but the subject is still *sub judice*. Examples of such statistics are as follows:

Brandt¹¹ reports:

		Maternal Mortality.	Fetal Mortality.
1889-1905.	Entirely expectant ...	23.6 %	31.3 %
1909-1912.	Entirely "active" ...	18.4 %	23.4 %
1913-1915.	"Active" plus narcotics... ..	15.0 %	34.4 %

Total 431 cases.

Essen-Möller¹² reports 64 cases:

Spontaneous delivery (12 cases) ...	14.2 %	—
Active treatment (52 cases) ...	13.4 %	—

Forssner¹³ reports:

1912-1915. 51 cases entirely expectant	9.8 %	—
--	-------	---

Whatever statistics are examined, the wide variations in mortality under either method of treatment are striking. The difficulty lies in the undoubted variation in severity that seems to occur in different towns and at different seasons.

Those who advocate active interference involving the most rapid delivery hold that as the ovum is the source of the toxin the sooner the child is delivered the better. To this the answer of the conservatives is that while it is true that the ovum is the origin of the toxin, yet the insult and shock to the organism involved by rapid delivery is so evil in its effects that it more than counterbalances the benefit derived from an immediate arrest of the production of the poison; that sedative treatment in controlling the fits robs the disease of its chief dangers though not immediately curing it; and, finally, that while the fits are controlled the elimination of the toxin already present is the rational procedure.

Now, for the treatment of a protean disease like eclampsia, it appears to me futile to lay down a rigid set of rules. If ever a case should be treated on its own merits it should be eclampsia, for scarcely two cases present the same clinical condition. We should approach these cases in a flexible attitude of mind, prepared to do

anything, from the simple injection of veratrine or morphine to the performance of Caesarean section and nephrotomy.

The greatest success will follow the path of the *via media*, each patient being treated on her merits. For example, a primigravida at term, developing frequent severe fits before labour, with the os closed and cervix not "taken up," and passing no urine, will probably do better if the child is removed by abdominal Caesarean section, combined with sedative and eliminative measures, than if labour is waited for or slowly induced, and allowed to drag on through many hours of fit-provoking pains.

But a multipara overtaken by fits, after premature labour has begun, with the prospect of a quick delivery, will certainly have a poorer chance if she is subjected to a forcible dilatation of the os, or cervical incisions, or vaginal Caesarean section. Broadly speaking, labour should be induced by a bag if it has not already started, but if it is established when the patient is first seen, it should only be interfered with if delayed, which is not common in eclampsia.

For the moderate cases I think the best is to employ the first few hours by sedative and eliminative treatment, which will diminish the degree of toxæmia, and put the patient in a better condition for the forthcoming labour. Of all the drugs veratrine appears the most satisfactory for the prevention of the fits and the reduction of albumin. Its chief physiological effect is the reduction of the blood pressure and pulse rate when they are high, a heavy fall occurring within half an hour after injection. It is not uncommon for no more fits to occur while the blood pressure is kept low by judiciously repeated injections of veratrine. The dose and time of injection are entirely conditioned by the state of the blood pressure and pulse—in fact, a dose should not be given unless both figures have just been determined.

The higher the tension and pulse the greater is the absolute fall after veratrine injections. The drug is potent, and liable to cause dangerous prostration if administered without due care. The general method of its use is to give an initial dose of 1 c.cm. where the tension is at 170 or above, with a correspondingly rapid pulse. For less high pressures a smaller dose, such as 0.75 or 0.5 c.cm., may be given. The first dose causes a rapid fall within half or three-quarters of an hour from 180 to perhaps 130, or less, usually with complete cessation of the fits, but it shows a tendency to rise again, sometimes within two hours, the pulse rate following suit. By repeated estimations of blood pressure every hour it is easy to arrive at the time for the next injection, usually of 0.5 or even 0.25 c.cm., according to the level of the tension. Veratrine does not stop restlessness in all cases, and for this troublesome and exhausting condition small doses of morphine are useful and without danger.

Having reduced the tension and pulse rate, and with this the liability to fits, say, after the first hour of treatment, it is necessary to have the colon washed out thoroughly until the washings are clear, as much as five or six pints being used if necessary. Gastric lavage is strongly advocated by many, but it is very disturbing to the patient, and may easily provoke a convulsion.

Every encouragement is to be given to free sweating by hot packs, electric lamps, or hot bottles, and after the colon has been washed out it is well to give saline rectal injections, containing glucose and sodium bicarbonate, up to a maximum of two pints within the first four hours. Further injections of saline are beneficial if there is good sweating and an increasing output of urine, but should there be a serious deficiency of the excretory activity too much saline injected is liable to embarrass the heart and cause pulmonary oedema, two not uncommon causes of death. Venesection is not so commonly employed as formerly, but is distinctly indicated if there is cyanosis and embarrassment of the right heart. It should always be considered in relation to the proximity of delivery, when a sufficient amount of blood may be lost from the uterus.

After twelve or more hours of this treatment the patient is usually in a much better condition and ready for the induction of labour or any other obstetric operation. The fits have ceased, the mental condition is less confused, the pulse slower and stronger, the blood pressure between 110 and 140, the skin acting freely, and the bladder containing more urine.

Where these conditions obtain in a multipara and labour

pains have not begun, I think the quickest and safest obstetric procedure is the insertion of a Champetier de Ribes bag. Labour is rapidly induced, and there is a minimum of shock. Should the presentation be a breech, an alternative is the bringing down of a leg. Observation of the blood pressure and pulse rate, with the administration of veratrine when necessary, should be continued for at least twelve hours after delivery, even when no further fits have occurred.

This is, of necessity, only the briefest account of the treatment of eclampsia—time forbids discussion of variations and elaborations of method. Suffice it to say that for cases of moderate severity I am a firm believer in the preliminary employment of conservative sedative and depletive treatment, followed later, and only if necessary, by obstetrical assistance. This should never be a violent interference, such as accouchement forcé by the vaginal route, but rather of the nature of the use of forceps, version, Champetier de Ribes's bag, and bringing down a leg, or, as an operative measure, abdominal Caesarean section. Few diseases show a greater variation in mortality. We find the same principles of treatment producing widely differing results in different towns and countries, rendering a comparison of statistics very difficult.

Some cases will die—whatever is done for them. No patient can survive if the liver is almost totally destroyed by massive necrosis. But it is in the pregnancy toxæmias that preventive medicine has one of its greatest opportunities. Eclampsia is almost an entirely preventable disease, for its premonitory signs are plain for any who take the trouble to watch for them.

A Collective Investigation

OF

TEN THOUSAND RECRUITS WITH DOUBTFUL HEART CONDITIONS.

Conducted at the National Hospital for Diseases of the Heart by C. CHAPMAN GIBBES, R. O. MOON, S. RUSSELL WELLS, P. HAMILL, FREDERICK W. PRICE, and J. STRICKLAND GOODALL.

REPORT IV.*

COMPILED BY

S. RUSSELL WELLS, M.D., B.Sc.

THE ETIOLOGY OF MITRAL STENOSIS.

IN dealing with the etiology of mitral stenosis we thought it wise only to take into consideration those cases where this lesion could be diagnosed with practical certainty. Excluding those cases where there was reason to believe that the murmur was really the so-called Flint, or was due to pericardial friction, we have taken as signs of mitral stenosis an apical presystolic murmur or a definitely apical murmur in diastole. This gave us an assemblage of 306 cases where the diagnosis of mitral stenosis depended mainly on the presence of a presystolic murmur, and an assemblage of 36 where either an early diastolic, a mid-diastolic, or a diastolic extending through the whole of diastole occurred at the apex. That is to say, in 342 of our 10,000 cases mitral stenosis was thought to be certainly present. There were, however, 48 cases in which mitral stenosis was strongly suspected, though no presystolic murmur nor definite diastolic could be heard. The reason for this opinion varied in the different cases, but it is needless to enter into the details here. Of these 48 cases 18 gave a history of rheumatic fever, and 30 no history of this affection. After careful consideration we thought it wiser to exclude these 48 cases entirely from our universe of discourse, which reduces the number of

*The earlier reports were published in the *BRITISH MEDICAL JOURNAL*, 1918, vol. i, p. 555; vol. ii, p. 248; 1919, vol. i, pp. 510 and 511.

cases we have to deal with from 10,000 to 9,952, of which 342 were considered to have mitral stenosis, and 9,610 to be free from this lesion. It is necessary to repeat the caution given when speaking of aortic regurgitation with regard to the nature of our material. It must be remembered in drawing any deductions that these cases consist of men alone, between the ages of 16 and 42; consequently any conclusions arrived at do not necessarily apply to women, nor are they necessarily valid for the earlier or later periods of life. In many of the 342 cases other lesions besides mitral stenosis were believed to be present.

TABLE I.—Showing the Diagnoses made.

Diagnoses.	No. of Cases.
Mitral stenosis alone	105
Mitral stenosis and mitral regurgitation	148
Total pure mitral lesions	253
Mitral stenosis and—	
Tricuspid regurgitation	1
Tricuspid regurgitation (secondary)	1
Mitral regurgitation and pulmonary stenosis	2
Mitral and tricuspid regurgitation	3
Mitral and tricuspid regurgitation and roughening of aortic valves	1
Mitral regurgitation and roughening of aortic valves	9
Mitral regurgitation and aortic stenosis	1
Aortic regurgitation	15
Mitral and aortic regurgitation	34
Mitral and aortic regurgitation and aortic stenosis	4
Pericardial roughening	2
Mitral regurgitation and pericardial roughening	13
Tricuspid regurgitation and pericardial roughening	1
Mitral and aortic regurgitation and pericardial roughening	2
Total mixed lesions	89
Total	342

Adopting the method pursued in investigating the etiology of aortic regurgitation, the incidence, as shown by the histories of the various antecedent diseases dealt with, was compared in the case of our 342 mitral stenotics and in our whole universe of 9,952 cases. Many of the cases, of course, gave histories of more than one of the diseases inquired for.

TABLE II.—Antecedent Diseases.

	9,952 Recruits.		342 Cases of Mitral Stenosis.	
	No. of Cases.	Percentage of 9,952.	No. of Cases.	Percentage of 342.
Rheumatic fever	2,084	20.9	152	44.4
Rheumatism	1,686	15.9	59	17.3
Growing pains	2,692	27.0	86	25.1
Chorea	258	2.6	43	12.6
Tonsillitis... ..	2,202	22.1	64	18.7
Scarlet fever	2,201	22.1	70	20.5
Diphtheria	744	7.5	21	6.1
Pneumonia	561	5.6	15	4.4
Influenza	5,646	55.7	150	43.8
Syphilis	207	2.1	7	2.0
Gonorrhoea	618	6.2	20	5.8
Strain	2,707	27.2	96	28.1

It will be noticed that the mitral stenotics show a much higher percentage giving a history of rheumatic fever than the average, and that the same applies to chorea, but that, with the exception that fewer stenotics than the average gave a history of influenza, the percentage for all the other illnesses were so similar in both cases as to make it appear that the incidence of these diseases in cases of mitral stenosis was purely accidental. A percentage table like this, though it has its uses, is open to many objections, so the degrees of association were calculated from Pearson's formula for Q_0 , which gives a fairly close approximation of the correlation coefficient r , and which involves no assumption as to the characters of the two variates. The values of χ^2 for a fourfold table have also been calculated, because by calculating χ^2 a quantity P can be reached, giving the

probability that the system is really a random sample from material in which the two variates are independent, quite apart from any assumption as to the nature of the distribution.

TABLE III.—Correlation between Mitral Stenosis and Rheumatic Fever and Chorea.

A.	B.	History of A. and B.	History of A. only.	History of B. only.	No History of A. or B.	Coefficient of Correlation.	Limit of Error.	χ^2
M.S.	Rheumatic fever	152	150	1,932	7,678	0.372	0.017	118.18
"	Rheumatism ...	59	283	1,627	7,583	0.007	0.020	0.024
"	Growing pains...	86	256	2,606	7,004	0.036	0.020	0.65
"	Chorea	43	299	215	9,395	0.319	0.018	139.71
"	Tonsillitis	64	278	2,138	7,472	0.073	0.020	2.39
"	Scarlet fever ...	70	272	2,131	7,479	0.034	0.020	0.56
"	Diphtheria	21	321	723	8,887	0.052	0.020	0.91
"	Pneumonia	15	327	546	9,064	0.060	0.020	1.04
"	Influenza... ..	150	192	5,496	4,114	0.208	0.019	23.91
"	Syphilis	7	335	200	9,410	0.003	0.020	0.002
"	Gonorrhoea	20	322	598	9,012	0.015	0.020	0.08
"	Strain	95	246	2,611	6,999	0.016	0.020	0.135

A = Mitral stenosis. B = Etiological factor under consideration—for example, rheumatic fever, chorea, or the like.

From the above table it will be seen that the correlation coefficients and the value of χ^2 both suggest that there is real correlation between mitral stenosis and a history of rheumatic fever and chorea, while the values of Q_0 and χ^2 in those cases giving a history of influenza seem to imply a similar though not so marked connexion. The correlation coefficients in the case of histories of the other diseases are so low as to be negligible, and the value of χ^2 is so small as strongly to suggest that the system is not really a random sample from material in which the two variates are independent.*

Since the correlation between mitral stenosis and a history of rheumatic fever and chorea is so definite we must be careful in ascribing mitral stenosis to any other cause when there is an antecedent history of either of these two affections. We have analysed in detail the cases of mitral stenosis with histories of the different diseases investigated, and have compared the percentages giving a history of rheumatic fever in each case with the percentage of the whole 342 cases with this history. If two diseases such as rheumatic fever and pneumonia were both causes of mitral stenosis we should expect to find a smaller proportion of cases with a history of rheumatic fever among those also giving a history of pneumonia than among the 342 as a whole.

It will be seen from Tables IV and IVa that with the exception of rheumatism, diphtheria, and strain, the percentage giving a history of rheumatic fever is higher than the percentage of the whole 342 giving this history.

When we were dealing with cases of aortic regurgitation it was found, just as with mitral stenosis, that the case, giving a history of rheumatism showed a lower percentage with a history of rheumatic fever as well than the averages and it was suggested that probably some cases of true rheumatic fever had been included in the "rheumatic" group. Probably the same explanation holds good for mitral stenosis, though the difference is not nearly so marked as with aortic regurgitation. With regard to the

* The formulae used were—

$$Q_0 = \sin^{-1} \frac{\pi}{2} \frac{1}{\sqrt{1 + K^2}}$$

$$\text{where } K^2 = \frac{4abcdN^2}{(a-d-b+c)^2(a+d)(b+c)}$$

Q_0 being taken as a sufficiently near approximation to r (see Pearson, *Phil. Trans.*, 1900, series A, vol. 195).

$$(Poc)\chi^2 = \frac{N(a-d-b+c)^2}{(a+b)(c+d)(b+d)(a+c)}$$

$$\text{Error: } \pm 2.02347 \times \frac{1-r^2}{\sqrt{N}}$$

mitral stenotics with a history of diphtheria, the difference between 44.6 per cent. and 42.9 per cent. is so small as to be negligible, but the strain figure of 26 per cent. is suggestive.

When we were dealing with the etiology of aortic regurgitation we pointed out that, since acute rheumatism frequently produces lesions of more than one of the cardiac valves, we can use the ratio between pure and mixed lesions in the cases giving a history of any particular antecedent disease as a method of investigating the etiology. With aortic regurgitation we found that cases showing pure lesions of the aortic valves were less common than those where some lesion of another valve was also present, and therefore the ratio of pure aortic to mixed lesions was less than unity. In this connexion, however, it must be borne in mind that since the diagnosis of mitral regurgitation necessarily largely depended on the presence of an apical systolic murmur, many of the cases of aortic regurgitation credited with mitral regurgitation as well may have been due to secondary stretching of the mitral ring. Such stretching is not likely to occur when mitral

Strain ...	71	50	21	2.4

stenosis is present. We found that as we passed from cases giving a history of rheumatic fever to those with no rheumatic history at all, the proportion of mixed lesions steadily rose, probably because the mitral was more likely to be affected when the cause was not true rheumatism. An inspection of the table at the commencement of this paper will show that with mitral stenosis pure mitral lesions are much more common than mixed lesions, and that of the 89 mixed cases in no less than 66 (practically three-quarters) aortic lesions were also present. Therefore the ratio between pure and mixed lesions in these cases of mitral stenosis is greater than unity.

It is interesting to notice (Table V) that the ratio 2.3 for chorea is very similar to that for rheumatic fever—2.53. In a previous paper we showed that there is a definite correlation between the incidence of these two diseases, and this similarity between the ratio of pure and mixed lesions is an additional support, though only a slight one, in favour of their identity.

The following table classifies the cases into three groups: (A) With definite rheumatic history, (B) with doubtful rheumatic history, (C) with no history at all suggestive of rheumatism. The ratio of mitral to mixed lesions suggests that there is some cause of mitral stenosis which is more likely to affect the mitral valve alone than does acute rheumatism.

TABLE VI.—Three Groups: Definite, Doubtful, and No History of Rheumatism.

Group.	Total.	Pure Mitral Lesions.		Mixed Lesions.		Ratio of Mitral to Mixed Lesions.
		Cases.	Per Cent.	Cases.	Per Cent.

	342	253		89		2.84

Age Incidence in Mitral Stenosis.

In dealing with aortic regurgitation we found that there was on the whole a decline in the incidence of this lesion between the ages of 17 and 41, but that when a history suggestive of rheumatism was excluded the incidence was practically the same for each quinquennial period. On taking the figures on the same method for mitral stenosis a somewhat similar general decline is found for the whole number of cases, but when any history suggestive of rheumatism is excluded there is a definite and fairly regular decline as the age advances. The numbers are not large, but, taken for what they are worth, they seem to indicate that the cause or causes of aortic regurgitation other than rheumatic fever have a fairly even incidence over the whole period between 17 and 41, while in the case of mitral stenosis such cause or causes are more active in the earlier portion under consideration.

TABLE VII.—Age Incidence in Mitral Stenosis.

(Omitting cases below 17 and over 41 years of age, and 47 cases of doubtful mitral stenosis.)

	Total Recruits Examined.	Total Mitral Stenotics.	M.S. with no History Suggestive of Rheumatism.
Ages 17 to 21 ...	2,091	82 = 3.92 %	32 = 1.53 %
.. 22 to 26 ...	2,008	69 = 3.44 %	22 = 1.09 %
.. 27 to 31 ...	2,298	85 = 3.70 %	24 = 1.04 %
.. 32 to 36 ...	2,107	61 = 2.90 %	14 = 0.66 %
.. 37 to 41 ...	1,409	43 = 3.05 %	11 = 0.78 %

We see that the evidence gathered by the percentage method, the evidence afforded by the correlation coefficient, and that gained by investigating the proportion of cases giving a history of rheumatic fever where there

is also a history of another disease, all strongly point to rheumatic fever and chorea as efficient agents in producing mitral stenosis. We therefore thought it wise to eliminate all cases giving a history of one or other of these diseases before attempting to arrive at any conclusion with regard to what other factors may stand in etiological relation with mitral stenosis.

The following table gives the correlation figures when these two histories have been excluded.

TABLE VIII.—Correlation Figures when Histories of Rheumatic Fever and Chorea have been excluded.

..	Strain ...	63	104	2,199	5,350	0.139	0.023	5.82

It will be noticed that the correlation coefficient for influenza, 0.248, and χ^2 15.42, are sufficiently large to make it worthy of consideration. When we excluded those cases giving a history of rheumatic fever from our cases of aortic regurgitation, we found that the correlation coefficient between a history of influenza and aortic regurgitation was 0.218, χ^2 being 11.18, figures which are only a little smaller than those found under comparable conditions for mitral stenosis. How are we to account for these figures?

A history of influenza frequently means little more than a history of some febrile ailment, usually accompanied by lassitude, headache, and wandering pains. It is probable that infections due to many different agents are described by patients when giving histories as influenza. The initial illness recounted by Rose Bradford, Bashford, and Wilson as occurring in the acute infective polyneuritis described by them in the early part of 1919, would almost certainly be described by a patient as an attack of influenza, and no doubt many other pyrexias of unknown origin would figure in the history given by a patient as influenza. Some time ago Sir Thomas Horder expressed the opinion that mitral stenosis was in certain cases produced by some short infective illness other than rheumatic fever. Dr. C. F. A. Moss, who has worked as a medical missionary at Tananarivo in Madagascar for thirty years, in a private communication to the writer, states that mitral stenosis is of quite frequent occurrence among the natives of Madagascar, but that as a result of thirty years in an extensive practice of an exceedingly general character, he should say that acute rheumatism does not exist there, at any rate in the centre of the island, while there are various forms of other febrile disorders which are very common.

The organism causing acute ulcerative endocarditis is probably not the same as that producing acute rheumatism, and it is possible that there may be slighter infections, bearing a similar relation to acute ulcerative endocarditis that a boil or a localized attack of furunculosis bears to general pyaemia. May we not in the figures just given see statistical indications of the existence of some disease capable of producing organic valvular lesions, and having a preference for the mitral rather than the aortic valves, such disease being characterized by symptoms which the patient would describe as influenza, or possibly in some cases as tonsillitis?

When dealing with aortic regurgitation we found evidence pointing to strain as an efficient cause in producing this lesion. The figures for mitral stenosis and strain are very different. When rheumatic fever was eliminated in the case of aortic regurgitation we got a correlation coefficient of 0.433, χ^2 being 59.10; the comparable figures for mitral stenosis are 0.139 for the correlation coefficient, χ^2 sinking to 5.8.

The following table gives the classification of our 342 cases of mitral stenosis according to the strain they were exposed to either as a result of their occupation or recreations, and divides them further according to whether they gave a definite history of rheumatic fever, a doubtful history, or no history at all of this ailment. The figures for the total number of recruits and the comparable figures for our 307 cases of aortic regurgitation are included for comparison.

TABLE IX.—Occupation and Exercise.

	Light.			Medium.			Heavy.		
	Per cent.

Aortic regurgitation without rheumatic history ...	23.6	11.1	65.3	23.6	11.1	65.3	23.6	11.1	65.3

Table IX shows that, as in aortic regurgitation, the patients suffering from mitral stenosis and giving a history of rheumatism show a drift from the heavy occupations and exercises to medium. As a history of rheumatism is eliminated there is an increasing percentage of cases who are engaged in heavy labour or indulge in strenuous recreations. This increase is much less pronounced among mitral stenotics than among aortic regurgitants. Since some of our cases of mitral stenosis also had their aortic valves affected, we thought it possible that the inclusion of such cases might account for the increase in the heavy exercise class. We therefore prepared the following table, contrasting the subjects of mitral stenosis in whom no other valve was affected with the subjects of aortic regurgitation in whom the aortic valves alone were affected. In each case we give the numbers for the mixed lesions as well for comparison.

TABLE X.—Occupations and Exercise. MITRAL STENOSIS.

		Pure Mitral Lesions.			Mixed Lesions.		
		L.	M.	H.	L.	M.	H.
		Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.

With no history suggestive of rheumatism ...	72	15.0	4.0	80.0	29.79	10.64	59.57

L. = Light; M. = medium; H. = heavy.

An inspection shows that while in the case of mitral stenosis there is an increased percentage of those who indulge in heavy exercise as we pass from a history of rheumatic fever to no history suggestive of rheumatism, the increase is in no way comparable with the increase in the case of pure aortic lesions; and, further, that as we pass from pure mitral lesions to pure aortic lesions where no history of rheumatism exists, there is again a steady increase in the percentage engaged in heavy exercise. Another remarkable fact that this table reveals is that the distribution between light, medium, and heavy exercise is practically the same for both aortic and mitral cases where there is a history of preceding rheumatic fever. The deductions which we are inclined to draw from these tables are that while strain has possibly some effect in producing mitral stenosis, it is nothing like so important a factor as it is in the production of aortic regurgitation. From the extremely similar numbers in aortic and mitral cases in the various strain groups, we cannot help suspecting that the disability that rheumatism causes, and which determines the amount of exercise or work the patient does, is more dependent upon some common factor, such as damage to the cardiac muscle, than on the particular valve affected.

When we were dealing with aortic regurgitation we compared the number of cases engaged in heavy, light, and medium labour who gave no history of acute rheumatism with numbers calculated on the assumption that strain and rheumatic fever were the two chief causes of aortic regurgitation, and we found a remarkably close agreement between the calculated and the actual figures; when we applied this method to the mitral stenotics the difference between the actual and calculated numbers was so great as to negative such an assumption, which again leads us to the same conclusion as the other figures in the present communication—namely, that there is another cause of mitral stenosis besides rheumatic fever, which is not strain.

SUMMARY.

Taking aortic regurgitation and mitral stenosis as the two typical valvular lesions which can be diagnosed with comparative certainty during life, the results of the present statistical inquiry lead us to the following conclusions:

1. The most important etiological factor in the production of organic lesions of the heart valves in men between the ages of 18 and 41 is rheumatic fever.
2. Strain can independently produce aortic regurgitation.
3. While strain may be a cause of mitral stenosis, it is a much less important factor than in the production of aortic regurgitation.
4. There is a third agent giving rise to symptoms simulating influenza, which is an efficient cause of mitral stenosis, and can possibly affect the aortic valves as well, but is not nearly so likely to do so.

We have been unable to find any statistical evidence that syphilis, scarlet fever, diphtheria, pneumonia, or gonorrhoea, are causes of valvular lesions, nor can we find statistical evidence that a history of growing pains points to affections productive of valvular lesions. The same may be said, with slight reservations, of a history of rheumatism where there is no clear account of pain, swelling of the joints, fever, or confinement to bed. The evidence in favour of chorea as an efficient cause of mitral stenosis is strong, and we have found some, though not very striking, evidence in confirmation of the view that chorea and rheumatic fever are both manifestations of the activity of a common cause.

THE IMMEDIATE CLOSURE OF EMPYEMATA.

BY

FRANK HATHAWAY, M.D.,

SRGEON, KING EDWARD VII HOSPITAL, WINDSOR.

THERE is nothing new under the sun, and I was very much surprised, after I had drafted this paper, to be told by a friend of mine that twenty-five years ago it was the custom at King's College Hospital, under Lord Lister, to wash out their cases of empyema and sew them up. The fact remains, however, that when I returned from France late in 1917, it struck me that in the treatment of

empyema it was not sufficient merely to open the abscess and put in a drainage tube, but that something more should be done and the wound immediately sutured.

These short notes are the result of my experience since I published my first successful case in a paper on the abuse of drainage tubes¹ in 1918, when I thought I had struck something original and really good. Although I am not a pioneer in the immediate closure of empyemata, I hope that the success I have met will stimulate others to follow the lines of treatment I find by experience to give the best results.

It stands to reason that the simple resection of rib, letting out of pus, and putting in of a drainage tube is not the ideal and complete treatment of empyema. Something more is wanted, because re-expansibility of lung is far more important than the mere evacuation of pus, and this re-expansibility can only be produced in two ways: (1) By introducing the whole hand into the pleural cavity and freeing the lung of all adhesions and removing all fibrous clots; (2) by immediate closure of the wound.

Those who have had experience of chest surgery in France learnt that the first thing was to do away with a "sucking wound." Why, then, should we by the use of a drainage tube deliberately establish one in the treatment of empyema? By using an open tube the atmospheric pressure in the pleural cavity must be greater than that in a collapsed lung, and in order to get a lung to re-expand as quickly as possible it is essential to produce a vacuum in the pleural cavity. This result can only be attained by immediate closure of the wound, after filling up the cavity with some fluid.

Every surgeon in France was surprised to observe how quickly the lung re-expanded after immediate closure for gunshot wounds, and the same holds true for empyemata. Breath sounds will be heard down to the base of the lung within a few days after operation, and the lung will rapidly push out the fluid left, so that it comes to lie under the skin and can be easily and painlessly evacuated.

Therefore we may lay it down as an axiom in chest surgery that the lung will quickly re-expand if only it is given a fair chance. This favourable condition can only be secured by freeing the lung from all adhesions and by closing the wound at once.

If these two main rules are carried out, we shall do away with the old-standing cases of empyema which go on from year to year, with collapsed lung and a persistent sinus, and eventually have an enormous Estlander operation performed. Is it too good to hope that this operation will become a thing of historical interest only?

As I have pointed out elsewhere, there is no reason why a pneumococcal infection should be treated on lines different from a tuberculous infection. In either case, by using an open drainage tube, we are asking for trouble by producing a secondary mixed infection.

It is important to note that a careful bacteriological examination is essential in every case of empyema. If pneumococci or pneumococci and staphylococci are present the wound may be sutured; but if streptococci are present, then I think it advisable to remove the stitches and treat by some open method—that is, Carrel-Dakin, packing with gauze, or by a drainage tube.

Operation.

I have, since my return from France, sewn up all my cases, and my experience up to date has taught me that the following are the best lines:

I have always used a local anaesthetic, but I am inclined to think that when handling the lung a little general anaesthetic with it is useful.

I resect sufficient rib, either a long section of one rib or adjacent parts of two ribs, to allow of the introduction of the whole hand into the pleural cavity. This is the first most important point, because, after evacuation of the pus, it is essential to pass the hand into the chest cavity and strip off the collapsed lung all adherent fibrin and separate the lung from all adhesions. In any early case this is easily done, but an old-standing one will require much freeing of the lung in order that it may recover its re-expansibility. I then wash out the pleural cavity with flavine till the fluid comes away quite clean, and fill up the chest with a 2 per cent. suspension of iodoform in sterilized paraffin. The pleural wound is then sewn up with catgut, not that I think this is very important, because these stitches soon give way. I then carry out immediate

closure of the skin wound with deep sutures, so as to leave no "sucking wound."

The next important point is the after-treatment. When dressing on the next and following days the wound will be bulging; this is due to a mixture of pus and iodoform and paraffin being pushed out of the pleural cavity by the expanding lung under the skin. Daily I introduce the needle of an exploring syringe between the edges of the wound—this is quite painless—and extract all the fluid I can. This process usually takes ten to fourteen days, depending on the re-expansion of the lung. Daily bacteriological report of this fluid shows that the number of organisms in a field steadily diminishes. A certain amount of this mixture of pus and iodoform and paraffin will ooze out also into the dressings.

The two most important points in technique, then, are—

1. Introduction of the whole hand into the pleural cavity to separate adhesions and remove all fibrin. The lung must be made to re-expand.

2. Daily evacuation by an exploring syringe of the pus and paraffin as it is pushed out under the skin by the re-expanding lung.

I have now sutured 9 cases. The ages of the patients were 55, 53, 44, 30, 27, 25, 18, 4, and 2½. All were pneumococcal except two; one was staphylococcal as well as pneumococcal, and one which was my only failure; this was a tuberculous case—a man, aged 44, with two big abscesses pointing under the skin, one behind and one in front. He was very debilitated and ill. As it was one of my early cases I did not sufficiently explore the chest with my hand; had I done so I should have found, as I did *post mortem*, that the lung was tied in a knot at the root. I sewed the incision up, and the patient died in twenty-four hours. After seeing the condition of his chest I am quite sure the result would have been the same had I drained with a drainage tube or sewn up.

Of the other eight cases, all made good and rapid recoveries. The temperature fell at once, and the pulse and respirations came down more gradually.

The duration of the disease in these cases varied from two to six weeks, after the resolution of the primary pneumonia.

A further suggestion has occurred to me, but I have not lately had an empyema to try it on. It is this: Whether it would not be a good plan to insert into the pleura a soft piece of folded rubber—that is, a passage tube—in order gradually to let out the iodoform and paraffin, and to do away with the daily needling of the collection under the skin. This piece of folded rubber will not allow air to enter the pleura, and will yet slowly allow the escape of pleural contents.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF FACIAL TROPHONEUROSIS WITH DEFORMITY OF THE HAND.

As progressive facial hemiatrophy is a rare condition, the notes of the following case observed during the examination of recruits will be of interest.

A boy, aged 17, presented the following structural abnormalities, which are seen in the photograph.

Bones.—There was atrophy of all the bones of the right side of the skull, including the cartilaginous portion of the external ear. The metacarpal and phalangeal bones of the thumb and right index finger were atrophied and deformed.

Muscles.—Wasting was noted on the right side in the muscles of the face and of the thenar eminence, and to a lesser degree in the muscles of the neck; the right sterno-mastoid, however, was well formed. The right upper limb was poorly developed although he was right-handed.

Nerves.—Epicritic and protopathic sensations were everywhere normal; in no muscle was there palsy.

Other points of interest were that the right carotid and radial pulses were perceptibly weaker than those of the left side, and that the skin of the affected side was of a more delicate texture.

The boy is a junior member of a family of fifteen, and I have excluded as far as possible the question of natal trauma with resultant torticollis and facial asymmetry.

Wrexham.

I. H. LLOYD, M.B., B.S. Lond.

FOREIGN BODY IN BRONCHUS.

THE case reported in the JOURNAL of May 1st, p. 602, by Mr. W. C. Cammock, in which a toy air balloon was present in the left bronchus, recalls a similar one with which I had to deal about three years ago.

A boy, aged 11, when playing in the street, inhaled a small rubber balloon with wooden mouthpiece which caused immediate and complete respiratory obstruction. This was relieved by tracheotomy, performed by a doctor near whose house the boy was at the time. He was then taken to the Liverpool Royal Infirmary, and when I saw him there soon after his arrival he was suffering considerably from shock, and surgical emphysema, originating no doubt from the tracheotomy wound, was present over the neck and a great part of the trunk. The boy's condition at the time did not justify any attempt to find and remove the foreign body which was probably then in the larynx. On the following day the rubber balloon without the wooden mouthpiece was coughed out, and the boy could breathe and phonate clearly on closing the tracheotomy opening. The surgical emphysema disappeared and his general condition improved, so that six days after the accident I considered it safe to endeavour to remove the mouthpiece which was presumed to be lying in some part of the bronchial tree, although there were no physical signs in the chest giving any clear indication of its position. Inferior bronchoscopy at once revealed its presence in the right main bronchus, from which it was removed without difficulty. The absence of physical signs of obstruction of the bronchus was due no doubt to the fact that air had passed freely through the lumen of the foreign body as well as between its walls and those of the bronchus in which it lay quite loosely.

CARBOHYDRATE EXCESS AND BERI-BERI.

CONSIDERABLE interest attaches to the fresh light thrown upon the pathogeny of rickets and beri-beri by Professor Mellanby in his opening remarks at the Section for the Study of Disease in Children of the Royal Society of Medicine on February 27th, 1920. While admitting that administration of the suitable vitamins in rickets and beri-beri will effect a cure, he holds it not improbable that the two diseases are brought about by some other elements in the diet, probably a carbohydrate excess, together with some considerable protein deficiency. Such facts are in agreement with results of observations I made some years ago upon the former diets of beri-beri patients, in which, generally speaking, in addition to the lack of the particular antineuritic vitamins, carbohydrate was found to bulk largely in the diet, with insufficient intake of protein derived principally from polished rice and dried fish.

The epidemiological distribution of beri-beri still, however, to some extent remains unsolved, in its special incidence upon sea-coast places, in which immigrants specially suffer, whilst residents partaking of an identical diet almost invariably escape. In regard to occupation I found a large number of those engaged in sedentary trades, such as the Chinese tailors in Singapore, specially prone to the disease.

Whilst I hesitate to introduce a further causative factor in beri-beri, it may well be that a degree of acidosis is the ultimate determining agent in the production of neuritic symptoms, a condition now known to be liable to arise in new arrivals to the hot moist climate of the seaboard towns of the Straits Settlements, being aggravated by the already mentioned dietary deficiencies and excesses, against which the Straits-born inhabitants have become more or less immune through prolonged residence.

The connexion between neuritis and acidosis may be further traced in the neuritis complicating diabetes and diphtheria, in which acidosis is usually a feature in cases which develop neuritis. There is some direct evidence in the results of Brandon, Cooper, and others in favour of the view that the offending element in the diet in polyneuritis avium is a carbohydrate excess.

Pellagra is now definitely known to result not from lack of a vitamine but from a diet of low biological value, such as maize.

Whether or not the function of the vitamine is to preside over metabolism through the stimulation of one or more hormones is yet undetermined, but such a view would appear feasible in the light of recent observations on the pathology of beri-beri and the kindred "deficiency" disease of rickets.

K. SIMPSON, M.D., M.R.C.P., D.P.H.,
late Medical Officer, Colonial Service.

Reports of Societies.

RADIUM THERAPY.

At a meeting of the Sheffield Medico-Chirurgical Society, held on April 15th, Dr. RUPERT HALLAM read a paper on the therapeutic uses of radium. After a brief description of the chemical and physical properties of the metal, he explained the methods employed in estimating the quantity of radio-activity in the various applicators used in medicine and surgery. The strength of each applicator supplied by the Sheffield Radium Institute is described in terms of radium metal, and he suggested that it would be of great advantage for the comparison of doses and results if this unit of dose were universally adopted. Although the Sheffield radium, which was purchased in 1915, was primarily intended for the treatment of inoperable malignant disease, it had also been used extensively for the treatment of certain skin diseases. In his experience the results obtained in the treatment of rodent ulcer, providing the ulcer did not involve the bone or conjunctiva, were good. He had latterly employed carbon dioxide snow in conjunction with the radium, and anticipated a higher percentage of non-recurrences. Thirty-three cases of cavernous naevi treated during the year 1919 had all responded exceedingly well, and he maintained that this method superseded all others. A large number of cases of malignant disease had been treated during the last four years by the surgeons of the four voluntary hospitals in Sheffield; cases of sarcoma apparently responded most favourably to the application of radium, and four such cases which had been free from recurrence for periods varying from one to four years were shown. The results of the treatment of carcinoma of the cervix had been disappointing. In no case of carcinoma of the mouth could improvement be said to have occurred. In conclusion, Dr. Hallam maintained that apparent cure of inoperable malignant disease by radium was exceedingly rare, but that it often relieved pain, lessened discharge, and gave patients hope.

At the close of the paper several members related their personal experience of the treatment of malignant disease with radium. Dr. MILES PHILLIPS had found it of little value in carcinoma of the cervix. He expressed the opinion that equally good results were obtained by cauterising the growth, and he related a case in which this method had been employed and the growth remained quiescent for four years. Dr. WILKINSON described several cases of sarcoma of the tonsil which had responded well to the treatment and were apparently free from disease. Mr. ARCHIBALD CUFF had employed it with satisfactory results in two cases of menorrhagia.

PSYCHOLOGICAL ANALYSIS.

At a meeting of the Manchester Medical Society, held on March 3rd, 1920, Professor R. B. WILD, the President, being in the chair, Professor T. H. PEAR read a paper on psychological analysis, which he defined (following Bernard Hart) as "any method whereby the nature and relationship of the causes responsible for the patient's (mental) condition are determined, and the condition is removed by the rearrangement and readjustment of these causes." The

term was said to be wider than psycho-analysis; the latter should be reserved to describe that method which owed its inception to Sigmund Freud. The purpose of the speaker was to describe the nature and uses of psychological analysis (of which psycho-analysis was one variety) in the diagnosis and treatment of what were known as the "functional nervous disorders." Of these disabilities there were two kinds, often but not always distinguished sharply from each other: (1) Conversion hysteria, (2) the anxiety neuroses. These two types of disorder might be symptomatic of different kinds of mentality in a patient, and the cure might necessitate different methods of treatment. Professor Pear said that, though psychological analysis was only one method in psycho-therapy, it was sometimes the only method which would ultimately be successful, because it was the only "radical" method. The different psychological processes involved in the methods known as suggestion, persuasion, and analysis were discussed and compared, and reference was made to the view taken by Bernard Hart of the differences between these disorders. It was pointed out that the meaning attached to the word "suggestion" was usually extremely vague, and that, though suggestion probably entered into treatment both by persuasion and analysis, it could be distinguished from them. The definitions of suggestion and persuasion given by Hart in the *Proceedings of the Royal Society of Medicine*, vol. xii (Section of Psychiatry, pp. 13-34) were further discussed. In conclusion, Professor Pear pointed out that the adoption of all methods of psycho-therapy, and in particular of the analytic method, required a knowledge of the technique and of the psychological processes underlying them. He emphasized the necessity of training medical students in the future to understand and to discriminate between the uses of the various methods.

Professor E. S. REYNOLDS, Dr. D. E. CORE, Dr. S. HERBERT, Dr. A. V. STOCKS, and Dr. S. R. WILSON took part in the subsequent discussion.

MIXED FUNCTIONAL AND ORGANIC PALSIES.

At a meeting, held on February 27th, of the Section of Medicine of the Royal Academy of Medicine in Ireland, the president, Dr. G. PEACOCKE, being in the chair, Dr. DRUMMOND showed a case of senile uveitis pigmentosa of fifteen years' duration in a man of 68. Dr. O'KELLY, who had examined sections of the skin, reported the presence of mast cells in large numbers; this was considered by Brock, Unna, and Gilchrist to be pathognomonic. This patient suffered also from auricular fibrillation, and had been treated by Dr. NESBITT, who showed slides of tracings taken to demonstrate the condition.

Dr. MAXWELL showed a patient of 58 suffering from pituitary tumour, who complained of difficulty in reading. There was a history of two years' headache and dizziness. She was found to be suffering from bitemporal hemianopsia; the turbinated bones on the right side were very oedematous.

Dr. PURSER stated that he had seen the case. There was bad headache, but not severe enough to make one suspect intracranial growth. Amenorrhoeic signs were of no value as the patient was past the menopause; fat was slightly increased and there was some loss of hair. The tumour of the pituitary was well shown by x-ray photograph. He asked for views as to operative treatment.

Dr. SPEARS showed a case of paralysis of the left arm and leg in a woman of 23. In February, 1919, she was delivered of a healthy male child. The placenta was torn; after its removal she had a hæmorrhage, and was unable to move her left arm or leg. A fortnight later she was sent to Monkstown Hospital, where she had electrical and massage treatment for nine months and improved greatly. She had severe pain on the left side of her head and face; the left side of her face was "crooked," and all food dropped out of her mouth on that side.

On examination the arm was held in a position of tetany, except that the interphalangeal joints were flexed instead of extended, and that the wrist was drawn to the radial instead of to the ulnar side. Sensation, except touch, was normal. After slight massage some movements of the arm were produced. Similar conditions were present in the leg. Reflexes: Left knee-jerk exaggerated, right sluggish, ankle clonus marked in left foot. Babinski? Abdominal reflexes absent.

Wasting of calf muscles of left leg; painless periarticular swelling of both knee-joints. Eyes normal; Wassermann test

negative. *Electrical reactions*: All muscles of arm and leg responded to faradic and galvanic currents.

Dr. PURSER said there was probably a functional element in the case, aggravated by not having been taken in hand earlier, but as the gait was characteristic of hemiplegia, he thought the condition was organic in origin, whether due to hæmorrhage or thrombosis, he could not say.

Dr. DRURY thought it was probably due to thrombosis caused by slow and scanty circulation through the brain. He knew of two other cases following pregnancy in previously healthy women.

Dr. SPEARS, in reply, said he thought the case was one of mixed paralysis—that of the arm was functional and that of the leg organic. He had not examined the cerebro-spinal fluid: he thought Dr. Drury's theory of origin was probably correct.

TUBERCULOSIS SOCIETY CONFERENCE.

A CONFERENCE under the auspices of the Tuberculosis Society was held on May 13th and 14th at Leeds; delegates, including tuberculosis officers, medical superintendents of sanatoriums and of tuberculosis colonies, were present from all parts of Great Britain and Ireland. At the opening of the conference in the Town Hall the Tuberculosis Society was welcomed to the city by the Lord Mayor and by the Vice-Chancellor of the University (Sir Michael Sadler).

Dr. H. de Carle Woodeock, in the course of his presidential address, remarked that in Leeds the civic authority had been less ready than private enterprise in the fight against disease. Robust democracies despised minorities, and the sick were a minority. Research should begin by co-ordinating our knowledge so that we knew where we stood in this matter. Dr. Benjamin Moore (Lister Institute) then moved the following resolution, which was carried unanimously:

That in the opinion of this congress a conference should take place between those actually engaged in tuberculosis work and those engaged in research work, to arrange the lines on which future investigation should be conducted, and the manner in which the records should be kept and collated and their results circulated.

On Thursday afternoon Dr. A. Triumble, chief tuberculosis officer, Belfast, in opening a discussion on tuberculosis in workshops, said there was little to be gained by demanding increased wages unless the workers themselves knew how to make the best use of them; increases spent on cinemas, railway travelling, theatre going, more tobacco or more liquor were useless. Smokeless and dustless roads were required. Mr. Fisher (secretary of the Glass Bottle Makers' Society, Hunslet) stated that eight out of ten of the deaths he had to record in that trade were due to tuberculosis. This could be largely overcome if the men had their own blowpipes and proper means of sterilizing and keeping them clean. Dr. Nathan Raw, M.P., said that sanatorium treatment had not been a success, first, because it was a dull, monotonous, and uncomfortable life; and secondly, because the patients did not stay there long enough. The Ministry of Health were about to form a special department to deal with tuberculosis alone.

At the School of Medicine Dr. Marcus Patterson, who opened a discussion on recent advances in treatment, said that it was within the last twenty years that it was first decided to open the windows of rooms in which consumptives were being treated; until recently treatment had consisted only of fattening by milk feeding. Sir Henry Gauvain described the treatment of non-pulmonary tuberculosis at the Treloar Cripples' Hospital at Alton, and illustrated by lantern slides the correction of various deformities. He said that whilst under treatment the children received instruction for three hours a day; crippled lads between the ages of 14 and 18 were taught a trade.

At the Section on "Tuberculosis and child life" papers were read by Dr. A. Wear, chief medical officer to the Leeds Education Committee, and by Dr. C. W. Vining. The Section on Farm Colonies was addressed by Dr. S. Jacob and by Mr. A. G. Ruston, lecturer on farm economics at Leeds University. On Thursday evening popular lectures were given by Sir Henry Gauvain and by Dr. Halliday Sutherland.

Tuberculous Ex-Soldiers.

On Friday a discussion on tuberculosis and the war was opened by Sir Montague Barlow, M.P., Parliamentary Secretary to the Ministry of Labour, who said that 40,000 ex-service men might fairly claim to have been affected with tuberculosis as a result of the war. If they were

allowed to return to ordinary life they would probably not only disappear very quickly but also infect others. The Interdepartmental Committee recommended that sanatorium accommodation, where deficient, should be increased; that after prolongation of the ordinary sanatorium treatment there should be facilities in connexion with many sanatoriums for a farm colony, with scope for employment in the workshop or on the farm; and that ten village settlements should be created. It was intended that the men should group themselves round the sanatorium in village life, with medical and industrial advantages; they should have pensions from the State. The Government had now set up a committee to establish as promptly as possible a reasonable number of these village settlements. It had been whispered to him that the money was going to be forthcoming, and that the Government were quite agreeable. Dr. Noel Bardswell stated that of 430 tuberculous ex-service men demobilized in the London area, 264, or 60 per cent., were already dead. The establishment of village settlements might take two or three years, and before this had been accomplished the great majority of the men would have succumbed.

Artificial Pneumothorax.

On Friday afternoon Dr. Vere Pearson opened a discussion on artificial pneumothorax. Careful observation, he said, was required in order to determine whether the less diseased side was capable of sustaining life. Refills should not be at too long intervals. He did not consider this treatment suitable as a routine for early cases. If one lung was collapsed the patient ran a greatly increased risk if he developed influenza or pneumonia. Dr. Morriston Davies said that no case was too early for pneumothorax. Adhesions, if they were fine bands, could be easily cut with a tenotome under x rays. Dr. Halliday Sutherland advised pneumothorax in suitable cases of recurring hæmorrhage. After induction of pneumothorax he found that many adhesions would give way or stretch if the patient were given breathing exercises; in suitable cases the results were brilliant.

At the Section on "Care Work" addresses were given by Dr. Jane Walker and by Dr. Stanley Tinker.

At the Central Tuberculosis Dispensary Dr. H. Ellis demonstrated his treatment of lupus.

At the closing session, held at Harrogate on Saturday, Dr. Halliday Sutherland outlined the policy of the Society. Two years ago there was no other organization to advance the material interests of tuberculosis officers. The status of tuberculosis officers was now recognized, and a group representing their interests was being formed within the Society of Medical Officers of Health. It was not desirable for the two societies to amalgamate, because the Tuberculosis Society included not only tuberculosis officers, but sanatorium superintendents, hospital physicians, bacteriologists, and others interested in various aspects of tuberculosis. Their primary aims were not medico-political, but they desired to make the society a clinical institution representative of every aspect of clinical tuberculosis work in the United Kingdom.

Rebieus.

BRITISH MOSQUITOS.

ONE of the most important functions of a large public museum is to publish monographs on subjects which are not attractive to the publisher; we may surely congratulate our own Natural History Museum on having produced in the last few months Hirst's work on *Demodex* and W. D. Lax's *Handbook of British Mosquitos*.¹ The practical importance of the twenty-one gnats or mosquitos (we are glad to see that the author makes no attempt to use these English words as if they meant different insects) which inhabit this country is fortunately small; though three species of *Anopheles* are included in the list, our low mean temperature, even in summer, makes it unlikely that malaria acquired in Britain will ever again be common. Fortunately Dr. Lang's book is written so that it can be used as an introduction to the study of mosquitos generally. We know no textbook of medical entomology which gives the man unversed in the systematics of the Culicidae so definite a grasp of the points on which genera and species are distinguished. Anyone who is willing to work

¹ *A Handbook of British Mosquitos*. By W. D. Lang, M.D., M.A. Sc.D. London: Longmans, Green, and Co., B. Quaritch, Ltd., Dulau and Co., Ltd., and the British Museum (Natural History). 1920. (Roy. 8vo, pp. 131; 5 coloured plates, 132 figs. £1.)

through a few of the British species with the aid of this book will find that he has equipped himself with a general knowledge of the structure of these insects—not merely their scales and nervures, but their claws, their genitalia, and their palps. Having this knowledge he should be able to study the mosquitos of any part of the world with the aid of the various more technical monographs which are available.

The chapter on the characters by which larvae may be distinguished is one of the best features of the book. The medical man in the tropics has often been puzzled by his inability to discover any absolute structural difference between two mosquito larvae which he felt sure represented different species; if he is willing to put himself to school and to study these pages he will have a clear idea of what distinguishing characters can generally be relied upon.

The book contains sound biology as well as sound morphology. We have all of us seen goats dancing in sheltered spots at dusk, but few of us know that the dancers are males, and that when a female approaches the dance becomes more and more frenzied; finally, the female overcomes her shyness, enters the swarm and is seized by a male with whom she leaves the dance; the males then continue to dance until another female enters the swarm and finds a partner. The prevalent idea that a feed of blood stimulates the female to pair appears to be true only of certain species of *Anopheles*.

The figures in the text and the coloured plates are alike excellent, though no magnification is given with most of the text figures. There is an index of specific names and synonyms, but no general index. In every other respect the book does immense credit to the author and the museum.

THE MEDICAL ANNUAL.

The *Medical Annual for 1920*,² the thirty-eighth volume of this valuable series, begins with a short section on recent advances in materia medica and therapeutics, including x ray work, radio-activity, and electro-therapeutics. This is followed by nearly four hundred pages in which the progress of medicine and surgery during the year 1919 is reviewed by some three dozen authorities, each of special competence in the subject with which he deals. Arranged as a dictionary of treatment, this part of the *Annual* is full of detailed information on all the urgent medical and surgical problems of the day. Deficiency diseases and vitamins are fully discussed, and the limits of fact and fancy in this interesting branch of chemical physiology are indicated. The most recent views on the dietetic treatment of diabetes mellitus are set out; lethargic encephalitis is described and its diagnosis discussed; a case is made out for the consumption of alcohol; the treatment of nasal catarrh and recurrent bronchitis by the administration of vaccines, preferably autogenous, is described, and much interesting information about bronchial asthma and hay fever has been collected. The various neuroses and allied states brought into prominence by the great war receive adequate consideration, and there is an excellent article on the surgical treatment of visceroptosis. The treatment of deep frontal headache by the administration of pituitary extract is described, and recent investigations into the pathology of paralysis agitans are summarized.

The third and last section of the *Annual* deals with numerous miscellaneous topics—public health administration, new books, sanatoriums, spas, and the like—of practical interest to medical men. The volume is provided with particularly good indexes, its illustrations are numerous and well reproduced, and its get-up does great credit to the publishers.

ANTHELMINTICS.

In Southern Brazil the State of Paraná has set up a scheme of rural prophylaxis against three local plagues—namely, malaria, ankylostomiasis, and leprosy. This is worked in conjunction with hospitals, dispensaries, bacteriological laboratories, and similar adjuncts over

a large area, under the direction of Dr. DE SOUZA ARAUJO,³ who has recently published an account of the first few years of the scheme's growth. This volume is very fully documented, and in addition contains clinical and administrative accounts of ankylostomiasis, infection with round worms, trichocephalus, and other intestinal parasites. He finds thymol and oil of chenopodium to be, speaking generally, the best anthelmintics. The thymol is given in capsules by the mouth, finely powdered and mixed with an equal weight of glucose; the dose of thymol is 1 gram at the ages 1 to 5, and 5 grams at the ages 20 to 50; the patient is made to lie down for a time after taking it. No permanent ill effects have followed in any of the 20,000 of these treatments given; and larger doses can be employed in the case of hospital patients, say, 6 grams, together with 3 c.cm. of chenopodium oil. This oil is superior to thymol as a vermifuge, according to Dr. Araujo; adults receive 1.5 c.cm., children 2 or 3 minims for each year of their age; an adequate dose of magnesium sulphate should be given as a purgo the night before. Ten days later this treatment is repeated. Neither thymol nor chenopodium oil can be expected to yield a radical cure for helminthiasis. It is reckoned that there are 600 to 800 lepers in Paraná; it is hoped to isolate these in colonies on some island off the coast, if the Federal Government will support the plan. There are many interesting points and discussions in this very full and florid report to which no reference can here be given; it is illustrated with many reproductions of photographs, and should be studied by all medical men interested in tropical medicine who can read Portuguese.

NOTES ON BOOKS.

THE fourth edition of Mr. RENDLE SHORT'S *The New Physiology in Surgical and General Practice*⁴ consists of a series of fourteen essays attractively written about subjects of interest to general practitioners of medicine and importance to students facing final examinations, particularly in surgery. The subjects dealt with are all of daily recurrence in the public or the medical press, and the author is to be congratulated upon the skill and completeness with which he gives a scientific presentation of them in terms easily comprehensible. They include such things as food deficiency diseases, researches on the blood, a chapter on the heart contributed by Drs. Carey Coombs and Herapath, surgical shock, chloroform poisoning, the growth of bone, and many other interesting topics. Possibly the account given of the pineal gland (page 197) might be fuller were the author to avail himself of Krabbe's monograph on the subject. The book may be cordially recommended to all readers wishing to keep abreast of recent progress in physiology.

Mr. R. P. P. ROWE'S *Concise Chronicle of Events of the Great War*⁵ provides a summary of the chief events that took place day by day in all the theatres of war 1914-1918. Seven appendixes are added, giving Austria's ultimatum to Serbia, Serbia's reply, Germany's declarations of war against Russia and France, President Wilson's Fourteen Points (we are reminded that *Le Bon Dieu lui-même n'en a que dix*), an abstract of the terms of the armistice, and an outline of the terms of the Peace signed at Versailles on June 28th, 1919. An excellent index closes the volume, which will have a permanent value as a work of reference.

Bulletins Nos. 4 and 5 of the *Stanford University Medical Publications*⁶ contain some seventy reprints of articles that have appeared in various medical, surgical, and pathological periodicals in America during the years 1916, 1917, and 1918. They deal with a great variety of subjects, and show no little activity on the part of the university's alumni.

² *A Prophylaxia Rural no Estado do Paraná*. Esboço de Geographia Médica. By Dr. Heraclides Cesar de Souza Araujo, Assistente-adjunto do Instituto "Oswaldo Cruz," etc. Vol. I, Anno I. Summario dos trabalhos realizados de Setembro de 1918 a A.osto de 1919. Curitiba-Paraná: Livraria Economica. 1919. (Med. 8vo, pp. 329; illustrated.)

FUTURE PROVISION OF MEDICAL SERVICES.

REPORT OF THE MEDICAL CONSULTATIVE COUNCIL FOR ENGLAND.

WHEN the Medical Consultative Council for England of the Ministry of Health was appointed, on October 1st, 1919, it was instructed

"to consider and make recommendations as to the scheme or schemes requisite for the systematized provision of such forms of medical and allied services as should, in the opinion of the Council, be available for the inhabitants of a given area."

The Minister of Health asked for an interim report at an early date. The Council has met on many occasions, and an interim report, signed by the chairman, Lord Dawson of Penn, and the vice-chairman, Mr. C. J. Bond, C.M.G., F.R.C.S., on behalf of the Council, has been issued, and has been placed on sale as from May 23rd.

The other members of the Council are Mr. N. G. Bennett, M.B., L.D.S. Eng., Dr. R. A. Bolam, Mr. Victor Bonney, F.R.C.S., Dr. H. G. Dain, Dr. A. Fulton, Sir William S. Glyn-Jones (secretary to the Pharmaceutical Society), Dr. T. A. Goodfellow, Dr. G. E. Haslip, Dr. T. Eustace Hill, Professor F. Gowland Hopkins, Miss M. H. F. Ivans, M.S., Miss Janet Lane Claydon, M.D., D.Sc., Dr. A. Linnell, Dr. J. A. Macdonald, Mr. E. W. Morris (House Governor of the London Hospital), Dr. John Robertson, Dr. T. W. Shore, and Sir William A. Tilden, D.Sc., F.R.S.

We are indebted to the courtesy of the Chairman of the Consultative Council for an advance copy, from which the following sketch of its arguments and recommendations has been prepared. The report itself fills 28 foolscap pages, and is illustrated by a diagram, a map, and plans showing designs for Primary Health Centres of three types—small, intermediate, and large.

To illustrate the character of the scheme evolved by the Consultative Council we have reproduced a diagrammatic sketch given in the report, showing the disposition of the primary Centres it proposes should be established, and their relation to a Secondary Centre, and, through it, to a Teaching Hospital Centre. Facing this diagram we have printed the "Summary of Recommendations" contained in Section VII of the report.

GENERAL PRINCIPLES AND A PARTICULAR APPLICATION.

The earlier part of the report points out that medical treatment must be both individual and communal, and that individual treatment may be either domiciliary or institutional. By communal treatment is to be understood pre-natal and maternity care, child welfare, the inspection and treatment of school children, dental treatment, clinics for early tuberculosis, and facilities for physical culture.

The general conception is that domiciliary treatment in each district should be based on a "Primary Health Centre." This institution would be conducted by the general practitioners of the district, and would be provided with an efficient nursing service. It would be linked with a "Secondary Health Centre" in some town conveniently placed in relation to the means of communication. Opportunities would be provided for consultation, either at the primary centre or at the homes of the patients, with physicians, surgeons, and specialists of the secondary centre, which would itself be brought into corresponding relation with a medical school hospital.

The general nature of the scheme proposed is illustrated by reference to that for Gloucestershire, described by Dr. J. Middleton Martin, county medical officer of health, in our columns of February 22nd, 1919, p. 218. The report states that the scheme has been approved by the county authorities, and by the authorities of the towns and hospitals, and that all the doctors in the county have agreed to the plan of service as framed. Details are given of the application of the scheme to the area of which the city of Gloucester is the centre. The area measures about thirty miles from north to south, and about twenty-four from

east to west. It is nearly bisected by the river Severn, over which there is no road bridge below Gloucester, though there is a railway bridge fourteen miles down the river. The area contains various types of population: the mining district of the Forest of Dean, the tin plate works at Lydney, cloth factories at Cam, and engineering works at Dursley. It includes also large rural districts, some of them sparsely populated. The report is illustrated by a map showing the places considered suitable for primary health centres, having regard to the distribution of the population and the means of communication. It indicates existing cottage hospitals and the provision proposed for supplementary services. The secondary centre would be in the city of Gloucester, which has a population of 50,000; it would be linked with the teaching hospitals and medical school of Bristol. A scheme on similar lines has, it is stated, been prepared by the North Eastern Hospitals Association for the counties of Durham and Northumberland.

DOMICILIARY SERVICE.

The domiciliary service, which is regarded as the first link in the chain of systematized treatment, would be rendered by the general practitioner, dentist, pharmacist, midwife, nurse, and health visitor.

Domiciliary nursing is regarded as an essential part of a health service, and the Consultative Council holds that nursing should be available for all illnesses and all persons when the doctor deems it necessary. The nursing services of a district should be based on the corresponding primary and secondary health centres, and existing organizations should be made use of for this purpose by the Health Authority. It is proposed that this subject should be referred to a special committee.

A PRIMARY HEALTH CENTRE.

The size and standard of equipment of a primary health centre would depend on the local conditions and needs of a neighbourhood. The distinguishing feature of the primary health centre in contradistinction to a secondary health centre would be that it would be staffed by general practitioners. Each centre would have general wards with an appropriate number of beds, also a midwifery ward. There would be provided also an operating room, radiography room, a laboratory for simple investigations, a dispensary, baths, and equipment for massage, electricity and physical culture, and a public mortuary. It is proposed that the general practitioner should attend at the primary health centre such of his patients as require hospital treatment, irrespective of their status. The centre would provide the patient with food, nursing, and all equipment for efficient treatment, but not with medical attendance, which would be paid for either by the patient, or through some method of insurance, or by the Health Authority. The centre would also contain a common room to serve as a meeting place for the general practitioners of the district, and for the storing of clinical records on a standardized system. Not all these various departments would be established at once at all the smaller centres, and it is hoped that the more fully equipped centres would render aid to those less well provided.

The primary health centre would have preventive as well as curative functions. The communal services, such as those for pre-natal care, child welfare, physical culture, and the examination of suspected cases of tuberculosis, would be gathered together at the primary centre. Domiciliary nursing is recognized to be an essential part of a health service, and residential accommodation would be provided at the primary centre, not only for nurses employed in it but also for those working in the district it serves and for midwives. An essential feature of the scheme is that the primary centres should be staffed by general practitioners, but that there should be opportunities for obtaining the assistance of consultants and specialists on the staff of the secondary health centres, who would attend at fixed intervals or make a special visit in an emergency. In suitable cases, of course, patients would be transferred to the secondary centre, and the scheme contemplates an ambulance service to maintain communication, on the one side between the home and the primary centre, and on the other between it and the secondary centre.

The dental clinic forming part of the primary centre would have a staff of visiting dental surgeons employed

* H. M. Stationery Office: through any bookseller, price 1s. Messrs. Eyre and Spottiswoode, East Harding Street, Fetter Lane, E.C.4, will supply a copy post free on receipt of a postal order for 1s. 3d. (under the new postage rates.)

either on a part-time or whole-time basis. It would provide for patients of all ages all ordinary treatment, including extractions under anaesthesia, conservative dentistry, the treatment of inflammatory infections of the jaws and gums, simple orthodontal cases, and the fitting of dentures. Where possible the present school dental service would be transferred to the clinic.

In the scheme the work of the general practitioner would be partly domiciliary and partly institutional, for at the primary centre he would treat such of his patients as attended or were referred to him there; in this way it is hoped to secure the advantage of organization, combined with the preservation of liberty of thought and action. The alternative of a whole-time salaried medical service was carefully considered by the Council, but the report expresses its conviction that the public would be serious losers by the adoption of such a plan, for the clinical worker, especially if a general practitioner, requires a knowledge not only of the disease, but of the patient. His work must be individual. The confidence of the patient, which is of vital importance to treatment, must rest not only on sound knowledge, but on personal harmony. On the other hand, it was considered that laboratory workers and medical administrators who do not come into personal contact with the sick could with advantage be paid entirely by salary.

As has been said, it is proposed that there should be accommodation for communal services at the primary centres; each communal clinic would be directed by a doctor, or more than one, practising in the area who had specially qualified himself for the post. The directorships of these communal services would be part-time posts, and paid on that basis. The report expresses the opinion that as a beginning it might be possible in many instances to adapt existing buildings, such as cottage hospitals or Poor Law infirmaries, to the purposes of a primary health centre, but extensive alterations to buildings are deprecated, since the adapted buildings could only be makeshifts. Health centres and hospitals require adequate ground to permit of extension and for open-air clinics, convalescent treatment and physical culture. Many war memorial hospitals, it is said, are likely to be defective because their promoters have not made such provision and have failed to realize that a modern hospital should be part of a more comprehensive organization.

SECONDARY HEALTH CENTRES.

Secondary health centres must be situated in towns where adequate equipment and an efficient staff of consultants and specialists exist, and to which means of communication are convenient. The secondary, like the primary health centres, would have both a preventive and a curative side. On the latter their services would mainly be consultative; they would receive cases referred from the primary centres for diagnosis or special treatment. It is recognized that in some towns it would be necessary that primary services also should be rendered at the secondary health centres. The equipment of a secondary

health centre would provide general services (medicine and surgery), and special services of midwifery and gynaecology, ophthalmology, laryngology, rhinology and otology, dermatology, genito-urinary surgery, orthopaedics, and dentistry, and for radiology, electrotherapy, hydrotherapy, physical culture, massage, and nursing. They would possess also fully equipped pathological laboratories.

Existing institutions would form the nucleus for the curative services of secondary health centres, but as their functions were extended present buildings would not be large enough. Their accommodation might in many instances be supplemented by linking them with existing Poor Law infirmaries, the beds in the allied institutions forming one field of work for an associated medical staff. It is considered, however, that in many areas it would be necessary to establish complete and model secondary health centres, and that where possible they should be built on open ground just outside the town. Patients

referred from the primary centres would either attend the out-patient clinic of the secondary centre or be admitted as in-patients. The medical staff of the secondary centre would be responsible for their treatment, and every facility would be afforded to general practitioners to keep in touch with their patients while they were attending the centre, and to resume their supervision on discharge. The clinical consultants at the secondary health centres would attend out-patient clinics regularly to see cases referred to them, would attend the referred cases in the wards, would pay periodical visits to the primary health centres allotted to them, and would be available to make special visits of emergency in consultation with general practitioners to the primary centre, or, if necessary, to the home of the patient. These consultants would be paid on a part-time basis, with extra fees for special visits. The non-clinical consultants—pathologists, radiologists and the officers connected with the communal and preventive services of the secondary health centres—some of whom would be

SUMMARY OF RECOMMENDATIONS.

A. DOMICILIARY— including both curative and preventive work.

Personnel.—Doctors; Pharmacists; Nurses; Midwives; Health Visitors and other officers of the Health Authority.

B. PRIMARY HEALTH CENTRES— including Medical, Surgical, and Maternity beds; Out-patient Clinics; Dental Clinics; Accommodation for equipment needed for treatment and investigation; Accommodation for the work of Communal Services; Ambulance Service.

Personnel.—General Practitioners; Visiting Consultants and Specialists; Officers engaged in Communal Services; Visiting Dental Surgeons; Workers in ancillary services.

C. SECONDARY HEALTH CENTRES— including Facilities for curative services in cases requiring highly specialized diagnosis or treatment; Accommodation for the work of Communal Services; Dental Clinics; Accommodation for workers in ancillary services; Ambulance Service.

Personnel.—Consultants and Specialists; Officers engaged in Communal Services; Dental Surgeons; Workers in ancillary services.

D. SUPPLEMENTARY SERVICES— including Provision for facilities for specialized treatment of such conditions as tuberculosis, mental disease, etc.

Personnel.— Specialists in the appropriate forms of treatment; Workers in ancillary services.

E. TEACHING HOSPITALS WITH MEDICAL SCHOOLS— including facilities for treatment of cases of unusual difficulty; Facilities for Research; Facilities for Post Graduate Study (including training for Communal Services).

Personnel.— Consultant, Teaching and Research Staff; Workers in ancillary services.

F. and G. RESEARCH; CLINICAL RECORDS.

It is recommended that provision should be included in any scheme for (F) the encouragement of research, and (G) the operation of a system of standardized clinical records.

H, I, and K.—ADMINISTRATION.

Recommendations as to the principles of administration are submitted; H, The establishment of a single Health Authority to supervise the local administration of all medical and allied services, whether curative or preventive. I, Representation of the medical profession on each such authority. K, Establishment of Local Medical Advisory Councils.

whole-time officers, would also visit in a consultant capacity the primary health centres allotted. The members of the consultant services would in practice be on the staff of the hospital or the institutions associated with it; they would be appointed on the recommendation of a committee of selection, representing the medical profession of the locality, the health authority, the hospitals themselves, and the medical faculty of the university within whose sphere of influence the secondary health centre was. To be eligible for such an appointment the applicant must produce evidence of special training and experience, such as would be afforded by (1) special academic distinction and post-graduate study; (2) tenure of hospital and other appointments affording special opportunities for acquiring experience; and (3) local professional recognition of competence in a consultative or expert capacity. It is intended that general practitioners shall be eligible for these posts, and it is considered that their representation in the consultant services and on the staffs of the secondary health centres would be an advantage.

PAYING WARDS.

The report expresses the view that it would probably be advisable to provide private self-supporting wards at health centres. The reasons given are, first, that the plan would be conducive to efficient and economic working, and, secondly, that the more the serious cases are limited to one place the more time is a doctor able to spend in caring for them and the less in travelling. The essential services in the public and private wards would be identical. The charges in these private wards would vary according to the accommodation and local conditions.

PAYMENTS AT HEALTH CENTRES.

The report does not advise that curative services should be provided by the health authority free of charge. Illness, it is said, is a direct and personal concern, and the patient should contribute in some form or another to the cost of cure; experience shows that he is willing to do so. He could contribute only a portion of the cost, for efficient treatment will often be beyond the means of most citizens to provide in its entirety. It is recommended that standard charges should be fixed for treatment in the public wards and other curative services, but it is recognized that the charge might vary in different parts of the country. It is suggested that the charges would usually be met by some method of insurance, though private patients recommended by their doctors would have a right to avail themselves of the services by direct payment.

The standard rate of payment at a primary health centre would include residence, food, and nursing, but not medical attendance. At the secondary centre, acting in its consultant capacity, the charge would include medical attendance, and would be defrayed by moneys allotted to such services. The patient would possess the right of selecting the consultants and specialists assisting in his treatment, and in the secondary centre would be entitled to request additional advice from a consultant or specialist of his selection, the patient being responsible for the fee.

SUPPLEMENTARY SERVICES.

It is proposed that certain institutional services should be correlated with both primary and secondary health centres; as examples of these supplementary services the following are indicated: Sanatoriums for tuberculosis; recuperative centres (convalescent centres); hospitals for curable and incurable mental disease; institutions for the feeble-minded; epileptic colonies; orthopaedic centres; hospitals for certain infectious diseases.

VOLUNTARY HOSPITALS.

It is considered that the nucleus of a health centre, especially in a town, will be the existing voluntary hospital. The incomes of these hospitals are less and less commensurate with their needs, owing to the increased complexity of equipment now required, so that a patient to-day costs twice as much as a patient twenty years ago. The opinion is expressed that grants for equipment and maintenance of communal clinics would, with the pay-

ments already mentioned for admission of patients, bring much-needed assistance to voluntary hospitals without interfering unduly with their management.

MEDICAL SCHOOL HOSPITALS.

Where possible every secondary centre should be brought into relation with a teaching hospital; the academic influence and the spirit of inquiry and progress associated with such a hospital would permeate the system of secondary, primary, and domiciliary services within the allotted sphere of influence of the school or hospital. It would receive cases of unusual difficulty requiring specialized knowledge and equipment, and its laboratories and special departments would be a court of reference.

THE HEALTH AUTHORITY.

In the section of the report dealing with administration it is advised that a new type of health authority is needed to bring about unity of local control for all health services, both curative and preventive, and to ensure continuity of idea and purpose and a complete system of reciprocal communication between the associated teaching hospitals, secondary centres, primary centres, and all domiciliary services, whether in town or country. The Council states that it has not been able to arrive at any final opinion on the question whether the new health authority should be an independent body set up for the purpose of administering health services alone or whether it should be a statutory committee of an existing local authority. It is, however, laid down that the success of the health service will depend upon the co-operation of the medical profession, so that its members must play a responsible part in the administration of the health authority. It is therefore recommended that the medical profession should be represented on the new health authority, and that a local medical advisory council should be associated with each such authority. It is recommended that the members of the authority should,

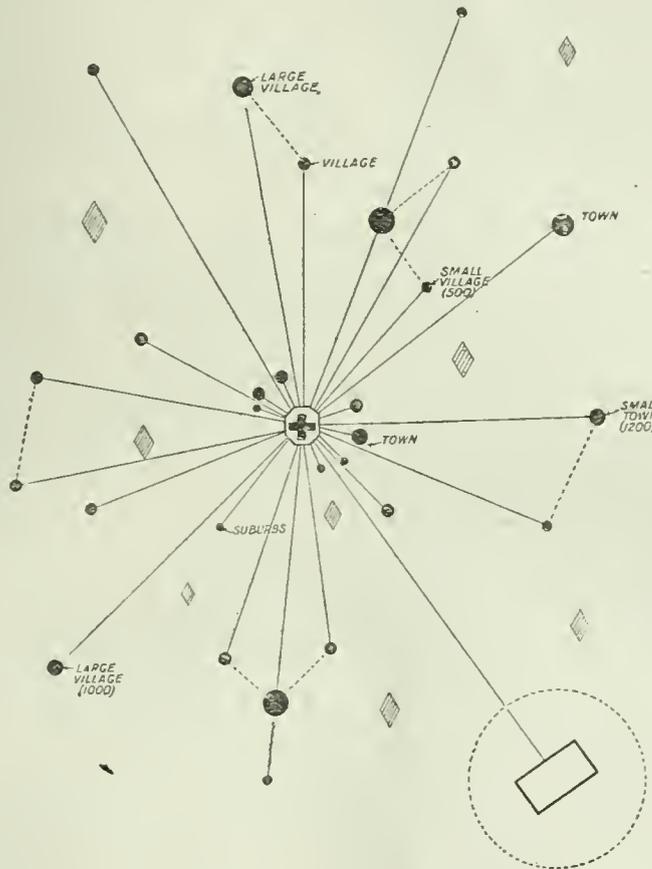

DIAGRAM OF AN AREA SHOWING HEALTH SERVICES.

The rectangle within a dotted circle indicates a teaching hospital with medical school; the black cross within an octagon, a secondary health centre; the black circles, primary health centres; the diamond-shaped figures, supplementary services.

as to two-fifths, be medical representatives nominated by the local Medical Advisory Council and other persons specially skilled in health questions; the other three-fifths of the authority would be representatives elected by popular vote.

The local Medical Advisory Council, it is recommended, should consist of ten to twenty members, according to the needs of the area. The members of this council would be elected periodically by and from among all the registered practitioners resident in the area by means of a postal vote conducted by the Health Authority. The principal medical officer and the two chief assistant medical officers would be *ex officio* members of the advisory council. The council should have power, for special purposes, to appoint committees, which would have the right to co-opt persons specially skilled in the subject under consideration. The Health Authority would be expected to invite the advice of the local Medical Advisory Council, which would be in a position to act as a medium for communicating to the Health Authority the collective opinion of the practitioners in the area.

MEDICAL OFFICERS OF THE HEALTH AUTHORITY.

The duties and responsibilities of the chief medical officer to the Health Authority would be more extensive than those possessed by existing medical officers of health, and it is therefore proposed that he should be called the Principal Medical Officer. He would be the administrative head of the medical services in the area of the authority and would have two chief assistant medical officers, the one specially concerned with the administration of the curative, and the other more especially with the preventive service. Under these would be assistant medical officers, their number varying with the size and needs of the area concerned. On the staff of the Principal Medical Officer would be the principal dental officer, principal matron, and so on.

LABORATORIES.

A sketch is given of a scheme for laboratory services. The first and essential function of the laboratory at a primary centre would be to give facilities to the general practitioner; it would be so equipped as to enable him personally to make any examinations he desires to undertake. The equipment would be supplied from the secondary centre and adapted to meet any increase in knowledge, skill, and interest displayed by the practitioners concerned. Some person must be placed in charge of such a laboratory; it is thought that his qualifications might vary with the size, geographical situation, and special needs of the centre. At the smaller primary centres the part-time services of a moderately skilled attendant might suffice; at larger primary centres persons with more training should be provided, and it is suggested as a matter for consideration whether, in certain cases, such persons might not combine the duties of the pharmacist with those of the laboratory worker. At the largest primary centres two laboratory workers might be required, especially at centres far remote from a secondary centre, to report, at least provisionally in case of urgency, as, for instance, when diphtheria is suspected. It is suggested that the laboratory workers at the primary centres should spend occasional periods in the laboratory of the secondary centre, for the improvement of their knowledge and skill. The responsibility for staffing primary centres would lie with the director of the laboratory of the secondary centre. In case of emergency, as on the outbreak of an epidemic, it would be possible to concentrate laboratory assistance in the locality by the transfer of workers. Certain types of work, as for instance histological examinations, might as a matter of routine be sent to the secondary centre. When materials must be taken from the patient, especially when quantitative methods are involved, a visit by a consultant might be necessary. The laboratory of a primary centre must be in communication by telephone and by motor transport with the related secondary centre.

The laboratory of a secondary centre should provide ample accommodation and equipment, and its senior staff should be highly qualified to do clinical laboratory work, both for the primary centre and for the hospital of the secondary centre; it would also do post-graduate teaching. The head of the laboratory would be a well qualified pathologist, and the staff would comprise specialists in morbid anatomy, bacteriology, and pathological chemistry. Some of the assistants would be preparing for the higher posts in the service; others, in an intermediate class, would furnish recruits for the staff of the primary centres.

The laboratory of the secondary centre would be linked with the chief or university centre, which would have a special laboratory for health services distinct from a professorial department, though in close contact with it. A separate health services laboratory would protect the academic staff from routine, leaving it free for teaching and fundamental research work. The staff of the health services laboratory would be recruited from that service and be dependent upon meritorious performance within it. At the same time it is recognized that no rigid barrier should be erected between the academic pathologist and those engaged in the health services. Though there would be two distinct careers circumstances would often cause individuals to pass from one to the other.

The health services laboratory of a university centre, in addition to the routine work, would carry out the more difficult investigations referred to it from the subsidiary centres, but it might also undertake much of the routine work for the university hospital. The director of such a

laboratory would rank with a university professor, but would usually be a distinguished pathologist with tastes inclined to organization and administration rather than teaching.

RESEARCH.

With regard to research, it is suggested that the organization throughout the proposed health service would facilitate inquiry into the causes of disease. It is suggested that the facts showing the need for inquiry might often be brought together in the first place by the medical practitioners in a locality; the manner in which it should be further presented would depend upon the subject, but research into fundamental problems would still continue to be conducted through the university and the Medical Research Council. A national organization of laboratories in touch with every branch of the health services would, it is believed, provide opportunity for systematic investigation and team work. The director of the health services laboratory at the university centre would be in a position to start machinery for the intensive investigation of any urgent problem, and with the goodwill of the general practitioners the investigation would include cases never available in the wards of a hospital. In particular, the earliest stages of disease might be made the subject of organized research, which, it is hoped, might be subsidized and perhaps supervised by the Medical Research Council.

DENTAL SERVICES.

The object of dental treatment is to secure normal formation of the jaws and dental arches and a clean and healthy mouth. While many of the impediments to the attainment of this ideal are to be found in pre-natal conditions, others are due to the environment of early childhood; the ill effects of dental disease and oral sepsis in adult life are well recognized. As dental treatment, therefore, comes into close relation with medical care, a dental clinic should form part of every primary health centre. It would provide ordinary treatment for young children under school age, school children, expectant and nursing mothers, and for the adult population generally. It would be staffed by one or more dental visiting surgeons, and a dental service would be attached to each centre.

At secondary health centres there would be similar dental clinics, but on a larger scale, especially as regards the fitting of artificial dentures, which would be made in an attached dental laboratory. Its staff would consist partly of part-time officers and partly of visiting dental surgeons, and it would have a staff of nurses and mechanics. Members of the dental staff would act as consulting dental surgeons at the primary centres, to which they would pay periodic visits. Arrangements should be made for the dental treatment of all persons admitted to convalescent homes, sanatoriums, and other institutions belonging to the supplementary services. All forms of dental treatment provided at the clinics of the primary and secondary health centres would be regarded as part of the necessary medical treatment, and would be arranged on an insurance basis or according to a scale of fees. The remuneration of dental surgeons would be on a time basis, and it is suggested that arrangements might be made to use the clinics for private patients. The payment of dental surgeons for consultations would be on the same basis as that of other consultants.

MATERNITY AND CHILD WELFARE.

It is the intention of the Council to appoint a committee to consider details of maternity and child welfare services, but the report contains an outline of what it is considered should be provided. The services would be domiciliary and institutional, the latter being given in primary and secondary health centres and teaching hospitals.

The domiciliary treatment would include advice and treatment for pregnant women unable to attend the health centre, and provision for attendance at the labour at the woman's home. A doctor and a midwife should be available for every labour, and also when necessary an anaesthetist. A midwife trained to know when a doctor is needed would attend natural labours, and it is suggested that additional assistance might be obtained from a service of home helps, exercising carefully defined functions and working under proper supervision. Sterilized maternity outfits should be obtainable from a primary health centre, and a practitioner should be able to

summon an expert obstetrician with the necessary assistance and outfit in a case of difficult labour. The service should also include the supervision at the home of the welfare of mother and infant and any necessary medical attendance, should the mother be unable to attend at the primary health centre.

The institutional treatment provided at the primary health centre should include beds for labour and after-care and arrangements for isolating any case of sepsis after delivery. The number of beds available for ante-natal, maternity, and post-natal cases would at first be limited, but should be increased by adding to the centre or by a separate institution, should the demand arise. The services of a consultant from a secondary centre would be available. Women suffering from gynaecological disorders, the result of child-bearing, would either be admitted to the wards of a primary health centre or sent to the secondary centre, being treated as in-patients or out-patients, as the practitioner might determine. The residential accommodation should make it possible for mothers to be accompanied by their infants, and an infant welfare department should be part of the primary centre.

STANDARDIZED CLINICAL RECORDS.

It is proposed that a uniform system of records of illness should be established and filed on the card index method. At the primary health centres they would be simple to avoid an undue tax upon the staff, but at the secondary health centres and teaching hospitals the aim would be to have a complete record, clinical, pathological, and communal. When a patient was transferred from one centre to another a copy of the record would accompany him. It is advised that an officer should be appointed at each secondary health centre and teaching hospital to take charge of the records, which it is believed would be very valuable for research into the nature of disease and the results of treatment. General direction would be in the hands of the teaching hospital, subject to the final control of the Ministry of Health in consultation with the Medical Research Council.

PHYSICAL CULTURE.

After reference to the policy of the Board of Education with regard to physical education in the schools, the Consultative Council expresses the opinion that every community should possess grounds for physical training, provided and maintained at the public expense, and so planned as to meet the needs of children, adolescents, and adults. It is recommended that a doctor specially skilled in the subject should be attached to each secondary health centre to supervise the work and training of masseurs and masseuses, and to act as consultant and adviser throughout the area. It is pointed out that though at present there is provision for the training of women, there is no training college for men. The Council proposes to set up a committee to consider this question of physical culture.

RECUPERATIVE CENTRES.

The establishment of recuperative centres is advised to serve the double purpose of restoring persons to health, either after illness or before their ill health has become disease. Such institutions are declared to be essential to any scheme of medical service, and would, it is said, be a great field for preventive medicine and for the study of the early manifestations of disease. The site should be sufficiently large and in an open situation, but elaborate buildings would not be required. It is pointed out that the experience of the Army Medical Service during the war in the establishment and conduct of convalescent and rest camps will be of great value to the civilian organization proposed.

PREFATORY NOTE BY THE MINISTER OF HEALTH.

The following is the text of a note prefixed to the Report by the Minister of Health:

"1. This Report, the first to be received from the Consultative Council on Medical and Allied Services established under the Ministry of Health Act, 1919, is published in order to facilitate discussion of the questions raised in it.

"2. Action is being taken by the Minister of Health and the local authorities in relation to a number of matters

touched upon in the Report; and proposals for action in other directions are in process of formulation.

"3. Many of the Council's recommendations must necessarily be considered in relation to a comprehensive policy for the extension and development of health services (including the question of the future administration of services at present entrusted to Poor Law authorities), which will be submitted to Parliament by the Government in due course.

May, 1920.

C. ADDISON."

MEDICINE AND THE STATE.

THE PRESIDENTIAL ADDRESS TO THE SECTION OF STATE
MEDICINE IN THE BRUSSELS CONGRESS OF THE
ROYAL INSTITUTE OF PUBLIC HEALTH,
MAY, 1920.

BY

THE RIGHT HON. LORD DAWSON OF PENN, G.C.V.O.,
K.C.M.G., C.B., M.D., F.R.C.P.

It is a convenient opportunity to pass briefly under review the relations of the medical profession to the State. These relations have undergone considerable changes during the last ten years, owing to a growing sense of the importance of health and the responsibility of the State thereto. This has led to a considerable extension of the activities of the State, and chiefly into the domain of curative medicine, and these extensions have been made one by one in answer to specific public need or demand rather than in accordance with any predetermined policy. There is further in contemplation the systematic provision of medical services for the use of all members of the community. I am omitting reference, for my present purpose, to either the public health service with its high and ever-growing reputation, or to the Poor Law, which by common consent should be superseded as unsound in principle and ineffective in application.

In 1912 the State, through the machinery of the Insurance Act, made organized provision for the medical care of three-quarters of the heads of families in the country, and, for the purpose of such treatment, supplements the contributions of the insured persons to the extent of over five millions annually in England alone. These rights are confined to manual workers and to persons earning not more than £250 per year—that is, they are determined by the occupation and the economic position of the patient. In other words, it is a service open to a limited class for all ordinary illnesses.

But the State is further providing, step by step, for a growing list of illnesses and disabilities, such provision being open to all citizens, irrespective of their economic position. To mention examples. It is the duty of the Local Education Authority to inspect medically and provide medical treatment for the children in elementary and continuation schools, and it is empowered to set up clinics and provide doctors, dentists, and nurses for this purpose. The local authority (county or county borough council) is responsible for the diagnosis and free treatment of tuberculosis; under the Act of 1917 it may provide clinics for the free treatment of venereal disease, and may pay for the travelling expenses of patients.

The latest example is furnished by the Maternity and Child Welfare Act of 1918, whereby the local sanitary authority is empowered to maintain maternity and child welfare centres, maternity homes and hospitals, and convalescent accommodation with the necessary provision of doctors and nurses and health visitors for both mothers and infants. It is easy to see that extension of these *ad hoc* services would soon embrace a large part of medical practice. It is a State medical service by instalments, almost by stealth, and before we go further it would be well to take stock of the position, and define our policy.

Underlying both these types of provision of medical services is the public opinion that the health of the people, like the education of the people, is of supreme importance to the State; that the best means of maintaining health and curing disease should be made available to all citizens; that such means need to be organized and distributed according to the needs of the community; and further, that the cost, being beyond the capacity of most citizens to provide, must be partly or wholly borne by public funds.

The first of the above organizations—namely, that of

the Insurance Act—is open to a limited class for all ordinary illnesses; and the second to all classes for some illnesses. As regards cost the first is contributory, and the second is free. In their functions they overlap; in their local administration they are disunited.

How far does each of them afford guidance for the development of medical services in the future?

With regard to what I may call the *ad hoc* services—such as those for maternity, school children, tubercle, venereal disease, etc.—these have the advantage of being adequately provided both in fabric and in personnel, but as at present constituted they are isolated units of effort, tending to be aloof from the medical practice and doctors of their district. It is a most important principle that the health services of a district should, wherever possible, be staffed on a part-time basis by the doctors practising in that district. The more the general practitioner is identified with the health of his community, and the more, through him, the correlation of preventive and curative medicine is realized, the better for the public interest. The staffing of these services by whole-time specialists narrows the scope of the general practitioner's work and discourages his ambitions, for it cannot be too much emphasized that to get good men one must provide good work.

The Insurance Act brings medical attendance within the reach of large masses of the population, and maintains freedom (of choice) for both doctor and patient. Its organization is widely distributed, but its service is restricted to certain classes of the community, is exclusively domiciliary, and is devoid of the complete equipment of both personnel and material necessary to that efficient service which the doctors desire to give and the public should receive. This is no criticism against insurance as such, but against its existing imperfections.

Seeing that some system of insurance is the only practicable alternative to entirely free provision of all medical services, there is no general desire on the part of either the public or the medical profession to destroy the present insurance organization, under which over 80 per cent. of the doctors of the country are doing medical service. There is, however, a strong desire to remedy its defects and extend its provisions.

Surely the wise course is to fit and mould the insurance organization into the larger scheme of systematized medical service, which, if the health of the people is to be secured, must be set up and made available for all sections of the community. Just as education requires schools and colleges, as well as teachers, so does the health of the people require clinics, hospitals, laboratories, and such like provision, as well as doctors, distributed according to the population and its needs.

But the parallel between education and health cannot be carried further, and therein lie many of the difficulties in health administration. The teacher is a salaried official, and his sphere of work and his pupils are allotted to him.

The problem of health provision is more complex, in that the people who have to be provided for are of all ages, are sick, and in large measure require individual attention in their homes as distinct from collective attention in institutions. Education is concerned with healthy youth, which is still under external control, though even here it is no uncommon experience to find a pupil who learns under one master while failing to learn under another, owing to some temperamental antagonism.

The sick person is intensely individual, and requires, besides knowledge, the support and confidence which comes from temperamental harmony between doctor and patient. From the point of view, therefore, of the patient, the voluntary association between him and his doctor should not be lightly put aside. It is a privilege highly valued by the people, as shown by the widespread demand for free choice of doctor.

Moreover, this voluntary association is of equal importance to the doctor and his work. It stimulates effort, encourages initiative, and the taking of responsibility. If a patient is allotted to a doctor under a State service, there is loss of the stimulating force of rivalry; responsibility is apt to be transferred rather than undertaken, and advancement is as likely to follow seniority and general flexibility as efficiency and enterprise.

Another difficult question is, whether health services should be entirely free or partly paid for. Let us not begin by trying to make everything free; we may easily get

something stereotyped and shoddy if we do. An early attempt to make everything free would cause much strain on public funds, reaction would follow, and so starvation and inefficiency of the services would ensue.

Why not let a tariff of charges be fixed for various kinds of services? Experience shows that the people are far from unwilling to contribute towards treatment of their illnesses. What they want to get rid of is the idea of charity associated with health institutions.

In practice, systems of insurance will most often secure the cost—not individual payments: and no doubt when an organized health service has been set up by public authority, the insurance companies of high standing will institute policies for health and against sickness, of which the middle classes will largely avail themselves. Those who are in misfortune, and devoid of means, could be paid for by charitable or public funds.

The foregoing remarks apply chiefly to curative services. With many preventive services the advantages to be received are more contingent and less obvious, and therefore would be unwillingly paid for, and consequently evaded. Such services should be free.

As regards payments to doctors, disturb the present system as little as possible, and leave the relation between doctor and patient free. If medical services are to be made available to all citizens, new and extended organization will be required, and all such health services will need to be administered by one local health authority in each area. On this authority the medical profession, as such, should be represented. Its responsible connexion with the administration will give to that administration the skilled guidance necessary to success, and ensure the confidence of the doctors as well as the public.

The principle of strengthening local governing bodies by adding to their membership non-elective or indirectly elected elements, has been adopted for many years, and in recent times has been employed to secure to the community the advantage of expert advice. For example, in the case of education the local authority was required to include in its Education Committee a minority of co-opted members skilled in education.

It is obvious that with the increase of knowledge, and especially with matters so technical as those connected with medicine, expert representation on the health authority is essential to efficiency. The majority of such expert members would be medical men, who would advantageously be nominated by the doctors resident in the district concerned. This plan has a precedent under the Scottish Education Act of 1918.

The responsible association of the medical profession with the health of the community would be productive of nothing but good. It would bring to health administration throughout the country the skilled knowledge necessary to sound judgement. On the other hand, it would strengthen the corporate life of the profession, increase its power of collective expression, and develop its civic sense.

The bringing of the knowledge of skilled callings to the aid of Government has shown further development in recent years by attaching advisory bodies to central administrations. Such bodies have been set up by statute in connexion with the Board of Education, the Ministry of Agriculture, and, more recently, the Ministry of Transport.

The Ministry of Transport Act, 1919, directs that certain advisory committees shall be set up; it prescribes a procedure which aims at making these committees representative, independent, and influential. In illustration the following paragraphs may be quoted:

1. For the purpose of giving advice and assistance to the Minister with respect to and for safeguarding any interests affected by the exercise of the powers and the performance of his duties under this Act in relation to roads, bridges, and vehicles and traffic thereon, a committee (hereinafter referred to as Roads Committee) shall be appointed.

2. The Roads Committee shall consist of not less than eleven members, of whom five shall be representative of highway authorities, appointed after consultation with such authorities, and five shall be representative of the users of horse and mechanical road traffic, appointed after consultation with the interests concerned, and one shall be a representative of labour appointed after consultation with the interests concerned.

The Act of Parliament which constituted the Ministry of Health approved and made provision for such advisory councils. "The Consultative Council on Medical and Allied Services" was constituted by the Minister to

represent as much as possible varieties of knowledge and experience, and in selecting the members the Minister asked advice of representative bodies in the medical profession.

The selection of the members of an advisory council presents difficulties. To be useful the size of the council must be limited, and the members must not only be individually suitable, but must form a good team. Direct election by all qualified practitioners would not secure an efficient council, and some method of indirect election or nomination would appear to be most appropriate.

The method of selection of the council and its representative character might at a later stage be improved, but the actual form the council has taken is of less importance than the principle it embodies. Such a consultative council attached to the Minister has within its proper sphere real power for good. It brings to the administration, in a responsible way, the views of the profession outside, and has the power to initiate advice. It is the principle of vocational representation applied to administration.

The usefulness of the Consultative Medical Council will depend on a comprehension of its proper functions. It should be acquainted with the lines of policy pursued by the Ministry, and have opportunity to influence that policy. Its chairman should be in the inner counsels of the Ministry, and be a member of all important departmental conferences which are concerned with policy rather than details of administration. Such co-operation between the Consultative Medical Council and the administrative staff should be of mutual advantage, and it need hardly be said that the ultimate responsibility for decisions would always rest with the Minister.

As the provision of medical service extends, the Ministry of Health will have increasing control over medical policy, and therefore over the medical profession, and this influence will be enhanced by the power of the purse. It is undesirable that the centre of gravity of a learned profession should be in a Government department, and the application of the principle of vocational representation would be a counterpoise to this tendency. Professions, like nations, have need of self-determination.

Reverting, in conclusion, to the general aspect of this question, the growing recognition of the necessity and desirability of vocations being represented in the spheres of government and administration is no doubt due to the increased range and technicality of the knowledge on which they are based, and to the advantage of securing the confidence of the members of the calling concerned. No body of departmental advisers, however able, could alone envisage all the problems which arise, and their bearing on different interests concerned. The supplementary information and advice of responsible advisory councils cannot fail to be advantageous, and would, if needful, be a useful corrective to bureaucratic tendencies. Vocational representation is, I venture to think, likely to play an increasingly important part in Government.

THE MANCHESTER RADIIUM INSTITUTE.

RESULTS IN CANCER.

The report by Dr. Arthur Burrows of the Manchester and District Radium Institute for 1919 deals generally with the 677 cases treated during the year, but lays special stress upon the radium treatment of cancer of the mouth and carcinoma of the cervix of the uterus.

Dr. Burrows states that hitherto radium therapy of carcinoma of the tongue, floor of the mouth, fauces, soft and hard palate, tonsils, and pharynx, has been looked upon as unsatisfactory. Until recently it was often doubted whether this treatment was worth while attempting. In discussing the general conditions known to be adverse to successful radium treatment it is said that as regards the mouth these include: (1) Large tumours with extensive infiltration; (2) deficient blood supply which produces a tendency to sloughing and ulceration; (3) the frequent involvement of bone; (4) the tendency to rapid dissemination; (5) the persistent purulent and inflammatory condition, usually a septic reaction, which sometimes follows the application of radium. In reviewing the conditions in which radium is often used, the report reads as follows:

The conditions which respond best to radium treatment are rodent ulcer, carcinoma of the skin, carcinoma of the breast,

carcinoma of the cervix of the uterus, carcinoma of the body of the uterus, endothelioma of the parotid gland, and sarcoma of the nasopharynx; a noteworthy feature being (with two exceptions) "accessibility." It would almost seem as if carcinoma of the cervix of the uterus is particularly responsive, as good results are reported from many varying methods of application. Examples of those growths which do not respond well as a rule are carcinoma of the rectum, melanotic sarcoma, and carcinoma of the mouth. Certain conditions, such as cancer of the larynx, oesophagus, and bowel, suffer markedly from the evil of inaccessibility.

The disappointments hitherto met with in cancer of the mouth have been so great that in many instances patients have been advised that radium treatment is inapplicable and useless. In view of this report and the results obtained by Dr. Burrows with the latest method the position needs reconsideration. To quote again:

The technique is as follows: After boiling one or more capillary emanation tubes of a strength of two to eight millicuries, the number of tubes varying with the size of the tumour, they are introduced into the growth by means of a large exploring syringe needle and stilette. The distance between them must never be less than one centimetre, nor must they be placed near to healthy tissue or bone, otherwise a painful reaction will follow. No attempt is made to remove the tubes unless one projects and is uncomfortable, when it may be taken out twenty-four hours or more after the application. To prevent sepsis the mouth should be cleansed before the application. If the rules for avoiding healthy tissue and bone are observed, a practically painless reaction will often follow. If adequate dosage is employed, it may not be necessary to give a second application, and, as a rule, in successful cases two or three is a maximum number. The three desiderata are therefore: (1) A method of application of radium to which cancer of the mouth is susceptible; (2) a treatment which needs little repetition and may be painless; (3) the element of sepsis is diminished or may not be of much account.

Following on this the question of the treatment of metastases is discussed. Glands with some mobility or a good blood supply, if not too large, may be treated by burying, for six to forty-eight hours, emanation tubes of 10 to 25 millicuries, screened by three-tenths of a millimetre of platinum or seven-tenths of silver; in addition, tubes should be buried along the course of the cervical lymphatics. Further, it is suggested that the neck area should be irradiated repeatedly from the outside by either radium or x rays. In cases in which very large or ill-nourished masses are present, too small a dose may produce no effect, and too large a dose sloughing, without any ultimate benefit to the patient; that is to say, no good result follows on the use of radium only. In such cases the only hope, and that a slight one, is to remove surgically, so far as can be safely done, the main or central mass of the tumour and treat the growth remaining by burying radium tubes in it. Among the cases related in the report are the following:

A male with a twelve months' history presented himself with a flat growth occupying the posterior two-thirds of the left side of the tongue, nodular and ulcerated. There was considerable induration, but no enlarged glands. Microscopically the growth was found to be carcinoma. In March, 1919, six unscreened emanation tubes, each of a strength of 2.5 millicuries, were buried in the growth. The reaction was practically painless. In the beginning of May the tumour was considerably smaller and flatter, and the improvement continued for some time. In July eight more unscreened emanation tubes, each of a strength of 2 millicuries, were inserted in the tumour. The reaction was again painless, and after it had passed off no growth could be palpated, but some scar thickening remained. The patient has remained in the same condition until the present time—a period of five months.

A second case had had a portion of the tongue removed for carcinoma in October, 1918. In March, 1919, he had a soft fungating swelling along the left side of the jaw with induration beneath. It was adherent to the jaw. No glands were palpable. Five unscreened emanation tubes, each of a strength of 3 millicuries, were buried in the tumour. The reaction was very severe, and the patient had much pain, with a considerable amount of sloughing. The jaw remained painful till July. In December, 1919, the pain had gone, and the patient was well, and no sign of growth could be found.

These cases are typical of those quoted in the report, and indicate the lines on which the treatment is being carried out and developed, and the results which are being obtained. The methods appear to be a distinct step forward in the treatment of an extremely unpromising condition. The report includes a description, illustrated by drawings, of the radium emanation plant, and this part concludes with a series of tables classifying the cases and the results.

British Medical Journal.

SATURDAY, MAY 29TH, 1920.

THE REPORT OF THE CONSULTATIVE COUNCIL.

THE anxiously expected report of the Medical Consultative Council of the Ministry of Health has been published this day (May 28th). The Council when appointed last October was instructed to draft a scheme for the systematized provision of the medical services which should be available for the inhabitants of a given area, but the document now issued is described as an interim report, for it was felt that certain questions raised could not be answered without instituting special inquiries.¹ As it stands, however, the report is something more than a sketch, and the application of its recommendations would have a profound effect on the future of medicine in England.

The suggestion to establish a whole-time salaried service was considered, but rejected, because "by its adoption the public would be serious losers." Under the plan proposed the general practitioner would retain all the liberty he now possesses, his facilities for doing good work would be increased, and he would not, save in the case of certain special posts, be a salaried officer. On the other hand, the members of the staffs of the general hospitals would become part-time, or, in some instances, whole-time salaried officers paid out of public funds. Each of the new health authorities would have in its area, which we may think of as a county, a number of whole-time salaried officers, a principal medical officer, two chief assistant medical officers—the one to look after the curative and the other the preventive work—a staff of assistant medical officers, a principal dental officer, and a principal matron. Medicine would not be "established" like the Church, but would have a new hierarchy.

The general features of the scheme propounded are easily understood, and can be seen at a glance in the diagram reproduced at page 741. In a conveniently situated town in the area of a health authority would be a "secondary health centre," consisting of a fully equipped general hospital, with annexes on suitable sites for special classes of cases. Linked to this centre would be a series of "primary health centres" in small towns or villages, or in suburbs. The staff of these outpost institutions would consist of the general practitioners of the neighbourhood. They would have the right to claim the assistance, in consultation, of the members of the staff of the secondary centre, and to transfer to that centre such patients as they considered to be in need of its more elaborate equipment.

The cost of the application of such a plan as this is not discussed, and it is to be gathered both from what the report contains and what it omits that the Council considered that it would best fulfil its duties by putting forward an ideal, and we are authorized to say that it has striven to develop this ideal without greater disturbance of existing machinery than was deemed necessary. Looked at from this point of view we may regard the primary health centres of the report as corresponding to existing cottage hospitals, and the secondary health centres as the equivalent

of the voluntary general hospitals without teaching schools. From the detailed analysis of the report given at p. 739, it will be seen that the Consultative Council contemplates a great development of primary health centres. To start the scheme it is proposed to utilize existing cottage hospitals extended as necessary, and to bring into it such poor law infirmaries, and it may be assumed such sick wards of work-houses, as may be found suitable when the promised abolition of the poor law system is realized.

The report agrees with the Ministry of Health Committee of the British Medical Association that general practitioner domiciliary attendance and treatment is the only foundation on which any systematic provision of other kinds of treatment can properly be based; it agrees also as to the importance of providing dental treatment, such ancillary services as those afforded by nurses and midwives, an opportunity for obtaining the opinion of consultants and specialists, and in the primary or local health centres beds for institutional treatment and laboratory facilities. Shortly, it may be said that the Council and the Committee agree that the general practitioner should have not only greater facilities for treating his patients under the best conditions, but also for contributing to the progress of knowledge. This he would be able to do through the laboratory and other facilities to be provided, but, as we gather, mainly by being able to keep in touch with such patients as he may refer, for consultation or treatment, to the secondary centres and the teaching hospitals. He would be the person to decide that a patient should be so referred, and the patient on leaving the hospital would return to his care. The Council recommends that in all this he should be assisted by a careful system of clinical records, begun by himself and carried through by the various institutions to which the patient might go.

The primary health centre would contain wards of various sizes, with a nursing staff and provision for midwifery: it would provide also clinics properly equipped, in which doctors could see their patients and consult with each other: it is considered that the custom whereby each practitioner has his consulting room in his own house should be continued, but it is recommended that where a doctor cannot provide adequate accommodation at his own expense, as in certain congested areas, the Health Authority should have power, after consultation with the local Medical Advisory Council, to provide such accommodation at the primary health centre. It is said, also, that where local conditions and medical opinion favour the plan, collective surgeries might be tried, either attached to a primary health centre or set up elsewhere. On this point there would seem to be difference of opinion between the Consultative Council and the Committee of the British Medical Association, as the latter has deprecated the establishment of general practitioner clinics "under the aegis of the State."

Communal services, by which is to be understood such services as those already provided for pre-natal care and child welfare, inspection and treatment of school children, tuberculosis, and physical culture, would be conducted in or from the primary centre, and each communal service would be directed by a doctor practising in the area who had specially qualified himself for the post. These directorships would be part-time posts.

Primary health centres would vary in size: in addition to a dispensary and laboratory to be provided everywhere, a complete centre would have equipment for radiography and electricity, and a staff for massage and electricity; such a centre would be

¹ For particulars of these and other details see page 739 *et seq.*

pected to help smaller neighbouring centres. The pathological laboratory would be a place in which the general practitioner could himself carry out or supervise simple investigations such as, to quote the instance given, the identification of the diphtheria bacillus, but many other instances might be given. The pathologists of the secondary centre would be available for consultation. A laboratory assistant, however, must be available on the spot, and the Council admits that it is difficult to decide what his qualifications should be. It intends to appoint a committee to report on this matter, but seems disposed to suggest that the pharmacist might be trained to do this work. Similar considerations would apply to radiology and electricity. The pharmacist might be trained to be a competent laboratory assistant, but a proposal to entrust him with radiology or diagnosis and treatment would be very debatable. The final opinions of the Council on these matters will be awaited with interest not unmingled with anxiety. Those most competent to judge are confident that these advantages will flow from the establishment of these outpost laboratories, and it is important to avoid an initial mistake in organization.

Proposals of far-reaching character are made with regard to the staff of secondary centres; they would consist of clinical consultants and what may be called laboratory consultants. The former would be part-time officers, paid on a time basis, with extra fees for special visits; in addition to attending, as now, the out-patient clinics and wards of the secondary centre which they were attached they would be required to pay periodical visits to the primary health centres allotted to them, as well as special visits either to these centres or to the homes of patients in consultation with the general practitioner.

The recognition of the consultant status of the pathologists and radiologists at the secondary centre is a very commendable feature of the report. In addition to the duties ordinarily discharged by such officers now, they would pay periodical visits to the primary health centres in the area. The officers of the communal services at the secondary health centre would similarly act in a consultant capacity at the local centres. The Council agrees with the Committee of the British Medical Association that the test of eligibility to serve as consultant or specialist should be evidence of special training and experience, and the definition of such qualifications is identical with that put forward by the Committee. Finally, it is intended that the secondary centres should be related to a teaching hospital.

We do not find definite evidence in the report of an intention to limit to insured persons, as by some had been expected, the benefits that it is hoped will flow from the scheme. In the address delivered by Lord Dawson in Brussels (p. 743) he expressed the view that the wise course will be to fit the insurance organization into the larger scheme of systematized medical service which the Council he presides over has put forward. He contends that the voluntary relation between the patient and doctor is highly valued by the former, and of equal importance to the doctor in his work. Certain members of the Council, we are told, were of opinion that curative and preventive services should be provided by the health authority free of charge to every individual patient. The majority, however, considered that this course would impose too heavy a burden on public funds, and Lord Dawson, as will be seen, maintains that experience proves that the people are far from unwilling to contribute towards the cost of the treatment of their illnesses. It is

recommended that standard charges should be made in the public wards and for other curative services, though the standard might vary in different parts of the country, and it is suggested that the charges would most often be met by some method of insurance, though private patients recommended by their doctors would have the right to avail themselves of these services by direct payment. It is generally agreed that the facilities for in-patient treatment at present open to the intermediate middle class are insufficient in quantity, and too often in quality, and the Council in the Section on Secondary Centres proposes that health centres should provide private wards at charges varying according to the accommodation and local conditions, the patient being responsible for medical fees. It suggests that these self-supporting wards should be "part of the fabric of health centres." The point is not free from difficulty, and separate institutions on the plan of St. Chad's Hospital at Birmingham¹ may prove a better solution of at least part of the problem.

Brief reference is made in the report to what are called supplementary services, including sanatoriums for tuberculosis, recuperative centres, orthopaedic centres, hospitals for mental disease and feeble-mindedness, epileptic colonies, and hospitals for certain infectious diseases. We would be glad to see this subject more fully developed, for we believe that it will be through such ancillary institutions that the pressure on the beds in the centres may most efficiently be relieved.

As to the constitution of the Health Authority, to which reference has already been made, the members of the Council are not in agreement; some would prefer a statutory committee of an existing local authority—presumably the county council or county borough council: others desire an independent body, elected for the purpose of administering health services alone. However constituted, the Health Authority, it is suggested, should have control of both curative and preventive services, and in order to ensure the cordial co-operation of the medical profession it is suggested that it should be represented as such on the Health Authority, and that each Health Authority should have a local Medical Advisory Council elected by and from all the registered practitioners resident in the area.

At a first glance, at any rate, it would seem that the scheme in its full symmetrical arrangement will be more easily adapted to rural counties than to industrial areas. A plan on the lines indicated has been elaborated in a part of Gloucestershire: the secondary centre is in the city of Gloucester; it is associated with the medical school hospitals in Bristol, with a series of twenty-four primary centres, and with a number of supplementary institutions in the manner indicated in the diagram reproduced on p. 741. We take it that the Consultative Council hopes that some other areas may shortly follow the example of Gloucester, so that experience may be gained of the working of such a scheme as it has outlined. The note prefixed to the report by the Minister of Health may be read in this sense: for he says that action is already being taken by the Ministry of Health and local authorities in relation to a number of matters raised in the report, and that proposals for action in other directions are in process of formation, but adds that many of the recommendations must be considered in relation to a comprehensive policy, including the future of the services at present entrusted to poor law authorities. A bill embodying such a policy is to be submitted to Parliament by the Government in due course.

¹ See BRITISH MEDICAL JOURNAL, February 21st, 1920, p. 263.

THE STEWART PRIZE.

THE Stewart Prize of the British Medical Association was awarded by the Council, at its meeting on May 19th, to Miss Harriette Chick, D.Sc. Dr. Chick, who has been an assistant in the department of experimental pathology at the Lister Institute since 1906, has published numerous papers on bacteriology and physical chemistry. Her work on the laws governing the germicidal action of chemical agents and hot water form the basis of the knowledge of the process of disinfection, and her researches upon heat-coagulation of proteins and the salting out of proteins, made in collaboration with Professor C. J. Martin, afforded an interpretation of these phenomena in terms of modern physical chemistry. Dr. Chick has also made a number of other discoveries in the chemistry of colloids, more particularly concerning proteins. Recently she has been mainly occupied in dietetic questions, with reference especially to deficiency diseases. When, towards the end of 1915, there were indications that troops in certain theatres of war were suffering from beri-beri and scurvy Dr. Chick made a study of the literature and instituted researches, the importance of which was at once appreciated by the War Office and the India Office. Dr. Chick organized and directed a band of workers at the Lister Institute, who extended the observations of Cooper, previously carried out there, on the anti-beri-beri vitamins in various foodstuffs. From a consideration of the mass of data collected and provided the military authorities were able to select the most manageable additions to the diet of troops. Starting from an observation made by Professor Fürst in 1912, to the effect that the antiscorbutic principle of fresh vegetables was developed as soon as the germination of seeds occurred, it was demonstrated that the active principle was produced in quantity sufficient to be of practical use, and that it was therefore possible to prevent scurvy amongst, for example, Indian troops, to whom, owing to military circumstances, it might be impossible to supply fresh vegetables for a considerable period. The fact that this could be done without increase of transport was of great military importance, for it was shown that dry pulses, if carried unsplit and soaked for twenty-four hours prior to cooking, germinated sufficiently to produce the accessory body. The addition of germinated pulses to the dietary was the only antiscorbutic element available to the troops at Archangel during the winter of 1918-19. It was completely successful. Observations were also made on the antiscorbutic value, weight for weight, of fresh and of dried and preserved foods, including various vegetables, fruits, eggs, milk, and meat. In this way adequate data were afforded not only for deciding on suitable additions to the diet of troops under the circumstances mentioned, but also as to the additions which might properly be made to the diet of infants reared on dried or preserved milk. In the course of the inquiry the suspicion which had arisen in recent years on epidemiological grounds, that the lime juice issued to the army was ineffective in preventing scurvy, was confirmed, and by a historical research into old Admiralty papers it was shown that the lime juice issued to the navy with good effect since the beginning of the nineteenth century was not the juice of limes but of lemons, a juice much richer in antiscorbutic principles. The information obtained during the extensive researches of Miss Chick and her colleagues has not only been of great service during the war, but is of permanent scientific value. Every fact had to be obtained by careful experiments on animals, often prolonged for five or six months. In the autumn of last year Dr. Chick, accompanied by a colleague, Miss Dalyell, went to Vienna to give assistance to the medical profession there in regulating diets, and to ascertain by observations upon the population of that unfortunate city how far the results of the experimental work on animals are applicable to mankind. Dr. Chick

has been very successful in establishing friendly relations with members of the medical profession in Vienna. She has in consequence obtained every facility for study, and has been able to enlist many keen collaborators from amongst some of the prominent physicians of Vienna. This is the first occasion upon which the Stewart Prize which is awarded every two years for researches regarding the origin, spread, and prevention of epidemic disease, has been awarded to a scientific worker not a member of the medical profession, and the first time also that it has been given to a woman.

GREEK SCIENCE AND MODERN SCIENCE.

DR. CHARLES SINGER delivered his inaugural lecture as lecturer in the history of medicine in the University of London on May 12th. His subject was "Greek science and modern science," and he indicated certain respects in which they were similar and certain others in which they were in contrast. Greek science, he said, might be regarded as having had its origin among the Ionian colonies in the seventh century B.C. But even the very earliest Greek writings, some of which could be referred to that date, presupposed long generations of research and careful record and observation. The self-centred character of the Greeks had often been remarked upon. Their science was the fruit of individual minds, not the product of the social consciousness. An element of Greek thought which united the Greeks to us was their conviction of the existence of order. It was the Greek faith that order reigned in Nature. This was a most vital contribution to scientific thought. Such a trust in the reign of law was due to faith or intuition, not to observation. Greek scientific workers often blundered in observation, and their besetting sin was a habit of making sweeping generalizations on inadequate evidence; but their firm faith in order was their crowning glory. From such points of similarity between ancient Greek science and that of the modern day Dr. Singer turned to certain elements which separated the two. We had nothing like the habitual inter-relation of science and philosophy which the Greeks exhibited. It was an inter-relation which originated in the historical basis of Greek science as a department of philosophy. No people were more free than the ancient Greeks from theological and social prejudices. Modern science did not arise as the offspring of philosophy, nor did it form any alliance therewith until it had gained some strength of its own. In its earliest stages modern science applied itself almost exclusively to the solution of so-called practical problems. The mediæval limitations within which modern science was cradled undoubtedly worked far more harm than good, though there were certain elements in our science, such as specialization and practical applicability, which we owed, in part at least, to those limitations. Greek science, save in mathematics, contained an intolerable amount of speculation. A more striking difference between Greek and modern science was in technical treatment. It was sometimes said that Greek science failed because it was without instrumental aid, and this could not reach the degree of precision of modern science. But this begged the question. Why had the Greeks no instruments of precision? Instruments of precision were the product of scientific discussion. Modern science found its expression in the periodical issue of memoirs on special subjects. These papers had a constant structure. The problem was first stated, then the efforts of others to solve it were recalled, then the worker detailed his own experiments and observations, or some of them, described at greater length his final line of verification, and summarized his conclusions in a short paragraph. The scientific workers of antiquity proceeded on very different lines. They set down only their conclusions, but not their experiments. It was as though we had a collection of the last few lines of a series of scientific articles. The great defect of Greek

science was the omission to record the process, save again in mathematics. To the Greek it was the general principle which was important. The modern scientist knew that it was the conclusions which were the temporary and local accidents, and that it was the process which really mattered. In justifying his lectureship Dr. Singer said that the history of science had been neglected in this country. What there was of it, alike in science and in medicine, was too frequently allied with superficial biography, which seemed to take account of every department of a man's life except his mental processes. The breakdown of the educational system based on the old humanities made the history of science an almost necessary element in the curriculum. The history of science provided, along with other elements in the history of civilization, just that view of the mental history of the race which had been given by a study of the classics of Greece and Rome. We were well accustomed to recognize that the store of scientific knowledge was a general treasury from which all men drew, but it was not always remembered that the guardianship of that treasure had been in the hands of a very small company. The organic apparatus by which new knowledge had been created was the work of a mere handful in all countries and periods; and the contemplation of the conditions under which those men worked and lived must be of value, even in the practical and everyday sense, to those who would follow in their footsteps.

THE LEPROSY PROBLEM IN INDIA.

A CONFERENCE attended by forty-six missionary superintendents of Indian leper asylums (including six medical missionaries) and four medical Government delegates was held in Calcutta last February to consider the leprosy problem in India. The Conference, after sitting for four days, unanimously passed a series of resolutions; those dealing with medical matters were drafted by a committee of medical delegates. The resolutions affirmed that leprosy is slowly contagious, often by the discharge of the causative bacilli in the nasal discharges, even in early cases with no outwardly visible sores; that, although not directly hereditary, children are especially susceptible to infection from an early age; segregation, therefore, is the most effective measure for reducing the prevalence of leprosy. The committee unanimously endorsed the memorandum regarding the amendment of the Indian Lepers Act of 1898, which has been submitted by the Indian Auxiliary of the Mission to Lepers to the Government of India, and has been the basis of an amending Act recently introduced into the Imperial Legislative Council at Delhi. This will remove the absurdity of existing regulations which allow pauper lepers to be retained in leper asylums only so long as they have open sores; it will give further powers to control vagrant lepers and those engaged in certain trades, such as those connected with food supplies. After recommending facilities for training medical assistants in the diagnosis and treatment of leprosy, the Conference recommended that, in view of the fecundity of female lepers especially, the separation of the sexes is desirable as far as possible, and that any children born of leper parents should be separated from them at the earliest possible age; it recorded that a test by fourteen medical officers of leper asylums throughout India of Sir Leonard Rogers's treatment with sodium salts of unsaturated fatty acids had given most favourable results, 72 per cent. showing marked improvement in spite of the fact that most of the cases were advanced and the period of treatment had been comparatively short; further research into the treatment of leprosy was recommended, and arrangements for this have been made in Calcutta. The general resolutions recommended that pauper lepers ought first to be segregated in suitable settlements, as they are the greatest menace to public health; for owing to the numbers of lepers it does not appear to be practicable at present to

segregate all those in India, although it has been accomplished with excellent results in the Philippines. The Conference was of the opinion that this measure would stamp out the disease in India if it were possible to apply it. A series of papers on the treatment of leprosy read at the Conference have been published in the April number of the *Indian Medical Gazette*, and include one by Sir Leonard Rogers, summarizing his results to date and reporting further progress with his researches. He now records ten cases in which the lesions have remained completely in abeyance for from one to two and a half years; but does not claim to cure the disease. Sodium morrhuate has proved to be as efficient and more easily used than sodium gynocardate, a point which is confirmed by the trials in the leper asylums. This led him to make similar preparations from other oils with still higher content of unsaturated fatty acids, and one of these, prepared from soya bean oil, has already given even better results than the former drugs; it has the great advantage of being almost painless when injected subcutaneously, and thus promises to prove a further important advance in the treatment of leprosy. The field is now opened up to further researches on this line. If those recommended by the Conference should indeed result in still more effective treatment which can be carried out in the proposed leper settlements, this should prove a powerful incentive to these dangerous patients to enter them voluntarily. In this way it may well prove an important factor in the future control, and eventual extermination, of this loathsome disease.

PREVENTION AND TREATMENT OF INSANITY.

THE first of the Maudsley lectures, founded by the bequest of the late Dr. Henry Maudsley, was delivered to the Medico-Psychological Association of Great Britain and Ireland by Sir James Crichton-Browne, at the house of the Royal Society of Medicine, on May 20th. The lecturer expressed the hope that the Maudsley lectures would prove a means of extending the usefulness of the Medico-Psychological Association, and of disseminating knowledge of its work. He dissented from the suggestions that had recently been made that asylum medical officers in England were deficient in knowledge of advances in psychiatry; these officers had in proportion to their numbers produced more than their fair quota of sound progressive scientific work; and in the diagnosis, treatment, and study of insanity this country had nothing to fear from comparison with others. Changes and reforms were necessary, but none recognized this more clearly than the asylum officer. The medical staff in some of the large asylums should be reinforced and more liberally remunerated. It was of the greatest importance that facilities should be provided for early treatment of mental disorder. In connexion with asylum treatment legal formalities, intended for the protection of the liberty of the subject, had led, if not to an increase of lunacy, to an accumulation of lunatics. The national shrinking from certification had in many cases converted what might have been a transitory illness into a permanent infirmity. It was to avoid such calamities and to facilitate early treatment that Maudsley had supplied the funds for the Denmark Hill hospital. Sir James Crichton-Browne went on to say that he looked forward to the establishment in large towns of similar hospitals and clinics, where early cases could receive treatment without incurring the odium of having been in an asylum. He anticipated also an extension and an improvement of the out-patient departments of public asylums: it was in these institutions that the chief bulk of the insane would always continue to be lodged and treated. He believed that during the war, when medical examination was essentially physical, many men of unsound mind had passed into the army; had their mental condition been examined as thoroughly as their physical state, a startling amount of mental unfitness in the adult male population would have been demonstrated. In consequence of the reawakening of public opinion to the importance

of national health, and the formation of the Ministry of Health, with a medical head, prompt steps would be taken for the better housing and feeding, and for the physical training of the people, for protection against over-fatigue, and for the restriction of the ravages of preventable disease, especially venereal disease. All these measures would be reflected in the course of time in the improvement of national mental vigour and a diminution in certain forms of mental disease. Improvement was also to be expected as a result of the new Education Act, but in order that education might be made fully effective in the prevention of insanity and its neurasthenic and hysterical harbingers, it was necessary that much study of the growing mind should be undertaken by psychological experts.

TREATMENT OF CEREBRO-SPINAL FEVER.

To the report by Surgeon-General R. S. F. Henderson, Director-General of Medical Services, New Zealand, on the health of the men in training camps during 1918, Captain J. W. Crawshaw contributes an account of an epidemic of cerebro-spinal fever at Featherston Camp. There were thirty-six cases among an establishment of 5,600, with eight deaths; a meningeal variety with early loss of consciousness, and a septicaemic variety were observed. In twenty-three cases the meningococcus was found on lumbar puncture; in five others the spinal fluid showed polymorphonuclear leucocytosis; thirteen out of twenty-four cases—an unusually high proportion—had the meningococcus in the blood. The low mortality of 22 per cent. is attributed to the vigorous use of antimeningitic serum given intrathecally, intravenously, or subcutaneously in average doses of about 50 c.cm., 150 c.cm., and 100 c.cm. respectively; repeated lumbar punctures were made in chronic cases, and if a serum rash had appeared a vaccine was used. Captain Crawshaw records a mild septicaemic case in which the meningococcus was found in the blood, although the cerebro-spinal fluid was clear and contained no organisms nor excess of leucocytes. Believing that the blood infection is primary and that of the meninges secondary, he advocates early intravenous (rather than intrathecal) injections of serum. The occurrence of cerebro-spinal fever was contemporaneous with a severe epidemic of influenza, which began in July and reached its maximum in November, producing altogether 8,528 cases. There were 287 deaths: of this number, 9 were directly due to cerebro-spinal meningitis. In the four camps there were 55 cases of cerebro-spinal fever, which in 31 cases followed directly on an influenza attack. The clinical features of the influenza observed were very similar to those of the British and American epidemics. The influenza bacillus or a streptococcus was usually found; there was a certain amount of evidence of a partial immunity during the first few weeks after an attack. The systematic use of inhaling chambers, in which a vapour containing a 1 per cent. solution of zinc sulphate was breathed quietly for three minutes (preferably twice a day), was found to diminish the incidence of nasopharyngeal catarrh, measles, and diphtheria; though it did not altogether prevent influenzal attacks, it was thought to lessen the severity of the illness in those who were attacked. Inhalation chambers were installed, on troopships, and a lessened incidence of severe infection followed.

The dinner in celebration of the services of the Royal Army Medical Corps, and the eminent civilians attached to it, during the recent war, will take place at the Connaught Rooms on Tuesday, June 8th. Lieut.-General Sir Alfred Keogh, G.C.B., G.C.V.O., will be the chief guest, and among those who have accepted invitations to be present, as commanders of armies, are Field-Marshal Viscount French, Field-Marshal Earl Haig, Generals Lord Horne, Lord Rawlinson, Sir Ian Hamilton, and Sir Archibald Murray. The Right Hon. Winston

Churchill, Secretary of State for War, and other members of the Army Council will be present. Some forty hosts will preside at the different tables; the committee being Lord Derby, Lord Middleton, Lord Edmund Talbot, General Seely, the Right Hon. H. J. Tennant, and Colonel Sir Edward Ward, to whom all communications should be addressed at 10, Grosvenor Street, W.1.

The first examinations for the newly established diplomas in psychological medicine and ophthalmic medicine and surgery of the Royal Colleges of Physicians and Surgeons will commence on June 28th and July 26th respectively. Full information can be obtained from the Secretary, Examination Hall, 8, Queen Square, Bloomsbury.

Medical Notes in Parliament.

The Parliamentary Session.

THE Whitsun recess gives little opportunity of taking stock of the parliamentary session, but nevertheless marks an important stage. It is intended as the briefest of breaks, and after the House of Commons reassembles on Tuesday, June 1st, great matters will within a very short time have to be settled. Dr. Addison has succeeded in passing the National Health Insurance Amending Bill, and Sir Robert Horne has had similar success with the second Profiteering Bill. Mr. Chamberlain, too, whatever the view taken of his enthusiasm for a levy on capital, has strengthened his reputation for courage in pressing a necessarily unpopular budget through Parliament. Mr. Bonar Law, it may be added, maintains to the full his hold upon the rank and file of Government supporters.

The main interest at the moment is in finance and houses, and indirectly in the question whether there will be an autumn session, because on the latter point will depend the decision what measures are to be advanced through all stages this year. There is a feeling in the House—not confined to one side—that the unsettled condition of affairs abroad, and spasmodic labour troubles at home, make a long recess of four or five months undesirable; and it is held by those who argue thus that the power to summon Parliament quickly would hardly meet an emergency situation, as it is a dangerous weapon to employ, being liable to accentuate trouble, whereas a Parliament sitting or about to sit might be of some use.

What, however, will probably determine the issue is whether the Cabinet decides to adopt the war wealth levy scheme, which Sir William Pearce's committee has found to be "practicable," while carefully refraining from offering any recommendation concerning it. Bankers and other financiers, not necessarily hostile to a levy on war wealth, condemn such a proposal as dangerous to credit being put forward after the money has been so widely applied to business (when it has not been dissipated), and they also urge that hardship would be caused by the inevitably arbitrary boundaries, and the inability to distinguish thrift from war wealth despite qualifications. Against these considerations is Mr. Chamberlain's eager desire to cut down the war debt by a big sum. If he should carry the Cabinet with him in favour of the scheme, then a highly controversial bill will occupy much time, and, by delaying other matters, involve an autumn session.

In that event it is possible that the promised Health Services Bill may be presented and possibly passed into law this year. Weighted as he is with so many other responsibilities, Dr. Addison could not be expected to produce this in time for it to be dealt with in a session ending in this summer, if, indeed, it can be done at all this year. As for the Licensing Bill, which was mentioned in the King's Speech, the belief is that in any case only a short renewing measure can be contemplated this year; and it is doubtful whether the bills dealing with labour questions can be taken, as they mean the completion of a variety of negotiations. As things stand, the last stage of the Budget has still to be passed. The Rents Restrictions Bill was only introduced last week; the Bill to amend State arrangements for agricultural production as regards guaranteed prices and wages is also at first reading; the Milk Bill, the Census Bill, the Bill for Training and Assistance of the Blind, and a host of small measures have yet to be discussed all through in both Houses. Then, too, the additional grant, which is contemplated to assist the building schemes, will bring that very serious problem

of housing accommodation before Parliament again in its varied aspects. Altogether the business before the House of Commons is very considerable, and there are always contingencies that may bring fresh calls upon time. The hardest worked department of all is the Ministry of Health, and it certainly should have every sympathy and encouragement in its energetic efforts to make good in a few years for the many years of slow going by the Local Government Board of the past, when public support was not behind the vital interests of preventive and protective services.

Financial Difficulties of London Hospitals.—Sir C. Kinloch Cooke asked the Minister of Health, on May 19th, to make a definite announcement regarding the steps he was taking to meet the difficulty that had arisen in connexion with the finance of London hospitals; whether he was aware that some hospitals were even now unable to meet their current liabilities, and that unless relief by grant in aid was immediate they would have no alternative but to curtail their beneficent work, and possibly close down altogether. Dr. Addison said that he was in consultation with the various authorities concerned, but was not yet in a position to make any definite statement. He was well aware that the matter was pressing, and hoped that it would not be long before he could make a statement.

Blind Persons Bill.—The Blind Persons Bill, introduced by the Minister of Health in response to an undertaking given in the discussion of the bill proposed by Mr. Ben Tillett, was read a second time on May 14th. The aim, Dr. Addison said, was not only to deal with blind persons, but to prevent the occurrence of blindness. As a result of the work of the Advisory Committee on the Blind, the Ministry had a complete survey of the existing methods of dealing with blind people, and Mr. Barnes had consented to preside over a special inquiry to advise on the steps which should be taken to improve preventive services. The two main provisions of the Government bill are, first, that county councils or county borough councils shall have power to provide for the training of the blind; and, secondly, that the conditions relating to old age pensions shall become applicable to blind persons at the age of 50.

Indian Services.—In reply to a question by Mr. Lunn, on May 15th, the Under Secretary of State for India gave the following particulars of the approximate cost per annum of the increases of pay sanctioned in the Indian services indicated:

	£
Indian Civil Service	360,000
Indian Police Service	130,000
Indian Educational Service	100,000
British officers of Indian army and of British troops in India	1,700,000
Indian Medical Service	250,000

He did not propose to publish his correspondence with the Government of India, which was very voluminous. The usual course was for the Government of India to announce decisions by resolutions promulgated in India, and this was the most convenient procedure.

Opium and Morphine.—Mr. Montagu has stated that the acreage under opium cultivation in India in the year 1916-17 was 204,186 as compared with 144,561 in the year 1913-14. The quantity exported to the United Kingdom on Government account in 1918-19 was 2,400 chests, of the value of Rs. 20,11,230. There was no export to the United Kingdom on private account, and comparative figures for pre-war years are not available. Sir Robert Horne has given particulars of the export of morphine from the United Kingdom during 1919. The total quantity of morphine and morphine salts manufactured in the United Kingdom and exported was: To British possessions 20,237 oz., of the value of £21,913; to foreign countries 333,733 oz., of the value of £314,918. These figures do not include exports through the post.

Vaccinal Condition of Small-pox Carriers.—Mr. R. Young, on May 18th, asked for particulars of the vaccinal condition of various small-pox carriers in England and Wales in the year 1919, given on pages 87-90 and pages 126-129 of the Medical Supplement of the 43th annual report of the Local Government Board. Dr. Addison replied that the soldiers at Pontefract, Emry St. Edmunds and Chorley Wood had been vaccinated in infancy; the soldier at Lincoln had been vaccinated in infancy and apparently revaccinated while in the army, but the latter operation was not successful. The vaccinal condition of the soldier at Croydon was not known; there was no evidence to show that he suffered from small-pox. The person who introduced small-pox into Wisbech had been vaccinated in infancy, as had also the first known case at Southend (that of a child). A relative of the soldier at Bishops Stortford was unvaccinated, the other had been vaccinated in infancy. The three cases removed from the ss. *Porto* were aged respectively 35, 5½, and 4½ years; the first mentioned had been vaccinated in infancy, the last two were unvaccinated. The reason that this information was not given in the sections of the report to which Mr. Young referred was that they were not specially concerned with the vaccinal conditions of the patients. Particulars of the vaccinal condition of the cases of small-pox occurring in the country during the year 1918 were given on page 179 in Appendix C of the Report, and similar particulars appeared in the Medical Supplement of the Annual Report of the Local Government

Board for several years past. Dr. Addison stated, in reply to a recent question, that the year in which the highest percentage of children was vaccinated in England and Wales was 1881; the year of the lowest percentage was 1917; the number of deaths in England and Wales from small-pox amongst children under 10 years of age in 1881 was 1,078; there were none in 1917.

Veneral Disease in the British Army.—In reply to a question by Captain Elliot as to the case rate of veneral disease amongst the British army in the United Kingdom, France and Flanders, and Germany (occupied country) in the years 1918, 1919, and the first quarter of 1920, the Secretary of State for War said: The approximate ratios per 1,000 of admission for veneral disease are as follows:

	Ratio per 1,000 per annum, 1918.	Ratio per 1,000 per annum, 1919.	Ratio per 1,000 First Quarter 1920.
United Kingdom	43	59	14.8
France	32	67	40.5
Army of Rhine	—	46	42.3

The ratios for 1919 and 1920 are to a large extent fallacious owing to rapid demobilization. As I stated in my answer on May 11th, there has been a rise in the incidence of veneral disease amongst the troops in France and Germany, but I am glad to say that the latest information shows some improvement.

Importation of Condensed Milk.—Sir Robert Horne stated, on May 19th, that during the first four months of 1920 this country received 344,024 cwt. of sweetened whole milk, and 114,696 cwt. of separated or skimmed, and 125,934 cwt. of unsweetened milk. The United States contributed 245,959 cwt. of sweetened whole milk, 5,074 cwt. of separated or skimmed, and 123,317 cwt. of unsweetened milk. It was impossible to say what proportion of imports was of the standard composition defined by the Government chemist in his annual report, as only a limited number of consignments were sampled. The number examined in Government laboratories from January 1st to March 31st was 34. Of these, 4 were samples of unsweetened milk and they showed a range of concentration of from 2.35 to 2.42. Of 30 samples of sweetened milk 19 had a concentration less than 2.5 (range 2.06 to 2.49), and 11 had a concentration of 2.5 and over (range 2.50 to 2.90). The definition of the Government chemist was milk reduced to two and a half to three times its original bulk by the evaporation of water.

Central Research Institute, Hampstead.—Colonel Burn, on May 20th, said that complaints had been made by residents about the howling of a dog kept at the Mount Vernon Hospital, Frogna, Hampstead, and asked whether a licence for vivisection was held by anyone in the hospital. The Home Secretary said that no complaints on the subject had been made to him, and he was unable on inquiry to find any confirmation of the complaint. The place was not now a hospital, but the Central Research Institute of the Medical Research Council was registered under Acts 39 and 40 Victoria, chap. 77, and several persons held licences available there. It was under regular inspection and supervision by His Majesty's inspectors under the Act, and he had every reason to believe that the regulations as to the treatment of animals under experiments were strictly carried out. He saw no ground for any further inquiry.

Typhus in Poland and Russia.—In reply to Mr. Lawson, on May 17th, Mr. Harnsworth, Under Secretary, Foreign Office, said that at the meeting, on March 13th, of the Third Session of the Council of the League of Nations it was decided, on the motion of the British member, to instruct the International Health Conference to consider what measures should be taken to prevent the spread of typhus in Poland and the neighbouring countries. The situation in Poland was certainly serious, but it could not be said that the country was ravaged. The recent military advance of the Poles did not modify the proposal before the League of Nations. On the contrary, the medical authorities interested held that to the extent that the advance secured better conditions of Government in the Ukraine it would increase the opportunities of controlling the epidemic. Lord Robert Cecil inquired whether there were as many as 250,000 cases of typhus in Poland, and whether this was five times greater than existed at this time last year. Mr. Harnsworth replied that he had not the exact figures on record.

Answers in Brief.

In reply to a question, on May 18th, as to the action to be taken on the report of the Medical Consultative Council, Dr. Addison said that no pledge could be given, as to the date on which the Health Services Bill would be introduced.

A discharged soldier in an institution for nerve strain does not draw a pension, but receives allowances, generally at the rate of 21s. a week, with additions for rank and dependants. The Ministry of Pensions defrays the charges of the institution. Pensions may be reduced by one-half or less if the treatment certified to be necessary in the man's own interest is refused. Every such case is considered on its individual merits.

England and Wales.

HEALTH SERVICES AND HOSPITALS IN LONDON.

It was reported to the London County Council on May 18th that the Minister of Health received a deputation from the Council on April 23rd to discuss the recent resolutions of the Council on the health services of London (*BRITISH MEDICAL JOURNAL*, December 27th, 1919, p. 861). Dr. Addison told the deputation that in any scheme which was proposed the question of London must be specially dealt with. In regard to many health services he said that it was essential that there should be an authority competent to deal with them over a considerable area, and the more highly specialized they became the wider generally must be the range of authority. When the draft stage was reached, he would consult freely with the Council. It was inconceivable that any system of health authority could be set up which did not include the hospital system. In any case 50 per cent. of the beds in the country generally—he did not know how it was in the London area—were in the Poor Law infirmaries, so that it seemed to him that it would not be possible to split up hospital supervision. Speaking in general terms, he thought that the main principles governing the Council's recommendations were unassailable.

BIRTHS AND DEATHS IN THE FIRST QUARTER, 1920.

The Registrar-General's last quarterly return, dated April 30th, shows that the deaths registered in England and Wales during the first quarter of 1920 numbered 137,637. Influenza was stated to be either a primary or a contributory cause of death in 4,037, or 2.9 per cent. of the total deaths in the quarter. Thirteen deaths from small-pox were registered. The total number of deaths was 22,877 more than in the preceding quarter, but 54,285 fewer than in the first quarter of 1919. Infant mortality, measured by the proportion of deaths under 1 year of age to registered deaths, was 88 per 1,000, being 32 per 1,000 below the average in the ten preceding first quarters, and the lowest recorded rate for any first quarter. During the same period 271,082 births were registered in England and Wales, being 47,513 more than in the first quarter of 1919; it was the highest number recorded in any quarter since the establishment of civil registration, and corresponded to an annual rate of 23 per 1,000 of total population. The natural increase of population in England and Wales by excess of births over deaths was 135,445, against 14,810 and 24,303 in the first quarters of 1917 and 1918, and a natural decrease of 47,002 in the first quarter of 1919. This statement excludes, however, all deaths among the armed forces, except those registered in this country.

PRESENTATION TO MR. F. C. LARKIN OF LIVERPOOL.

Mr. F. C. Larkin, F.R.C.S., of Liverpool, has just retired from the post of honorary surgeon to the Liverpool Stanley Hospital, where he has worked for nearly thirty years. He has also recently retired from the secretaryship of the Lancashire and Cheshire Branch of the British Medical Association and from the chairmanship of the Organization Committee of the Central Council of the Association. Though not personally engaged in panel practice, he has acted as chairman of the Liverpool Local Medical and Panel Committees from their formation. A committee has been formed, with Sir James Barr as chairman, from the members of the Liverpool Division and the Liverpool Panel Committee, and from St. Helens and Burnley, to arrange that Mr. Larkin shall receive some recognition of his work. An appeal which has been issued states that, while heartily engaged in his professional work, Mr. Larkin has devoted much time and energy to the important though often thankless task of organizing his medical brethren in their own defence, and whatever measure of success has attended the movement for the betterment of the medical profession in recent years must be largely attributed to the pioneer work of Mr. Larkin and those who acted with him in London and the provinces. Subscriptions, not to exceed one guinea each, should be forwarded to the honorary treasurer and secretary, Mr. F. Strong Heaney, secretary of the Lancashire and Cheshire Branch of the British Medical Association, at 36, Rodney Street, Liverpool.

PAYMENT OF VISITING STAFFS OF VOLUNTARY HOSPITALS.

A conference of representatives of the honorary visiting staffs of some of the larger voluntary hospitals of the Midlands was held at the Leicester Royal Infirmary on May 18th. The hospitals represented included those of Birmingham, Barton, Coventry, Derby, Leicester, Loughborough, Manchester, Northampton, Nottingham, Salford, Sheffield, Stoke-on-Trent, West Bromwich, and Wolverhampton. Thirty-six representatives were present. The chair was taken by Sir Richard Luce of Derby. The questions brought up for discussion were:

1. The desirability of payment for the visiting staff for work done at their hospital on behalf of the Ministry of Pensions, the Ministry of Health, or the local medical health authorities, and, if so, at what rates.

2. Whether the time has come to ask for payment for the visiting staff for all work done by them at the hospitals, and, if so, whether this should take the form of an honorarium, a salary, or a percentage of the expenses of the hospital. If not, what alteration in the existing management or financial arrangements of the hospitals would create the need for such a request.

After full discussion the following resolutions were passed:

1. That payment for the visiting staffs is desirable for work done at their hospitals on behalf of the Ministry of Pensions, the Ministry of Health, or for the local medical health authorities.
2. That the time has not come for visiting staffs to ask for payment for all work done by them at the hospitals. But that the need for such a request would arise if the State or local authorities should assume control over the hospitals or if the income of the hospitals ceased to be derived from voluntary contributions.

The question of methods and rates of pay was referred to a committee for detailed consideration and report. No definite organization was formed for future meetings, but the chairman and secretary to the meeting were instructed to reassemble the Conference at their discretion.

CENTRAL MIDWIVES BOARD.

A special session of the Central Midwives Board for England and Wales was held on May 20th, with Sir Francis Champneys in the chair. Two women were removed from the roll; decision was postponed in one case for report; and two midwives were cautioned. One application for restoration to the roll was granted. At the ordinary monthly meeting, held on the same day, Dr. Fairbairn raised the question of reconsidering the conditions on which approval of midwives as teachers is granted, and also the question of arranging for courses of training for midwives seeking approval as teachers. It was decided to ask the Approval Subcommittee to consider and report on a scheme for the further instruction of teachers, and that Dr. Griffith be added to the committee for this purpose. In reply to a letter signed by all the examiners at the Birmingham centre, it was resolved to increase the number of examiners at that centre from six to eight, and to inform these examiners that if they will forward to the Board a request from the examiners at all the examination centres that the fees be increased, with reasons therefor, the Board will favourably consider such request.

Scotland.

GENERAL NURSING COUNCIL FOR SCOTLAND.

The first meeting of the General Nursing Council for Scotland was held on May 10th at the office of the Scottish Board of Health, Edinburgh. The meeting was opened by Sir Leslie Mackenzie, of the Board of Health. Captain C. B. Balfour, of Newton Den, and Miss Norah Milne, B.Sc., were appointed chairman and vice chairman of the Council respectively. Mr. C. L. Farmer, of the Scottish Board of Health, was appointed interim secretary.

TREATMENT OF VENEREAL DISEASES.

The Scottish Board of Health states that it has under consideration the question of extending the application of the Venereal Diseases Schemes inaugurated or to be inaugurated in Scotland in pursuance of the Public Health (Venereal Diseases) Regulations (Scotland), 1916, to cases of syphilis other than those to which the operation of the

schemes is at present restricted. In the light of the experience which has already been gained, the Board has been advised of the difficulty in distinguishing between communicable and non-communicable phases of the disease. It has accordingly decided that differentiation between communicable and non-communicable cases should no longer be attempted, and that all cases requiring anti-syphilitic treatment should be regarded as being properly included within the scope of the schemes for the control of venereal diseases, with the exception of those of general paralysis of the insane, the majority of which are removed to asylums.

Correspondence.

THE GENERAL PRACTITIONER AND THE HEALTH SERVICES.

SIR,—Dr. Brackenbury's paper, which appeared in the SUPPLEMENT of May 15th, should be carefully studied by every general practitioner. The position might be summed up as follows:

The health of the community depends chiefly on three main factors: (1) A good mother, (2) a good general practitioner, (3) a good scavenger.

Now that the mother has a vote she must insist that the general practitioner is made easily accessible to her, that her daughters are no longer spoilt by the so-called educational authorities, and that the scavenger does his cleaning thoroughly and minds his own business.

The general practitioner must now wake up and make sure that all the other factors in the so-called health services, which are only really valuable in proportion to the assistance they give him—and through him to the mother—are kept in their proper place and are not allowed to push him aside or to become his masters.—I am, etc.,

WILLIAM PATERSON, M.B., Ch.B., Edin.,
Honorary Secretary, Willesden Division.

Harlesden, N.W., May 22nd.

EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS.

SIR,—Dr. Thomas Beattie's description of the common signs and symptoms of early phthisis (January 24th, 1920) is so far from that I have encountered in this country that it may interest your readers to know the differences.

Haemoptysis without apparent cause or prior symptoms is, unless due to hydatid cyst, always tuberculous in origin here. Pleurisy without effusion is rare unless there is some accompanying disease, but pleurisy with effusion of the so-called idiopathic type without any apparent cause is equally always tuberculous. Not every case subsequently develops phthisis, but it is a perfectly safe thing to treat all such cases as being of tuberculous origin. I make a rule of having the cytology of all puncture fluids reported on and, in addition, all pleural fluids injected into a guinea-pig, in order to leave no doubt as to the origin of the effusion.

The general ill health and toxic symptoms—dyspepsia, wasting, etc.—are the same, but recur from time to time, and in the absence of any obvious cause, such as poor teeth or bad habits in eating or drinking, should lead to a regular investigation of the temperature. The charts of early phthisis we get here are quite distinctive—97° in morning and 99.4° or so in the afternoon—and, other causes being excluded, are as positive an indication of phthisis as can be had even without physical signs.

I am surprised to see no mention made of cough as an invariable accompaniment of active tuberculosis. I have never yet encountered a case in which this was absent. I should not call a case with the physical signs he describes an early case; I should regard it as long past the early stage. Personally I always try to make a diagnosis irrespective of physical signs; in this country it is quite simple. Loss of weight and appetite plus cough and a characteristic temperature chart, other sources of such trouble being excluded, are reliable indications.

Dr. Beattie's statement as to the occurrence of tubercle "at any site in the lungs," where it may cause physical signs, is not in accordance with my experience. The

contiguous borders of the upper and lower lobes, close to the edges, and more frequently on the right side, is where I have learned to look. I have never encountered early phthisis anywhere else.

I doubt if there is such a primary disease as bronchitis, except from the direct irritation of dust and such like causes. The bronchitis of the textbooks is a disease I have been on the look-out for for the last thirty years without yet encountering a case which was not either tuberculous in origin or accompanied by some evidence of parenchymatous disease of the lung. I heartily endorse Dr. Beattie's remarks on the value of sputum examination.

X-ray examination is my routine in all cases, as cysts in the lung are not uncommon and will exactly simulate phthisis. A clear conception of the deficient expansion of an apex is most easily obtained by this means.

As to the use of tuberculin, I have given it up as being far too dangerous, and I should feel exceedingly sorry to find I had stirred up enough focal reaction to increase the physical signs.—I am, etc.,

Christchurch, New Zealand,
March 22nd.

ALFRED FOSTER,
Hon. Physician, Christchurch
General Hospital.

TREATMENT OF ANTE-PARTUM HAEMORRHAGE.

SIR,—In the discussion on the treatment of ante-partum haemorrhage, as reported on page 672 of your issue of May 15th, mention is not made of the patient with severe external accidental haemorrhage who is still not in labour twenty-four hours after plugging cervix and vagina.

In a recent case of this nature I left a black catheter in the uterus before replugging the vagina. Labour terminated satisfactorily for the mother ten hours later. If I again meet with a case of severe external accidental haemorrhage in which the patient is not in labour it is my intention at the outset to pass several gum-elastic bougies into the uterus and plug the vagina without removing the bougies.—I am, etc.,

Hove, May 18th.

H. S. HOLLIS, M.B., Lond.

THE EARLY DIAGNOSIS OF SYPHILIS.

SIR,—In regard to the two letters under this title that appeared in your issues of May 1st and 15th, may I be permitted, as one of the earliest writers in this country on the laboratory diagnosis of early syphilis, to record my opinion on this important subject?

During the period 1903-1913 my interest was largely confined to the study of the clinical pathology of syphilis especially in regard to the early diagnosis; whilst since that date I have had more opportunity of studying syphilis from the clinical side.

I am in cordial agreement with the writers of the letter in your issue of May 15th as to the importance of clinical observations, and I think it is a matter beyond doubt that a large number of cases of syphilis in the early primary stage can be diagnosed with absolute certainty by clinical observation alone, and that valuable time may be lost while waiting for confirmation by laboratory methods. If the history of the incubation period, the appearance and induration of the sore, and the associated inguinal adenitis, all conform to a diagnosis of syphilis, I am of the opinion that it is best to accept this evidence as conclusive, and to immediately adopt anti-syphilitic treatment. I have on more than one occasion in the past delayed treatment until I have been able to obtain corroborative pathological evidence, and have only been able to obtain this evidence concurrently with the onset of secondary symptoms, and thus much valuable time—indeed, time of almost vital importance—has been lost. On the other hand, there are very many sores which I have not been able to diagnose as syphilitic by their clinical appearance or history, but in which I have been able to find typical *Sp. pallida*. It must be the experience of nearly every one with an extensive experience of examination by dark-ground illumination how frequently *Sp. pallida* are found in sores that are quite atypical in appearance. It appears to me, therefore, to be a matter of very grave importance that all sores atypical of syphilis should be subjected to a searching examination for *Sp. pallida*.

I have no great faith in the Wassermann reaction as a means for the early diagnosis of syphilis, and I do not

quite understand the rationale of Dr. Johnson's procedure. If he does not find the *Sp. pallida* he gives two injections of 0.45 gram of novarseno-bezol at a month's interval, the first followed by two blood tests a week and fortnight after injection, and the second by a blood test a week after the injection. If all these blood tests are negative I gather that he concludes the patient is not suffering from syphilis. Such evidence cannot be accepted as conclusive. If the clinical appearance and history are atypical and the dark-ground illumination and Wassermann reaction both negative, I should prefer to omit all but local treatment until the occurrence of definite clinical or pathological evidence of syphilitic infection.

It is very rare to fail to find *Sp. pallida* in a recent sore (even if local antiseptics have been applied by the patient before consultation) if the sore is treated with hypertonic saline solution for a couple of days.

A negative Wassermann reaction is also extremely common, even with well-marked and typical sores in which large numbers of *Sp. pallida* are present; indeed, I place no diagnostic value whatever on a negative Wassermann with a sore which has not been present for over a month. I conclude, therefore, that clinical observation and pathological examinations are of equal importance under different circumstances.—I am, etc.,

London, W., May 18th,

H. WANSEY BAYLY.

AORTITIS AND AORTIC REGURGITATION.

SIR,—Dr. Theodore Fisher's letter in the JOURNAL of May 15th, p. 688, calls for a reply, if only to thank him for the courteous manner in which he has written. I think I may also say that his two letters show that we are in complete agreement on the main issue—namely, the extreme importance of the cardio-vascular lesions of syphilis.

I should, perhaps, in my letter in the JOURNAL of May 8th, have given definite reference to recent American writings upon the question under discussion. Warthin (*American Journal of the Medical Sciences*, 1916, vol. ciii) describes the presence of spirochaetes in the aortic tissues and in the myocardium. His work has been quoted by several writers in the *Medical Clinics of North America* (Dr. Thomas McCrae, vol. i, No. 2, and Dr. Charles Louis Mix, vol. i, No. 5).

In the last five cases of cardio-vascular syphilis on which we obtained a *post-mortem* examination a myocarditis was in three instances considered to be present on naked-eye appearance. We have not as yet undertaken the demonstration of the presence of spirochaetes in these cases.—I am, etc.,

Belfast, May 17th.

JOHN E. MACILWAINE.

Obituary.

WE regret to record the death of Dr. WILSON EAGER, which took place at his residence in Woodbridge, Suffolk, on May 11th, 1920. He was born on May 10th, 1845, and was the son of Dr. Richard Eager, a surgeon in Guildford, Surrey. Like his elder brother, Dr. Reginald Eager, he was educated at Guy's Hospital, and eventually made his life-work the study of mental disease and the cure of the insane. Dr. Wilson Eager, having taken the M.R.C.S., L.R.C.P., and L.S.A. diplomas in 1871, became clinical assistant at Bethlem Hospital; thence he went as assistant medical officer to the Prestwich Asylum. In 1876 he was appointed resident physician and superintendent of the Suffolk County Asylum, Melton (now St. Audry's Hospital), a position from which he retired in 1897 after twenty-one years' successful service. Dr. Eager was responsible for greatly improving the lighting, heating, and structural arrangements of this institution, which during the latter part of the eighteenth century had been the Woodbridge workhouse. Besides being an able administrator Dr. Eager was of an inventive frame of mind; he introduced into the institution many ingenious appliances for institutional nursing and equipment. Dr. Eager took a warm interest in the social life of the institution: he was fond of music, and by his own personal efforts secured the provision of an excellent organ for the chapel. On leaving the County Asylum Dr. Eager joined his brother in partnership at a private asylum near Bristol, but after ten years he decided to retire, and went to live in Woodbridge, where he had many friends. He leaves a

son, Dr. Richard Eager, O.B.E., who is deputy medical superintendent of the Devon Mental Hospital, and a married daughter, who lived with him for many years. His wife predeceased him by twelve years.

Medico-Legal.

AN ABORTIONIST'S SENTENCE.

IN the JOURNAL of April 24th, p. 589, a short account was given of the trial at the Central Criminal Court before Mr. Justice Shearman, of Devi Dayal Sasun, L.R.C.P. and S. Edin., L.R.F.P.S. Glasg., of Brady Street, Bethnal Green, for the murder of a young single woman. The prosecution alleged that the woman died as the result of an illegal operation performed by the prisoner. The jury acquitted Sasun of the charge of murder but found him guilty of manslaughter, and he was sentenced to ten years' penal servitude. In the Court of Criminal Appeal on May 17th, before the Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Roche, Sasun applied for leave to appeal against his conviction and sentence, and also for leave to call further evidence. The Lord Chief Justice in giving judgement, as reported in *The Times*, said that the court was seized of the case, and neither the comments nor the additional evidence of a doctor could assist it. The case against the appellant was that he had performed an operation with intent to procure abortion, and that the woman died of shock from the operation. Regarding the contention that the operation was not proved to be the cause of death, his lordship observed that the woman undoubtedly visited Sasun on the day before she was found dead. There was considerable mystery about what happened in the surgery and after she had left it, but there was evidence that the woman had died in the surgery, and that she had been carried by the appellant to an archway and left there. The main case for the appellant was that he had not done an operation on the woman. Dr. Spilsbury's evidence for the prosecution established that the woman's death was due to the insertion of an instrument used upon her, and that she had died within two or three minutes from shock following the operation. Death very rarely ensued in that way, but Dr. Spilsbury said he had known other cases. Apart from such cause there was no indication of a cause of death. In a bag found on the body of the woman there was a bottle of chloral, and in her stomach $7\frac{1}{2}$ grains of chloral were found; but it was clear from the medical evidence that chloral was not the cause of death. Three obstetric physicians had been called for the defence, but all that they could say was that in the course of their normal and legitimate experience in cases in which all care had been taken they had not had a similar case. In dismissing the application his Lordship said that all the facts had been fully presented to the jury, who on a proper direction by the judge found that Sasun had committed manslaughter, and had killed the woman by performing an illegal operation upon her. The jury might well have found a verdict of murder, but had taken a more merciful course. Having regard to the fact that the appellant was found to be a professional abortionist, the sentence was not too severe.

Universities and Colleges.

UNIVERSITY OF LONDON.

OFFER OF A SITE.

PRESENTATION DAY at the University of London this year was made memorable by the simultaneous publication of an offer by the Government of a large site in Bloomsbury made through the Chancellor, Lord Rosebery. The site comprises 11½ acres, and lies immediately to the north-west of the British Museum; it extends from the west side of Russell Square to the back of Gower Street, and from the British Museum to the south side of Gordon Square. The site is at present covered by houses, but the lease of many of them expire before 1924, of others in 1923, and of most of the remainder in 1939. The ground is offered as a site for the head quarters of the University, and for colleges and institutions connected with it, including King's College, whose premises in the Strand are now inadequate for its needs. The Government has reluctantly decided that while it is prepared to make such provision as will secure the University from loss in respect of maintenance charges on the new University head quarters, the state of the national finances does not justify it in providing the cost of the buildings themselves from public funds. It believes that the University may look with confidence to the generosity and public spirit which has always marked the citizens of London.

The presentation ceremony took place in the Albert Hall on May 19th. The Principal Officer, Sir Cooper Perry, said that the resources of the University were strained to the utmost. The admissions amounted to 6,295 as compared with 3,852 in 1913-14, and the total number of candidates for all examinations to 18,352 as against 11,920 in 1913-14.

In the evening a graduation dinner took place in the Guildhall, when the Vice-Chancellor of the University, Dr. S. Russell Wells, presided. After dinner the Lord Chancellor said he rejoiced to be able to pay a tribute in his presence to Lord Haldane for the part he had taken in building up the army which won the war. The Minister of Education (Mr. Fisher) claimed that the present Government had shown no lack of interest in educational improvements. The war had made the country alive to the value of education, and the universities of

the country were fuller than ever before. To the University of London the war had given a great opportunity, for the German universities were under a cloud, the Dominions were anxious to take advantage of the seats of learning in this country, America was ready to send thousands of students, and the allied countries were more alive than ever before to the resources of English learning and the elasticity of English genius. The Government, he said, had no desire to force on the Senate the gift of the site, but hoped that the citizens of London would realize that the opportunity thus offered to them would make the University of London the central seat of the higher learning and research of the whole empire. The site was part of a larger area which might by degrees be acquired as university needs developed.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on May 13th.

Issue of Diplomas.—Diplomas of membership were granted to seventy candidates found qualified at the recent examinations. Diplomas in Public Health were granted jointly with the Royal College of Physicians to nine candidates. Diplomas in Tropical Medicine and Hygiene were granted to thirteen candidates.

Anatomical Nomenclature.—A report from the Court of Examiners expressing agreement with the Anatomical Society of Great Britain and Ireland in recommending that the old nomenclature should not be departed from in anatomical textbooks or by medical men in general, was adopted by the Council.

Diplomas in Psychological Medicine and in Ophthalmic Medicine and Surgery.—The Council agreed to the regulations for diplomas in Psychological Medicine (D.P.M., R.C.P. and S. Eng.), and in ophthalmic medicine and surgery (D.O.M.S., R.C.P. and S. Eng.), details of which were given in the report of the meeting of the Royal College of Physicians on April 29th (BRITISH MEDICAL JOURNAL, May 8th, p. 658).

Examinations for these diplomas will commence on June 23rd and July 26th respectively. Full particulars can be obtained from the secretary, Examination Hall, 8, Queen Square, Bloomsbury, W.C.1.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following, after examination, have been admitted Fellows:

J. S. Arkle, C. V. Baigent, H. Banks, M. R. Boc, A. L. Buchanan, C. H. Corbett, P. C. Datta, J. N. F. Ferguson, F. C. Greig, E. W. Hall, A. D. Haydon, A. E. Herman, W. H. Johnston, G. J. Joubert, C. N. Laver, A. P. Lawrence, C. R. Merrilies, R. K. Merson, R. P. Nash, J. M. Pringle, F. H. Robbins, H. F. Seymour, F. M. Spencer, R. Stevenson, C. B. Tudehope, C. A. Verge, R. G. Walker, A. Walbrugh, N. J. Watt, H. Williamson, G. S. Woodman.

The Bathgate Memorial Prize, consisting of bronze medal and set of books, has, after a competitive examination in materia medica, been awarded to John Herbert Appleyard.

The Ivison Macadam Memorial Prize in chemistry, consisting of bronze medal and set of books, has, after competitive examination, been awarded to Leonard Alexander Watson.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.

THE following have been admitted Fellows: James Devon, Alexander Morton, Edward J. Primrose.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been admitted diplomates in Public Health:

M. E. Willecock, S. Honeyman, G. King, I. C. Mackay, R. J. Tait, Margaret A. Alexander, T. M. Anderson, P. C. Livingston, J. W. K. Bruce, H. F. W. Adams, E. F. Fisher, Jessie A. MacLaren, T. P. Herriot, A. Bremner, A. G. Carment.

The Services.

HONOURS.

MENTIONED IN DISPATCHES.

A SPECIAL Supplement to the *London Gazette*, dated May 18th, includes the following in a list of names brought to the notice of the Secretary of State for War for valuable services rendered in connexion with the military operations in the area indicated during the period April 1st, 1917, to May 31st, 1918.

North-West Frontier of India: Colonels W. E. Hardy, I.M.S., and A. E. Tate, A.M.S. (R.P.); Major W. T. McCowen, I.M.S., and Muhammad Raza Khan, 1st Class Sub-Assistant Surgeon, I.M.D.

East Persia: Assistant Surgeon W. J. Marshall and Sub-Assistant Surgeon Lambodar Misra, I.M.D.

South Persia: Lieut.-Colonel (temporary Colonel) H. Burden, C.I.E., I.M.S.; Captain (temporary Lieut.-Colonel) H. R. B. Gibson, I.M.S., and Jemadar Muntaz Ali, I.M.D.

The following are included in a list of officers and others mentioned by General Sir G. F. Milne for continuous distinguished and devoted service during the evacuation of the Caucasus: Temporary Colonel A. G. Phear, A.M.S. Tem-

porary Captains: G. G. Bruce, (acting Major) A. Dick, J. Elder, (acting Major) J. D. Gunn, and G. B. Wild, of the R.A.M.C. Captains: R. Chevassut, F. B. Jago, G. E. Tilsley, and W. A. Weatherhead, of the R.A.M.C.(S.R.); Captain (acting Major) G. Y. Thomson, I.M.S., and Assistant Surgeon De Noronha, of the I.M.D.

Surgeon Commander D. W. Hewitt, C.M.G., R.N., S.M.O., in charge of medical arrangements on Dwina River, has been mentioned for services in a dispatch, dated January 1st, 1920, from Rear Admiral J. F. E. Green, late senior naval officer, White Sea.

Captain (acting Major) J. M. Weddell, R.A.M.C., has been mentioned for valuable services in connexion with the military operations in Kurdistan and Persia.

Medical News.

MR. ARTHUR EVANS, surgeon to the Westminster Hospital, will open a discussion on alcohol and alcoholism in relation to venereal disease, at a meeting of the Society for the Study of Inebriety, 11, Chandos Street, W., on Tuesday, July 13th, at 4 p.m.

The Section of the Study of Disease in Children of the Royal Society of Medicine will hold a meeting at Manchester on June 18th and 19th. The time of the meeting will be chiefly given up to visits to hospitals and medical, surgical, and pathological demonstrations, but papers will be read on Friday afternoon, June 18th. On Saturday visits will be paid to the Children's Hospital, Pendlebury, the Swinton Schools for Crippled Children, the Sandlebridge Colony for the Feeble-minded, the Soss Moss Schools for Epileptic Children, and the Schools for the Deaf, Old Trafford.

THE National Council for Combating Venereal Diseases will hold its fifth annual meeting on June 7th, at the Royal Society of Medicine, 1, Wimpole Street, W.1, at 5 p.m. The meeting will be addressed by the Right Hon. Viscount Astor, Parliamentary Secretary to the Ministry of Health.

THE King of the Belgians has awarded the Médaille du Roi Albert to Dr. A. C. Magian of Manchester, who had previously received the Médaille de la Reconnaissance Française in silver and the Associate's medal of the Order of St. John of Jerusalem, for services rendered to the Allies during the war. Last year the Belgian community in Manchester gave him a testimonial, and he has received a presentation from medical colleagues associated with the Manchester French Hospital, of which he is founder and honorary director.

A COURSE of twelve practical demonstrations on the management and feeding of infants and young children will be given by Dr. Eric Pritchard at the St. Marylebone Dispensary, 77, Welbeck Street, W.1, on Tuesdays and Thursdays at 10.30 a.m. and 3 p.m. respectively, commencing on June 1st. The fee for the course is 2 guineas.

AT the annual general meeting of the Society for Relief of Widows and Orphans of Medical Men, when Sir Alfred Pearce Gould was in the chair, Sir Malcolm Morris and Dr. Needham were elected vice-presidents, and eight new directors were chosen to fill vacancies in the court. Since the last report nineteen new members have been elected and fifteen have been lost by death or resignation. The society consists at present of 1 honorary, 160 life, and 135 ordinary members. The total number of members has remained practically stationary during the past twenty-five years. The invested capital has increased from £95,700 in 1895 to £144,250 in 1920, owing mainly to a large legacy received from the late Mr. Brickwell. The annual grants have increased from £3,280 to £4,937. The total income in 1920 was £4,927 and the working expenses £285. At the present time the widow of any member who has an income of £100 a year or under receives a grant of, on the average, £50 a year, and each orphan £45 a year up to the age of 16. Grants, however, can be paid from special funds to orphans over the age of 16 and to widows. Membership of the society is open to any registered medical practitioner who, at the time of his election, is resident within a radius of twenty miles of Charing Cross; the annual subscription for a member under 40 years of age at the time of his election is 2 guineas.

THE Chinese Red Cross Society, founded in 1904, has now 26,000 members and 30 district committees.

THE Mexican Board of Health has decided to place in quarantine all ships coming from Havana, where there is an epidemic of meningitis.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology, Westrand, London*; telephone, 2531, Gerrard.
2. FINANCIAL SECRETARY and BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2530, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Dacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

TREATMENT OF PSORIASIS.

DR. J. ALDREN WRIGHT (Cambridge) writes, in reply to "F. B. E.": I have given a course of "606" substitutes to several patients suffering at the same time from syphilis and psoriasis—without any apparent effect on the psoriasis.

DR. LEONARD J. KIDD (London, N.W.3) refers "F. B. E." to a paper by Léopold-Lévi in the *Comptes Rendus de la Société de Biologie*, 1913, lxxiv, p. 1156, on the value of testis powder (0.20 gram in a cachet daily) in severe pruriginous psoriasis. Brisson found that the testis is rich in sulphur and has a marked action on the skin. Long ago Brown-Séquard found that testicular extract was as active therapeutically in women as in men.

INCOME TAX.

R. J. F. inquires as to the limit of income above which allowances for wife and children cease.

* * Under the proposals of the Finance Bill for 1920 there is no limit, the allowances in question being extended to everybody, irrespective of the amount of their incomes. The forms now being issued by the Revenue authorities were no doubt printed some months ago. We advise our correspondent to complete the declarations in respect of wife and children, on page 4 of the form, disregarding the stated limit of £800—it will presumably avoid the necessity which he would otherwise be under of making supplementary claims later in the year.

W. O. W. disposed of his panel practice on December 31st, 1919, retaining a small amount of private practice and a life assurance examinership. What is his position as regards the years 1919-20 and 1920-21?

* * In our opinion W. O. W. is entitled to treat his panel practice as a separable section or branch of his practice, and as from December 31st, 1919, to exclude from the average on which he is chargeable the profits—not, of course, the gross receipts derived therefrom. His successor in that practice stands in the converse position. We suggest that he makes his return for 1920-21 on that basis, stating the facts, and that he requests the local inspector of taxes to adjust the tax for the last quarter of 1919-20 accordingly. The claim for an income falling by 10 per cent. can be made for 1919-20, but that cannot be depended on for 1920-21.

V. V. V. feels that he has grounds of complaint as to the degree of care exercised in the office of the local inspector of taxes with regard to confidential returns. He is assessed by the Special Commissioners, and since an error on the part of the inspector's staff was pointed out he has been continually requested for details of income and expenditure. What is his best course of action?

* * We would like to suggest that perhaps some personal conversation with the inspector might result in an amicable settlement of the matter, but we realize that our correspondent may reasonably feel disinclined to adopt that course. Returns for assessment by the Special Commissioners properly pass through the inspector's hands; in fact, the form contains a direction to send it to him in the first place, but the responsibility for the assessment rests with the Commissioners themselves. V. V. V. would be adopting a correct legal course in appealing to them, and attending their appeal meeting with his books when requested to do so.

LETTERS, NOTES, ETC.

MODE OF QUININE ADMINISTRATION.

WE have had a number of further letters on this subject, from which we print the following extracts:

Dr. R. VAN SOMEREN (Muswell Hill) writes: After fifteen years' tropical experience in various parts of Uganda I am convinced that it is not wise to dogmatize about the best methods of administering quinine and its correct dosage—so widely do the common clinical manifestations of malaria vary in different regions. In one station, where the subtertian cases were mild, and not usually accompanied by vomiting, I used the oral method; sixty miles away severe vomiting was frequent, and there I used nothing but intramuscular or intravenous injections. So great was the relief that the patients used to beg for them. After the attack I gave gr. v of the bilydrochlorate night and morning for a fortnight, then at night for a fortnight, then every other night for a fortnight, and then every Sunday for six weeks. My assistants and I never found that injections were followed by necrosis, the occurrence of which I attribute to faulty technique. Quinine injections did not aggravate haemoglobinuria in blackwater fever.

Dr. S. SOLIS COHEN (Philadelphia) writes: Since 1884 I have used quinine and urea hydrochloride, given intravenously, for the treatment of malaria and pneumonia. Although necrosis and sloughing occurred in a few of the earlier cases we soon learned how to avoid it; since then, although in about 4 cases in 1,000 one does meet with slight mishaps (ranging from persistent induration to superficial or even deep ulceration) serious accidents have never been seen. For oral administration the best salt to use is the dihydrobromide; for intravenous use the dihydrobromide, the dihydrochloride, or quinine and urea hydrochloride (1 to 10 per cent. in physiological saline solution). For intramuscular injection quinine and urea hydrochloride is preferable on account of its greater solubility.

Dr. W. M. HEWITSON (Sinoia, South Rhodesia) writes: The fundamental difference between the administration of quinine by the mouth or rectum on the one hand and intravenously or intramuscularly on the other, is that in the former case the quinine must pass through the portal system before reaching the systemic circulation, whereas in the latter method the systemic circulation is reached directly. In malarial attacks the spleen is acutely affected, and I have seen its lower margin descend two inches in sixteen hours as a consequence of an attack. In the liver chronic changes are known to occur, and severe bilious vomiting and stoppage of digestive function are characteristic of acute attacks. The acute stages of malaria show that there is much disturbance of the liver and spleen. If muscular tissue undergoes necrosis from contact with quinine may not damage occur from the action of the latter on the delicate liver cells? I have always found intramuscular injection to be very powerfully effective—more so than oral administration. I have found among the laity a general desire for, and belief in, intramuscular injections. I have never had an abscess after intramuscular injection.

DICKENS ON THE TREATMENT OF MALARIA.

DR. J. H. ELMES (Lusikisiki, Pondoland) writes: With reference to Dr. Robertson's and Major Law's letters of February 7th and 21st, on the treatment of malaria, it is curious to note that in a review of *The Narrative of the Expedition to the Niger in 1841*, written by Charles Dickens in 1848, the following passage occurs: "It appears to yield to calomel in the first instance and strong doses of quinine afterwards more than to any other remedies." History repeats itself.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 34, 35, and 36.

THE following appointments of certifying factory surgeons are vacant: Frome (Somerset), Garstang (Lancaster), Redditch (Worcester), Tooting (London), Uttoxeter (Derby and Stafford).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	7	6
Each additional line... ..	0	1	3
Whole single column	6	0	0
Whole page	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post-restante* letters addressed either in initials or numbers.

Clinical Observations

ON

JEJUNO-COLIC FISTULA FOLLOWING GASTRO-JEJUNOSTOMY.

BY

CHARLES BOLTON, C.B.E., M.D., F.R.S.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL;

AND

WILFRED TROTTER, M.S., F.R.C.S.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

THAT the operation of gastro-jejuno-stomy is occasionally followed by the formation of a jejunal ulcer is a well established fact. The frequency with which this serious after-result occurs is unknown, but it has been estimated at from 1 to 2 per cent. of operations. The ulcer forms at the anastomosis, from which it commonly spreads in the jejunum, sometimes in the stomach, occasionally in both; or it arises primarily in the jejunum near the anastomosis, but sometimes at a greater or lesser distance from it in the efferent limb. A little over 10 per cent. of jejunal ulcers become adherent to the transverse colon and perforate into it, thus establishing a jejuno-colic fistula, or much less commonly a gastro-colic or a gastro-jejuno-colic fistula. Four such cases have recently come under our observation, and a reference to the literature shows that there are already twenty-seven cases on record. Most of the cases have naturally been published as isolated observations, but a paper or two have been written on the analysis of such cases, which clearly show that the condition possesses a definite and characteristic, though variable, clinical picture, which is worthy of closer study, particularly as this complication of gastro-jejuno-stomy has hitherto attracted very little attention in England.

HISTORICAL.

The first case on record was a gastro-colic fistula, which was operated upon by Czerny¹ and published in 1903. An ulcer on the anterior wall of the stomach originating at the edge of the gastro-jejuno-stomy opening had perforated into the transverse colon, which had become adherent to the base of the ulcer. In 1905 von Herzfel² published the first operation on a jejuno-colic fistula formed by the perforation of a jejunal ulcer situated in the efferent limb opposite the anastomosis into the transverse colon. In the following year Kaufmann³ described a case of his, which was operated on by Gërster and in which there were two fistulae, one between the stomach and colon, and a second between the jejunum and colon. Gosset's⁴ first case was published in the same year, and in 1909 Lion and Morcan⁵ wrote a paper on this subject based on the above-mentioned cases and two additional ones, which were operated on by Nélaton and Gosset (second case) respectively. They appear to have overlooked a case reported by Port and Reitzenstein⁶ in 1907, in which the fistula connected the colon with the stomach and jejunum.

In a paper on jejunal ulcer Paterson,⁷ in 1909, quotes four of the above cases, and in addition a *post-mortem* examination by Cackovic, in which an unexpected jejuno-colic fistula was found opposite the anastomosis. In the following year Van Roojen⁸ also published a communication on jejunal ulcer, and found that of the cases he had collected nine had perforated into the colon. He quoted four cases which have not been mentioned above, namely, those of Van Stockum, Koch, Wickershausen, and von Herzfel (second case). In 1913 Pelya⁹ described a case and summarized the knowledge obtained up to date on this subject, and quoted the additional cases of Pinner, Scsin, Spassokukozki, Gosset (third case), and two of von Eiselsberg. Since this year a further eight cases have been published. In 1915 Hamann¹⁰ described the case of a medical man in whom a jejuno-colic fistula was operated on four years after the gastro-enterostomy was performed. Barling,¹¹ in 1917, published the case of a man in whom a jejuno-colic fistula was diagnosed three years after gastro-enterostomy. The patient died five months later of general peritonitis due to the perforation of a second jejunal ulcer. At the New York Surgical

Society on April 10th, 1918, Downes¹² read a paper on the case of a man who first had the appendix removed without benefit, and then a gastro-enterostomy performed five months later. The following month a second operation was done for closure of the stoma. Eleven months later an anastomotic ulcer was excised and gastro-enterostomy again done. During the following year he had three haemorrhages from the bowel, and was treated medically. Two years later symptoms of fistula appeared, and after two months the fistula was closed and the gastro-enterostomy opening enlarged. The patient was reported well three months later. At the discussion which followed the reading of this paper Erdmann related the case of a male patient of his on whom he had successfully operated for jejuno-colic fistula a year previously.

Carnot, Froussard, and De Martel¹³ in 1918 gave a very full and interesting account of their observations on a case which showed definite symptoms of fistula two years after gastro-enterostomy. The parts were resected and end-to-end anastomosis of the large and small intestine with closure of the gastro-enterostomy stoma performed. Clairmont¹⁴ in 1918 showed three cases at the Medical Society of Vienna on whom he had done extensive resections for jejuno-colic fistula. The details of these operations are given in a later paper.¹⁵

Two further papers, by Mathiew¹⁶ and Urrutia¹⁷ respectively, have been published on this subject, but we have been unable to obtain copies of them in London. Thus 27 cases at least have been recorded, and the addition of our 4 cases brings up the total to 31. No doubt many unpublished cases exist.¹⁸ We shall now give reports of these 4 cases, which were primarily patients of one of us (C. B.). The first three were operated on by the other of us (W. T.), and the fourth case died after a laparotomy by another surgeon had failed to find the cause of the faecal vomiting.

CASE I.—*Perforated Duodenal Ulcer: Gastro-jejuno-stomy (1915): later Vomiting and Diarrhoea: Operation (1919) for Jejuno-colic Fistula: Temporary Caecostomy: Recovery.*

T. G., male, aged 37, railway attendant, was admitted to University College Hospital on March 14th, 1919.

History.

The symptoms began in 1901 with pain in the right part of the epigastrium under the costal margin, two hours after meals and relieved by food. Sometimes it was a "doubling up" pain, at other times milder. There was fullness in the epigastrium, and eructations of wind and acid fluid; vomiting was rare. These symptoms recurred at intervals in attacks which lasted a few months. In the intervals the patient was quite well. In 1915 the ulcer, which was duodenal, perforated. He was operated on at University College Hospital; the opening was stitched up and posterior gastro-jejuno-stomy performed at the same time. The patient recovered, but almost at once began to suffer from gripping pain in the lower part of the abdomen, which had continued intermittently ever since, though for the last twelve months it had been less marked, and had recently disappeared. The bowels were regular.

Six months before admission the old pain under the right ribs reappeared. It came on, as before, two hours after meals, and was relieved by food, but was not so severe and gripping, although otherwise of the same character. There were also fullness and eructations of wind. Two months before admission the patient began to notice that very offensive gas and fluid were eructated, and a fortnight later he suddenly vomited over a pint of light-coloured very offensive material. A second attack of vomiting occurred two weeks before admission, and was preceded by a sensation of constriction in the upper part of the abdomen. The material was of the same nature as before, but smaller in amount. A third attack occurred the day before admission. The vomit was light coloured and offensive as before, but less than a pint in amount. There was no vomiting in the intervals between these three attacks, but offensive gas and fluid were eructated.

Diarrhoea commenced just before the first attack of vomiting two months ago, the bowels having been quite normal previously. The diarrhoea having once started continued more or less incessantly, occurring any time in the day or night. The stools were light-coloured and contained a little mucus but no blood. They were very similar to the vomited material. During the last two months pain was also felt in the left hypochondrium and down the left side. The pain in the epigastrium was dull and aching and radiated downwards over the whole abdomen. It was more or less constant, coming on at any time, and being relieved by food for a time and also by the vomiting. Patient had a severe attack of intestinal colic two weeks before admission. Wasting began with the first attack of vomiting, and during the two months he lost 10 lb. The appetite was moderate and sleep poor. Patient stated that he felt better when the bowels were confined.

Condition on Admission.

The patient was pale and thin, weighing 8 st. 5 lb. 12 oz. He vomited on two occasions, bringing up about 6 oz. of light-brown coloured liquid material of faecal odour and not containing any solid masses. His symptoms were as described above.

Diarrhoea did not occur on every day, an enema simplex being necessary on two occasions. The stool was light-brown and soupy, did not contain any amount of solid material, and was in appearance like the vomit. It contained 85 per cent. water. The total fats were 13.8 grams per cent. dry weight, the fatty acids and neutral fats being each 9.4 per cent. There were some undigested muscle fibres, but no evidence of either trypsin or starch digesting ferment. There was no lienteric diarrhoea.

A test meal showed a total acidity of 0.1095 gram per cent. There was no free HCl, no lactic acid; the protein HCl was 0.1095 gram per cent. Albumoses were present, and the digested power of the fluid was 52 per cent.

Physical examination of the abdomen showed a median epigastric scar. There was a tender spot under the right costal margin, but no marked rigidity of the recti muscles, and no cutaneous hyperaesthesia. The stomach was distended with gas, the resulting swelling was confined to the epigastrium, but no peristalsis was seen and no distension of the colon could be made out. The urine was normal; the temperature rose to 100° F. on one occasion, but was otherwise normal.

X-ray Examination.—The lowest point of the stomach was situated 2½ in. below the umbilicus; it emptied rapidly, and in two hours there was a large shadow in the caecum and lower part of the small intestine. A doubtful shadow was seen in the descending colon, but it was possibly in the small intestine. In four hours the caecum was empty and the transverse colon filled. A considerable amount collected in the small intestine, which probably ran through the fistula. The stomach did not fill up. The examination was thus inconclusive. A faecal fistula was diagnosed without further investigation.

Operation (W. T.).

An incision was made through the left rectus. There were many firm adhesions in the region of the anastomosis and involving the stomach, transverse colon, and spleen. When these had been separated the anterior aspect of the jejunum at the anastomosis was found to be firmly united to the posterior aspect of the transverse colon over an area about ¾ in. in diameter. There was obviously a communication between the two organs at this point. The colon and jejunum were now dissected apart, the fistula being thereby opened. It was found possible to separate the two organs freely without encroaching on either unduly. The resulting openings in the colon and jejunum were stitched up, the gastro-jejuno-stomy being left intact. A temporary caecostomy opening was made through a short incision in the right iliac fossa.

The operation was difficult on account of the adhesions. Although these were separated with great care, a laceration of the spleen was produced, which bled profusely until it was closed by sutures.

Subsequent Course.

The case ran a normal course and the patient left the hospital in three weeks. For the first ten days he passed a motion each day, which was light coloured as before the operation; then the motions became darker and were practically normal when the patient left the hospital; in fact he required an occasional aperient. There was no pain or other symptom. He was seen again in February, 1920, and stated that he had been very well until two months previously. He then developed pain one hour after meals in the left hypochondrium, with a feeling of distension. There had been no vomiting nor diarrhoea. He now and then experienced the old ulcer pain. His weight was 9 st. 12 lb.

CASE II.—*Gastro-jejuno-stomy (January, 1918): Constriction of Jejunum and Second Operation (ten days later): Later Diarrhoea and Intestinal Pains: Two Operations for Jejunocolic Fistula (November, 1918, and March, 1919, with Temporary Caecostomy): Recovery.*

L. M., male, aged 42, was first seen in October, 1918.

History.

He began to suffer from "indigestion" at the age of 18 years, and definite duodenal pain commenced five years later. He had recurrent attacks of pain at varying intervals, and was treated by many medical men from this time till January, 1918, when he was operated upon and a posterior gastro-jejuno-stomy performed. "The stomach was dilated and hypertrophied, and the gall bladder was adherent to a large scarred ulcer extending over the whole of the anterior surface of the duodenum. In addition there had at some time been a small ulcer on its posterior surface. There was considerable induration of the head of the pancreas. The appendix was also removed and showed traces of old inflammatory trouble." The patient went on well for ten days, and then felt nausea and vomited a considerable quantity of "bile." This recurred a day or two later, and a second operation was therefore performed. "The jejunum at the centre of the anastomosis was constricted by a band of adhesions, which passed from the mesocolon to the mesentery of the jejunum. The band was intimately adherent to the intestine and could not be freed. A longitudinal incision was therefore made through this part, which was then sutured vertically." Three weeks after the operation a sharp pain occurred under the left ribs, more at the back than the

front, but this passed off in a few days, and the patient was sent into the country on March 1st, 1918. Towards the end of April he began to have slight pain in the intestines, particularly low down on the right side, otherwise he was fairly well, and had a very good appetite. Early in May the pain increased, and he suffered from diarrhoea constantly. There was no gripping pain or sudden call to defaecate, but the patient could pass a liquid and pale stool two or three times a day. As the diarrhoea increased the intestinal pain decreased. About this time he complained of eructations of foul-smelling gas and nausea, but never had any vomiting. On May 12th he suddenly vomited half a large basinful of brown liquid having a bad odour. He thought this was "bile." He was put into a nursing home and had his stomach washed out once or twice, and in a few days the nausea and diarrhoea ceased. After this for about six weeks he was considerably better, but the foul flatulence troubled him, and he had some pain. He used to often wash out his stomach in the early morning by drinking a solution of sodium bicarbonate and making himself vomit; a small amount of dark and bad-smelling fluid came up and pieces of stuff like brown paint; occasionally at night he used to feel as if the stomach had not emptied, and on making himself vomit a pint or more of brown material came up. He increased in weight from 8 st. 13 lb. to 9 st. 5 lb. in August. The abdominal pain now began to increase, and he had very bad nights and was kept awake by pain and diarrhoea. The pain was always worse and came on sooner when he was lying down or sitting in a chair, but in the upright position he was much more free from pain. The diarrhoea was practically continuous, and he began to lose weight. He had a good appetite and ate a liberal diet. The foul flavour was more frequent, and on several occasions he made himself vomit and brought up a large amount of brown bad-smelling material. He only vomited involuntarily once or twice during the whole period. In addition to the acute intestinal pain in the lower part of the abdomen he also described pain and distension in the upper part, but the pain seemed to spread over the whole abdomen. An examination of the faeces in September showed them to be acid in reaction; no bile pigments, blood, or mucus were present. The total fats were 38 per cent. Microscopically large numbers of muscle fibres, fat globules, and bacteria were seen.

Present State.

When he came under observation (October, 1918) he was thin and under his ordinary weight. The pain he complained of was a severe gripping in the region of the caecum and transverse colon, with some pain in the left hypochondrium, and also general distension and pain in the whole abdomen. There were occasional eructations of foul gas. The appetite was excellent. Physical examination revealed nothing of importance.

A test meal was administered and the amount withdrawn was only 1 oz., so that the stomach emptied rapidly. It was yellowish in colour but was not foul in smell, and on analysis showed:

Total acidity	0.144 per cent.
Protein HCl...	0.108 "
Free HCl	0.036 "

Subsequently four specimens of vomit were obtained by the patient making himself sick when he felt his stomach distended.

Specimen 1.—A pint or more of thick brown, semi-fluid material of an obvious faecal odour. This was the only occasion on which faecal material was observed.

Specimen 2.

Total acidity	0.365 per cent.
Protein HCl...	0.146 "
No free HCl	0.18 "
Organic acids	0.18 "

Bile absent. Stercobilin absent. Starch and fat-splitting ferments present in large amounts. There was a large amount of undigested muscle fibre.

Specimen 3.—Dirty yellowish in colour, containing a fair amount of undigested food and some flakes of mucus, also some small masses of soft completely digested material.

Reaction: Acid to phenolphthalein.

Total acidity	0.145 per cent.
Acidity due to HCl	0.1095 "
Acidity due to organic acids	0.0365 "

Stercobilin was isolated from the vomit and gave the typical bands spectroscopically. Indol was obtained by distillation. The vomit contained a fat and a starch-splitting ferment.

Specimen 4.—The vomit separated into three layers, a lower layer and an upper layer of soft yellowish-white puttyaceous material, which contained a lot of fat and was quite structureless and completely digested. Extraction gave evidence of stercobilin. Otherwise like result of Specimen 3.

Examination of the faeces showed them to consist of a liquid brownish-white material, with small hard whitish masses. There was no blood or mucus. Microscopically there was no undigested muscle or vegetable fibre. No free undigested starch. The stool contained 80 per cent. water.

Total fats, dry weight	29.72 grams per cent.
Fatty acids and soaps	20.56 "
Neutral fats	8.76 "

It seemed plain from these results that faeces were intermittently entering the stomach and a jejunocolic fistula was diagnosed. The stomach emptied itself quite well at times, but the regurgitation into it of faeces and duodenal contents simulated retention of food. It was also clear that the direction of flow was from the colon into the stomach, and not vice versa,

as no undigested food or excess of fat was present in the faeces. In spite of the presence of faeces in the stomach the appetite was unimpaired, the secretion of HCl was what is usually found after a gastro-enterostomy, and there was practically no vomiting. The passage of the colonic contents along the small intestine no doubt was responsible for the diarrhoea.

An x-ray examination of the alimentary canal did not help much. The stomach showed nothing abnormal and emptied through the stoma within two hours, a small quantity passing through the pylorus and duodenum. Five and a half hours after ingestion only a small quantity of the meal was in the lower coils of the ileum, the bulk being in the colon, extending into the ascending part of the organ. The passage through the small intestine was thus abnormally rapid. The whole of the meal had been evacuated after twenty-five hours. An opaque enema flavoured with peppermint was administered. A shadow was seen to distend the descending colon and splenic flexure and to pass along the course of the transverse colon. No gas flavoured with peppermint was eructated.

A faint shadow appeared above the level of the transverse colon, but it was not definite enough to lead one to infer that the enema had passed into the stomach. The x-ray examination thus merely demonstrated the rapid emptying of the stomach and the great irritability of the intestine.

First Operation, November 25th, 1915 (W. T.).

There were many adhesions and much distortion of the parts. The fistula was in the same position as that described in the previous case, and was opened up by dissecting the colon away from the jejunum. On account of the very severe inanition of the patient, which did not seem to permit of a prolonged operation, the separation of the colon and jejunum was carried only just far enough to define the openings which had contributed to the fistula and allow of them being sutured. Even so the operation had been a prolonged one through the difficulties presented by adhesions.

For the first week or ten days after the operation there was very pronounced distension of the caecum and ascending colon, which could be felt in the right side of the abdomen as a firm resonant swelling. It was feared at one time that the condition would pass into one of complete obstruction. Gradually, however, it subsided, though for several weeks the caecum remained unduly prominent, and showed visible and palpable peristalsis.

Subsequent Course.

The patient gradually put on weight and by the end of February, 1919, was able to walk out. He passed three or four light and loose motions a day for a time. An examination of a stool on December 31st, 1918. Whitish and containing a lot of viscid mucus. Acid to phenolphthalein, the acidity being 0.073 gram per cent. and due to fatty acids. It contained a fair amount of undigested starch and a very little muscle fibre. *B. coli*, streptococci, and a fair number of anaerobes were present.

Chemical examination:

Water 87 per cent.
Total fats = 14.382 grams per cent. dry weight.
Fatty acids = 14.1, and neutral fats 0.282 per cent.

Stercobilin but no bile present. No digestive ferments present.

This looseness was controlled by chalk and Dover's powder, and finally he passed one light coloured solid motion a day. He had no severe pain as before, but had distension of the gut on and off, giving rise to slight pain. On March 6th, 1919, he vomited up voluntarily a large quantity of material with obvious faecal odour, and it was quite evident that the fistula had become re-established.

Second Operation, March 10th, 1919 (W. T.).

The difficulties of defining the parts involved were greater than at the foregoing operation. Doubtless as the result of the prolonged distension of the caecum and ascending colon the affected organs had been displaced far into the left hypochondriac region and had become fixed there. Full definition was, however, at length obtained, and showed that the fistula had re-established itself apparently by the formation of a small abscess between the line of suture in the jejunum and that in the colon. There was, moreover, in the jejunum, just below the level of the fistula, a stricture which made it plain that a resection of this segment would be necessary, and a stricture in the colon above the fistula which reduced the lumen of the bowel to the size of the little finger. A resection of the colon was therefore also necessary. The segment of the stomach wall containing the gastro-jejunosomy opening was cut out and the stomach wall closed, thus abolishing the anastomosis. A length of jejunum of three or four inches, including the anastomosis, the fistula, and the stricture, was removed, and the bowel joined end to end. A length of colon about five inches, including the fistula and the stricture, was then removed and the gap closed by end-to-end suture. Finally, a temporary caecostomy opening was made.

Subsequent Course.

The caecostomy wound closed in a few days. The patient gradually put on flesh and recovered much more quickly than from the first operation. He had slight distension and discomfort, but no pain or trouble with the bowels. He passed one motion a day, which was formed and gradually became darker in colour. At one time he was a little constipated. When seen last, in December, 1919, he was in a good condition, and had no pain, but only slight distension occasionally.

CASE III. Posterior Gastro-enterostomy (December, 1910): Constipation and Intestinal Pain for Five Years; then Diarrhoea and Vomiting: Operation for Jejuno-colic Fistula (July, 1916); Improvement: Recurrence of Symptoms.

A medical practitioner, aged 49, came under observation on October 25th, 1910.

History.

He had suffered from indigestion for fifteen years, and for the past seven years pain under the right costal margin, occurring two to three hours after a meal and having all the characters of that due to a duodenal ulcer. There was never any bleeding. He had lost flesh. There was a tender point about the tip of the ninth right rib cartilage. The total HCl secreted was 0.29 per cent., and an x-ray examination showed that the stomach was dilated, but emptied itself within four hours. He was treated in bed on a graduated diet, and was much better in every way, but he still had occasional pain.

Gastro-enterostomy.

An operation was recommended, and this was performed on December 12th, 1910. A duodenal ulcer was found which had considerably narrowed the duodenum. There were no adhesions to the liver or gall bladder. The stomach was considerably dilated and there was some obliteration of the lesser sac towards the pyloric end of the stomach. Posterior gastro-enterostomy was performed, and the day after the operation the patient vomited a considerable quantity of blood.

After-History.

He recovered and went away to Cornwall, and in February, 1911, wrote that "the least attempt to eat to full satisfaction was always followed by much discomfort." His diet was of the simplest. His pain under the right costal margin had disappeared, and continued absent for four or five years, when it commenced again, but was not so severe or constant as formerly. Soon after the operation the bowels became very constipated, and the patient suffered from colicky pains in the lower part of the abdomen on and off. He would sometimes have three or four attacks in the day, and they often came on two to three hours after food. Till June, 1916, the patient suffered now and then from these pains and constipation, and, in addition, the old pain had also been present for a year or more. At the end of June, 1916, diarrhoea commenced, and one day there was "constant nausea and a horrible taste in the mouth." In the evening of that day he vomited up a large quantity of material with faecal smell and became quite collapsed. The vomiting recurred on several succeeding days, and a faecal fistula was diagnosed.

Operation for Jejuno-colic Fistula.

Operation on the fifteenth day after the vomiting commenced (W. T.). A fistula similar to that present in the cases already described was found. The transverse colon and jejunum were dissected apart, and the resulting openings were closed by suture. This was effected without encroaching on the anastomosis or unduly limiting the lumen of either of the segments of gut.

Subsequent Course.

The faecal vomiting was at once arrested and the patient's general condition, which had been extremely bad at the time of the operation, began to improve forthwith. The patient remained comparatively well till March, 1917, when the old pain returned and melaena occurred. In January, 1918, another attack of the old pain occurred, and amounted to a hunger pain, being relieved by food and alkalis; also a paroxysmal pain, about or below the umbilicus, appeared, and was associated with constipation. These pains continued on and off till May, 1918, when melaena recurred. Since this time he has had several attacks of pain.

CASE IV.—Posterior Retro-colic Gastro-jejunosomy (June, 1914): Haematemesis followed by Diarrhoea; Faecal Vomiting; Laparotomy (March, 1916): Death.

G. I., male, aged 53 years, was first seen on May 7th, 1914.

History.

He gave a history of five years' illness. He had a boring pain situated in the abdomen, just above the umbilicus and extending outwards to the sides and round the back; at times it would extend up over the front of the chest and shoulders. It came on one hour after food and woke him in the night. It had become more constant and continuous for the last two years, the only relief being for about four months in the summer. There was no vomiting, unless voluntarily induced, when it relieved the pain. There was never any bleeding. He had a feeling of fullness, but there were no eructations. His appetite was bad; the bowels were regular. He had lost flesh, but was still fairly well nourished. There was no tenderness. The stomach was dilated and a marked splash was obtained, but no visible peristalsis.

A test meal showed:

Total acidity	0.401 per cent.
Free HCl	0.292 "
Protein HCl	0.109 "
Total HCl	0.401 "

An x-ray examination confirmed the dilatation of the stomach, and showed that the organ emptied itself in four hours. No irregularity suggesting ulcer was seen.

Posterior Retro-colic Gastro-jejunostomy.

The patient was operated upon in June. The stomach was dilated. A hard mass was situated at the pylorus and fixed posteriorly, the gall bladder being adherent. A posterior retro-colic gastro-jejunostomy was performed.

Symptoms of Jejuno-colic Fistula: Laparotomy: Death.

The patient came under observation again in March, 1916. He had kept well for four months after the operation and then the same pain had started again, and he had vomited blood twice in large quantities. The blood was clotted and coffee-coloured. The pain continued off and on till eight months ago, when it ceased with the onset of diarrhoea. The diarrhoea had continued to the present time. He passed ten or twelve motions a day at the beginning, but at present only three or four. The motions were light in colour. There was a good deal of eructation of wind. The appetite was poor and the patient was wasted. Vomiting had commenced three weeks before; it occurred one hour after food, and was said to consist of a bad-smelling brown liquid. An examination of the vomit showed that it was faecal.

A laparotomy was performed, but the cause of the vomiting was not discovered, and the patient died the next day.

Necropsy.

The transverse colon was adherent to the stomach and the jejunum, the three being matted together in the region of the gastro-jejunostomy stoma. The stoma was $1\frac{1}{2}$ in. in diameter and its edges quite smooth. The fistulous opening between the jejunum and the colon was $\frac{3}{4}$ in. in diameter and situated about $\frac{1}{2}$ in. from the stoma; it was lower in level than the stoma and a little to the left of it. There was a stricture of the transverse colon situated at the right edge of the fistula, and the colon was a little dilated behind the stricture. The edges of the fistula were quite smooth and healed. This portion of the jejunum was to some extent dilated. (See diagram.)

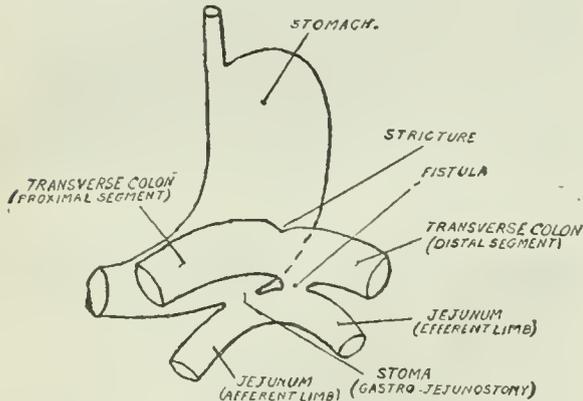

Diagram to illustrate the position of the fistula in Case IV. (The colon is pulled upwards to expose its junction with the jejunum.)

PATHOLOGY.

The condition present in these cases is nearly always a fistulous communication between the jejunum and the transverse colon, the fistula being situated quite close to gastro-jejunostomy stoma and below it. The colon is situated in front and above the jejunum. This was the condition in our four cases. The descriptions of the exact anatomy of the parts is not always quite clear, but it appears to be uncommon for the stomach itself, through a new aperture or through the stoma, to communicate directly with the colon. Both the stomach and the jejunum may, however, open into the colon in the same case. The fistula may in rare cases be situated a few centimetres lower down the efferent limb. Multiple jejunal ulcers may be present sometimes, and these may either bleed or perforate. The edges of the fistula are smooth and healed, and the gastro-enterostomy stoma may be closed. The ulceration has probably been more widespread than appears to be the case, since both closure of the stoma and narrowing of the colon are due to the healing of ulceration. A localized perforation into the anterior abdominal wall may have occurred with the formation of an inflammatory swelling. In most cases, as is evident from a consideration of the anatomy of the parts, the usual result is regurgitation of the contents of the colon into the jejunum, and a minimal passage only of jejunal contents into the colon. This accounts for the absence of undigested food in the stools in most cases. The degree of regurgitation into the jejunum obviously depends also upon the condition of the contents of the colon; the more liquid they are the more likely are they

to regurgitate; and, in fact, at this position in the colon the contents are normally considerably inspissated, hence these patients may only suffer from considerable regurgitation when they have diarrhoea. Thus the regurgitation is intermittent, and the patient feels better when he is constipated. When regurgitation occurs into the jejunum the fluid no doubt passes in considerable quantity down the efferent limb into the small intestine, and in smaller amount into the duodenum and through the stoma into the stomach itself; hence vomiting may be absent or occur at rare intervals only, and the functions of the stomach, both with regard to secretion and motion, be comparatively uninterfered with. The vomit may have different compositions at different times. The circulation of the colonic contents through the small intestine no doubt infects it, and is responsible for keeping up the diarrhoea. Foul gas is more commonly eructated, as the escape of this into the jejunum does not depend on the fluidity of the faeces. How often stricture of the colon results is uncertain, but when it does it is the cause of faecal stasis in the caecum and parts proximal to the fistula, with colic in this portion of the bowel. The nutrition of the patient is frequently fairly maintained for a time owing to the absence of vomiting and the retention of appetite, but wasting gradually supervenes, and progresses more or less rapidly. If the stomach directly communicates with the colon—and also sometimes in jejunal fistula—the gastric contents directly pass into the colon, and lenteric diarrhoea supervenes.

SYMPTOMATOLOGY.

The fact that all the recorded cases are of the male sex need cause no surprise when it is remembered that about 80 per cent. of jejunal ulcers occur in men.

The symptoms of fistula may be preceded for a longer or shorter time by those of jejunal ulcer—namely, pain, vomiting, or bleeding, or even those of local peritonitis—but such symptoms may be entirely absent, and the fistula appear to occur in the midst of good health. An unsuspected fistula may be found at an operation undertaken for the relief of recurrent symptoms following gastro-jejunostomy.

The time between the performance of the gastro-jejunostomy and the development of symptoms of fistula varies from a few weeks to nine and a half years.

Onset.

Perhaps the earliest symptom in most cases is diarrhoea, usually with intestinal colic, which may begin quite suddenly, and is gradually followed by wasting and occasional vomiting. In a minority of cases the malady frankly declares itself at once by a sudden and profuse attack of faecal vomiting followed by diarrhoea.

Diarrhoea.

Diarrhoea does not appear to be as a rule continuous but rather occurs in attacks. It is not a watery diarrhoea, neither are very frequent motions passed as a rule. There is no blood nor mucus separate from the motion. The motion is pale and grumous, and undigested food is usually absent; if a few muscle fibres are found this is rather due to the condition of diarrhoea than to direct passage from the stomach. Neither is the fat usually increased, the proportion of split and neutral fat being about normal. Now and then lenteric diarrhoea is observed and a high percentage of fat. In the intervals formed motions are passed, and at such times the patient appears better in all respects.

Vomiting.

Although vomiting may be one of the earliest symptoms, and may regularly occur with the diarrhoea, it may be absent or only occasional, or simply induced voluntarily to procure relief. Such cases are very liable to be overlooked, inasmuch as the vomited matter may not be available for inspection, and, if it is, it may not be faeculent at the time. The vomited matter may be quite similar to that passed by the bowel and have a typical faecal odour, but at other times the vomit simply has a sour smell, and contains bile and pancreatic forments. In such cases the vomit should be examined for stercobilin and indol due to admixture with small amounts of faecal material.

Gas.

Eruclation of foul-smelling gas appears to be an early and fairly constant symptom, but it would be a mistake to suppose that large quantities of gas are present in the stomach as in some cases of gastro-colic fistula; such is not the case.

Pain.

Pain of intestinal origin is a symptom of the disease. It is more or less general in distribution, and due to colic of both small and large intestines, but pain below the umbilicus due to colic in the colon is more especially seen, and particularly on the right side. It is probable that in such cases there is more or less narrowing of the transverse colon. Two of our cases had a great deal of pain in the left hypochondrium. The pain may be relieved when diarrhoea appears.

Appetite.

The appetite is often lost, but it is remarkable that sometimes it is quite good and even increased. In one of our cases the patient after vomiting would become quite hungry and eat a good meal. Wasting is a constant symptom, and the patient tends to go slowly downhill.

Physical Examination.

Nothing characteristic of the disease is revealed by physical examination of the abdomen. There may be some distension, particularly on the right side. Peristalsis of the proximal portion of the colon may be seen. In one case an inflammatory swelling occurred, due to a local perforation of the jejunal ulcer.

Gastric Contents.

After a test meal the gastric contents show the presence of hydrochloric acid, usually diminished in percentage, as is usual after a gastro-jejunosomy. Free HCl may be present.

X-ray Examination.

X-ray examination may or may not be of value. In our cases it was inconclusive. In the case of Carnot two examinations were made: at the first the bismuth enema was arrested at the centre of the transverse colon and then passed, little by little, towards the hepatic flexure, whilst at the point of arrest the shadow of the stomach gradually appeared and was separated by an air bubble from the colon. At the second examination there was no gastric reflux to be seen. In the case of Downes the bismuth was seen to pass in both directions. Other observers obtained negative results and others again positive.

Other Methods of Examination.

Similarly in the case of other methods which have been used for the recognition of gastro-colic fistula, a positive result may or may not occur; such methods as have been employed are:

1. The giving of substances by the mouth which shortly afterwards may be recognized in the faeces (for example, charcoal or poppy seeds.)
2. The recovery of a coloured fluid by tubage of the stomach which has been injected as an enema.
3. The direct passage of air into the stomach on insufflation of the rectum, and vice versa.

It is not astonishing that these methods have yielded different results, when one considers that the cases differ considerably in the exact position and size of the fistula and probably in the fact that the opening may be in some cases valvular.

DIAGNOSIS.

The diagnosis is made by finding faecal material in the vomit or gastric contents of the patient. This may be very difficult when the leak is intermittent, but when the other symptoms suggest a fistula the attempt should be repeatedly made. If faecal material is present, the only condition likely to be confounded with fistula is intestinal obstruction, which might be suggested by the visible peristalsis which is seen in some cases of fistula, but the persistent diarrhoea and the fact that when constipated the patient is obviously better should prevent confusion. It is so easy to miss these cases that they should always be kept in mind and every case of vomiting and diarrhoea after gastro-jejunosomy thoroughly investigated. The special methods of investigation mentioned above are not

likely to prove of value when faecal material is persistently absent from the vomit, but when foul gas is eructated and there is no vomiting the stomach contents should be investigated and these methods systematically employed. The presence of lenteric diarrhoea, if it happens, is by no means conclusive, as this may occur in intestinal catarrh.

PROGNOSIS.

The immediate prognosis is good if the case is operated upon. Probably it is always eventually fatal if not operated upon. Of the 31 cases recorded 4 were not operated on and all died, one of perforation of another jejunal ulcer, one of haemorrhage, and two of inanition. Of the 27 cases operated on 21 recovered and 6 died. Of the 6 deaths in 2 a laparotomy was performed, but the fistula was not touched. Of the cases which recovered, 3 were operated on twice and one three times. The further history of these cases remains to be recorded.

TREATMENT.

The only treatment of any avail when a jejuno-colic fistula is established is by operation. The aim should, however, be to prevent the occurrence of jejunal ulcer, which is the cause of the fistula.

PROPHYLAXIS.

Whether the jejunal ulcer commences at the anastomosis and is the result of the injury inflicted by the operation, or whether it occurs in the jejunum at a distance from the stoma and involves another etiological factor, there is no doubt that the free HCl of the gastric contents plays the same part during the process of the formation, of the spread, and of the healing of the ulcer, as it does in the case of ulcer of the stomach. The experiments of one of us (C. B.¹⁹) have demonstrated what are the precise effects of this acid at each of the above mentioned stages. The HCl acts as a protoplasmic poison in strengths such as may be found in the condition of hyperacidity; it possesses irritant properties, and causes gastritis and follicular ulceration; it also possesses necrotic properties, and in strengths which are of themselves inert it can add its devitalizing power to that of another agent, and thus initiate self-digestion. Thus the formation and spread of an ulcer are greatly facilitated or even initiated, and the healing is delayed owing to necrosis of the connective tissue base of the ulcer, so that the epithelium has no stroma over which to grow.

After the operation of gastro-jejunosomy the percentage of HCl in the gastric contents is, as shown by Paterson²⁰ and Wilcox,²¹ diminished, and it is sometimes absent, but several observers have shown that in jejunal ulcer hyperacidity is commonly present, and Paterson,²² who strongly supports the importance of this action of HCl, has shown that in such a case the acidity fell on a milk diet, and remained down after operation, but that later, with a recurrence of the pain, hyperacidity again appeared.

The work of Pavlov²³ has shown that certain foods call forth but little secretion of gastric juice, whilst others produce a maximum secretion. We have thus a method whereby we can control the amount of gastric juice secreted, and if after the operation of gastro-jejunosomy we put these physiological principles into practice, and carefully diet our patients, we shall be doing our best to remove one of the causes of jejunal ulcer. At the same time, the administration of alkalis will materially assist towards this end.

REMARKS ON SURGICAL TREATMENT (W. T.).

It is obvious that the three cases that have come under my care do not afford material for any very wide general conclusions. It would seem that in general the obliteration of the fistula without interference with the gastro-jejunal anastomosis is the best procedure to carry out if it is possible and there is no contra-indication such as active ulceration or the presence of a stricture.

To secure satisfactory closure of the openings which have constituted the fistula it is essential that the colon and jejunum should be freely separated from one another, and it is desirable that a piece of omentum should be put between them.

If it is not possible to get the colon and jejunum well separated without encroaching on the anastomosis, then the latter must be sacrificed and the piece of stomach wall

containing it excised. If a stricture is actually present or suture of the opening is likely to narrow too much the lumen of jejunum or colon, an appropriate resection will be necessary.

In any case the establishment of a temporary caecostomy is of the greatest value. The sole purpose of such an opening is to prevent the accumulation of flatus in the colon above the suture line. By it the sutures are relieved from any strain and the patient is entirely spared the discomfort and danger of post-operative distension.

If the pylorus is still obstructed and it is necessary to obliterate the anastomosis, a fresh gastro-enterostomy must be done or an extensive resection of the stomach, such as described by Clairmont.

SOME NOTES ON MILITARY ORTHOPAEDICS.

BY

R. W. SUTHERLAND, M.B., Ch.B.,

MAJOR R.A.M.C.,

LATE SURGEON SPECIALIST AND OFFICER IN CHARGE SURGICAL
DIVISION, — MILITARY HOSPITAL;

AND

J. M. CHRISTIE, M.B., Ch.B., F.R.C.S. EDIN.,

CAPTAIN R.A.M.C.,

LATE SURGEON SPECIALIST AND OFFICER IN CHARGE ORTHOPAEDIC
DEPARTMENT, — MILITARY HOSPITAL; SURGICAL SPECIALIST,
MINISTRY OF PENSIONS.

In this article, which is based upon experience gained in the orthopaedic department of a central military hospital, we desire to draw attention to certain principles which are not so widely known to the profession generally as they ought to be, and to give some few illustrative details. We do not claim to have made original discoveries, but we have had ample opportunity of applying and learning the value of those made by others, and of working out methods of treatment best suited to the multiplicity of complicated lesions with which we have had to deal.

Our work was under the ultimate supervision of Colonel Carless, C.B.E., A.M.S., Consulting Surgeon to the Eastern Command, whose kindly criticism and unsparing help, and commendation when earned, made it possible.

The accumulation in England of chronic cases showing gross deformity and loss of function, the result of severe gunshot wounds, made it necessary to collect them in centres where they could be studied in detail and collectively, and where treatment could be instituted to restore the maximum function possible.

It was early seen that an authoritative statement of military orthopaedic principles, based on an exact knowledge of anatomy, physiology, and pathology, was necessary. The principles of treatment were established, and in this matter our country has been fortunate in possessing as Director of Military Orthopaedics one who has been described in America as the greatest orthopaedic surgeon in the world—Sir Robert Jones.

It was abundantly clear to those of us responsible for surgical cases in military hospitals that no one man could carry out satisfactorily the complicated investigation and detailed treatment required. No haphazard method would suffice, but a system must be instituted. Team work in the widest sense was necessary to achieve the best results, with the greatest economy of effort.

Team Work.

Each case was examined by the various men who specialized in some branch of investigation, and when the notes were completed, with photographs, stereoscopic radiographs, pathologists' reports, reports on electrical examination, results of dental examination, etc., the case was reviewed as a whole. The sequence of treatment, operative and otherwise, was considered, with the ultimate result to be hoped for. Each specialist carried out his share, and the head of the department reviewed the cases weekly. The individuals engaged in this work, by exchange of views and discussion of cases, gained a wider knowledge and a broader view than was possible singly. We all felt that by this means we were achieving results which justified our methods.

Those of us who served in the army abroad and had to deal with the severest primary lesions, and who on pension boards are now considering the ultimate results of such cases, are astonished at the wonderful functional recoveries which come before us. When it is remembered that the country has undertaken financial responsibility for these lesions, assessed on the existing degree of disability, it at once becomes apparent how well worth while this work has been to the nation, apart from the increased productive capacity and happiness of the wounded.

In noting these results it is hardly to be wondered at that Sir Robert Jones, whose principles have formed the foundation of military orthopaedic surgery, wishes to hand on to the civilian population the benefits now conferred on the soldier. The question is a national one, and comparison of expenditure and results to be obtained will show such a plan to be a national economy through the resulting increase in productive capacity.

In no field of medicine is the necessity for exact observation and clear thinking so necessary. A limb which at first sight appears hopeless may, as investigation is carried into each detail of its function, finally give a ray of hope, which persistent treatment justifies. Again, have we not often heard of useless massage, patiently carried out, for a joint with bony ankylosis? Examples could be multiplied.

Repair: Principles and Details.

In dealing with chronic sepsis and repair, the questions of phthisis, nephritis, syphilis, dental caries, secondary anaemia, and intestinal toxæmia are of the greatest importance. In the matter of "fresh air" we were able to make an interesting experiment. Our hospital was by the sea. Our surgical wards, built for that purpose, were of brick, large and airy, and we think would have been pronounced excellent by the greatest purist; but we moved our worst cases to temporary huts by the beach, where their beds could be carried out to the sea front, and where they remained all day. The effect was excellent. As the sun and wind bronzed them, so it seemed their appetites increased, they put on weight, sepsis diminished, and wounds healed. As they watched the bathers in the sea and the children on the beach their whole outlook on life changed, their neurasthenia diminished, and they too were on holiday and wanted to be up and doing again. Employment, amusement, surroundings, fresh air, and sleep—everything helped. The diet was varied and generous, and, when possible, adapted to suit particular tastes.

Anaesthesia.

In the giving of anaesthetics we found a useful field for ether by the rectum, with morphine and atropine. This was specially valuable in head, neck, and chest cases, and in patients who had been gassed or were bronchitic. An enema was given on the day preceding operation; rectal lavage with saline on the morning of operation, and a moderate breakfast. Morphine gr. $\frac{1}{4}$ with atropine gr. $\frac{1}{10}$ was given, and half an hour later 6 oz. of ether to 2 oz. of olive oil were very slowly run into the rectum by gravitation; this took twenty minutes to administer. Absolute quiet and suggestion of sleep were employed. When the patient appeared to be sleeping soundly he was carried from the ward to the theatre. Immediately the operation was over a flatus tube was introduced and the anaesthetic evacuated. The rectum was washed out several times with saline, and 2 oz. of pure olive oil introduced. The anaesthesia was light, without post-operative shock, and we had neither sequelae nor complications.

Vaccines.

Our experience of autogenous vaccines led us to believe that they undoubtedly assisted in the combating of sepsis, and that they were a safeguard against the "flare up" of a chronic lesion when an operation had to be performed.

Operation.

We early learned the value of as perfect an aseptic technique as we could practise. An already chronically infected wound gave added reason for the avoidance of a superadded sepsis in a debilitated patient.

We placed great importance on the line of approach to the focus we proposed excising, planning our incision and operation on anatomical principles. Sinuses very frequently lie in close proximity to important structures, and the scar tissue, moreover, tends to drag those structures out of their normal position. It is therefore unwise to follow a sinus as a matter of routine. Kocher's principles regarding incisions, which carefully avoid all nerves, were our guide. When possible muscle planes were followed. The ultimate scar of the operation and any limitation of movement which it might cause had also to be considered.

We may cite an illustrative case:

An officer was admitted with a sinus in the axilla, running through a dense mass of scar tissue to the scapula at the origin of the long head of the triceps. Several attempts had been made to reach the focus without success. Finally we approached it by detaching the infraspinatus from its scapular origin, thus exposing with ease the axillary border of the scapula. A considerable sequestrum was readily removed and unhealthy bone excised. The flap was replaced and the axillary sinus healed rapidly. With the recognized after-treatment the functional result was excellent.

In the young soldier the importance of the epiphysis must not be overlooked.

An apparently minor point, but one of very great importance, is that of fascial planes, spaces, and sheaths. An impressive example of this is to be found in lesions of the hand and wrist. It is most unfortunate that the surgery of this region is generally regarded as "minor," and practised so casually; it resolves itself into that of planes.

Sepsis in Bone.

The excision of infected wounds whenever possible, which was practised in primary wounds as a routine with such success in the later days of the war, proved to be of equal value in chronic cases. The curetting of sinuses leading to infected bone was a useless procedure. Bone cavities with chronic osteomyelitis, and with or without sequestra, called for complete excision and the removal of overhanging edges. The cavity was left wide open and packed with gauze. We believe it mattered little what antiseptic was used if the operation was properly performed, and no antiseptic could make up for an incomplete operation. In our hands dichloramine-T in eucalyptol, etc., gave the most rapid results, producing healthy red granulations in a few days. The cavity was secondarily closed or covered in by sliding, pedicle, or Thiersch grafts, each method having its own indications.

The avoidance of unnecessary trauma was of primary importance if a severe reaction was to be averted. We used stonemason's chisels, made of hardened steel with very sharp edges. The chronic discharging sinuses of many months, and even years, were securely healed, and the function of the limb could now secure undivided attention.

Reamputations.

The principle that no plastic operation may be safely performed in the presence of sepsis is universally accepted. That reamputation is a plastic operation was early forced upon us in going into the history of patients who had undergone amputation; many showed repeated reamputations and reinfections—a little bit more of the limb had been lopped off on each occasion. Ill-considered surgery had increased the disability it had set out to cure.

In several cases of short thigh stumps with the scar adherent to the end of bone, we were able to turn a muscle flap over the bone end and so secure a good stump without further shortening.

Skin-grafts.

Many patients were disabled owing to weak scars, especially if adherent to bone, muscle, or tendon. The

raising of such scars, with the introduction of fat grafts between them and the deeper structures, was not successful. The scar tissue sloughed—no doubt from interference with its blood supply. The only satisfactory procedure was to excise the scar and fill the gap, if primary suture were impossible, by a sliding graft of skin taken from over soft tissues in the neighbourhood—Thiersch grafting the denuded area, if necessary. It was important to remember that such grafts contracted, and must therefore be cut larger than at first sight appeared necessary. In some cases the condition of the limb did not permit of a sliding graft and pedicled grafts from a distant area were used. The operation was in three stages—(1) the fashioning of the pedicle; (2) the transference of the graft to the area to be filled; (3) the severance of the pedicle and its replacement. Some surgeons have reported unfavourably on this operation, but our experience was good. Possibly undue haste in performing the successive stages may account for failures. We allowed a fortnight to three weeks between each.

Muscles, Tendons, and Nerves.

The lesions of muscles, tendons, and nerves are closely associated. Our experience of muscles has been that of investigation and remedial treatment by means other than operative. The wasting, contracture, or lengthening in neglected cases was most difficult to overcome, and required patient treatment by massage, electrical stimulation, posture, contrast donching, and active exercises.

Where tendons were limited in movement by adhesions we employed a fat graft, after division of the limiting bands, with satisfactory results. At a later date, and especially in the secondary suture of severed tendons, we replaced the fat graft by a piece of aponeurosis removed from the front of the leg immediately above the ankle joint. This we wrapped round the traumatized tendon and suture line, with the deep (smooth) surface outwards (Mayer). In transplantation of tendons we made use of the minimum number consistent with fair function and the natural balance of antagonistic muscles. We realized the importance of correct alignment of the muscles and tendons and posture to approximate their origin and insertion. We found it equally important to avoid overcorrection. Whenever possible, following the researches of Mayer and Bieszski, we made use of the sheath of the paralysed or damaged tendon. Every effort was made to secure implantation into bone which undoubtedly gave the best functional results.

Nerve lesions present a multiplicity of phenomena, some of an associated functional and organic syndrome which the investigations of Tinel, Dejerine, and others have done so much to elucidate. Here again we employed fat grafts after suture of divided ends when the junction lay in the midst of much fibrous tissue. In severed nerves end-to-end suture was the only method which gave favourable results in our hands. In regeneration of nerves Tinel's test of formication on percussion is undoubtedly the finest at our service.

Joints.

No lesion of joints are more common than ankylosis following injury or the injury of structures affecting them. No conditions require more careful consideration before interference. The established practice of putting a joint through its complete range of movement under an anaesthetic in cases of adhesions following disuse and certain non-pyogenic infections is rarely applicable to the conditions so frequently existing in war wounds. Massive adhesions may preclude movement by reason of the risk of fracture, or the production of considerable trauma by forcible movement may result in the same degree of limitation as before treatment. The gradual stretching of intractable adhesions by the various forms of rack splint yields much more favourable results. In many cases, especially when complicated by nerve lesions with long-standing paralysis or severe scarring with loss of muscle, it was felt best to leave the joint severely alone if in or near the optimum position.

In malposition we practised excision of the joint, in some cases with a view to ankylosis, in others—for example, the elbow—to obtain as much active movement as possible. It was surprising to find how great a range of useful movement could be secured, especially at elbow and

shoulder, after excision. It was our practice to sacrifice diseased or doubtful bone quite freely, following rigidly the subperiosteal method of Ollier. We commenced passive movements on the day following operation, and encouraged attempts at active movement as soon as the swelling or reaction had subsided. We used splints which enabled patients to get up as soon as the effects of the operation had passed off.

Bone.

We have already referred to our experience in dealing with sepsis in bone, and will only mention the subject of mal-union and non-union. In mal-union, where the conditions interfered with the function of the limb, we believed it wise to avoid the lately infected area if there had been extensive or deep sepsis, and to do an osteotomy in a healthy area. In non-union, often with a considerable gap, we employed lateral grafts or medullary pegs. We preferred the medullary peg, taking it from the tibia. This enabled a portion of healthy bone to be placed in firm contact with a vascular area in the affected bone, whereas in a sliding graft bone is being dealt with which is often rarefied by disuse or porous by previous infection. Transplantation of a massive lateral graft, including medulla, gave good results, but it was very difficult to secure a firm apposition. The medullary peg has the advantage of stability.

This paper has mainly dealt with certain points, in investigation and operative treatment, which have appealed to us. We would give a wrong impression of the work did we not mention in conclusion that the after-care of the patient occupied the bulk of our time. In the massage and electrical departments, in the gymnasium and workshops, in organized exercises, sports and amusements, the gradual re-education of function was attempted. It may be interesting to mention that little special equipment was obtained for this work; the adaptation of the material to be found in any hospital met most of our requirements.

The enthusiasm and organizing ability of Lieut.-Colonel C. R. Sylvester Bradley, R.A.M.C., overcame all difficulties, and to him we are indebted for permission to publish this article, based on the practical work in the hospital under his command.

PHYSIOPATHIC PARALYSIS OF THE HAND, AND ITS CAUSATION.

By R. G. ABERCROMBIE, M.D.,

ASSISTANT PHYSICIAN, SHEFFIELD ROYAL HOSPITAL; MEDICAL
DIRECTOR, EDGAR ALLEN INSTITUTE, SHEFFIELD.

BABINSKI,¹ who first clearly described the condition, suggested the name of "physiopathic paralysis" for certain anomalous cases of paralysis and contracture of the hand following upon wounds of the upper extremity. The cases are of special neurological interest in that their general characteristics point to a psychological origin, yet, unlike other forms of functional paralysis, they exhibit well-marked organic changes in the tissues.

Clinical Features.

A large number of cases amongst soldiers and war pensioners, recently under my care, have provided material for the following observations, which are chiefly concerned with those features which serve to elucidate the pathology.

Without apparent adequate cause, a wound of the upper limb is followed by loss of power in the hand of the affected side. Neither the situation nor character of the wound bears any relation to the grade of the subsequent paresis; none of the symptoms correspond to the territory of any particular nerve.

The short muscles of the hand and the long flexors are chiefly affected. The muscles are sometimes limp, more often spasmodically contracted, so that the hand assumes various postures; frequently the palm is hollowed and the fingers imbricated one over the other, to form the so-called "accoucheur's hand." The paralysis is usually not complete; feeble movements can be performed in a tremulous or "wagging" manner. The thumb often escapes, so that the hand can meet the needs of a hospital patient or pensioner, though inadequate for any useful purpose.

The sensory symptoms are limited to an uncertain and varying hypo-aesthesia and contortions of apparent pain

on the performance of passive movements. The patients are unduly apprehensive of pain, and are devoid of the normal impulse towards recovery.

The affected muscles waste, often extremely; they exhibit mechanical hyperexcitability; slight electrical changes occur, but the reaction of degeneration is not present. The skin, subcutaneous tissue, and bones share in the atrophy, so that the whole hand appears attenuated and smaller than its fellow. The skin is salmon-pink or cherry-red in colour, with a satin-like sheen around the roots of the nails. Trophic sores do not occur. The nails are curved and longitudinally grooved, sometimes greatly deformed; beneath their free margin a small fold of skin is often visible.

Profuse sweating of the palm is a common and striking feature; and it is of special interest that this symptom is directly influenced by emotion. If the affected hand be unexpectedly seized and examined, the palm may be found normal or slightly moist; if now the hand be made the subject of discourse to bystanders, beads of sweat form upon its palmar surface, until finally a sheet of moisture is formed over the whole palm. The palm of the opposite hand may also become moist, but not to anything like the same extent; meanwhile the rest of the body shows no abnormal sweating. Localized flushing of the affected hand may sometimes be similarly produced.

Cases are sometimes left in massage departments without adequate psychological treatment, so that the natural evolution of the symptoms is undisturbed. Such cases in process of time enter a clearly marked late or secondary stage, in which the profuse sweating, the congestion, and the idio-muscular reflex have disappeared, but the wasting and the paresis persist; the latter is often accentuated by adhesions, and in severe cases by actual distortion of the joints.

The foot may be affected, but this is rare. I have seen five such cases with well-marked trophic changes during the last year. The inverted and hollowed sole and tense tendo Achillis appear to exercise a great attraction for surgeons; three of the five cases, from different parts of the country, had been submitted to tenotomy. In each case operation rendered the condition worse.

Pathology.

Babinski has suggested that the symptoms are reflex phenomena, the peripheral wound supplying an irritative stimulus to a centre in the cord, from which centrifugal impulses pass to the affected member. This view has not, however, been widely accepted in this country; the general features, and especially the rapid and striking improvement which often follows appropriate psychological treatment, have led to the general belief that the symptoms are essentially of psychological origin. The paralysis is thus regarded as hysterical and the trophic changes as merely the result of disuse.²

This explanation, completely adequate for the motor symptoms, is quite insufficient for the trophic changes which constitute the essential distinction between these cases and those of ordinary hysteria. In the first place, many long-standing cases of hysterical paralysis of the hand occur in which the disuse causes no trophic changes at all, or at the most a slight general wasting of the muscles; whereas in physiopathic cases severe trophic changes may occur with considerable rapidity. Again, were it true that the trophic changes were merely the result of disuse, they would become more accentuated the longer the disuse lasted. But this does not occur; on the contrary, in long-standing cases, as mentioned above, the profuse sweating, congestion, and idio-muscular reflex tend to disappear, notwithstanding the persistence of the paralysis. Finally, the physiopathic condition is essentially a war phenomenon; Weir Mitchell noticed similar cases during the American Civil War.³ In civilian hysterical paralysis localized sweating sometimes occurs, and may be regarded as a minor physiopathic manifestation; but severe trophic changes are exceedingly rare.

Some additional factor must therefore be imported by the effects of war, capable of superadding trophic changes in cases of functional paralysis.

Certain general symptoms, occasionally observed in unwounded men during medical inspection behind the line, throw light on the nature of this additional factor. Excessive sweating of a truly remarkable grade was sometimes to be noticed; even in cold weather the sweat

streamed down the upper arm from the axilla, and fell in rapid drops from the elbow to the ground; while the hairy scalp smoked from the warm moisture. Men showing this phenomenon were usually wasted, and a light tap on the pectorals provoked a strong idio-muscular contraction. These symptoms were seen in men going forwards, prepared to do their duty; the higher faculties still retained control of the machine, although the emotional strain of war had clearly produced a disturbance of the sympathetic system with its associated perversion of the internal secretions. The sweating, wasting, and muscular mechanical hyperexcitability thus produced are precisely the prominent symptoms in physiopathic paralysis.

Explanation of Symptoms.

The emotional strain of war induces an increased suggestibility (of which the exact process, conscious or subconscious, is outside the scope of this paper), so that a wound of the upper extremity is readily followed by hysterical paralysis of the hand. If the emotional strain has also brought about the profound disturbance of the sympathetic and internal secretions described above, these will specially affect the paralysed member, the nutrition of which is already lowered by immobilization. Further, since local sweating of the affected hand may be produced by emotion, it is reasonable to assume that other sympathetic impulses governing nutrition may be similarly affected.

In neurasthenia, morbid emotional states are generally credited with the power of causing functional disorders which may ultimately result in organic changes, as for example, in the abdomen. In physiopathic paralysis this process may be watched; and it is of special interest to observe its localization in the member towards which the patient's attention is directed, and which is the focal point of his emotions.

The physiopathic condition may thus be regarded as forming a link between hysteria and neurasthenia. The frequency of its occurrence in war is well explained by the depth of the emotional disturbance which war produces.

Relation to Nerve Lesions.

An irritative nerve lesion, owing to the pain and discomfort it causes, is not infrequently the provoking agent of a physiopathic condition; thus different areas of the same hand may show physiopathic changes side by side with the results of an organic nerve lesion. Such cases are often misunderstood; careful examination, however, readily discriminates the two conditions, the organic irritative lesion being distinguished by such features as the position of the wound, group-wasting, muscular tenderness, trophic sores and desquamation. The colour of the skin in the two areas is also often different. On examining such a hand I have often noticed the physiopathic area profusely bedewed with sweat, whereas the organically affected area remained dry, doubtless owing to the obstruction of the sympathetic impulses.

Treatment.

Psychological treatment by means of explanation, strong encouragement and re-education is the essence of success in dealing with these cases. The removal of the morbid mental state cures the paralysis and simultaneously eliminates the source of the perverted sympathetic impulses which are the cause of the trophic changes, the disappearance of the latter being greatly facilitated by movement and physical therapeutics. Recovery is almost invariable, and relapse is rare. Treatment is rendered noticeably easier by the patient's demobilization from the army.

Conclusion.

The emotional strain of war causes an increased suggestibility, with consequent liability to hysterical paralysis; the same emotional strain may also induce a disturbance of the sympathetic, the circulatory and trophic effects of which show themselves specially in the tissues of the paralysed member, partly on account of its immobility and partly owing to the localizing influence of the patient's emotions. This two-fold effect of hysterical paralysis with severe trophic changes constitutes the physiopathic condition.

SOME REMARKS UPON SYPHILIS, MORE ESPECIALLY INHERITED SYPHILIS.

BY

FREDERIC H. HAYNES, M.D. LOND., F.R.C.P.,
CONSULTING PHYSICIAN TO THE WARNEFORD HOSPITAL,
LEAMINGTON SPA.

SIR JONATHAN HUTCHINSON said that "thousands of men marry at or about the end of two years after having had primary syphilis, and many at much shorter periods, yet the instances of communication to their wives or children are but infrequent." With this statement I cannot agree. I have for many years watched the children of men whom I have known to have had syphilis, and in almost every case a serious defect of some kind has shown itself in their children; this is true in cases where the parents were carefully treated, some for as long as five years, and more than one by Sir Jonathan Hutchinson himself. The usual manifestations of inherited syphilis are well known, but I wish to make special mention of certain diseases which are not generally recognized as due to this cause.

Nervous Diseases.—I think the large majority of cases of epilepsy occurring in the young are due to syphilis either in the parent or in the grandparent. Epilepsy occurs most commonly in infancy and at puberty. Recurring "convulsions" in infants are usually epileptic and may be cured by a course of mercury; I usually rely on hyd. cum creta (gr. $\frac{1}{2}$ to 1 ter die), or inunction with ung. hydrargyri fort. Epilepsy beginning later is curable, provided the disease be at once treated with mercury; but when such cases are left untreated for a few years cure is less certain and treatment has often to be carried out for two years or more. For adults, and even for older children, I nearly always prescribe mercury perchloride, which I prefer to the green or red iodide, because, in contrast with the iodides, I have never known it to produce salivation, although continued for many months, or even years.

As an illustration I mention the case of a girl of 15, who suffered from large lymphadenomata on both sides of the neck, that on the left side beginning later in spite of a course of treatment by potassium iodide in large doses. This patient was given mercury perchloride gr. $\frac{2}{5}$ ter die, increased gradually to gr. $\frac{3}{4}$ ter die. The treatment lasted for over seven years without intermission, and there was never the slightest sign of salivation; the tumours almost completely disappeared. In this case the father denied having had syphilis, but he died at the age of 84 in an asylum, and had Argyll Robertson pupils. This girl at 42 is still well and has had no recurrence.

For epilepsy occurring in later life similar treatment is invaluable. The following case is instructive:

A man of 65 began to have epileptic fits, which occurred during a period of some weeks. He admitted having had syphilis when 23 years old. He was treated with mercury perchloride, and his fits soon disappeared. He died from spastic paraplegia at the age of 77.

I am acquainted with many cases in which one or more children of syphilitic fathers developed epilepsy at puberty, and were cured by courses of treatment by mercury. I know of two or three cases of optic neuritis occurring in adults whose fathers were syphilitic.

One of these was treated by an eminent oculist, but did not receive mercury. His father sent him to Pagenstecker, who took him into his house for a few weeks and cured him by rubbing in mercurial ointment.

Another youth, who had well-marked syphilitic teeth, otitis media, and interstitial keratitis, was treated by oculists for nearly two years, being given potassium iodide and ten drops of liq. hydrargyri perchloridi (that is, gr. $\frac{1}{15}$ ter die). Pagenstecker cured him in a month by mercurial inunction.

The following is a remarkable case, showing, I believe, the effects of syphilis on the third generation.

A girl of 24 consulted me for spastic paraplegia with weakness of the arms and affection of the eyesight. Her grandfather and grandmother died between 50 and 60 years of age from tabes dorsalis and apoplexy respectively. Her father, who denied having contracted syphilis, was nervous and shortsighted; he had had an attack of unconsciousness lasting for a week (he died from carcinoma of the caecum subsequently to his daughter's illness). Treatment of the patient by mercuric perchloride led to very striking recovery of the eyesight and arms; the legs did not improve.

I have traced the cause of several cases of enuresis to hereditary syphilis, and have cured them by a course of mercury.

Skin Diseases.

I have treated several cases of severe psoriasis with mercury. My first case came under observation at an early age, and showed an excellent result:

A boy of 12 or 13 had widespread psoriasis with abundant rash. Treatment with Fowler's solution in large doses caused improvement, but there were three relapses. I treated him with mercury perchloride and he made a good recovery, having no relapse during the many years in which I continued to come into contact with him. Subsequently his father consulted me for paresis of the right arm, and admitted having had a Hunterian chancre before the boy was born.

Tuberculosis of various types is not uncommon in syphilitics and their children; I mention two cases:

A lady suffered from fibroid phthisis, and died at the age of 39. Subsequently her father consulted me for severe headache, and acknowledged having had a Hunterian sore before his marriage.

A man of 35 suffered from haemoptysis, and tubercle bacilli had been found in the sputum. He admitted having had syphilis; I gave him treatment by mercuric perchloride. He took a voyage to the Cape and has remained well for ten years.

A careful study of family histories has convinced me that there is a want of stability about children of syphilitics. Among such cases I know of two who fell down dead when engaged in a paper chase, another who shot himself, and two who were rusticated from college. Of the latter, one died of phthisis and the other has a chronic suppurating sinus. I believe, also, that there is a much nearer relation between syphilis and cancer than is usually believed, and more especially between contracted syphilis in the parent and cancer in the offspring. I know of six syphilitics (acquired) who died from cancer of the gullet.

Of the wives of men who have had syphilis, I find that some seem to be unaffected and live to a good age, but a certain number die young. I can recall four or five instances of such women who have died from so-called puerperal fever, and several cases who have suffered from albuminuria, convulsions, or iliac thrombosis during or after pregnancy. I am acquainted with a case of Graves's disease cured by mercury, which occurred in the wife of a syphilitic; also with a similar one in the daughter of a syphilitic. A man I know had syphilis; his first wife had one child, and died from alcoholism; his second wife died from puerperal convulsions following albuminuria and dropsy. Other instances which I have observed of diseases occurring in those whom I have known to be affected with syphilis are: Dupuytren's contracture (several cases), so-called tuberculous glands of the neck, and ulcerative keratitis. I believe that Bright's disease is usually syphilitic, and recall the striking case of a medical man who had a digital chancre, and died at the age of 44 from Bright's disease.

It is often stated that congenital syphilitics may have healthy children. With this I agree, but I believe it partly depends upon whether one or both parents are congenitally syphilitic. I am acquainted with one case in which the son of a syphilitic married the daughter of a syphilitic; they had three children, but all died young. I knew the children of a healthy mother and a father who was congenitally syphilitic; one child died suffering from marasmus and an eruption; the others were apparently healthy.

I have a strong suspicion that many chronic diseases are due to a syphilitic taint. These cases, however, are very difficult to prove, and as one meets only one or two in a lifetime I make this remark that others may be induced to follow up clues. I have been designated a "syphilophobic," but I claim to have found evidence of many unrecognized cases of this disease. It is extremely important first to inquire most carefully regarding the family history, and, secondly, to examine the teeth. In many cases of congenital syphilis, although the typical teeth as described by Sir Jonathan Hutchinson may not be present, the teeth are irregular and the lateral incisors are often small or absent. Early decay is frequent. Some hereditary syphilitics have good teeth, but are affected in other ways.

TRANSFUSION OF BLOOD IN NEPHRITIS.

BY

JEFFREY RAMSAY, M.D., CAPTAIN R.A.M.C., T.F.,

BLACKBURN.

IN view of the interest which will be aroused by Dr. W. Blair Bell's article in the BRITISH MEDICAL JOURNAL of May 8th on the treatment of eclampsia by transfusion of blood, it may not be out of place to record the notes, made at the time, of the following case, which was admitted under my care to No. 64 Casualty Clearing Station in France during the summer of 1918.

The comparative incompleteness of the notes must be excused by the fact that the casualty clearing station was extremely busy at the moment.

A private, aged 22, who had previously been healthy, suffered from headache and vague generalized pains for ten days. On admission he was slightly drowsy and had a coated tongue; the systolic pressure was 100 mm. of mercury, the diastolic 60. The urine was acid, specific gravity 1010, with much albumin present, but no sugar; the centrifuged deposit showed the presence of many casts (chiefly granular), but no blood cells were noted on this nor any subsequent occasion. Respiratory, circulatory, and other organs appeared to be normal. His vomiting continued, and he could not retain anything given per rectum. During the first and second days he passed 10½ oz. and 2 oz. of urine respectively, and on the second his blood pressure fell to 90 mm. systolic, 40 mm. diastolic; suppression of urine seemed imminent and his condition was very grave. It was decided to try the effect of blood transfusion, and I injected intravenously 1,140 c.c.m. of fresh blood from a donor of the same group (IV) as the patient; the blood pressure subsequently rose to 100 mm. systolic and 50 mm. diastolic. Next day the diastolic pressure rose to 70 mm. of mercury; vomiting became much less frequent and in the ensuing twenty-four hours he excreted 24 oz. of urine. He was able to retain "rectal salines" and was given hot packs, as well as 1 c.c.m. of pituitrin six-hourly. Captain J. W. McLeod, R.A.M.C., kindly examined a specimen of blood and reported marked deficiency of fixed alkali, as estimated by Sellard's method.

Next day, in spite of retention of the "salines" and diminution of vomiting, urinary excretion fell to 16½ oz.; he was given intravenously one pint of a 2 per cent. solution of sodium bicarbonate, and during the next twenty-four hours he only vomited once and passed 22 oz. of urine. A pint and a half of sodium bicarbonate solution was given intravenously next day; vomiting ceased, and he passed 27½ oz. of urine in the twenty-four hours. He was now able to retain fluids given by the mouth, and 20 grains of sodium bicarbonate were given two-hourly. The excretion of urine rose to 54, 56½, and 61 oz. during the next three days respectively; the urine still remaining acid, the dose of sodium bicarbonate was increased to 30 grains, and he was given in addition 15 grains of potassium citrate three times a day, whereupon he passed alkaline urine to the amount of 61 to 81 oz. per diem during the next five days. By this time his general condition had become excellent, and the fixed alkali in the blood, as determined by Sellard's method, was normal. He was evacuated to the base on the sixteenth day; a last specimen of urine examined contained a faint cloud of albumin, and epithelial and granular casts were still present.

From a review of this case it seems clear that the transfusion of blood, performed when the patient was so ill that recovery seemed almost impossible, was the turning point in the course of the disease. We are still in a large measure ignorant of the metabolic changes associated with nephritis; the disease may depend on a deficiency of some chemical substance in the blood or tissues, or it may be due to an infective process the nature of which has not yet been determined. In either case, and in view of the low blood pressure, to introduce blood from a healthy donor of the same group appeared a rational procedure. It is important to point out, however, that there is no evidence that a solution of sodium bicarbonate given in the first instance would not have produced an equally satisfactory result; in the next similar case which comes under my care I shall give the bicarbonate first and the blood afterwards, if necessary. Everyone who has kept a careful record of blood pressure in nephritis will agree that the prognosis is worse on the whole in cases having a low systolic pressure; in such cases the above method of treatment seems to offer a hope of success. It would interest me to know if this was the first time that transfusion of blood was used in the treatment of nephritis.

THE physicians and surgeons of Madrid have adopted a resolution expressing determination to refuse to serve in hospitals unless well-to-do persons are forbidden to take advantage of free consultations. They declare their readiness to treat the poor without fee at hospital and dispensary consultations.

MEDICAL, SURGICAL, OBSTETRICAL.

BRONCHIECTASIS.

DR. JEX-BLAKE'S admirable lecture on bronchiectasis reported in the *BRITISH MEDICAL JOURNAL* on May 1st, 1920, serves to recall some interesting features of cases of this malady seen by me recently.

A man, aged 48, died from bronchiectasis of pneumonic origin after fourteen years. He suffered from recurrent severe haemoptysis, and from profuse purulent expectoration which would be suddenly ejected in considerable quantity, filling his mouth and nose. Chronic rhinitis resulted by direct infection from the pus, and both maxillary antra were in turn affected and drained for empyema. Another prominent symptom was severe frontal headache, which was undoubtedly due to a chronic inflammatory state of the frontal sinus, although no pus was at any time made out by radiographic examination. It is noteworthy that in this case, despite severe local lesions, general vigour was well preserved for many years.

A second case, aged 57, has suffered from bronchiectasis of simple origin for eight years, and his general state, despite multiple lesions, including nephritis, is still well maintained. The interesting features are (1) the tongue is enlarged, deeply fissured, and looks unhealthy generally, which condition is probably due to direct infection from the expectorated pus, for the more usual causes of glossitis are not present.

These direct effects of contact with the purulent exudate suggest a frequent use of mouth-washes, and also of nasal antiseptic fluids in suitable cases.

The second case for a year at least has suffered from chronic nephritis with albuminuria to the extent of 4 parts per 1,000 (Esbach). In the absence of other antecedent causes the nephritis is probably due to lardaceous disease, for the spleen is palpable, but no hepatic enlargement is present. There is no polyuria or other urinary changes usually associated with lardaceous disease.

The variability of the physical signs described by Dr. Jex-Blake can usually be shown at the time of examination, as it is not difficult to secure the expulsion of an ounce or more of pus.

IVOR J. DAVIES, M.D., M.R.C.P.,
Physician with charge of Out-patients, King Edward
Hospital, Cardiff.

SPONTANEOUS RUPTURE OF MALARIAL SPLEEN.

SIR JOSEPH SKEVINGTON'S note on spontaneous rupture of a malarial spleen (April 24th, p. 571) leads me to relate two cases of this rare accident which I saw about fifteen months ago in Macedonia. I can only speak from memory, for I have no notes.

The first was an English soldier admitted for malaria late one night to a hospital reserved for medical cases. He had come a long distance over rough roads with a large convoy. On admission nothing special was noted. In the morning he complained of abdominal pain, but his symptoms were not sufficient to arouse anxiety till evening, when it was thought, according to various opinions, that he had perforated gastric ulcer or acute appendicitis. As there was no surgeon in this hospital I was sent for from a neighbouring one to see him. He was very pale, which I thought might be accounted for by the anaemia of malaria; his pulse was rapid and feeble; the whole abdomen tender, rigid, and distended. He was cold sweating, and appeared to be *in extremis*. He gave a history that would well fit with a chronic gastric ulcer. I agreed with the diagnosis of perforated gastric ulcer, and arranged for immediate operation. Open ether was given and saline infusion started; then a median incision was made, and to my surprise I found the belly full of blood. As the spleen seemed to be the most probable source, I cut across the left rectus and excised the spleen as quickly as possible. There were a lesion between the spleen and the diaphragm. At the end of the operation he was so nearly dead that we never expected to get him off the table alive; he, however, reacted to strenuous measures of resuscitation, and made a steady recovery to the point when his stitches—through and through all layers—were taken out; then he burst, but was reclosed and got on all right after that.

The other case was a Russian; the spleen ruptured whilst he was sitting up in bed. He was operated on at a neighbouring hospital, and transferred to my division about a week later. The stitches tore out, the wound gaped. Further attempts to sew it up were fruitless. He died.

It seems from these cases that the healing powers are so reduced by the cachexia of malaria and loss of blood that the tissues possess little healing power and should therefore be sewn up as carefully as the condition of the patient

permits, and that deep stitches should be left in much longer than usual.

The spleen which I removed was about six times the normal bulk; there were adhesions to the diaphragm and a large subcapsular haematoma, with a small rent in the capsule. My idea is that during the jolting of the journey the capsule adherent to the diaphragm had torn away from the pulp and so started haemorrhage, and that some time next morning the capsule had given way, allowing haemorrhage to continue.—I am, etc.,

Guilford.

E. W. SHEAF, M.C. Cantab.

Reports of Societies.

PUERPERAL SUPPRESSION OF URINE.

At a meeting of the Edinburgh Obstetrical Society, held on May 12th, with Dr. WILLIAM FORBES, President, in the chair, Professor ROBERT JARDINE and Dr. A. M. KENNEDY read a paper on suppression of urine in pregnancy and the puerperium, and its relation to symmetrical necrosis of the kidney. The histories of eleven cases were reported and the pathological findings were described except in the one case which recovered.

The patients were all towards the end of pregnancy, except one in whom the condition developed at four and a half months. Suppression in one case lasted eight days. Unlike typical eclampsia, fits were not characteristic. The condition corresponded more to an eclamptic state in which the bulk of the mischief fell on the kidneys. The cases showed that where the suppression was completely established the condition was hopeless. In the case which recovered the suppression was only partial. The damage to the kidneys was, in a completely established case, so extreme that decapsulation was of no avail. The kidneys showed more or less uniform necrosis of the outer two-thirds of the cortex, which were separated from the living inner third by a haemorrhagic zone. At intervals from this zone of congestion numerous strands of congestion passed out to the surface, which had a mottled appearance. The necrosed area also involved the inter-pyramidal cortex. The kidneys were symmetrically involved. On microscopic examination the kidneys usually showed no evidence of antecedent disease. Rarely signs of preceding chronic nephritis might be present. The degree of necrosis corresponded with the duration of the suppression of urine. In the early stage the necrosis was of a patchy character and in the neighbourhood of the patches there was intense congestion. There was extensive thrombosis of the cortical blood vessels, which did not extend beyond the margin of the necrotic area nor involve the vascular arches; it was more widespread in the oldest cases. In the earliest case thrombosis was infrequent. The explanation of the changes was somewhat difficult. One of the cases had symptoms of Raynaud's disease, and the question arose as to whether the condition was dependent upon spasm of the smaller renal arteries, with consequent thrombosis and anaemic infarction. This interpretation was ruled out as evidence of arterial spasm was present in only one case of the series. It seemed more likely that the changes were due to the direct action of the toxin, which damaged the endothelium, thus causing thrombosis and then necrosis. The changes in the liver were similar to those found in eclampsia.

Professor LORRAIN SMITH agreed that the condition suggested the presence of a toxin which led to such universal damage to the blood vessels that it eliminated the function of the kidney even before it had passed through to the tubular structures. He referred to the very special way in which the poison attacked the renal vessels.

Sir DAVID WALLACE was struck by the fact that in these cases the suppression seemed to kill the patient very quickly. In surgical cases of suppression the patients lived very much longer, sometimes as long as fourteen days. He agreed that decapsulation seemed to be of little value in these cases.

Dr. MILLER had frequently been struck by the toxic condition of the kidneys in pregnant women who had died from intercurrent disease. It seemed to him that in eclampsia one must look for an exaggeration of the same poison which was always present.

Dr. BERRY HART congratulated Professor Jardine and Dr. Kennedy on the persistence with which they pursued their investigations from year to year. With reference to the question of how long a patient could live with complete suppression of urine he referred to a case in which a horse-shoe kidney was removed by the surgeon in mistake for an abdominal tumour. The patient lived eleven days.

Dr. HAIG FERGUSON referred to the advantage of antenatal care of the pregnant woman. In the Lauriston Home in Edinburgh for unmarried girls pregnant for the first time, which admitted an average of seventy cases a year, there had been no case of eclampsia over a period of nineteen years. He believed that the toxin was derived from the placenta, and in a case where the cervix was closed and there was no attempt at labour he strongly advised Caesarean section.

Dr. JAMES YOUNG noted that in three of Professor Jardine's cases there was evidence of haemorrhage before the birth of the child; one was accidental haemorrhage, the others were placenta praevia. The point arose as to whether the toxic state was not secondary to a degeneration in the placenta subsequent to its detachment from the uterine wall.

The PRESIDENT said he had repeatedly seen cases of suppression of urine recover, though he had never had a case of complete suppression.

FOR AND AGAINST CIRCUMCISION.

At a meeting, held on March 12th, of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, the President, Dr. HASTINGS TWEEDY, in the chair, Dr. SPENCER SHEILL read a paper on circumcision as an ancient rite and as a surgical procedure, in which he dealt with the antiquity of the rite among the Mohammedans, Copts, Memons, Boris, the New South Wales and Amazonian tribes, and the Semitic races. He pointed out that the Jewish operation had not the result of reducing sexual desire; the inner layer of the foreskin, which carried most of the sensory nerves, was not amputated. Dr. Sheill showed that fertility in the female was directly aided by circumcision. He condemned non-use of anaesthesia in ritual circumcision as inflicting unnecessary pain on the infant. Circumcision should be advised as a real help to the weakest spot in the human character.

Dr. SOLOMONS said that the subject was contentious and very important. Most educated people asked to have their sons circumcised; he thought it an excellent thing to do; it helped to prevent hernia due to straining, and later it helped in preventing masturbation. The ordinary schoolboy was not taught to keep himself clean, and if he were taught he thought too much about the matter. No anaesthetic was necessary when circumcising infants—in fact it was harmful. According to statistics by Breitenstein, syphilis was five times greater in the uncircumcised.

The MASTER OF THE ROTUNDA said that when consulted on the subject he advised the operation. He had seen it done very dexterously as a Jewish rite, and had adopted that method. He thought the uncircumcised more likely to contract syphilis.

Dr. TWEEDY had never satisfied himself that the craze for circumcision was justifiable. According to the laws of evolution the foreskin must have been greatly needed by the human race or it would not have persisted. The statistics quoted by Dr. Solomons had little value. He knew of three fatal cases, one from chloroform. There was often alarming haemorrhage.

COLONIC ETHER ANAESTHESIA.

At a meeting, held on April 9th, of the Section of Surgery of the Royal Academy of Medicine in Ireland, the President, Mr. J. B. STORY, in the chair, Dr. A. E. BOYD read a paper on oil ether colonic anaesthesia. After a description of Gwathmey's technique, in which an ounce of 75 per cent. ether in olive oil is injected for every 20 lb. body weight of the adult patient, he described his own method of using a 50 per cent. solution of ether in oil. He believed that control was greater and the margin of safety wider with the weaker mixture, of which the effect could be supplemented by a little ether on an open mask. The danger of colonic

irritation was also lessened; only one of his cases had had any irritation at all. He described a number of difficult cases successfully anaesthetized by this method. One only had given cause for anxiety which could be attributed to the anaesthetic. The method was invaluable for operations on the head and neck, and especially when it was desirable to avoid the factor of psychic shock, since the patient was unaware of the nature of the colonic injection.

Dr. MELDON asked whether this method was contra-indicated in cases in which the caecum had to be used in the neighbourhood of the month. Excretion by the lungs went on for hours after colonic etherization.

Sir W. I. DE C. WHEELER had to record a fatality under rectal anaesthesia in a pensioner, a robust man who had a hole in his skull the result of injury.

The technique was that recommended by Gwathmey, a 5 grain capsule of chloroform being inserted into the rectum. The bowel was washed out the night before and on the morning of the operation; six ounces of ether and two ounces olive oil were given per rectum an hour before. Open ether was also given by the mouth. Anaesthesia was very light. The bowel was carefully washed out at the end of the operation, which lasted one hour. An hour afterwards there was an accumulation of mucus in the man's throat; he was very cyanosed, but did not wake up sufficiently to get rid of the mucus himself. He died four hours after operation.

This death the speaker attributed to anaesthesia.

Mr. MCCONNELL said that this method in practice was quite simple. He had seen a good many of the cases to which Dr. Boyd referred; he was greatly struck by the lack of congestion about the face. One case of malignant glands in the neck in an old, feeble patient was fatal after seventy-two hours, death being due to hypostatic pneumonia, which did not start at once, but twenty-four hours after operation. He had used the actual caecum in the mouth for up to twenty minutes at a time.

Dr. BOYD, in reply, said that secretion of mucus was increased, but not so much as with ordinary ether anaesthesia. The anaesthesia was, in fact, fairly dry, but this was probably due to the use of atropine. If 75 per cent. ether were used, it might be inflammable. Though 65 per cent. solutions gave a deeper anaesthesia, he never used more than 50 per cent., which was much more easily controlled. The danger of the actual caecum should always be borne in mind.

Arthroplasty of the Knee-joint.

Sir W. I. DE C. WHEELER showed a case of arthroplasty of the knee-joint, with radiograms taken before and after operation.

The patient, a little girl, had osteo-myelitis six years ago, resulting in a double ankylosis, the left knee being flexed and the right extended. The right, operated on four weeks previously, was in plaster. The left arthroplasty was of four months' standing. Using lateral incisions he had remodelled the femoral and tibial condyles, and had interposed lateral flaps of the soft tissues. The articulating surfaces should be as wide as possible to anticipate lateral instability. The child demonstrated the excellence of the result by flexing and extending the right knee through more than a right angle, and by hopping across the room on the left foot, the left knee being unsupported by apparatus.

Mr. PRINGLE said that he had done a similar operation some years ago, but the result was not nearly so good; the man had a movable joint, but it was painful, and it was necessary to excise it six months later.

Mr. A. K. HENRY showed a case of loose bodies after gunshot wound of the knee-joint.

When he first saw the man, six months previously, there were lumps over the external condyle forming a mass the size of two hazel nuts, which had been diagnosed as exostoses. On examination these were found to be movable, and a skiagram showed that the fragments corresponded to a defect in the external condyle. It was remarkable that these loose bony fragments had remained uninfected. In six months they had diminished considerably in size, and had become more movable.

Early Symptoms of Cancer of the Colon.

Mr. SERON PRINGLE, who read a paper on early symptoms of cancer of the colon, said that patients came, as a rule, too late to operation for good results to be secured, in spite of the fact that the growth remained localized for a long period.

In 70 per cent. of those cases in his series not accompanied by obstruction, the diagnosis was made by discovering a tumour; but in 80 per cent. of the cases where no obstruction was

present, the growth was in the pelvic colon, and was frequently not palpable. In 33 per cent. of his series colostomy for obstruction had preceded resection, and 40 per cent. had recurrence within two years. These figures showed the need for revising the criteria of the disease.

He believed that the presence of blood, mucus, and pus, with an increase in the number of daily evacuations, together with a sensation of dissatisfaction after defaecation, constituted a syndrome characteristic of early colonic stricture associated with ulceration. Since the commonest cause of these conditions was cancer, laparotomy was justified in the presence either of pus, etc., or of the symptom of dissatisfaction. He distrusted negative findings by the *x* ray or sigmoidoscope. "Faecal impaction" was, he believed, rare *per se*, ending usually in colostomy and the discovery of a malignant stricture.

Sir W. I. DE C. WHEELER said that in these cases he took the *x*-ray findings with a grain of salt. Exploratory laparotomy in these cases was a difficult thing to advise, and the advice was not usually well received. The sigmoidoscope might easily miss the growth, going either too high or not high enough to enable it to be seen.

Mr. PEARSON thought the use of *x* rays was very limited; he had had a patient with cancer of the colon who had been told by a careful radiologist that he had not cancer. Examination under an anaesthetic was very useful before doing an exploratory laparotomy.

Mr. SETON PRINGLE, in reply, said that he read his paper because many medical men did not seem to think of cancer in these cases. In a patient who had been treated for nine months for mucous colitis he had diagnosed and found at operation cancer of the colon. Examination under anaesthesia was too seldom practised.

THE NERVOUS SYSTEM AND THE ENDOCRINE GLANDS.

At a meeting of the London Association of the Medical Women's Federation, held on May 18th, with the President, Mrs. E. E. FLEMING, M.D., in the chair, Dr. SYBIL I. WELSH read a paper on the nervous system and the endocrine glands. She said that Hughlings Jackson had described the development of the nervous system in man as taking place at three levels—the vegetative or autonomic, the sensori-motor, and the psychic.

On the psychic level (continued Dr. Welsh) the receptors through which man receives impressions are the sense organs of sight, hearing, taste, and smell, and it is through these that he comes into relation with the external world. By association fibres in the cerebral lobes he gains the power of balancing knowledge with emotion and intuition with instinct, knowledge and intuition tending to be individual as compared with emotion and instinct, which are racial and shared by his kind. At this level he becomes an individual member of a herd. On the sensori-motor level the body has acquired the power of balance and progression through space, coming into contact with externals through the skin receptors of touch, pain, heat, and cold, and acquiring self-control through its proprio-receptive system, whose centres are in the labyrinth, and through the cerebellum, which receives and co-ordinates all the impulses of sense of position and movement. At this level he becomes an individual and is able to move about. On both the psychic and sensori-motor levels the controlling nervous mechanism is a centralized one, and control is conscious as well as subconscious. On the autonomic level centralized control is no longer essential. This level governs the most primitive reactions of nutrition, reproduction, and self-defence; at this point the organism is a mere existence without individuality or sociability. In man this level is represented by the mutually antagonistic sympathetic and para-sympathetic nervous systems, and their working is unconscious. Developmentally, this nervous system is not centralized, and in the lowest vertebrates the place of the sympathetic cells is taken by masses of chromaffin cells. In many these cells are chiefly found in the suprarenal medulla, and are derived developmentally from the same mass of cells that gives rise to the sympathetic ganglion. This shows how an organ which deals with the chemical type of stimulus progresses into one producing the higher type of nervous stimulus, and that, below the level of the most simple type of nervous control, there is a set of systems of chemical control—a set, in fact, of endocrine glands. There is thus a digestive system of chemical control affecting the secreting glands, a reproductive system bringing into functional co-operation the remote sexual glands, and a system influencing growth and development. The active principles of the endocrine glands are comparatively simple and identical for all animals.

Dr. Welsh described the distribution and functions of the two divisions of the sympathetic nervous system,

stimulation of the sympathetic producing means of defence, and stimulation of the parasympathetic promoting nutrition. She referred to the treatment of deficiency diseases by gland extracts, and to the increase in exophthalmic goitre since the war. It was suggested that as there was anatomical evidence of a double control, chemical and nervous, of the endocrine glands, there might be a possibility of a double form of treatment, one being the restoration of nervous control by psycho-therapeutic measures.

Rebicus.

ROSE AND CARLESS'S MANUAL OF SURGERY.

AN interval of three years has ordinarily been regarded as long enough between editions of modern textbooks, the changes being sufficiently numerous within that period of time to warrant a new issue. The world-shaking events of recent years compelled a lengthening to five years of the intervening period from the ninth to the present, the tenth, edition of Rose and Carless's *Manual of Surgery*.¹

A considerable amount of new material has been added, consisting mainly of descriptions of methods found valuable in war surgery, the treatment of infected wounds, the mechanical handling of compound fractures of the long bones, and the ingenious reparative operations of plastic surgery. These new sections are thorough and complete and present to the reader a very good survey of all that we have learnt from recent experience, most of it bitter enough. It is with special commendation we note the high esteem in which Mr. CARLESS holds the Thomas splint in its various slight modifications, and those of us who used it for so many cases know that with this splint and a Balkan frame most excellent functional results and easy nursing were the uniform experience. It is strange that only with a European war should the Thomas splint and many of the "orthopaedic" ideas of the Liverpool school reach an almost universal acceptance.

Mr. Carless expresses regret—though we venture to think that no such expression is called for—that the book is necessarily larger, and he expects that possibly some of the newer war-originated material may be dispensed with in future editions. Possibly so, but we hope that the newer generations of students will for many years continue to learn the principles and methods of antiseptics and to appreciate the application of mechanical ingenuity which war surgery has forced upon us. A textbook cannot, of course, be allowed to grow out of manageable proportions, and some things must in time find their way to the scrap-heap; perhaps it would be no great loss if in future editions we found that references to taxis in strangulated hernia and many amputations of the foot and knee, and the present nomenclature of the cancers, had been relegated to the scrap-heap—there is no reason why, for example, "scirrhus" should be preserved, when it only means "hard," and "encephaloid," when it means really "brain-like" and is used to mean "soft." Another milder anachronism is disclosed in a remark on the surgical damage a "hansom cab" may do (p. 1172).

We are satisfied that the new "Rose and Carless" will still preserve its high place in the affections of the student and the practitioner. Its teaching is essentially the surgery of the British school, which is the soundest in the world. Carless travelled far in his war experience and met many men to whom his name and his book stood for all that is best in the memory of hospital and student days at home, and all hearts would open to him. Incidentally we remark that this mingling with the army has perhaps permitted a little more free use of some expressions such as "asking for trouble" (p. 1234). No one will object to more picturesqueness of language and homeliness—even colloquialness—of phrase in textbooks, but the ephemeral language of slang, even of the army sort, may not be generally understood. There are remarkably few errors of proof-reading; two will be found on pages 614 and 616. A commendable feature is that the *x*-ray pictures are printed on art paper and collected at the end.

¹ *Manual of Surgery* (Rose and Carless). For Students and Practitioners. By Albert Carless, C.P.E., M.B., M.S. Lond., F.R.C.S. Tenth edition, University Series. London: Baillière, Tindall, and Cox 1920. (Demy 8vo, pp. xii + 1562; 614 figures, 33 plates (16 coloured). 30s. net.)

RADIOLOGY.

THE second edition of Dr. ALBERT WEIL'S manual entitled *Éléments de Radiologie*² is a comprehensive publication which deals with the whole subject of the uses of x rays in diagnosis and treatment. The author is the well-known French radiologist, chief of the staff of the x-ray department of the Hôpital Trousseau, and his book is one of the most important written by a French author. The first edition gained the Itard prize of the Académie de Médecine. The present edition, whilst on the same plan as the first, has been brought up to date, most of the chapters having been rewritten, the illustrations increased in number, and a full description of the Coolidge tube added. Of the three sections into which it is divided the first consists of a description of instruments, the second covers the whole ground of x-ray diagnosis, and the third is given up to therapeutics. The text is illustrated by 552 reproductions of radiographs and numerous diagrams, which serve to make the author's meaning clear. The radiographs suffer to a certain extent from being reproduced on the same paper as the letterpress, but serve their purpose as demonstrating morbid conditions. The book can be recommended to those who wish to become well acquainted with x-ray work as practised by the best French workers.

In his *Aids to Electro-therapeutics*,³ Mr. J. M. REDDING, F.R.C.S., has added another to the already long list of small books which, under the title of the Students' Aids Series, are designed to assist students in grouping and committing to memory the subjects upon which they are to be examined. Looked at from this point of view, the present volume seems to fulfil its purpose. After a short introductory chapter there follow thirteen others dealing concisely with the various forms of electricity and electrical apparatus used for therapeutic purposes, and amongst other things are included galvanism, faradism, ionization, diathermy, and high frequency. A rather more elaborate chapter then deals with x rays, and it is somewhat remarkable what an enormous amount of information, both technical and practical, the author has managed to condense into relatively few words. Nothing of importance appears to have been omitted concerning apparatus and its uses, and the advantages and disadvantages of different pieces of apparatus are well set forth. In concluding this chapter short references are made to all the usual conditions in which x-ray treatment is indicated, and the lines on which it should be carried out. Radium therapy is then dealt with rather shortly, and perhaps this chapter might with advantage have been somewhat extended. Finally, after an account of the electro-diagnosis of nerve lesions and myopathies, there is an index of treatment in which diseases are arranged alphabetically, and the indications for their treatment by one or other methods stated. As a concise aid to the memory a book of this kind should be useful to medical students.

Many expert radiographers will find the small monograph by WENDELL, entitled *The Systematic Development of X-ray Plates and Films*,⁴ useful for reference. All photographic assistants in x-ray departments would be saved endless trouble if they were well acquainted with the fundamental principles of the development of plates here so well, so plainly, and so lucidly set forth. There is practically nothing to criticize unfavourably in the book. It states in plain, easily understood English all the important points in the treatment of an exposed x-ray plate in order to obtain the best possible photographic result. Perhaps the author is a little too enthusiastic as to tank development, and a little too severe in his strictures on the more usual method of tray, or visual inspection, development; but as a very old amateur photographer and x-ray worker the reviewer has a great deal of sympathy with him, and it is really remarkable how little some of the very best x-ray workers know of the technical side of producing the best photographic results. We can strongly recommend this book as eminently practical and brimful

of useful information; the principles of development of a negative are admirably portrayed in simple and easily understood language; the reasons for each chemical used in a developer are clearly stated; and finally, the illustrations are well chosen and convincing.

To those interested in the Coolidge tube the translation of H. PILON'S essay on it⁵ will be instructive. Its first section deals with the tube itself, describes its construction and the various models, the methods of heating the filament, and the starting and regulation of the tube. The second describes the properties of and the radiations emitted by a Coolidge tube. The concluding part discusses certain criticisms, for the most part groundless, which have from time to time been made concerning the working of these tubes; the author criticizes severely the assertion often made that the Coolidge tube is dangerous. Admitting that it is dangerous in the sense of the power it possesses, he maintains that it permits of very simple methods of protection which not only allow of complete control of direct radiations, but also eliminate all secondary radiations, and that therefore it is really a very safe tube. The opinion is expressed that in the near future every works laboratory will possess a radio-metallographic installation. Amongst other interesting illustrations there is one of a radiograph in which the shadows of lead figures are shown through a steel gauge 45 mm. in thickness.

GYNAECOLOGY.

A SECOND edition of *A Guide to Gynaecology in General Practice*,⁶ by Mr. COMYNS BERKELEY and Mr. VICTOR BONNEY, was only to be expected, for, as we pointed out on its first appearance, it has many features which make it a book of unique value to the section of the profession for which it is designed. The whole text, it is said, has been revised, and in regard to its substance this is no doubt the case. There still remain, however, several slips which ought not to have escaped the attention either of the authors or of the printer's reader. Amongst these are one or two to which, if our recollection is correct, we drew attention in our notice of the first edition. The very valuable section on the medico legal aspects of gynaecology has undergone a special revision with the assistance of Mr. C. F. Lowenthal, and in particular the discussion of the attitude of the practitioner in regard to a case of criminal abortion is treated in such a way as to make it the most valuable and practical guidance upon this subject known to us. New sections dealing with x rays and radium have been added, which provide the practitioner with all the pros and cons to be considered by him and to be placed before his patient in regard to the treatment of fibroids and cancer by these means. Unfortunately the experience of the authors does not make them enthusiastic over the curative powers of these rays, but the discussion is very fair and well balanced. The new edition maintains the admirable specificity of the book. It is written throughout with the one idea of helping the general practitioner in his gynaecological cases, and every other aspect of the subject is rigidly and wisely excluded.

The call for a second edition of EDEN and LOCKYER'S *Gynaecology*⁷ within four years of its first appearance is satisfactory evidence that it has met with the approval which we predicted for it. Some thirty pages appear to have been added, containing both new matter and fresh illustrations, and including a brief appendix on the transfusion of blood by Mr. Rendle Short. Whether this last is really in place in a textbook of special surgery is at least debatable. We are glad to note that the authors have discarded the use of the term capsular haemorrhage, to which we objected in the first edition, in favour of the simpler term tubal haemorrhage. Would that they had also seen their way to a more euphonious classification of

² *Éléments de Radiologie*. By Dr. E. Albert-Weil. Paris: Félix Alcan. 1920. (Roy. 8vo, pp. 883; 552 figures. 40 francs net.)

³ *Aids to Electro-therapeutics*. By J. Magnus Redding, F.R.C.S. London: Baillière, Tindall, and Cox. 1920. (Fcap. 8vo, pp. 204; 16 figures. 5s. net.)

⁴ *The Systematic Development of X-ray Plates and Films*. By Ichman Wendell, B.S., D.D.S., Chief of the Photographic Work, University of Minnesota. London: Henry Kimpton. 1920. (Med. 8vo, pp. 78; 33 figures. 12s. net.)

⁵ *The Coolidge Tube: Its Scientific Applications, Medical and Industrial*, by H. Pilon. Authorized translation. London: Baillière, Tindall, and Cox. 1920. (Cr. 8vo, pp. 104; 59 figures. 7s. 6d. net.)

⁶ *A Guide to Gynaecology in General Practice*. By Comyns Berkeley, M.A., M.D., M.C., F.R.C.P., and Victor Bonney, M.S., M.D., B.Sc., F.R.C.S. Eng. London: Henry Frowde, and Hodder and Stoughton. 1919. (Cr. 4to, pp. xxiii + 467; 168 figures. 31s. 6d. net.)

⁷ *Gynaecology for Students and Practitioners*. By Thomas Watts Eden, M.D., F.R.C.S. Edin., F.R.C.P., and Cuthbert Lockyer, M.D., B.S., F.R.C.S., F.R.C.P. London: J. and A. Churchill. 1920. (Roy. 8vo, pp. xvi + 928; 513 figures, 24 coloured plates. 38s. net.)

endometritis! The reader turns with interest to that great and ever-pressing problem of gynaecology, the treatment of cervical carcinoma. The writers are very guarded in their statements as to the prospects of radium and x rays either as direct curative agents or as adjuvants to operation, and are satisfied that as yet the only hope of cure lies in the free excision of the whole diseased area. For this purpose the abdominal route, it is said, is still the most promising; in the first place it enables a larger number of cases to be included as operable than does the vaginal route, even although the primary mortality still hovers about 20 per cent. Wertheim was able to claim 41 per cent. of cures on a five years basis, while for the vaginal operation De Ott claims from 34 to 37 per cent. on the same basis. Fortunately the condition of the patient who has had her uterus removed and subsequently becomes the victim of recurrence of carcinoma is, as regards local symptoms, much less distressing than that of the woman whose case is inoperable or not operated upon. In every way the new edition maintains the high standard of its predecessor, and it will continue to rank as probably the most satisfactory all-round textbook of moderate size on the subject published in this country.

NOTES ON BOOKS.

IN his book on *Psychology from the Standpoint of a Behaviorist* Professor WATSON describes psychology as a science of behaviour. Its eleven chapters contain a clear account of the methods, mechanisms, and results of psychological study approached from the author's special point of view. Beyond all things, Professor Watson is informal, averse to abstraction; his book should prove attractive to elementary students of the subject.

In the fourth edition of *The Sexual Disabilities of Man*,⁹ by Mr. ARTHUR COOPER, many changes have been effected. The text has been brought up to date, and two new chapters on hygiene and continence have been added. This little book has undoubtedly helped to fill a gap in the knowledge of the average student of medicine, and the new chapters make it more complete. The question of sexual continence has been much debated in recent months, and the author's examination of the subject shows restraint and discrimination.

In *Half-past Twelve*,¹⁰ Mr. G. W. GOUGH puts the outlines of practical economies before the reader in the form of six-and-twenty short chapters or "dinner hour studies for the odd half-hours." This short and well written introduction to political economy may be warmly recommended to readers of every class. Mr. Gough's point of view is strictly non-political and his exposition lucidly itself.

In the May number of the *Fortnightly Review* Mr. Edward Clodd asserts that "the extent to which occultism has spread, and is spreading in these latter days, will, in vulgar phrase, be an 'eye-opener' to many who have dismissed this matter as the passing freak of a handful of cranks." It is a like opinion, no doubt, that has induced Surgeon Captain C. MARSH BEADNELL, R.N., to publish a pamphlet entitled *The Reality or Unreality of Spiritualistic Phenomena*.¹¹ To deal with all the divagations of so-called spiritualists—although, indeed, they better deserve the term "materialists"—would be a very lengthy business, and the author has confined himself to a criticism of certain writings of Mr. W. J. Crawford, D.Sc., who seems to have been a willing victim and to be ready to find explanations for every dubious manifestation. The value of the pamphlet lies in the detailed examination of Dr. Crawford's statements, and this cannot be shown by quotation. It should be read as a whole.

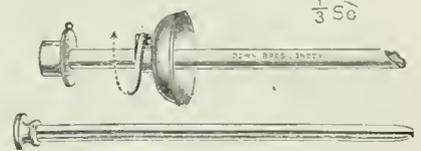

The fourth edition of Professor BIRK's *Sauglingskrankheiten*¹² provides students and practitioners of medicine

with a practical account of the signs, symptoms, diagnosis, and treatment of the diseases of infancy as met with and looked after in Germany. The author as a pupil of Czerny, has much to say about spasmophilia; in spasm of the pylorus he mentions operative treatment as the *ultima ratio*. The book is full and clearly written, not unduly weighted on the scientific side.

APPLIANCES AND PREPARATIONS.

A Urethroscopic Tube.

MR. NORMAN LUMB (London, W.) writes: In the course of urethroscopic work I have often felt the need, both in treatment and demonstration, for a device which would retain a particular field in view. The movable-cup tube illustrated here answers the purpose. The tube is inserted in the ordinary way, and, when the affected area is in the field, the cup is moved down to the glans and locked in position by means of the short lever. The weight of the urethroscope is thus balanced, and no difficulty is experienced in keeping it steady. As the tube is withdrawn during the examination the cup may be allowed to remain in contact with the glans, when it can be locked at any stage by simply pressing on the lever. The cups are made in the usual sizes. The device is especially useful when used in conjunction with Wyndham Powell's new cantherizing tube (BRITISH MEDICAL JOURNAL, August 9th, 1919), in the incision of peri-urethral abscesses, or for endoscopic treatment of the anterior or posterior urethra. The instrument is made by Messrs. Down Bros.

THE MEDICAL DEFENCE UNION.

AT a special general meeting of the Medical Defence Union, held at the house of the Medical Society of London on May 20th, the following resolutions were carried *nem. con.*:

1. That on and after January 1st, 1921, the annual subscription to the Medical Defence Union shall be £1, which payment shall provide each member with indemnity against damages and costs awarded against him, to the extent of £2,500, in any case which is undertaken on behalf of the member by the Medical Defence Union, and that a member elected on or after July 1st in any year shall pay half the current subscription for that year.
2. That the fee for life membership shall remain at £25, which payment shall include all the benefits of the indemnity mentioned in the foregoing resolution, on and after January 1st, 1921. Life members who have compounded for a less sum and are still in practice shall be asked to pay a subscription to the Medical Defence Union of 5s. per annum, to cover the indemnity before mentioned, if they wish to secure the benefits thereof.
3. That newly registered medical practitioners shall be admitted to membership of the Medical Defence Union, on and after January 1st, 1921, without payment of an entrance fee, provided that they join the Medical Defence Union within one year of the date of their registration.

AT a general meeting of the United Services Medical Society held at the Royal Army Medical College on May 28th, 1920, it was resolved to amalgamate with the War Section of the Royal Society of Medicine on the condition that the late members of former society are accepted without entrance fee to the War Section, but subject to an annual fee of one guinea. The United Services Medical Society decided to hand over to the Royal Society of Medicine the balance of cash as shown on January 1st, 1915, the remainder to be divided amongst the subscribers since that date. To permit of this adjustment it is requested that those subscribers will forward their present addresses to the Secretary, Major E. M. Middleton, at the College.

The following appointments to the Order of the British Empire are announced in recognition of war work:—*K.B.E.*: Dr. John O'Connor, head of British Hospital, Buenos Aires. *O.B.E.*: Mrs. C. M. Astley Macer, civil surgeon, attached R.A.M.C. *M.B.E.*: Dr. H. A. Macdonald, medical officer, Alverstoke Auxiliary Hospital.

IN Java last March there were 936 cases of plague, all of them, it is significantly added, fatal

⁹ *Psychology from the Standpoint of a Behaviorist*. By John B. Watson, Professor of Psychology, the Johns Hopkins University, Philadelphia and London: J. B. Lippincott Company, 1920. (Demy 8vo, pp. xi + 423; 66 figures, 10s. 6d. net.)

¹⁰ *The Sexual Disabilities of Man and their Treatment and Prevention*. By Arthur Cooper. Fourth Edition, revised and enlarged. London: H. K. Lewis and Co., Ltd., 1920. (Cr. 8vo, pp. 274, 2 plates; 7s. 6d. net.)

¹¹ *Half-past Twelve*. Dinner Hour Studies for the Odd Half-hours. By George W. Gough. London: Sells, Ltd., and Methuen and Co., New York: G. P. Putnam's Sons, 1920. (Demy 8vo, pp. 77. 1s.)

¹³ *Sauglingskrankheiten*. By Dr. Walter Birk, Professor der Kinderheilkunde Vorstand der Universitäts-Kinderklinik zu Tübingen. Fourth edition. Bonn: A. Marcus and E. Welbers Verlag, 1920. (Med. 8vo, pp. 276; 25 figures. M 15. bound M.13.60.)

EIGHTY-EIGHTH ANNUAL MEETING

OF THE

British Medical Association,
CAMBRIDGE, 1920.

THE PRESENT MEDICAL SCHOOL

SIR CLIFFORD ALBUTT tells us that when he was an undergraduate, about 1855, the number of medical students at Cambridge was only 6; to-day the number is about 500. The last official figures (Michaelmas term, 1919) were as follows

First year	185
Second year	209
Third year	54
Fourth year	13
Fifth and later	26

The thin years represent the reduced entries during the war.

Of these students, 30 are from British Colonies, 6 from India, and one each from Greece, Rumania, China, Persia, Sumatra, Egypt, Argentina, and the United States.

The laboratories and museums of nearly all the natural science departments of the University are conveniently near together and centrally situated. They occupy sites on both sides of Pembroke Street and its continuation as Downing Street. The site on the north side of these streets was formerly the Botanic Garden presented to the University by Richard Walker, D.D., in 1760, and some centuries earlier had been occupied by the Augustinian Friary. The site on the south side of the same streets was purchased by the University from Downing College.

The new building in which the departments of medicine and surgery are housed occupies nearly half the frontage of the Botanic Garden site, the remainder of the frontage being occupied by the chemical laboratory. Behind these are the buildings of the departments of zoology, human anatomy, biochemistry, engineering (mechanical and electrical), mineralogy, and physics. Behind these again are the Arts School and the examination rooms.

The street front of the Downing College site is occupied by the Museum of Archaeology and Ethnology, the Law School, and the Geological Museum. Behind these are the laboratories of the botanical, agricultural, physiological, psychological, and forestry departments.

Such a group of buildings has provided a great opportunity for the architects of the last sixty years, but it cannot be said that they have made the best use of it. Some of the buildings are plain, some handsome, but they do not show that relation between form and function which characterized mediæval buildings. They present a mixture of the pretentious ornament of city offices, the plainness of a factory or warehouse, and the picturesqueness of a seventeenth century chateau, but not much suggestion of their functions as laboratories and museums. Above all, they have no local character—no relationship, either in detail or in material, with the Cambridge buildings of the olden time, so natural and so pleasing. Perhaps the most appropriate of the new buildings is the Botanical Laboratory, whose architectural features are a fair expression of its function, meaningless ornament being almost—would that it were quite—dispensed with.

The Cavendish Physical Laboratory, presented in 1874 by the Duke of Devonshire, Chancellor of the University, has a moderately successful exterior in which Tudor details are used. Its interior has the advantage of unplastered brick walls, which are more pleasing in appearance than plaster, and are at the same time better adapted for wear and tear. The internal arrangements of these science buildings are generally more commendable than the external, the Chemical Laboratory being notable in this respect, but some of the earlier buildings have been so often altered since they were first built that their internal topography is almost labyrinthine.

It should be understood that the object of the Cambridge science schools is research and instruction—not display. The museums are not public exhibitions; the valuable collections are distributed in a number of buildings of moderate size, and great quantities of specimens are stored in cupboards and drawers. Among the best displayed collections are those of Zoology, Pathological Anatomy, and Geology. When the new Medical Buildings were erected, nearly twenty years ago, a special wing called "the Humphry Museum" was built to receive the Pathological Anatomy collection; this building stands partly on the site of the former Rotunda, than which it is more com-

modious, if hardly less ugly. The most finely displayed of all the collections is the Geological, occupying a sumptuous building which masquerades externally as a seventeenth-century German "Schloss." In the medical and surgical building are laboratories for Pathology, Pharmacology, Public Health, and Medical Biology, in addition to the rooms used by the Professors of Medicine and Surgery.

The most recent and one of the best equipped laboratories is the Physiological, for which the University is indebted to the munificence of the Worshipful Company of Drapers. Forming an annexe to this is the Psychological laboratory, presented by the family of Dr. C. S. Myers.

Addenbrooke's Hospital is very pleasantly situated in Trumpington Street, a residential neighbourhood. Since its first building in 1766, it has been frequently enlarged. As remodelled by Sir M. Digby Wyatt in 1864-5, it was a building of very appropriate design, and with its spacious

lawn and fine trees it gave the impression of a very comfortable home for the sick and suffering. But recent additions to the building, especially a shapeless out-patient department in the foreground, have stultified Wyatt's design and made an ensemble of quite ingenious ugliness.

The hospital has 192 beds for ordinary cases, also isolation wards. The out-patient building contains ophthalmic and other special departments, and an instalment of x-ray and other electric apparatus. The pathological wing contains, beside the morbid anatomy department, a fully equipped clinical laboratory.

Attendance at this hospital is recognized by all licensing bodies, and it is an excellent place for the initiation of students in clinical work.

About two miles south of Cambridge, on the Hills Road, is a small research hospital for the systematic study of disease. It is situated on high ground, with a good garden and a pleasing view of the Gog-Magog Hills, and patients whose maladies require special clinical investigation find the hospital a very comfortable place for a sojourn. It has a well equipped clinical laboratory, including a complete x-ray installation. Visitors to Cambridge who go to the golf links must pass this hospital, and they would do well to halt for a few minutes to inspect it.

The Botanic Garden, on the Trumpington Road, south of the town, replaces the Walker Botanic Garden. It was laid out in 1846 and following years, Walker's site being at the same time appropriated for the building of science museums and laboratories. The present garden covers

MEDICAL SCHOOL: HUMPHRY MUSEUM AND
SOUTH FRONT.

* Previous articles in this series of descriptive and historical notes on the University and town of Cambridge have appeared in the issues of January 3rd, January 24th, March 13th, April 10th, and May 8th, 1920.

20 acres, and a further area of 17 acres is available for future enlargement. The grounds are laid out in various ways, with aquatic and marsh plants, rock plants, xerophytes, systematic groups, etc. In addition there are extensive modern hot and cool houses, a laboratory, a library, and a reading room. Some of the landscape

SAXON TOWER, ST. BENET'S CHURCH.

effects are good, and the garden forms a pleasant place for intellectual recreation.

SOME EMINENT CAMBRIDGE SCIENTISTS.

It has been said that Oxford has produced England's great movements, and Cambridge her great men. The truth of the latter proposition is evident when we consider that Cambridge has produced Milton, Wordsworth, Byron, and Tennyson, also Harvey, Newton, Thomas Young, and Darwin. These are only the most outstanding instances; other eminent Cambridge men are numerous enough; our readers will think of many of them, especially of the great physicists, Cavendish, Stokes, Kelvin, Clerk Maxwell, and Rayleigh. Francis Bacon must be referred to as holding a peculiar position. Primarily a literary man, he acquired a reputation as a natural philosopher by studying and expounding the writings of his namesake Roger Bacon, who was an Oxonian.

The scientists who took part in the development of the school of science and medicine in Cambridge have been already mentioned in these articles—such as Nigel de Thornton, Caius, Glisson, Ray, Newton, Hales, Addenbrooke, Heberden, Harwood, Clark, George Paget, and Humphry. Besides these there were several who were educated at Cambridge, but pursued their life-work elsewhere; the chief of these were as follows, but it is to be noted that some of them belonged to Oxford as well as Cambridge.¹

¹ For the particulars which we quote we are largely indebted to the *Dictionary of National Biography*, to which the reader is recommended for further information.

William Gilbert, 1540–1603. Born at Colchester. Fellow of St. John's College 1561, M.D. 1569, F.R.C.P. 1573. A pioneer in the study of magnetism; the first to describe the earth as a magnet, in a work entitled *De Magnete, Magneticisque Corporibus, et de Magno Magnete Tellure, Physiologia Nova*.

William Harvey, 1578–1657. Born at Folkestone. Entered Gonville and Caius College 1593. Proceeded to Padua in 1598, where he graduated M.D. in 1602. Returning to England, he was admitted M.D. by incorporation at Cambridge, and settled in London, where his great researches in anatomy and physiology were carried out. He always retained an affection for Gonville and Caius College, and bequeathed to it the house of his birth at Folkestone.

Thomas Wharton, 1614–73. Entered Pembroke College in 1638; afterwards moved to Oxford. M.D. Oxon. 1647, M.D. Cambridge 1652 by incorporation, F.R.C.P. 1650. Best known for his original work on glands, entitled *Adenographia, sive Glandularum totius Corporis Descriptio*, in which he described for the first time the duct of the submaxillary gland, since named after him. "He did not trust much to theory but a great deal to dissection and experiment."²

George Joyliffe, 1621–58. Born at East Stower, Dorset. Entered Wadhams College, Oxford, in 1637. Came to Clare College, Cambridge, as fellow commoner in 1650, M.D. Cambridge 1652. Discovered the lymphatic system and described the discovery to Glisson in 1652, but did not publish it. A year or two later he was forestalled in publication by Rudbeck and Bartholinus, who had made the discovery independently.

Clopton Havers. Born between 1650 and 1660 died 1702. Entered St. Catharine's College, but took no degree. M.D. Utrecht 1685. F.R.S. 1686. Famous for his work on the bones, entitled *Osteologia Nova*, in which he gave the first description of the vascular canals, which are now known by his name.

John Woodward, 1665–1728. Entered Pembroke College 1695. Admitted M.D. same year. F.R.C.P. 1702–3. One of the founders of the science of geology. Bequeathed his

SAXON ARCH, ST. BENET'S CHURCH.

collection of specimens to the University, and founded the Professorship of Geology. Was also a botanist, and carried out experimental researches on plant physiology.

James Jurin, 1684–1750. Born in London. Entered Trinity College 1702, became Fellow 1706, M.D. 1716, F.R.C.P. 1719, Pres. R.C.P. 1750, F.R.S. 1717–18, Sec. R.S.

² *Dictionary of National Biography*.

1721. Pupil of Newton and advocate of his theories. Published researches on the ascent and suspension of water in capillary tubes, the motion of running water, the force of bodies in motion, the specific gravity of human blood, and the power of the heart.

William Hyde Wollaston, 1766-1823. Born at East Dereham, Norfolk. Entered Caius College 1782, M.D. 1793, F.R.C.P. 1795. Relinquished medical practice in favour of experimental science. "Published 56 papers on pathology, physiology, chemistry, optics, mineralogy, crystallography, astronomy, electricity, mechanics, and botany; and almost every paper marks a distinct advance in the particular science concerned."¹

Thomas Young, 1773-1829. Born at Milverton, Somerset. Studied medicine first in London, then at Göttingen. M.D. Göttingen 1796. Entered Emmanuel College, Cambridge, as fellow commoner, 1797. M.D. Cambridge 1808, F.R.C.P. 1809. Found Cambridge life congenial and formed many friendships here, as among scientific and artistic men elsewhere.

Thomas Young was not only a scientist of the first rank, but also an exceptionally accomplished linguist, a skilled musician, and a connoisseur of other fine arts. He was proficient in the following languages: Latin, Greek, Hebrew, Chaldee, Arabic, Syriac, Persian, French, Italian, Spanish, German, and turned his philological skill to account by finding the key to the interpretation of Egyptian hieroglyphics. He was the first to demonstrate that accommodation of the eye is effected by a change of convexity of the crystalline lens. He demon-

¹ *Dictionary of National Biography.*

strated the phenomena of interference of vibrations in sound and light, and thereby established the wave theory of light. He propounded the three-primary-sensations theory of colour vision. He investigated the hydraulics of the circulation, and the theory of tides. He was the first to use the terms "energy" and "labour expended" in their present-day sense, and introduced the term "modulus of elasticity." As a physician he appears to have been in advance of his time, but he did not really like medical practice, and relinquished it as soon as he was in a position to do so. Unlike too many men of very active intellect, he was of good physique, and fond of bodily exercise, including dancing and singing. He was also of genial disposition and fond of society. Sir Humphry Davy described him as

"a most amiable and good-tempered man . . . of universal erudition and almost universal accomplishments . . . he knew so much that it was difficult to say what he did not know."

Surely his was the most expansive intellect of which we have record. The nearest approach was that of Leonardo da Vinci, which however did not cover so wide a range. It is noteworthy that Young's county, Somerset, also produced two other men who had immense influence on science and philosophy, namely, Roger Bacon and John Locke; while Christopher

Wren, another man of wonderfully expansive intellect, was born in Wiltshire, at East Knoyle, near the Somerset boundary. The other great intellect comparable with Wren and Young, less expansive but more profound, namely Isaac Newton, was produced far away in Lincolnshire.

(After the portrait by Sir Thomas Lawrence.)

PSYCHOLOGY AND MENTAL PATHOLOGY.

M. PIERRE JANET, Professor of Psychology at the Collège de France, gave a course of three lectures for the University of London last month. They were delivered at the Royal Society of Medicine, when Dr. HENRY HEAD, F.R.S., was in the chair.

Professor JANET stated that two methods of psychological investigation are available in the study of mental pathology—we may study the mental states of our patients by endeavouring to obtain introspective information from them and by inference from our own subjective states, or we may concentrate our attention on the objective disorders of conduct. When we adopt the former method the study of the psychopathic individual presents in some degree the same difficulties that we encounter when we seek to understand the psychology of animals by inference from our own self-consciousness. Animal psychology has only made progress since psychologists have abandoned any attempt to inquire into the subjective states of the animal, and have concentrated their attention on behaviour. Medical psychology should likewise devote itself exclusively to the study of conduct. It can as yet hope for little aid from physiological psychology. The bodily reactions accompanying emotional states have been to some extent described, but they cannot as yet be interpreted in terms of conscious sensation.

The key to the scientific study of conduct is found in the fact that all psychical processes are movements. Movement may be exteriorized by action and speech, but thought is also movement or internal speech. The descriptive psychology of medicine is therefore not qualitative but quantitative. It endeavours to estimate the

dynamic value of the response of the organism to psychical stimuli and the adequacy of the response or its adaptation to its environment. The evaluation of a psychical response in term of energy may be justified by the foregoing conception of thought as movement. The same idea is implicit in the language of daily life when a character is described as weak or strong. It is possible in dynamic phraseology to characterize a psychical response by its intensity, its duration, and its latency. The principle of the economy of psychical energy is the fundamental law governing all mental activity. Speech is an economy of energy replacing gesture. Thought is internal speech replacing actual experimental action, and as speech involves an expenditure of energy. The modes of psychical activity may be arranged in an ascending scale—at the bottom stands the purely animal reflex, at the apex the altruism of the moral man and the creative power of the artist.

Belief can be regarded as a potential promise of movement; thus when we express our belief in certain conditions we assert that the conditions are such that if we act at all it will be in a certain manner. Our test of the truth of a belief is the coincidence of the movement predicted by our belief with that called forth by the actual conditions. We thus arrive at reality by a process of trial and error.

Reasoning in terms of energy is a process of auto-discussion manifested by the movements which constitute our internal language or thought. Memory again is a process of narration or the movements of internal speech. Consciousness is social in origin and appears when the social relations of the self to the external world exercise an influence on movements which were originally called forth as responses to stimuli affecting the self alone. A reserve

store of potential energy is attached to the higher directive planes of psychical activity and is mobilized as an inhibitory force when the response of the lower centres would be inimical to higher ethical or rational considerations.

If mind be regarded thus from a dynamic standpoint, the neuroses manifest themselves as disturbances of the law of economy of psychical energy. Such disturbances may take the form of the excessive mobilization of the lower planes of psychical energy to meet a strain the nature of which is not appreciated by the higher intellectual faculties, and this state of things constitutes the anxiety neurosis. The higher faculties may fail to inhibit the irrational output of the lower, as in mania; they may fail to arouse an adequate response, as in dementia praecox; or they may themselves become atrophied, leaving the psychical dynamic system free to act at a lower plane, as in the various forms of dementia. Minor disturbances of the economy of dynamic force are of daily occurrence in the mental life of the normal individual. When the highest faculties alone are affected the situation is one for ethical and possibly juridical treatment; when the change is pronounced and affects the lower faculties in the intellectual hierarchy the cases come before the alienist. In each case the problem is the same—as far as possible to restore the balance of the economy of psychical energy.

VITAL STATISTICS OF ENGLAND AND WALES.

THE annual report of the Registrar-General for England and Wales, for the year 1918, has been issued, with the usual detailed review of the vital statistics for the year by Dr. T. H. C. Stevenson, Superintendent of Statistics. The salient features of the year were that the marriage rate had recovered from the depression of the previous year, and was about the same as the rate before the war. The birth rate (17.7) was the lowest on record, being 0.1 below that for 1917, and 6.1 below that for 1914. The death rate was 17.6, being 3.2 above the rate in the preceding year. Infant mortality was 97 per 1,000 births, which was 1 per 1,000 above the rate in the preceding year, but 10 per 1,000 below the average of the ten years 1903-1917.

POPULATION.

The total civilian population was estimated by addition to the census population of 1911 of births, migrations, and discharges from the services, and by deduction from that population of deaths, emigrations, and men known to have joined the services. In this way totals of 13,777,100 civilian males and 19,697,600 females were reached. The several age groups, as in the two previous years, were estimated, as far as possible, by calculating civilian survivors in each group from the estimated number of those aged 1 year younger in 1917; in the absence of a record of numbers enlisted from each age group, it was necessary in this mode of estimation to treat males of 15 to 45 as a single group. The civilian populations of separate localities were derived from two independent sources—the National Register count of the second quarter of 1918 and the reports made under the food rationing scheme. Neither of these enumerations is wholly satisfactory from a statistical point of view, but reliance was chiefly placed for 1918 on the food reports, which are believed to have improved with successive issues of coupons.

TUBERCULOSIS.

The deaths assigned to tuberculous infections of all kinds in 1918 numbered 58,073 (31,027 males and 27,046 females), or 2,139 more than in the previous year. Of the deaths 1,369 occurred among non-civilians. The mortality in the civilian population was equal to 1,694 per million, which was in excess of the mortality recorded for any year since 1904. Dr. Stevenson, however, thinks that the position is less unfavourable than these figures would suggest, the increase in mortality being probably attributable to the epidemic of influenza. In the first two quarters of 1918 the tubercle rate was 8 and 9 per cent. respectively below that for the corresponding quarters in 1917; the third quarter of 1918, in which the first influenza epidemic occurred, brought an increase of 8 per cent., and

the fourth, in which the main outbreak took place, of no less than 31 per cent. The conclusion is held to be confirmed by the fact that in 1918 the seasonal occurrence differed from that of the seven preceding years, inasmuch as there were few deaths in the first and second quarters, and many in the third and fourth. Dr. Stevenson considers that the progress of tubercle mortality during 1918 can only be judged from its behaviour in the first six months, and that owing to the absence of males in the fighting services the conclusions must be based on the female sex alone. Judged in this way he thinks that the record of 1918 shows a considerable improvement upon 1917, but compares disadvantageously with that of each of the six preceding years. He also states that the increase in 1918 was limited to phthisis, other forms of tubercle showing a slight reduction, even during the quarter of the great epidemic wave of influenza. Dr. Stevenson considers that the explanation of the facts he has accumulated is that the increase of tubercle mortality was due to deaths from influenza amongst the population suffering from pulmonary tuberculosis, but that influenza did not bring about any corresponding increase of mortality in the population suffering from non-pulmonary tuberculosis. The serious increase in tuberculosis was limited to later childhood and early adult life. There was a decline in the mortality in the first two years of life, but after that the rate was higher at every age up to 45-55. The decline in tubercle in the first two years is to be noted both in respect of tuberculous meningitis and tubercle of the peritoneum and intestines.

Attention is again drawn to the high mortality from tubercle in lunatic asylums; in 1918 the deaths numbered 5,605, as against 4,189 in 1917, and an average of just over 1,800 in the three years 1912-14. The increase occurred in spite of a decrease in the number of inmates of lunatic asylums. As the total increase in tubercle deaths over 1912-14, when mortality from this cause reached its lowest point, was in 1918 about 8,000, it follows, Dr. Stevenson observes, that nearly half of the total increase has occurred among this small section of the population, consisting of just under 100,000 persons. He does not think that the explanations offered by the Beard of Control—inferior quantity and quality of food, and overcrowding—suffice to explain the great increase in deaths from tuberculosis in asylums. On the other hand, the fact that the increase was considerably greater among male inmates than female, is held to support the view that deficiencies in the staff may have had something to do with the increased prevalence of the disease.

CLINICAL UNITS IN MEDICAL SCHOOLS.

THE University Grants Committee has issued the following memorandum, dated April, 1920:

1. The case for the establishment of Clinical Units in Medical Schools of University standard has its origin some distance back in the past. The origin is twofold—namely, the advance of medicine itself and the evolution of the form of medical education. Medicine itself was of course revolutionized in Western Europe first by the renaissance and the revival of learning, and then in our own times by the advance of biology in the middle of last century, and the discovery of the etiology of infective disease in the last half of the century. These things gave a new content to medicine and formed the basis of profound changes in the science and art of medicine. Then in the second place there has been an evolution in the education of the medical man. A century ago he became a practitioner by apprenticeship; this was followed in due course by what may be called the hospital system—in other words, an application of the apprenticeship system on a large scale in the wards of a hospital; and lastly, there came the more systematic education of the medical student in the preliminary sciences and the intermediate subjects before he was trained on the clinical side. It is important to recognize that the Clinical Unit, in principle and philosophy, is not a sudden offshoot or "outcrop," but a further stage in a long process of evolution.

2. The relationship of the State to this evolution began with various Medical Acts for Registration, Qualification, etc., the formation of the General Medical Council, and more recently the subsidizing of medical education by the

Government. In 1912 Mr. Abraham Flexner's Report on "Medical Education in Europe" was published, and *inter alia* it advocated a development of medical teaching by the formation of Clinical Units. In 1913 the Report of the Royal Commission on University Education in London summarized the whole question as it affected London and crystallized further the case for the formation of Clinical Units there. Finally, in 1918, the President of the Board of Education called for a report from Sir George Newman, in his capacity as Medical Assessor to the Board, on the general working of the grant aid which had been given by the Board in aid of medical schools in England and Wales during the previous ten years.¹ In this last mentioned document the case for the establishment of clinical units is discussed at length.

3. Continuing attention for a moment to the virtues and defects of the British system of Clinical teaching we may say briefly that it is a system of applied apprenticeship by means of clerking and dressing, which has at least four great advantages:

- (i) The student himself became an observer and a practitioner.
- (ii) A close personal relationship was established between the student and patient.
- (iii) The art of medicine was taught by practice.
- (iv) The student was, in fact, holding a responsible office and cultivating his sense of responsibility.

These four points have proved invaluable and have resulted in producing a good standard of practitioner, perhaps indeed the best in the world. But there are disadvantages, and three may be named:

- (i) The student's work tends to become empirical and not sufficiently inspired by the science of medicine.
- (ii) The student is in the main brought into association with the end-results of disease, and is insufficiently equipped to deal with disease at its beginnings.
- (iii) The instruction in his clinical work tends to become discontinuous and unsystematic; his studies in biology and chemistry, in anatomy, physiology, and pathology, are systematized and organized on a scientific basis; his clinical instruction is, on the contrary, in a large degree unorganized.

4. It will be admitted that while these virtues are great the defects are serious, and their seriousness becomes the more grave in view of the large and increasing responsibilities placed upon the practitioner by the advance of medicine, by the social requirements of the time, and by the new duties imposed upon him by the State. There arises, therefore, a demand for substantial reform—though not revolution—in the system of clinical teaching at the Universities. The situation, though existent in all medical schools, is particularly acute in the metropolis. If in London there were a unified University—as, for example, in Edinburgh—the position would be the same as in other University centres which have had for many years the germ, and indeed almost the essentials, of Clinical Units.

5. The conclusion seems, then, to be this:

- (i) That a University Medical Education requires that the latest advances in sciences which affect medicine, chemistry and physics, anatomy and physiology, pathology and pharmacology, should be continually brought into the teaching of the clinical subjects and applied to the observation and treatment of disease.
- (ii) That in order that education may be of this scientific standard, and that students may come into direct contact with knowledge at its growing point, there is needed a system of instruction by teachers who are actively engaged in scientific research.
- (iii) That such teachers must be provided with proper equipment, adequate staff, and sufficient time if their work is to be comparable with the best scientific and practical teaching of, say, the Professor of Physiology.

The system of Clinical Units is designed to secure these ends.

6. The essentials of this clinical system consists of three parts or units which should be interrelated and separable, dealing with medicine, surgery, and obstetrics (including gynaecology) respectively. In each of these subjects a Clinical Unit should include—

A Professor or Director who would devote the greater part of his time to teaching, treatment, and research, competent above everything else to teach, of sound scientific training, and possessing scientific imagination, who shall have—

- (a) An adequate whole-time and part-time staff.
- (b) The control of wards (50-100 beds).
- (c) A proper and effective out-patient department.
- (d) Ample laboratory accommodation for research and pathological work.
- (e) Adequate scientific equipment for effective clinical teaching.
- (f) A *post-mortem* service.

Such units should work along with and supplement the ordinary ward services in which practical teaching will still be carried on as before. But while the ordinary services are organized only for the immediate needs of the patient and the practical training of students, the Clinical Unit will, in addition, be especially equipped for scientific instruction and scientific research.

The purpose of the Clinical Unit system is therefore (a) to provide improved practical and systematic teaching for all the students in a Medical School in their clinical years of study (it is important that the advantages should not be restricted to selected students), and (b) to co-ordinate the Preliminary Science subjects with the Intermediate subjects, and both with the clinical work. In order to secure these desirable ends it is necessary that the terms of appointment and employment of Professors and their assistants should be appropriate. As the Final Report of the Royal Commission on University Education in London, 1913, stated:

"Experience has shown that the University cannot be certain of securing suitable conditions for the teachers when they are paid for by bodies over which it has no financial control. The first necessity is therefore that the University should provide its own teaching, by which we mean that it should appoint, pay, pension, and dismiss its teachers, and not leave these primary duties in the hands of independent corporations. With this control in its hands the University may be trusted—

- "(i) to choose its staff for individual excellence from the widest possible field;
- "(ii) to give them such remuneration, including superannuation, and such conditions of tenure as will free them from the pressure of material anxiety;
- "(iii) to arrange that their teaching duties leave ample time for their own individual work;
- "(iv) to arrange that the libraries, laboratories, and other means of assistance provided for them are such as to permit of advanced work and research; and
- "(v) to give them a voice in the selection of their colleagues."

Whether the Head of the Unit be occupied in his professional duties whole-time or the major part of his time, whether he be allowed private practice or not, by what methods he integrates the intermediate subjects with clinical teaching—these and many other points are relatively matters of detail if he be paid an adequate salary and be put into a position in regard both to staff and equipment to carry out his functions effectually.

A complete and well organized Medical School should thoroughly co-ordinate the work of the Units themselves and associate them closely with that of the various and necessary special departments.

7. Further essentials for the successful development of the system described appear to be—

- (1) That the training which the students receive in the preliminary scientific and intermediate subjects is satisfactory;
- (2) That the hospital and school are effectually associated and suitably equipped; and that there is appropriate accommodation for the unit teaching, namely, wards, out-patient department and laboratories conveniently arranged in relation to each other;
- (3) That appropriate and competent persons are available for the various posts in the unit.

PRINCIPAL S. H. GAIGER of the Glasgow Veterinary College, in the course of the investigation of a very fatal form of dysentery in lambs, isolated an organism under conditions which make it probable that it is the cause of the disease. It is of the type of *B. coli*, and belongs to the group of which Friedländer's bacillus is the type. When inoculated subcutaneously it produces fatal enteritis in young rabbits. The disease attacks only lambs up to about 3 weeks' old, and an antiserum is being prepared which it is recommended should be used as soon after birth as possible.

British Medical Journal.

SATURDAY, JUNE 5TH, 1920.

HELMINTHS IN CANCER.

IN the recent communication by Fibiger of Copenhagen on the production of cancer of the stomach in rats fed on the larvae of the nematode *Spiroptera neoplastica*, on which we commented in our issue of May 15th, it was mentioned that the experimenter had in a few cases produced cancer of the rat's tongue. Further particulars regarding this are now available.¹ The study was conducted on 217 rats, including not only those of his laboratory strain but other strains of piebald rats and cross-breeds between piebald and the wild rat. The nematode had been transmitted to them on one or several occasions by feeding them on infected cockroaches or by causing them to ingest the larvae of the spiroptera. Of 132 rats which survived for 89 days or more, counting from the first or only ingestion, 64 were found to have glossitis and 2 definite carcinoma of the tongue. Of 85 rats which died after a period of from 90 to 180 days at least after ingestion, only 4 had glossitis, whilst in 3 cases cancer of the tongue was discovered.

The lower frequency of glossitis in rats of longer survival is considered to be due to the fact that the spiroptera in these rats disappeared from the tongue, and the glossitis had ceased before the fatal issue brought about by the lesions in the stomach or from some other affection. In a certain number of cases it was possible to study the beginning, progress, and disappearance of this glossitis. As a general rule it started a few days after the ingestion of the spiroptera, and in the great majority of cases it was spontaneously cured in two and a half to six months; cases of longer duration were rare. The glossitis attacked all parts of the tongue; but usually it was most marked at the base, where the thickened, swollen, and desquamating epithelium contained spiroptera. Microscopically, evidence of considerable inflammation was seen, with intense thickening and proliferation of the epithelium, which penetrated into the underlying tissue. The condition resembled that regularly found in lesions produced by spiroptera in the stomach. That these changes may progress so far as to constitute indubitable cancer of the tongue is shown by the figures quoted—five rats which had survived for 52 to 201 days after the first (in two cases the only) ingestion of the spiroptera. Fibiger says that the carcinoma of the tongue of his rats was absolutely similar, macroscopically and microscopically, to that found in the tongue of man, and especially the epithelioma of the papillary type. The microscope showed a destructive carcinoma of deep growth, invading the muscles of the tongue. In two cases there was permeation of the perineural lymphatics of the organ. In the first three rats that died the tongue showed, in addition to the carcinoma, glossitis and nematodes; in the other two carcinoma alone was found. In all these the gastric cul-de-sac was the seat of an intense spiropteral inflammation accompanied in four by carcinoma.

Thus the *Spiroptera neoplastica* (also called *Gonylonema neoplasticum*) may induce in rats a rapidly

developing glossitis which, in the great majority of cases, diminishes as the nematodes disappear from the tongue, but in some cases it may be accompanied by carcinoma, which will persist after the disappearance of the nematodes and of the glossitis. The development of spiropteral carcinoma in the tongue of the rat thus offers a complete analogy with human lingual carcinoma, which also may accompany or follow desquamative glossitis (leucoplakia). Fibiger refers to the development of epithelioma of the lip in two cases of chronic trichinosis in man, and of epithelioma of the tongue in two other cases; in all of these the trichina was demonstrated in the immediate neighbourhood of the tumour.

It must not be assumed that spontaneous tumours of rats and mice are commonly caused by the ingestion of food containing the *Spiroptera neoplastica*, still less that cancers of higher animals and man are produced by a similar, or indeed by any, parasite. The observations are of laboratory interest in the study of the origin of malignant growths, and are instances of one particular form of irritation presiding at the inception of a neoplastic process. How this irritation brings about malignant development of the cells, what property it supplies to or excites in the cells, or what restraining influence it removes to allow of unceasing and destructive proliferation, can only be matters of speculation in view of our present knowledge.

Fourteen years ago Borrel published some observations on the relation between cysticercus and sarcoma development in the rat. Since then numerous communications have appeared showing that it is no uncommon thing to find primary sarcoma of the liver or other organs of the rat invaded by the cysticercus. These sarcomata are of different types; in many cases they formed metastases; and, indeed, transplantation experiments with the tumour tissue have succeeded. Eiken² states that in the *post-mortem* examinations of upwards of 2,500 rats in the Pathological Institute of Copenhagen University only a single animal showed cysticercus sarcoma. This was one of Fibiger's rats which had been fed on cockroaches infected with the *Spiroptera neoplastica*. Between the coils of intestine there was found a yellowish-white ovoid tumour (4 by 3 by 3 cm.), in the centre of which lay a *Cysticercus fasciolaris*, of typical appearance, measuring 5 cm. in length. Other cysticerci were noted about the liver unaccompanied by tumour formation. Microscopically the tumour was a round-cell sarcoma, with many polynucleated cells. No metastases were found. The wall of the cul-de-sac of the stomach was markedly thickened, and contained numerous spiropterae. Microscopic examination revealed a small typical epithelioma penetrating the submucous tissue.

It was calculated that the latter tumour was about three weeks old, and probably was considerably younger than the more advanced sarcoma. As the cysticercus present in the latter was in perfect preservation, it was concluded that the development of the sarcoma did not depend on the death and absorption of the parasite. What is of especial interest is the production by two different worms, parasitic in the same animal, of two different malignant tumours, and the fact that neither the parasitism of the cysticercus nor the consequent development of a sarcoma necessarily prevented development of a carcinoma subsequently produced by the spiroptera. Borrel considered that the power which such parasites had of bringing about tumour formation consisted in some unknown virus which they transmitted; Fibiger and others believed that the production of such tumours was due to toxic substances formed by the parasite.

¹ *Comptes rendus de la Société de Biologie*, vol. lxxxiii, No. 16.

² *Comptes rendus de la Société de Biologie*, vol. lxxxiii, No. 16.

With the latter view Eiken agrees. He regards the observation as showing that in the same animal two different neoplasms may be produced by the toxic secretions of two worms of different species, and that the secretions of one worm do not necessarily exclude the production of tumours by the toxic substances of another worm.

The following facts may serve to prevent hasty conclusions regarding the part played by the cysticercus. Of the reported cases of malignant disease of rats, sarcomata by far outnumber carcinomata; more than half the sarcomata occur in the liver, and of these hepatic sarcomata at least 90 per cent. contain the cysticercus. The cysticercus is a common parasite of the liver of rats. On the other hand, it is as frequently found in the livers of mice, and yet, out of the hundreds of thousands of malignant tumours of mice that have been met with, there is not a single case of hepatic sarcoma on record.

SMALL-POX: ITS TYPES AND PREVENTION.

COLONEL W. G. KING, C.I.E., I.M.S., has published, in the *Transactions of the Society of Tropical Medicine and Hygiene*,¹ an interesting epidemiological study of small-pox. He set himself the task of elucidating the types and strains of small-pox throughout the world, and to that end prepared a map upon which he entered the fatality rates of the disease as indicated by the most reliable statistics he could gather.

Colonel King classifies small-pox as follows: (1) The most virulent form occurs east of long. 40° E. and between lat. 40° N. and 6° S. The fatality ranges in the vaccinated from 30 to 60 per cent., and in the unvaccinated from 60 to 80 per cent. This may be termed "the Eastern Type." (2) West of long. 40° E. virulence is diminished and a strain is found capable on rare occasions of reverting to the primitive form. The general fatality in pre-vaccination days was from 18 to 25 per cent.; since that time, rarely more than 7 per cent. in vaccinated, but from 19.3 per cent. to 47 per cent. in unvaccinated persons. (3) In certain west European countries, mostly those which enforce vaccination, the fatality is sufficiently reduced to justify a subclassification and to permit one to speak of the "western substrain" of low fatality. (4) In South Africa there exists a second type of small-pox distinguishable both from the eastern type and its western strain, or substrain, by the mildness of the constitutional symptoms notwithstanding a considerable skin disturbance. The general fatality is not more than 4.3 per cent. From this source may have been evolved the strain of low virulence which has exhibited itself in races of European origin in America, Canada, and Australia.

Colonel King suggests that "if human beings in a state of low vitality—resulting, say, from ill feeding—be placed in overcrowded and filthy dwellings, and amongst them a strain of small-pox be introduced, in the course of transmission there will result an alteration of its characteristics in the direction of virulence if the strain at the time of introduction be mild, or it will simply retain its mild or virulent properties as introduced if the conditions to which it is submitted be those under which it has hitherto maintained its vitality." Attention is also directed to the fact that territories within the sphere of influence of a virulent type, but where use is made of vaccination, seem to suffer a lower fatality rate. Instances are Baghdad, contrasted with other districts inhabited by Turks and Arabs, and Algiers compared with Tunisia.

The paper deserves careful study. It is no doubt true that such a statistical comparison as Colonel King has made is open to criticism, inasmuch as the fatality rates, particularly those derived from hospital statistics, must be affected by factors other than the type of disease prevalent. In semi-civilized countries with few hospitals it is hardly possible to accept the hospital fatality rates as proper measures of the general severity of the disease. It is also perhaps questionable whether the author has carried his comparisons sufficiently far back to justify the inferences that either in the east or west the types have not varied. Thus Rhazes asserted that small-pox was less dangerous than the disease "Hasbah," which came to be translated "morbilli" and then "measles," perhaps being, as Haeser thought, scarlet fever—an opinion partly endorsed by Richter. Creighton's evidence of a change of type in small-pox before the days of either inoculation or vaccination is also too strong to be ignored.

But the practical lesson Colonel King seeks to instil is not weakened, is indeed strengthened by these criticisms. This generation has witnessed a remarkable change of type in two directions. Scarlet fever has declined in severity and fallen to a lowly place amongst the destructive diseases. Influenza has risen to the front rank of enemies of mankind, not merely as a vexatious but as a deadly foe. It is surely to risk the disillusionment which awaited the physicians of a hundred years ago when they proclaimed scarlet fever a conquered enemy if we now make similar assertions with regard to small-pox. In our opinion, Dr. McVail and Colonel King are fully justified in asserting that the rigorous enforcement of vaccination and revaccination of the whole of the population is the plain duty of a civilized state.

Several correspondents have asked for information about "alastrim," which was mentioned in the review, published on May 1st, of Dr. McVail's *Half a Century of Small-pox and Vaccination*. The term "alastrim" has been used to designate certain epidemics of an infectious eruptive disease which has been variously held to be different from, or to be a mild form of, small-pox. The word appears to have been used locally to designate a disease which was, and is, prevalent in Brazil; possibly it is derived from the Portuguese *alastrar*, which, according to Vieyra's dictionary, means "to strew" or "to cover all over." According to Dr. C. J. Martin,² Dr. Ribas, chief sanitary medical officer of the State of São Paulo, and subsequently, in 1911, Dr. Aragão gave an account of this disease.³ During a few years 250,000 cases of "alastrim" occurred in five or six of the states of Brazil. Dr. Ribas came to the conclusion that the Brazilian disease was not small-pox, but identical with the South African milk-pox, or amaas, for the following reasons: "(1) Its low mortality (0.5 per cent.), whereas the usual mortality from small-pox under similar conditions is 30 to 60 per cent.; (2) the absence of secondary fever; (3) absence of a characteristic smell of small-pox; (4) non-occurrence of deep scars; and (5) the short duration of the immunity against vaccinia, it being possible to vaccinate the larger proportion of persons who have suffered from the disease within six months of their recovery." At the same meeting of the Epidemiological Section of the Royal Society of Medicine, Dr. W. G. Armstrong, senior medical officer of public health, New South Wales, described an outbreak of over 1,000 cases of small-pox occurring in Sydney in 1913, with one death (that of a parturient patient

¹ Vol. xlii No. 6. pp. 95-116.

² *Proceedings of the Royal Society of Medicine*, vol. viii, Part II, p. 53, 1914.

³ *Memórias do Instituto Oswaldo Cruz*.

who died two and a half hours after delivery); he concluded that the epidemic was identical with the epidemic infectious disease variously known as "alastrim," "Spanish measles," "milk-pox," etc., which had prevailed during recent years in various parts of the Americas. Dr. Armstrong's account of the clinical characters of the epidemic agrees with the description of alastrim in Brazil as regards the low mortality, absence of secondary fever, and non-occurrence of deep scars, but in the Australian outbreak the typical variolous odour was noticed in the severer cases; the epidemic was too small for observation to be made of the duration of the subsequent immunity to vaccinia. The Sydney outbreak showed the same incubation period and symptomatology as small-pox, but, even in the confluent cases, after the disappearance of the eruption the patients had no fever and felt well; similar cases have occurred in subsequent years. Dr. Copeman, in a communication to the Royal Society of Medicine,¹ pointed out that the Sydney outbreak resembled an epidemic which he had investigated at Cambridge some years ago, and which was first regarded as chicken-pox, but proved later to be small-pox of low infectivity and mild character. Nearly all those who took part in the discussion expressed the opinion that the Sydney "alastrim" was a mild form of true small-pox. Dr. Copeman has since investigated an outbreak of mild varioloid disease occurring in East Anglia, and expressed the opinion that it was closely related to "alastrim."

SIR CLIFFORD ALLBUTT.

THE Association of American Physicians has for the first time elected honorary members who live outside the United States, and the first honorary member elected was Sir Clifford Allbutt. Subsequently M. Roux, until recently director of the Pasteur Institute, Paris, Professor Heger of Brussels, and Professor Marchiafava of Rome, were also elected honorary members. Sir William Osler, who was an honorary member, was one of the founders of the association and was elected when still resident at Baltimore. So once more these two names—Osler and Allbutt—are associated in the possession of no ordinary distinction. The compliment thus paid to Sir Clifford Allbutt will give great pleasure to all members of the profession in this country, for by all he is regarded with respect and affection. Time does not change nor custom stale his infinite variety, and we are all looking forward to the presidential address which, on the evening of Tuesday, June 29th, he will give to the Annual Meeting of the British Medical Association in Cambridge.

INTERNATIONAL GOOD-FELLOWSHIP.

THERE are, as we have frequently ventured to say, great possibilities in the Fellowship of Medicine. The idea by which its founders were inspired was the promotion of closer relations between the members of the medical profession of the allied and friendly nations. It proposed to do this primarily by affording better opportunities to members of the profession within and beyond the seven seas to become personally acquainted, and to understand that the British profession was ready and anxious to welcome them as fellow-workers and personal friends. It was really as an after-thought—to meet the emergency at the end of 1918, when the armistice brought so many medical officers of the Dominion and United States forces to this country—that it established the post-graduate courses by which it is perhaps best known to the medical public. By its amalgamation with the Post-Graduate Medical Association an important step was taken towards

placing graduate medical instruction in London on a more secure basis, and one which we greatly hope may presently be made permanent. It was natural that the Fellowship should be centred in London, and it at present enjoys the hospitality of the Royal Society of Medicine for its office work; but the amalgamated body is not a London institution, it seeks to encourage and organize post-graduate instruction in all parts of Great Britain. Recently, further opportunities for extension have been opened up, and there is an immediate prospect of the establishment of local centres of the Fellowship in the Dominions and in the United States. France, also, has shown a desire to co-operate, and the Fellowship has been invited to consider the formation of a branch in Paris for English-speaking students. We have already mentioned that the profession in Bath have arranged a course in hydrology for members of the profession in this and other countries; it begins on June 7th. We now learn that a course (in English) will be held also at Vichy, beginning on June 15th. It will be conducted by M. Monod-Walter, M.D. Paris, M.R.C.P. Lond., physician to the Vichy Thermal Hospital, and will include lectures on dyspepsia and dyspeptics (gastric pains, dilatation of the stomach and visceroptosis, aerophagia, dieting) and practical hydrology at the bathing establishment. Special terms for accommodation will be arranged. Additional information can be obtained from the Secretary to the Fellowship, 1, Wimpole Street, W.1. A programme of work in Paris will be published later.

THE AMERICAN HOSPITAL IN LONDON.

WE announced a short time ago that the London Committee of the American Hospital it is proposed to establish in London intended to entertain Dr. Charles W. Mayo of Rochester, Minnesota, at dinner in July. Dr. Charles Mayo is a member of the Medical Committee in America, along with his brother Dr. William Mayo; among other members are Dr. Crile, Dr. Ochsner, and Dr. Franklin Martin of Chicago, and Dr. Matas of New Orleans. The resolution by which the American Hospital was founded defined one of its most important aims to be "to act as a link in binding together the two nations for the advancement of medical science as affecting the welfare of humanity." The Medical Committee in this country will be anxious to do all in its power to further this most admirable object, and through the projected hospital and the Fellowship of Medicine to provide for American graduates the facilities in London and other parts of Great Britain which they used formerly to seek in Berlin or Vienna. As already announced, ex-President Taft is the president of the General Committee in America, and Mr. J. P. Morgan has recently become vice-president. As soon as the institution has become incorporated according to the laws of the State of New York, this committee will set to work to raise an endowment fund of several million dollars. It is not proposed at present to erect a new building in London, but the committee here believes that it will shortly be in a position to open a temporary building for the reception of patients and as a centre for American graduates visiting this country. The invitations to the dinner, which is to take place at Claridge's Hotel, Brook Street, London, on July 6th, are issued by the Earl of Reading (president of the committee in this country), Viscount Bryce (vice-president), the American Ambassador, and the Board of Governors of the hospital.

JAMESON.

ON May 22nd the body of Leander Starr Jameson found its last resting place in the Matopo Hills, close to the tomb of his friend Cecil Rhodes. Jameson was a very remarkable man. General Smuts, as Premier of South Africa, did justice to his great qualities in a telegram to the Rhodesian Administration on May 21st, when he described him as a great South African whose human

¹ *Proc. Roy. Soc. Med.*, vol. viii, Part II, p. 33, 1914.

qualities endeared him to all who knew him. "With the exception of Rhodes," General Smuts continued, "no man had a better right to be called the founder of Rhodesia. His work at the National Convention entitles him to the further distinction of being one of the makers of the new South Africa. In this solemn hour, when his dust is made for ever an integral part of British South Africa, we, of whatever race and speech, unite in remembering his great services and doing honour to his memory. On behalf of the Government and people of the Union, in whose public life he occupied so great a place, I express to you and the people of Rhodesia reverence for the dead and sympathy and fellow-feeling in our common loss." Jameson was a student of University College Hospital in the seventies. He graduated M.B. in 1875 and M.D. in 1877 in the University of London, and was resident medical officer of the hospital when an offer to join a practice in Kimberley appealed to his impecuniosity and love of adventure. It was in Kimberley that he met Cecil Rhodes, and it has been said that there were times when Jameson and his partners were the only people who had any ready money in Kimberley. However this may be, there is no doubt that Jameson became deeply involved in the speculation then so nearly allied to the politics of that part of South Africa. But he cared less for money than power; from 1891 to 1895 he was administrator of Rhodesia for the British South Africa Company. Devoted friend as he was of Rhodes it was he who "upset the apple cart" by the raid on the Transvaal in the last days of 1895. He was taken prisoner by the Boers and was tried in London and condemned, but shortly afterwards released. He served during the South African war in 1899-1900. He entered politics in 1900 as member for Kimberley in the Cape Legislative Assembly, and four years later was Premier of Cape Colony. The shifting sands of South African politics brought his political career there to an end in 1903, and he came to London, where he had always had one foot. He was sworn of the Privy Council in 1907, and created a baronet in 1911. During the later years of his life he was president of the British South Africa Company, but when he died in London on November 26th, 1917, he left no great fortune. The final funeral was an impressive ceremony. The body, which was accompanied by Sir Thomas Smartt, K.C.M.G., the leader of the Unionist Party in South Africa, was received at Bulawayo by a guard of honour. The service was attended by pioneers from all parts of Rhodesia, by the administrators of both provinces, by many members of the Legislative Council, and by representatives of the Chartered Company.

A UNIVERSITY QUARTER FOR LONDON.

The offer of the Government, made through the Minister of Education, to provide a site of 11½ acres on the north of the British Museum for the head quarters of the University of London and for other university purposes, is a revival of a scheme first mooted at the beginning of 1912. The Royal Commission on University Education in London had published at the end of 1911 an interim report expressing the unanimous opinion that the University of London should be recognized as a great public institution, and that it "should have for its head quarters permanent buildings appropriate in design to its dignity and importance, adequate in extent, and specially constructed for its purposes, situated conveniently for the work it has to do, bearing its name, and under its own control." In February, 1912, it was announced that certain friends of the University had obtained an option on four plots of land lying immediately north of the British Museum. It was stated that the price asked for the site was £375,000, that this price might be reduced, and that promises of contributions amounting to £355,000 had been received. The proposal did not at that time meet with a cordial reception from the senate of the university, and nothing more was heard

about it until Mr. Fisher's letter to the Chancellor of the University the other day. The Government is prepared to give the land as a site for the new head quarters of the university and the colleges and institutions connected with it—including King's College, now in very cramped quarters in the Strand—and is prepared also to secure the university from loss in respect of maintenance charges on the new university head quarters. The erection of the buildings would be left to public munificence. Mr. Fisher pointed out the advantages which might be expected to follow the concentration of the head quarters of the university and its two incorporated colleges on a single site in a quiet residential quarter close to the national library and museum, and yet capable of expansion in the future should need arise. The offer, will not, we feel sure, be lightly refused by the Senate; it is now under the consideration of a committee of that body. It is true that the financial position of the University of London is such that it has to live from hand to mouth, and that aspect of the question must no doubt have very full consideration, but if it reject the offer the Senate will incur a very serious responsibility. The University of London is now a lodger in the Imperial Institute; there is no university quarter in London, and university life suffers in consequence.

SIR JOHN BLAND-SUTTON.

It was announced at the quarterly meeting last week of the Governors of the Middlesex Hospital that Sir John Bland-Sutton was retiring from the active staff. He became a student of the Middlesex Hospital in 1878, and was successively demonstrator and lecturer on anatomy; during this time he was also prosector to the Zoological Society, and old members of the Pathological Society will remember the numerous specimens he brought before it from the zoological laboratories during the presidency of Sir James Paget, who took many occasions of drawing the moral that the field of pathology was not limited to man. In these early days, too, he displayed an understanding of the influence which the theory of evolution must have on medicine and pathology, and in 1890 he published a book on *Evolution and Disease*. The Bland-Sutton Institute of Pathology which he established and endowed at the Middlesex Hospital was a practical application of the doctrine he has always maintained that the practice of medicine and surgery must rest on physiology and pathology, and can progress only as they advance. Readers of medical literature know his mastery of happy phrase and apt illustration, and, taking the last word literally, we may note that he is one of the few who have sustained the art of woodcutting in this time of its neglect. The pictures his papers contain prove that engraving on wood can present pathological appearances far better than the mechanical reproduction of photographs. He is a vice-president of the Royal College of Surgeons of England, and we had occasion only the other day to report that his brother surgeons had done him the distinguished honour of electing him the first president of the Association of Surgeons of Great Britain and Ireland.

CHAIR OF ANATOMY AT CAMBRIDGE.

PROFESSOR JAMES T. WILSON, at present incumbent of the Challis Chair of Anatomy in the University of Sydney, has been appointed Professor of Anatomy in the University of Cambridge, in succession to the late Professor Alexander Macalister, who died in September last. Professor Wilson was born in Dumfriesshire in 1861, and educated at Edinburgh, where he graduated M.B., C.M. in 1883. Like so many more of the leading British anatomists of this generation, he was demonstrator of anatomy in the University of Edinburgh under Sir William Turner. His contributions to science have been concerned chiefly with embryology, but also with comparative anatomy generally. He was elected a Fellow of the Royal Society in 1909. He has held the chair in Sydney since 1890.

PROFESSOR VAN BENEDEN OF LIÈGE.

A LIFE-SIZED bronze statue of Van Beneden, professor of zoology in the University of Liège, who died four years ago, was unveiled on May 24th. The statue stands at the entrance to the Zoological Institute where Van Beneden worked and taught for over thirty years. The ceremony was attended by a large number of his old colleagues, by representatives of other Belgian universities and scientific societies, and by delegates from British universities. Both King Albert and the Belgian Parliament were represented. The representatives of the British universities were Professor Sarolea (Edinburgh), Sir Leslie Mackenzie of the Local Government Board of Scotland (Aberdeen), and Professor Sir Thomas Oliver (Durham). Professor R. W. Hegner represented the Johns Hopkins University, Baltimore. When fully mustered the company marched in procession to the class-room where Van Beneden had taught and in which was gathered a large number of old and present students and his widow and relatives. The Rector was in the chair. Dr. Nolf, Professor of Pathology in the University, delivered a memorial address, during which a beautifully executed bronze mural tablet, pronounced to be an excellent likeness, was unveiled. Professor Gravis (botany), M. Lamcere (President of the Belgian Royal Academy of Science), Professor Van der Stricht (Ghent), Professor Sarolea (Edinburgh), and Professor Dumas, successor to the late professor, delivered addresses containing references to the epoch-making researches of the great embryologist and his work upon fecundation and cell reproduction. The speaker who drew the greatest applause was Van der Stricht, who, while pleading for the University of Ghent, insisted upon it retaining its French character as opposed to a purely Flemish institution. When he had finished his address the Rector, rising amidst the applause of the audience, kissed the distinguished Fleming upon both cheeks. Afterwards the audience proceeded to the front entrance, where the full-sized statue in bronze was unveiled. A luncheon, attended by several of the delegates and the Rector of the University, followed.

MORRISON OF PEKING.

DR. G. E. MORRISON of Peking died at Sidmouth on May 30th, after a long illness, which he faced with his accustomed courage. He was a patriot of the larger mould, and as *The Times*, whose correspondent he was for many years, has said, "his passion was that Great Britain might play her part in China's development." He was born in 1862 at Geelong, Victoria, where his father, a Scot, was principal of the college. While still a student at Melbourne he began his travels. His idea of travelling, whether in Australia or China, was to go on foot, for in this way he saw most of the country and of the people. While in charge of a small pioneer expedition to New Guinea he was wounded and left for dead with two spearheads in his body; for treatment he went to Professor Cheyne in Edinburgh and there graduated M.D., C.M. in 1887. He walked from Shanghai to Rangoon in 1894 and in the following year published his delightful book, *An Australian in China: Being the Narrative of a Quiet Journey across China to Burmah*. It was in that year that he became special correspondent to *The Times* in Peking, and proved himself one of the most accomplished journalists of the day. It was his intimate knowledge of China and the Chinese that gave him the great influence he had, and at one time or another he had visited every province in China except Tibet. In 1912 he resigned his connexion with *The Times* in order to accept the invitation of the first President of the new Chinese Republic to become his political adviser. He formed a very large Chinese library, and when his books were sold a short time ago sinologues gathered from all countries. When the list is made of members of the medical profession who have achieved great distinction in other spheres of activity, Morrison's name will not be omitted.

FUTURE PROVISION OF MEDICAL SERVICES IN WALES.

REPORT OF THE CONSULTATIVE COUNCIL.

THE Welsh Consultative Council is not a medical body, although it contains medical members; the chairman is Sir Edgar R. Jones, M.P., and among the members are representatives of nurses, friendly societies, county and rural district councils, Insurance Committees, and of labour organizations. The medical members are Professor D. Hepburn, C.M.G. (Cardiff), Dr. Robyn-Jones (county M.O.H., Monmouthshire), Dr. Hugh Jones (Dolgelly), Dr. Ewen J. Maclean (Cardiff), Dr. E. Ll. Parry-Edwards (county medical officer, Carnarvonshire), and Dr. W. E. Thomas (chairman of the Glamorgan Paed Committee).

The first report of the Council was formally laid on the table of the House of Commons on May 19th, but has not yet been published. Its substance, however, can be stated. In the introduction to the scheme submitted by the Council the principle is laid down that the object to be sought is to maintain the people in good health, and that such maintenance should begin before birth and be actively promoted throughout life. It is laid down that a family doctor should be available for every household and that he should be kept in effective touch with the household through the scheme.

Health Visitors.

The first matter dealt with is the adequate supply of health visitors, but the new type of health visitors recommended is not to be taken as meaning merely extended service for those now employed by local authorities. The scheme of proposed duties is as follows:

Male Health Visitors.—To render (i) Nursing aid for men in early nerve cases threatening to become mental. (ii) Necessary help at clinics for children. (iii) Attendance at male venereal diseases clinics or ablation stations. (iv) Incidental assistance in general sanitary work and removal of infectious cases, if and when required. (v) Services under the Children's Act. (vi) Services under the Juvenile Employment Act. (vii) Services under the Mental Deficiency Act—when necessary.

Female Health Visitors.—(i) Domiciliary visits for (a) ante-natal work; (b) work arising out of notification of births; (c) visitation of schools, and following up school cases of defects; (d) tuberculosis cases from institute or visiting station; (e) mental deficiency cases which are under supervision or observation. (ii) Clinic work in connexion with (a) maternity (ante-natal and post-natal work) and infant welfare; (b) treatment of school children found defective; (c) tuberculosis cases at visiting station; (d) to notify the evidence of venereal diseases and give advice.

Special Health Visiting.—(i) Fever nursing—epidemic or fever nursing by way of domiciliary visits and help. (ii) District nursing. (iii) Whole-time nursing for special cases.

The minimum number of qualified female health visitors for carrying out enlarged duties in connexion with infant welfare work and school medical inspection should be 1 per 1,000 houses in the larger centres and 1 per 500 to 750 houses in the smaller towns and rural districts.

Dental Service.

The Council holds it of urgent and paramount importance that properly qualified dental treatment should be available for all, with priority for young children and expectant mothers. Attention is directed to the serious inadequacy of qualified dentists in Wales and to the mischief wrought by unqualified persons. A minimum provision of qualified dentists, if available, would probably be 1 to 4,000 of the population. The Council urges immediate action.

Medical Service.

Acting with the assistance of the various officers whose duties had thus been outlined, one doctor should, as a general rule, be available for 400 homes in urban communities and for 300 in rural. The unequal distribution of the population complicates the problem of specialists and consultants, which, it is said, should be approached on national rather than on purely local lines; a full report on the subject is to be prepared.

The Council holds that all health institutions, including voluntary hospitals, should form part of the future public services, but considers that until the general question of health administration in Wales has been fully considered the formulation of proposals as to the highest grade of institutions should be postponed. Subject to this, the

various institutions to be included in the national scheme would be:

(i) Central institutes for general medical and surgical purposes; local institutes (on a smaller scale) for the same purposes; subsidiary hospitals; various kinds and grades of clinics; provision for invalid cooking.

(ii) Asylums and mental deficiency homes, with suitable subsidiary institutions for cases showing early signs of mental trouble.

(iii) Fever, small-pox, plague, cholera, and dysentery hospitals; isolation hospitals with appropriate provision for dealing with contacts; seaport quarantine stations.

(iv) Tuberculosis sanatoriums and hospitals.

(v) Various kinds and grades of rest (or holiday) homes, convalescent homes, health centres, open-air schools, health colonies for children.

(vi) Institutions for the blind and deaf, epileptics, and cripples.

Motor Transport.

The success of the whole scheme for health visitors, home helps, midwives, registered nurses, doctors, dentists, and institutions will depend for efficient administration upon a large systematic motor transport service. Telephonic communication for all concerned is also insisted upon as highly necessary.

Application to Industrial and Rural Areas.

The Council gives reports from three of its committees who visited typical areas.

Industrial.

The Aberdare committee estimates the requirements for an industrial and urban area, in presenting the needs for this district, as follows:

The General Hospital at Aberdare, as the principal local centre, should comprise—

(a) 100 beds for general medical and surgical conditions.

(b) A maternity and child welfare department and clinic, affording 40 additional beds, with a proportion for pre-natal cases and isolation.

(c) A school clinic with a lien on, say, 15 further beds.

(d) A fully equipped radiological section, including apparatus for electrical treatment and massage.

(e) Various clinics—for example, dental, tuberculosis, venereal, paediatric, psychiatric, etc.

(f) A fully equipped out-patient department both for casualties and the usual departments.

(g) A separate block in close proximity containing 50 beds to which cases requiring after-care and supervision might go, thus relieving the primary beds.

(h) An essential requirement would be a medical institute and laboratory, including a library and facilities for dealing statistically with health records of the area.

At Mountain Ash, a similar centre on half scale would be required, omitting the medical institute and laboratory.

A Mixed Area.

East Carmarthenshire was taken as typical of both an industrial and rural area. The Council suggests that Swansea should, as at present, be regarded as the centre for a large and fully equipped institution, and that at Llanelly also there should be a central institute to serve as a hospital for the south-eastern portion of the area, with subsidiary hospitals at Ammanford and Pontyberem respectively. The establishment of a hospital at Ammanford subsidiary to that of Llanelly would depend largely on the construction of an arterial road. After mentioning that there should be a fever hospital for the whole area, the Council advises that provision should be made in the area for public baths, pithead baths, and douche baths in connexion with factories and works. It is held that open-air schools should be established in every district, not only for defective children but for normal children also.

A Rural Area.

Merionethshire is reported upon as the type of a purely rural area. The Committee is of opinion that such a county, with a scattered population of only 50,000, should have its needs met by the provision of central institutions in association with other areas and not for this county alone, and by the provision of local institutions to serve local needs. They advise that large hospitals or institutes be provided at three central places—for example, at Bangor, Wrexham, and some other place—to serve parts of Merionethshire, Montgomeryshire, and parts of mid-Wales.

Minister's Comment.

Dr. Addison has pointed out that the recommendations must be considered in relation to the whole scheme of health services to be submitted to Parliament for the different parts of the United Kingdom—or at any rate of Great Britain. This observation is necessary in view of the financial changes the scheme would involve, to whatever degree the aid of the general practitioner be sought—the employment of so many other persons being contemplated.

England and Wales.

TREATMENT OF TUBERCULOSIS IN LONDON.

At the meeting of the London Insurance Committee on May 27th a report on sanatorium benefit in 1919 was presented. The new cases placed under institutional treatment by the Committee numbered 3,839; of this total 1,930 were cases of ex-service men, in all of whom the tuberculosis was held by the Ministry of Pensions to be connected with war service. Of the remaining cases 921 were males and 938 females. The number of civilian male cases was the smallest for any year since sanatorium benefit came into operation in 1912, although included in the figures were a number of patients who were on active service during the war, but in whose cases no connexion had been established between the disease and army service. In 25.9 per cent. of the total cases the period of institutional treatment was from one to two months; in 24.2 per cent. from two to three months, and in 19.2 per cent. from three to four months. At the end of the year 2,276 cases were in institutions, and 84 were on the waiting list. The number of patients who received domiciliary treatment during 1919 (treatment by the insurance doctor, with or without extra nourishment) was 8,364, and those receiving dispensary treatment 190. The medical adviser reported that the average length of residence in sanatoriums had increased. Roughly, 50 per cent. of all male patients discharged themselves; the remainder were almost all discharged on the recommendation of the medical superintendents, the usual ground for the recommendation being the improbability of further improvement. It was found that 47 per cent. of the ex-service men, 43 per cent. of the civilian males, and 39 per cent. of the females were unfit for any work after discharge, and that the proportion fit for full work only represented 8, 15, and 8 per cent. respectively in the three categories. The balance were discharged as fit for light work, which in practice meant that patients were unfit to follow their usual occupations. The number of patients recommended for sanatorium treatment who were sent for a preliminary period of observation to three consumption hospitals had increased; a considerable proportion were found unsuited for sanatorium and were recommended for domiciliary treatment.

BOARDING-OUT OF CHILDREN.

It appears from a circular issued by the Ministry of Health that in January, 1919, about 3,500, and in January, 1920, about 3,100 children more than 3 years old were living in Poor Law institutions. As it is necessary to reduce this number it has been decided that the boarding-out fee may now be fixed by the guardians instead of by the central authority, and that in certain circumstances the sending of a child to a foster-parent whose creed is different from that of the parents may be sanctioned. A list of certified schools and institutions which have spare accommodation for children is appended to the circular.

Scotland.

SMALL-POX IN SCOTLAND.

Cases of small-pox have continued to occur in Glasgow during the last fortnight. On May 30th there were 156 cases under treatment in hospital; 34 cases had been admitted during the four preceding days and 14 recovered patients discharged. Two deaths occurred at the end of last week—one male unvaccinated and one woman vaccinated in infancy. The cases appear to be most numerous in the Bridgeton and Parkhead districts, but are occurring in many other parts of the city. Precautions are being taken all over Scotland, and free vaccination is being offered in most districts. In Edinburgh twelve centres for vaccination have been established; they are to be open from 6 to 9 every evening, and a special staff of doctors has been engaged to attend for a fee of a guinea an evening. Three cases have occurred in Dundee but no fresh cases are reported in Edinburgh.

OBSTRUCTION OF A DOCTOR'S CAR.

For negligently interrupting the passage of a motor car in which Dr. Young, of West Calder, and his assistant were being driven along the Edinburgh-Ayr road to an urgent case, a motor lorry driver has been fined £2 in Edinburgh Sheriff Court. Dr. Young said in his evidence that the driver of the car sounded his horn continually, but the driver of the motor lorry paid no attention, and kept his vehicle in the middle of the road. The obstruction continued for a distance of two miles until the doctor's car had reached its destination. The accused said that, having been made aware by a pedestrian that a car was trying to pass him, he allowed the doctor's car to pass at the first moment when he thought it safe to do so.

Ireland.

MEETING OF COUNTY WEXFORD PRACTITIONERS.

The medical practitioners of county Wexford, at a recent meeting held at Enniscorthy, recorded their belief

that a settlement of the Irish medical question satisfactory to the profession and the public cannot be effected without legislation, which must provide for such radical medical reforms as will secure that the present cumbersome and ineffective administration is replaced by more up-to-date and uniform methods, both as regards preventive and curative medicine.

The meeting resolved that the inadequate salaries of Poor Law medical officers ought to be increased, with retrospective effect, and passed a number of detailed resolutions regarding increases in rates of salary and scales of fees for professional services. Among these were resolutions that fees for attendance on private patients should be increased by 50 per cent., and that the rate of payment for contract practice be increased by 25 per cent. A vote of thanks was passed to Drs. T. J. Kelly, C. R. Boyce, S. V. O'Connor, and James Ryan, M.P., for the able manner in which they put the case of the doctors in relation to the roads question before the Wexford County Council.

THE PROPOSED SANATORIUM AT CRAIGAVON, BELFAST.

The Down County Council has received from the Local Government Board a letter stating that the application for sanction to borrow £27,000 for the purchase of Craigavon as a sanatorium for consumptives has been refused. The reasons for this are stated as follows:

In the Board's view, the main issue raised in the inquiry turns on the conflict of public interest—on the one hand of the need of the County Down patients for tuberculosis treatment and on the other of the welfare of Belfast.

Seeing that the Belfast Corporation, as the local authority, have publicly, and on grounds which were not refuted, represented the scheme of the Down County Council as injurious to the development and progress of the County Borough, the Board can only come to the conclusion, though with some regret, that the proposition is not one to which they should afford facilities by consenting to the application for a loan.

THE ULSTER MEDICAL SOCIETY.

The annual meeting of the Ulster Medical Society was held on May 27th, when the president, Mr. Andrew Fullerton, C.B., C.M.G., F.R.C.S.I., was in the chair. The reports of the honorary secretary, treasurer, and librarian were presented, discussed, and adopted. A debit balance of £39 was shown, but otherwise the reports showed a session of great activity and much professional interest, upon which the office-bearers were congratulated. The following office-bearers were elected for the ensuing year:

President: Dr. Thomas Houston, Belfast.

Vice-Presidents: Dr. James Agnew, Lurgan; Dr. J. E. MacIlwaine, Belfast.

Honorary Treasurer: Dr. S. I. Tarkington, Belfast.

Honorary Librarian: Dr. W. L. Storey, Belfast.

Honorary Secretary: Dr. W. W. D. Thompson, Belfast.

Assistant Editing Secretary: Dr. Robert Marshall.

Council: Dr. C. G. Lowry, Mr. H. Stevenson, Mr. S. T. Irwin, Dr. Wm. Baras, Dr. V. G. L. Fielden, Dr. S. B. Boyd Campbell.

IN reply to a question on June 1st, when the House of Commons resumed after the Whitsun recess, Dr. Addison repeated his statement that the Government did not intend to take over voluntary hospitals, adding that within the limits of a reply he was unable to discuss the exact relation of voluntary institutions to the general scheme of health services, but hoped to be able to make a satisfactory statement before long.

Correspondence.

FUTURE PROVISION OF MEDICAL SERVICES.

The Primary Centres.

SIR.—To appreciate fully the scheme put forward by the Consultative Council¹ it is necessary to understand the conditions for which it is to be the remedy. Of these there are three main ones:

1. The doctors in their practice being isolated, and with but a limited resource in regard to methods, are not able to give their patients the benefit of those methods which the progress of medicine has provided. The equipment of the primary health centres will afford the doctor the opportunity of giving every patient these benefits.

2. Every thoughtful general practitioner has found on entering practice that his education had been woefully deficient, in that he was unable to recognize the complaints of the vast majority of his patients, and that he had to begin a re-education of himself. Until the teaching at the schools is improved, these primary health centres, where he will meet his more experienced brethren, will greatly help him in this respect.

3. It has been realized that there is a great lack of medical knowledge in regard to the early stages of disease. Research and education have been mainly concerned with the advanced stages of those diseases which are common amongst the people, and it was not understood how this lack of knowledge of the early stages could be made good. It has only lately been recognized that for this kind of research the general practitioner was the only individual who had the opportunity, but hitherto the means for undertaking this kind of work have been denied him. This state of affairs will be remedied by the establishment of the primary health centres.

The scheme is a bold one, designed to deal with an urgent need, and its magnitude may well cause doubts as to its wisdom. The more the condition of medicine is considered the greater will be found the necessity for some such drastic revolution. The one fear is that it may be entered upon too hastily, before the doctors who will carry it on are sufficiently experienced. If this be recognized, and a careful inquiry be made as to the best methods to be employed, and then a few centres started under doctors with some experience, a workable scheme will without doubt be discovered.

The cost of the scheme may at first sight appear too large, but if the various medical services are co-ordinated, and as far as possible carried on in one building, with one set of laboratories, the cost need not be so great.

The secondary health centres need not be established at first, for when the possibilities of the primary health centres are fully realized, the kind of secondary health centre needed will be better understood, or it may be found not to be required. I am confident that with the efficient carrying out of the primary health centre, the attitude towards hospitals and medical schools will be profoundly modified.

The Consultative Council are to be congratulated on having produced a very wise and practicable scheme, which, if properly carried out, will have a far-reaching and beneficial effect in the whole field of medical knowledge and practice.—I am, etc.,

J. MACKENZIE.

The Clinical Institute, St. Andrews, Fife.

May 29th.

Provision of Private Wards in Health Centres.

SIR.—The report of the Consultative Council proposes to meet the needs of the very large class of patients who are only able to afford a moderate inclusive fee for nursing home accommodation and expert medical treatment by the provision of private and self-supporting wards as part of the fabric of health centres. The essential services in the public and private wards would be identical.

¹ The Interim Report of the Consultative Council on Medical and Allied Services is published by H.M. Stationery Office, and may be purchased through any bookseller, price 1s. Messrs. Eyre and Spottiswoode, East Harding Street, Fetter Lane, E.C.4, will supply a copy post free on receipt of a postal order for 1s. 3d. (under the new postage rates.)

The proposal, occupying less than a dozen lines of the report, rather suggests a desire on the part of the Council to create a niche in a homogeneous ideal medical service for an awkward class of patient than a carefully considered plan to meet the urgent need there is in every large centre of population for the provision on an adequate and efficient scale for patients able to pay the full cost of maintenance (including nursing and all charges apart from medical fees) and a moderate fee for medical attendance. It is the inclusive cost that dominates the situation: cheap nursing-home accommodation alone is useless. In the report there is no suggestion as to how, or by whom, the medical charges are to be determined.

Provided that the patient can pay the economic cost of maintenance, nursing, etc., in a large private institution (which at present is about £6 6s. a week), the need can be met by the application of ordinary business principles, and the problem solved without resort to charitable or public funds. It is, however, essential that the medical profession in each large centre should take the initiative in establishing a hospital for paying patients on sound ethical lines, and should retain control over all matters affecting the admission of patients, the assessment of inclusive fees, and the personnel of the medical staff. That a hospital of this kind can be successfully established St. Chad's Hospital, Birmingham,¹ has demonstrated; upwards of 1,000 in-patients are now being treated there. What Birmingham has done other cities can equally well do and do quickly.

The proposals of the Consultative Council, admirable as they are in theory, involve such extensive reorganization and such vast expenditure of public funds, that much time must necessarily elapse before they can fully materialize. Any alternative which will satisfy quickly part of the requirements of their suggested complete medical service without interfering with the scheme as a whole, and without making any demands upon the public purse, should be welcomed on these grounds alone. Whether the provision of self-supporting wards as part of the hospital accommodation of secondary health centres would prove altogether satisfactory is open to doubt. Many difficulties in connexion with such a scheme present themselves to one's mind. Destructive criticism is, however, of little value unless a better alternative can be devised, and this, I firmly believe, would be the establishment in each large centre of private institutions run on the lines of St. Chad's, in which there is a combined desire on the part of the shareholders and the medical staff to bring the whole cost of expert medical treatment within the reach of people of moderate means without resort to charity or outside assistance of any kind.—I am, etc..

WILLIAM BILLINGTON, M.S.Loud., F.R.C.S.

Birmingham, June 1st.

The Position of General Practitioners.

SIR,—Your sketch of this important and long-looked-for report is most welcome, and should encourage every medical and dental practitioner to invest the sixteen pence necessary in order to obtain the document and to give it the fullest detailed consideration. There are, however, three questions which seem to jump at once to the eye, and will prove probably to be fundamental.

1. The medical profession in 1910 decided by about 80 per cent. vote not to approve placing any domiciliary or institutional clinical service under the control of the county or county borough medical officer of health. Is it of a different opinion now?

2. What inducements or facilities are offered to the general practitioner to make the part-time State service one for preventive treatment, and not, as heretofore, one for curative treatment only?

3. Seeing that a general practitioner service is said to be the foundation on which to build an institutional service, how is it proposed to draw in those practitioners (50 per cent. of the profession) who disapprove of the State Insurance and Poor Law medical services, and who, consequently, will keep their patients away from any contact with the same?

For obvious reasons I sign myself—

May 31st.

GENERAL PRACTITIONER.

CIVIL MOTOR AMBULANCE SERVICE.

SIR,—The report issued by the Consultative Council of the Ministry of Health embodies recommendations which will necessarily entail a considerable increase in the work

of transport of the sick and injured in this country, and the Council draw special attention to the necessity for an ambulance service.

I am happy to say that the Joint Council of the British Red Cross Society and the Order of St. John has been able to anticipate this demand, and has during the past twelve months established over 300 motor ambulance stations throughout the country. That the need existed for an efficient ambulance service even before the establishment of the system of linked hospitals foreshadowed in the report, is shown by the fact that though a large proportion of the ambulances have been in service for only a few months, they have already been the means of transporting over 12,000 cases.

The administration of our ambulances has been delegated through county directors to local organizations or public health authorities as circumstances dictated, but central control of the service is maintained at head quarters, and we are thus in a position to develop and extend the scheme on such lines as may prove most desirable to meet the needs of a co-ordinated health service.—I am, etc.,

ARTHUR STANLEY, Chairman.

Joint Council British Red Cross and
Order of St. John,
19, Berkeley Street, W. 1, May 29th.

THE GENERAL PRACTITIONER AND THE HEALTH SERVICES.

SIR,—I have read with surprise the letter under the above heading written by Mr. William Paterson, M.B., Ch.B. Edin. The tenor of his letter is decidedly unfortunate. Everything that has been done towards ameliorating the health of the community appears to be wrong, presumably because he does not agree with it. Is this attitude brought about by a subconscious fear that the "so-called health services" have proved of greater utility, and have done their work more thoroughly, than the average general practitioner, and that the ruling powers recognize this and their growing strength?

Perhaps it is symptomatic that a medical man should call a fellow practitioner—who, incidentally, has had an extended and specialized training—a scavenger. I cannot fathom why the whole-time medical man in the health service should be the butt for the enmity of a certain type of man in another branch of the profession. He is already called upon to bear more than his share of the kicks and considerably less than his share of the halfpence. (I judge upon the average life and earnings of a panel practitioner.) Even though they be scavengers, they are nevertheless hard-worked whole-time practitioners in the service of their country's government and working for that country's good. From humble beginnings they have raised the "so-called health services" into a living, complicated, and efficient organization. Can the same be said of the panel system, and if it can, why the present agitation for greater efficiency? Be it noted that this agitation has had no reference to the established public health services, but to the services rendered under the Insurance Act.

If the general practitioners had, as a body, worked with the health authorities, rather than against them, relations would have been more harmonious, proceedings more effective, and the profession would have gained much needed dignity and cohesion. Health work should undoubtedly be a part of a private practitioner's duty. It is easier for him to advise and to see that advice is followed than it is for the administrative official. How many of them put the easy theory into hard practice?

A letter such as that alluded to is pernicious. Particularly is it so when appearing in the official organ of the British Medical Association. The prominence given to the letter is suggestive of the Association's attitude towards the whole-time medical—or should I say scavenging?—services.

The cordial co-operation between private practitioners and whole-time public health service men is a consummation devoutly to be desired. It is for the majority to show the way, but the way is not that taken by the Honorary Secretary of the Willosden Branch.—I am, etc.,

OSCAR M. HOLDEN, M.D., D.P.H.,

Medical Officer of Health, County
Borough of Dewsbury.

May 31st.

*** The universal custom of the press would, we should have thought, have made it unnecessary to state that the opinions expressed in a letter published in the BRITISH

¹ BRITISH MEDICAL JOURNAL, February 21st, 1920, p. 263.

MEDICAL JOURNAL are those of the writer, and do not in any way commit either the Association or the JOURNAL. The correspondence columns of the JOURNAL are intended, so far as space permits, to be a forum for discussion and free expression of individual opinions.

THE PERMEABILITY OF THE MENINGES TO ARSENIC.

SIR,—Intraspinal injections of atoxyl (Magalléas, Congrès International de Médecin, Lisbon, 1906, Part II, p. 304) and neo-kharsivan (Marshall, BRITISH MEDICAL JOURNAL, May 22nd, 1920, p. 702) have been recommended in the treatment of sleeping sickness, presumably on the assumption that organic arsenic compounds do not permeate the meninges. I therefore wish to state that I found arsenic in the cerebro-spinal fluids of experimental donkeys after treatment with atoxyl (*Ann. Trop. Med. and Parasit.*, 1908, vol. ii, p. 327). Out of eight donkeys examined, seven contained arsenic in the cerebro-spinal fluid in approximately the same concentration as in the blood serum.—I am, etc.,

M. NIERNSTEIN, D.Sc., Ph.D.,

University of Bristol, May 29th. Lecturer in Biochemistry.

SMALL-POX IN SCOTLAND.

SIR,—In your issue of May 22nd, page 721, it is stated that over 4,000 persons accepted the offer of free vaccination in 1901. The correct number should have been over 400,000. I personally revaccinated over 2,000 at that time.

Practically one-half of the population of Glasgow was revaccinated, and in the second epidemic not a single case of small-pox occurred amongst the 400,000 who had been revaccinated. It was an experiment on a large scale.—I am, etc.,

Erdington, Birmingham, May 30th.

R. ANDERSON, M.D.

MEMORIAL TO SIR VICTOR HORSLEY.

SIR,—I am very glad to be able to announce that the scheme for providing a memorial to Sir Victor Horsley has now been given a definite start. The nucleus of a committee has been formed, with Sir Charles Ballance as chairman, Sir Frederick Mott and Dr. H. H. Tooth will act as honorary treasurers *pro tem.*, and Sir Arbuthnot Lane will act as joint secretary with myself. Lady Horsley has withdrawn any objection she had previously expressed, and it is hoped to found a lectureship bearing Sir Victor Horsley's name, probably under the auspices of the University of London, but all details have yet to be formulated by the much larger committee which is in course of formation. I need only add that the names of any persons associated with any branch of work in which Sir Victor Horsley was interested who wish to take part may be sent to me or Sir Arbuthnot Lane.

In view of the many appeals now before the medical profession and the public it is not intended to ask for any very large subscriptions, but it is hoped that the number of subscribers will be otherwise large enough to provide the sum required.—I am, etc.,

EDWARD J. DOMVILLE.

Symondsbury, Bridport, Dorset, May 28th.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on May 21st the following medical degrees were conferred:

M.B., B.Ch.—F. J. Bennett, J. V. Bates, R. A. Woodhouse.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

THIRD M.B., B.S.—*G. B. Dowling, *G. E. Elkington, †G. P. B. Huddy, ‡M. Marcus, †J. P. Ross (University Medal), *G. M. J. Slot, I. M. Abd-El-Said, B. W. Armstrong, E. M. Atkinson, Marjorie Back, C. F. Beyers, J. A. Birrell, W. R. Biore, T. G. D. Bonar, Ella M. Britten, W. W. K. Brown, E. E. Carter, D. G. Churcher, W. H. Coldwell, H. C. Cox, R. Coyte, Joyce E. Craggs, E. I. Davies, Sarah H. Davies, H. A. De Morgan, C. Y. Eccles, A. Eidinow, T. L. Ellis, A. Evans, J. Fanning, Kathleen Field, Alice M. Griffiths, E. F. Guy, H. L. Heimann, C. E. E. Herington, C. L. Hewer, N. H. Hill, G. O. Hume, D. Hunter, E. F. Kerby, G. E. Kidman, J. V. Laduan, S. S. Lindsay, N. P. L. Lumb, H. M. C. Macaulay, P. G. McEvedy, S. F. Mahmood, Ida

C. Mann, J. P. Padshah, Dorothy Pantin, W. W. Payne, N. A. M. Peterson, Norah D. Pinkerton, Beatrice D. Pullinger, A. L. H. Rackham, H. E. Reburn, Frances E. Rendel, Esther Richards, H. C. Roak, T. C. Russell, E. J. Samuel, P. D. Scott, J. V. A. Simpson, J. B. Thackeray, J. A. van Icerden, A. S. Wakely, R. L. Walker, M. J. T. Wallis, L. H. W. Williams, P. E. B. Willis, Jane E. Wood, W. Yeoman.

Distinguished in Medicine, † Pathology, ‡ Forensic, § Surgery.

UNIVERSITY OF ST. ANDREWS.

Honorary Degrees.

AMONG the honorary degrees to be conferred at the public graduation ceremony on July 2nd are the degree of LL.D. on Dr. Leon Fredericq, for nearly forty years Professor of Pathology in the University of Liège, Belgium; Mr. W. J. Matheson, president of the biological laboratory at Brooklyn, and scientific adviser in chemistry to the Board of Health for the city of New York, and Dr. Norman Walker, His Majesty's inspector of anatomy for Scotland and direct representative of the profession in Scotland on the General Medical Council.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY MEETING of the Royal College of Physicians of Edinburgh was held on May 4th, Sir Robert Philip, President, in the chair.

Dr. Andrew Graham Ritchie was elected a Fellow, and Dr. George Sandison Brock, M.B.E., Dr. Chung Yik Wang, and Dr. Thomas Frederick Corkill were elected members.

The Lister Fellowship for Original Research was awarded to Dr. G. W. Marshall Findlay.

The subject of the essay for the next competition for the prize founded by the late Dr. John Parkin is "On the curative effects of carbonic acid gas or other forms of carbon in cholera, for different forms of fever and other diseases." Essays must be received not later than December 31st, 1920, by the Secretary of the College, from whom full particulars can be obtained. The prize is of the value of £100, and is open to competitors of all nations, but the essay must be written in English.

Medical News.

DR. J. G. ADAMI, C.B.E., F.R.S., Vice-Chancellor of the University of Liverpool, and lately Stratheona Professor of Pathology and Bacteriology in McGill University, Montreal, has been elected to an honorary Fellowship at Christ's College, Cambridge, of which he was formerly a scholar.

THE Minister of Health has appointed Mr. Llewelyn Williams, M.C., F.R.C.S., D.P.H., to be Medical Member of the Welsh Board of Health with the status of a Senior Medical Officer of the Ministry of Health. Dr. Meredith Richards, who has been acting temporarily as Medical Member of the Welsh Board of Health, has been appointed to the head quarters establishment of the Ministry of Health.

MR. H. LLOYD WILLIAMS, M.R.C.S., L.D.S., has been appointed a justice of the peace for the county of Middlesex.

DR. A. F. HURST will deliver the Croonian Lectures before the Royal College of Physicians this month. The first lecture will be given on June 10th at 5 p.m. The subject is the psychology of the special senses and their hysterical disorders.

AT a meeting of the Royal Sanitary Institute at Lincoln, on the evening of June 11th, a discussion on the development of maternity and child welfare work in a small county borough will be opened by Dr. J. C. Cole, M.O.H. Lincoln.

DR. WILLIAM M. PARSONS, of Manchester, New Hampshire, the oldest medical practitioner in New England, has celebrated his 94th birthday; during the day he attended as usual to patients coming to consult him.

DR. W. BRAMLEY TAYLOR, J.P., honorary librarian to the Society of Apothecaries of London, has received from the King of the Belgians the Médaille du Roi Albert for continuous services rendered to Belgian refugees in Weybridge during the five years of the war.

THE Bromley Division of the British Medical Association arranged a golf tournament for doctors living in the Division. The meeting was held at Langley Park Golf Club by kind permission of the committee on Thursday, May 27th. The competition was a handicap round against bogey. The result was: First, Dr. Soper (6), 1 down; second, Drs. Hawke (13) and Stilwell (12), 3 down. Drs. Tennyson Smith, Wynne Thomas, Randall M. Curtis, Umney, Clements, Hott, Colyer, Blake, Henshaw, Bailey, Cogswell, Michael, Giddings, and Colonel Smith, R.A.M.C., also played.

AFTER a meeting of the Faculty of Medicine of the University of Brussels on May 22nd, the Vice-Chancellor publicly presented the Medal of Honour of the University to Lord Dawson, Sir Leslie Mackenzie, and Sir W. Smith, in recognition of their distinguished services to preventive medicine.

THE Florence Nightingale Medal was instituted by the International Red Cross Committee in Geneva in 1912 in memory of the work of Florence Nightingale, to be distributed annually to six trained nurses who, in the opinion of the committee, have rendered exceptional service in connexion with nursing. During the war no distribution was made, but shortly after the signing of peace, it was decided to award fifty of these medals, and all National Red Cross Societies were requested to submit recommendations for consideration by the Committee: forty-two medals have been awarded. The recipients are nine British nurses, including one each from Canada, New Zealand, and South Africa, eight nurses of France, six of the United States, five of Italy, three of Japan, two of Belgium, two of Czecho-Slovakia, one of Greece, and one of Rumania. The medal is also awarded to one Danish nurse who worked in France, and to two Austrian and two Hungarian nurses.

THE American and Canadian Section of the International Association of Medical Museums held its thirteenth annual meeting at Cornell University on April 1st. Professor O. Klotz of Pittsburgh, who was in the chair, and Dr. Maude E. Abbott gave addresses on the pathological collections and the activities on behalf of the Medical Museum and the Museums Association of the late Sir William Osler. A resolution was adopted authorizing the council to take steps to raise a fund to bring into working order the Central Bureau for North America for the preservation of microscopic results of medical research, which some years ago it was resolved to establish. Two demonstrations were given from the Canadian National War Museum, one on facial injuries, by Major E. F. Ridsen of Toronto, and the other on the Canadian army medical arrangements at the front, by Major G. A. Campbell of Ottawa. Major F. B. Gurd of Montreal exhibited specimens showing infectious of gunshot wounds by *B. aerogenes*; Professor James Ewing of Cornell showed a large series of tumours of bone, including some unusual forms, and Professor Klotz spoke on the teaching value of the small museum specimen. A number of papers on preservation of specimens were read, including one by Dr. Homer Swift of New York, on the preservation of stock cultures of bacteria. A meeting of the Association of Pathologists and Bacteriologists was held at the same time, and for the advantage of both an exhibition was arranged. Dr. W. M. L. Coplin of Philadelphia was elected president for the ensuing year.

that a new set of tyres to replace old ones is not purely a revenue expense if they cost more than the original tyres cost, which is almost a *reductio ad absurdum*. But in the long run it may not make much difference: if depreciation is allowed to professional men using motor cars—as the Royal Commission on Income Tax recommended—our correspondent will be able to claim depreciation on £505 if he is now allowed only £60, but only on £510 if he is allowed £255, and even if this change in the law should not be effected the increased allowance now would operate to reduce the future allowance when No. 2 is replaced. We consider that our correspondent should have the allowance now, but it is worth while to take this view of the matter into account before he embarks on the trouble of an appeal against the practice of the Revenue authorities.

LETTERS, NOTES, ETC.

THE issue of Evans' *Analytical Notes*, the annual publication of which has been suspended since 1914, has been resumed. The account given by Messrs. Evans Sons, Lescher, and Webb of the analyses conducted in their laboratories contains much interesting pharmaceutical information. Copies may be obtained by medical practitioners on application to 56, Hanover Street, Liverpool.

REGISTRABLE FOREIGN DEGREES.

IN a note on the issue of the *Medical Register* for 1920, published in the *JOURNAL* of April 10th, it was inadvertently said that the degrees of nineteen foreign universities in Europe and eight in the United States of America were registrable in this country. It ought to have been said that the degrees of such universities, if obtained before June 25th, 1886, were registrable as additional titles by practitioners previously registered. The Medical Act of 1886 provided that an Order in Council might be issued applying Part II of the Medical Act to any foreign country which affords to the registered medical practitioners of the United Kingdom reciprocal privileges of practising. Under this provision, the Act was extended to Italy in 1901, and to Japan in 1905. Belgian degrees were made registrable in the Foreign List in 1915 under the special circumstances of that time. Foreign degrees or diplomas entitling a foreign practitioner to have his name entered on the Foreign List must be those approved by the General Medical Council. The number of names on the Foreign List of the *Medical Register* for 1920 was 165.

AN OPPORTUNITY FOR INVALIDS.

DR. H. F. LECHMERE TAYLOR, Secretary and Superintendent of the Edinburgh Medical Missionary Society, writes: To those cut off by bodily weakness from the wider activities of life the Invalids Auxiliary of this society offers an interesting opening. The auxiliary was founded some fifty years ago, and has as its aim to give invalids an opportunity of helping fellow sufferers in other lands. A sale is held about the end of the year, in Edinburgh, of work contributed by members of the auxiliary, the proceeds being apportioned amongst various medical missions. Contributors are kept informed as to the destination of their gifts, and an endeavour is made to establish a living link of sympathy between those who give and those who get. To many invalids in past years the auxiliary has brought an added interest in life and a congenial means of useful service. The committee will welcome new contributors, and would suggest to doctors and nurses who have the care of invalids to bring this form of activity to the notice of their patients, who would benefit by being interested in helping other sufferers. Further particulars will gladly be furnished by Miss Clark, 16, Coates Gardens, Edinburgh, or Miss Anne Walker, Assistant Secretary, Edinburgh Medical Missionary Society, 56, George Square, Edinburgh.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 38, 39, 40, 41, 42, and 43 of our advertisement columns, and advertisements as to partners, assistants, and locum tenencies at pages 36, 37, and 38.

THE following appointments of certifying factory surgeons are vacant: Branitree Essex; Johnstone Renfrew.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 423, Strand, W.C.2, on receipt of proof.

AS, owing to printing difficulties, the *JOURNAL* must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

IN order to avoid delay, it is particularly requested that ALL letters of a general character to the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

THE postal address of the *BRITISH MEDICAL ASSOCIATION* and the *BRITISH MEDICAL JOURNAL* is 423, Strand, London, W.C.2. The telegraphic address is:

- 1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Antiology*, 423 Strand, London, W.C.2, telephone 2621 (4 lines).
- 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertising, etc.), *Antiology*, 423 Strand, London, W.C.2, telephone, 2620 (4 lines).
- 3. MEDICAL SECRETARY, *Antiology*, 423 Strand, London, W.C.2, telephone, 2624 (4 lines). The address of the *Office of the British Medical Association* is 15, South Frederick Street, Dublin (Telephone, Dublin, 4737, D.). The address of the *Secretariat Office*, 8, Bedford Square, London, W.C.1, telegrams, *Antiology*, London, telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

W. G. bought a new car No. 1 in 1914 for £510 and sold it in 1917 for £250; in February, 1920, he bought another new car (No. 2) for £505. What is the proper allowance for the "cost" of the first car?

As the new car is no better than the original one we consider that our correspondent should be allowed £505 less £250, that is, £255 and not the £510 less £250, that is, £60—the amount put in No. 1 which is the view apparently taken by the Revenue authorities. Logically that view seems to imply

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	—	—	0 7 6
Each additional line	—	—	0 1 3
Whole single column	—	—	6 0 0
Whole page	—	—	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No remittance will be accepted for any such remittance not so satisfied.

All advertisements should be delivered, addressed to the Manager, 429 Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-*restante* letters addressed either in initials or numbers.

THE CORRELATION OF FUNCTION :

WITH SPECIAL REFERENCE TO THE ORGANS
OF INTERNAL SECRETION AND THE
REPRODUCTIVE SYSTEM.

A BRITISH MEDICAL ASSOCIATION LECTURE DELIVERED BEFORE
THE PRESTON DIVISION ON MAY 21ST, 1920.

BY

W. BLAIR BELL, B.S., M.D.LOND.,

GYNAECOLOGICAL SURGEON TO THE ROYAL INFIRMARY AND LECTURER
ON CLINICAL GYNAECOLOGY IN THE UNIVERSITY, LIVERPOOL.

FIFTY years ago specialists were composed of a body of men who had been carried by their scientific bias to limit their practical work, as far as possible, but rarely completely, to medicine, surgery, or midwifery; and I venture to think that men who shot over the rough before attempting to bring down driven partridges and rocketing pheasants made specialists who had a wider outlook and greater power of practical deduction than would have been the case had they been fed on high game from the cradle. Yet, with the tremendous and rapidly accumulating knowledge that came like an avalanche at the end of the Victorian era, and has continued ever since, it became inevitable that, unless the brain of the practitioner of medicine expanded proportionately, some must devote themselves to narrow issues in order to advance knowledge along special lines and to render themselves available for consultation on certain points. But there has been one evil in the tendency to the ultra specialism of to-day—a tendency which I am glad to believe is not likely to go further—and it is that, driven by the force of circumstances, and also no doubt in obedience to the dictates of professional etiquette, men have attached themselves too rigorously to their own little bit of anatomical territory, and have not dared to take into consideration what may be called the Correlation of Function. That an eye is an eye, and a tooth is a tooth, is not the whole truth, though the refinements of specialism have almost made it appear so. An eye functions on behalf of the body; a tooth, likewise, serves and is served by the whole organism.

I hope I have expressed myself clearly; if so, it will be understood how it has come about that some of us have been forced to look beyond the narrow confines of our special region for a solution of our many difficulties, and I do not think I am wrong in advising everybody, whether he be a general practitioner or specialist, to remember that not only the structure but also the function of every part of the body is in close correlation with the rest. I believe, if this truth be held in the forefront, our work becomes more interesting and more capable of improvement, for it must be clear to all general practitioners, with the splendid example of men like Sir James Mackenzie in front of them, that to each a scientific career of discovery lies at hand, especially, as that great physician has said, in regard to beginnings of disease. And this is essentially true in regard to the subject of the ductless glands: the shadow of their influence is over all; every patient you see has her metabolism reflected in her system of ductless glands.

It may be asked how I, a surgeon, came to be specially interested in the organs of internal secretion. May I now justify what I dare say some have considered nothing more than a useful hobby, and at the same time say that all surgeons should be as conversant with physiology as with anatomy?

It is hard to understand the difficulties that others have faced, but I feel sure my own difficulties represent a common picture. Had I been orthodox I should have kept my eyes on the pelvis and not have looked outside for an explanation of the function of menstruation and other difficult problems with which my speciality has so long been burdened. Nevertheless I have often been handicapped, partly for the want of certain knowledge that would bear on the subject, but even more because I have felt that what was still looked upon as a primary process might really be secondary, could we go back to the beginning. It is still a debatable point, for instance, whether in many definite cases of mental disease, such as dementia praecox, the primary lesion is in the brain, or whether it is a lesion in the genitalia or elsewhere that produces the mental disturbance. Who is to decide if it be not the man who sees the early phases of these complicated conditions?

Once we grasp the fact that, as Weismann, Ray Lankester, and others have insisted, the individual exists to perpetuate the species, it is not difficult to realize that the metabolic factors concerned in reproduction are the same as those related to the individual metabolism. In other words, as I have stated elsewhere, the individual metabolism is the reproductive metabolism. It follows, therefore, that the ductless glands which regulate the individual metabolism concern equally the reproductive. So it is that we must seek in the metabolism of the mother—or hostess as we may call her—and in the regulation of her own metabolism, the factors that are most closely concerned in the preparation for and performance of reproduction. Moreover, closely linked to the individual and reproductive processes is the mind of the hostess; its normality is dependent on the integrity of the internal secretory organs and the metabolism; and what obtains physiologically is emphasized pathologically.

The ductless glands are concerned, then, not only in such gross manifestations as disorders of the reproductive system and of the characteristics of sex, but also in the more elusive disorders of the emotions—that is, of the mind. There is a wide field of study for those who see the beginnings of these disturbances, and it will make the study more interesting and more instructive, and certainly more complete, if it be remembered that the beginning of a disorder of an organ of internal secretion is shown in triplicate, as it were—in the mind, in the body, and in the reproductive system, all inseparably linked together.

What, then, do we know of the connexion between the ductless glands and the reproductive system? There is much left for us to discover. Most of our information is based on the results of animal experiments and on pathological investigations; and I propose to relate some of the more important facts obtained in the laboratories, and then indicate how these facts may be turned to use in practice.

WHAT IS A WOMAN, AND WHY IS SHE NOT A MAN?

This is the first point of interest that presents itself in a consideration of the genital functions. We ask ourselves whether the organs of internal secretion have any influence in this respect, and in reaching our present physiological knowledge on the subject we have worked backwards: we have discovered certain facts in regard to pathological conditions, and we now know that what is seen as an abnormality represents a disturbance of normal physiological processes.

Further advances in our knowledge have made it more and more clear that sex differences are pronounced. I dare say a good many of you know that I hold strong views in regard to the functions of woman, and that I look upon any divergence, sociological or otherwise, as abnormal.

I have spoken of the triplication of effects, and in considering the question of the differences between a man and a woman we find that these differences exist in the ductless glands, in the metabolism, and in the mental processes. I do not propose to consider the matter in detail, for I have often done so in other publications; but I will call attention to those remarkable instances in which a woman is or becomes masculine in her secondary characteristics, and males feminine. This is seen in the congenital abnormality known as partial hermaphroditism, and in acquired lesions of the pituitary and suprarenal glands.

Partial hermaphroditism is a very curious and interesting state. I have been fortunate enough to have under my close observation one of the three or four authentic cases of so-called "true hermaphroditism." There is no such thing in the higher animals as true hermaphroditism, although this is seen low down in the scale of evolution. But in the few cases of this type of hermaphroditism, so called, in Man, better known as partial glandular hermaphroditism, we have found what are known as ovotestes—that is to say, the gonads are composed of both ovarian and testicular elements. In my case the patient commenced life as a girl, and menstruated for a year or two regularly. Then menstruation stopped, she grew a moustache and much hair in other parts of the body, and the voice became bass. Removal of the genital organs caused a return to femininity, with slight symptoms of the artificial menopause. The other form of partial hermaphroditism, known as tubular partial hermaphroditism,

is not uncommon. In these cases the gonads are usually testicular in structure, whereas the secondary characteristics are invariably those of the opposite sex, and the external genitals most commonly conform with the secondary characteristics. I have seen a beautiful girl, as was thought, whose gonads were testes.

In passing I must make allusion to the practical side of these conditions. It has usually been taught that, owing to the frequency with which the gonad is testicular, the subject from childhood should be brought up as a boy. With the best will in the world it is impossible to suspect or to know in a majority of these cases the nature of the gonad, unless an operation be performed and part of the genital gland removed. As a result, most partial hermaphrodites reach adult life as girls, and look the part. I have known a case in which a hermaphrodite of this type was married. Legally, that marriage could have been annulled, and I am waiting with interest for the time when one of these abnormal individuals will be entitled, in accordance with the structure of the gonad, to be considered the heir as the eldest son. I am prepared to argue that the structure of the gonad is not necessarily the criterion of sex. I believe it would be better at once to put the question on a proper legal footing. I call your attention to this important matter because any one may come across such a case at any time.

The most outstanding of the acquired lesions producing masculinity in women are hyperplasia or neoplasia of the suprarenal cortex. I can best describe the changes which occur in previously normal women by repeating the description of a French writer: The voice, which was previously soprano, became like that of a lieutenant, and the woman, previously gentle and amenable, became rough and aggressive. Practically all these persons develop excellent beards, and no doubt in the days gone by the bearded woman of the country fair was one who had a lesion in her suprarenal cortex. If further confirmatory pathological evidence were required, we have it in the cases of so-called infant Hercules—boys with suprarenal tumours who are often fully-grown men at the age of five or six; that is to say, excessive masculinity is produced in males suffering with lesions in this and certain other organs. My friend and colleague, Professor Ernest Glynn, has written a classical paper on the pathological aspect of such lesions in the suprarenals.

Again, if a woman have acromegaly, which we believe is the result of hyperplasia or neoplasia in the anterior lobe of the pituitary, she shows well marked masculine traits. Her voice becomes deep, her skin coarse, and her metabolism, especially in regard to the deposition of calcareous salts, closely akin to that of man. In these women there is amenorrhoea, simply and solely because they have become masculine, and not because of the lesion in the pituitary as such; indeed, hyperplasia in the anterior lobe should, if it did not produce masculinity, stimulate activity in the genitalia. It is these facts which give rise to the apparent paradox that destructive lesions, as well as hyperplastic lesions in the anterior lobe of the pituitary, produce amenorrhoea. It is interesting to note that acromegaly in the male is often associated with increased sexuality, whereas destructive lesions in the same region in men produce impotence and a change towards femininity as far as possible in the male—that is to say, the skin becomes soft, hair on the face falls out, and the fingers become fine and tapering.

Another interesting sex-characteristic or distinction in regard to the pituitary is of considerable medico-legal importance, although I do not think it has yet found its way into the textbooks on jurisprudence. It is that once a woman has a child the pituitary becomes and remains larger than normal; indeed the average size of the pituitary of multiparous women is considerably greater than the average size of that of men. Moreover, the staining reactions of the cells of the pars anterior are much altered, so much so that an expert in the histology of the pituitary gland cannot fail to recognise the effect and cause.

The subject of the sex-characteristics and the ductless glands is so extensive, being related not only to the glands mentioned but also to the pineal, the thyroid and to some extent to the gonads, that I fear I cannot discuss it further. I have brought forward these details to show that my bias on the subject of the differences in the two sexes is produced by weight of scientific evidence.

ASSOCIATED DISTURBANCES IN THE DUCTLESS GLANDS AND GENITAL ORGANS.

We come now to the gynaecological disturbances due to the correlations of internal secretions and their disorders.

The Ovaries.

In the first place, what have we learned from experiments on animals regarding the place of the ovary in the system of ductless glands? My deductions lead me to look on the ovary as a connecting link in the chain—a link that is only temporarily employed during the reproductive period; that is to say, the metabolism of boys and girls is probably not greatly different, nor is that of women after the menopause much different from that of men in late life. During the reproductive period, however, a woman is called upon for great metabolic effort in order that she may be able to nourish her child in the womb, and, after parturition, at the breast; consequently, the ovary is concerned in keeping the other organs of internal secretion and the resultant metabolism in touch with the genital system and its needs. In my mind menstruation represents merely the monthly excretion of substances that would be concerned in the building up of a child were the woman pregnant. For this reason a woman usually has amenorrhoea for, at any rate, five months of lactation, and should she nurse for more than nine months her metabolism is apt to be drained if she be menstruating at the same time; she suffers, in other words, with the symptoms of superlactation.

What, then, happens at the menopause? Nature is gentle in her methods, and woman is usually let down, so to speak, by degrees. A majority of women suffer with flushes and other disturbances, many of them due to instability in the vasomotor system.

Experiments on animals have shown that if the ovaries be removed changes are produced in the other ductless glands, especially in the pituitary and thyroid. It appears, therefore, that the menopausal disturbances are due to an upheaval of the internal secretory system. The symptoms usually indicate the line of treatment. Many women after the menopause show an unusual degree of atrophy in the thyroid, coincidental with ovarian atrophy, with the result well known to all; not only are the reproductive organs concerned, but also the ductless gland system, and the mind—the patient becomes depressed and melancholy. The obvious treatment is the administration of thyroid extract. This specific example is interesting, for it shows clearly not only the triplication of effects, but also how these effects are produced by an easily recognizable lesion. It has been shown recently by Mott that in all such cases the cells of the brain and nervous system undergo definite changes.

Before leaving the problems connected with the ovaries, I wish to call attention to a matter that, in this country at any rate, has been strangely neglected: I refer to the transplantation of ovarian tissue, a procedure based on physiological experiments. All who have studied the question in animals have found that if the ovaries be removed and some ovarian tissue transplanted the uterus, a section of which is taken at the time when the ovaries are removed, does not undergo atrophy as is the case when the ovaries are removed and no graft is made. We know, too, that in rodents it is the interstitial cells and not the follicles that are important in respect to the integrity of the uterus. The ovaries of rodents, in contrast with the human ovary, contain much of this interstitial tissue, and this is probably the reason why transplantation is almost invariably successful in the lower animals and not constantly so in women. After an ovarian graft has been made, the uterus is an important indicator, for if this organ remains normal no changes are to be observed in the other organs of internal secretion, such as occur after oophorectomy alone; in other words, an autogenous ovarian graft may be as effective as undisturbed normal ovarian tissue, except, of course, in regard to reproduction. It is, however, important to remember that the best—indeed, the only satisfactory—results are obtained with autogenous grafts, and that a graft taken from one woman's ovary and placed in the muscles of another woman rarely grows. We are only now learning how remarkably individual people are in regard to their blood and other tissues. I have not time to discuss this interesting subject which may account for selective sterility and many other hitherto obscure phenomena.

Unfortunately, as I think, many gynaecologists in this

and in other countries have not much respect for the ovaries in the presence of other pelvic lesions; should they be operating for pyosalpinges, for instance, they invariably remove all the ovarian tissue. I know of a sad case of a young girl who had both ovaries removed for dysmenorrhoea. I can hardly control my words in stating what I think of such an unscientific procedure. This girl has been in an asylum for more than twenty years. No doubt she had a neuropathic tendency. But I doubt if she would ever have broken down if her ovarian tissue had been left alone. There is no reason for removing the whole of the ovarian tissue in any woman, unless the lesion be malignant. In malignant disease the lesser evil is chosen, in view of the fact that we have therapeutical measures which can lessen to some extent the symptoms of the artificial menopause, and probably prevent such a disaster as that of which I have just spoken.

I never leave an ovary in the pelvis if infection be present. I remove all the diseased structures, and, as the ovary can play no further part in reproduction because the tubes have been destroyed so far as their function is concerned, I transplant a piece of healthy, or even infected ovarian tissue, into the muscles of the abdominal wall or some other vascular site. I think I have cause to be satisfied with this procedure, for many of the patients have menstruated, although part of the uterus has been removed in most of the cases; so far as I know at present, no patient has complained of pronounced menopausal symptoms. There may be difficulty in deciding this point. We must not pay attention to agreement with a leading question; but, if the patient volunteers the statement that she is sorely troubled with hot flushes, I would immediately consider that she had menopausal symptoms. Nevertheless, even this is not an absolute indication that the ovarian transplantation has failed. I have in mind at the moment the cases of two private patients, from both of whom I removed double ovarian abscesses with pyosalpinges, and in whom I implanted infected ovarian grafts. Some two or three months subsequently to the operation they complained of discomfort and flushing, yet both of them menstruated shortly afterwards with fair regularity, and the disturbing symptoms ceased. In these cases, as in all in which complaint of such symptoms is made, I administer ovarian and thyroid extracts, which are discontinued when the patient recommences to menstruate.

There are other uses for ovarian transplantation of which I have had satisfactory experiences, but time will not allow of my giving the facts in detail. Transplantation of ovarian tissue is no doubt a complicated surgical problem, and deserves much further consideration. I hope one day to make use of an opportunity such as the present to bring forward a collection of these cases of ovarian transplantation, with which I and those who assist me always endeavour to keep in touch.

I now come to the consideration of primary disorders of the ductless glands which affect the genital functions.

Through the courtesy of many friends I have had an unusual opportunity of seeing a large number of these cases. Generally the patient has complained of amenorrhoea and sterility. It is interesting to speculate as to what happened to all these patients in the days gone by. I notice that in the textbooks of twenty years ago, even in some of those of to-day, obesity, without qualification, occupies a considerable importance in regard to amenorrhoea. I do not say that amenorrhoea and sterility cannot be produced in animals by overfeeding, but, after all, obesity in these circumstances is probably a reflection in the organs of internal secretion of some disturbance in metabolism. It is interesting to note that the two disorders associated with obesity and amenorrhoea, that are seen every day in practice, are connected with the pituitary and thyroid glands. With any considerable insufficiency in these organs the carbohydrate tolerance increases, and the patient becomes obese, as not infrequently happens after the menopause.

I shall now consider these derangements as primary lesions in the ductless gland concerned. I have already considered the other side of the picture.

The Pituitary.

This wonderful little organ, about which so much has been written of recent years, has, as we have

already seen, an important influence on sex-characterization and on the reproductive functions. I wish now to discuss the question of insufficiency of its secretion or secretions, and in so doing I shall first call attention to certain important physiological observations which have helped us greatly in forming clinical conclusions; and in these observations you will recognize at once the difference between scientific deduction and guessing.

In animals and birds periodic variations in pituitary activity are normal, even as we have seen variations are normal in connexion with reproduction in women. As I have said, in such cases it is usual to find adiposity when the pituitary is inactive; I shall mention certain apparent exceptions directly.

It has been shown, and I myself have observed, that during hibernation in animals the pituitary gland undergoes remarkable retrogression, which cannot be mistaken by those conversant with the normal active organ. In the hedgehog, which I have studied, there is a remarkable deposition of fat throughout the tissues of the body, most evident perhaps in the subcutaneous tissues. In such circumstances this small animal has a coat of fat as much as one and a half inches in thickness. No doubt this protects the creature from the winter cold and provides nutriment. Associated with this, as I have said, is atrophy of the pituitary.

Fat deposition and somnolence, so well seen in the hibernating animals, are the chief characteristics of acquired insufficiency in the pituitary. It has been suggested, and is indeed probable, that the other organs of internal secretion also undergo some retrogression in hibernation. I have found, too, that the pituitary of the broody hen shows similar changes, but in this case fat does not appear usually to be deposited, perhaps because food is still to be obtained.

Now what is normal in animals may be pathological in Man. I shall not refer here to the wonderful clinical results which have been obtained with the extract of the posterior lobe of the pituitary. They are well known; the subject is one in which I have been specially interested, and it is summarized in my book on the pituitary.

Experiments on animals, apart from the histological investigations to which reference has just been made, have afforded information of the highest importance in regard to the interpretation to be placed on corresponding clinical signs and symptoms. Unfortunately, but few successful series of cases have been published in which operations on the pituitaries of animals have been performed. To Paulesco belongs the credit of being the pioneer in this matter, although he was by no means the first to attempt such experiments. I shall briefly summarize the results of lesions experimentally produced on the pituitary, which are now accepted as being correct; and I may say the conclusions formed from the experiments of Paulesco, Cushing, and myself differ in only one or two important respects.

It is known that extirpation of the whole pituitary is inconsistent with life. The removal of large portions of the pars anterior may lead to the death of the animal, but if it does not do so, intense genital atrophy ensues, and in young animals general stunting. Cushing and Paulesco also observed obesity in these circumstances, but, on the other hand, I did not observe this result of carbohydrate tolerance. Removal of the posterior lobe causes no symptoms. There is a divergence of opinion concerning the results of compression of the stalk of the pituitary: Paulesco considered this to be a fatal operation; Cushing believed it produced effects similar to those following removal of the whole pituitary with immediate transplantation.

In my experiments the operation of compression of the stalk, whereby the blood supply to the pituitary is cut off, was found to lead to the syndrome of dystrophia adiposogenitalis—somnolence, obesity, and total atrophy of the genitalia—an exact counterpart of the disease in Man. I may add that Cushing has privately conceded the correctness of my experiments and deductions, as opposed to his own and those of Paulesco. Cushing is only concerned with the truth, and his work on the various aspects of the pituitary activity is an imperishable monument to his genius.

I have conducted a few experiments whereby an artificial tumour was introduced into the cranial cavity in the neighbourhood of the pituitary. When there was pressure on the stalk symptoms of dystrophia adiposogenitalis were

produced; when irritation from the proximity of the tumour was caused there was glycosuria and emaciation.

We occasionally see in Man congenital insufficiency of the pituitary, in which there is genital inactivity, often associated with poor somatic development. I have seen several cases of this sort. When there is general somatic underdevelopment, that in the pituitary may simply be part of universal insufficiency; but in other cases the patient may be finely developed, yet have inactive functions. I remember an interesting example of this. The patient was about 18 years of age and had not menstruated. She was beautifully developed, but had an infantile uterus. A radiograph showed the sella turcica to be one-third of the normal average size. She was fed on pituitary extract for a long time, and at the age of 22 years, sometime after discontinuing treatment, she commenced to menstruate regularly and freely.

In acquired lesions of the pituitary there is usually enlargement of the sella turcica, and I have mentioned radiography of this region. This is valuable when carried out by a skilled radiographer, and I am indebted to my colleague, Mr. Thurstan Holland, for the trouble he has so often taken and the skill with which he has helped me in many difficult cases. It must not be forgotten that hemianopia, which may go on to complete blindness, occurs with enlargements of the pituitary fossa, and headache may be persistent and severe. But it will be remembered that pressure on the stalk can be experimentally produced, and that this lesion causes dystrophia adiposogenitalis. It is interesting, therefore, to note that in Man all the symptoms of dystrophia adiposogenitalis, without expansion of the sella turcica, may be caused by a suprasellar tumour. In such cases a definite diagnosis can be made by the symptoms and the absence of enlargement of the sella turcica on radiographic examination.

There are other methods of investigation which may help. I have spoken of carbohydrate tolerance, by which is meant the power to retain carbohydrates and deposit fat in the tissues instead of the ability to excrete carbohydrates in excess of the usual limit. The normal person is able to take about 110 grams of dextrose without the appearance of glycosuria. The power to retain more than about 150 grams may be considered pathological. The carbohydrate tolerance, then, of a patient may be measured, and it will be found to be raised in cases of pituitary insufficiency. I have known a patient swallow—with difficulty be it admitted—500 grams of sugar without subsequently passing sugar in the urine.

Then, again, we have what is known as the "thermic reaction." All cases of severe pituitary insufficiency show a subnormal temperature, which may be raised by the intramuscular injection of an extract of the anterior lobe. I cannot affirm, however, that this reaction is always striking. Moreover, the blood pressure is often very low, but can be raised with an extract of the posterior lobe—that is, by infundibulin injected intramuscularly. But, of course, this alone is not a specific test, as infundibulin administered intramuscularly will always raise a reduced blood pressure.

With regard to serious lesions of the pituitary and their effects on the genitalia, treatment is not always satisfactory. If there be a cyst in the pars anterior it may be safely evacuated, and the patient may recover completely. In other cases, feeding with whole-gland pituitary extract may give good results, especially if associated with operation.

Our knowledge of the minor disorders of the pituitary is less definite, because the conditions do not lend themselves so well to experimentation as do the grosser lesions. We have, however, the important facts of the physiological states of hibernation in animals and brooding in birds to help us, for we see in them a temporary phase of insufficiency, and we are led to realize that similar conditions may be found in Man. I have already mentioned that the opposite state—that of hyperplasia—occurs in women during gestation. Furthermore, experiment has shown that changes occur in the pituitary as the result of inoculations with bacteria. I would call special attention to this point in regard to the pituitary, without considering the coincidental changes that are seen in the suprarenals and elsewhere in the ductless gland system, for I feel sure many of the minor insufficiencies seen in practice may be the immediate sequel of bacterial infections. The lesions may be slight and curable. It is not always possible,

however, to get a definite history, but "a cold" is frequently mentioned as the starting point of secondary amenorrhoea.

When the fact that the organ chiefly at fault is the pituitary can be established, then treatment is, I believe, fairly satisfactory. I have seen patients in whom regular menstruation has been induced by pituitary feeding.

The Thyroid.

As intimate as the relation of the pituitary to the genital functions is the association between the thyroid gland and the genitalia. Here again we are to a great extent indebted to experimental research, but no less to pathological investigations; moreover, clinical observers have had a good chance to advance our knowledge of the thyroid, for this organ is accessible to ordinary physical examination.

A matter of considerable interest has come to light as the result of experimental extirpation of the thyroid; in rodents, such as the rabbit, removal of this gland is not only compatible with continued existence, but appears hardly to disturb the animal. Three reasons may be suggested for this comparative immunity to the effect of thyroidectomy, as opposed to the disastrous effects of the same operation in carnivora. First, it is known that a meat diet makes a greater call than a purely herbivorous on the activity of the thyroid. Second, in herbivorous animals the parathyroids usually escape removal with the thyroid itself, whereas in carnivorous animals it is not always possible to conserve all the parathyroids, which are closely adherent to the thyroid. Third, the thyroid is not so active in herbivorous animals as in carnivorous animals, perhaps primarily because of the diet, but also because the ovarian interstitial tissue in these mammals is more in evidence than in the carnivores.

Man being omnivorous should come half way between the two orders in regard to thyroid activity, if it were purely a question of diet; but I do not think it is. In Man we have seen there is little interstitial ovarian tissue, which, from a genital point of view, means a very active thyroid. Extirpation of the thyroid in animals is followed by a considerable degree of atrophy of the uterus, but strangely enough ovarian retrogression is not seen.

As with the removal of the ovaries and also with partial removal of the pituitary, thyroidectomy is followed by definite changes in the other ductless glands, and these changes are particularly noticeable in the pituitary, which undergoes hyperplasia in all parts.

It is a too common observation in the experience of every one for me to do more than recall the curious enlargement often seen in girls during menstruation; but I believe that it is important to bear in mind that this enlargement may exist in two forms. It is either a primary lesion in the thyroid which persists between the monthly periods, in which case menstruation is profuse; or it may be due to a temporary state of hyperplasia, when the ovaries are not very active and supplementary action is required to establish menstruation. In the last-named circumstances menstruation is usually scanty and painful.

The treatment, of course, is obvious; in the first type of case attempts must be made to reduce thyroid activity, if symptoms are sufficient to warrant interference, because I believe exophthalmic goitre may supervene. Radiations of x-rays carefully managed appear to be a valuable method of treatment. I have also found intramuscular injections of infundibulin and the administration of calcium salts efficient in many cases. In the second type there is an attempt, as I have said, on the part of the thyroid to supplement ovarian insufficiency; consequently, we must treat the case by the administration of thyroid and ovarian extracts. I believe ovarian extract alone is useless, and this, I think, is the general experience of most clinicians; but I have seen excellent results when whole ovary extract is given in conjunction with thyroid extract. We must remember that in the blood stream the internal secretions meet and activate, or inhibit.

In myxoedema the most wonderful results are obtained with the administration of thyroid extract. A melancholic, obese, non-menstruating sterile woman, becomes happy, is reduced in weight, menstruates and may even conceive. An illustration again of the triplication of effects. But it is, after all, the minor degrees of insufficiency in organs of internal secretion that escape notice while they are still easy to treat, and I beg you to

be on the look-out for the protean signs and symptoms that are discernible very early.

I have not time to deal with insufficiencies of the other ductless glands; nor have I time to mention some of these glands at all. You will find in my book, *The Sex Complex*, especially in the new edition about to be issued, a more complete picture. I shall be amply satisfied if I have been lucid in this hasty sketch with which I have sought to attract your attention to the triplication of effects—in the mind, in the soma, and in the reproductive organs—which forms such striking evidence of what I have called the Correlation of Function.

THE COMMONER COMPLICATIONS OF BACILLARY DYSENTERY IN MILITARY PRACTICE.

BY

PHILIP MANSON-BAHR, D.S.O., M.D., M.R.C.P.,

ASSISTANT PHYSICIAN, HOSPITAL FOR TROPICAL DISEASES, ENDSLEIGH GARDENS, AND ALBERT DOCK HOSPITAL; LECTURER, LONDON SCHOOL OF TROPICAL MEDICINE.

THE complications of bacillary dysentery have received scant attention from medical writers in the past, but since the recent campaigns in the East many symptoms, apparently due to the absorption of the toxins of the *Bacillus dysenteriae*, have occurred with considerable frequency in military practice.

Arthritis in Bacillary Dysentery.

Of these complications, monoarthritis, or more generally polyarthritis, have been frequently noted during the Egyptian and Palestine campaigns.

That such an arthritis may supervene during the course of a bacillary dysentery, even of a mild type and untreated by any specific serum, and that the joint disintegration so produced may persist for a long time—even a year or more—and may result in permanent disability, has long been recognized, though in many epidemics in India and elsewhere such occurrences have been rare. Davidson,¹ who wrote mainly from Indian experiences, remarked upon the tolerable frequency of arthritis in dysentery unaccompanied by any involvement of the endocardium. This, he noted, may be ushered in by pyrexia, either during the acute stage of the disease, or when, apparently, the bowel condition has once more become normal. In the Döberitz epidemic in Germany, in 1900, arthritis supervened in 3.75 per cent. of all cases, and the condition persisted from four days to four months. It is significant that, writing in 1913, Sir Leonard Rogers² mentions only a single case of arthritis of an obstinate character as having occurred to his knowledge during the course of such an epidemic in India.

In a bacillary epidemic of a more virulent character, which visited the Fiji Islands in 1897, I was informed by Daniels that fully 10 per cent. of the patients developed arthritis, whilst in 1910, during a study of 300 cases in the same colony, I did not see a single one.

During the war on the eastern European front 7 cases of arthritis out of a series of 600 have been reported. A streptococcus is said to have been isolated from the blood of one case, and the joint symptoms were regarded therefore as a result of streptococcal septicaemia secondary to the bacillary infection.

Arthritis occurring in the course of amoebic dysentery appears to be very rare. I have only been able to find a record of one case.

During the first nine months of 1916 a number of cases of arthritis occurred amongst patients suffering from bacillary dysentery in Egypt. The bacillus responsible was the Shiga bacillus in all cases which could be properly investigated, and it is noteworthy that no cases of arthritis were observed at the same time in Flexner-Y infections. Though the latter bacillus was commonly met with amongst the numerous cases of bacillary dysentery in Turks at the Prisoners of War Hospital, Heliopolis, Cairo, yet no instances of joint involvement were noted amongst these patients.

Arthritis in Cases Untreated by Serum.

The majority of the cases of arthritis encountered during the course of bacillary dysentery have been those previously injected with antidysenteric serum, though

arthritis was observed twice in cases untreated by serum of any kind.

In one such case the right knee alone was affected, and there was a large effusion into the subcutaneous pouch, which was very gradually absorbed. In the other cases all joints were affected, including the temporo-maxillary and the interphalangeal; there was also a uniform swelling of the right parotid gland. Arthritic symptoms in both instances supervened during convalescence from dysentery and while the stools were completely faeculent.

Arthritis occurring Subsequent to the Administration of Antidysenteric Serum.

According to my personal observation, arthritis occurring in a patient subsequent to the administration of antidysenteric serum, either by the subcutaneous or the intravenous route, can be classified under two headings:

(a) Fugitive polyarthritis, with or without joint effusions, occurring during the course of "serum sickness."

(b) Intractable polyarthritis, with effusion into joints and wasting of adjoining muscles, apparently due to absorption of dysenteric toxins.

(a) *The Fugitive Form.*—Eleven out of 29 acute cases of bacillary dysentery injected intravenously with doses of from 30 to 40 c.cm. of antidysenteric serum developed a fugitive polyarthritis seven to twelve days after the injection; that is to say, the arthritis was ushered in with pyrexia, urticaria, general malaise, and hyperaesthesia of the muscles. This condition lasted as a general rule for two to three days and then cleared up, and might possibly be ascribed to the elimination of foreign proteins originally contained in the serum injected.

(b) *The Intractable Form.*—Eight out of 29 cases (or 27 per cent.) developed joint symptoms, often of a very intractable nature, with intra-articular effusions. This came on generally from the sixth to the tenth day after injection of serum. This is a much higher percentage of incidence of arthritis than in the series from France and Mesopotamia recently described by Klein³ and Waller⁴; the latter reported 12.4 per cent. of arthritis as occurring in his cases treated by serum.

The effusions in my cases took place with surprising rapidity, accompanied by acute pain and a rise of temperature to 102° to 103° F., especially when the knee-joint was involved. The one death in this series was preceded by profuse watery diarrhoea with a septic pyrexia ending finally in collapse.

In the knee-joint the effusion took place into the subcutaneous pouch and, in less than twenty-four hours from the commencement, the joint cavities were distended to their utmost capacity and the superjacent skin was stretched and shiny. There were no signs of local inflammation such as hyperaemia of the adjacent tissues. In the interphalangeal joints the swelling occurred into the tissues immediately surrounding the articulations, thus giving the spindle-shaped appearance of rheumatoid arthritis.

In one case large sterile effusions took place into the substance of the gluteus maximus and latissimus dorsi muscles, and subsided very slowly so that the patient was incapacitated for six months. The stage of the disease at which the arthritis supervenes is of importance; in all the cases I observed, the arthritic symptoms commenced at a time when the intestinal condition had considerably improved—even, in some cases, when the stools had been apparently normal for a week or more. The effusion was straw-coloured and slightly viscid, sterile on culture and containing a considerable number of polymorph cells. According to Klein this fluid agglutinates the specific bacilli in high dilutions.

In all cases observed, and especially in several cases not included in the series quoted above, intermittent pyrexia persisted as long as the joint symptoms were in evidence. Another characteristic seems to be that the pain, or, in some cases, a sense of stiffness, appears to be more marked at night time or in the early mornings.

As bearing on the etiology it is important to note that in two cases previous arthritis of rheumatic or traumatic origin had occurred a year or more before the onset of dysentery; it therefore seems probable that previous joint injury may exert a very definite predisposing influence on the supervention of joint symptoms in a subject subsequently attacked by a bacillary dysentery.

The question now arises whether the brand of the serum employed played any active part in the causation of this particularly intractable form of polyarthritis. I think there can be no question that polyarthritis may occur during the course of bacillary dysentery, quite independently of any serum treatment, but may it not be that some substance in the brand of antidysenteric serum employed, such as a large proportion of toxic proteins, can exert a deciding influence on the production of joint effusions? There would appear to be, from the figures at my disposal, some grounds for such a supposition; for amongst my series of cases a polyarthritis occurred in 8 out of 29 injected with a certain brand of serum (that is, 27 per cent.), whereas in 335 convalescent and slight bacillary cases admitted to hospital during the same period, and who were not treated with serum of any kind, only one case of arthritis occurred.

In addition to this evidence, through the kindness of Lieut.-Colonel C. J. Martin, C.M.G., D.S.O., F.R.S., I have been able to obtain his statistics from an Australian General Hospital for comparison with my figures. The Australian statistics show the remarkable fact that 358 cases, from nearly all of whose stools the specific bacillus was isolated, were treated with large intravenous injections (100 c.cm. or more) of Lister Institute antidysenteric serum with apparently favourable results, and without the super-vention of a single case of arthritis. Similarly, in 1910 I gave over one hundred consecutive intravenous injections of Lister Institute antidysenteric serum without the supervention of a single complication of this nature.

Infrequent Complications.

Iridocyclitis and *parotitis*, which have recently been noted.

The *iridocyclitis* occurred in two cases six weeks after the initial dysenteric attack; one patient suffered from arthritic symptoms, whilst the other did not.

Parotitis was observed in three cases presenting no obvious signs of oral sepsis. In one there was a unilateral and in the other two a uniform bilateral swelling of the parotid gland which appeared suddenly and disappeared almost as suddenly. In both cases the swelling of the parotid coincided with the development of the concomitant arthritis.

SUMMARY.

It is reasonable to suppose that there exists an idiopathic dysenteric arthritis due to the absorption of specific dysenteric toxins from the bowel wall and their excretion (as is known to be the case during the absorption of toxins of septic and gonorrhoeal origin) into the joint cavities.

In the same manner the arthritic symptoms occurring during the course of serum sickness may be justly regarded as representing an effort on the part of the organism to rid itself of toxins peculiar to horse serum; and it is possible that a particularly high percentage of these toxins, even when introduced in moderate doses into a subject already suffering from dysentery in which *per se* arthritis is not an infrequent complication, may not only determine the onset of the condition, but also the amount of disintegration of the joint thus produced.

INSTINCT AND HYSTERIA.

BY

V. T. CARRUTHERS, M.B., F.R.C.S. EDIN.,
MAJOR R.A.M.C.

THE springs of conduct are obscure and not to be discovered at a glance, but it seems likely that our actions can be traced back to a basis of psycho-physical dispositions, more or less modified by outside influences and by interaction between such dispositions themselves. The innate dispositions, when considered in their simplest manifestations, are known as the primary instincts. On analysis an instinct is found to consist of three elements--the cognitive or afferent, the affective or central, and the conative or efferent. McDougall describes a number of primary instincts, to each of which he assigns a primary emotion, which is the affective element of the instinct.

He describes others in which the emotion, though doubtless present, has no name. From his list we select the following as having a bearing on our subject:

- (a) The instinct of flight and the emotion of fear.
- (b) The instinct of curiosity and the emotion of wonder.
- (c) The instinct of pugnacity and the emotion of anger.
- (d) The instincts of self-abasement or subjection, and self-assertion or display; of which the affective sides are the emotions of subjection and elation, or negative and positive self-feeling.
- (e) The parental instinct and the tender emotion.
- (f) The sex instinct.

When we watch the play of instincts we notice that their conative activity is directed to the attainment of pleasure, the elimination of painful feeling, and to the good of the individual or species; in other words, that the conation arising in the activity of an instinct is of a teleological or purposive nature. But this is not the same as to say that it is a conscious endeavour towards a foreseen end; for example, the salmon, surmounting the waterfall by a supreme effort, has not directly in view the good of its progeny. And many a man who all his life has held strong political views, imagining them to be founded on the dictates of pure reason, would be offended if it could be shown that his opinions are founded (as is often the case) on his instinct of pugnacity and the emotion of anger against those who hold opposite views. The action of running away under the impulse of fear might seem to be a consciously directed endeavour; but the other motor activities, such as rapidity of the heart's action and respiration, are equally part of the flight instinct, and are obviously not consciously directed.

Instinctive behaviour is sometimes extremely simple, at other times complicated to a high degree. The simpler forms are commonest among the lower animals, and the highest complications are found in man. As an example, the instinct of pugnacity when aroused may result in an attempt to hurt an opponent by a blow, or in the complex and long-lasting efforts involved in a lawsuit. An observer who was unacquainted with civilized man might find some difficulty in classifying under the same heading the conduct of the cock that flies at his enemy's head at sight, and that of the prosecutor in a lawsuit sitting for weeks in a court listening to speeches, conferring with counsel, and taking notes. A savage, also, whose notion of the sex instinct was limited to the sexual act, would be puzzled to account for the civilized young man writing verses "To Chloe, on fusing her fan." But though man shows the highest degrees of complicated instinctive behaviour, in animals also the conative aspect of an instinct may be exceedingly complex. This is seen in the case of bees, spiders, birds, etc., in whom the parental instinct is greatly modified and complicated. Differences between the modifications of the instinctive behaviour of animals and man lie in the fact that the complicated conative disposition of animals is the same in different individuals and is transmitted unchanged to their descendants; whereas no two men act exactly in the same way under the influence of fear, anger, wonder, elation, and the rest, and complications are not transmitted as such. Though we can observe instinctive behaviour modified and complicated almost out of all recognition in both man and animals, the factors producing these modifications are somewhat obscure. That the intelligence may play a large part in the case of man is seen in such an instinct as curiosity, which is the mainspring of scientific research; but how birds were moved to build nests by the parental instinct, or how certain species of rats, moved by their flight instinct, adopted an aquatic life, and why these complications of originally simple conations were transmitted to their offspring, we do not know.

In the study of the etiology of certain functional disorders it has seemed that some advantage might be derived from considering the primary instincts. As is well known, mutism, paraplegias, parasthesias, blindness, deafness, amnesia, etc., are common during the strain of battle. All these are disorders which incapacitate a man from service and cause his removal from a dangerous area to hospital and safety; in this way they serve the instinct of flight, which, like other instincts, is teleological or purposive in its conative aspects. It is surely not more remarkable that the flight instinct should make a man paraplegic than that the parental instinct should cause a bird to build a nest; or that the sex instinct should lead

Orlando to pin verses on to trees. At the first glance all these activities seem equally remote from the primitive, efferent function of the instinct; but they have in common the one fact that they advance the purpose of the instinct. This does not necessarily imply conscious endeavour to a foreseen end. When such endeavour is present we may (apart from malingering) get the phenomenon of the self-inflicted wound, which is an example of the intelligence usurping the entire conative functions of the instinct of flight.

This parallelism of the activities of the reasoned and uncensored conations, producing in each case the same result (namely, illness), is a point that seems interesting to note, and can be matched in the play of other instincts besides that of flight.

In the study of the most common functional or "hysterical" troubles outside military life the instincts of self-abasement and self-assertion should be recalled.

Self-abasement, with its emotion of negative self-feeling or subjection, is evoked by failure in the primitive human occupations—war, love, reproduction—and by pain and fear. Its conative activity consists in crouching, cringing, or slinking attitudes of body, or (in the civilized) of mind. Its object seems to be the propitiation of a superior power or the eliciting of sympathy or pity; it is well seen in the whipped dog. An interesting human example was seen by the writer in the case of a Tamil soldier who, being accidentally shot on the range by a soldier, fell on his knees and salaamed repeatedly to the man who had shot him. One does not often witness the bodily exhibition of the instinct among civilized people, though the mental equivalent is very common. If the instinct of self-abasement is successful in gaining the sympathy or consideration which is its object, it is liable to change in a curious way into the instinct of self-display. If the cringing dog is given a few words of encouragement it immediately starts exaggerated gambols and friskiness, and becomes animated by impulses directly opposed to those that at first kept it cringing and shivering at its master's feet. The case of over-scrivile persons will readily occur to the mind as an instance of the same thing in the mental sphere. The instinct of self-display or self-assertion is chiefly evoked by success in the primary human activities, such as war and sport, love and reproduction. Its affective side, positive self-feeling or elation, is pleasurable; but its conative side, which consists simply in conduct known to boys as "showing off," does not seem to be of any great service to the individual or species. The point that should be noticed in both the instinct of self-display and self-abasement is the frequency with which they operate in close association with the sex instinct. This perhaps explains the original purpose of self-display.

Returning to the etiology of "hysterical" manifestations, we find that the symptoms (aphonia, monoplegia, analgesia, or what not) are commonly found to follow an incident such as an unfortunate love affair, the discovery of a disease of the reproductive system, or a terrifying and painful occurrence. Here we have those factors which evoke the instinct of self-abasement—failure in love or reproduction, fear and pain. The goal of the instinct is to elicit pity, sympathy, or attention from other people. In modern civilized life the best way to do this is to be ill; for the primitive conative activities of crouching, wailing, rending of garments, putting dust on the head, etc., no longer impress the public as of old, and may even excite ridicule. Accordingly the patient exhibits symptoms that often go with organic disease, and can sometimes hardly be distinguished from the latter even by an expert. That such phenomena can be seen apart from any voluntary origin, is shown by the fact that the symptoms are very often of a kind that are not under voluntary control at all, such as excessive borborygmi, local vasomotor disturbances, spasm of the oesophagus, and the other visceral manifestations of hysteria. These activities of the instinct of self-abasement are often seen to awaken (when successful) the instinct of self-display and the manifestations of positive self-feeling, in the manner alluded to above in the case of the dog. In other words, the patient, from being humbly miserable, comes, under the influence of wondering and sympathetic friends, and perhaps of the zealous physician, to take a pride in her symptoms and to derive undoubted gratification

from showing them off and developing new ones. Hence the value of isolation treatment.

As, when surveying the involuntary disorders arising under the instinct of flight, we saw in self-inflicted wounds a parallel phenomenon guided by the intelligence, so in the "hysterical" class we observe conditions such as dermatitis artefacta, apparent fasting, alleged anuria, etc., which are all instigated by purposive intelligent conation.

The scope of suggestion in the production of functional troubles has not, so far, been mentioned. Some authorities, notably Babinski, attach extreme importance to it. There is no doubt that it often determines the type of symptom that arises. For instance, a slight injury to a limb may be followed by a monoplegia. A difficulty in swallowing during painful emotion, especially when accompanied by weeping, may initiate the globus hystericus. But it is here suggested that as imitation and suggestion play such a very large part in the causation of normal conduct, we should admit that they may have the same part in producing hysterical behaviour, without being the original causes of it.

In conclusion, how does the theory put forward in the preceding observations agree with the Freudian hypothesis? The school of Freud appears to explain morbid functional disturbances by supposing that the natural conative activity of an instinct (always the sexual) is liable to repression by the censorship of the moral nature or of education. The normal conation being thus in abeyance, the energy of the affect is transferred to an abnormal conative disposition, and functional disease follows. In this connexion it is interesting to turn again to the animal world. There we find beetles which, instead of running away when frightened, slam death; and birds which, under the influence of the parental instinct, develop a functional paralysis of a wing. What in these cases is the censor that represses the normal conative activity of the instincts, and what determines the exceedingly useful conative disposition that shall become linked to the affect; and could such repression of the conation and transfer of affective energy be transmitted to offspring as intact dispositions? The difficulty of answering these questions has led to the hypothesis advanced in these notes.

Summary.

1. Men and animals alike are swayed by a purposive impulse in their fundamental activities, and this impulse, or teleological striving, can be studied in the conative aspect of the instincts. In many animals instinctive behaviour consists in quite simple reactions, but we also find animals, especially insects, in which the behaviour is extremely complicated. We do not know in the least how this complexity of animal behaviour is produced, but there is reason to believe it is due to something different from human intelligence.

2. In man the complexity of his instinctive behaviour is due partly to intelligence and partly to the same cause that modifies the primitive responses of the animal.

3. It is here suggested that certain functional diseases often represent the modified conative activity of primary instincts—especially of flight, self-abasement and self-display; and that "hysteria" is an example in man of the complications which conations, originally simple, are known to undergo in animals.

THE USE OF X RAYS AS IMMUNITY-RAISING AGENTS BEFORE AND AFTER OPERATION FOR CANCER.

BY
FRANCIS HERNAMAN-JOHNSON, M.D.,

RADIOLOGIST TO THE FRENCH HOSPITAL; PHYSICIAN TO THE X-RAY DEPARTMENT, THE MARGARET STREET HOSPITAL FOR CONSUMPTION.

POST-OPERATIVE x-ray treatment in breast cancer is generally regarded as right and proper, but it appears necessary to emphasize the fact that before operation a peculiarly favourable opportunity is presented for treatment by radiation. The knife may be a means of disseminating stray cancer cells, but if, before the possibility of such dissemination occurs, we can bring about either (1) the

weakening of the malignant cells or (2) an increase in the resistance of the body tissues as a whole—or, better still, both of these desirable results—then the chance of successful colony formation by the parent growth will be much reduced. There is very good reason to believe that these favourable pre-operative conditions may be established by means of suitable x-ray preparation.

It has been shown experimentally that mouse cancer which has been exposed to radium or x rays is grafted with difficulty, or not at all, into fresh tracts, and that an animal which has been suitably irradiated is resistant to cancer grafts. There is also some clinical evidence which suggests that x rays have a helpful action in cancer, no matter to what part of the body they are applied. Such action can scarcely be exercised otherwise than through the blood. Morley Roberts would have us believe that cancer is the result of abnormal growth due to disturbed hormone balance; which disturbance is reflected in the composition of the blood. Certainly we know, on the one hand, that a few cases of cancer of the breast appear to have cleared up under thyroid administration; also that x rays powerfully affect the ductless glands, and have an influence on the cellular elements of the blood, and possibly on its plasma.

Such speculations, however, carry us beyond the intended scope of this article. The important point is that x rays act as much by their stimulating or regulating action upon the body, locally or generally, as by direct depression of cancer cells. Radiation undoubtedly has a deleterious effect upon embryonic cells, and in so far as cancer cells approach this type they are injured by it before normal cells. To this extent the action is "specific" in the same sense as quinine is a "specific" against the malaria parasite—that is, the parasite is injured by doses which have little or no effect on the cells of the body. So with mercury and salvarsan in syphilis.

But, apart from the treatment of rodent ulcer, which does not tend to metastasize, the general stimulating and regulating action of x rays is of more value than its "specific" local effect upon pseudo-embryonic cells. We may speak of the process in general terms as "raising the resistance" to cancer. That the general resistance can be so raised has been conclusively proved so far as mouse cancer is concerned. W. S. Bainbridge¹ quotes Murphy and Norton, of the Rockefeller Institute, as follows:

They found that the chief characteristic of a failing heteroplastic graft in the unsuitable host is a marked local accumulation of lymphocytes. The histological position was found to be identical with that noticed in a failing cancer graft in an immune animal of the same species. Synchronous with the establishment of the cancer immunity, and during the period in which the lymphocytes are accumulating round the cancer graft, there is a lymphocytic crisis in the circulating blood, this being observed in actively immunized animals as well as those possessing a natural immunity, but being totally absent in animals susceptible to the cancer graft. If this lymphocytic crisis be prevented in immune animals by previous destruction of the lymphoid elements by the x ray, the potentially immune animal is changed to a susceptible one. Leaving out of consideration the complicated question of the direct effect of x ray on cancer they studied this artificial method of producing a lymphocytosis in relation to the resistance of mice to their own spontaneous tumours.

In order to do this they removed the cancer, and then subjected the animal to a stimulating dose of the x rays. A graft of the original tumour was then immediately replaced in the groin of the animal. The same procedure, with the omission of the x rays, was carried out in control animals. In others, as a further check to the experiments, the cancers were removed and exposed directly to the same amount of x ray that the animals of the first group had received, a graft of the tumour being then returned to its original host. An x-ray dose they found which produced a lymphocytosis when administered direct to the animal, was sufficient to render 50 per cent. of the mice so treated immune to a return graft of their own tumour; and, in the other 50 per cent., greatly to retard the return of the disease. A similar dose given to the cancer direct outside the body did not influence the subsequent growth of a graft of this tumour when returned to its original host.

These observers considered that, if this pronounced result could be obtained with one stimulating dose, it is probable that a more pronounced effect might be obtained by a second exposure to x ray after a suitable interval.

In man the immunity produced by x rays is not, however, specific, as the same treatment will cause great improvement in the subjects of tuberculosis, or, for that matter, of various other sorts of microbial infection.

A consideration of these facts should lead to clear ideas of what may be and what ought not to be expected from

x rays in cancer. In so far as their effect is a direct one upon a localized growth, they are an alternative to other local procedures, and each case must be judged upon its merits. Rodent ulcer practically always, and sarcoma sometimes, should be treated by radiation. The case as between x rays and radium must be decided by their local results, and these in turn must be judged against those of surgery, diathermy, etc.

But when we come to final issues we have the question of raising immunity—in other words, it is only in so far as we can aid the body to resist fresh invasions that we prolong life. The immunity produced by x rays is partial and non-specific, and it has yet to be proved that that induced by radium is any different in quality or quantity. Where a wide distribution of radiation is desirable, as in the treatment of breast cancer, the practical advantages of x rays over radium are generally admitted, even by those who believe that the latter would be preferable, were it to be had in abundance.

The local superiority of radium in cancer of the lip and of mucous membranes in general is undoubted, but unless the general increased resistance is of a different type from that produced by x rays, hopes based upon the employment of radium in large quantities would appear unlikely to be fulfilled. At the present moment we possess x-ray apparatus capable of giving a practically unlimited output of rays, but no great advantage accrues, as it is easy to push the dosage to a point at which the general resistance is actually lowered.

Even quite recently I have seen questions in the medical press as to the desirability of using an agent in the treatment of cancer which can actually induce the disease. The best answer to this is to be found in a consideration of such a drug as arsenic. Arsenic is of the utmost value as a tonic, and in certain diseases of the blood, the nervous system, and the skin, yet excessive or too prolonged dosage involves a risk of neuritis or dermatitis, or both. In x-ray therapy it is important not to exhaust the response of the system. "Staleness" to x rays may ensue even before the danger point is reached. Therefore, in my opinion, a single course should not exceed two months in length, nor should another be given until an equal interval of time has elapsed.

But although clinical experience teaches that a favourable response continues to be elicited by x rays for many weeks, this does not mean that the full period should be used in pre-operative raying. We must ask: What is the minimum time in which an appreciable effect can be produced in a breast cancer? My experience in this matter is derived from (1) cases of recurrence in the other breast, after operation; (2) tumours in old people when operation is refused or not indicated; (3) a few rare instances when cancer coincides with some condition such as cardiac trouble, where the risk to life of surgical measures is too great. I have no hesitation in saying that a definite effect can be produced in less than three weeks.

By this I mean that the lump is visibly smaller, and pain, if present, relieved. This result is accomplished by six to eight sittings spaced at intervals of two to three days. The doses are comparatively small, and no visible skin reaction is produced. The effect, in the writer's opinion, is rather of resistance-raising than of direct injury to the growth. This makes it all the more valuable, as we desire to render the body in so far as possible generally immune, so that the settlement of any cancer cells freed by the knife may be opposed, no matter where they may be carried by the blood stream. Also, no matter what the cause may be of the shrinkage of the tumour, there can be little doubt that its component cells will be less able to establish themselves in new surroundings than they were before this shrinkage began.

The fact that a case has received pre-operative treatment does not in any way modify the obligation to give post-operative irradiation. But this may be safely delayed for a month—that is, until the patient is about again.

What can be said against the procedure advocated? The visible good effects of x rays upon cancerous growths where operation is contraindicated are beyond doubt. There is no evidence that pre-operative raying in any way interferes with the healing of the wound. The sole argument against the procedure must therefore be that it delays operation for two to three weeks. But this argument, to be valid, implies a belief that the cancer, although improving to the eye—which cannot be denied—is never-

theless spreading in the depth. While this might be so with improper technique, as by limiting the rays to the tumour itself, it cannot happen during the "stage of response" provided that a wide cone of rays is used, so that practically the whole chest, neck, and upper abdomen are exposed. The rays must also be filtered through at least 3mm. of aluminium, and be highly penetrating. Under these conditions a growth which has already spread to the mediastinum can often be beneficially affected, so that it is almost inconceivable that any deep spreading should occur in the circumstances under discussion.

Nothing which has been said here is to be taken as meaning that the growth would not ultimately spread, in spite of x-ray treatment, supposing no operation to be done. Why this should be so we do not understand. But it appears that after a time the tissue response fails, as it does to arsenic in pernicious anaemia. Hence the necessity for operative removal, whenever possible, before the crest of the wave of improvement under x rays has been reached.

It is obvious that if we can increase resistance to cancer by x rays, we should do so after operation as well as before. Although we do not know what is going to happen in any individual case, we know that in a large percentage of all cases operated on for cancer of the breast, recurrence—or, at any rate, further growth—will occur. The rate of recurrence is estimated at 40 per cent. by the optimists, up to as high as 80 per cent. by the more pessimistically inclined. But even if we side with the optimists, two out of every five cases are certain to go wrong. So little do we know where the recurrence will occur—whether in the breast, in the stomach, the liver, spine, or ovaries—that a local effect, even though widely spread beyond the original site of the disease, must in itself be insufficient in many cases to prevent disaster. But the production of a general immunity is well worth aiming at. It may soon be possible, by using blood tests as criteria, to gauge scientifically the dosage at each sitting, the number of sittings in a course with their spacing, and finally, the intervals between successive courses.

Meanwhile, so long as we are not dealing with actual recurrence, we must be very careful to give too little rather than too much. The present writer feels that the possession of powerful apparatus has of late years led to unduly heavy dosage for prophylactic purposes. The experimentally verified fact that small doses of x rays raise immunity to cancer, whereas large ones decrease or abolish it, will, if kept carefully in mind, at least safeguard the radiologist from transgressing that fundamental therapeutic precept, *nil nocere*.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FATAL POISONING BY WATER DROPWORT
(OENANTHE CROCATA).

THE following case of poisoning by *Oenanthe crocata* is of interest because of its rarity and rapid course:

A single man, aged about 40, had for many years shown slight mental abnormality; I had seen him eighteen days before his death, when he was despondent and believed that he had committed some unforgivable sin. When summoned to him at 3 p.m., on April 24th, I found him lying on the floor of his bedroom; his face was bloated and livid, the eyes fixed and staring, and the pupils were dilated, his breathing was laboured and stertorous, and the pulse feeble. Blood-stained froth escaped from his mouth, and he was totally insensible and violently convulsed. Lying under his bed were a large number of roots, which when broken emitted a nauseous somewhat mouse-like odour like that of hemlock. When the convulsion had ceased the teeth were prized open and the stomach was repeatedly washed out with tepid water; the washings contained particles of vegetable debris, and had also the characteristic odour of hemlock. Lavage was continued until he had another violent and prolonged convulsion; when this had ceased respiration and circulation rapidly became fainter, and stopped ten minutes after my arrival. It appeared that he had gathered the roots in the early forenoon. He went to bed at 1.30 and an hour later was noticed to be restless and twisting. This was the first convulsion; he had two others before my arrival and was unconscious during his remaining three-quarters of an hour of life.

Examination of the roots showed them to consist of a series of tubers, varying from two to ten in each plant, some of them oblong, smooth, and succulent, others thinner and more fibrous and tapering, like bunches of small parsnips, for which they are apt to be mistaken. Their colour was yellowish-white, and when cut across were found to be dotted over with little brown pin head spots, the whole becoming yellow on exposure to the air. They were quite characteristic of the plant variously known as *Oenanthe crocata* (the classical name, from *oinos*, wine, and *anthos*, a flower—owing to the vinous scent of the flowers), "hemlock water dropwort," "horsebane," and "five finger root." It is also called "water hemlock," but this name is more accurately applied to an allied poisonous plant *Cicuta virosa*, or "cowbane." *Oenanthe crocata* is one of the most virulent of vegetable poisons, more deadly even than the more familiar *Conium maculatum*, or "spotted hemlock." It contains "oenanthotoxin," which causes convulsions by its action on the spinal medulla. The symptoms in this case were quite typical.

The plant is very common along the banks of ditches and small streams in this neighbourhood, where it is familiarly known as "hech-how." It has on several occasions in recent years caused the death of cattle, and a more remote instance is on record in which it proved fatal to a number of stranger seamen who partook of its roots under the impression that they were a harmless kind of parsnip.

T. HARVEY THOMSON, M.D., C.M., D.P.H.

Campbeltown, Argyll.

DIURNAL ENURESIS IN A CHILD: TREATMENT
WITH GALVANISM.

A. A., aged 5 years, had suffered from frequency of micturition during the day only, and never at night. A fortnight after an attack of measles she had great frequency of micturition, passing water every five minutes. This was treated for a fortnight with increasing doses of belladonna, and then for a week with belladonna and lycopodium. The condition slightly improved; she then passed water about every twenty minutes, but no further improvement could be obtained. She was ordered small doses of iron, and galvanism was applied for ten minutes to the suprapubic region. After the first application the frequency was diminished to once an hour, and after the second application to once in two hours and a half. This was two months ago, and there has been no return. On each occasion two cells of the battery were used. The ampérage was not measured, as my dynamometer is away for repairs.

STANLEY E. DENVER, C.M.G.,

M.D.Camb., F.R.C.S.Eng.

Acting Honorary Physician, Hull Infirmary.

HEAT HYPERPYREXIA.

I SERVED with the Indian Expeditionary Force during the summer—May to August, 1916—at Nasircech on the Euphrates; as the troops were in tents and hospital reed huts we had not the luxury of electric fans or punkahs.

I was attached to a combined field ambulance as second in command, and had charge of the European cases coming into the field hospital.

The treatment that my commanding officer and I adopted was as follows: Our brigade was holding one bank of the river. We dug a trench 6 ft. long by 8 ft. broad and 4 ft. deep, and covered it with reeds. The majority of cases of hyperpyrexia came into hospital between 4 and 6 p.m. The rectal temperature was never less than 108° F. As these cases came in unconscious and cyanosed, on stretchers, they were placed across the trench and I injected $\frac{1}{2}$ grain of strychnine and then proceeded with artificial respiration and the lavage. I had relays of orderlies lent from the battalion, who poured water over them. The trench very quickly filled, so that the patients' bodies were immersed except their heads. The rectal temperatures fluctuated a good deal, so that it was never safe to stop the douching until the temperature remained fixed at, but never lower than, 101° F. An invariable sign of recovery was vomiting. After the patients had recovered consciousness they were immediately removed into one of the hospital reed huts, and thin calico sheets wrapped round them—heads and trunks. I posted orderlies who passed down the lines of patients and

poured water over them, thus keeping the sheets constantly wet. As soon as the sun went down they were brought out into the open and the same method repeated until there was a decided fall in the atmospheric temperature, which usually occurred after midnight. On the following day, before it began to get very hot, I gave each patient an intramuscular injection of 3 grains of quinine bihydrochloride; I had no case of gluteal abscess or sloughing. I was able to keep these patients under observation for eight to ten days before they could be evacuated. During the whole of this period and during the journey to the base wet sheets were used. No death occurred among 40 odd cases of this type of heat hyperpyrexia treated by this method.

In one case of the choleraic type, after transfusion with Rogers's hypertonic saline, the temperature from subnormal gradually rose in two days to 108° F., and, despite all efforts, the man died. I had one gastric case—an officer—who was treated with lavage and full doses of mercury perchloride, with opium and sips of champagne. He recovered. There was no opportunity of making blood examinations or chemical analysis of urine, nor could we use modern methods of treatment, but the result was a good testimony to our methods, though crude.

AN ACUTE ATTACK OF ASTHMATIC DYSPNOEA CAUSED BY FILARIAL EMBRYOS.

I was called at 7.30 p.m. on February 24th, 1920, to a man, aged about 50, who since the previous night had been unable to sleep and had breathed with great difficulty. He was unable either to lie down or sit up, and maintained a semi-recumbent position; his face and lips were blue; respirations were 28, pulse 100, temperature 99°. He denied having had a similar attack before, but said he had had malaria some years ago. Sibilant and sonorous rhonchi and large and small râles were heard all over the chest. The diagnosis was made of an acute attack of asthma, brought on by exposure during the previous night.

An injection of 0.5 c.cm. adrenalin (1 in 1,000) was made, and a mixture of potassium iodide and potassium nitrate prescribed; a blood smear was also taken from a finger. On the morning of February 25th the dyspnoea was still worse; the patient had not slept and had vomited the mixture. For his feeling of constriction of the chest a mustard plaster was prescribed, but without effect. A hypodermic injection of morphine gr. $\frac{1}{2}$ was given, and belladonna was added to the mixture; the diagnosis of true asthma was now regarded with some doubt. The blood smear was examined in the afternoon, when two filarial embryos were detected; a leucocyte count showed the following picture—namely, increase of polymorphs and eosinophiles: Polymorphs, 80 per cent.; large mononuclears, 10 per cent.; small mononuclears, 6 per cent.; eosinophiles, 4 per cent.

It was now clear that the asthma was due to the irritation caused by the filarial embryos in the pulmonary capillaries; the failure of adrenalin, potassium iodide, belladonna, and morphine was explained. The same evening the opinion was expressed that the attack would now subside without further treatment, as the filarial embryos would retire into the lymphatic vessels and glands of the posterior mediastinum. At 7 p.m. the patient had no more dyspnoea, as foretold, but a few rhonchi and râles were present. Another injection of morphine $\frac{1}{2}$ grain was given, and he slept comfortably; breathing henceforward was easy.

On the morning of the 26th the patient complained of heaviness of the right arm, and was unable to raise it. There was no loss of sensation, nor paralysis, and the symptom was attributed to the presence of microfilariae in the lymphatics of the axilla, a condition which would pass off as the embryos retired into the deeper lymphatic system, there to remain until another exposure or chill caused swelling of an extremity, filarial fever, or another attack of asthma.

D.T.M. and H.

Bombay.

A COURSE of advanced lectures on diseases of the gastrointestinal canal will be given at the Hôtel-Dieu, Paris, beginning on July 10th and ending on July 24th. The course will consist of lectures and demonstrations, and the fee is 150 francs. It is open to foreign as well as French doctors. At the end of the first week there will be a trip to Vichy and the spas of Auvergne.

Reports of Societies.

DIPHTHERIA BACILLI IN THE THROAT.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine, on May 28th, the President, Dr. E. W. GOODALL, in the chair, Dr. P. HARTLEY and Professor C. J. MARTIN, F.R.S., read a paper on the apparent rate of disappearance of diphtheria bacilli from the throat. The authors had been able to study the apparent rate of disappearance of diphtheria bacilli from the throat under exceptionally favourable circumstances, as all the cases, 457 in number, occurred in soldiers in France, and treatment and methods of examination attained a degree of uniformity which is not likely to be met with in civil practice. The data, when subjected to statistical analysis, revealed some interesting features. When the numbers still carrying *B. diphtheriae* were plotted as ordinates, against periods of five days along the abscissa, it was found that after the first five days had elapsed the observations fell upon a regular curve. The numbers fall rapidly at first, and then more and more slowly. The form of the curve suggested a logarithmic relationship, and when the logarithms of the numbers remaining infective were plotted against time the points fell on a straight line. An equation to the curve enabled a series of calculated values to be arrived at, and these agreed in a remarkable way with the figures actually observed. The conclusion seemed justified that the rate at which a population frees itself from diphtheria bacilli can be represented by a simple expression which yields a constant (the constant being the tangent of the angle where the line cuts the abscissae). This constant expressed the velocity with which the carrier state apparently disappeared. Such a simple relationship suggested that the disappearance of bacilli from the throat was due to the operation of a number of small causes—that is, to chance—except in the relatively rare cases of persons with abnormal throats.

In the series under consideration the criterion of freedom from infection chosen was three successive negative examinations of the throat at weekly intervals. The standard adopted was a compromise, and it was not claimed that three successive negatives excluded the possibility of discharging some convalescents who still harboured diphtheria bacilli. Other workers had deemed two, or even one, negative finding sufficient. The authors then analysed their figures in order to determine what the apparent rate of disappearance would be if one, two, or three successive negative examinations respectively had been taken as the criterion of freedom. The value for the constant *K* was 0.0363, 0.0264, and 0.0218 respectively. In the authors' experience the rate of discharge from hospital, as presumably free from infection, was 4.9 per cent. per day when three successive negatives were demanded, 5.4 per cent. per day on a basis of two successive negatives, and 7.1 per cent. per day if only one negative examination were required. The percentage of carriers missed, even when three negatives were demanded, was probably considerable, but the number would have been increased by 9.3 per cent. and 29 per cent. respectively if two or only one negative examination had been the criterion adopted.

The authors compared their results with those of earlier workers (Park and Beebe, 1894; Scheller, 1906; Tjaden, 1907). The figures of Park and Beebe and Tjaden showed the same logarithmic relation; those of Scheller, whose observations were made on out-patients, many of whom were lost sight of, were irregular. The striking fact was the difference in the rate of disappearance. In Tjaden's cases it was six times as rapid as in the authors' series on the same basis—namely, one negative finding. The data collected by Woodhead from all the hospitals of the Metropolitan Asylums Board for the years 1895 and 1896, and those published by the Massachusetts State Board of Health for the years 1896 to 1905, was also studied and analysed. The rate of disappearance of bacilli in the Metropolitan Asylums Board figures was a little slower than in the authors' series, while in the case of the American series the rate was considerably quicker. The interval before the steady fall began was much greater in these two series of cases, which might be due to the

fact that in those early days the dose of antitoxin administered was much less, and the duration of illness longer in consequence.

The authors estimated that the average duration of stay in hospital in their series was forty-five days, twenty of which were taken up in procuring information regarding the absence of bacilli in the throat. During this latter period the patient might be, and often was, fit to leave. If two successive negative examinations had been required instead of three, the duration of stay in hospital would have been reduced to thirty-four days, while if only one negative examination had been demanded the period would have been further reduced to twenty-one days. As pointed out above, this economy in respect of stay in hospital was accompanied by a diminution of accuracy, and the risk of discharging patients still harbouring bacilli was increased. The authors encountered four convalescents with abnormally large tonsils with deep crypts, who proved to be stubborn carriers. They supported the opinion of Pegler (1905) and Sears (1919) that the best treatment in these cases was radical enucleation of the tonsils. This was done in their four cases, and the subsequent findings were uniformly negative.

The paper was discussed by Dr. BROWNLEE, Dr. TURNER, Dr. DUDFIELD, Dr. BRINCKER, Dr. HUNTER, Dr. BOND, Dr. BUTLER, Dr. GREENWOOD, and the PRESIDENT.

ENTEROPTOSIS.

At a meeting of the Medico-Chirurgical Society of Edinburgh, on June 2nd, Emeritus Professor F. M. CAIRD presiding, Dr. HOPE FOWLER showed a series of slides demonstrating downward displacement of stomach and intestines, and also the frequently associated cardioptosis.

Dr. CHALMERS WATSON then opened a discussion on enteroptosis and associated conditions. The condition was very common in men and children, as well as in women, and in his series of 510 cases the proportion was 2 men to 3 women. After referring to the symptomatology, to the organic diseases in appendix, stomach, and duodenum simulated by it, to the frequency of bands and membranes which, in his view, were not congenital but secondary to the dragging on peritoneal folds and mesenteries, he dealt with the skeletal changes, especially with the virginal type where there was narrowing of the thorax and a downward slanting of the lower ribs, and the maternal type, where these thoracic changes were absent. In addition to the flabby abdominal wall there was often faulty action of the diaphragm, with important effects not only on the intestinal muscles, but also on the intestinal circulation. If microscopic lesions in the colon developed, and this was frequent, septic absorption took place and largely accounted for the symptoms of toxæmia. Evidence of this septic change and absorption was to be found in the motions and in the condition of the urine (bacteriuria and pyuria). This toxæmia explained such general conditions as arthritis, neuro-muscular changes and neurasthenia. A considerable degree of enteroptosis might exist without symptoms, but he believed that it was never present where there was a high grade of general health; and it frequently began quite early in life, being dependent in those cases on lack of breast-nursing, on constipation, on defective education in personal hygiene, on faulty respiration as produced by adenoids. The great variation in the symptoms was mainly accounted for by the varying activity of three factors—the degree of enteroptosis (mechanical), the amount of septic absorption (toxic), and the mental tone (psychical). He attached much importance to the psychical factor, both in pathology and in treatment. As to treatment, he insisted on the value of prophylactic and early measures, in the form of massage and selected exercises which maintained or restored the efficiency of the diaphragm and the abdominal muscles.

Professor A. ROBINSON said that in the dissecting-room visceroptosis, and bands and kinks were often present in old people without having produced symptoms during life; and that much of the evidence of visceroptosis produced by clinicians was faulty in being uncontrolled. In his belief visceroptosis, when associated with symptoms, was only part of a general incapacity, and this subnormal condition had existed from birth.

Professor Sir HAROLD STILES was convinced that the condition was developmental, and that heredity was a

factor; enteroptosis was often associated with a long and slender frame. He was certain that many children were born with a degree of enteroptosis, this not producing symptoms unless aggravated in later life. Physical education in school children was therefore greatly needed to prevent the aggravated types of adult life. In addition, there might be some subtle sexual condition at work, which would account for the greater frequency of the condition in women. An abdominal support was of value, but only if prepared from a cast of the abdominal wall in the Trendelenburg position. In extreme cases he advised removal of the proximal half of the colon.

Professor MEAKINS said that there was not reliable evidence of toxæmia in enteroptosis unless there was also a dilated caecum, and that this was a superadded condition. A well fitted abdominal belt was of value. He did not approve of operation unless in a few selected cases. Mr. J. W. DOWDEN said that besides the acquired type of enteroptosis so frequent in modern women there was also a congenital variety. Intestinal kinks often produced no symptoms. Too much stress had been laid on laxity of the abdominal wall, while severe constipation might exist without toxic symptoms. Dr. H. RAINY summarized his experience of 800 x-ray examinations. He believed in a toxic absorption from the caecum and colon. Mr. D. P. D. WILKIE gave the results of 400 *post-mortem* examinations in adults and stillborn children. These supported the view that abnormal bands and membranes were congenital. He also suggested that duodenal dilatation might account for some of the symptoms of enteroptosis. Mr. J. W. STRUTHERS said that a normal standard was still lacking for the true appreciation of the x-ray appearances of enteroptosis. These patients were of congenitally poor physique. Dr. E. BRAMWELL emphasized the emotions as a factor in initiating the cycle, and spoke of the danger of the doctor producing an anxiety neurosis in these patients.

Dr. CHALMERS WATSON replied.

VENTILATION AND HEATING OF TUBERCULOSIS INSTITUTIONS.

A MEETING of the newly formed Society of Superintendents of Tuberculosis Institutions was held on May 17th at 122, Harley Street, Dr. JANE WALKER, President, being in the chair. Twenty-nine new ordinary members and nineteen associate members were elected. Dr. H. O. BLANFORD (Millhurst) and Dr. Vere Pearson (Mundesley) were elected to the Executive Committee.

Dr. LEONARD HILL, F.R.S., opened a discussion on the physiological principles involved in the ventilation and heating of tuberculosis institutions. The effects of bad ventilation were not, he said, produced by the excess of CO₂, nor by diminution of the percentage of oxygen in the air. Workers in submarines could easily tolerate without discomfort as much as 3 per cent. of CO₂; in the high Alps the oxygen might fall to 17 per cent. or less without affecting the health of the mountain dwellers. The view that obnoxious organic matter in exhaled air was at fault was no longer held. There was the clearest evidence that the physical properties of the atmosphere had a great influence on the physiology of the body, and the determining factors in good ventilation were the coolness, the movement, and the dryness of the air. The lecturer described his kata-thermometer, and showed how cool air of low humidity inspired through the nostrils is raised by means of the increased flow of arterial blood through the nasal mucosa to a constant temperature at the back of the nose. In addition, there was a greater flow of lymph, which evaporated. This might be increased as much as five or ten times by exercise in the open air. The drier the air (within limits) the better. The greater the vascular activity of the nose the greater was the power of resisting disease; hence the resistance of outdoor workers to respiratory diseases. Apart from influenza, our soldiers and sailors in the war were singularly free from respiratory diseases. Through its cooling power the skin controlled the metabolism of the body. Cooling of the skin by outdoor life might double the resting metabolism, which, with exercise, might be increased five or more times, with concomitant improvement in appetite, assimilation of food, and elimination of harmful waste products.

DR. JANE WALKER, DR. JAMES WATT, DR. MARCUS PATERSON, DR. W. C. FOWLER, DR. NOEL BARDSWELL, DR. P. W. EDWARDS, and DR. H. O. BLANFORD contributed to the discussion. In reply to questions, DR. HILL stated that people should wear as little clothing as possible. It was the absolute and not the relative humidity of the air which mattered. In wet mists it was preferable to keep patients indoors. The ideal condition of heating was the radiant heat of the sun. In ordinary dwellings steam pipes tended to heat the air at the ceiling and to leave the air near the floor as much as 10 degrees cooler. It was not harmful, however, to have different parts of the body under different conditions of temperature. Such differences kept up the nervous tone, avoided monotony, and acted as a stimulant. He commended the practice of many sanatoriums in shutting up and heating by radiators rooms not in use, and making use of the radiant heat stored in the walls when the rooms had to be opened up for patients. The practical questions of clothing and of heating in open-air institutions would be dealt with in a forthcoming publication of the Medical Research Council.

DR. MARCUS PATERSON opened a discussion on the relative value of butter and margarine in the treatment of tuberculosis. He believed that in institutions where margarine was used the necessary supply of the fat-soluble A vitamin was quite well obtained from cod-liver oil or from milk, as well as from the animal fats of meat, bacon, and dripping. In most institutions 14 pints of milk were consumed per patient per week, and this quantity contained the equivalent of from 10 to 12 oz. of butter. On the whole, opinion in the subsequent discussion was strongly in favour of the use of margarine in place of the more expensive butter, in cases in which milk or cod-liver oil formed part of the dietary.

Rebicus.

THE SURGERY OF THE TEMPORAL BONE.

SIR CHARLES BALLANCE has long been looked upon as the aural surgeon's most reliable guide through the difficulties of the diagnosis and treatment of the dangerous sequelae of suppurative disease of the middle ear—in other words, the highest authority on the *Surgery of the Temporal Bone*,¹ the title of the book he has now published in collaboration with Dr. C. D. GREEN. This book forces itself on our attention from the earliest days of our studies in osteology till the end of our careers as general practitioners, surgeons, physicians, or specialists. Its diseases carry with them far more danger to health and life than those of the eye, a fact well known to Celsus, as is noted in the historical chapter in this book. In spite of this fact the tendency has been to place the study of ear disease in a much lower position than that of diseases of the eye in the medical curriculum, professional examinations, and hospital installations. Sir Charles Ballance makes a powerful and almost passionate protest against this incongruity. It is to be hoped that it will not fall on deaf ears, and that his plea for the establishment of otology in its rightful position as a princess and not as a Cinderella in the realm of medicine may receive the attention it deserves. The publication of the two impressive volumes of which this work consists should give pause to those who put spokes in the wheel of progress in otology as a branch of surgery, equal in importance with any other, and deserving of equal dignity.

The great characteristic of this book is its comprehensiveness as regards the work of the author himself, scattered through various transactions, journals, and lectures, and even more as regards that of other authors of all nationalities.

Those who were fortunate enough to have read Sir Charles Ballance's article, entitled "Some Ear Cases," in the first edition of Clifford Allbutt's *System of Medicine* at the time of its publication, had a concentrated gallery of illustration of the dangerous sequelae of suppurative disease in the temporal bone to which comparatively little has been added since. The elaboration of the principles

¹ *Essays on the Surgery of the Temporal Bone*. By Sir Charles A. Ballance, K.C.M.G., C.B., M.V.O., M.S., F.R.C.S., with the assistance of Charles David Green, M.D., F.R.C.S. Illustrated by 125 plates and 120 figures. In two volumes. London: Macmillan and Co., Ltd., 1919. (Med. 4to, pp. 612; 250 plates, 240 figures. £5 5s. net, two volumes.)

there set forth and the methods of diagnosis and treatment founded on them may be said to form the foundation of the present work. The writings of other authors of all nations dealing with the subject are so fully quoted, epitomized, and analysed that we have before us a compendium of the literature in which scarcely any papers of importance escape reference. The anatomical, pathological, and clinical aspects are set out with a wealth of detail and a profusion of illustration such as have not before been offered. Many quotations are from works which have not hitherto been noticed by English writers, and those who are not familiar with foreign languages will thus find this treatise invaluable. As a minor illustration, Rudloff's drawings of the position of the sigmoid sinus and its surface anatomy in infancy and childhood would seem to have been overlooked by others, but they are here reproduced in their original form. Stiles's investigations as to the position of the facial nerve in infancy and childhood are not so well known as they deserve; they are given here in full detail. All that is of practical importance in regard to the recently developed labyrinthine tests and to operations on the labyrinth also finds a place.

In every respect these two handsome volumes contain practically all that can be said with regard to the surgery of the temporal bone in its widest sense. Aural specialists will find their views classified and widened by this presentation of the subject by a general surgeon who is also a specialist, and general surgeons will be grateful for the help here afforded them towards the elucidation of the "special" aspects of this important subject as a branch of surgery. Aurist and surgeon will be led by the study of this book to a better and fuller understanding of each other's point of view, to the advantage of both. The credit of British otology and surgery will be materially increased in all lands by the publication of this epoch-making work.

RADIOGRAPHY IN PULMONARY TUBERCULOSIS.

The first volume of Dr. WALKER OVEREND'S book, *The Radiography of the Chest*,² is concerned with pulmonary tuberculosis. Great stress is laid upon the value of an x-ray examination. He maintains that in many instances radiography alone is absolutely diagnostic, but admits that it is always expedient to check and compare results by the usual means of investigation. This is, of course, the sane method to be adopted in the investigation of disease; no one method should be solely used when several are available, nor should it be expected from radiographers that an opinion should be given on an x-ray examination alone.

In the consideration of diseases of the chest it is obviously of importance to have a thorough knowledge of the normal, both as shown by a screen examination, and as shown on plates taken in the various standard positions, and the first chapter is restricted to a careful description of the normal shadows and their meaning. In discussing the pulmonary reticulum it is stated that the actual anatomical substratum to which the tracery is attributable is still a matter of discussion, but hardly sufficient reference is made to the valuable pioneer work of Dunham, whose experiments appear to prove beyond all doubt the manner in which these shadows are built up. The chapter on tuberculosis of the bronchial glands is illustrated by many effective radiographs, some of them all the more interesting and conclusive because the physical signs and history of the cases are related, and in some the *post-mortem* appearances are compared with the radiographic. In summing up this part of the subject the author expresses the opinion that there are no clinical criteria of any value, and that radiological examination is necessary for the diagnosis of tuberculosis of the bronchial glands.

The rest of the book deals with the various manifestations of tubercle of the lungs and their radiographic appearances. Perhaps too much is made of the different ways in which tubercle attacks the lung, and too great stress is laid upon the names designed to point out the different varieties. After all, tubercle is tubercle, and whether it invades and spreads from one focus or area or another is of no great importance from the radiographic

² *The Radiography of the Chest*. Vol. I, Pulmonary Tuberculosis. By Walker Overend, M.A., M.D., B.Sc. London: William Heinemann (Medical Books), Limited, 1920. (Demy 8vo, pp. 119; 99 radiograms, 9 diagrams. 17s. 6d. net.)

standpoint; it is the abnormal shadows which are seen on the plates and their correct interpretation which are of importance; whether, in the first place, the shadows are or are not likely to be caused by tubercle; and, in the second place, whether they are radiographically more likely to be caused by active, quiescent, or cured tubercle.

The chapters on bronchopneumonic and nodal types, on bronchopneumonic pseudo-lobar tubercle, on miner's phthisis, on fibroid phthisis, on pneumonic phthisis, on miliary tubercle, and on the complications of pulmonary tuberculosis, which follow are written on the same lines: a detailed description of the condition under discussion is followed by a review of the physical signs to be expected, the narration of the salient features of cases, the signs being contrasted with the radiographic findings, numerous typical illustrations are given, and then general remarks and conclusions are stated.

In the concluding chapter the author sums up the present position as to the radiological diagnosis of pulmonary phthisis, points out the advantages of a skilled x-ray investigation, and insists upon the co-operation between the clinician, pathologist, and radiologist which is necessary to increase the knowledge of the disease in its incipient stages and in its principal types, and to mature the methods of its treatment and control.

Well written, well and profusely illustrated, the case for radiography is admirably and graphically set forth.

PATON'S "PHYSIOLOGY."

THE fifth edition of Professor NOËL PATON'S *Essentials of Human Physiology*⁵ offers the student a well informed and clearly written critical account of the subject, calculated to make the reader think, as well as learn by memory. The new edition is a hundred pages longer than the fourth and has forty more diagrams; the augmentation may be put down as legitimate growth rather than the beginnings of giantism, and the book certainly gives a satisfactorily complete account of its subjects. After a brief account of the growth of physiology, Professor Paton describes protoplasm, the cell, and the various tissues. The latter he puts in two classes, the "vegetative tissues," and the "master tissues" or nerve and muscle. The greater part of the volume is taken up with the nutrition of the tissues; it is interesting in these parlous days to find a physiologist who will put in a good word for alcohol. Professor Paton recognizes its value as a food and as a drug, adding that it may and does increase the pleasure of life, and that its great use is in extreme fatigue when the work is over; most people can fully oxidize about 2 oz. of it in the twenty-four hours.

Emphasis is laid on the importance of co-ordinating practical work with reading in the study of physiology, and constant references to the methods and results of experiment are made the keynote of the volume. Describing the glands with internal secretions, Professor Paton calls them the "endocrinetes"; it may be noted that the word *θυμωσ* on page 610 should be *θυμω*. The illustrations, for the most part diagrammatic, are well chosen, and full advantage of variations in the type is taken—a great help to the reader. To students preparing for examinations in physiology the book should prove of great service.

NOTES ON BOOKS.

PROGRESS in the teaching of surgery can never be furthered by the indiscriminate production of textbooks which are merely epitomes. Yet, as the author of *A Textbook of Surgery*,⁴ Dr. W. Q. WOOD, points out, the student has scanty time to read through the longer manuals. In this work some five hundred pages are packed with facts, but there are no illustrations. The brevity of the sections on the pathology and treatment of the various surgical disorders was no doubt unavoidable, but it should have been possible to incorporate into the whole work the essential leaven of surgical principles. We can picture the student using this type of book and underlining statements which are either bare half-truths or errors—all to be committed to memory. Thus we quote at random from the section

dealing with congenital stenosis of the pylorus: "If improvement does not quickly follow" (that is, medical treatment), "a gastro-jejunostomy may be performed, but the mortality is high." This sentence comprises all that we have observed to be said about surgical treatment of congenital pyloric stenosis in this textbook. It is to be doubted whether a book of this type is likely to be of much value to the undergraduate student.

Professor SAMAJA'S short book on von Recklinghausen's disease⁵ contains a workmanlike summary of the extensive literature devoted to this affection of the skin and peripheral nerves, the first published case dating very possibly from the year 1793, though the disorder was not described by von Recklinghausen until 1832. The diagnosis from no less than fifteen other diseases that may resemble it has to be made, according to the author's enumeration; the treatment or treatments that may on occasion prove serviceable are shortly considered on the last two pages of the text. The book ends with an admirably sorted bibliography, and may be warmly recommended to the attention of the pathologist and of the specialist in diseases of the skin.

Miss BARBER'S pamphlet entitled *A British Nurse in Bolshevik Russia*⁶ gives a brief general account of what she saw and did in Russia and Armenia between April, 1916, and December, 1919. The general impression left by this simple story is that the disordered state of Bolshevik Russia is not so happy as its upholders would have us believe, nor quite so hopeless as its critics aver. Of atrocities Miss Barber saw nothing herself; she thinks that they are committed by both sides, and do not in themselves justify the support of either party.

⁵ *Il Morbo di Recklinghausen*. By Professor Dott. Nina Samaja, Libero docente di Patologia speciale nella R. Università di Bologna. Milan: Società Editrice Libreria. 1919. (Sup. roy. 8vo, pp. 85; 9 plates. 12 lire.)

⁶ *A British Nurse in Bolshevik Russia*. By Margaret H. Barber. London: A. F. Field. 1920. (Cr. 8vo, pp. 61; 1 photograph. 1s. 6d. net.)

BIOMETRIC AND EUGENIC LABORATORIES AT UNIVERSITY COLLEGE.

THE new building given by Sir Herbert Bartlett, Bt., to the Department of Applied Statistics formed by the Drapers' Company and Galton Laboratories at University College, London, was opened on June 4th by the Minister of Health. The Drapers' Company Biometric Laboratory was instituted under the direction of Professor Karl Pearson in 1904; it is a research laboratory and training school in the modern mathematical theory of statistics. The Galton Laboratory for National Eugenics was instituted in 1905, and was, by Sir Francis Galton's wish, associated with the other. When Sir Francis Galton died in 1911 he bequeathed a large part of his estate to found the Galton professorship, and Professor Karl Pearson was appointed to the chair. At the same time the Senate of the University appealed for funds for building and equipment, and Sir Herbert Bartlett came forward with an offer to provide the building on a site at the north-west front of the college. During the war the new building was used as a military hospital, and only now has the Department been able to take full possession. On the ground floor of the building is a large museum for the illustration of heredity, statistical processes, and social problems, a lecture theatre, a room for the exhibition of Galton relics and apparatus, and an anthropometric laboratory. On the first floor there are laboratories, a library, and a common room, and on the second a photographic studio, a large room for biometric workers in craniometry, and rooms for archives and instruments. The apartments in all number over twenty, and it was announced that a site has been reserved for extension, which will include animal breeding accommodation.

The Vice-Chancellor of the University (Dr. RUSSELL WELLS), who presided over the opening ceremony, said that statistics, properly understood, was one of the most difficult and advanced of mathematical studies, but it was a dangerous weapon in the hands of the partially educated. Medicine in particular had suffered greatly from its misuse. The method introduced by Professor Karl Pearson would make it possible to arrive at the proof of many complicated medical problems. He himself had a paper in the BRITISH MEDICAL JOURNAL of May 29th in which he had

⁵ *Essentials of Human Physiology*. By D. Noël Paton, M.D., R.Sc., F.R.S. Fifth edition, revised and enlarged. Edinburgh: W. Green and Son, Ltd. 1920. (Demy 8vo, pp. 698; 252 figures. 25s. net.)

⁴ *A Textbook of Surgery*. By W. Q. Wood, M.D., F.R.C.S. Edin. Edinburgh: James Galloway. 1919. (Cr. 8vo, pp. viii + 554. 15s.)

used the formula for correlation which Professor Karl Pearson had evolved. In sketching the history of the department, he reminded the audience of Florence Nightingale's well known interest in statistics, and of her desire to found a professorship of applied statistics at University College, for which, however, her means were not sufficient. It was not until the generous provision of the Drapers' Company was made that a start became possible. Incidentally, the munificence of the City companies in educational matters had been such that the universities should be the first to defend those ancient bodies against popular cynicism.

Dr. ADDISON gave an appreciation of the value of statistics which he had discovered when Minister of Munitions. There were few branches of public service with greater scope for the trained statistician than that of communal health, but here and in social science many statistics had been of a thoroughly incomplete and unsatisfactory nature. He commended to the support of the public the further appeal which University College was making to maintain and complete the equipment of the new building.

The Provost (Sir GREGORY FOSTER) expressed the thanks of those present to Dr. Addison. The thanks of the University to Sir Herbert Bartlett for his gift were expressed by the Vice-Chairman of the College Committee (Dr. J. BOURNE BENSON), who said that while a number of people were ready to endow a scholarship or a chair, few were ready to find the building in which it could have space. Professor KARL PEARSON said that one English monarch for whom he had a reverential regard was Henry VI. He saluted his statue whenever he crossed the lawn at King's College, Cambridge. In the fifteenth century it was possible to spend money on wars in France or on the founding of monasteries, but Henry chose to found King's College. And to encourage learning was still the surest way to secure that one's name was held in honour through grateful generations.

FUTURE PROVISION OF MEDICAL SERVICES.

LORD DAWSON ON THE CONSULTATIVE COUNCIL'S REPORT.

LORD DAWSON OF PENN, G.C.V.O., M.D., addressed the Stratford Division of the British Medical Association on June 3rd on the subject of the interim report of the Consultative Medical Council. The meeting was held in the Educational Offices at Stratford, with Dr. FRANK CHALLANS in the chair. About sixty members of the profession were present, and the greatest interest was manifested; in spite of the late hour at which the meeting terminated (11.30 p.m.), all but a very few remained to the end to hear Lord Dawson's reply.

Lord Dawson, in acknowledging the Chairman's congratulations on his recent honour, said he regarded that honour not so much as a recognition of any services of his own, but as marking a desire on the part of the State to see the profession take a more prominent part in the affairs of the body politic. The individualistic attitude which the profession had taken in the past was very natural. Medicine was an exhausting profession, taxing the mental and physical resources to the utmost, and very little energy was left for other interests. By tradition and habit, therefore, the profession had been content to look at matters from the individualistic point of view. But it was now compelled to take the communal outlook. During the last fifteen or twenty years there had been a distinct tendency to set up communal organization for securing the health of the people. One result was to draw a line through the profession; on one side of the line were the men who continued to do their work in the old individualistic way, and on the other side were the men engaged in communal work, and the tendency was for one piece of work after another to be transferred from private practitioners to salaried officials of the State.

What had led to the investigation and report of the Consultative Council was, in the first place, the almost universal conviction that the *status quo* could not continue. However much men might disagree as to what changes in organization were required, there could be no difference of opinion as to the evident fact that

the machine was outworn. The public was placing a higher value on health than formerly. The health of the citizen was now seen to be of supreme importance, and it was agreed that organized measures must be taken for securing it. A series of whole-time services had been set up one by one. The school service, for example, had become almost a detached service, with a certain number of doctors earning their living entirely as school medical officers. More recently there was set up a tuberculosis service, then a venereal service, and last, in point of time, a maternity service. The second evident fact was that medical men to-day were not in a position to do or give the best for their patients along purely individual lines. In his hospital days a man had every facility for following up his cases in the various departments; he could look at the x-ray image, he could see the testing of the secretions, and he could go into the operating theatre and the *post-mortem* room. He had the opportunity throughout of maintaining a high standard of intellectual interest. On going into practice, however, this man dropped suddenly down to the limited opportunities of a surgery in a private house, and when he went to the homes of the people the social surroundings were often such that he could not do his best. That drop got keener and deeper as time went on, and the astonishment to him (Lord Dawson) was—and it was a great tribute to the clinical sense of the profession—that the men in practice kept up so high a standard as they did. It was clear, therefore, that the practice of medicine right through the community must have proper organization and provision.

These considerations led up to the reference to the Consultative Council. The Insurance Act was one endeavour to bring medical treatment within the reach of the people more completely than before, but if the best means for the treatment of the community were to be made available the range of benefit must not be restricted to insured persons. The State could not be asked to make those means available only for one section of the community. The reference to the Consultative Council was therefore to suggest ways whereby the medical services of the country could be so systematized as to provide what should be made reasonably available for all members of the community.

Lord Dawson then quoted from the report to show that the recommendations were designed to secure: (1) The provision of buildings and equipment; (2) services correlated and made available for all; (3) opportunity for practitioners to do their best work and further their knowledge; (4) co-ordination of preventive and curative medicine; and (5) freedom of action for doctor and patient. It was difficult to combine all these ideals. If the point of view of the administrator alone were considered, recourse would be to a whole-time service. But that was felt not to be the best thing in the interest of the health of the community. The correlation of preventive and curative medicine was most important, and at present the general practitioner was not identified closely enough with prevention and with the maintenance of communal health. He had yet to be brought into contact with the preventive services. The higher posts in such services must necessarily be in the hands of specialists, but the practitioner, nevertheless, must somehow be identified with preventive work. With the advance of knowledge, the line of demarcation between prevention and cure became increasingly blurred. A further principle upon which the Council had acted was that the work of a district should as far as possible be performed by the doctors of that district—(Hear, hear)—who should be paid on a part-time basis. This in itself would bring preventive medicine more under the ken of the general practitioner. Then it was realized also that the practitioners must have opportunities of following up cases and investigating disease from different standpoints. The work of medicine was becoming less the work of an individual, more the work of a team, and a team could only work together in the same harness. An increase of institutional provision was therefore indicated. Although domiciliary treatment of illness was and must remain the larger part of practice, it required supplementing by institutional provision, access to which should be afforded to the doctors of the district. It was fully realized that what was suggested was something new; there was no experience from any other country to guide them; indeed, other countries were

watching the experiment with a view to imitating it. The scheme could only be built up if the profession showed its warm approval, and, moreover, it could only be built up step by step, but the laying of the first stones was of importance; apart from any further erection they lent themselves immediately to good service in the locality, but they also provided the groundwork for the larger edifice presently to follow. (Applause.)

The term "health centre" was employed because something bigger and more embracing was desired than the term "hospital." The centre might be defined as an organization to bring together the curative and preventive services of a given district. In a typical instance it might contain fifty beds, with certain clinical accommodation where consultations might take place and patients be seen other than those in the beds; also a radiographic room, a laboratory and other departments, and a common room, where doctors could hold meetings. The essential thing about the primary health centre was that it should be staffed by the general practitioners of the district, and that when a patient left his home and went into the clinic he would be followed there by his own doctor. The primary health centres in a given area would be connected up with a secondary centre, which instead of being staffed by general practitioners, would be staffed by consultants, or by general practitioners acting in a consultative capacity. Then, to complete this ideal arrangement, the secondary centres would be linked up with a teaching hospital, which would be scheduled as a national institution with a "zone of influence" attaching to it. Primary health centres in Bedfordshire, for example, would be linked up with secondary centres at, say, Bedford and elsewhere, and these, somewhat loosely, with the teaching hospital at Cambridge.

The question of payment was, he admitted, an important and complicated one. It was impossible to proceed as though the Insurance Act were not in existence, with over 80 per cent. of the doctors serving under it. He imagined that the insured person would be provided for in the primary health centre, but the idea of the Council was that these institutions must be available to all, insured and non-insured. The complete upheaval of our social life as a consequence of the war had to be reckoned with, and the professional man with £800 a year and three children to keep and educate was a poor man to-day. Furthermore, it had to be remembered that every advance in medical science increased the cost of treatment. As medicine became more complex, it became more a matter of teamwork, and on this account and on account of equipment, the cost went up. And with the increase of cost, the number of people in the community able completely to pay for it correspondingly diminished. At the present time the medical profession was working without adequate equipment, which should be set up and made available for all classes. The provision had to be made all-embracing, and the only way in which he saw that this could be done was by having standard rates. But this matter must be left vague for the present; it was undesirable to be in a hurry to go into details. In view of the difficulties which arose out of the desire to preserve freedom of relationship between doctor and patient, and the obvious argument of the administrator that it would be easier to set up a whole-time civil medical service and have done with it, the first thing to consider was whether the profession did desire to preserve the principle of freedom as between doctor and patient. The men detached from practice, he believed, were more likely to urge the alternative of whole-time State service than were the men in practice, but it was a question for discussion. A State medical service was at present coming into this country by stealth. Each time the State set up a new *ad hoc* salaried service it was lopping off something from the responsibilities and duties of the private doctor.

As for the proposed arrangement now put forward, he thought it would simplify matters if the subject was looked at from an extra-London point of view. To a large extent the report left London alone for the present. London had special difficulties arising partly out of its bulk and partly out of the complexity of its administration. If the difficulties in smaller places could first be solved it would be easier to apply the scheme to the great province of London. Further, he did not believe that any thinking person wanted the Ministry of Health to "run" the health of the community from Whitehall. The

Ministry of Health should only be guide, philosopher, and friend, and, he hoped, benefactor. It was not for him to say at the present juncture what the composition of the local authority responsible for the arrangements should be; they did not want to be drawn, if they could help it, into controversies affecting local government. But any local authority charged with this duty had to fulfil certain conditions: It had to be the one authority for all matters concerning health; it had to be responsible for a considerable area so as to secure the best men and to get away from local politics; and it should admit also of interaction between town and country. The medical profession as such should be represented on the local authority, on the principle of vocational representation. On all such authorities there should be a co-opted minority consisting of the people who were specially expert in health matters.

Lord Dawson more than once in his exposition had offered to desist from speaking in order to allow fuller opportunity for discussion, but the meeting signified its desire that he should continue, and the lateness of the hour then precluded a formal debate. But a number of questions were asked from the audience and were answered by Lord Dawson at the close. Practically all those who made any remarks in the discussion declared emphatically against a whole-time State medical service.

Dr. ALFRED COX (the Medical Secretary) declared himself a hearty supporter of the Council's report. It embodied many ideas which the British Medical Association had been laying down for the last five or six years. He supported the report in the first place because it gave the public something very much better than the public had at present, and in the second place because it enabled the profession to stave off the demand made by academic people and others to nationalize the medical profession. He noticed that the press—with the very few exceptions which might have been anticipated—was heartily in favour of the report also. It seemed to be generally agreed that freedom of choice was a good thing to preserve. The report, however, must have popular force behind it, and as a beginning, on which the Stratford Division was to be congratulated, he wanted Lord Dawson to go away feeling that the general sense of that first meeting was thoroughly in favour of the report. (Applause.)

Dr. PERCY ROSE said that the meeting ought to have some practical outcome in the form of a resolution, and accordingly he moved:

That the medical practitioners of the Stratford Division be asked to form committees in each sanitary area entering into the Division, with the following objects:

1. To ascertain in each area what are the facilities for preventive and curative medicine at present existing.
2. To recommend what steps might be taken to improve the medical services of each area on the lines laid down in the Interim Report of the Consultative Council on Medical and Allied Services, 1920.
3. To send a copy of their report on items 1 and 2 to the Honorary Secretary of the Division not later than October 31st of this year.

The resolution was seconded and unanimously adopted.

Dr. H. S. BEADLES criticized the primary health centre on the ground that a primary centre could hardly be one containing beds. He thought that a beginning might be made with something smaller than had been indicated.

One or two other speakers asked whether there would not be danger of the local authority imposing schemes upon the local medical profession.

Lord Dawson, before replying to the questions, said that he thought the profession owed a great debt of gratitude to Dr. Addison for the liberality with which he had approached this subject. (Hear, hear.) Dr. Addison's suggestion that an interim report should be published showed how anxious he was to have the benefit of the collective wisdom of the profession in the steps which had to be taken. A good many of the comments which had been made could be met by the reply that this was an interim report, and that it was meant to show the trend of thought of the Council rather than to embody final conclusions. No one supposed that the institutions he had outlined were going to be set up at once. They might take years, but the important thing was to be aware of the direction. A big view must be taken and time given for the scheme to fructify. The clinics were not bound to be on rigid lines, and a collective surgery was within the four corners of the scheme. As for free choice of doctor, the desire for this was rooted in the English

people. There was no profession more individual than theirs, and none in which personal harmony between the professional man and his client was so necessary. The primary health centre had been criticized on the ground that it was too large, but it would not be possible to get the efficiency they wanted save in institutions above a certain size; moreover, they wanted something which would create a motive for bringing men together. In conclusion, he hoped that the profession would realize the importance of the present issue. Medicine had the opportunity to make its voice heard in the putting forward of a collective policy. A clear vision of the needs of the future was needed, and boldness and comprehensiveness in meeting those needs. The profession must stand united on essentials, and have no useless disputation over non-essentials; it must realize also that its strength and interests alike lay in the study of the public weal. The profession would then go on to ever-increasing influence and esteem. (Applause.)

A vote of thanks was accorded to Lord Dawson by acclamation.

VITAL STATISTICS OF ENGLAND AND WALES.

(Continued from p. 775.)

CANCER MORTALITY.

In 1918 there were recorded 41,227 deaths from cancer—18,078 among males, including 443 in non-civilians, and 23,149 among females; for both sexes these figures imply the highest crude mortalities yet recorded. Of the 41,227 deaths, 27,080 were ascribed to carcinoma, 2,175 to sarcoma, and 11,972 to "cancer." The standardized mortality rates were 953 per million among male civilians, 986 among females, and 969 among all civilian persons, as compared with rates of 914, 994, and 955 respectively in the years 1911-14. Owing to the limitation in 1918 of the statistics for males to the civilian population, on the assumption that cancer mortality of males at 15-45 has remained as in 1911-14 (as it has, substantially, at higher ages), the standardized mortality of males is reduced to 912 in 1918. It may thus be stated that since 1914 cancer mortality has shown no increase for either sex. The principal features of the tables showing the parts of the body affected by fatal cancer, and the mortality rates at different ages from cancer of various organs remain much the same year after year; for instance, the mortality of females from cancer of the portion of the alimentary canal above the stomach is a small fraction only of that among males, but females suffer more from intestinal cancer. There were 3,669 cases of cancer of the stomach and 1,841 of cancer of the rectum in males, but only 3,185 and 1,456 respectively in females. Among females there were 392 fatal cases of skin cancer as compared with 647 (of which, however, 195 occurred in the penis and scrotum) among males. The excess of cancer mortality in the female sex is dependent on diseases of the breast and generative organs; if such deaths are excluded among both sexes, deaths of females are reduced from 23,149 to 14,070, but those of males only from 18,078 to 17,242.

At the request of the Director of the Cancer Research Fund, and with the object of comparing institutional experience—in which in the majority of cases the causes of death have received *post-mortem* confirmation—with the certification of other cases of cancer in which this evidence has been lacking, separate tabular statements are given of deaths occurring in institutions. Dr. Stevenson remarks, however, that the institutional deaths cannot be assumed to be a fair sample of the whole; they are subject to some selection by age, and it is possible that there may be a greater relative frequency of cancer of certain sites among that section of the population which chiefly furnishes deaths reported from institutions.

TUMOURS NOT RETURNED AS MALIGNANT.

The deaths from tumours other than those ascribed to cancer or other malignant tumours are grouped together in a table which includes deaths from glioma, from uterine fibroid, fibromyoma and myoma, from ovarian cysts and cystadenoma, from laryngeal papilloma and from pancreatic cyst, as well as deaths ascribed to non-malignant tumours or tumours of unstated nature in any site; in all 2,032 deaths are included, of which 933 and 1,099 were returned

as due to tumour of non-malignant and unascertained nature respectively.

Of the 1,099 cases of undetermined nature no less than 752 were cerebral tumours, regarding the nature of which it is difficult even in institutional practice to obtain precise information. An examination of the age distribution of the 347 tumours of undetermined nature affecting organs other than the brain showed that nearly 85 per cent. occurred after the age of 45, as compared with about 90 per cent. for cancer and 67 per cent. for benign tumours, so that a large proportion of this group may have been malignant. Of the 752 deaths from cerebral tumour of unstated nature, 434 occurred among persons below 35 years of age; many of these tumours may thus have been of non-malignant character. Deaths ascribed to non-malignant tumours were nearly thrice as numerous among females as among males. If, however, the large number of deaths from ovarian and uterine tumour be deducted, the male mortality in this group considerably exceeds the female; this is due to the frequency among males of fatal non-malignant tumours of the bladder and prostate. If every death ascribed to tumour of unascertained nature were assumed to be malignant, the cancer mortality figure would only be increased by 3 per cent.

VARIOLA AND VACCINIA.

The number of deaths from small-pox during 1918 was three, but the diagnosis was uncertain in two of them. One was a woman aged 50, whose death was attributed by a coroner's jury to fatty degeneration of the heart consequent upon toxic purpura, but the Local Government Board suspected haemorrhagic small-pox. In the one case in which there was no doubt, the patient was a girl aged 5 (a Belgian refugee), who apparently contracted the infection on a ship, as she developed the disease shortly after arrival in this country. The number of non-fatal cases of small-pox notified rose from 4 in 1917 to 63 in 1918.

Three deaths were assigned to vaccinia; two occurred in infancy, being associated in one instance with pneumonia, and in the other with bronchitis and cellulitis of the scrotum. A third death was of a male aged 18 years, returned as due to vaccinia of twenty-one days' and septicaemia of eight days' duration. In another case an infant aged 8 months, recently vaccinated, was certified as dying from erysipelas and pertussis. The death of one soldier from asthma after antityphoid inoculation was recorded but classed as asthma.

(To be continued.)

ROYAL MEDICAL BENEVOLENT FUND.

At the meeting of the Committee, held on May 11th, 25 cases were considered and £218 8s. voted to 17 of the applicants. The following is a summary of some of the cases relieved:

Daughter, aged 60, of M.R.C.S.Eng. who died in 1875. Health very bad through overwork, which was voluntary, in an army canteen. She lives with a friend, and they share expenses. Applicant is a trained nurse. Income from shares £28, from property £25. Voted £12 in twelve instalments.

M.R.C.S.Eng., aged 79, widower, has two daughters, ages 43 and 41, living at home, the elder as housekeeper, the younger an artist, who earns a very precarious living; two other daughters are nurses, and contribute £32 each a year towards the home. Other income from investments £120, the capital of which cannot be used. Rent and rates £54 9s. Applicant in a very delicate state of health, as are the two daughters living at home. Voted £26 in twelve instalments.

Daughter, aged 68, of M.R.C.S.Eng. who died when applicant was a child. Had an accident a few years ago, and is now lame and unable to work. Only income an occasional gift from friends. Rent 7s. 6d. a week for one room. Relieved six times, £46. Voted £12 in twelve instalments.

Daughter, aged 35, of M.R.C.S.Eng. who died in 1906. Suffers from very bad health, and is now in a nursing home, and her sister has to pay all expenses, which she cannot afford to do. Applicant quite incapable to work. Relieved three times, £45. Voted £18 in twelve instalments.

Widow, aged 46, of M.B.Glas. who died in 1910. Has one son, aged 12, at school. Was left unprovided for, and is now making a living by letting rooms. Last year she received £168 by this. Rent and rates £68. Finds she cannot manage owing to the high cost of living. Relieved once, £10. Voted £10 in two instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, C.B., F.R.C.S., at 11, Chandos Street, Cavendish Square, London, W. 1.

British Medical Journal.

SATURDAY, JUNE 12TH, 1920.

THE GALTON CHAIR OF NATIONAL EUGENICS.

ELSEWHERE in this issue we describe the formal opening by the Minister of Health of the new institute of eugenics and applied statistics in the University of London. The new buildings are the outward and visible sign of a movement of scientific opinion which has already affected all the biological sciences in this country, medicine and sociology in particular, and will affect their development to an increasing degree in the future. The movement dates from 1895, when Professor Karl Pearson, then Professor of Applied Mathematics at University College, delivered a course on the mathematical theory of statistics. This was the beginning of the Biometric School in which he gathered about him a small band of workers, men and women who shared his enthusiasm. The doctrine to be spread was that statistics in one form or another are fundamental in nearly every branch of science in the same manner that mathematics are fundamental in astronomy and physics. Like all innovations, the new doctrine incurred opposition and even ridicule. This was not surprising, since it implied that inadequate and even erroneous processes were being employed in medicine, anthropology, and sociology, and that new and sounder technical methods must be learnt and used. Criticism was met by hard work, and ridicule with the rapier of fact. From the first the new school had the sympathy of a few, among whom Francis Galton and Weldon were the chief. Professor Pearson proved himself a first class fighting man; the courage and skill with which he defended the new doctrine proved the strength of his conviction, and must have weighed with the Drapers' Company of the City of London in giving its support by way of an annual grant, which has been devoted to defraying the cost of the publication of a long series of *Research Memoirs*. The Eugenics Laboratory has also published a series of memoirs and lectures, and *Biometrika*, a journal founded in 1900 with the assistance of Professor Weldon and Sir Francis Galton, affords scope for publication of current memoirs from both laboratories.

The importance of the study of eugenics to a nation just emerged from a catastrophic war is sufficiently evident, and, had Professor Karl Pearson done no more than develop the ideas of Francis Galton in this department of research, his claim upon our gratitude would have been great. But the influence of the Galton professor has been wider than this. In his presidential address to the British Medical Association last year,¹ Sir Clifford Allbutt pointed out that statistics, once a byword, were becoming powerful instruments of medical research. That this is so is due far more to Professor Pearson than to any of his contemporaries or predecessors. A majority of those

now applying statistical methods to medical problems were his pupils and all have been inspired by his publications.

The reason for this widespread influence is instructive. There have been in the past statisticians as deeply versed in mathematical science as Professor Pearson; there may even have been—although we cannot recall any name save that of Farr—as zealous and prolific researchers; but Professor Pearson stands alone in his mastery of the art of combining theory with practice. We recall a modern textbook of mathematical statistics by an eminent German professor which contains hundreds of equations but not, from cover to cover, a single arithmetical example of the manner in which these equations can be applied to practice. Professor Pearson has put forth many abstruse mathematical arguments, but he has never failed to illustrate them with arithmetical examples. The consequence is that all his papers can be consulted with some advantage by those whose training does not suffice to allow them to follow a purely mathematical argument. That a great mathematician should impose upon himself the heavy additional labour of rendering his work intelligible to the non-specialist is a matter for comment. It is an example which might well be followed by many specialists within our own profession whose temptations to remain obscure are much less strong.

This is not the place to particularize the many discoveries of importance to scientific medicine which Professor Pearson has made; sometimes the conclusions at which he has arrived have not been acceptable to all, but they have invariably been supported by arguments of great force luminously expressed. We know that we give expression to the opinion of all medical men when we assure Professor Pearson that members of our profession take a national pride in the work which he has done during the past twenty years, and express the hope that the newly established institute will, under his direction, continue to contribute to the advancement of those sciences of which he has been so devoted a servant.

We have here dwelt on the importance of the work the institute can do for medicine and its allied sciences, but similar work is as urgently needed in sociology and in economics. That it is needed also in commerce and industry is evidenced by the fact that the giver of the new buildings, Sir Henry Bartlett, is engaged in a pursuit which involves both. The new buildings are admirably adapted to their purpose, but they are imperfectly equipped and inadequately manned. The University has therefore authorized an appeal for an additional income of £5,000 a year in the form either of capital endowment or of annual grants. The Drapers' Company has been so well rewarded for the help it has given to this new and very important department of science that it may well be encouraged to do more, and we hope that other city companies will be prepared to follow its example.

SECURITY OF TENURE FOR HEALTH OFFICERS.

It is a long cry back to 1904, but on reference to the files relating to the subject it appears that in October of that year the President of the Local Government Board was asked by the British Medical Association to include provision for security of tenure for medical officers of health in any public health legislation it might be contemplated to bring before Parliament at an early date. Since that time the fruits of victory

¹ *Proceedings of the Special Clinical and Scientific Meeting*. London, April 8th to 11th, 1919. London: The British Medical Association. (Demy 8vo, pp. xvi + 435.) The volume is published at the price of 3s., but copies will be supplied to members of the Association free on application to the Financial Secretary of the Association, 423, Strand, London, W.C.2.

have more than once been almost within the grasp of the Association, but a change of Government or some unexpected event has snatched them away and a fresh start has had to be made.

A Public Health Bill was prepared by the Association in 1906, but a deputation which had been arranged fell through because the Government went out of office. Further efforts at legislation were made in 1907, but the Association's bill had to be dropped. In 1908 the bill obtained a first reading, but got no further. An effort was then made to get security of tenure by means of amendments in the Housing and Town Planning Bill in 1909, but these were ruled out of order. In 1912 a new bill was prepared, but parliamentary congestion prevented its introduction; in 1913 a bill was again read for the first time, but eventually dropped. Meanwhile, with the able assistance of Sir Philip Magnus, valuable spade-work was being done, and in June, 1914, a large and influential deputation, consisting of members of the Association, medical officers of health, sanitary inspectors, and members of the Housing and Town Planning Association, together with other influential persons, was received by the Chancellor of the Exchequer, the President of the Local Government Board, and the President of the Board of Education. This deputation was introduced by Sir Philip Magnus and Dr. Addison. Promises were then given which were considered entirely satisfactory, and an Order granting security of tenure was actually drafted when the war intervened, and again the clock was put back. Recently, however, the Association, feeling that public health affairs were returning to their normal state, wrote to the Minister of Health reminding him of the promises made to the deputation and asking when effect would be given to them. Sir Philip Magnus also took the matter in hand, and he has received from Dr. Addison the following letter, which seems to indicate that the long struggle has at last ended successfully: "I have looked into the question of giving security of tenure to medical officers of health who give their whole time to public work. I find that the Local Government Board had an Order prepared to give effect to the promise which was made to you in this matter, but that it was not issued, partly because of the disorganization of the medical services of local authorities due to the war and partly because of the doubt whether security of tenure could be given to existing officers who were appointed for limited periods. Now that the medical staff of local authorities is restored to its normal strength, I will have the Order proceeded with, and will go as far as I can in giving security to whole-time medical officers. I propose to include sanitary inspectors and inspectors of nuisances in the Order on the same terms."

Intimately wrapped up with security of tenure has been the question of superannuation for public health officers, and there are not wanting signs that this question will soon be settled on a satisfactory basis.

The thanks of the Association and of medical officers of health are due first of all to Dr. Herbert Jones of Hereford, who has been the pioneer of the movement, the chief draughtsman of most of the memorandums and petitions on the subject, and the chief spokesman on many occasions. He may well feel proud of his share in this achievement. Sir Philip Magnus's parliamentary work has been invaluable, and he has shown a persistence, a sympathetic interest in the subject, and a perception of the right time to act which have added greatly to the debt the medical profession already owed him. Dr. Addison's action will be gratefully recognized by the profession. As

an unofficial member of Parliament he did all he could to further this reform. Now, when in a position to do so, he gives effect to it.

THE COMPOSITION OF SALVARSAN.

THE position of salvarsan is in some ways unique. Represented as an organic compound of definite structure, it yet exhibits, in different samples, variations of toxicity so considerable that a rigid biological control of the properties of every batch is essential. Although these variations are the result of inappreciable and uncontrollable differences in the process of manufacture, their basis must ultimately be chemical, even though they may be due not so much to the presence of impurities which are toxic in themselves, as to small changes in the physical properties of the product, which small fluctuations in the proportion of certain by-products entail. Any further light on the chemistry of salvarsan, as prepared on the large scale and issued for therapeutic use, is therefore greatly to be welcomed. The important paper by Fargher and Pyman,¹ which was recently issued from the Wellcome Laboratories, probably contains, in condensed form, the most extensive account hitherto published of the chemistry of the commercial product, and of the directions in which it differs from the substance represented by the theoretical formula.

The most interesting and illuminating section of the paper is that dealing with the sulphur content of salvarsan. Ehrlich and Berthelm had mentioned the formation of toxic impurities during the reduction by hyposulphite, in which sulphur was attached to the arsenic of the molecule, and had prescribed the addition of magnesium chloride to the reduction bath to prevent this; the recommendation has always been obscure, and is not here dealt with. Fargher and Pyman, however, seem to have been the first to recognize that all specimens of salvarsan prepared by the hyposulphite process contain sulphur in varying proportions. This observation they had privately communicated to the Salvarsan Committee,² and it had been independently noted by American workers since then. They are now able to describe the separation from commercial salvarsan of a small proportion of a definite compound, in which the sulphur is attached to one of the amino groups as a sulphamic acid. The remainder of the sulphur they suppose, with Ehrlich and Berthelm, to be attached to the arsenic, though they suggest that some may be in merely physical association with salvarsan.

It would seem, then, that salvarsan as ordinarily made by reducing nitro hydroxy-arsenobenzene with hyposulphite, includes small but varying proportions of at least two sulphur-containing compounds, which are not represented in the familiar formula. It should be added that there is no clear evidence that these by-products increase the toxicity of the preparation; on the contrary, as mentioned in the Salvarsan Committee's report above quoted, a sample of very pure "606," prepared by Dr. Pyman with the aid of hypophosphorous acid as reducing agent, and therefore quite free from sulphur, was deficient in solubility and more toxic than the ordinary less pure product. But whether such by-products are harmful, or, as seems possible, have in certain proportions a beneficial effect on the properties of the product, a clearer definition of their nature and the isolation of one of them mark an important advance in our knowledge of this wonderful remedy.

BIRTHDAY HONOURS.

PERHAPS the most interesting statement in the birthday honours list is that the honour of knighthood to Professor Frederick William Andrewes is bestowed "for valuable work in medical research." Never was the reason for giving an honour more succinctly and truly stated, for Professor Andrewes, whether as an observer, experimenter, or critic, wields a great influence in the study and teaching of pathology in this country. The K.B.E. is conferred on Dr. J. Dundas Grant, president of the special aural board at the Ministry of Pensions, and well known otherwise as an aural surgeon; on Mr. Arnold Lawson, ophthalmic surgeon to the Middlesex Hospital, in recognition of his work as ophthalmic surgeon to St. Dunstan's Hostel for the Blind; and on Colonel William Taylor, C.B., A.M.S., who became consulting surgeon to the forces in Ireland in 1916, and is an ex-president of the Royal College of Surgeons in Ireland. The honour of knighthood is conferred on Dr. S. R. Alexander, mayor of Faversham 1908-19, for his public and municipal services; on Dr. Sydney Beauchamp, who was resident medical officer to the British delegation during nearly the whole of the peace conference in Paris; on Alderman Charles O'Brien Harding, L.R.C.P., mayor of Eastbourne in 1903 and from 1906-19; and on Colonel H. E. Banatvala, C.S.I., I.M.S., late Inspector-General, Civil Hospitals, Assam. The Kaisar-i-Hind medal for public services in India has been received by Dr. D. H. Mehta, medical officer Patao Hospital, Baroda, and Dr. S. R. Moolgavkar, principal medical officer Bikaner State, Rajputana.

PSYCHOLOGY AND MENTAL PATHOLOGY.

THE notes of the three lectures on psychology Professor Janet delivered in London for the University of London (published in the *JOURNAL* of June 5th) will have been sufficient to show that he is an apostle of behaviourism in its most extreme aspect. He adopts the view that our body is an instrument which receives movement from the outside and restores it to the external world. The brain differs from other parts of the body in that it does not always reproduce the energy it receives immediately in movement, but may store it up for ulterior movements. The body and brain together are an instrument of movement and nothing else; and in movement we must not look for anything else than what is observable. If the brain is diseased, it is only its movement and nothing else that is affected. So far the dynamic view of Janet follows the views of Bergson, but Bergson parts company when Janet denies that material movements can produce psychical or conscious life. So long as it is recognized that a consistent physical view such as that advocated by Janet is a methodological abstraction there is little to be urged against it. It is in agreement with the view of Münsterberg, who also is of opinion that the whole of psychology is a temporary stop-gap by which we eke out our defective physiology, and that sooner or later it must cease to be of use and therefore cease to exist as physiology advances. Nor does it lay itself open to the reproaches that Averniarius has heaped on the "introjectionist" transformation of the naively realistic standpoint. It may well be that for the purposes of the physician the study of movements or behaviour afford the only safe data for the elucidation of mental disease. We must, however, be prepared to pay a price—teleological unity of interest or purpose must be ruthlessly banished from the study of psychology. The ethical appreciation of human conduct and the historical interpretation of it in terms of ends and ideals becomes impossible, for they can only be expressed in teleological terms, and we suspect the same limitations will be found to apply to aesthetics. We can hardly quarrel with the tendency of the English and Scottish school which resolutely refuses to thus limit its terms of reference. A methodological survey of the scope of medical psychology

is of urgent importance; Professor Janet has clearly defined his attitude, and we would welcome some similar pronouncement on the part of our own teachers of psychotherapy.

OPERATION FOR ARTERIAL EMBOLISM.

THE treatment of arterial embolism by operation and removal of the embolus appears to have been first attempted in 1895, by Ssabanjeff, in the femoral artery; so far as the lesser circulation is concerned, the extraction of a pulmonary embolus was first attempted in 1907 by Trendelenburg. In neither instance was the operation successful. Dr. H. Sundberg¹ has collected from the literature twenty cases of operation on arteries for embolism, with six successes, four of them, including his own case, achieved by Swedish surgeons. His patient was a landholder aged 63, admitted to hospital with heart-failure; the heart's action was completely irregular, no murmur was identified, the blood pressure was 145 mm. Hg, the arteries were sclerosed, and digitalis and diuretin were given. Nine days later symptoms and signs of embolism of the left femoral artery suddenly appeared, and Sundberg concluded that the obstruction was at the point where the profunda femoris branches off from the femoral artery. He operated twelve hours after the onset, under local anaesthesia and one-fifth of a grain of morphine, exposing the arteries above and below their junction. The femoral artery was found to be filled with a solid mass extending 2 cm. above this point; an incision 2 cm. long was made into it opposite the origin of the profunda, and the proximal piece of clot was carefully withdrawn after clamping the free artery above. The profunda bled freely, and was clamped. Relaxation of the clamp on the femoral artery was followed immediately by free haemorrhage. The distal portion of the clot was then grasped with forceps and carefully withdrawn. It proved to be 86 cm. (almost 34 in.) in length, smooth, with a single short branch at about the bifurcation of the popliteal into the anterior and posterior tibial arteries; its distal end was even and smooth. Removal of this clot was followed by a gush of blood, and the vessel was clamped. The opening in the femoral artery was then sewn up, great care being taken to pass the needle through the external and middle coats only, and to leave the arterial intima untouched; very fine silk soaked in paraffin was used for the sutures. The three clamps were removed, no bleeding followed. Catgut subcutaneous sutures were inserted, and the wound closed. Five days later signs of thrombophlebitis appeared in the left calf, but this settled down in a fortnight. The patient was up and about six weeks after the operation, and presently returned to his home, writing thence two months later to say that he was well, and his left leg free from unpleasant feelings. Sundberg does not specify the nature of the embolus in his case; with regard to the clot, he remarks that it was of the same length as the patient's leg from the opening in the artery to the sole of the foot, and he quotes cases operated on fourteen and ten hours after the embolism, in which the clots found on operation were 12 and 3 cm. long respectively.

AN OUTBREAK OF PELLAGRA IN A REFUGEE CAMP.

THE Public Health Department of the Egyptian Ministry of the Interior has published a report by Dr. R. G. White, Deputy Director of the Public Health Laboratories, Cairo, on an outbreak of pellagra which occurred during 1916-17 in the Armenian refugee camp near Port Said. Armenians to the number of 4,058, including 700 adult males, were driven by the Turks from hillside villages near Antioch, and arrived in a debilitated and exhausted condition at the camp in September, 1915. The camp had an admirable water supply from the Port Said system and efficient

¹ *Hygiea*, Stockholm, 1920, lxxxii, 1.

sanitation. In February, 1916, the first manifestations of pellagra appeared in the form of gastro-enteritis, stomatitis, and gingivitis; parotid swelling was uncommon. Two months later dermatitis was noted, and early in May the outbreak was recognized to be pellagra. The skin lesions noticed were symmetrical erythematous dermatitis of the hands, feet, face, and neck; the demarcation lines showed a raised edge. In severe cases anaemia, cachexia, and nervous symptoms supervened; the mortality was about 4.7 per cent. of those affected. Bacteriological examination of the skin lesions, buccal secretions, and excreta showed nothing of importance, and *Simuliidae*, or other blood-sucking insects, were not found near the camp. Blood examinations showed slight neutrophilia, with a small relative increase of myelocytes, metamyelocytes, and red-nucleated cells. The refugees came from a district where pellagra is unknown, and Dr. White regrets that, owing to the insufficiency of the medical staff, it was not possible to make fuller investigations of the origin of the epidemic. It is clear, however, from the report that the disease was primarily due to a faulty dietary. During the first six months after the arrival of the refugees the ration issued was far from sufficient, and their means of adding to it were unsatisfactory; it was at the end of this time that pellagrous symptoms were noted. During a period when the men received employment outside the camp and were able to supplement the official rations a great improvement became evident, and the number of new cases was diminished. When this employment ceased and the refugees had to depend on the official dietary, the disease recurred in a more severe form. In February, 1917, a full ration was issued to all occupants of the camp irrespective of any additions they might themselves be able to make; a special ration was issued to those showing any signs of pellagra, and special meals were served to the children. As a consequence of these measures no new case of pellagra was seen after June, 1917. It was not found possible to establish with any precision the existence of dietetic factors to the presence or deficiency of which the outbreak could be attributed. It was concluded that the consumption of maize—which in the early months formed 25 per cent. of the flour used—could only have been a factor in the causation of the outbreak in so far as it was responsible for some deficiency in the diet; it had no direct causal relation to the disease. The composition of the daily diet of the adult male in the period preceding the epidemic was: Protein 47.6 grams, biological value 23 grams (approximately 95 per cent. from vegetable sources); fat, 26 grams; carbohydrates, 449 grams; heat value, 2,280 kilo-calories. It is possible that the very low fat value of this diet was of importance in the causation of the outbreak. Dr. W. H. Wilson points out that the lesions of pellagra appear in tissues such as the skin and nervous system, where fats are specially important. 83 per cent. of the fat of the diet was derived from vegetable sources; it included 23 per cent. of cottonseed oil, which the Armenians (who had been accustomed to olive oil) disliked. It is interesting to note that at Alexandria, in an encampment of Jewish refugees from Palestine, who did not exhibit such a dislike and partook freely of the same oil, no pellagra occurred. But this observation does not throw much light on the matter, for their bread was not mixed with maize, and they were able to supplement their official ration by purchases made from their earnings.

ADVANCED CANCER OF THE CERVIX RENDERED OPERABLE BY RADIUM THERAPY.

It is a matter of common experience that the great majority of cases of cancer of the cervix uteri when first seen by the surgeon have already reached the inoperable stage. Occasionally this may be attributable to the omission of the medical attendant, before prescribing treatment for cases of irregular haemorrhage or

discharge, to make a local examination; usually, however, it is due to the neglect of the patient to seek medical advice at the time of the appearance of the earliest symptoms. Many reports have been made of the palliative application of radium in inoperable cases;¹ as a rule there has resulted a shrinkage of the growth and its extensions, together with abatement or disappearance of the chief symptoms; although recurrences or relapses have usually followed, the patients have gained at least twelve months' extension of life. Few instances, however, have been reported of radium therapy used with the purpose of making it possible subsequently to perform hysterectomy by Wertheim's method; particular interest, therefore, attaches to the experience recorded by Dr. Fletcher Shaw and Dr. Arthur Burrows, of Manchester, at the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, on June 3rd. Dr. Fletcher Shaw attempted to perform wide hysterectomy in fourteen cases in which radium had been applied two months previously, at a time when the cancerous condition appeared to be inoperable. In six of these cases operation had to be abandoned on account of the presence of scar tissue, of cartilaginous consistency, which was found to adhere to the ureters or bladder, and to prevent the dissection which is a necessary preliminary to wide hysterectomy. Of the remaining eight cases, one died two days after operation, as a consequence of intestinal obstruction; two exhibited recurrence within eighteen months; and five had remained well—six years, two and three-quarter years, one and three-quarter years, fourteen months, and ten months respectively after the operation. Formerly in inoperable cases, when the patient was opposed to radical measures, the combined treatment was not pressed; as a result of his experience, however, Dr. Fletcher Shaw now feels justified in speaking much more favourably of the results of radium therapy employed as a preparatory measure before operation. It is to be noted that of the patients in whom the combined treatment was completed all but one had passed the menopause. Dr. Burrows recommends the insertion for twenty-four hours of five or more $\frac{1}{16}$ mm. pointed platinum tubes; a larger central silver tube is introduced into the cervical canal. Not less than 240 mg. of radium bromide, corresponding to about 120 mg. of radium metal, or 120 millicuries of emanation, are used at one, two, or rarely three sittings. Among 150 cases of inoperable cancer of the cervix treated by radium up to 1917 he found that twenty-eight, or 20 per cent., became operable. Of his cases treated during the last two and a half years, 20 per cent. were well at the end of one year, and had nearly all become operable. Many other surgeons in operating after the application of radium have encountered difficulties, due to the presence—near the ureters especially—of dense, unyielding scar tissue, which, as a result of the action of radium emanations, has replaced neoplastic and inflammatory material. Dr. Fletcher Shaw and Dr. Burrows, as well as other gynaecologists who contributed to the discussion at the Royal Society of Medicine, proposed to consider the advisability of operating on the second day after the completion of the exposure to radium—that is to say, at a time when the destructive action of the emanation on the malignant cells has been completed and the hard hyaline fibrous tissue, which at operation makes dissection so difficult, has not yet been formed. In contemplating such a procedure, however, the risk of post-operative sloughing has to be taken into account. According to Dr. Burrows, the use of radium therapy is not advisable if the tumour be very voluminous, or if a large excavated ulcer is surrounded by a thin shell of damaged tissue; in such cases there is risk of extensive sloughing and formation of fistulous communications. Several surgeons have reported the formation, after application of radium, of fistulas between the vagina and the rectum, urethra, or bladder. Dr. Burrows believes that if excessive

¹ See the article on the report of work of the Radium Institute for 1919, BRITISH MEDICAL JOURNAL, May 8th, 1920, p. 612.

dosage is avoided and unsuitable cases are excluded from radium therapy these results occur in at least as small a proportion of treated as of untreated cases.

THE BATHS OF OLD LONDON.

THE spas, baths, and wells of old London were made the subject of an interesting antiquarian study by Dr. Sunderland a few years ago,¹ and more recently he has written an account² of the baths that were established in the metropolis in times long past. The oldest of these, and by a happy chance one of the very few survivors, is the old Roman spring bath or plunge bath in Strand Lane, near King's College. Thought to have been built in the time of Titus or Vespasian, it preserves what appears to be Roman masonry in its walls, and is supplied with a runnel of clear water coming from springs at Hampstead. In the year 1502 baths fed from the St. Agnes-le-Clair spring near St. Luke's Hospital were established; they fell into disuse in the middle of last century, and their site is now occupied by St. Agnes Terrace between City Road and Hoxton. The Templars' Bath, adjoining the Roman bath from which it obtained its water supply, was built by the Earl of Essex in 1588, and was used for three centuries by residents in the Temple; it was closed in 1893, and its site is now occupied by the larder of the Norfolk Hotel. Queen Elizabeth's bath in the King's Mews, near Charing Cross, thought to date from the fifteenth century, was destroyed only ninety years ago in the creation of Trafalgar Square. In addition to these four older baths, several other bathing pools were established in the seventeenth century, with varying fortune. Among these may be mentioned Peerless Pool, behind and north-west of St. Luke's Hospital, in the City Road, drained in 1850; the Cold Bath, at the north-west end of Tottenham Court Road; the Cold Bath, Clerkenwell, off Farringdon Street and near the river Fleet; a bath at Shadwell Spa, Wapping, recommended in 1745 for scorbutic and cutaneous disorders; Queen Anne's bath, fed by a chalybeate spring, at the back of what is now No. 35, Endell Street, Long Acre; and the Grotto Cold Bath in Marylebone, near the present Grotto Passage. The river Thames sported two floating baths as late as 1868, no doubt much like those now visible on the Seine in Paris, and Pepys makes mention of such a bath in 1688. Dr. Sunderland also catalogues a number of the "sweating baths" so common in the London of the later middle ages and subsequently; after a period of disuse they reappeared towards the end of the seventeenth century under the Italian name "Bagnio," to pursue a chequered and often scandalous career, ending in suppression. He adds a note to the effect that baths and washhouses for the working classes originated in 1844, thanks to the labours of an association for promoting cleanliness among the poor.

THE SERVICES OF THE ARMY MEDICAL DEPARTMENT.

WHAT the Earl of Middleton described as a public ovation—the only instance since the armistice of such a tribute to a particular branch of the army—was given in honour of the Royal Army Medical Department and its associated civilians on June 8th. The appreciation took the form of a dinner at the Connaught Rooms, when the single toast (apart from the loyal toast) was "The Royal Army Medical Department and the eminent civilians attached to it during the war." About 180 sat down at the tables, and the thirty hosts included many eminent administrators, both military and civil. Lord Middleton occupied the chair because, with the exception of Lord Lansdowne—one of the hosts, who was unable to be present—he was the senior in point of date of those who had held the office of Secretary of State for War. On his left hand was Mr. Winston Churchill, the present War Secretary,

on his right the guest of the evening, Sir Alfred Keogh, and next to him Field-Marshal Earl Haig. Among those at the principal table were the Marquis of Salisbury, the Earl of Donoughmore, Earl Fitzwilliam, Viscount Burnham, Lord Dawson, Lord Horae, Lord Methuen, Lord Rawlinson, Sir William Babbie, Sir Anthony Bowlby, Sir John Goodwin, Sir Arbutnot Lane, Sir George Makins, and Sir Arthur Sloggett; while among those presiding over the smaller tables were Lords Knutsford, Desborough, Somerleyton, Harris, Lee of Fareham, and Waverley, Lord Edmund Talbot, Sir Arthur Stanley, Sir Herbert Creedy, Sir Ivor Philipps, and the secretary of the dinner committee, Sir Edward Ward. A message was read from the Duke of Connaught, expressing his pride at being colonel-in-chief of a corps which had rendered such great service to army and country, and there were other messages from Lord Derby (one of the hosts), Viscount French, and Lord Islington. The toast of the evening had three proposers—the Chairman, Mr. Churchill, and Lord Haig—and Sir Alfred Keogh, Sir John Goodwin, and Sir George Makins replied. A report of the speeches will appear in our next issue. During a visit to the Military Hospital at Millbank on June 8th the King inspected the memorial tablets placed in the recreation room. The tablets show the removal of a wounded man from a front line trench, a regimental aid post, a main dressing station, and a hospital train. The memorial inscription runs as follows: "This room was remodelled and the sculptures erected in appreciation of the devotion to duty of the R.A.M.C. and of their sufferings in the relief of suffering in the great war. The cost was defrayed out of a fund generously placed at the disposal of King George V by Major W. Keefer of Toronto—1914–1919." The King also visited the nursing home for senior officers at the hospital and invested General Gorgas, P.M.O. of the American army, with the insignia of K.C.M.G., in recognition of his services to the British Empire and to the commercial world, especially through the work he did as Chief Health Officer during the construction of the Panama Canal. We regret to learn that General Gorgas is a patient in the hospital, and hope for his speedy recovery.

NAVAL MEDICINE AT THE IMPERIAL WAR MUSEUM.

In the Naval Medical Section of the Imperial War Museum, opened by His Majesty the King at the Crystal Palace on June 9th, the opportunity is afforded of learning something of medical treatment as carried out in specially difficult conditions of naval warfare. The naval section of the museum contains models, schematic sections, and photographs of hospital ships; a picture of such a ship at night, with abundant illumination, including a prominent red cross, is of interest when the fate of several British hospital ships is remembered. The disposition and treatment of the wounded within the combatant vessels are well illustrated in a series of noteworthy pictures by Jan Gordon and by Oswald Moser. Specimens are shown of the light-tight scuttle ventilators devised by Surgeon Commander M. H. Knapp; these admit air freely to well-lighted sick quarters, but preserve invisibility. Transport of the wounded is a matter of special importance in naval warfare, and examples are shown of the cots, cages, slings, and stretchers employed, as well as photographs of the internal arrangements of the naval ambulance train, which was described in our issue of July 27th, 1918. Preventive methods are illustrated by models of the special helmets, gloves, and clothing worn for "anti-flame" and "anti-flash" protection during action. An interesting exhibit shows the development of the naval respirator, which can be worn in three or four different positions, and in order to prevent deviation of the compass is provided with a container of brass. The museum contains numerous examples of medical appliances used in the German navy. Among these are a life-saving jacket, with a compressed air cylinder and a purifying chamber, and an apparatus for

¹ See the BRITISH MEDICAL JOURNAL, 1915, ii, 869.

² Transactions and Eighth Annual Report of the London Dermatological Society, London: J. Bale, Sons and Danielsson, Ltd. 1920. (Demy vo, pp. 75. 2s. 6d. net.)

delivering oxygen to four individuals; both these appliances are for use in submarines. The German sick-bay cot consists of an iron cage suspended from two metal uprights, and is extremely heavy as compared with that used in the British fleet. Bandages and lint made of paper, as well as a tourniquet in which indiarubber is replaced by a spring, are examples of expedients devised by the Germans to make up for their lack of raw materials.

Medical Notes in Parliament.

Proposed New Site for the University of London.

NUMEROUS questions have been addressed to the Minister of Education and to the Chancellor of the Exchequer in the House of Commons concerning the offer of a site of eleven and a half acres north of the British Museum, made by Mr. Fisher on behalf of the Government to the Senate of the University of London. Mr. Fisher, in his letter to Lord Rosebery on May 20th, said that the Government had at one time hoped to be able to provide the building as well as the site. This was before the war, however, and they could not, he said, undertake that expenditure in the fresh conditions. But the Government was prepared to make such provision as would secure the University from loss in respect of maintenance charges on the new site. The University now occupies quarters at the Imperial Institute under a Treasury minute of 1899, which not only provides for maintenance but frees it of rates and taxes. According to an unauthoritative estimate, to provide accommodation equal to that afforded at South Kensington would cost £4,000,000, and the buildings now contemplated might mean a liability for rates and taxes of between £60,000 and £80,000 a year. King's College was built upon a site granted by the Government on a lease for 999 years. The building was erected by public subscription, and the question whether the Senate is at liberty to sell has been raised.

In the House of Commons, on June 1st, Mr. Fisher said that the matter was still under negotiation, and he was therefore not able to make any statement as to the price proposed to be paid to the Duke of Bedford. The Government, after full consideration, had decided that the Foundling Hospital site was less suitable. The Government was not attempting to force the University to accept the site. To the objection that so large an expenditure out of public funds should not be incurred at the present time, Mr. Fisher replied that there was the offset of the value of the site and buildings occupied in the Imperial Institute, and added that the buildings held by King's College would be liberated—which suggests that he assumed that the latter buildings were to be regarded as Government property.

On June 3rd Mr. Chamberlain told Sir W. Joynson-Hicks that when the two sites were considered before the war, it appeared that the cost of the Foundling Hospital site would be rather greater than that of the Bedford site. Sir W. Joynson-Hicks put it to the Chancellor that no suggestion had been made to the Foundling Hospital since the war, but Mr. Chamberlain responded that the Government had decided upon what it thought was the best site. He declined to answer an inquiry by Mr. Palmer as to whether the cost of the Bedford site was now a million sterling as compared with £367,000 before the war.

On June 7th Mr. Fisher, in reply to further questions, told the House of Commons that the Government had considered the possibilities of a number of sites, including the Foundling Hospital, a site south of the river between the new County Hall and Hungerford Bridge; another between Waterloo Bridge and Blackfriars Bridge, and also the feasibility of utilizing Somerset House, or of effecting an extension of the present university quarters in the Imperial Institute. Because the Government regarded the Bedford site as the most suitable, negotiations for properties less suitable were not opened. The site offered included four vacant plots, and as the majority of the leases would fall in at different periods after 1925, it would only come into occupation gradually, and it was not necessary therefore at this stage to attempt to estimate the number of persons who might eventually be displaced. The House would, he added, have an opportunity of discussing the matter when the Estimates for public works and buildings were taken.

Medical Practitioners and Motor Car Taxation.

Sir A. Sykes asked the Chancellor of the Exchequer, on June 3rd, whether he could see his way to make some rebate of the horse-power tax on motor cars in the case of medical practitioners, especially those who practise in rural areas, in view of the fact that their work necessitated the use of cars of considerable power, and left only a small margin of profit. Mr. Neal, Parliamentary Secretary to the Ministry of Transport, said the point had been very carefully considered, but, for the reasons stated in paragraph 25 of the Report of the Departmental Committee on

the Taxation of Road Vehicles, the Minister of Transport was unable to recommend a rebate of the proposed taxation of motor vehicles in the case of those used by medical practitioners.

Medical Staff of Ministry of Health.—Mr. Spoor asked the Minister of Pensions, on June 3rd, whether his attention had been called to an advertisement issued by the Minister of Health, inviting medical men to apply for appointments in the Ministry of Health at salaries of £1,000, rising to £1,400 per annum, with pension rights, etc.; whether these appointments were calculated to draw medical officers from the Ministry of Pensions; and whether he could see his way to giving similar salaries and advantages to the medical staff employed by the Ministry of Pensions. Mr. Macpherson replied that his attention had been drawn to the advertisement, which related to certain appointments of a permanent character requiring special scientific qualifications. It was, of course, open to the medical members of his own staff to become candidates. He could not undertake to revise the scales of remuneration of the temporary medical service of the Ministry of Pensions, which were settled so recently as January of the present year. It was not yet possible to forecast the permanent medical arrangements which would be necessary for the purposes of the Ministry. Major Nall asked whether Mr. Macpherson was taking any steps to place disabled medical men in appointments such as this. Mr. Macpherson replied that quite a large number of disabled medical men, certainly men who had served, were now on the staff.

Health Insurance Finance.—Dr. Addison, on June 3rd, in answer to Major Barnes, said that the moneys accumulated under the National Health Insurance Acts up to March 31st, 1920, were as follows:

Investments in the hands of approved societies, or invested on their behalf under Section 56 of the Act of 1911 in securities selected by them, cost £29,000,000.

Investments in the hands of the National Debt Commissioners under Section 51 of the Act of 1911, cost £47,500,000.

Balances of cash in the several National Health Insurance Funds, and in the hands of approved societies and of Insurance Committees, £1,500,000.

The estimated liability in respect of contributions and State grants arising under the National Health Insurance Act, 1920, for the period July, 1920, to July, 1921, was £36,692,000, of which £14,400,000 would be payable by insured persons, £15,350,000 by their employers, and the balance, £6,942,000 out of moneys provided by Parliament.

Asked what would be the increased annual cost if sickness, disablement, and maternity benefits were increased by 140 per cent. over those provided by the Act of 1911, Dr. Addison said that the corresponding cost on the present actuarial basis of the scheme would be increased by £17,950,000, of which £3,400,000 would fall on the Exchequer and the balance on insured persons and their employers. If the benefits for women were on such increased basis made equal to those for men, the total cost would be still further increased by £2,600,000, of which £700,000 would be payable by the State.

Air Raid Claims.—Asked by Mr. Blair, on June 3rd, if a soldier on leave who lost his right arm by enemy action during an air raid was deprived of pension on the ground that his injury was not due to war service, Mr. Macpherson said that was so. If, however, the injury sustained led to the soldier's discharge he might be eligible for a gratuity. Such a man would be considered for training by the Ministry of Labour.

Pensions and Pensioners.—The number of persons receiving pensions in the United Kingdom in respect of disability or death in the present war is approximately 1,700,000, and in addition nearly 1,800,000 wives, children, and other persons dependent on pensioners are receiving allowances, thus making the total number of beneficiaries approximately 3,500,000. The precise number of persons receiving similar pensions or allowances in France is not available, but is said to be in excess of three millions. The number of persons in the employ of the British Ministry of Pensions is 24,892. The corresponding figure for France is not available. The cost of war pensions for the financial year 1920-21 is estimated at £118,211,000. This includes the cost of treatment but excludes administrative expenses.

Rabies in Imported Dogs.—The Ministry of Agriculture reports that two undoubted cases of rabies have occurred among dogs landed from abroad and undergoing quarantine, and a third highly suspicious case is under investigation. In both the cases confirmed as rabies the dogs were landed in an apparently healthy condition. In one case the disease manifested itself after two and a half months' quarantine, and in the other after a period of four months. In the circumstances the Ministry hold the increase in the period of quarantine to be fully justified. No case of rabies has occurred in any animal liberated as healthy after undergoing the statutory period of quarantine.

Answers in Brief.

The number of administrative posts, including those strictly defined as executive, in the Ministry of Health, held by men with a salary of over £500 a year, is 103.

The number of soldiers in hospitals in the United Kingdom who are eligible for demobilization is about 5,000, and the daily cost £2,500. The War Office is satisfied that the hospital treatment is thoroughly adequate.

The total amount of income subject to tax before the deduction of the various personal reliefs and allowances was for the year 1913-14 about £950,000,000; for the year 1920-21 it is estimated that the amount will be in the neighbourhood of £2,200,000,000. Owing to changes in the law relating to income tax the basis of the estimates for the two years differs materially.

England and Wales.

FUTURE PROVISION OF MEDICAL SERVICES IN WALES.

The report¹ of the Welsh Consultative Council on the provision of medical and allied services in Wales has now been issued. We were able last week (p. 781) to give an outline of the report and of its principal recommendations, to which little can be added except with regard to the recommendations for North Wales, which is largely a rural area. The Council recommends that the whole of North Wales, with the northern portions of Brecon, Cardigan, and Radnor, should be regarded as a single area, with large hospitals or institutes at three central places, of which Bangor and Wrexham are specified. There should also be available for the area a large asylum or mental home providing 1,000 beds, a mental deficiency home providing 300 or 400 beds on a site away from the asylum, a central tuberculosis sanatorium, with an adequate number of beds for North Wales, convalescent homes and rest or holiday homes to meet, in particular, the needs of mothers after confinement, provision for the blind and deaf, and for cripples, separate provision for epileptics, a fever hospital in or easily reached from each county, as well as a small-pox, plague, cholera, and dysentery hospital for North Wales. With regard to the local institutions in the various areas of North Wales, it is recommended that each should include, say, 20 beds for medical and surgical cases, a maternity ward, a school clinic, various clinics—for example, dental, tuberculosis, venereal, paediatric, psychiatric—a fully equipped outpatient department, and a hostel for nurses. "The staff of such an institution should include a fully qualified medical officer who, in addition to being the house-surgeon and house-physician, would also be in charge of the various clinics. The cases admitted to these hospitals would, however, be followed through by the general practitioners concerned." Such an institution might serve contiguous areas in the neighbouring counties. It is also recommended that further school and other clinics should be provided in such parts of a county as may not be conveniently served by the proposed local institutes; at these clinics the nurse or nurses in the district should reside and at least two beds should be available for such cases as can properly be dealt with at such institutions. In the selection of centres for these local clinics regard should be had to the character of the locality and not merely to the size of the population.

WELSH BOARD OF HEALTH.

The Welsh Board of Health is at present constituted as follows: Sir Thomas Hughes (Chairman), Dr. D. Llewelyn Williams (Medical Member); Mr. John Rowland, C.B.E., M.V.O. (Deputy Controller of Insurance for Wales); Mr. A. Lloyd Thomas (Housing Commissioner); with Mr. Percy E. Watkins (Secretary, Administrative Officer for Public Health and *ex officio* Member of the Board).

ADVERTISEMENTS FOR MEDICAL OFFICERS.

The Colchester Town Council on June 2nd discussed the salary of the new assistant medical officer of health and assistant school medical officer. The Education Committee recommended that a salary of £500 be offered for the post, but Councillor Jarmin proposed that this recommendation be sent back to the Education Committee for further consideration. He said the retiring assistant medical officer (Dr. Vercoe), who had served them well, had been receiving £375 and £25 war bonus, and there was no explanation, reason, or justification for increasing the salary by £100 beyond the fact that medical journals had refused to insert the advertisement unless £500 were offered. He thought there should have been a more weighty reason than that. Under their medical officer he thought a junior medical man would have been sufficient for the position, and there was no reason at all why a presumably young man should be offered £100 more than their retiring assistant medical officer. While they were turning down applications for increases in all directions, he thought that, as a matter of sheer consistency, they could not offer for a new appointment a salary of £100 more than a very able officer had been satisfied with. He moved that the recom-

mendation be referred back with the observation that £400, including bonus, was sufficient commencing salary. Councillor Harris seconded. Alderman Blaxill (Chairman of the Education Committee), after paying a tribute to the services of the retiring assistant medical officer, said it was a fact that medical journals had declined to insert the advertisement for an assistant medical officer at a lesser salary than £500. Other authorities, however, had had difficulty in getting replies to advertisements offering £450, and the Committee felt, although they did not like the attitude of the BRITISH MEDICAL JOURNAL or other papers, that there was now more reason for the minimum salary suggested by those journals than on the last occasion. The medical union was perhaps the strongest trade union in the country. Many authorities were offering assistant medical officers considerably in excess of £500. Dr. Vercoe had himself obtained a post as one of six assistants at Willesden at a salary of £710, rising to £840; therefore, £500 did not seem an excessive figure. Councillor Jarmin maintained that they were not necessarily beaten because another authority had failed. He objected to dictation by a medical union as by any other union. The amendment was lost by 15 votes to 9, and the recommendation that £500 be offered was carried and adopted.

SCHOOLS AND INSTITUTIONS FOR THE PHYSICALLY AND MENTALLY DEFECTIVE.

The Board of Education has issued a list¹ of certified schools and institutions for blind, deaf, defective, and epileptic children and young persons in England and Wales. In England there are thirty-three day schools for blind children—of which twenty-one are in London—and twenty-five residential schools. There are twenty-nine day and twenty residential schools for deaf children. London has eighty-four day schools and one residential school for mentally defective children, compared with eighty-eight day and nineteen residential schools in the rest of England. For crippled children there are fifty-seven day and thirteen residential schools, thirty-six of the former being in London. The smallness of the provision hitherto made for delicate children and those suffering from tuberculosis is indicated in Section V; there are only twenty-seven day open-air schools in England and Wales; of these London has six. There are in England six residential schools for epileptic children and two for children suffering from ophthalmia. Wales has only seven day and two residential schools—all situated in Glamorganshire—for the above mentioned classes of children. Twenty-eight institutions in England and one in Wales provide full-time courses of instruction and preparation for a trade for cripples, epileptics, or the blind. One institution—the Worcester College for the Blind, at Whittington—is recognized by the Board of Education for the higher education of the blind. Five schools and classes for blind students, thirteen for deaf students, and two for physically defective students, are recognized under the regulations for technical schools. A list is also given of approved boarding-out committees for blind, deaf, defective, and epileptic children.

Scotland.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.

At their meeting on Friday, May 28th, the directors of the Edinburgh Royal Maternity Hospital confirmed the appointment of Dr. R. W. Johnstone, Dr. James Young, and Dr. Hugh S. Davidson to be assistant physicians to the hospital. These are the first appointments made under the new arrangement concluded with the University of Edinburgh for closer relations, especially for teaching purposes. The following are some of the clauses of the agreement which has been reached by the two bodies:

The clinical medical staff shall include the professor of midwifery *ex officio*, three physicians, an extra physician, and four assistant physicians. These physicians and assistant physicians shall be university lecturers. The professor of pathology shall, *ex officio*, be pathologist to the hospital. The

¹[Cmd. 703.] H.M. Stationery Office. Through any bookseller. Price 9d. net.

¹List 42. H.M. Stationery Office, 1920 (6d. net).

consulting physician, consulting surgeon, consulting obstetricians, and the consulting ophthalmic surgeon remain as before members of the Medical Board, but are not included in the clinical medical staff; there are also extern assistant physicians appointed in connexion with certain associated dispensaries.

The professor of midwifery shall, up to the age of 65, hold his appointment during his tenure of the chair and shall be a director of the institution.

As vacancies occur among the assistant physicians they shall be duly advertised and the applications of candidates shall be considered by a nomination board composed of four members appointed by the directors of the Royal Maternity Hospital and three members of the Faculty of Medicine of the University. The names selected shall be submitted to the directors of the Maternity Hospital for approval and appointment. Each physician and assistant physician shall be appointed for five years. The renewal of an appointment shall not be automatic, but only take place after due consideration by the directors. No physician or assistant physician shall hold office after the age of 65.

The professor of midwifery shall be chairman of the clinical medical staff, and all proposals in regard to teaching arrangements in the hospital shall be submitted by them through him for approval to the Faculty of Medicine and the directors of the Maternity Hospital.

The clinics to students shall be limited as to numbers, and shall be compulsory and recognized as an integral part of the university course of midwifery. The clinics shall be open to all registered medical students on payment of such fees as may be fixed by the directors after consultation with the University Court.

The professor of midwifery, besides having the general direction of the hospital and being responsible for the teaching in the first quarter, shall have the right of teaching in any of the other three quarters, the details to be arranged in consultation with the clinical medical staff.

The names of suitable candidates for the post of house-surgeon shall be selected by the clinical medical staff and submitted to the directors for approval and appointment.

It will be noted that the system by which each physician and assistant physician was in charge of the hospital for one quarter of the year is in the main retained in the new scheme of working the institution; the extra physician, however, who is in charge of the antenatal and venereal diseases departments is on duty all the year round. It may be added that the position of house-surgeon to the antenatal department and to the extension of the hospital is now open to women medical graduates and is at the present time held by one.

"LIBERTON."

The Court of the University of Edinburgh at its meeting on May 17th determined to give the name "Liberton" to the site of 115 acres it has recently acquired to the south of the city. It is understood that whilst it is intended to transfer to the buildings to be erected at Liberton the teaching of advanced chemistry, it has not yet been decided what other subjects (scientific and medical) may be dealt with there; nor has a name been settled on for the buildings themselves, although the fact that His Majesty the King has consented to lay the foundation stone next month seems to suggest possibilities of nomenclature. The Liberton site lies under the lee of Blackford Hill, with the Craigmillar Park golf course looking upon it. It has West Mains Road as a northern and Braid Burn as a southern boundary, and the Braid Hills lie to the west of it. Further to the south is Liberton Tower and Upper Liberton, whilst to the east are the hamlets of Liberton Dams and Nether Liberton, with South Edinburgh reaching out towards and passing between them. To the south-east is Liberton itself, and the lands of Graecmound and St. Catherine's with its famous "balm well."

The new site formed part of the Barony of Liberton, which, in the sixteenth century, belonged to Mr. Clement Little, who, by his gift in 1580 of some three hundred volumes (not an inconsiderable number in those days), founded the library of the university, soon afterwards to be enriched by the collection of the poet, William Drummond, of Hawthornden. This same Clement, "Commissary of Edinburgh," was instrumental in stirring up the town council to begin erecting the college buildings on the site provided for the purpose (Kirk-of-Field) in 1582. So the old buildings and these newest ones at Liberton are linked together by him. There was also William Little, a kinsman of Clement, who was Provost of Edinburgh in 1591; he, too, assisted at the birth of the young university. He was Laird of Over-Liberton, and the family tomb in Greyfriars Churchyard (within a stone's throw of the medical

part of the university) is a rather remarkable structure. It is, writes James Grant in his *Old and New Edinburgh* (vol. ii, p. 382):

a mausoleum composed of a recumbent female figure, with a pillar-supported canopy above her, on which stand four female figures at the several corners; the popular story is that the lady [perhaps the Provost's wife] was poisoned by her four daughters, whose statues were placed over her in eternal remembrance of their wickedness; but the effigies are in reality those of Justice, Charity, Faith, etc. . . . and the object in placing them there was merely ornamental.

The tomb was erected by a great-grandchild in 1683, perhaps because that year marked the first centenary of the university which the Littles had done so much to found. Littles and Little-Gilmours continued at Liberton till recent times, and in one of Kay's *Portraits* (No. xxvi)—that of Dr. John Brown, author of the Brunonian system of medicine—there is a miniature scene in the background representing Mr. John Lamont, surgeon, Lord Bellenden ("playing on the fiddle"), Dr. William Cullen, Dr. Alexander Hamilton, Professor of Midwifery, James Graham (of the Temple of Health and Hymen, Pall Mall), and "Mr. Little of Liberton." This must have been etched about the close of the eighteenth century.

Liberton village was originally Lepertown, and its situation on rising ground, about two and a half miles south-east of the centre of Edinburgh, probably made it a convenient place at which to segregate the sufferers from the dreaded leprosy of the Middle Ages. Possibly also the lepers may have got treatment at the Balm Well of St. Catherine. The late Mr. Charles Green, the medical and law publisher, was much interested in this well, which was situated in his property, and readily welcomed physicians and others desirous of seeing its black oily contents. Hector Boece in his Latin *History of Scotland* (1526) described the well, and John Bellenden (who himself spelled his name also Ballantyne or Balleutynne) translated the description:

Nocht two milis fra Edinburgh is ane fontane, dedicat to Sanct Katrine, quhair sternis of oulie springis ithandle with sic abundance, that, howbeit the samin be gaderit away, it springis incontinent with gret abundance. This oulie hes ane singulare virtew aganis all maner of cankir and skawis.

There is a most interesting pamphlet on *The Oylly Well* by Matthew Mackail, an apothecary in Edinburgh and afterwards an M.D. of Aberdeen, which was published in 1664. In his "Topographico Spagyricall Description of the Oylly Well, at St. Catharines-Chappel, in the Paroch of Liberton," Mackail says:

Its profundity equalleth the length of a pike, and is alwaies replet with water; and at the bottom of it there remaineth a great quantity of black oyl in some veins of the earth. . . . His Majesty King James the Sixth, the first Monarch of Great Britain, of blessed memory, had such a great estimation of this rare Well, that when he returned from England, to visit this His ancient Kingdom of Scotland, in anno 1617, he went in person to see it, and ordered that it should be built with stones from the bottom to the top, and that a door and a pair of stairs should be made for it, that men might have the more easie access unto its bottom, for getting of the Oyl. This royal command being obeyed, the Well was adorned and preserved until the year 1650, when that execrable Regicide and Usurper, Oliver Cromwell, with his rebellious and sacrilegious complices, did invade this Kingdom; and not only deface such rare and ancient monuments of Nature's handwork, but also the Synagogues of the God of Nature.

Mackail has much to say of wells in general and of the "black fatness or Oyl" of St. Catherine's in particular; but the modern reader will scarcely peruse his pamphlet with patience, although he may note that he traced the oil to Parret coal, "being frequent in these parts." Russel Walker, in the *Proceedings of the Society of Antiquaries of Scotland*, in more recent times described *Holy Wells in Scotland*, including, of course, St. Catherine's, and the *Scottish Field* for November, 1918, brought its story quite up to date. "As a balsam or aperient the oil has lost its virtue"; and, as for its origin, "In these matter-of-fact days the appearance of the miraculous oil is attributed to the fact that the well is sunk on the edge of the rich shale field which was operated on by the Clippens Oil Company at Straiton." There is a legend that James IV bathed in the wonder working "oyl" before marching south to Flodden; but if so the balm failed to work wonders for him,

New South Wales.

THE LATE PROFESSOR SIR THOMAS ANDERSON STUART.

SIR THOMAS ANDERSON STUART, Professor of Physiology and Dean of the Faculty of Medicine in the University of Sydney for the last thirty-seven years, and Chairman of the Board of Directors of the Royal Prince Alfred Hospital, Sydney, died on February 29th in his sixty-fifth year. He was born in Dumfries, Scotland, and entered the University of Edinburgh as a student of medicine at the age of 19 years. After a brilliant career he gained the Btles Scholarship on graduation as M.B., M.Ch., and two years later the university gold medal for his thesis for the degree of M.D. While he was at Edinburgh he was president of the Royal Medical Society, and was also demonstrator and assistant to the professor of physiology. When it was decided to establish a school of medicine at the University of Sydney, Dr. Anderson Stuart was chosen as professor of physiology and anatomy. He arrived in Sydney in the year 1883, and was at once appointed dean of the faculty of medicine; in virtue of that office he was a member of the Senate of the University, and continued to retain that position, being the oldest member of that body at the time of his death. When Professor Stuart arrived the medical school had four students. He designed the present buildings for the medical school, which at the time they were opened (in 1891) were thought to be far in excess of the requirements of the school; they proved to be not large enough for the increasing number of students; additions have been made, and more will be required in the near future. Later Professor Stuart founded the Dental School, and he was responsible for the foundation and erection of the University Dental Hospital. He subsequently took a prominent part in the foundation of the United Dental Hospital, and was its first president.

By virtue of his position as Dean of the Faculty of Medicine Professor Stuart became an *ex officio* member of the Board of Directors of the Royal Prince Alfred Hospital, a position he continued to hold up to the time of his death. He was appointed honorary secretary to the hospital in 1900, and a few months later, on the death of Sir Edward Knox, he became chairman. It is chiefly due to his initiative and wonderful organizing powers that this hospital has developed into the largest general hospital in Australasia. He had a large share in the extension of the nurses' home, the pathological department, and other buildings. He was for a period of four years President of the Board of Health and medical adviser to the Government; he designed the offices and laboratories of the Board of Health, and was the author of important health legislation. He continued to be a member of the Board of Health till his death. In the year 1891 while on a visit to Europe he was appointed by the Governments of New South Wales, South Australia, and New Zealand to proceed to Berlin to investigate and report upon Dr. Koch's work in connexion with the treatment of tuberculosis by tuberculin.

For many years Professor Stuart was associated with the Royal Society of New South Wales, as member of the council, as honorary secretary, as chairman of the medical section, and as president of the society for two years. He also took an active part in public in other directions, such as the Industrial Blind Institution, the Highland Society, and the Zoological Society. He was the first to take steps towards organizing a school for tropical medicine in Australia. This ultimately merged into the Australian Institute of Tropical Medicine. It was largely in connexion with this and other public and philanthropic movements that he received the honour of knighthood in 1914.

Sir Thomas was well known as a man of most active mind and of great force of character, but probably few, if any, realized how fully these characteristics would be manifested during this past year. Some twelve months ago he was found, quite unexpectedly, to be suffering from extensive malignant disease of the peritoneum, and it was not expected that he would live more than a few months. Still he never slackened his work in any direction and continued his lectures at the university up to the end of the last term of 1919. At the end of the session, as it was

well known that he would not be able again to meet his students in lectures, he was given a true students' "send off." He still continued to direct the work of the hospital and attended the meetings of the board almost up to the time of his death. One of his closest friends remarked, "His indomitable spirit was simply marvellous—he was a Scotsman in every fibre of his being." He leaves a widow and four sons, two of whom are students in medicine at the university.

The funeral was one of the largest ever seen in Sydney. The hearse was preceded by a long procession of medical students in academic dress, and a very large number of citizens of all classes surrounded the grave in the little cemetery at South Head at the entrance to Sydney Harbour. The service at the graveside was conducted by his old friend the Rev. John Ferguson of St. Stephen's Presbyterian Church, Sydney. The Masonic service followed.

The Senate of the University of Sydney met on March 1st, and after having passed the following resolution, adjourned to March 8th as a mark of respect to the memory of the late Sir Thomas Anderson Stuart:

The Senate desires to place on record an expression of the sense of the loss sustained by the University through the death of Sir Thomas Anderson Stuart, M.D., LL.D., D.Sc. From the inception of the medical school in 1883—a period of thirty-seven years—he rendered eminent service to the university and to the cause of medical education by his great gifts as a teacher in the chair of physiology, to which anatomy was at first attached, and by his capacity for organization as Dean of the Faculty of Medicine and as a Fellow of the Senate, as a director and president of the Royal Prince Alfred Hospital, and in other public activities.

A similar resolution was passed by the Faculty of Medicine at its meeting on March 22nd.

EXTENSION OF THE RED CROSS FIELDS OF LABOUR.

The Executive Committee of the Red Cross Society in New South Wales has issued a circular setting out the aims of the following objectives of the future activities of the society.

The first is the extension of the voluntary aid detachment movement throughout Australia, and the second is the maintenance and extension of all Red Cross schemes for the benefit of disabled soldiers, sailors, and military nurses. The third object sought is help in providing nurses for soldiers' settlements, which include a large proportion of invalid soldiers. The fourth is to promote national health and mitigate suffering. It is suggested that the attention of the Red Cross country branches might well be directed towards assisting the nearest district or cottage hospital, or, should there be none, any other medical institution, and in giving help to the local bush nurse.

An important point emphasized is that the Red Cross funds at present to the credit of branches, being raised for the benefit of sick and wounded soldiers, sailors, and military nurses, can only be used for this purpose. Funds raised in the future might be devoted to local civilian hospital purposes, with the provision that soldiers and their dependants would have the first claim on Red Cross care and attention.

REFORMATIVE TREATMENT OF SOLDIER PRISONERS.

The State Government of New South Wales has decided not to submit returned soldiers convicted of criminal offences to ordinary methods of gaol punishment. An effort is to be made to restore them to both physical and mental health by a process of segregation and open-air treatment. The Minister of Justice is interesting himself specially in this matter; he recognizes that there are many cases in which offences proved against returned soldiers have, on investigation, been shown to be the direct result of wounds, shell shock or "war neuroses." Such cases of course require to be treated with the greatest possible sympathy, and arrangements are now being made for their segregation in suitable surroundings, and for a treatment which will conduce to their restoration to a normal condition of life. Special attention is to be paid to the physical health of these men, and open-air treatment will be applied in all cases.

Correspondence.

FUTURE PROVISION OF MEDICAL SERVICES.

SIR,—That the medical press has not instantly been inundated by correspondence for or against the recommendations of the Interim Report of the Consultative Council is merely an indication that the profession, taught by experience, is considering the situation. It may be said to be at gaze with the politician who, in the name of philanthropy, is again about to attack both its professional freedom and economic interests.

Remembering the origin of the Medical Benefit Section of the National Insurance Act, few will be surprised at this further extension in the direction of a nationalization of medicine. That it has been long, perhaps always, contemplated, and the means for its accomplishment considered, appears to be shown by the engaging candour of the noble Chairman of the Consultative Council, in his address at the Brussels Congress, reported in the *BRITISH MEDICAL JOURNAL* of May 29th (p. 743). The State medical service by instalments, almost by stealth, has, to use his own words, taken another step forwards: "As the provision of medical service extends, the Ministry of Health will have increasing control over medical policy, and therefore over the medical profession, and this influence will be enhanced by the power of the purse." Lord Dawson of Penn, foreseeing this result, and unequivocally indicating the means by which it is to be brought about, is, nevertheless, averse to "the centre of gravity of a learned profession" being in a Government department, and believes "vocational representation" will safeguard a profession which, like a nation, he is good enough to say, has need of self-determination. But it seems that the direct election by all qualified practitioners of their representatives to such a committee would not secure a good team whose function it would be to work in harmony with the Minister responsible, and therefore a team of harmonious character must be selected by other means. What a conception of the freedom of a liberal profession! As two souls are said to struggle in the human breast by John Arbuthnot in his *Grothi Scanton*, two emotions affect one in perusing Lord Dawson's address—amusement and indignation. I verily predict the triumph of amusement, and believe this precious scheme will die, as it deserves to die, amid the laughter of the profession it is intended to harness for its execution.

The medical profession, let it be said without circumlocution, if a useful and beneficent calling, occupying a definite status in a social system, is not organized solely for philanthropic effort on terms disadvantageous to itself. Its members neither claim nor receive any exceptional leniency from those instrumentalities whose function it is to keep the coffers of the State full. They naturally claim the right to make their own terms for their services. That these are arranged, in the vast majority of cases, with every consideration for the patient, will not be denied by any who know the actual facts of the case. The economic position of the profession which was attacked in the Medical Benefit Section of the Insurance Act, although reluctantly improved by the originators on the demand of those who took service under the Act, is still further attacked by the measures contemplated in the scheme sketched by the Consultative Council.

At the recent gathering of an approved society in now classical Leamington, the president referred regretfully to the good old days when the doctor seemed to live for going about and doing good, whereas now, alas! how often does he seem to be influenced by sordid motives! Need I recall the magnanimity with which the proletariat treated their medical servitors in the heyday of power of the benefit societies! For the action taken by the British Medical Association towards those would-be philanthropists, the profession owes it a lasting debt of gratitude. May that debt be renewed and increased in the near future, if it again speaks and acts in defence of the profession as its chief organ, with the more powerful forces with which it is now confronted.

I think I am in accord with what is or was the general policy of the Association when I remark that State medical service, apart from the proper functions of a Public Health Office in surveying and preventing disease, should have as its care the so-called "necessitous classes,"

however that term be defined and whatever wage limit or income be connoted by it. If this be so, may we not look to it to protect the profession against the further encroachments upon its economic interests now contemplated? We cannot, like Canute, sit on the seashore and order the sea back, but we may unitedly build a breakwater which will add picturesqueness to the impotent if somewhat annoyed ocean, without unduly wetting our own feet. It is to the building of this breakwater that the profession must now devote itself.

The scientific questions, preventive and curative, involved in the exercise of our calling, to which so much attention has been drawn, with, at times, a certain esoteric solemnity by some, have not, in very many cases, the complexity, inscrutability, and urgency which is averred. We have all to study our craft and learn our craft. We have done so in the past, do so now, and shall do so in the future, in the light of corresponding periods. But the picture of a common surgery (a notion now abandoned) or primary collaborative centres, where patients may study not only one another's diseases but also one another's doctors, is one of the amusing and impracticable features in the scheme of the Council.

The scheme itself seems to have been inspired by the ordinary practice of any general hospital. A patient of a certain and admissible social type is referred by a practitioner to a medical or surgical officer at a hospital. He, in his turn, may find it necessary to refer him to a special department, and the patient may even in some cases run the whole gamut of institutional investigation and treatment before he returns to the "periphery" and his own doctor. Such a process is doubtless beyond the financial capacity of many (and for these, arrangements convenient for them can always be made), therefore all citizens, whatever their means, must be brought under the scheme, or, to use the words of the Council, treatment must be made available for all citizens. Practitioners, presumably members of a liberal profession, a moiety of whom may find higher work, are thus to disport themselves with general observation at the "periphery," such as ante-natal and other domestic attentions of a not very exacting order, for the primary centre is not likely to materialize. Their efficiency is therefore certain to decay with a limitation of their responsibility and of the scope of their exertions, and the last state of the visiting apothecary under this scheme promises to be worse than the first, from which, by his own efforts, he had emerged prior to the intrusion of the politician as philanthropist into medicine. The profession, therefore, is scarcely likely to accept the scheme, and it is improbable that even the threat of whole-time officers, so effectual in cowering the practitioner in 1913, will be equally successful in 1920, or at any later date.—I am, etc.,

ALEXANDER BLACKHALL-MORISON.

London, W., June 7th.

AIR-WAY INFECTIONS.

SIR,—Mr. Benians's article on air-way infections, in your issue of May 15th, p. 663, in which stress is laid on the means already provided by the body to prevent the inroads of bacteria, is extremely suggestive. He does not go so far as to suggest in what ways we might improve, or as he says "exploit," these factors, but it is sufficiently clear that we cannot substitute others without due care and consideration. This brings to issue the question whether or not it is advisable to wash out the nasal cavities. In suitable cases, and under proper supervision, for a time at least, this is no doubt advisable, but since the recent outbreaks of influenza this process has become almost epidemic, supported as it has been by semi-official proclamations, and by over zealous journalism. It requires neither knowledge nor effort of imagination to discover that the nasal cavities are not adapted to the aqueous ablutions used to cleanse the external parts of the body.

I feel confident, from my experience with private patients, that this process of repeatedly washing out the nose often leads to very harmful results. I constantly see cases of chronic mucosal inflammation of the nasal cavities, often associated with severe infective conditions of the sinuses and infective complications of the ears. I ask as a matter of routine whether the patient makes a practice of washing out the nose, and am told, "Oh, yes, once every day." This has happened so frequently of late as to make me feel that this tampering with the nasal cavities has actually

interfered with the normal protective capacities of the nasal mucosa and has led directly to infection. In the light of Mr. Benians's paper, the value of washing out the nose, even when prophylactic measures are urgently indicated, requires very careful consideration. To wash out the nose from the inside by an increase of the normal secretions would no doubt be the ideal method, but even if we cannot do that effectively, surely to remove the normal protective secretions already present is a dangerous proceeding. I should be very much surprised to hear that my experience as regards these nasal and sinus infections is an isolated one.—I am, etc.,

C. H. HAYDEN, F.R.C.S. Edin.,
Surgeon in charge Nose Throat and Ear
Department, Prince of Wales Hospital,
Tottenham.

May 18th.

“VAGASTHENIA.”

Sir,—Is Major Watts right in saying that the tachycardia, etc., which follow fright or shock have always been supposed to be due to suppression of vagus control? If so, the supposition seems to have been wrong. Study of the irritable hearts and irritable tempers of war strained and shocked pensioners suggests that the irritability is due, not to a lazy vagus, but to an unusually energetic sympathetic. For what do we find? Rapid pulse, precordial pain, unstable temper, general jumpiness, tremor, and raised blood pressure. The men are in a condition of hypertension, not of hypotension. Often they are difficult patients to handle because of their general jumpiness. Usually they have suffered prolonged strain or terrifying experiences, or both, and more often than not they repeat their experiences night after night in their dreams.

Ingenious physiologists have shown most convincingly that emotions—particularly emotions of fear and rage—are accompanied by increased activity of the suprarenals, with consequent bucking up of the sympathetic nervous system; and observation of the habits of pensioners with D.A.H. suggests that their trouble is due to constant overactivity of the suprarenals.

Three days ago I examined casually in my out-patient room four pensioners with D.A.H., with the following result:

A. Pulse-rate...	144	S.B.P....	180
B. " " ...	120	" " ...	148
C. " " ...	88	" " ...	160
D. " " ...	120	" " ...	180

They were all young men, and all were very sorry for themselves—with reason.

The term “vagasthenia” is exceedingly ugly, and so should be turned down. Further, it has been coined without any convincing excuse. D.A.H. is a convenient term, and it does convey a certain amount of truth—that the heart is disordered in its action.

Major Watts's suggestion that the unfortunate men with D.A.H. shall be thrown to the psycho-analysts, must be jumped on hard. They deserve well of their country. They have done nothing that justifies us in driving them into the laboratories of those who would tear their souls into small pieces.—I am, etc.,

Walsall, May 22nd.

FRANK G. LAYTON.

Obituary.

WE regret to announce the death of Dr. ROBERT EDWARDS, of Carlisle, which took place after a brief illness, on May 26th. Dr. Edwards was a native of Edinburgh, where he graduated M.B. and Ch.B. in 1907. After acting as house-surgeon at the Cumberland Infirmary, the Royal Sea Bathing Hospital at Margate, and the Hospital for Sick Children in Great Ormond Street, he began to practise in Carlisle, where, in 1912, he was appointed honorary radiographer to the infirmary. At the outbreak of war Dr. Edwards replaced Dr. Norman Maclaren and did much useful work as acting assistant surgeon to the institution; subsequently he joined the army and served abroad. He had to return to England in consequence of the failure of his health, and for some time did military orthopaedic work at Liverpool. He was appointed surgeon (with the rank of major) to the hospital at Fusehill, and also acted as orthopaedic surgeon at the Gretna Hospital. It will be

remembered that at the Gretna Green railway disaster five years ago Dr. Edwards crept beneath the débris of a burning troop train and, although exposed to grave personal risk, amputated the legs of two soldiers who were pinned beneath one of the burning coaches. Dr. Edwards, who was only 35 years of age, was an accomplished surgeon and was very popular with his professional brethren, his patients, and his many friends. He leaves a widow and two children, with whom deep sympathy is felt.

It is with feelings of deep regret that we record the death of Dr. WALTER JOSEPH SCHULLER, which occurred suddenly whilst on a visit to an old fellow student at Windlesham. He was just 49 years of age. He received his medical education at the London Hospital, and took the diplomas of L.R.C.P. and M.R.C.S. in 1898; he was a most popular student. Quiet, unassuming, sympathetic, with a fund of dry humour, he possessed all the qualities that go to make the successful practitioner. On the outbreak of the South African war he joined as civil surgeon, and after the war entered on general practice in Cape Town. He returned to England some years later for an operation, necessitated by blood poisoning contracted from a patient. His health was never robust after this, so that he was unable to undertake the responsibilities of a practice of his own, but spent the greater part of his life as locum tenens to his old friends, who knew that Schuller would look after their interests as well as any, and often better than they could themselves.

DR. WILLIAM SAUNDERS, who died suddenly on April 19th, was the son of the late Dr. James Warnes Saunders, and was born in 1853. He was educated at University College, London, taking the M.R.C.S. Eng. and L.S.A. Lond. in 1878. Subsequently he studied at King's College, London, at Birmingham, and at Newcastle-upon-Tyne. He practised at Stockton-on-Tees, Dudley, Wellingborough, and finally at Backworth, Newcastle-upon-Tyne, where he was in partnership with his son, Dr. W. E. Roper Saunders. At Dudley he was resident medical officer to the dispensary. He was for many years a member of the British Medical Association. His principal recreations were music and Freemasonry. During the war he served on recruiting and pensions boards, and, although he had been in ill health for about two years, continued his work until January, 1920. He took a keen interest in public health matters.

THE premature death—he was only 43 years old—of Dr. LEONARD DONCASTER, professor of zoology in the University of Liverpool, is a serious loss to science. He was a scholar of King's College, Cambridge, was in the first class of the natural science tripos, Part I, in 1898, and in the second part in 1900 was distinguished in zoology. He took the degree of Sc.D. in 1913. In 1915, when he was superintendent of the University Museum of Zoology, Cambridge, his researches into the Mendelian hypothesis led to his election as F.R.S. From 1906 to 1910 he was lecturer in zoology in the University of Birmingham.

The Services.

INDIAN MEDICAL SERVICE.

REVISED RATES OF PENSION.

A COMMUNIQUE issued to the press by the Secretary of State for India announces revised scales of pension for officers of the Indian Army and of the Indian Medical Service. It contains the following references to the Indian Medical Service (except where otherwise stated “rank” means substantive rank):

Revised rates of pension for the Indian Medical Service have also been approved at the following rates: £400 a year after seventeen years' service, and thereafter for successive years £430, £460, £500, £540, £580, £620, £660, £700, £750, and £800.* The maximum (£800) will be admissible after twenty-seven years' service. The additional pensions for administrative officers of the Indian Medical Service will be continued at the existing rates—namely, £125 for a colonel after two years' active service as such

* The rates hereby replaced were: After seventeen years' service £300, and thereafter for successive years £320, £360, £400, £420, £440, £460, £480, £500, £540, £580.

and £250 after four years; £300 for a major-general after one and a half years' active service as such and £350 after three years.

The revised rates will be payable as from April 1st, 1919, to all regular officers who, being otherwise entitled, have rendered satisfactory paid military service during the Great War, including officers who have retired on pension before the war, have been re-employed as officers during the war, and have thereafter reverted to retirement. The pension of the latter officers will be re-assessed on their service prior to original retirement, except in the case of officers serving for increased pension under Indian Army Circulars, 1893, Clause 99. The new rates of pension will not be drawn by officers for any period during which they were re-employed. Unemployed service up to June 30th, but not beyond, will reckon for pension under these rules.

Temporary rank held during the Great War, followed by substantive promotion to that rank, will count as service in the rank towards pension. Service in the temporary rank of Brigadier-General or higher rank will count as service in the rank of Colonel or lower substantive rank held by the officer on retirement. The rules for the grant of Good Service Pensions are not affected by the revision.

Forms of application for revision of pension under the foregoing rules will be sent out as soon as possible. Any officer who comes within the terms specified, who does not receive a form of application within a fortnight of the present date [June 3rd] should address the Secretary, Military Department, Room 157, India Office, S.W.1, on the subject.

The revised rates of pension herein set forth will be subject to alteration, either upwards or downwards, after July 1st, 1924, to an extent not exceeding 20 per cent., according as the cost of living rises or falls, and after July 1st, 1924, a further revision may take place every three years, but in the case of an officer who entered the Indian Army before July 1st, 1920, the pension will not in any case be reduced below that which he would have received under the old scale, service for pension being calculated under the new rules.

Revised rates of leave pay, pay while on duty in Europe, and unemployed pay will be announced shortly. Officers will be free to elect the revised rules or to remain under existing rules, but they must be finally accepted as a whole, that is, it will not be permissible for an officer to elect the existing rates of unemployed pay and the new scale of pensions, or vice versa.

ANNUAL DINNER IN LONDON.

The annual dinner in London of the Indian Medical Service took place on the evening of June 8th, when Major-General G. F. A. Harris, C.S.I., formerly Surgeon-General, Bengal, was in the chair. The officers present were:

Major-Generals: Sir R. Havelock Charles, G.C.V.O., T. Grainger, C.B., P. Hehir, C.B., C.M.G., C.I.E.

Colonels: C. W. Carr-Calthrop, C.B.E., J. Crimmin, V.C., C.B., C.I.E., Sir P. J. Freyer, K.C.B., C. M. Goodbody, C.I.E., D.S.O., D. E. Hughes, G. B. Irvine, C.B., W. H. Ogilvie, C.M.G., J. J. Pratt.

Lieutenant Colonels: A. Alcock, C.I.E., W. G. P. Alpin, O.B.E., J. Anderson, C.I.E., W. R. Batye, D.S.O., A. T. Bown, R. Bryson, J. T. Calvert, C.I.E., R. H. Castor, D. G. Crawford, C. Duer, R. H. Elliot, F. F. Elwes, S. C. Evans, A. B. Fry, C.I.E., D.S.O., G. H. D. Gimlette, C.I.E., T. A. Granger, C.M.G., H. Greany, A. W. M. Harvey, J. G. Hulbert, C. H. James, C.I.E., S. P. James, J. Lloyd Jones, J. G. Jordan, R. W. Knox, D.S.O., Clayton Lane, S. Little, T. R. Mulrooney, R. A. Needham, C.I.E., D.S.O., A. H. Nott, S. Browning Smith, C.M.G., R. F. Standage, R. Steen, T. H. Symons, O.B.E., W. H. Thornhill, J. H. Tull Walsh, Ellacott L. Ward, C.B.E., J. W. Watson, C.I.E., H. G. L. Wortabet, H. R. Woolbert, A. C. Younan.

Majors: W. M. Anderson, C.I.E., A. Cameron, S. Chuckerbutty, R. G. G. Croly, J. Forrest, C. A. Godson, M.C., E. T. Harris, D.S.O., A. H. Napier, E. S. Phipson, M. Purvis, J. J. Robb, W. C. Ross, W. R. J. Scroggie, C.I.E., P. E. Wilson.

Captains: U. J. Bourke, W. B. Keyworth, N. N. G. C. McVean, J. G. B. Shand, H. Stott, O.B.E.

The guests were the Editors of the *British Medical Journal* and of the *Lancet*.

ROYAL NAVAL MEDICAL CLUB.

The annual dinner of the Royal Navy Medical Club took place at the Trocadero Restaurant on May 28th, 1920, when the Medical Director-General of the Navy, Surgeon Rear Admiral Sir Robert Hill, K.C.M.G., C.B., C.V.O., was in the chair. The guests were Sir George Lenthal Cheate, K.C.B., C.V.O., and Surgeon Commander E. J. Steegman, O.B.E., R.N.V.R. The following members were present: Surgeon Captain O. W. Andrews, C.B.E., Surgeon Commander E. L. Atkinson, D.S.O., Surgeon Commander A. R. Bankart, C.V.O., K.H.P., Surgeon Rear Admiral T. W. Bussell-Smith, C.B., C.M.G., Surgeon Commander G. D. Bateman, Surgeon Commander C. T. Baxter, Surgeon Captain C. M. Beadnell, Surgeon Commander K. D. Bell, Surgeon Rear Admiral W. Bett, M.V.O., Surgeon Commander R. St. G. S. Bond, Surgeon Rear Admiral J. Chambers, C.M.G., Surgeon Commander C. J. E. Cock, Surgeon Captain

E. C. Cridland, Surgeon Commander F. J. A. Dalton, C.M.G., Surgeon Rear Admiral G. A. Dreaper, Surgeon Commander J. S. Dudding, Surgeon Commander J. H. Fergusson, Surgeon Commander A. F. Fleming, D.S.O., Surgeon Commander A. Gaskell, C.B., O.B.E., Surgeon Captain J. F. Hall, C.M.G., Surgeon Rear Admiral D. T. Hoskyn, Surgeon Commander R. Hughes, Surgeon Commander W. W. Keir, C.M.G., Surgeon Commander H. A. Kellond-Knight, Surgeon Commander M. H. Knapp, Surgeon Commander R. H. McGiffin, O.B.E., Surgeon Rear Admiral Sir D. J. P. McNabb, K.B.E., C.B., Surgeon Lieutenant Commander J. H. B. Martin, Surgeon Commander P. M. May, Surgeon Commander N. S. Meiklejohn, D.S.O., Surgeon Commander J. O'Hea, Surgeon Captain F. W. Parker, O.B.E., Surgeon Commander J. H. Pead, Surgeon Captain E. A. Penfold, D.S.O., Surgeon Commander B. P. Pick, Surgeon Commander S. Roach, Surgeon Commander M. L. B. Rodd, O.B.E., Surgeon Commander R. A. Ross, Surgeon Lieutenant Commander F. L. Smith, Surgeon Captain W. H. S. Stalkart, Surgeon Lieutenant Commander H. E. R. Stephens, O.B.E., Surgeon Commander J. Stoddart, Surgeon Commander E. Sutton, C.M.G., Surgeon Commander J. A. Thompson, Surgeon Commander A. J. Wernet.

ARMY FEES FOR CIVILIAN DOCTORS.

An Army Council Instruction lays down that civilian medical practitioners giving professional attendance to soldiers will now be paid day fees ranging from 3s. 9d. to 7s. 9d., according as the distances travelled vary from under one mile to under five miles. Night fees for similar distances will range from 5s. 3d. to 13s. 3d. Extra fees will be allowed for distances over five miles, but the limit for an ordinary visit will be £1.

HONOURS.

FOREIGN DECORATIONS.

The following decorations have been conferred in recognition of valuable and distinguished services rendered during the war:

By the President of the French Republic.

Order of the Legion of Honour.—Chevalier: Dr. Septimus P. Sunderland. Médaille d'Honneur avec glaires "en Fermeil": Colonel Arthur D. Ducat, D.S.O., T.D., A.M.S.(T.F.), Captain Matthew Wallace Paterson, O.B.E., M.C., R.A.M.C.(S.R.), and Captains Richard Payne Pollard, M.C., and David Jobson Scott, O.B.E., M.C., R.A.M.C.(T.F.). Médaille des Epidémies "en Argent": Temporary Captain (acting Major) James Robertson Anderson, R.A.M.C.

By the King of Rumania.

Order of the Star of Rumania (with Swords).—Chevalier: Captain Duncan Campbell Lloyd Fitzwilliams, C.M.G., R.A.M.C.(T.F.).

Sir W. R. Smith, M.D., ex-Sheriff of the City of London, has been appointed by the King of the Hellenes a Commander of the Order of George I, and has received from the President of the Chinese Republic the decoration of Second Class, with Grand Cordon, of the Order of the Excellent Crop.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

DIPLOMA OF PSYCHOLOGICAL MEDICINE.

The dates for the next examination have been fixed as follows: For Part I, October 13th, 14th, and 15th; for Part II, December 1st, 2nd, and 3rd. The examination for Part I will be held in Cambridge; that for Part II in London.

Course of Instruction for the Diploma.

Courses of instruction for both parts will be held in Cambridge from July 19th to August 21st. For Part I Dr. Thacker, Anatomy and Physiology of the Nervous System; Dr. Lawson, Psychology. For Part II Dr. Pridaux, Psychopathology; Dr. Archdale, Diagnosis, Prognosis and Treatment of Mental Disorders.

The fee for the full course is 10 guineas; the course for either part may be taken separately at a fee of 5 guineas.

Entries should be sent to Dr. E. D. Adrian, Trinity College, Cambridge, from whom further information may be obtained.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved at the examinations indicated:

SURGERY.—†G. S. Ashby, †J. G. Barrie, †M. L. Barst, †C. C. Bennett, †W. H. Cellier, †M. J. Erdberg, †A. Keilin, †J. Kendall, †W. A. O'Connor, †W. H. Summerskill, †G. V. L. Van Acker.
MEDICINE.—†L. Burvill Holmes, †A. R. Crane, †M. J. Erdberg, †A. G. B. Fenwick, †A. Furniss.
FORENSIC MEDICINE.—L. Burvill Holmes, M. J. Erdberg, H. D. L. Jones.
MIDWIFERY.—M. J. Erdberg, P. N. Gray, G. V. L. Van Acker.

* Section I.

† Section II.

The diploma of the Society has been granted to Messrs. G. S. Ashby, J. G. Barrie, C. C. Bennett, M. J. Erdberg, A. G. B. Fenwick, A. Furniss, A. Keilin, and J. Kendall.

Medical News.

A SUM of £165,000 from the bequest of the late Sir William Dunn has been given to the University of Cambridge for the endowment of the institute of bio-chemistry.

THE Section of Laryngology of the Royal Society of Medicine will hold its second annual summer congress at the house of the society on June 24th and 25th. On the first day a series of papers on cancer of the throat will be read. A collection of pathological specimens and drawings will be on view, and also an exhibition of surgical instruments and drugs. There will be a dinner at the Café Royal on the evening of June 24th.

A MEETING of Old Epsomians interested in the College War Memorial will be held at the offices of the school, 49, Bedford Square, W.C.1. on Thursday, June 24th, at 5 p.m., (1) to discuss the immediate erection of a tablet of commemoration, as it is not possible to begin the chapel rebuilding for some time; (2) to meet the committee specially appointed to collect subscriptions and donations; and (3) to decide on the form which the tablet is to take.

THE Cavendish Lecture and Conversazione of the West London Medico-Chirurgical Society will be held at the Kensington Town Hall on Friday, June 25th. Members desiring tickets for guests are requested to communicate at once with the senior honorary secretary, Dr. J. F. Halls Dally, M.D., M.R.C.P., 95, Harley Street, W.1. Professor Sherrington has chosen "Posture" as the subject of his Cavendish Lecture.

THE first annual dinner of the 48th General Hospital will take place at the Piccadilly Hotel (Adams's Room), London, on June 24th, at 7.30 p.m. Dinner 21s., exclusive of wines. Those who intend to be present are asked to communicate with Dr. B. Holroyd Slater, St. Luke's Hospital, Bradford.

THE Cambridge Medical Graduates' Club will hold its summer dinner at Oddenino's Imperial Restaurant, Regent Street, W., on June 24th, at 7.30 o'clock. The honorary secretary is Mr. R. Davies-Colley, C.M.G., M.Ch., 10, Devonshire Place, W.1.

LECTURES open to students and graduates will be given in the Surgical Unit at the London Hospital Medical College as follows:—On June 16th and 17th Mr. Robert Milne: Bone grafting; on June 23rd, 25th, and 30th Mr. Russell Howard: The acute abdomen; and on July 14th and 21st Mr. Frank Kidd: *B. coli* infection of the kidney.

A COURSE of operative surgery, specially adapted to the needs of general practitioners, will be held at the London School of Clinical Medicine, the Seamen's Hospital, Greenwich, on Mondays, Tuesdays, and Wednesdays, at 2.30 p.m., from June 21st to July 28th. The fee for the course is 10 guineas. Further particulars can be obtained from the Dean, at the Seamen's Hospital, Greenwich.

FLECHSIG celebrated on May 23rd the fiftieth anniversary of his doctorate. The son of a pastor of Zwickau, he was born in 1847 and studied medicine in the University of Leipzig, where he became assistant to the Physiological Institute under Ludwig. In 1882 he took charge of the Leipzig Nervenkl. of which he is still the head. His reputation as a neurologist is well known, and in celebration of his jubilee is being published the first volume of a new work on the anatomy of the brain and spinal cord.

THE Ministry of Health has issued a circular (96, May 18th, 1920) to which is appended a list of the treatment centres for venereal diseases so far approved by the Ministry under the Public Health (Venereal Diseases) Regulations, 1916. Information is given as to the days and hours of the out-patient clinics, and the days and hours for irrigation of cases of gonorrhoea during the intervals between the clinics. The list should be of particular service in the case of patients who remove from one area to another and need further treatment. There are now, it appears, 157 treatment centres in England and Wales, distributed throughout the cities and principal towns. In London there are 35 centres; Liverpool and Manchester each have 5; Sheffield 4; Birmingham 3, Cardiff, Bristol, and Southampton have 2 each. With the exception of a few special institutions each clinic has accommodation for the treatment of both males and females.

THE Executive Committee of the Women Sanitary Inspectors' and Health Visitors' Association, having affirmed the principle of equal pay for men and women officials working side by side in Public Health Departments, has adopted the following scale of salaries:

(a) Assistant women inspectors or assistant health visitors £250, rising by £10 per year to £350. (b) Women sanitary inspectors, women inspectors of nuisances or health visitors, £350 minimum, rising by £15 per year to £500. (c) Chief women inspectors or chief health visitors, £500 minimum. This scale is identical with that adopted by the General Council of the Sanitary Inspectors' Association. In an explanatory memorandum it is claimed that the duties performed by women public health officials are highly specialized, arduous, and exacting; that for their due performance a long and highly technical training is required; and that they are in no way of less value to the community than are those performed by men sanitary inspectors. These claims, it is added, have already been recognized in four London boroughs, where equal salaries are now being paid.

THE Harrogate Corporation has issued a pamphlet giving much interesting information concerning Harrogate and its surroundings, and the Harrogate medicinal baths and waters. New and very full analyses have been made by Professor A. Smithells, F.R.S., of the mineral waters of Harrogate, and a summary of his results is included. An account of Harrogate Spa was given in our issue of July 19th, 1919, p. 78. Grove House, one of the largest residences in the town, is now being converted into a home for clinical investigation, under the auspices of the Harrogate Medical Society.

ACCORDING to the fourteenth annual report of the Trinidad Association for the Prevention and Treatment of Tuberculosis, the mortality from tuberculosis in the island has diminished progressively since 1905; the average annual death rate was 155 per 100,000 during the period 1912-18, as compared with 221 during the previous seven years. In 1918 there were 545 deaths (compared with 505 in 1917) among a population of 379,000; Port of Spain, with only 68,000 inhabitants, contributed 262 deaths. The association earnestly advocates the provision of a sanatorium for treatment of early cases; it also asks for funds to be applied to the home relief of necessitous consumptives in all stages of the disease.

THE Department of Industrial Administration of the College of Technology, Manchester, is publishing through the Manchester University Press a series of pamphlets on economic questions of the day. Those so far issued are reprints of lectures given last autumn, one by Professor J. B. Baillie on *Industrial Unrest*, another by Mr. G. D. H. Cole, M.A., on *Democracy in Industry*, and a third by Mr. Percy Alden, honorary secretary of the British Institute of Social Science, on *Unemployment*. The lectures deal rather with general principles than detail. The causes of trouble and possible remedies are concisely discussed. Mr. Alden's remedies are the regularization of industry to reduce cyclical fluctuations, the creation of fresh industries, the establishment of garden cities, and the enforcement of a universal compulsory scheme of insurance against unemployment.

THE Committee of the Armenian Red Cross and Refugee Fund ask for continued aid by the old subscribers and assistance from new sources. Fresh inroads made by the Turks have compelled many more refugees to leave their temporary resting places and flee to already overcrowded territory at Erivan, where infectious diseases are causing a very heavy mortality. The acceptance of relief is said to be abhorrent to the independent spirit of the Armenian people. As an instance, an American relief worker at Jerusalem reports that all the local communities are receiving doles from the military authorities, helped by private charity; "the exception is the Armenians, every single able-bodied one of whom has found work to do and has become self-supporting." The gross amount received by the fund in the past quarter was £4,564: to each pound a Treasury grant of the same amount is added. £5,000 worth of stores were given for Armenian relief by the British Red Cross Society and the Order of St. John of Jerusalem. The secretary of the fund is Miss Emily J. Robinson, of 35A, Elsham Road, W. 14.

ACCORDING to a tabular statement issued by the Public Health Department of the Ministry of the Interior, there were in Egypt during 1919, among Egyptians 833 cases of plague with 445 deaths, and among foreigners 44 cases with 28 deaths. In Cairo and Alexandria there were only 5 cases. Cases admitted to hospital comprised 563 cases of bubonic, 13 of septicaemic, and 51 of pneumonic plague. The percentage mortality among hospital cases was 40.06, as compared with 32.22 and 40.64, in 1918 and 1917 respectively.

MR. WILLIAM HEINEMANN will shortly publish *Venereal Diseases: their Clinical Aspect and Treatment*, by Mr. J. E. R. McDonagh.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

As, owing to printing difficulties, the *JOURNAL* must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

In order to avoid delay, it is particularly requested that **ALL** letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

The postal address of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
2. **FINANCIAL SECRETARY AND BUSINESS MANAGER** (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. **MEDICAL SECRETARY**, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bucillus*, Dublin; telephone, 4737, Dublin), and of the *Scottish Office*, 6, Rutland Square, Edinburgh (telegrams: *Associate*, Edinburgh; telephone, 4361, Central).

QUERIES AND ANSWERS.

INCOME TAX.

RETIRED PAY inquires as to how his income will be assessed for 1920-21; the income is as follows: Army pension £765, investment income £110, leasehold house £68, an uncertain sum for work under the Pensions Ministry, say £100 after deducting expenses; total £1,043.

*. * The earned income, after deduction of the 10 per cent. allowance, amounts to £778 10s.—that is, £765 + £100 = £865 10s.—and the investment income to £110 + £68, therefore the total assessable income is £956 10s. From this he is entitled to deduct £225, allowance for self and wife, leaving chargeable to tax £731 10s., of which £225 will be chargeable at 3s. and the balance, £506 10s., at 6s.; the allowance for life assurance at 3s. or 4s. 6d., according to the date of the policy, provides a deduction from the tax so calculated.

C. H. S. purchased a practice in 1919, paying for it in two instalments. Can he deduct as an expense the second instalment, which, of course, was paid after C. H. S. had commenced his practice work.

*. * No; the second instalment, like the first, is a payment of a capital nature for the purchase of the practice, and is not an expense incurred in conducting the practice. The payment is not assessable as income in the hands of the recipient or deductible as a payment in the accounts of the payer.

C. F. M. inquires as to the different rates of income tax for the R.A.M.C. and the ordinary civilian rates.

*. * A whole-time medical practitioner is entitled to the special service rate only on that portion of his income which he receives for distinctively military work. The actual rates would depend on the amount of total income; if that amount is between £1,000 and £1,500 the rates for 1919-20 would be 2s. 3d. and 3s. 9d. for military and civil earnings respectively.

LETTERS, NOTES, ETC.

RATS AND PLAGUE.

LIEUT.-COLONEL R. COBB, I.M.S. (ret.), sends us a note with reference to the passages in the Book of Samuel, where models of swellings and golden images of rats are described, as it is believed, in relation to plague. Sir James Cantlie is reported to have said in a recent lecture, that when he was at Hong Kong six-and-twenty years ago a clergyman drew his attention to the passages, and suggested that rats were the cause of plague. Colonel Cobb states that on Sunday, April 19th, 1896, he heard 1 Samuel, chapter vi, read as the first lesson in Calcutta Cathedral; his attention was arrested by the mention of the great destruction caused by "emroids," which was then translated in the margin of the Bible as "haemorrhoids," but it is now given as "tumours." A further study of the history of the plague in other countries supplied several examples of the association of rats and plague, which was especially interesting later, when plague appeared in Calcutta. "In October, 1896," Lieut.-Colonel Cobb continues, "I was asked by Dr. Simpson to see a case in consultation which proved to be plague. On leaving the patient's room I saw, on the stairs, a sickly, mangy and dazed looking rat. My mind being full of the connexion between rats and the plague, I suggested to Dr. Simpson to take the animal to his Municipal Laboratory. Dr. Simpson not only demonstrated the presence of plague diplo-bacteria in its body, but subsequently made successful cultures of the

organism. Dr. Simpson informed me that rats had been found dead in large numbers in Calcutta, especially in the vicinity of the grain shops. Measures were then taken to destroy the rats, which were now proved to be carriers of the disease, and since then rat destruction has been the main factor in the prevention of the spread of plague."

INFECTION IN PNEUMONIA.

DR. J. M. DUNCAN SCOTT (Cambridge) writes, in reply to "H. G.," April 17th (p. 550), who asked for authenticated examples, dating before 1914, of several persons under one roof contracting pneumonia in the manner which has recently become common:

I cannot give specific cases, as the records are inaccessible, but such examples as he desires were fairly frequent in the native compounds on the Rand before the year he mentions. The cases of pneumonia coming from these native compounds were even then regarded, certainly by some authorities, as probably for the most part infectious. The infectious nature of the disease was then so far recognized that instructions were in force, certainly on one group of mines, that where several cases occurred in one room in a compound, that room was to be closed until disinfection had been carried out, and in the hospitals pneumonia cases were as far as possible isolated in separate wards. The type of disease closely resembled influenzal pneumonia.

VALUE OF LEGUMES IN BERI-BERI.

DR. E. F. WILLS (London Mission Hospital and Leper Home, Siakokan, C. China) writes: In 1917 I was M.O. on a boat carrying 1,700 Chinese coolies to France. The journey took three months. The food was supplied from Hong Kong, and consisted of white polished rice from Saigon, various dried fish, potatoes, and sometimes gourd, when obtainable at ports. When we reached Colombo about the end of May—over three weeks' journey—forty-six coolies showed signs of beri-beri, and were landed. The ship was delayed there two weeks for raiders, and twenty-six were fit to resume the journey. The white rice was changed for red coolie rice, lentils were added to the daily diet, and yeast given to recently recovered cases. The course taken was round the Cape, and Sierra Leone was reached on July 14th. By that time the red rice and lentils were finished, and once more about thirty to forty men showed signs of beri-beri. Arrived at Sierra Leone, I was told that date of arrival at Plymouth was very uncertain because of submarines. Owing to the kindness of a clerk in Messrs. Elder Dempster's, and backed by the General-in-Command, I secured 8,000 lb. of dried legumes in the stores. They were from America. For the next two weeks we had to continue white rice, but added peas, or beans, or lentils at every meal. When Plymouth was reached on July 30th there was no sign left of beri-beri. A previous ship that did the same journey but failed to secure legumes registered over 20 deaths from beri-beri; a second boat had 17, I think. The legumes we used were simply boiled and served in gravy.

FOOD AND DISEASE.

DR. JOHN HADDON (Denholm, Hawick) writes: Mr. Rowland's lecture on gall stones is to me most interesting and instructive and clears up many cases that I met with in practice long ago; but what I would like to call attention to is the fact that Case 1 is that of a medical man who kept a note of his symptoms. If that practice were followed by all medical men, what progress would be made! It was by watching my own symptoms and trying to find out their primary cause that I discovered that food is the chief cause of disease. It is the most difficult subject I ever tackled; there are so many conjunct causes, as Sydenham knew. But let any doctor who has any chronic ailment watch his symptoms and note his food and he will soon become convinced of the truth of my statement.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 34, 35, 36, 37, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 32, 33, and 34.

The appointment of certifying factory surgeon at Liverpool, Central (Lancaster) is vacant.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-restant letters addressed either in initials or numbers.

A British Medical Association Lecture

ON

THE PASSIVE MECHANICAL FACTOR
IN HEART DISEASE:

ITS INFLUENCE AND MANAGEMENT.*

BY

ALEXANDER BLACKHALL-MORISON, M.D.,

F.R.C.P. LOND. AND EDIN.,

CONSULTING PHYSICIAN TO THE GREAT NORTHERN CENTRAL HOSPITAL;
CARDIOLOGIST TO MOUNT VERNON HOSPITAL.

(With Special Plate.)

By the "passive mechanical factor in heart disease" I understand the conditions which promote or impede the effective exercise of the active factor—the cardiac muscle. The matter so defined is, obviously, both physiological and pathological, and its adequate treatment might well occupy several lectures instead of one, but I shall endeavour so to deal with it that its practical importance may be apparent without claiming for it more than its due weight.

In his interesting Linacre Lecture on the "Law of the Heart," delivered in 1915, Dr. Starling has endeavoured to show the great adaptability of the heart in dealing with a wide variation in the quantity of blood it receives, in spite of much difference in the arterial pressure it has to overcome, and he experimentally tries also to demonstrate that the physiological law applies in disease when, in addition to variations of arterial resistance, mechanical disabilities, such as destruction of the aortic valves, is brought about. The output of the ventricle, within certain wide limits, remains the same provided the inflow be constant. Although under these circumstances altering the arterial pressure has no influence, a great effect is produced by varying the inflow. Increased inflow is associated with increased outflow, and there is no damming up of blood on the venous side. These conditions Dr. Starling illustrates by an ingenious heart-lung preparation, as he terms it, which he described in his lecture.

It must, however, be noted that, although Starling's detached or eviscerated heart disposes of large or small amounts of blood, with the same *sang-froid*, its rate is in no ways varied. It slogs at the same monotonous pace whatever work it has to do. This is not so *in corpore*. While, therefore, the heart may show, by some augmentation of total chemical changes, that it does more active work the larger the amount of blood it has to dispose of, there is evidently a passive factor in the situation which must be recognized.

Hill and Barnard, whose work on gravitation in the circulation is well known, maintain that the principle of the siphon is not applicable to the vascular system, as the arteries on the one hand and the veins on the other are of such different distensibility and elasticity.¹

But does this conclusion, even if correct, apply to the lesser or pulmonary circulation? Hill² presents the analogy of the "rheochord" to the siphon as affecting, in any case, the systemic circulation, on account of the innervation of the vascular system. In the case of the cerebral circulation, however, even after the demonstration of its rich innervation, which I gave in 1898,³ he maintained the *Monro doctrine*, and, so far as I know, does so still. Bradford has also shown that the pulmonary circulation responds to nervous stimulation, but there is little doubt that both the pulmonic and cerebral circulation have, for physical reasons, a large passive element in their conduction.

In an exhaustive consideration of asphyxia neonatorum which was published in the *Lancet* of 1894, like Dr. Starling, I also constructed a heart-lung apparatus, but with the dead heart of a sheep, a system of tubes, and a lung bottle, which convinced me of the important rôle of the passive force of gravitation in the circulation as distinguished from the active forces of aspiration and propulsion. Still earlier, in 1878,⁴ an anatomical comparison of the heart and vascular system of the quadruped

and man appeared to me to argue the greater ease in the conduction of the erect as compared with the horizontal circulation.

But the investigation of the conditions of the pulmonary circulation is one of the most difficult tasks the physiologist can set himself, as is acknowledged in Tigerstedt's exhaustive article on the subject.⁵ It has nevertheless been reasonably concluded that the pressure variation in the pulmonary circuit is much less than in the systemic circulation and the velocity of the blood greater.⁶

In the supply from the right to the left heart a passive siphonage appears to play a large part, and, while a chemical estimation of cardiac energy may show, as I have stated, greater work on the part of the heart, the passive force referred to probably makes the efficiency of that organ under the circumstances possible. What, however, the experimental physiologist, with all his ingenuity and skill, fails to accomplish is at times brought about by what I have termed the vivisection of disease. In an address given to the Esculapian Society of London, on cardiac motion as revealed by the vivisection of disease,⁷ I gave full particulars of the clinical history and necropsy of a case of sarcoma of the heart, which placed the right auricle and ventricle out of action, and in which the circulation was for long maintained by the left side of the heart alone. The patient ultimately died without giving any evidence of the anasarca or effusion into serous cavities which so limited an amount of cardiac activity would *a priori* have suggested as probable. The only portions of the right ventricle which could by any conception be regarded as effective were the right ventricular aspect of the septum ventriculorum and a small portion of the posterior wall.

That the circulation was effectively carried on thus for a considerable period is evident from the degree in which the heart was involved in the morbid process. It was not merely pushed aside by or adherent to the growth, as frequently happens, but was involved in it and replaced by it, a process requiring time. The aspiratory and propulsive aid of the right chambers of the heart may, therefore, be regarded as having been extinguished, and the process of their extinction was clinically marked by the gradual silencing of a rough tricuspid bruit—a bruit of tricuspid fixation—which was a marked feature of the case in its first period. The *cadaver* showed no oedema of limb or excess of fluid in the peritoneal cavity; 13 oz. of blood-stained fluid found in the right pleural sac could be accounted for by local conditions. Both lungs were adherent to the ribs and the base of the left to the diaphragm. No more striking evidence, in my opinion, of the passive force in the transmission of the blood from the right to the left heart could be conceived, and sections of the growth show that both the conus arteriosus and the aorta were held by it as in a vice, encroached upon but, of course, not occluded.

In this connexion I may also mention the conditions of the fetal circulation and of cases of dextro-cardiac malformation which survive in some cases to middle and even old age, and in others are so malformed as to render any length of life impossible. Communication with the left heart may be free, but active propulsion remains the rôle of the right heart. The passive siphon of the pulmonary circulation fails to be established or to be only inadequately established, and the length of life of the bearer of the lesion is in proportion to the dextro-cardiac activity thus imposed, although the most cardiacally malformed fetus, under the hydraulics of its circulation *in utero*, may come into the world well nourished and generally well developed. The maternal circulation, while anatomically distinct from that of the fetus, is so related to it, through placental pressure, as to transmit to it not only oxygen, but also nutriment and hydraulic force. In this case, whether the placenta be at a higher level than the fetal heart or below it, the passive pressure from a higher source remains, and the circulation is well maintained until pulmonic siphonage becomes due.

It has frequently been stated that there is a marked difference between the development of the dextral chambers in the fetal heart before and after birth, but at term the relative muscularity of the right and of the left chambers of the heart is very much that which it is in extrauterine life. I show a specimen to demonstrate this fact, obtained from a child 7 days old, who died of atelectasis pulmonum, and in whom the heart was normal.

* Delivered before the Edinburgh Branch of the Association on February 27th, 1920.

The fetal communications will be seen to be still pervious. On this subject Dr. George Alexander Gibson wrote interestingly, and it is a pleasure to me to recall his genial personality and his valuable work.⁸

The Oliver-Sharpey lecturer of 1911 and the Lumleian lecturer of 1917 both made merry in their orations over what they were pleased to consider "back pressure," an ancient and erroneous conception as a cause of cardiac failure discarded by the greater acumen of that new cardiology, of which they regarded themselves as exponents. The back pressure which they triumphantly demolished was, however, a creation of their own imagination. For no one ever called in question loss of power in cardiac muscle as being the cause of its failure. That waning power is, however, unquestionably the outcome in many cases of the additional work imposed upon it by mechanical passive defects. The Lumleian lecturer, however, remarked, "We do not fully understand the underlying causes of oliguria in cardiac cases, any more than we know the exact mechanism of cardiac oedema," and, unless the principle of the passive force in the lesser circulation be grasped and that of stagnation or back pressure be appreciated, it will be difficult, in my opinion, for anyone to find a satisfactory solution to these questions. By its aid the matter becomes clear.

One of the earliest signs of failure in the easy current from the right to the left heart is the occurrence of a reversible crepitation at the base, usually in the first instance, of the left lung. There are sufficient anatomical reasons, as I long ago pointed out,⁹ for the selection of this site. The patient manifesting it on left or right decubitus, as the case may be, by a single revolution on his own axis loses it in the uppermost lung.¹⁰

The French with their customary happiness of expression have termed this sign "*oedème à bascule*," a see-saw oedema. It is the first evidence of stagnation in the left horn of the pulmonary siphon. Normally this siphon carries the blood to the left ventricle, where, like a well-judged leg hit, the hæmic ball is easily lifted into the far field of the arterial stream. But when the cricketer, the left ventricle, is fatigued, there is a degree of impotence in the stroke which declares failure, and the evidence of this is noted by the sign in question. It is the first stage in a stagnation which gradually extends or may extend to the whole venous inflow as ventricular effort wanes, and may, as we shall presently learn, even develop into a powerful repulsion into the superior caval venous system and also into the abdominal venous cistern, of which the inferior cava is the mouth. Both the cardiac lung and the cardiac kidney are explicable by a recognition of lessened arterial impulse and increased venous sluggishness.

The heart, suspended in the thorax within its pericardial sac, has a certain relation to lungs, diaphragm, and thoracic parietes. Under normal circumstances these relations are perfectly adapted to allow, without friction, the limited changes in position and dimensions which occur in systole and diastole. These perfect relations may be disturbed by the genesis of states in which the normal territory of the heart is invaded or encroached upon or in which the heart itself oversteps its boundaries. By such encroachment or excursion the free and unhampered systole and diastole in the upper and lower chambers of the heart are interfered with, and, to use an engineer's phrase, which has also been used in this connexion by that master of the English language, our President, Sir Clifford Allbutt, the "sweet run" of the mechanism is replaced by friction, effort, impediment, and disadvantage. Even the beneficial action of agents which would otherwise prove successful in removing disability may from such passive causes be rendered nugatory.

The *exocardial* conditions which aid or interfere with this *sweet run* of the machinery, may be conditions of negative or positive pressure within the chest, intrathoracic inflammations of various kinds and in various phases, neoplasms, distortions of the cage in which the heart is contained and works, and certain developmental states, in which the viscera are transposed.

Hypermyosis, excessive hypertrophy or *cor bovinum*, is usually of endocardial origin or of this combined with *exocardial* tethering, but, as *cor bovinum*, its bulk alone in relation to the thoracic contents and wall may be regarded as an *exocardial* excursion beyond the normal boundaries of the heart. From mere bulk it may be one of the factors

deranging the smooth working of the organ and provoking signs of cardiac difficulty or distress.

Intrathoracic pressure under normal circumstances is always negative, but is at its maximum in inspiration and at its minimum in expiration. Inspiration is aspiratory from the venous cistern into the chest, and expiration is propulsive towards the left heart. The greater the inspiration the more the retention of blood in the chest by the thoracic vacuum, and, in dyspnoeic conditions, inspiration gains the upper hand, tending to dilate the auricles and to a less extent the ventricles, but the thin-walled upper chambers naturally feel this force most. This is well shown on a model devised by Herman.¹¹

The asthmatic, with his prolonged expiratory snore or wheeze, acquires a fixity of chest which impedes the venous inflow, and experience teaches us that this condition may be most promptly dealt with by a rhythmical compression of the chest in the expiratory phase of respiration. In some cases I have prescribed nothing else, when the chest has retained resiliency.¹²

What we may at any time demonstrate in the dyspnoea of the asthmatic we also see in that of the cardiopath, and here, when lung and heart are fixed by adhesions, impeding the rhythmical play of the former and the contraction or systole of the latter, we have to deal with conditions which induce in many cases a hypertrophy of heart which causes that organ, by its mere increase in muscle and its greater blood content, still farther to disturb the balance between the respiratory and circulatory pumps.

In these circumstances we may struggle in vain to relieve the burdened and tethered heart by cardiac tonics or by any other means, but may, by affording the organ more room to act in, transform in some cases a hopeless condition of embarrassed circulation into one of comfort and convalescence by cardiolysis or thoracotomy. To this point I wish to draw particular attention because of its great practical importance.

Brauer of Heidelberg first practised cardiolysis for symphysis cordis in 1902,¹³ and I used the same method for hypermyosis without symphysis in 1907.¹⁴ I have now had considerable experience in precordial thoracotomy, but a detailed discussion of the measure is not possible in this place. I wish, however, to state with all the emphasis in my power that the surgeon may here at times, under the guidance of the physician, very effectively come to the aid of the latter, and shall relate one experience on this point which will speak for itself.

Just as the indication for most fruitful venesection is a degree of venous turgidity which is associated with cyanosis, so the best guide to precordial thoracotomy is an amount of systolic movement in the costal or sterno-costal thorax which is the necessary consequence of an enlarged and usually adherent heart. For obvious reasons this is best seen in the young, in whom also a permanent precordial bulging may indicate the adaptation of a mouldable cage to its enlarged cardiac content. With such adaptation there may be an absence of signs warranting thoracotomy. The *modus operandi* of the measure is simply the relief of intrathoracic pressure resulting in greater mobility of heart and improved siphonage, the more resilient the chest the better the result as a rule, which is not, however, without exceptions.

The question of an anaesthetic has given me much concern in these cases, and I have known one to die on the table under general anaesthesia before operation could be undertaken. But that anxiety is now a matter of the past, for I have found that local anaesthesia serves every purpose and is safe. In the following case the measure indicated definitely saved life.

F. P., aged 10 years, was admitted under my care to the Great Northern Central Hospital on February 11th, 1919, with a history of having suffered six weeks previously from rheumatic fever, and of having been confined to bed since. On admission he merely complained of pain in his arms and legs, but his face had begun to swell. The temperature varied from 98° in the morning to 99° in the evening; the respirations ranged from 24 to 26, and the pulse from 96 to 120. It had evidently not been his first attack of rheumatism. The area of cardiac dullness was large, and he had a well developed apical systolic bruit. The lungs were, however, clear, and the urine free from albumin. There was visible and palpable pulsation from the fourth to the sixth interspace, and the cardiac impulse heaved the thorax. A rough systolic bruit was audible at the apex, traceable to the left and heard in the back. The second sound was accentuated in the area of the pulmonary arterial cusps,

and in the aortic area was closed. He improved under treatment, and a month later was sent to a relief hospital in connexion with the Great Northern Central, but was readmitted on April 23rd, 1919, with a history of having exhibited swelling of the face and abdomen two weeks previously. He then showed enlargement of the liver with effusion into the peritoneal cavity, and crepitation and rhonchi on auscultation at both pulmonary bases.

By radiography the cardiac area was seen to be much enlarged (Plate, Fig. 3) and free fluid was removed from the abdomen by paracentesis on April 24th. The patient, who was all this time confined to bed, was taking digitalis and continued to do so, fruitlessly, for the following month. During this time his condition became steadily worse and his legs and body generally anasarcaous, the liver enlarged in size, the peritoneal effusion reaccumulated; there was effusion also in the left pleural cavity, the urine became albuminous, and I regarded the condition of the patient as hopeless.

Believing I had to deal with an enlarged and adherent heart, I advised cardiolysis as the only hope of altering the situation, but expressed a cautious prognosis as to even temporary benefit, stating that, so far as I could judge, death was otherwise inevitable. After some days' reflection the parents consented to operation, and I asked my colleague, Mr. Barrington-Ward, to remove ribs and cartilages in the area of maximum impulse to the left of the sternum. I stipulated, however, that the operation should be performed under local anaesthesia, as I did not consider that the patient could survive a general anaesthetic.

Operation.

On May 23rd, 1919, portions of the sixth and seventh ribs with their cartilages were removed. The periosteum was not peeled off the pleura, but was divided to relieve tension. The left pleural cavity was accidentally punctured and fluid escaped, air at the same time being sucked in on inspiration. The puncture was closed by suture. The patient cried a good deal during the operation, but confessed afterwards that he had been more frightened than hurt. I confess that, even after the operation, I was not sanguine of any striking benefit, and was, consequently, astonished by the result, which was chronicled, to my dictation, in the notes of my house-surgeon, (Captain Huxtable, M.C., as follows:—"29.5.19 (that is, six days after the operation): pulse 108, regular; respirations 36; anasarca entirely disappeared; no free fluid in peritoneum; no swelling of face; subjectively quite comfortable; sleeps quietly, which was not the case previously."

The use of digitalis was continued after the operation and later abandoned. When it had been left off for a time there was some return of peritoneal effusion, the liver remaining enlarged. The fluid was drawn off, the digitalis resumed, and the effusion did not recur. The pulse throughout was regular, but of rather high rate (112-120). The patient was later removed to Mount Vernon Hospital, to be under my care, and is there now, more as a convalescent than as a patient (Figs. 4 and 5). He travelled to London recently for the purpose of radiography, and I exhibit the radiograms made. The chief

FIG. 5.—A, Cardiogram. This case having been a low thoracotomy (sixth and seventh ribs) and the periosteum not having been removed, the systolic excursion of the ventricular systole is not so pronounced as in a higher thoracotomy. B, Radial pulse of low tension.

difference these exhibit is in the diminished distension of the right heart and a clearer distinction between it and the diaphragm on the right side in those taken after the operation as compared with the skiagram taken before operation, in which an inclined plane runs from the right heart directly into the liver shadow (Plate, Figs. 2 and 3).

Present Condition.—He has gained 9 lb. in weight since admission; pulse regular, rate 84 and of good force. There is heaving pulsation in the precordium, including the lower half of the sternum. The area of cardiac dullness is 5 in. by 7 in., the right border of dullness extending 2 in. to the right of the mid-sternal line. The apex beat is in the fifth space 3 in. from mid sternum. A systolic bruit of musical pitch is traceable to the left posterior axillary line and as far as mid-sternum to the right. The bruit is audible also in the back and loudest in the left paravertebral groove. The second sound is accentuated over the pulmonary arterial valves and is normal in the aortic area, the sigmoid valves closing. The respiratory rate is 30, the pulmonary auscultatory signs are quite normal, as are the dimensions of the liver. There is no abnormal effusion into any tissue or cavity. The systolic blood pressure is 95 to 100 mm. of mercury and the diastolic 65 to 70 mm. He takes moderate exercise without any discomfort.

Nothing further need be said of the other *exocardial* conditions mentioned than that their effect is to crowd intrathoracic space and disturb the balance of pressure within the thorax, as well as to hamper the action of the heart, and deprive the blood stream of the full force of the

passive element in its transit which we have discussed, and incidentally to render more difficult the chemical interchanges of the respiratory function. The removal or diminution of such positive intrathoracic pressure when possible is obviously indicated, and it is usually possible, except in developmental states, by well-recognized means which need not be further considered.

The *endocardial* passive factor in heart disease is mainly valvular. In the period immediately prior to the war a certain school of thought, already referred to, covered with scorn both the undue importance attributed by some to valvular aid in the circulation, and the old and well known conception of what was and is termed "compensation" in the cardiac mechanism, for conditions rendering the circulation more difficult. In itself the term, properly understood, offers no serious objection. To the establishment of compensation the slow onset of difficulty is necessary. The physiologist may destroy valves in the laboratory, and, notwithstanding, for a time register a satisfactory arterial pressure, in such an apparatus as that of Starling already mentioned, but the clinician knows that rupture of a valve in man—a rare event—is frequently very rapidly fatal even in the right heart. The organ has not time afforded it to establish what is quite intelligibly termed compensation, that is, sufficient muscular force behind the suddenly disabled valve to enable the circulation to be efficiently maintained.

I know no more striking proof of the value of the passive valvular factor than is afforded by observation of the circulation in the heart and vessels before the valves have come into being. This is best observed in the transparent embryo of the fish, in which the powerful ventricle void of valve may be seen to be associated at the aortic end with propulsion in the systolic phase and with reflux in the diastolic, and at the sinal end with reflux in the systolic and heart-ward aspiration in the diastolic phase. In the dorsal aorta the blood stream may also be seen to be not steadily progressive but swinging to and fro in a see-saw manner, in obedience to the systole and diastole of the ventricle. In short, in the embryo fish may be seen the best demonstration possible of the Corrigan pulse of well-marked aortic insufficiency. After the formation of the valves and increase of rate in the heart's action the stream becomes purely progressive, and in high rates of heart-beat as continuous as the venous inflow.

In this connexion I may be permitted a few words on methods of examination for the purpose of diagnosis, prognosis, and treatment. While recognizing the general interest, in some cases the utility and in others the necessity for examining a patient by graphic methods mechanical and electrical, and adding radiospection to the employment of our eyes and fingers, it will not surprise you if I express the hope that there may be no abatement in the assiduous cultivation of the old and classical methods. Every method must be used to determine not only the condition of the cardiac muscle, but also which of and to what extent the passive mechanical factors are involved in any given case.

In practice the *degree*, moreover, of the valvular deficiency or obstruction in any case is important. As I have endeavoured to show, the largely passive siphonage from the right to the left heart is effective up to the left ventricle. The featureless left auricle with the undefended pulmonary veins show how much is expected from the powerful mitral valve, and here also the *degree* in which the auricle is defended is important, as also is the case with which the entrance of the blood into the ventricle is secured.

The depreciation of the importance of the passive valvular factor before the war, under the influence of the school of thought mentioned, was responsible for the passing into the army of a good many men who, from valvular defect, were incapable of standing the strain of war conditions. The lesson drawn from experience in the war was the revision on the part of these optimists of their views, certainly as regards the influence of aortic and mitral stenotic lesions; but they still retain some impenitence as regards mitral reflux. It is their last ditch, and they fight valiantly in it.¹⁵

But it may be said, cases of both aortic and mitral disease may be adduced which passed through the strenuous experience of war without disability. Such certainly occur, but not frequently, and here again the

degree of defect is as important as the nature of it. How can this be gauged? He would be a bold, not to say an imprudent, man who claimed precision in his estimate of this condition—in the answer, that is, to this question. But it may be affirmed with reason that the determination of the systolic and diastolic blood pressure by the sphygmomanometer is an aid not to be despised. The low diastolic figures of aortic regurgitant disease frequently reveal a considerable degree of this lesion, even when auditory and other signs would lead to a more favourable estimate, and the value of the aortic platform is nowhere better shown than in the normal ventricle behind a large aneurysm of the aorta when the valves are perfect, and the hypertrophied chamber behind valves which leak under these circumstances.

Similarly the height of the systolic blood pressure and the size of the pulse form a useful gauge of the freedom of entry of blood into the left ventricle through a stenosed mitral orifice. With pronounced muscular failure stenosis of the aortic orifice may reach such a degree as to render the radial pulses imperceptible and the diagnosis of any valvular lesion whatever impossible. This was so in a case from which I show a specimen.

On the other hand, obstruction at the mitral orifice may so engorge the right heart as to cause the right ventricle to throw a powerful systolic wave upwards into the superior caval venous system, and downwards into the inferior cava and hepatic sinuses. This may be seen in cases both with and without associated auricular fibrillation. It must be remembered that right ventricular systole occurs during right auricular diastole, and that the auricle may contract for a time more or less efficiently during the subsequent ventricular diastole, even when right ventricular retro-pulsion through a defective tricuspid valve has for some time been well marked. In one case, the heart from which is shown—that of severe mitral stenosis—there was present at the same time heart-block, probably of the left limb of the auriculo-ventricular bundle, according to electro-cardiography, for I postponed the anatomical investigation of the point until I had shown the specimen here, so as not to damage the aortic orifice.* In another case, the heart from which is also shown—that of aortic valvular disease and stenosis both of the mitral and tricuspid orifices, and all due to rheumatic endocarditis—the powerful right ventricular retro-pulsion, as exhibited in the phlebogram shown, and which was grossly visible to the naked eye, was associated with a regular pulse, indicating the absence of auricular fibrillation. At a later period, however, after a severe attack of paroxysmal tachycardia lasting for some days, a persistent irregularity of heart's action (auricular fibrillation) became established. This was also the sequence in a case of persistent *foramen primum* with hypertrophied right cardiac chambers, of which I recently published an account.¹⁶

But paroxysmal tachycardia may be followed by ventricular failure with the development of well-marked mitral reflux and death, but without any auricular fibrillation. In such a case observed by myself, the paroxysmal tachycardia was sudden in onset and as sudden in cessation, and of about twenty-four hours' duration. As, however, is often observed, such tachycardias may recur with some frequency, without entailing either auricular fibrillation or ventricular failure as a consequence. This condition was wont to be regarded as a cardiac neurosis, a term less discredited now than it was prior to the demonstration of the full innervation of the excitatory system of the heart.¹⁷

In these attacks we have also to remember, as Martius¹⁸ and others have pointed out, that auricular repletion and distension is a late, not early, condition in a valvularly sound heart. The tachycardial ventricle, unequal to sufficient output, accumulates blood which gradually distends and disables the auricle, which may collapse in fine tremor and systolic impotence—conditions synonymous with fibrillation of that chamber.

Similarly, there is no doubt that the ventricle, accelerated by exertion or emotion, or by both these states combined, may likewise distend and disable the auricle, even when the general condition of its musculature is healthy. This

is especially prone to occur if there be at the same time some local passive mechanical impediment to easy blood flow through the heart. I show a specimen from such a case which occurred in a youth during a football match, in whom *post-mortem* examination, some years later, showed only a slight degree of mitral stenosis. In this case thoracotomy had been performed, and I show a photograph and some tracings. I have observed the same sequence in another case, in which an active workman who helped to extinguish a fire broke down in auricular fibrillation immediately afterwards. In him also, some years later, I found a definitely stenosed mitral valve, due, so far as could be ascertained, to an almost forgotten chorea in very early life. Why, then, is auricular fibrillation not more frequently observed in cases of cardiac failure with aortic valvular disease? Of the failure in such a case I show an instructive series of tracings, together with a photograph of the heart and an exhibition of the effect upon it of sufficient doses of digitalis. The comparative rarity of auricular fibrillation in aortic valvular failure, as well as the rarity of dropsies in such cases, is, I believe, mainly due to the protection of the pulmonary circulation by the powerful mitral valve and the delaying of that much criticized back pressure or venous stagnation which is favoured by an undefended or obstructed left auricle. It is a matter of experience that few aortic valvular cases die waterlogged. As Dr. George Balfour states, "It is only rarely that dropsy and other secondary diseases of a serious character are established in such cases."¹⁹

It might, indeed, be argued in a case such as that to which I have referred, in which a degree of heart-block was present in association with auricular fibrillation, that the blockage was advantageous, rather than otherwise, by reducing the ventricular rate independently of the normal relation between the lower and upper chambers of the heart. This case is at once an example of that vivisection by disease to which I have already referred, and of that series of interstitial passive and pathological factors which it is impossible within the limits of our time to discuss to-day. It also showed a positive Wassermann reaction and had a cirrhotic liver, which I exhibit, and died waterlogged, but very slowly. This liver, as well as that from another case with powerful venous retro-pulsion, which I also show, demonstrates, in the wide and gaping inferior caval entrance and dilated hepatic sinuses entering it, the effects of the powerful venous retro-pulsion which both exhibited and phlebograms of which I have shown.

Again, when we consider the *duration* of some cases of pronounced auricular fibrillation of the tachycardial type, compatible more or less with corporeal activity and often with little subjective discomfort, we may reasonably attribute this to the presence in such cases of a sound valvular apparatus. I show a radiogram from such a case of eleven years' standing, in which it will be observed that there is very little evidence of dilatation of any of the chambers of the heart.

I submit that the continuance for any length of time of auricular fibrillation, with ventricular action of high rate, in cases of valvular disease of the heart is a very rare event. In auricular fibrillation with tachycardia in these circumstances, either the rate must be reduced more or less promptly or the patient dies. No better evidence of the value of valvular integrity need be sought than this fact, which all who have had much clinical experience will, I feel certain, be in a position to confirm.

While, therefore, from the time of Harvey to the present moment, no one has disputed the pre-eminence of the muscular factor in maintaining the circulation of the blood, the importance, likewise, of valvular integrity and freedom in movement of the heart is undeniable.

The combination of exocardial and endocardial passive mechanical factors finds a place in many cases of heart disease—in some the one class and in others the other preponderating. The management, therefore, of the problems involved is, like the factors themselves, one which combines dealing with both. Thus the thoracotomy or other method used for the removal of exocardial impediment may be necessary to the successful treatment, by appropriate agents, of disorders due to or aggravated by defects of passive endocardial factors. In considering the passive exocardial factors, we found that to influence beneficially the action of the cardiac muscle we had to deal with impediments to its action outside the heart

* Anatomical examination since made showed that the branch of the bundle involved was the right, not the left. For confirmation I submitted sections to Professor Arthur Keith, who kindly examined them with me.—A. B. M.

itself. In treating the endocardial passive factor we can only influence it by action upon the cardiac muscle and the blood content of the heart.

In the management of the passive mechanical factor in heart disease, a maintenance of efficient respiration is of the first importance. One of the earliest evidences of imperfect circulation through the heart, it has long been recognized, is some degree of embarrassment of respiration, of what has conventionally been called breathlessness and technically dyspnoea. It may be very slight, transient, and only evoked by circumstances which make an additional call on the heart by exertion, not only of the organ but of the organism. Or it may be more urgent and a consequence of failure of the organ itself to do its particular work, even when the organism as a whole is resting. In any case, the condition has to be dealt with on three lines—namely, by posture; in certain cases by rhythmical manual expiratory pressure and it may be also by manipulatory inspiration, in short, by artificial respiration; and thirdly, by strychnine.

Strychnine is to the distressed pulmonary function as useful as digitalis is to the disordered cardiac muscle. So much so is this the case that it has gained a deservedly high reputation as a cardiac tonic.

The laboratory experimentalist, and even some clinicians, are inclined to believe that strychnine has no effect on the heart. Experience, however, has shown incontestably that the dyspnoea of cardiac failure is relieved by the use of strychnine; and as such dyspnoea is a result of failure of the heart, the latter must be regarded as also eased by strychnine indirectly. This indirect benefit is due to improved respiration and a consequent promotion of better siphonage in the cardio-pulmonary circulation. The powerful action of strychnine on the respiratory centre and upon the spinal cord in raising its reflex irritability is not denied, even by the laboratory therapist.

The so-called Nauheim treatment owed, in my opinion, much of the good produced in the cases benefited by it as largely to the effect of the exercises practised on the respiratory function as it did to its effect upon the heart itself, or to the balneological element introduced. So, too, in so-called Oertelism, with its hill-climbing and its restricted imbibition of fluids, the improvement of respiratory capacity with the more free cardio-pulmonary siphonage resulting, played no small part in the general relief experienced in cases suitable for that mode of treatment. That some who were submitted to it died on the hillsides they climbed, was a regrettable detail.

As regards the blood content factor, no one can have removed a large clot from one of the chambers of the heart *post mortem*, and witnessed its immediate shrinkage from elasticity, without being struck with the importance of this mechanical factor in dealing with the engorged heart. This effect, naturally, is most evident in the thinner and more distensible auricle, in which the shrinkage reminds one of the contraction of the uterus after removal of the placenta or of blood clot.

With such cardiac dilatation during life valvular incompetency frequently occurs, although even this has been denied by some. Sir Charles Ballance, in his recent lectures on the surgery of the heart,²⁰ properly regards any direct cardio-puncture for this state as a "freak operation," and one not to be undertaken lightly, but quotes Dr. Sloan's well known case, in which life was saved by puncture of the heart. In this case the needle of an aspirator was plunged into the heart in the fourth space half an inch to the left of the sternum. It must, therefore, have entered the left ventricle, and while ten ounces of "pure blood" were withdrawn, it is probable that direct stimulation of the muscle must have played a part in restoring its activity.²¹

But while such an heroic measure may not be frequently justifiable, venesection, which our ancestors practised too indiscriminately, still has a place in the rational treatment of heart disease.

By the use of a model of the heart-lung type²² it may be shown that any interruption to the venous inflow at once facilitates cardio-pulmonary siphonage and shrinkage of the dextral chambers of the heart. This limitation of inflow the distressed cardiopath seeks by the assumption of the orthopnoic position, in which gravity retards dextro-cardiac repletion. Dr. George Balfour, whose memory is still green among Edinburgh men, laid much stress on securing recumbency in aortic valvular reflux, and advised the use even of an anaesthetic to lay the orthopnoic flat.²³

But, according to the views expressed in this lecture regarding the passive factors in the circulation, the effect of gravity on the inferior caval column and the siphonage of the pulmonary circuit favoured by the posture in orthopnoea, call in question the desirability of changing the upright position for one in which, whatever its effect in diminishing aortic reflux, there is no question as to its favouring dextro-cardiac repletion and increasing pulmonary embarrassment. Were it indeed possible to compress the inferior vena cava without at the same time obstructing the aorta, which unfortunately it is not, such caval compression would have the same effect upon the cardio-pulmonary circulation as a free venesection and without the effusion of blood.

In the presence of cyanosis venesection is certainly indicated, and I have practised it myself with benefit under these circumstances. In aortic valvular cases Hodgkin²⁴ found bleeding of little service, and the reason for this is evident from the above remarks. To appreciate fully the benefit to be derived from venesection in suitable cases one must, however, consult the experience and practice of our predecessors of a past generation. Thus, we read that in a case of tricuspid and pulmonary obstruction Mr. Kinglake bled the patient during two years upon 312 occasions, to the average amount of 4 oz.—that is, to a heartful—and states that to describe the benefit gained by each bleeding would be to express the difference between the most affecting pain and comparative ease.²⁵

Venesection, like cardiolysis, may be a necessary preliminary to the effective use of that agent, indispensable to the cardiologist for action upon the passive endocardial factor—namely, digitalis—concerning which he is prone to wax eloquent.

"Dotted all over our upland pastures," writes Dr. George Balfour, "there is no nobler plant of our indigenous flora than the *Digitalis purpurea*, and there is no more potent benefactor of mankind among the many constituents of our materia medica."²⁶ There are also few agents concerning the *modus operandi* of which there has been more controversy. To discuss this question in any detail would require a lecture to itself. What, however, every clinician has convinced himself of is that in digitalis he has a trusty means whereby he has on numberless occasions benefited a disordered heart and with which he has at times positively saved life.

If we believe that all cardiac muscle, excitatory and executive, is under the control of the inhibitory, accelerant, and augmentative nervous system, and we succeed by medicinal agents in inhibiting, accelerating, or augmenting cardiac action, it seems reasonable to assume that we do so by the effect of the agents in question upon the nervous system proper for the control or execution of these actions. The only alternative would be to suppose that the use of certain agents renders the cardiac muscle refractory or resistant to their action, or, on the other hand, impulsively obedient to them.

But, leaving speculative disquisition and betaking ourselves to the important field of clinical observation, we can take firm ground on certain facts of experience. If such an attitude be regarded as empirical, so be it. From our empiricism emerges benefit. The most striking results of digitalis are unquestionably observed in the control by it of the paroxysmal tachycardial irregularities of the heart's action found in association with mitral valvular disease, whether obstructive or regurgitant. The heart slows, the tumult is stilled, and quiet reigns. Older writers therefore regarded digitalis as the "opium of the heart," and one of the most recent²⁷ considers it hypnotic to that organ. But it is not only in tumult with irregularity, but in tumult—that is acceleration—with regular action, that this drug is found to still the storm. The regular failing aortic valvular heart may be succoured, as well as the irregular failing mitral heart, and the failing heart which is neither aortic nor mitral, but has a sound valvular apparatus. These facts are undeniable by clinicians of any experience, and the result is an improvement of the mechanical efficiency of the passive valvular factor when this is defective, and an entire restitution in some cases of its action when the valves are without organic disease.

Cardiac action has always been known to be auriculo-ventricular in sequence, from the upper to the lower chambers, but it is only in our own day that the channel

for this normal sequence has been discovered. We have, moreover, learnt still more recently that this channel, like all muscle throughout the body, is under nerve control. The retardant and accelerant nerves must therefore act through this channel in an important measure. In this connexion one of the cases I have mentioned appears to be instructive—namely, that in which there was at the same time auricular fibrillation and ventricular retardation. The auricular storm continued, but the ventricular action remained slow, though somewhat irregular, because the storm—for we may regard the quiver of fibrillation as storm—in the upper chamber could not spread to the lower on account of anatomical blockage. When digitalis lays the general auriculo-ventricular stop, it lays wholly or in great measure both the auricular and ventricular tumult. Which does it still first and how does it still it? It is conceivable that it may act by interrupting, as in pathological block, the passage of impulses from the auricle to the ventricle, so quieting the latter, and, with a subsidence of tumult in it, allowing the impotent quiver of the former to recover. This view would be favoured by Thomas Lewis, to whom we owe the view that auricular fibrillation is the cause of ventricular irregularity. Or, as Professor Cushing has suggested, digitalis may by some undefined direct action on the ventricle restore its tone, and with this, necessarily, a restoration of efficiency of the auriculo-ventricular valves would follow, and so protect the auricles from distension as to enable them to recover. Between the latter view and older conceptions of the restoration of ventricular elasticity or tone there does not appear to be much difference. In any case the slowed ventricle, with increased contractile power and restored elastic recoil, implies both better closure of the valvular apparatus and improved aspirative action, which promote an easier siphonage in the cardio-pulmonary circuit. What I have said of digitalis applies, of course, to the whole group in which it is *facile princeps*, strophanthus alone approaching it in power and reliability.

Did time permit, other agents, such as atropine, camphor, and ether, etc., might in this connexion be fruitfully considered from the clinician's point of view, but I must desist.

I have thus endeavoured to call attention afresh to the passive mechanical factors in heart disease, which have in recent years, in my opinion, been unduly and unwisely ignored or minimized, but I trust I have done so without claiming for them more than their due weight. I have also pointed out that the removal when possible of passive impediment to the heart's action, and the remedy or modification, also when possible, of defect in the action of the passive mechanism within the organ, as well as placing the patient in a position in which he may derive the greatest benefit from the passive as distinguished from the active forces in the blood flow through the heart, are essential to dealing successfully with ineffective action on the part of that all-important organ.

ACCORDING to the report of the South Travancore Medical Mission for 1919, the mission hospitals, by inducing larger numbers of well-to-do patients to pay for their treatment, have made further progress towards self-support. During the year 657 major and 6,165 minor operations were performed. The major operations included 37 gastro-enterostomies and 6 operations for amoebic abscess of the liver; the latter was treated by puncture by a large trocar and drainage by a tube subsequently introduced through the cannula. The medical mission, which is administered by the London Missionary Society, also has charge of homes for leprosy men, women, and children. All the hospitals are greatly in need of linen and nursing appliances: gifts and subscriptions may be sent to Dr. S. H. Pugh, Neyoor Hospital, South Travancore.

DEFICIENCY DISEASE:

WITH SPECIAL REFERENCE TO GASTRO-INTESTINAL DISORDERS.

A BRITISH MEDICAL ASSOCIATION LECTURE DELIVERED TO THE SOUTH WALES AND MONMOUTHSHIRE BRANCH.

BY

ROBERT McCARRISON, M.D., D.Sc., LL.D.,

FELLOW OF THE ROYAL COLLEGE OF PHYSICIANS; BREVET LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE.

[With Special Plate.]

Custom has sanctioned the application of the term "deficiency disease" to a group of maladies the chief causal factor of which is deficiency in the food of certain substances other than proteins, carbohydrates, fats, and salts. These substances are spoken of as "accessory food factors," or more commonly "vitamines";* they are not foods in the sense of tissue builders or producers of energy; they aid the body to utilize food material sufficiently and its cells to perform their functions. Their true nature is unknown, but probably they are of the nature of organized catalysts or enzymes. They are found in the germs and peripheral layers of such seeds as wheat and rice, and throughout the whole seed in peas, beans, and other pulses. They occur abundantly in the cells of yeast, the yolks of eggs, and in varying proportions in the different parts of plants and in the organs and tissues of the animal body. They are more plentiful in the brain, liver and kidney, than in the muscles. Animals derive them directly from the plants they eat, or indirectly from fresh animal foods. It does not appear that the animal body is capable of manufacturing them itself. Some are soluble in oils and fat, and are contained in the majority of animal fats. Lard is said to be an exception, but though this is no doubt true of stall-fed pigs, I doubt whether it is true of pigs living on raw vegetable foods. These fat-soluble or A-vitamines readily undergo decomposition; they do not exist, or but sparingly, in vegetable oils; consequently artificial substitutes for butter, when made from vegetable oils, do not contain them. They occur in abundance in the green leaves and growing parts of plants, but are deficient in roots and root vegetables. Butter made from the milk of cows fed on green fodder contains a substance which tends to prevent oedema in pigeons fed on autoclaved rice, while that made from the milk of cows fed on dry fodder does not do so to the same extent. There is reason to believe that the absence of these fat-soluble or A-vitamines from the dietary, or of vitamines allied to them, is the actual or predisposing cause of rickets. Other vitamines are soluble in water and are known as B-vitamines. The chief sources of them is grain, fruit, and egg yolk. As they are soluble in water they are liable to be dissolved out of grains and fruit in the process of boiling; as they are concentrated in the germs of seeds they are frequently removed in the milling process. They resist considerable degrees of heat. They are not destroyed by boiling for a short time, but exposure to temperatures up to 130° C. for an hour and a half destroys them. They are commonly referred to as "antineuritic vitamines," since their absence from the food is the actual or predisposing cause of beri-beri.

Vitamines of a third group, the "antiscorbutic" or C factors, are also soluble in water; they are found in the green parts of plants and vegetables and in fruit. They are unstable, and are very susceptible to the action of heat and alkalis. They are thus readily destroyed in the process of cooking, especially—as often happens—when sodium bicarbonate is added to the water in which vegetables are cooked. Dry grain does not contain them; they develop when the seeds germinate. Tinned or dried vegetables and fruit may contain them, but in reduced quantity and quality, and not in such perfection as the fresh raw products. Experiment shows that among the food materials lemon juice and cabbage juice are richest in them; fresh milk contains them in small amount only.

* The terms "deficiency disease" and "vitamine" are used in this lecture because both are in current use, but neither is satisfactory. Professor H. E. Armstrong, F.R.S., has proposed to replace the term "vitamine" by "advitant," indicating that the substance is necessary to life.

A. BLACKHALL-MORISON: THE PASSIVE MECHANICAL FACTOR IN HEART DISEASE.

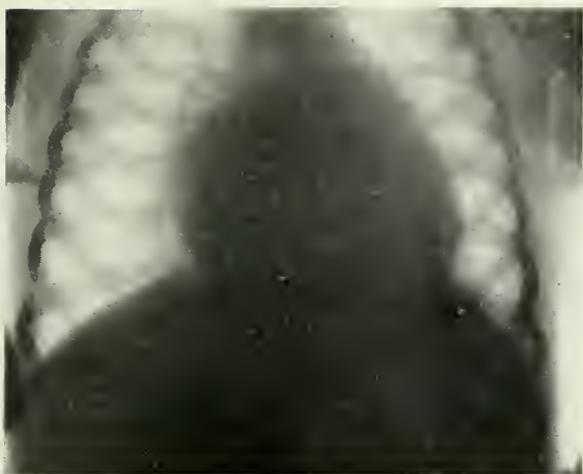

FIG. 1.—Before operation. April, 1919. Skiagraphed by Dr. John Morison. Obtuse right cardio-phrenic angle. Transverse measurement of thorax 2½ in.; of heart 1½ in.

FIG. 2.—After operation. August, 1919. Skiagraphed by Dr. John Morison. Acute right cardio-phrenic angle. Transverse measurement of thorax 2½ in.; of heart 1½ in. Sixth and seventh left ribs seen deostated. Focus the same in both figures. Blood entering and leaving the heart more easily. Respiration improved. Note narrowing of cavo-aortic zone and increase of auriculo-ventricular diameter.

FIG. 3.—After operation. February, 1920. Skiagraphed by Dr. Martin Berry. Conditions the same as in Fig. 2. Focus longer. Object slightly more magnified.

FIG. 4.—F. P., aged 11. Mitral regurgitation, with symphysis cordis and cardiac hypertrophy. The patient has now gained weight and the enlargement of the liver has disappeared. In the photograph the liver is still enlarged. Note the total absence of all anasarca, which was marked when the case was operated upon. Note also the cicatrix of the wound over the site of the removed ribs and cartilages.

FIG. 1.—Gastro-intestinal tract of healthy adult monkey. Note size of empty stomach, normal appearance of small intestine, and the longitudinal muscular bands and rugae of the colon.

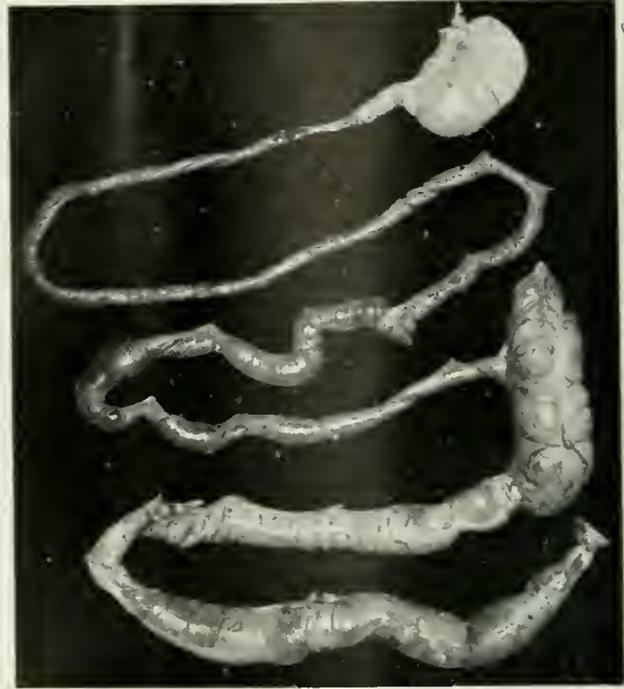

FIG. 2.—Gastro intestinal tract of adult monkey fed on auto-claved food for ninety-eight days. Note dilatation of empty stomach, large ileal intussusception, great dilatation of colon and atrophy of its longitudinal muscular bands; also inert appearance of the colon.

FIG. 3.—Section of wall of colon from healthy adult monkey, showing longitudinal muscular bands (L.M.B.); also ganglion of Auerbach, indicated by arrow G.

FIG. 4.—Section of wall of colon from adult monkey fed on devitaminized food. Note great atrophy of longitudinal muscular band (L.M.B.) and swelling and degeneration of the ganglia of Auerbach (G). Same magnification as Fig. 3.

FIG. 5.—Section of ganglion of Auerbach from healthy adult monkey. $\times 265$.

FIG. 6.—Section of ganglion of Auerbach from adult monkey fed on devitaminized food. Note swelling and degeneration of its cells. $\times 255$.

It is seen, therefore, that though vitamins are plentifully distributed in the raw materials which both man and animals instinctively use as food, they are very prone to be dangerously reduced in amount in their preparation for consumption. Thus boiled polished rice, which forms the staple food of many Eastern peoples, is often wholly devoid of them; so, too, is white flour, the staple food of so many in England.

A properly constituted food must contain vitamins in small but definite quantity, which varies with the species, the sex, the age and the individual idiosyncrasy of the animal. Without vitamins, the proximate principles of the food—proteins, carbohydrates, and fats—are in a sense dead foods which cannot sustain life. In their absence life may for a short time be sustained by the body utilizing its reserve stores of vitamins and sacrificing its less important tissues; but there is a limit beyond which such stores cannot be drawn upon and once this is reached the cells of higher function begin to lack vigour and depreciate in functional capacity, although the tissues may still hold considerable stores of vitamins. An instructive illustration of this cardinal effect is afforded by the nervous tissues of pigeons suffering from experimentally produced polyneuritis avium. In such cases, where the cerebellar type of the disorder is well marked, where astasia is complete and inco-ordination extreme, when convulsive seizures are occurring every few moments, the birds can be freed within six to twelve hours of all evidences of nervous disorder—with the exception of slight residual effects due to the death of nerve cells—by administering a vitaminic extract made from the yolk of eggs. The atrophic pancreas of animals fed on food deficient in these substances provides also striking evidence of the same depression of cellular function. In microscopic sections its cells are seen to be shrunken and devoid of the granular evidences of an efficient output of work. The important lesson to be learnt from such examples is not so much that the deficiency of vitamins causes the death and disintegration of a number of cells of higher function—for in the case of the nervous system this rarely exceeds 15 per cent. of the whole mass—but that it results in depreciation of function in a much larger number. The bodily engine stops not because a comparatively small proportion of its cellular elements have died, but because the greater mass have ceased to function. It is this conception of the action of vitamins which holds such wide promise in the cure of disease due to or favoured by deficiencies in the food, for with the limited knowledge we already possess, though we cannot restore to life cells already dead, we can restore to normal the depressed functional capacity of the general mass of the body's cells.

The conception that vitamins provide the cells of the body with the capacity—one might almost say the will—to work, has this great merit, that it furnishes a working hypothesis on which to found our treatment. For whatever be the accepted view of the causation of a particular disorder, it must be admitted that to recover from it the body must be provided with substances which excite the cells to effort as well as with those which furnish them with energy and building materials, and with a suitable medium in which to perform their tasks. We should not restrict our vision of deficiency disease to such ailments as beri-beri, rickets, and scurvy—conditions so obvious and so severe that we cannot well overlook them—we should consider every state of ill health from this point of view, so that we may be in a position to rectify nutritive errors and to provide the body cells with the requisite materials to enable them to fulfil their functions efficiently. I am, for example, impressed with the comparative frequency with which beri-beri symptoms may manifest themselves in sufferers from dysentery during the course of treatment in the East, where, as often happens, rice water is used as a food suitable for dysenterics. It is necessary to take care that our invalid foods shall not be deficient foods. The fear of introducing pathogenic agents into the digestive tract by way of the food has led to error, because sterilization of foods to the extent practised nowadays may deprive the cells of the body of those very substances which fit them to resist invasion by the pathogenic agent.

Although, in general, animals of the same species require about the same amount of vitamins, individuals may exhibit wide variations. Amongst the 400 odd pigeons which served in my investigations, about 5 to

10 per cent. survived an exclusive diet of the polished rice for over one hundred days, although the majority succumbed to its effect within forty days. When the supply of vitamins is diminished the time of onset of symptoms (certainly in pigeons) is in almost direct relation with the degree of the diminution. Thus, rice autoclaved in bulk at a temperature of 130 C. for an hour and a half will produce polyneuritis colubarum about twice as quickly as rice autoclaved in bulk at the same temperature for half the time. It is important to note that though when the vitaminic destruction is less complete the onset is longer delayed, the malady in both cases ultimately manifests itself; in practice it is not with complete vitaminic starvation that we have as a rule to deal, but with partial vitaminic starvation. The former means rapid dissolution and death, the latter slow dissolution and disease. Incomplete provision of vitamins for prolonged periods leads eventually to the same end, to the same manifestations of disease as their more complete deprivation for shorter periods.

Again the effects of vitaminic deficiency are modified by the age of the animal. Growing animals are more susceptible than mature; it would seem that they require more vitamins for the acceleration of the chemical reactions requisite for their growth. I have noted this frequently in pigeons which I bred for the purpose. It is almost impossible—as Dr. Mellanby tells us—to produce rickets in puppies more than 4 or 5 months old by the methods he has adopted.

Sex, too, has some influence. When, for example, pigeons are allowed to eat as they will of polished rice, males develop polyneuritis avium more rapidly on the average than females. This may be due to the fact that males eat more, for there is some reason to believe that the demand for vitamins is greater the greater the carbohydrate intake. But apart from this, sex has an influence in other directions which as yet is not understood. Thus, while the pituitary body enlarges in male pigeons and in male monkeys fed exclusively on autoclaved rice, it does not do so in females.

As individuals vary in their susceptibility to given vitaminic defects so also do different organs of the body, and the same organs in different individuals of the same species: in one the pancreas may become markedly atrophic, while in another it appears on naked-eye examination to be little affected. Further, not all organs of the body are affected in like manner by a deficiency of vitamins: the adrenals, the pituitary body, and the brain tend to increase in weight, while all other organs undergo atrophy, except the kidneys, which as a rule are little affected. A factor of great importance influencing the production of symptoms or their time of onset is the composition of the diet with respect to proximate principles. The effects of "vitaminic" deficiency are relatively less marked when the food is well balanced. In the case of monkeys, when the protein intake is adequate and in proper proportion to carbohydrates and fats, the onset of symptoms due to lack of vitamins is much longer delayed and the loss of weight is not excessive. Where, on the other hand, deficiency of vitamins is associated with great excess of carbohydrates, the onset of symptoms is more rapid and the loss of weight is great. The onset of symptoms is more rapid still and the loss of weight greater when to the defects above mentioned is added an excess of fats. In practice it is almost impossible to dissociate the effects of deficiency of B-vitamins from those of carbohydrate excess and deficiency of suitable protein; the two last frequently accompany the first.

Environment, too, plays an important part; lack of fresh air and sunlight hasten that functional depression of cells initiated by the vitaminic deficiency. The fortuitous occurrence of pathogenic agents in the body also plays a part. For example, healthy monkeys, carriers of cysts of *Entamoeba histolytica*, may develop amoebic dysentery when fed on devitaminized food, while those fed on a well-balanced dietary, although confined in the same animal room and equally exposed to infection through the medium of flies, will, although they may be carriers of the cysts, escape this disease. Such, at least, is my experience in the case of thirty-six monkeys caught in the Madras jungles. Similarly organisms of the hog cholera group may, in an infected area, infect every pigeon fed exclusively on polished rice, while the majority of controls fed on a well-

proportioned diet escape. Rats also, when fed on food deficient in A-vitamine, will develop xerophthalmia with unflinching regularity, but not, as Miss Bulley has shown, if the conjunctival sacs are cleansed daily and the offending organisms removed. Thus pathogenic saprophytes find in the unhealth and lack of vigour of the cells a suitable soil for growth; or, as I prefer to say, the tissues of the body when properly nourished are highly resistant to the invasions of pathogenic organisms. Exercise, too, appears to hinder the onset of symptoms attributable to vitamine deficiency. Dr. Mellanby, in his experiments on dogs, noted the interesting fact that in animals which ate most bread and took least exercise the rachitic tendency was accentuated. The effect of exercise is probably, as Dr. Mellanby suggests, due to its action in stimulating the processes of metabolism, a suggestion which falls into line with the fact that small additions of thyroid substance to a dietary of polished rice delay the onset of polyneuritis avium.

As, then, the manifestations of deficiency disease are influenced by a number of factors apart from the actual deficiency itself, we may expect to find in human beings wide variations in the incidence, the time of onset, and the character of the symptoms, as well as considerable variations in the organs and tissues affected where the dietetic defect is apparently the same. Thus I recently saw a family of five children amongst whom mucous disease and acidosis occurred in alternate members. The mother had brought them all up from birth in the same way—the same proprietary foods, the same sterilized milk, the same excess of carbohydrates and deficiency of suitable protein, the same deficiency of fresh fruit and vegetables. It is a salutary reflection that while British surgery has in India gained the implicit confidence of her peoples, British medicine has not done so to the same extent, mainly because the Indian mind cannot understand our apparent neglect in treatment of dietetic measures. No such reflection can, however, be cast on our profession at the present time; the danger is rather that in a too restricted or "vitaminic" outlook we may forget the well established truths of dietetics. The study of "vitamines" cannot be wholly successful unless due attention is paid to the general principles of metabolism. When we know how many vitamins there are, and what are the specific functions of each, it may become possible to correct the defect and to relieve with certainty the specific symptoms, as we do now in the case of scurvy.

At present the problem before man is to obtain a satisfying meal. This he frequently does by loading the stomach two or three times a day, it may be with boiled polished rice, vegetable oils and spices, or with white bread, margarine, and jam; or in the case of infants, with almost vitamine-less proprietary foods, sterilized and diluted milk. Such meals are dangerously unbalanced and dangerously deficient in vitamins and in suitable protein and excessively rich in carbohydrates.

The clinical and pathological effects observed in monkeys whose food presents these defects are the combined result of four factors: (1) deficiency of vitamins, (2) deficiency of suitable protein, (3) excess of carbohydrate—combined in some cases, to which I shall make special reference, with excess of fats, and (4) pathogenic organisms, the presence of which in the animal body may be regarded as fortuitous.

The clinical effects as seen in monkeys are these: failure of appetite, loathing of food, loss of weight, progressive anaemia and asthenia, failing health of the skin, staring hair, loss of hair, eruptions and eczematous patches, low temperature, slow respiration, headache, vomiting occasionally, diarrhoea, dysentery, impaired sensation, great muscular weakness, inco-ordination, and paresis. Death occurs within a hundred days in the monkey (*Macacus sinicus*). It is greatly hastened when deficiency of vitamins and excess of carbohydrates is associated with an excess of fats in the food. In these circumstances the loss of weight is more rapid; the stools may have a sprue-like character, fatty acids are present in them in great excess; atrophy of the pancreas, of the thyroid, the heart, the lungs, the spleen, and the submaxillary glands is marked, while, on the other hand, the weight of the brain is one-seventh part greater than in healthy control monkeys. All these symptoms may not occur, or may not be equally severe in every animal, but they are the common clinical manifestations of the dietetic error in

monkeys, and may be supposed to be the common clinical manifestations of the same dietetic errors in man.

However remarkable the production of these disorders in monkeys may appear to be, it is even more remarkable to note the rapidity with which they disappear when the deficient and ill-balanced dietary is replaced by one more perfectly proportioned and containing an adequate supply of vitamins. Colitis can be produced by a deficient diet with great regularity in monkeys, and can be cured by the provision of suitable food; so also can the anaemia and the dyspeptic disturbances. We know in a general way that in man digestive disturbances will cause anaemia, or that blood-destroying agents will do so; we know that dysenteric organisms may cause colitis; but, apart from the little that we know of these matters, I ask, What is the cause of the colitis which is so common and is not due to dysenteric organisms, or what is the cause of the dyspepsia that is so common and is not due to gross lesions of the stomach, or what is the cause of anaemia not due to blood-destroying organisms? I submit that a common cause of all of them is food deficient in vitamins and ill balanced with respect to proximate principles, and that by giving suitable simple vitamine-containing foods we can cure or greatly relieve them.

Diets thus defective lead not only to great muscular wasting, loss of fat and loss of weight, but to certain changes in the viscera. These are marked loss of weight of the thymus, the heart, the submaxillary glands, the pancreas, the spleen, the liver, the lungs, the thyroid, the testicles, and the digestive tube. The kidneys are often little affected. The atrophy affects most markedly those organs which are least essential to the life of the individual. To these must be added thinning of bone and diminution in numbers of the red cells of the blood. Increase in the weight and in the adrenalin-content of the adrenal glands also occurs (except when fresh butter is added to the deficient dietary, when the adrenalin-content is not increased), as does increase in weight of the brain (especially when the diet contains excess of fats), and of the pituitary body, especially in males. The most important changes observed *post mortem* are seen in the abdominal viscera. They comprise (see special plate) great loss of omental fat, enlargement of the mesenteric glands, especially those of the colon, dilatation of the stomach, thinning and ballooning of the walls of the small and large intestine, the frequent occurrence of intussusception, atrophy of the longitudinal muscular bands of the colon and loss in places of its characteristic rugae, congestion of the bowels, and subperitoneal ecchymoses (often intense), congestion of the mucous coat of the stomach and duodenum, and of the small intestine less often, and the almost invariable presence of colitis of more or less wide distribution. All these changes are not equally well marked, nor are all of them present in every case. It often happens that one part of the tract is more affected than another. Dilatation of the stomach, with great ballooning and thinning of the walls of the small intestine, "air-lock" and colitis are, for example, more marked if the diet is also excessively rich in carbohydrates. The pancreas, although almost invariably atrophied to some extent, may be markedly so in some, slightly in others, the atrophy being most marked when the deficiency of vitamins and protein is associated with an excess of carbohydrates and fats.

The histo-pathological changes in the digestive organs, some of which are shown by the microphotographs printed in the special plate, comprise (a) atrophic changes in the submaxillary glands, in the pancreas, and in all coats of the stomach, the small and great bowel; (b) congestive and inflammatory changes in the mucous and submucous coats of the stomach, duodenum, lower ileum, and colon; (c) degenerative changes in the gastric and pyloric glands, in the glands of Brunner, the glands of Lieberkühn, and the mucous glands of the colon; (d) atrophy and necrosis of the villi; (e) atrophy of the muscular coats of the bowel; (f) degenerative changes in the plexus of Auerbach; (g) colitis; (h) great loss of lymphoid elements throughout the tract; (i) invasion of the bowel walls by bacterial organisms which in some cases I have been able to trace through the thickness of the walls to the subperitoneal coat, and in fortunate sections actually into subperitoneal vessels; (j) infection of the mesenteric glands by bacteria, which can be cultivated from the enlarged and discoloured organs. Pathological changes of such severity as these may not often be encountered in

man; they are the end results of the deficient dietaries and of the nutritive errors we are dealing with, the goal towards which this form of malnutrition tends. But that they often exist in lesser degree in human beings who persistently use such dietaries there can be no reasonable doubt. Nor can it be doubted that they cause in the human subject grave depreciation of function of the digestive and absorptive organs and grave depreciation of their resources against infecting agents present as pathogenic saprophytes in the tract. The normal production of the gastro-intestinal, biliary, and pancreatic secretions is impeded, the cells available for protective dietaries are reduced in numbers and in energy, absorption of food materials is less perfect, and the absorption of toxic products more easy; the neuro-muscular control of bowel movements is likewise impaired. In this way the resources of the gastro-intestinal tract against infecting agents are reduced. The histo-pathological changes occurring in the stomach are such as would tend to lowered resistance, to hypoacidity, or even to achylia, and to gastric ulcer, which occurred in three out of ten monkeys fed on dietaries deficient in vitamins. It has recently been shown by Ivy that in dogs, if these conditions exist, chronic ulceration of the stomach may be produced by feeding them with streptococci. The origin of such ulceration thus falls into line with that of xerophthalmia, which, as we have seen, is induced by two factors—the lowered resistance of the tissues and the presence of the specific pathogenic agent. The condition does not arise without the presence of both, nor would it appear from Ivy's experiments that chronic ulcer of the stomach will arise in dogs without the presence of these two factors and the added one of hypoacidity.

Digestive disturbances and dilatation of the stomach are so constantly present in monkeys fed on these deficient dietaries that they may be regarded as cardinal signs of such deficiency. It is clear that no amount of gastric lavage could restore the stomach to normal function in the absence of an adequate supply of vitamins, while gastro-enterostomy would be likely to yield disappointing results. The provision of these substances in the food will restore this organ to normal activity in the human subject where the derangement is definitely due to the absence of vitamins. The following is a case in point which recently came under my care:

A man, aged 60, had for twenty years been a confirmed invalid. He was a martyr to dyspepsia and had a greatly dilated stomach, which he washed out three or more times a week—to his great exhaustion. He had not had a natural motion of the bowels for many years, but used a glycerin enema daily. He was very anaemic and of a colour which one associates with cancer of the pylorus. On examination I found a dilated stomach, a tender duodenum, "air-lock" in the small intestine, and a tender caecal region, but no evidences of cancer. For many years he had been subsisting on a diet excessively rich in carbohydrates, deficient in suitable proteins and in vitamins. He never ate fresh fruit and but rarely vegetables, and then overcooked. He complained of neuritic pains in the lower limbs and felt that he was losing the use of them. As his diet was very similar to that of my monkeys I resolved to treat him in the light of the results I had noted in those animals. He was put to bed, given a small quantity by the mouth of raw milk every two hours, and a solution of vitamins at night. Gradually the food was adjusted so as to contain an adequate supply of vitamins and of proximate principles in due proportion; it was made up mainly of eggs, cheese, fish, fresh fruit, wholemeal bread, and green vegetables. He was deprived of his stomach tube and glycerin enema syringe and given paraffin only. The vitaminic extract in solution was continued. He made rapid strides towards recovery; in two and a half months he gained 10 lb. in weight, was freed of all symptoms of dyspepsia, and the bowels—aided by the paraffin—acted normally.

I relate this case for two reasons: first, to emphasize the importance of a study of the "dietetic history" in every case of gastro-intestinal disorder, and secondly, to mention a lesson which this case taught me. It was this: When the patient had been taking the "vitaminic extract" for ten days or so he drew the attention of his medical attendant to the fact that his stools, which previously had been of a dirty white colour, offensive, and loaded with fatty acids, were now dark and well formed. So they remained until the supply of vitaminic extract with which he was provided from my laboratory ran out; then the stools again began to lose their dark colour and to return to a white offensive state. This observation can have but one explanation, namely, that the vitaminic extract

promoted the flow of bile and of pancreatic juice. The experimental confirmation of this clinical observation and of my own histopathological studies in monkeys is provided by the work of Wegelin and Meyer, who have recently shown that intravenous injections of a vitaminic extract of brewer's yeast has the same effect in increasing the flow of biliary and pancreatic secretions as has secretion. The case is of importance also because it illustrates the need for the provision of vitamins in a readily absorbable form, for in this case the flow of the biliary and pancreatic juices was not sufficiently excited by the vitamins in the food, due no doubt to the fact that the processes of repair and regeneration of the digestive organs take place slowly. Pancreatic deficiency is, in my own experience, a comparatively common disorder. It may be recognized clinically with sufficient accuracy by the observation of the "oatmeal" fatty stools.

The very frequent occurrence of intussusception in monkeys fed on deficient food is of great interest. The majority of these intussusceptions were produced in the death agony, but a proportion presented appearances suggestive of an earlier onset. I have hesitated to attach much importance to their occurrence since intussusceptions are often met with in laboratory animals at necropsy; but the greatly increased incidence of intussusception amongst children in Germany during the very lean years of the late war has recently been commented on in the writings of German physicians. Without going too far, we may safely say that children who are properly fed will be less liable to suffer from intussusception. No doubt there is nothing new in such a statement, but I do not think we have realized hitherto that the neuro-muscular control of the bowel is dependent in great measure on the adequate provision of vitamins in the food.

Of other gastro-intestinal disorders probably connected in their origin or in their continuance with dietetic deficiency and lack of balance of the food there are four which call for special reference. These are mucous disease of children, coeliac disease, intestinal toxæmia, and gastro-intestinal stasis. The first—mucous disease—is very common in India amongst European children. It is probably equally common in England. Its true nature is often not recognized unless the stools are examined as a routine measure. The pathological process underlying it is chronic gastro-intestinal catarrh, which is readily produced by a diet deficient in vitamins and suitable protein while excessively rich in carbohydrates. It is easily recognized clinically by the mucous stools, the attacks of diarrhoea, the peevishness, the night terrors, the pasty skin, the digestive disturbances, and above all by the dietetic history of the case. The child's food is made up of sterilized milk, proprietary foods, white bread, polished rice, poor butter, overcooked vegetable or fruit, and excessive quantities of starch and sugar, or of other aliments having the two main defects of carbohydrate excess and deficiency of vitamins. The malady is very amenable to treatment by the limitation of the carbohydrates, the provision of a more liberal supply of suitable protein in the form of a lightly boiled, poached, or raw egg, and of foods containing vitamins combined with the administration of a solvent of mucus and an evacuant such as grey powder. The histological results clearly indicate that the entry into the blood stream through the debilitated intestinal mucosa, not only of toxins but of bacterial agents, is likely frequently to occur, so that deficient and ill balanced diets of the kind fed to my monkeys may be regarded as common causes of intestinal toxæmia in its widest sense. With regard to the chronic intestinal stasis I shall say only that if failure of the neuro-muscular control of the bowel is a factor in its causation or maintenance, deficiency of vitamins is the most ready means by which such failure may be produced.

As my own experience has not brought me into contact with "coeliac disease," I speak of it with reserve. It presents, however, many features suggestive of vitaminic deficiency, and the surmise arises that its origin may be connected with such deficiency, or that a number of its characteristics may be secondary to the imperfect assimilation of vitamins. These characteristics are: Its absence in breast-fed children; its onset between the age of nine months and two years; the cessation of growth; the diarrhoea which so frequently precedes it; the ill-formed, pale "oatmeal" fatty stools; the frequent association of scorbutic

symptoms; the abdominal distension; the diminished size of the liver; the occurrence of oedema; the thin bones; the muscular feebleness, and its afebrile nature. All have their counterpart in animals subjected to vitaminic deficiency under experimental conditions. It may be, therefore, that a study of the malady from the vitaminic point of view might throw further light on its causation and treatment.

In this lecture I have dealt only with deficient intake of vitamins as the cause of "deficiency disease." But it is possible that deficient assimilation of these substances—consequent on derangements of the digestive organs from whatever cause arising—may give rise to symptoms of deficiency disease. It has seemed to me that solutions of vitamins have improved cases of enfeebled digestion and of biliary and pancreatic insufficiency more certainly than have the natural foods from which the solutions of vitamins were prepared.

There is much that I have been compelled to omit in so brief a consideration of the subject as this: amenorrhoea, sterility, inability of women to suckle their children, the effects on breast-fed infants of human milk deficient in vitamins, dental caries, rickets, beri-beri, oedemas, and the special effects of vitaminic deficiency on the endocrine organs. All these and much more are deserving of the closest study in connexion with the great question of diet as a factor in the causation of disease and racial degeneration. There is, indeed, no more important problem before the country at the present moment than the proper provision to the people of a properly constituted food, and no more urgent necessity than their instruction in these matters. I hope, however, that I have said enough to excite interest in the wider aspects of "deficiency disease," for I am convinced that with our increasing mastery of these dietetic problems our mastery over disease will increase also.

POISONING BY ARSENIURETTED HYDROGEN.

BY

THOMAS H. WIGNALL, M.B., B.S. VICT.,
MANCHESTER.

TEXTBOOKS dealing with industrial processes in which metals in gaseous combination are involved generally do not give definite facts as to minimum quantities capable of causing rapid death by toxæmia. Of course such data cannot be concise because of individual idiosyncrasy and the varying strength of gas acting lethally. My experience, therefore, in dealing with a particular example of this class—namely, poisoning by arseniuretted hydrogen, AsH_3 —may therefore be of interest.

This gas, which possesses by weight a considerable proportion of arsenic and is of an acid type (not actually corrosive but resembling H_2S), is chiefly met with by workers on processes in which nascent hydrogen is liberated, or in which hydrogen is used as a gas—by lead burners or for the inflation of balloons or airships. Where hydrogen is derived from the interaction of a metal and an acid or alkali, either one or both may contain large amounts of arsenic, and under these conditions the hydrogen is very liable to be contaminated by AsH_3 . In the process of reducing certain benzene derivatives from one stage to another, zinc dust (or iron filings) is mixed with weak hydrochloric acid and ice in the presence of the body to be reduced; in another method zinc dust is heated with a caustic solution in tubs, vats, or pans. These materials frequently contain arsenic as an impurity, and this combining with the hydrogen produced is inhaled by the workmen. The same gas may also occur in drains or wells where chemical fluids can accumulate.

Dr. Alice Hamilton, of the Labour Bureau, New York, in her recent monograph, *Hygienic Control of the Aniline Dye Industry in Europe*, published as a result of a tour over many British and Continental chemical works, quotes the statement in Rambon's well-known work on industrial poisoning, that the hundredth part of a milligram of As taken in the form of arseniuretted hydrogen is rapidly fatal to human beings. My experience, which has extended over two years, shows, on the contrary, that much more than this amount can be taken and although the result is serious, it is not necessarily fatal.

I have only met with one case in which death might actually be due to this cause.

This man was seen by me only a few days preceding death. There were obviously present some of the leading symptoms, such as icterus and a low typhoid type of delirium, but the urine was not available for analytical purposes.

Post mortem the macroscopic appearance of main organs had no distinctive features, but as the man had worked on a reducing process it was inferred that death was due to toxæmia. Specimens of viscera for analysis were obtained but not reported upon.

In subsequent cases which I saw from the onset, there were symptoms which at once directed attention to the causative agent. Where a hæmaturia of porter-like appearance occurred, a quantitative test of the urine for arsenic was immediately made; all the men working on or near the process were examined carefully and their urine was submitted to investigation. By this means a few men were found to be excreting arsenic in the urine while not appearing ill and continuing at work in the ordinary way. The possibility of these men having ingested the arsenic in food or on unclean hands was considered, but proved untenable.

Arseniuretted hydrogen when inhaled in toxic amounts rapidly produces hæmolysis, with destruction of the red corpuscles and conversion of hæmoglobin into methæmoglobin and oxyhæmoglobin; there is a destructive effect on renal tubules and epithelium, and hæmaturia results. The daily output of urine is not necessarily reduced, and such cases do not always during the first few days feel ill enough to stop work; thus they may present themselves already having an icteric appearance, complaining of languor and anorexia and having a rapid feeble pulse of tension below 100 mm. Hg. Such cases sent at once to hospital and notified as suffering from this gas toxæmia have invariably recovered, and the urine in the course of three to four weeks has ceased to contain more than what may be considered normal amounts of arsenic.

Not any of the workers on this process has to my knowledge developed nerve lesions, such as peripheral neuritis, known to follow the taking of excessive amounts of arsenic by the mouth, nor has any splenic abnormality, icterus, nor biliary obstruction of any type remained as a subsequent feature.

From the amount of arsenic excreted by the urine over the period of detention in hospital—say, three to four weeks—it is easy to conclude that a far greater amount of this gas may be taken by inhalation without causing death than has hitherto been believed possible. Naturally the factors of concentration or dilution of gas, in any given case, are unknown; in men examined every twenty-one days the period of absorption is limited to less than three weeks.

Case 1, working on reduction process, was seen at home on November 14th, 1918. He had been ill a few days, had marked icterus and was feeble; there was no delirium. The urine was of a dark porter colour, containing methæmoglobin, epithelial cells and tube casts, as well as 795 milligramms of As_2O_3 per 100 c.c.m. On December 12th the urine contained epithelial cells, much exalate of lime, traces of albumin and indican, no tube casts and less than 10 mgm. of As_2O_3 per 100 c.c.m. This patient made an uninterrupted slow recovery and has not been ill since; there has been no nerve lesion.

Case 2 was seen on November 9th, 1918. He complained of malaise, and passed porter-coloured urine containing 35 mgm. As_2O_3 per 100 c.c.m. No icterus was at any time evident; he stayed at home, and on December 20th his urine contained less than 10 mgm. As_2O_3 per 100 c.c.m.

Case 3, who complained of hæmaturia, was seen on December 5th, 1918. When admitted to hospital his urine was black, specific gravity 1025, acid, and albuminous; it contained 200 mgm. As_2O_3 per 100 c.c.m. His recovery was uninterrupted; on January 30th, 1919, his urine contained less than 10 mgm. of As_2O_3 per 100 c.c.m. He has since been quite well.

Case 4, who complained of abdominal pain and vomiting, and whose skin, conjunctivæ, and palate were faintly icteric, was seen on January 24th, 1919, and sent to hospital. His urine was of a deep-red burgundy colour, clear, specific gravity 1025, and acid. It contained much albumin. Methæmoglobin and oxyhæmoglobin were present, as well as 185 mgm. As_2O_3 per 100 c.c.m. On February 26th his urine contained less than 10 mgm. As_2O_3 per 100 c.c.m., and he made a perfect recovery.

Case 5, who had no pain and no icterus, was detected while discharging his duties in the usual routine of the reduction process. On February 15th, 1919, his urine was dark-brown in colour, acid, specific gravity 1009, and contained a good deal of albumin, a few vesical epithelial cells coloured brown, no tube casts, some fibrinous clots, some brownish granular masses, and 70 mgm. As_2O_3 per 100 c.c.m. By February 27th, 1919, the arsenic

had been reduced to less than 10 mmg. per 100 c.cm., and he made an uninterrupted recovery.

I am indebted to Professor Delépine, of the Public Health Laboratory, Manchester, for the analytical reports submitted, and to Mr. Thomas Callan, M.Sc., Ph.D., for help in subsequent analyses.

RUPTURED MALARIAL SPLEEN: SPLENECTOMY: RECOVERY.

BY

CYRIL A. RAISON, M.B., Ch.B.,

LATE ACTING MAJOR R.A.M.C. (T.),

OFFICER IN CHARGE SURGICAL DIVISION 33RD STATIONARY HOSPITAL.

BATTLE wrote: "The rupture of a malarial spleen may be compared with that of an aneurysm—the rupture of a normal spleen to that of a large artery," while Lieut.-Colonel Crawford, in the *Indian Medical Gazette*, summarizes his extensive experience in a statement that "Ruptured spleens not infrequently come under the notice of surgeons in India—not as a rule in hospital during life, but after death in the subject of a judicial *post-mortem* examination. The injury is always of grave importance and practically always fatal." The late Surgeon-General Coull-MacKenzie stated that 68.9 per cent. of cases of splenic rupture end fatally within half an hour. Captain Jamison published an interesting series of six cases in the *BRITISH MEDICAL JOURNAL*, September 14th, 1918, but in view of the fact that relatively few recoveries have been recorded, the following case may be of interest:

A Macedonian, 56 years old, was admitted on May 30th, 1918. He was very collapsed and complained of great abdominal pain, aggravated by movement or by coughing; his expression was extremely anxious and few words could be elicited from him. His skin was sallow, his lips were pale and slightly cyanotic. The pulse was 145, and the respirations were 44 per minute; they were shallow, and there were signs of diffuse bronchitis. The abdominal wall scarcely moved and was rigid and tender generally, but particularly in the left hypochondrium. The left part of the upper abdomen was distinctly prominent; the knees were flexed. The splenic dullness extended to the umbilicus, and both flanks were dull on percussion. There was no external sign of bruising.

Operation.—Under local anaesthesia by $\frac{1}{2}$ per cent. novocain a median incision was made above the umbilicus. When the peritoneum was opened a large quantity of blood gushed forth. Morphine gr. $\frac{3}{4}$ was given, and Captain A. C. Smith induced gas and oxygen anaesthesia. An oblique incision was made through the left rectus parallel to and one inch below the costal margin. The spleen was seen to be greatly enlarged, the anterior surface of its capsule was almost completely raised from the matrix, and showed an irregular tear about four inches long, through which blood was coming. In consequence of adhesions to the diaphragm it was impossible to bring the spleen up, and therefore (with considerable difficulty) the pelvicle was clamped from the front. Intravenous injection of glucose and sodium bicarbonate was made throughout the remainder of the operation. The adhesions giving considerable trouble, they were divided between clamps and ligatured after the removal of the spleen. The abdominal cavity, which contained much blood, was irrigated with warm saline solution, and a certain amount being allowed to remain inside, the abdomen was closed.

The patient's condition was critical, but on the following day he was much improved, the pulse falling to 128 about twelve hours after the operation. He was given 10 grains of quinine four-hourly, and made steady progress, the evening pyrexia, which disappeared on the tenth day, being the only point of note. When last seen, in February, 1919, he said he had never felt better in his life; he certainly looked many years younger.

The spleen was found to be 13½ inches long, and 6½ inches wide, and to weigh 3 lb. 2 oz. In the upper end there was an irregular tear about four inches long, penetrating two inches into the substance; the capsule was raised in front. The blood, limited above by the diaphragmatic adhesions, had burrowed beneath the capsule, which had eventually given way, a tear being produced. The blood count made on June 6th (a week after operation) showed 3,520,000 erythrocytes, and 26,000 leucocytes (polynuclears 67 per cent., eosinophils 4 per cent., small lymphocytes 11 per cent., large lymphocytes 9 per cent., large hyalines 9 per cent.); many red cells showed poikilocytophilia.

Three days subsequent to the operation the following history was obtained from the patient's wife, but doubt is cast on its accuracy: "He had had malaria for many years. Four or five days before his operation he had been kicked in the back by a donkey, but felt little the worse and continued his ordinary work. During the early hours of the morning prior to his

admission he suddenly awoke with great pain in his left side and then in his abdomen. He vomited several times."

The interesting features of this case are that the rupture occurred in a man of 56, that the spleen was the largest I can trace as having been removed in a case which subsequently recovered, and that there were massive adhesions. According to Vanverts the presence of the latter in splenectomies for malarial hypertrophy without rupture raises the mortality from 5.7 per cent. to 72 per cent.

SYPHILIS INSONTIUM.

BY

J. C. McWALTER, M.D., LL.D., M.R.I.A.,

SOMETIME SPECIALIST SANITARY OFFICER R.A.M.C.

D'ARCY POWER teaches that syphilis is transmitted to the fetus only at conception or in the earlier months of pregnancy. Almost all the experts seem to hold the same view, and hence it may be worth while to record a case, at present under my care, which appears to prove conclusively that infection can take place in the eighth month of pregnancy.

It is also of great importance to have definite and scientific records of cases of syphilis insontium, because there is usually something short of conclusive proof that a case of syphilis was extragenital in origin.

My patient was a married woman in the earlier thirties with four healthy children and no history of abortion. She consulted me about an ulcer at the angle of the mouth; it was shallow and of greyish colour; at first I supposed it to be due to pyorrhoea. She expected her confinement in the following month. I prescribed some solution of iodine with glycerin, but when she returned the following week the ulcer was no better, the sub-maxillary glands had become inflamed, and the whole sore began to exhibit a typically chancroid appearance. I sent her to the Pathological Laboratory at Trinity College, Dublin, and it was reported that the sore was teeming with *Spirochaeta pallida*.

One is peculiarly prone to jump to rash conclusions in these cases, and I presumed that the woman's husband was responsible. I interviewed and examined him, but he had no trace of the disease. It then seemed probable that the woman herself was to blame, when further investigation showed that she had got the sore on her mouth from kissing a child who had an acutely virulent sore on its mouth.

On consultation, it was decided that salvarsan treatment might be risky, in view of the expected early confinement, and the patient was put on an ordinary course of mercury, cinchona, and iodides. The sore rapidly healed, and in four weeks she was delivered of a fine infant, which exhibited no signs of syphilis at birth, or for four weeks afterwards. The child had never a primary sore.

I had begun to conclude that the infant had escaped syphilis when the mother reported that it had commenced to look unwell, and when examined in the fifth week it showed slight but unmistakable signs of congenital syphilis. These cleared up so rapidly under mercurial treatment that it is with great difficulty the mother can be induced to continue the treatment for her child.

Does the *Spirochaeta pallida* pass directly from the maternal blood to the infant's? The patient would seem to prove the affirmative. This case proves, I think—

1. Infection of a mother with syphilis in the eighth month of her pregnancy results in infection of the child.
2. The syphilis in the child is of a milder form and develops later than ordinary congenital syphilis.
3. Infection of the mother with syphilis in the later months of pregnancy may have no deleterious effect on her confinement.
4. There are some cases of syphilis insontium capable of the most rigid proof.

PROFESSOR P. LEBEAU, of the School of Pharmacy of the University of Paris, will give two advanced lectures in chemistry at the end of this month at King's College, London. The first lecture, on June 23rd, at 5 p.m., will deal with the ammonium metals in organic chemistry; in the second, on June 30th, the theoretical and practical results of the work of M. Moissan will be discussed.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF MALIGNANT PUSTULE IN WHICH THE INCUBATION PERIOD WAS KNOWN.

The main points of interest in this case are that the patient, having contracted anthrax from a shaving brush, knew: (a) When he cut himself; (b) when the painful papule appeared at the site of the cut; (c) when the papule became a vesicle. It is also noteworthy that on admission to hospital, seven days after the onset of the disease, the patient had received no specific treatment and yet appeared to be well on the road to recovery.

A study of the literature shows that most cases of cutaneous anthrax have started as a papule; one, however, recorded by J. and C. Regan in the *American Journal of the Medical Sciences*, vol. 157, 1919, started from a cut, and here, as in the following case, thirty hours elapsed before the appearance of the papule.

A schoolmaster, aged 36, was admitted to St. Bartholomew's Hospital on January 25th, 1920, complaining of a pustule on the left side of his face which he believed to be anthrax.

History.—On January 4th he used for the first time a shaving brush which had been presented to him eighteen months before. On January 17th, at noon, he was shaving, and cut himself for the first time since using the new brush. On January 18th, at 6 p.m., the patient noticed a painful "pimple" at the site of the cut on the left side of his face; and on the morning of January 19th the "pimple" had become a "blister"; this history was confirmed by independent questioning of the patient's wife. The subsequent history was that the "blister" discharged, and that the left side of the neck became very "stiff" and swollen on the 21st. Next day he began to get better; the swelling began to go down, although glands swelled on the right side of his neck. A friend who worked amongst hides told him that he thought the condition was anthrax. On the 23rd—this being the first treatment—he applied fomentations; a thin yellow discharge exuded from the pustule. On the 24th he consulted a doctor, who advised him to go to hospital.

Condition on Admission, January 25th, 1920.

The patient did not look or feel very ill; there was a typical malignant pustule over the lower border of the left lower jaw about one-third of the way between the angle of the jaw and the symphysis menti. The cervical glands were enlarged. His temperature was 99.2°, his pulse was 104, and respirations were 24. There was no oedema of the face or neck and nothing abnormal was found elsewhere.

Treatment and Subsequent History.

On the day of admission the pustule with about one inch of skin round it was excised and the wound dressed with tincture of iodine; 50 c.cm. of Mulford anti-anthrax serum was injected into the left median basilic vein. The patient slept well, and did not complain of any pain. On the following day 30 c.cm. of Sclavo's serum was injected hypodermically. The patient continued to improve, and on January 30th was discharged, having a granulating wound and a few enlarged glands in both sides of the neck. On May 1st, 1920, the wound was completely healed and the cervical glands were no longer enlarged.

Pathological Reports by Dr. Mervyn Gordon.

"The pustule shows chiefly staphylococci, but on searching the film preparation made from the swab a few Gram-positive bacilli were found, some of which closely resembled anthrax in shape."

"A culture from the scab gave a majority of *Staphylococcus aureus* and two colonies of anthrax bacillus."

"An examination of the shaving brush was made, and a Gram-positive spore-bearing bacillus indistinguishable from *B. anthracis* was cultured from it. A guinea-pig, however, which was inoculated with a broth emulsion of the hairs of the shaving brush, was apparently unaffected."

It would seem, therefore, that if the micro-organism present in the shaving brush was anthrax, its virulence was attenuated.

For permission to publish this case I am obliged to Sir D'Arcy Power, into whose wards it was admitted.

SUBCUTANEOUS INJECTIONS OF CAMPHOR.

UNDER Letters, Notes, etc., for March 13th, p. 388, the reply is given to a correspondent that heroic doses up to 30 grains of camphor have been given but are dangerous. It may be of interest to record that, in a certain large stationary hospital in France during the severe influenza epidemics, I gave, almost as a routine, intramuscular injections into the gluteal region of camphor in oil, gr. v in m xv, every four hours without untoward results in a single instance. In selected cases—for example, in cases

of influenzal pneumonia where the physical signs varied from day to day—I am convinced that the intramuscular injection of camphor in oil gr. v proved of the greatest value, and, in many cases where the toxæmia was not too intense and the heart required that little bit more of stimulation to pull the patient through the crisis, this method of treatment was the means of saving life.

In cases with definite signs of impending heart failure I have given gr. x in one injection, with marked beneficial results on the pulse both in tension and rate. Fifteen minutes to half an hour usually elapsed before the heart responded to the camphor, and the effects lasted from three and a half to four hours after injection. There is no other cardiac stimulant to my knowledge which can produce such marked and prolonged stimulation from one dose.

It is important to plunge the needle up to the hilt and inject very slowly, withdrawing very gradually at the same time, which usually avoids pain from pressure. The pain may be severe at the site of injection if this is given too quickly. Parke, Davis, and Co., and one or two other manufacturing chemists, have always had ampoules containing 1½ and 3 grains of camphor in sterile olive oil. It is easy to make one's own preparation by dissolving the camphor in ether before mixing with the sterile oil. Should the camphor not be dissolved first of all, it precipitates out when the oil cools.

A. D. GORMAN, Capt. R.A.M.C.(S.R.).

SEVERE ANGIO-NEUROTIC OEDEMA.

A BOY, aged 3 years and 10 months, complained, on April 25th, of pain in the left leg, which the mother noticed had become swollen.

When I saw him on the following day the limb was oedematous and painful from the toes to the lower third of the thigh. The boy was fretful and the temperature was 101° F. On April 27th the child was obviously ill—temperature 101.5°—and, in addition to the lower limb, the left forearm and hand were oedematous and also the lower part of the back. On April 28th the swelling had completely disappeared from the limbs, but the right side of the scalp was intensely oedematous, extending to the eyelids, which were completely closed. On attempting to open the lids a blood-stained fluid spurted out with some force; the conjunctiva was purplish in colour.

Next day the whole scalp was involved, and both eyes were closed and oozing sanious fluid; the swelling in the left forearm and hand had returned. During the following night there was a copious evacuation of bright blood from the rectum—about half a pint. Recovery now rapidly ensued; in two days the swelling had entirely disappeared, and the child appeared quite well.

The temperature throughout remained at 101° to 101.5° F.; the urine was scanty and loaded with urates; the tongue was dry and the condition was somewhat alarming, especially as he complained of some fullness in the throat. Had this type of oedema invaded the larynx, the condition would have become immediately dangerous.

Treatment consisted in the administration of calomel and salines, followed by calcium lactate, 10 grains every two hours. Recovery appeared to follow the use of the last-named drug in such a way as to suggest that it had an influence on the condition; and in future cases I should begin it at the outset. The possibility of laryngeal invasion was, of course, prepared for.

The child is of intensely nervous type, and reacts acutely to insect bites. Otherwise there is nothing in the history of interest, nor could any reason be suggested for the attack. Of interest was the distribution of the swelling, the fact that the right limbs and other parts were unaffected throughout suggesting a nervous origin.

Haywards Heath. REGINALD ALDENSON, M.D., B.S.Durb.

HERPES AND VARICELLA.

IN connexion with the suggested relation between these diseases the following cases merit record:

On April 10th A. L. came to Tunbridge Wells with his wife and son F. L. They stayed in small apartments, and, as the weather was wet, were pretty closely associated. On April 13th A. L., aged 49, complained to his wife of a sharp pain in the right groin and leg. Two days later a few vesicles appeared on the right buttock and were

followed by a gradually developing herpetic eruption, commencing in the inguinal region, and distributed over the inner side of the right thigh and calf. When I first saw him, on April 17th, the case was typical and it followed a normal course.

On May 1st F. L., aged 18, noticed a few small pearly spots on his forehead, and by May 3rd he was covered with hundreds of typical chicken-pox spots, distributed all over the body, accompanied by considerable fever and much constitutional disturbance. So far as can be ascertained he had not been near any case of chicken-pox.

Tunbridge Wells.

CLAUDE WILSON, M.D.

Reports of Societies.

RUPTURE OF THE UTERUS.

At a meeting, held on June 3rd, 1920, of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine, Mr. J. D. MALCOLM, President, in the chair, Mr. PHILIP D. TURNER communicated an account of a case of traumatic rupture of the pedicle of a subperitoneal fibroid.

A lady, aged 47, fell 6 ft. while cycling and pitched on her left hip. The next day there were signs of intraperitoneal injury and effusion of blood; a hard calcified fibroid was to be felt rising out of the pelvis. The abdomen was opened twenty-four hours after the fall; the peritoneum was full of blood and clots, and blood was seen to be issuing from a longitudinal tear in the pedicle of the fibroid, which was calcified, pedunculated, and attached to the fundus uteri. The fibroid was removed and two small arteries which were found to be bleeding were under-run; the wound in the fundus was closed by deep stitches. Recovery was uninterrupted.

Dr. FORD ANDERSON read a short communication on a case of rupture of the uterus treated by gauze packing.

A 4-para of 33 was delivered elsewhere of a fetus of about four months, which presented by the feet; delivery was said to have been easy, although the accoucheur subsequently discovered a tear of the cervix extending outwards on the left side. He removed the placenta "with the fingers," and found intestinal coils within the uterus. Dr. Ford Anderson first saw the patient fourteen hours after delivery, when she was in a state of extreme collapse; blood was oozing from her, the uterus was relaxed, and the cervix was contracted. Examined under an anaesthetic showed a coil of (probably) large intestine in the uterus, the fundus of which was transversely torn for three or four inches. The tear of the cervix on the left side was quite independent of this. Operation was judged to be inadvisable, and under anaesthesia, in Sims's position, with raised pelvis, the prolapsed bowel was replaced, and contraction of the lax uterus being stimulated by pressure of the left hand on the fundus, the uterus was packed with sterilized gauze. Thirty hours afterwards the first packing was removed and replaced by a similar one; thirty hours later the gauze was finally removed. The patient, who was kept recumbent, also received pituitrin, morphine, saline solution per rectum, and douches of 1 to 320 lysol, as well as oxygen inhalations. From the first there were swelling and tenderness in the left iliac region, and during the first few days the temperature varied from 103° to 104°; the lochia were fetid. By the eighteenth day the cervical and uterine tears had healed and discharge had almost ceased; pyrexia and evidences of left pelvic cellulitis were still present, when, on the twenty-fifth day, the patient insisted on leaving hospital. Dr. Anderson learned that a pelvic abscess afterwards had to be opened, but that two months later she was completely well.

Convalescence would have been much speedier but for the consequences of the cervical tear. Probably the majority of medical men would hold that in such a case as this operation offered the best prospect of cure. In the present case operation was not considered possible on account of the extremely bad condition of the patient, and the procedure adopted was carried out with but little hope of success. As a result of the present case, and after reading Dr. Herbert Spencer's account in the *Obstetrical Transactions for 1900* (vol. xlii) of four such cases successfully treated by packing with iodoform gauze, the author was inclined to modify his views.

In the discussion that followed, Dr. AMAND ROUTH thought that packing should be reserved for cases ruptured into the broad ligament, or cases in which the laceration had not included the peritoneum. He congratulated Dr. Anderson on the result, but could not understand how the patient escaped peritoneal infection, after replacement of the intestines in an evidently septic case.

Dr. DRUMMOND ROBINSON said that twenty years ago he had a somewhat similar case, in which a mass of intestine protruded from the vulva; the cervix and body of the

uterus were lacerated. The intestine was pushed back and the laceration plugged with gauze; the patient recovered and subsequently had two children.

In reply Dr. FORD ANDERSON pointed out that the bowel, which had not prolapsed beyond the cervix, was replaced with all possible aseptic precautions.

He quoted a letter in which Dr. Herbert Spencer, after stating that packing was the best treatment for many cases, said that though many cases had been recorded as successfully treated by hysterectomy, many of these had been badly treated by version, etc., and should not have been ruptured at all. Dr. Spencer also wrote that "one Russian obstetrician had a long list of such cases, which were no guide to the treatment of the ordinary cases of rupture seen in a condition of profound shock."

Dr. W. FLETCHER SHAW and Dr. ARTHUR BURROWS read a paper on Wertheim's hysterectomy for advanced carcinoma of the cervix, made possible by the use of radium. This communication was summarized in our issue of June 12th, p. 805.

In the discussion which followed, Dr. R. A. GIBBONS stated that before the war the late Dr. Pozzi of Paris told him that he had been working on this subject for some time, and had operated on many cases which before the application of radium had been regarded as inoperable.

Dr. A. W. BOURNE related a case of spontaneous rupture of the uterus following pituitrin. The patient was a 12-para, whose previous labours had been easy.

The twelfth labour being slow, $\frac{1}{2}$ c.cm. of pituitrin was administered hypodermically when the cervix was fully dilated, and the head in the perineum. An hour later the pains became extremely violent, and the patient suddenly collapsed; the head receded and the pains ceased. When admitted to St. Mary's Hospital she was in a condition of profound shock; the abdomen was soft, the fetal parts could be easily palpated through the abdominal wall, and there was dullness in both flanks. After an intravenous injection of gum solution and a hypodermic injection of $\frac{1}{4}$ gr. of morphine, an attempt was made to deliver the patient. The head was removed by perforation and cutting through the neck, but before the rest of the child could be removed the patient again collapsed, and in spite of blood transfusion she died at 1 a.m. *Post mortem*, the child's trunk and the placenta lay free in the abdomen; there was a rent five inches long in the uterus, beginning in the lateral wall and lower segment and extending downwards and inwards to the cervix.

Dr. Bourne considered this case noteworthy on account of the rupture occurring in the absence of any obstruction, and after a sluggish and short labour when the head was in the act of being born.

Dr. WILLIAMSON said that he had seen a case of spontaneous rupture of the uterus following the administration of pituitrin before the cervix was fully dilated. He believed and he taught that the use of pituitrin before the birth of a child was a dangerous procedure.

Dr. FLETCHER SHAW was certain that a large number of cases of rupture occurred through the administration of pituitrin; he taught his students that it must never be given before the termination of the second stage, except in haemorrhage.

Dr. EARDLEY HOLLAND stated that in his opinion pituitrin might be a source of grave danger to the mother and fetus, and alluded to the dangerous effects produced by the so-called sensitization of the uterus by the administration of pituitrin preliminary to the introduction of bougies. In two cases of this he had seen tonic contraction of the uterus. Pituitrin was often responsible for the death of fetuses; he had performed *post-mortem* examinations on at least four with tears of the tentorium cerebelli and cerebral haemorrhage brought about by a precipitate second stage of labour following injection of pituitrin. Dr. FORD ANDERSON thought that pituitrin, if used at all before the birth of a child, should be employed with all the precautions which had always been enjoined for ergot of rye.

In the first number of *The Handicapped Worker*, issued by the New York Institute for Crippled and Disabled Men, Miss Gertrude R. Stein summarizes the work which has been done in the United States for industrial cripples as distinguished from ex-soldier cripples. Organized training has been authorized by the Legislature of eleven States, in five of which the work has already been begun. In other States the provision of training and employment for the crippled is left to voluntary specialized employment agencies. Generally the aim has been to deal with the cases intensively, and it has been sought to deal thoroughly with few rather than superficially with many.

Reviews.

DISEASES OF THROAT, NOSE AND EAR.

THE third edition of PORTER'S *Diseases of the Throat, Nose, and Ear*¹ has been revised by his friends and colleagues under the editorship of Dr. LOGAN TURNER. The second edition was produced in 1916, but unfortunately the author, who had become Major Porter, D.S.O., was killed in France while serving with the Royal Artillery in the following year. The object of this book is to provide the practitioner and senior student with a volume of moderate size, containing sufficient information on the subject to be of practical value, without entering into the details of operative surgery. The book fulfils its purpose admirably and is kept within the intentionally limited scope. The new edition is brought well up to date, especially in the section which deals with diseases of the ear. There are, however, some portions in which the advice given as to treatment may reasonably be considered open to criticism, particularly when it is remembered into whose hands the book is intended to pass. Thus a much more active treatment for laryngeal tuberculosis is described than is now considered beneficial or even safe by those most experienced in the subject. Again, the siphon douche for the nose is described and there is even a figure of it in use, whilst its dangers are stated to have been exaggerated; they are, however, widely recognized and the method has been generally abandoned. The illustrations are, perhaps, rather limited, but include seven coloured plates containing forty-four illustrations. The value of such coloured plates is a little doubtful, and they are, of course, expensive to produce, so that it might have been better to have increased the number of illustrations in black and white instead. Nevertheless the coloured plates are good of their kind and form an attractive feature of the book. The book should continue to serve the good purpose which the success of the previous editions shows it has served in the past, and it may be recommended both for the convenience of its size and the excellence of the text. The editor and his collaborators are to be congratulated on the good taste they have shown in choosing this method of perpetuating the memory of their former colleague; they have carried out their task just as he might have desired could he have made his wishes known.

Mr. TILLEY has rendered a notable service to British laryngology in producing a fourth edition of his well known book on *Diseases of the Nose and Throat*.² During the space of eleven years which has elapsed between the last two editions the progress of laryngology has been rapid, and as a result the latest edition exceeds the former in length by some 300 pages, but the use of thinner paper to some extent compensates the increase in bulk. It may be said at once that with the exception of the chapter dealing with asthma and hay fever, in which there is no reference to the modern views connecting these conditions with anaphylaxis, the reader will find the most recent information upon any subject about which he may seek enlightenment. Nor will he search in vain for any topic connected with laryngology, for all methods of bronchoscopy and oesophagoscopy are fully described. A chapter on diseases of the oesophagus and another on diseases of the trachea are to be found, as well as sections on intranasal dacryocystotomy and the removal of pituitary tumours. The author strongly advocates the intranasal operation for chronic empyema of the frontal sinus, and is of opinion that the dangers of the external operation, to which he himself so candidly drew attention some years ago, may be to a great extent eliminated by this means. The parts of the book dealing with operative surgery have been amplified with considerable judgement. The various methods of removing nasopharyngeal fibroma, for example are fully discussed in this edition, and there is an excellent

description of laryngo-fissure illustrated with very clear drawings supplied by Dr. Irwin Moore. All through the book the drawings are admirable and the author has wisely refrained from introducing coloured plates. There are naturally blemishes and inequalities in a book of this size: for instance, it is difficult to understand how the operation of submucous resection can be performed through the incision which is both described and figured, and the subject of malignant disease of the pharynx is treated somewhat briefly. The work, however, is so comprehensive that it should be a valuable book of reference, whilst it is not too large to serve as an ordinary textbook. The most attractive and perhaps the most valuable feature of the book, which distinguishes it from a mere compilation, is the way in which the personality and observation of the author appear in his writing. Mr. Tilley draws freely upon the wide clinical knowledge he possesses in order to illustrate his points, without quoting tedious histories of cases, and the reader is made to feel that every piece of advice offered is the result of personal experience.

The second French edition of Dr. GEORGES LAUREN'S *Oto-Rhino-Laryngology*³ has been translated by Mr. CLAYTON FOX, who has kept faithfully to the text; the translation, indeed, is apparently so literal that it has occasionally led to minor errors. The book is written for the student and practitioner, and contains a surprisingly detailed account of how to examine and treat patients, telling both what to do and what not to do. This detailed account of how to grapple with the elementary problems which beset the beginner forms the main theme of the book, and, carefully studied, it should prove of great value to anyone commencing to learn about the examination and care of patients in this department of medicine. It is the minor difficulties, which are often so bewildering and exasperating, that the author seeks to solve for his reader, and to render his points clear there is a profusion of simple line drawings which adorn practically every page. It must be understood, however, that it is French methods and opinions which will be gained from a study of this book, and that they do not in every way coincide with the accepted English practice. For some this may endow the book with a refreshing novelty and the change from the stereotyped English textbooks may make a successful appeal. Some of the views, however, might prove misleading if accepted without some practical knowledge. Thus, for removal of the tonsils the author says: "Never employ the guillotine." Cancer of the pharynx occupies just half a page, and the section ends "Treatment=0. Especially no surgery. Only palliatives, such as cocaine, morphine, and local applications of pure adrenalin." The work, however, fulfils its object and should prove helpful, especially by virtue of its carefully studied details and its wealth of illustrations.

CEREBRO-CRANIAL INJURIES

PROFESSOR DURET'S monumental work of fifteen hundred printed pages on cerebral-cranial injuries⁴ is the outcome of patient labours extending over more than forty years. It was nearing completion when the German army entered Lille, and the Prussian authorities forebore their intention to destroy it, on the grounds of "humanity." So at least they told the author.

The subject truly is big so is the book, but it deals with etiology, the mechanism of production, and with localizing symptoms only. Some idea of the thoroughness of Professor Duret's method may be gained from the mention of separate sections upon the injuries caused by falls from ladders and those by tumbling downstairs. There are masses of facts; there are masses of case records; there is a massive index. It will hardly be possible for an intending contributor to current journals not to find here a parallel to his own "unique" case.

We do not recommend the book to the junior student.

¹ *Diseases of the Throat, Nose and Ear*. For Practitioners and Students. By W. G. Porter, M.B., B.Sc., F.R.C.S. Edin. Third edition, fully revised under the editorship of A. Logan Turner, M.D. Edin., F.R.C.S. Edin. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.; Toronto: The Macmillan Co. of Canada, Ltd. 1919. (Demy 8vo, pp. xv + 300; 79 figures, 44 in colour. 12s. 6d. net.)

² *Diseases of the Nose and Throat*. By Herbert Tilley, B.S. Lond., F.R.C.S. Edin. Fourth edition. London: H. K. Lewis and Co., Ltd. 1919. (Demy 8vo, pp. xx + 844; 266 figures, 74 plates. 25s. net.)

³ *Oto-Rhino-Laryngology*. For the Student and Practitioner. By Dr. Georges Laurens. Authorized English translation of the second revised French edition by H. Clayton Fox, F.R.C.S. Irel. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. Toronto: The Macmillan Co. of Canada, Ltd.; 1919. (Demy 8vo, pp. x + 339; 592 figures. 17s. 6d. net.)

⁴ *Traumatismes Cranio-Cérébraux. Mécanisme et Etiologie, Fractures de la Voûte et de la Base, Symptômes Localisateurs*. By H. Duret. Paris: Felix Alcan, 1919. (Roy. 8vo, pp. xxx + 1562; 320 figures. Fr. 75.)

It is surely intended for the reference library, and will indeed be the envy and despair of those voluminous writers whose fellow-countrymen withheld the hands that had already deliberately destroyed—Louvain.

MILITARY PHYSICAL ORTHOPAEDICS.

In this country, owing to that unique organization comprising the Military Orthopaedic Centres—later thinly disguised under the ambiguous title of Special Surgical Centres—all the methods of treatment included in physiotherapy were rapidly standardized and the knowledge thus gained widely diffused. Lieut.-Colonel A. S. HERBERT, of the New Zealand Medical Corps, working during the war isolated from such opportunities, developed a hospital in New Zealand in which purely non-operative treatment was given. He has expressed his views on the physiotherapeutic treatment appropriate for the results of gunshot injuries of nerves in a small work—*Military Physical Orthopaedics (Part I, Gunshot Wound of Nerve)*.⁵ Written in 1917 but, owing to difficulties in printing, published in 1918, this little book has now lost some of its interest. In the chapters dealing with the examination of patients with nerve injuries and general physical methods of treatment, the author proceeds on conventional lines. A goodly proportion of the book is devoted to a consideration of the use of artificial muscles. It is claimed that an elastic band may act either as a passive support or as an active muscle, the latter only if it is attached to an opposing muscle which normally contracts simultaneously with the muscle which is paralysed in the particular case. This is the real thesis of the book and is claimed as original by the author. His reasoning is, however, unconvincing. His plea for simplicity in temporary apparatus is sound, and, in the conditions under which he worked, his employment of elastic supports designed to maintain relaxation of paralysed muscles showed considerable mechanical resource. He recommends the maintenance of full extension of the fingers in musculo-spiral paralysis, but no doubt since this was written he has had many chances of seeing the unfortunate results of this exaggeration of the principle of muscle relaxation. The book in its make-up suffers from the disadvantage of having all the illustrations grouped together at the end of the letterpress.

NOTES ON BOOKS.

THE book on practical urology,⁶ by Dr. I. COHN of Berlin, is a straightforward pedestrian account of the subject for medical men who have to deal with diseases of the kidney, bladder, and urinary passages. It is also suitable for medical students with a knowledge of German. The author treats his subject throughout from the practical rather than the scientific point of view.

The *Tenth Annual Report of the Commissioner of Health for the Commonwealth of Pennsylvania*,⁷ for the year 1915, dated 1918, is a large and well printed volume in which all sorts of matters connected with the public health of this extensive district are reported on in a style both statistical and discursive. It is clear that the sanitary organization in the Commonwealth has reached a high degree of complexity and shows great evidences of activity.

Salies-de-Béarn.

Situated in the Basses-Pyrénées, not far from Pau, Salies-de-Béarn is a mineral water station, some two hundred feet above sea level, with a warm climate, and most frequented in spring and late autumn, though open all the year round. Its mineral water, coming from the Bayaa spring, contains 25 per cent. of solid matter, mainly sodium chloride; in addition sulphates, bromides, iodides, and metals of the alkalis and alkaline earths are present, but the spring shows no radio-activity. The waters are for external application only and are yellowish in colour; they are employed pure or diluted, as baths or as douches. The

mother liquor left behind after removal of most of the sodium chloride, comparatively rich in bromides and iodides, is also used for baths and for compresses. The establishment is fitted with 140 baths, and is well provided with apparatus for special bathing, douching, and treatment by hydrotherapy of all sorts. Dr. DAVID* describes the waters as beneficial in a great variety of disorders, including chorea, exophthalmic goitre, locomotor ataxy with lightning pains, muscular atrophies of many varieties, stiff joints, and phlebitis. There is also a special establishment for the treatment of gynaecological cases of all sorts, and another for the treatment of children with rickets and all forms of chronic tuberculosis of the glands, bones, joints, and peritonium. Professor Reclus, it is said, obtained excellent results in tuberculous orbitis at Salies-de-Béarn.

* *Quelques précisions rapides sur Salies-de-Béarn et le rôle de ses Eaux en Chirurgie.* Par Docteur David, Ancien Professeur à l'École de Médecine de Limoges, etc. — Limoges: Imprimerie-Librairie Ducourtieux et Gout. 1914. (Demy 8vo. pp. 22.)

THE ROYAL ARMY MEDICAL DEPARTMENT

APPRECIATION OF ITS SERVICES DURING THE WAR.

THE dinner in appreciation of the splendid services of the Royal Army Medical Department and the eminent civilians attached to it during the war, which was held at the Connaught Rooms on June 8th, was briefly reported in our last number at p. 807. Below we give some account of the impressive speeches made in proposing and responding to the toast of the evening.

THE EARL OF MIDDLETON, K.P., who presided, said that the medical record of the war just gloriously terminated was all the more inspiring when one reflected upon the chequered history of the medical service previously. In every former war the medical service had been hurried into the field although its peace time strength had been starved, its pay insufficient, and it had been denied leisure and opportunity for scientific training; it had suffered also from being secluded by a watertight partition from the great civil profession which was its only effective reserve, and it had had scant opportunity for practising modern surgery. In the field it invariably took a back seat; the last man to hear of any intended move was the senior medical officer. Lord Middleton dated the beginning of reform from Lord Wolsley's adjutant-generalship* in the eighties. Under Wolsley and under Roberts the men who held commands in peace were so chosen as to hold commands in war, the equipment designed for peace was made the same as that designed for war, and the gap between civilian and professional soldiers was so bridged over that the professional service became capable of developing into a truly national force. In the Army Medical Department these principles were so applied in the years before the great war that the department was able to conciliate the support of the great civil profession, and the equipment was overhauled so that no change had been necessary in any of the campaigns since 1914. A new chapter began with the organization of a Sanitary Branch in 1908, and while typhus, that scourge of armies from time immemorial, had been kept wholly at bay, the low figures for enteric fever in the recent war, especially when compared with the ravages of enteric in South Africa, constituted the war's finest record. Had the incidence of cases of the typhoid group in the recent war reached the level of the South African war, the cases would have numbered nearly a million and a quarter, and the deaths 160,000. Instead of that, our records in France, Egypt, Salonica, Italy, and Mesopotamia showed but 15,800 cases and 766 deaths (Applause.) The expansion of the R.A.M.C. was also a remarkable achievement. In July, 1914, the corps consisted of 1,800 officers and 9,000 other ranks; in 1919 it included 16,000 officers and 152,000 other ranks. By that time it exceeded in size the original Expeditionary Force which left these islands at the beginning of the war. Nor did these figures tell the whole story, for the vast amount of freely given service by busy civilian practitioners in attendance at the hospitals, not forgetting the V.A.D.'s and others, must be put on grateful record. It was the greatest of tributes to the successive heads of the Army Medical Department at home and abroad that this gigantic multiplication did not lead to hopeless confusion. The chief guest of that evening, Sir Alfred Keogh, typified the administrative genius, the executive efficiency, and the scientific skill which carried through this great adventure.

⁵ *Military Physical Orthopaedics. Part I, Gunshot Wound of Nerve.* By Arthur Stanley Herbert, M.D., B.S., Lieut.-Colonel, New Zealand Medical Corps, F.M.O. of the Rotorna Orthopaedic Hospital, Government Balmceologist. Wellington: Marcus F. Marks. 1918. (Demy 8vo. pp. 136; 62 figures. 6s. net.)

⁶ *Urologisches Praktikum.* Mit besonderer Berücksichtigung der instrumentellen Technik. Für Aerzte und Studierende. By Sanitätsrat Dr. I. Cohn, Berlin, and Vienna: Urban and Schwarzenberg, 1919. (Cr. 8vo. pp. x + 391; 79 figures, 3 plates. M. 16.)

⁷ *Tenth Annual Report of the Commissioner of Health for the Commonwealth of Pennsylvania, 1915.* Part I. Harrisburg, Pa.: J. L. L. Kuhn. 1918. (Med. 8vo. pp. 1559; illustrated.)

He it was who turned to account the reforms with which the names of Sir Frederick Treves, Sir Alfred Fripp, and Sir Cooper Perry would always be associated. During four fateful years Sir Alfred Keogh had wielded an autocracy which only an Irishman could appreciate, and which even an American President might envy. (Laughter.) He engaged 20,000 of the civilian practitioners of the country; he "cornered" the quinine of the world, and he was never at a loss whatever the emergency. His mantle had well fallen upon Sir John Goodwin, whose name also he coupled with the toast; yet another name to be added was that of Sir George Makins, who was a fit representative of the men to whom military rank could add no further eminence. (Applause.)

Mr. WINSTON CHURCHILL, Secretary of State for War, associated himself with what Lord Middleton had said. Every form of national effort which produced the devices of destruction had had its tribute, but surely those also who, under conditions of equal hardship and danger, had been saving life while others had been taking it, healing wounds while others had been inflicting them, were entitled in fitting season to their meed of popular applause. This island nation with its Empire gathered about it had suddenly to embark upon a vast enterprise. Everything had to get forty times bigger than it was before. For the first year or so of the war the men who were right were the men who thought bigger than anyone else dared to think. In no instance was this multiplication more remarkable than in the Army Medical Department. Seven thousand beds were available for its use when the war began, and 700,000 when it ended. Judged from the standpoint of bulk and magnification alone, nothing was more wonderful, not even the multiplication of man-power generally or the production of artillery and explosives. But there was more than multiplication. The improvement in the methods of treating this great mass of human suffering—these shattered figures who were thrown back upon the healing science of the British nation—was as impressive as the multiplication itself. And how greatly did this matter to the hundreds of thousands of men who cast themselves on the mercy of the R.A.M.C. and never found that mercy lacking! No one knew anything about the war who had not been in a large casualty clearing station six or seven hours after a great battle had begun. A more terrible spectacle, a spectacle more calculated to imprint itself indelibly upon the mental retina, could not be. And the only comfort a sound and healthy man had when he saw the appalling misery which was poured from one automobile after another was that everything that a passionate humanity and sympathy could suggest and that science and professional skill could execute was at the disposal of those heroic beings who lay scattered in this sea of helplessness and pain, while the cannonade thundering in the distance gave promise of yet more to come. The R.A.M.C. achieved a better, a more humane, a more scientific, a more refined treatment than was arrived at by any other of the great nations who were engaged as deeply in the war. It would be wrong, Mr. Churchill concluded, to dwell upon the achievements of the R.A.M.C. without making the fullest acknowledgement of the immense services rendered so freely and generously by the eminent civilians. The R.A.M.C. could not have achieved what it did, either in the domain of medicine and surgery or in that of military hygiene, had it not received this immense reinforcement from the finest scientific brains in the country devoted to the healing of human suffering. (Applause.)

Field-Marshal Earl Haig said that he knew he expressed the feeling of the commanders in the field when he thanked the R.A.M.C. and the eminent civilians for all that they did to help in winning the war. It was impossible to exaggerate the debt. He recalled the work of the attached medical units when he commanded the First Army (1914-15) during the fighting on the Aisne. At that time the dressing and evacuating of the wounded was particularly difficult and exacting. It was their first experience of trench warfare, and the trenches were unlighted, and altogether very poor compared with those subsequently made. The corps suffered heavy casualties, there were no motor ambulances available, and the conditions altogether were most trying. But the conduct of the medical units was perfectly splendid, so unselfish and devoted. (Applause.) Some leaders like himself, who realized that the success of the army depended very much

on an efficient medical service, viewed with misgiving the difficulties consequent upon its great expansion, but as the army grew the medical service grew with it, and remained throughout its multiplication thoroughly efficient. The problem which the service had to deal with was huge, but everything worked smoothly. All ranks showed devotion and gallantry, alike the regimental medical services, the field ambulances, and the medical corps of the Dominions. That they all sustained heavy casualties demonstrated how zealously they did their duty. He would like to bear witness to the good feeling and confidence which existed between the fighting portion of the army and their medical comrades, and also to acknowledge his personal indebtedness to Sir Arthur Sloggett (to whom this good feeling and confidence was largely due) and Sir Charles Burtelaell, and their deputies, Sir William Macpherson and Sir H. N. Thompson. The untiring professional zeal of the civilians was also beyond all praise. He would mention the names of two senior consulting surgeons, Sir George Makins and Sir Anthony Bowlby, and of two consulting physicians, Lord Dawson and Sir John Rose Bradford. Another name he must mention was that of Sir Wilmot Herringham, of whose devotion in a casualty clearing station on one occasion he had a vivid recollection. He concluded with a word of praise to the scientists who had helped to make the gas attacks innocuous. All alike had played the game as men. (Applause.)

There were three responses to the toast.

Sir ALFRED KEOGH, after making his personal acknowledgements of the wonderful tribute paid to the work of the Army Medical Service and to himself, said that the first great inspirer of the medical department was Lord Herbert of Lea, and there was always to be associated with this War Minister of the middle nineteenth century the name of Florence Nightingale. In latter days the army had had two statesmen who understood the Army Medical Department. The first was Lord Middleton and the second Lord Haldane. What Lord Haldane did could never have been accomplished but for the labours of his predecessor. Lord Middleton gave them the opportunity of post-commission study, established the Royal Army Medical College and reconstituted their units. Lord Haldane enabled them to come into organic union with their brethren of the civil part of the profession. There were not two professions, but only one, and there was no great difficulty therefore in joining together in the great Territorial service which Lord Haldane set up. After paying a warm tribute to the Red Cross Society and emphasizing the need for its existence, Sir Alfred Keogh went on to refer to the cordiality of the general officers commanding in the field, without which it would have been impossible for the medical service to have done what it did. This held good not only in the armies in France, but in Salonica, Palestine, the Dardanelles, and, later on when the War Office took over the Mesopotamian campaign. Nothing could have been done in the Mediterranean area, for example, had it not been for the noble Field-Marshal then Commander-in-Chief at Malta (Lord Methuen), who was present that evening, and to whom he was eternally grateful. (Applause.)

Sir JOHN GOODWIN said that whatever success the R.A.M.C. had in the recent war was due to three main factors: the progress which had taken place in the medical services during the twelve years since the end of the South African war; the action of the civil profession who from the outbreak of the war came forward and placed everything at the disposal of the army; and the great change which had taken place in the direction of a better understanding between the army generally and the medical service. He believed that the British army had at present the best army medical service in the world, but it was capable of improvement, and he hoped that improvement would be forthcoming. Social unrest in England would, he believed, now be much more pronounced were it not for the fact that every man who had served in the war knew, and his relatives also knew, that an honest endeavour was made throughout to prevent distress and relieve suffering. It was now no longer a question of the civil profession on the one side and the R.A.M.C. on the other. They had all served together, and together they had passed through trials and vicissitudes. A thing never to be forgotten also was the early co-operation of America in the matter of medical provision. He went over to the United States and interviewed General

Gorgas and others, and within a very few months more than 1,000 American doctors and 700 nurses, equipped, uniformed, and paid, were placed unreservedly at the disposal of the British armies. (Applause.) Speaking for himself, he said that he entered upon his present post with trepidation, but he had served under two Adjutant-Generals, and from them and from the members of the Army Council he had received every possible sympathy and kindness.

Sir GEORGE MARINS said that of all civilians who took part in war service the men of his own profession were the most happy, for they were called upon to do work in connexion with the army which was the same work they had been accustomed to do all their lives. They had the satisfaction of feeling that they brought to the Army Medical Service a source of medical strength, and they also, many of them, were taken out of the ruts of a somewhat monotonous practice and saw new countries and made new friends. He himself was supposed to be responding for the senior civilian surgeons, but as much or more was due to the junior members of the profession who formed the rank and file. Moreover, great as were the triumphs of surgery in the war, the advance in medicine was equally impressive. The success of the Army Medical Service was due in no small part to the enlightened policy of the authorities of the War Office and the Army Council.

GRADUATE MEDICAL EDUCATION IN THE UNITED STATES.

BY

SIR HUMPHRY ROLLESTON, K.C.B., M.D., F.R.C.P.,

EMERITUS PHYSICIAN, ST. GEORGE'S HOSPITAL; PRESIDENT OF THE ROYAL SOCIETY OF MEDICINE;

AND

H. J. WARING, M.S., F.R.C.S.,

SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

A RECENT visit to America, as representatives of the Royal Colleges of Physicians and Surgeons, in response to the invitation of the National Board of Medical Examiners to visit their examinations, afforded full opportunities of inspecting the chief medical schools. This experience has impressed upon our minds that graduate education is attracting much serious attention, that steps with this aim in view are being actively pushed forward, and, further, that the direction in which the most important developments are occurring is different from that in this country. In Great Britain graduate or post-graduate¹ teaching is mainly arranged for men in general practice who wish to keep up to date, and consists in revision or "refresher" courses of comparatively short duration, or in attendance on the clinical practice of their old schools. In the United States graduate education is divided into (1) short courses, much on the same lines as the post-graduate teaching as usually understood in this country, and (2) a form of advanced and intensive education lasting one to three years, and aiming, as its finished product, at rendering a man fully qualified to practise medicine or surgery in the highest or most specialized branches, or to undertake research or teaching. It is to this form of graduate education that some of the more progressive American schools are paying great attention, and it is for facilities of this kind that American graduates coming to this country may in the future be expected to make inquiry. As this does not appear to be generally recognized in this country it may be well briefly to describe this form of graduate education in America.

For this advanced and intensive graduate education, extending over one to three years, there is already very considerable demand, and it is rather surprising to learn from the recent Report of the Committee on Graduate Medical Education, appointed by the American Medical Association,² that during the year 1919-1920 there were probably four thousand applicants for this form of graduate teaching. The vast majority of these applicants were

anxious to specialize in some branch of clinical practice, those aiming at a public health career, or at teaching posts, or at research work in the fundamental subjects of anatomy, physiology, biochemistry, bacteriology, or pharmacology, forming a very small minority. Thus out of 1,021 inquiries for graduate work at the Mayo Clinic, Rochester, since January 1st, 1919, four only were primarily for work in the fundamental branches, though 90 per cent. of the "fellows" taking clinical work as their "major" subject chose pathology as a "minor" subject.

To make the general ideal of this form of graduate education clearer the following extract may be quoted from the above mentioned Report of the Committee on Graduate Medical Education:

Most of these men need opportunity to work alone, not in classes though under general supervision, for six months to a year in one or more of the fundamental branches. They then need clinical material and laboratory and library facilities for two or more years of intensive work in diagnosis and treatment. They need personal responsibility for patients, inspiration to investigation, keen criticism, and opportunity for fearless discussion with real leaders in their specialty. They need little, if any, formal teaching, of which most of them have already had too much. It is believed that these needs might be met in large measure by medical schools and hospitals if their present resources were more definitely organized with that end in view.

As regards the steps that have been taken in America to meet this want: although the American Committee consider that "opportunities by which graduate students may properly prepare themselves by long periods of work for scientific and skilful practice of clinical specialties are woefully lacking," a very substantial beginning has been made, especially by the Mayo Foundation, to which reference may now be made.

Prolonged Graduate Instruction.

The Mayo Foundation for Medical Education and Research was established by Drs. W. J. and C. H. Mayo on a permanent basis in February, 1915, and in the following June the University of Minnesota and the Mayo Foundation entered into an agreement by which the funds and income of the Mayo Foundation are devoted, under the direction of the Regents of the University, to the promotion of graduate work and research in medicine. In 1917 the funds and income of the Mayo Foundation were transferred entirely to the Board of Regents of the Minnesota University; and the staff, clinics, laboratories, library, and records at Rochester, Minnesota, were also put at the disposal of the University. The graduate school, which is thus extremely well endowed and equipped, is put on the same basis as those of the other faculties, and the graduate student is under the same conditions as a candidate for the degree of Ph.D., say, in chemistry. At the University of Minnesota a student takes seven years to obtain the M.D. degree, and then, if he is accepted as a graduate student, he may after three years' work gain the special degrees of Master of Science (M.S.) or Doctor of Philosophy (Ph.D.) in Medicine, Surgery, Ophthalmology, Obstetrics, Pathology, and so forth. Entrance to the graduate school is not confined to graduates of the Minnesota University, for graduates from other universities are selected on the grounds of their work. For admission the graduates must have the bachelor's degree in arts or science or its equivalent, the doctorate of medicine from an acceptable institution (namely, those in Class A of the American Medical Association's classification) and a year's experience as an intern in an approved hospital or laboratory. This endowment provides fellowships and scholarships for a number of graduates; there are about 17 teaching fellowships of the value of 600, 750, and 1,000 dollars for the first, second, and third years respectively, the fellows doing a small amount of teaching and devoting the whole of the remainder of their time, except a yearly vacation of three weeks, to graduate work leading to a degree. There are also 86 non-teaching Mayo fellowships, of which 60 are in clinical and experimental surgery and 12 in clinical and experimental medicine. As a rule there is only one graduate student a year in each subject, but there is some elasticity in this respect. The competition is severe—thus out of more than 1,000 applicants since January, 1919, 42 fellows have been selected. There is a regular scale of fees. If a student does not promise well, he is got rid of, usually before the end of his second year.

¹ It might perhaps be convenient to follow the University of Minnesota in confining the adjective *post-graduate* to the revision or refresher courses taken some considerable time after graduation, and to use *graduate* for education received shortly after graduation and as a continuation of undergraduate study.

² Vide *Journ. Amer. Med. Assoc.*, Chicago, 1920, lxxiv, 1248.

Each student on admission selects a "minor" subject which is logically related to his "major" subject—for example, as pathology is to surgery—and is mainly carried on in a laboratory during the first year; in his second year he finishes his "minor" subject and passes an examination in it and in French and German, and devotes himself to his "major" subject; in the third year he does more responsible work; thus a surgeon works in the operating theatre and performs operations of all sorts, and is in charge of the junior assistants; he also writes his thesis for the graduate degree (Ph.D. or M.S.). The Ph.D. degree, which is the most highly prized degree in American universities, as it is not conferred as an honour or compliment, is given for theses of exceptional merit only, and so far only about 5 per cent. of the "fellows" have gained this blue ribbon. The work is done partly at Rochester and partly at Minneapolis, where the buildings of the University of Minnesota are situated, the students moving to and fro for different phases of their work.

In comparing these facilities with those available in this country it is obvious that no such completely organized scheme exists here. The laboratory work in the "minor" subject—for example, pathology or anatomy—could no doubt be arranged for, on the lines of the "advanced student's" work in other branches of science at the universities and elsewhere; but the third year's work, corresponding to that of chief assistant in a clinic, though open to men at their own hospital, would seldom be obtainable by graduate students from outside, and could hardly be open to American graduates unless they had taken some British qualification.

The organization of the Mayo Foundation and Minnesota University Graduate School is so complete that it has been described at some length, but the idea is being taken up by other universities. Thus the University of Pennsylvania is organizing a clinical graduate school on a considerable scale with opportunities of gaining a graduate degree or certificate. At Philadelphia the Medico-Chirurgical Hospital and the Polyclinic have become a part of the University of Pennsylvania, and form the clinical centre of a graduate medical school. This school, with separate administration offices in the University buildings and a separate dean, has associated with it or affiliated to it a considerable number of the special hospitals in Philadelphia. The central hospital has a service of 300 beds. The object of the University of Pennsylvania in establishing this graduate school in medicine is so to train the acceptable graduate in medicine that he shall be properly qualified to begin special medical practice or teaching, and be stimulated to "productive" medical research, and in addition to perform the public service of affording reputable physicians opportunities to keep in touch with medical advances by coming in contact with the newer things in medicine as exemplified by the practice of masters of the various fields of medical work. It is proposed to give courses of one and in certain subjects of two years' duration which, if satisfactorily followed, may lead to a degree or special certificate. There are also four-months' courses, which appear to be on the same lines as the revision classes for practitioners and may lead to a special certificate. It is intended to develop this graduate school so as ultimately to provide courses and instruction and special work in practically all the branches of medicine and its allied subjects. The special degrees to be given are Master in Medical Science and Doctor in Medical Science. The master's degree is to be confined exclusively to these candidates who have become qualified to begin the practice of a medical, surgical, or laboratory specialty, and the doctor's degree to those candidates who have done "productive research" or work of considerable merit. The Master in Medical Science does not, as in the Mayo-Minnesota graduate school, demand three years' work. The University of Harvard gives a certificate in Public Health in Industrial Hygiene after one year's work, the degree of Doctor in Public Health (Dr.P.H.) in Industrial Hygiene after two years' work, and the degree of Doctor of Philosophy in Industrial Hygiene after three years' work, but it does not offer a degree for graduate work in clinical medicine alone as in the Mayo-Minnesota scheme. This school in industrial medicine is a new development, for it is both a training school for medical men who intend to take up work in connexion with factories and a research institution, but it is not part of the graduate medical school of

Harvard University, which is fully developed on lines more familiar in this country. Several other universities give the degrees of Master of Science or Doctor of Philosophy for research work in laboratories in the fundamental subjects (anatomy, physiology, biochemistry, bacteriology, and pathology), but not for clinical work.

SHORT COURSES.

A few words may be added about the short courses of instruction to medical graduates in America, which are more on the lines of post-graduate education as understood here. These courses usually occupy from two weeks to four months; and it has been estimated that in the year 1919-20 there were probably 6,000 applicants for these courses. The applicants are—

(a) General practitioners, anxious to keep their knowledge up to date, who being established in practice cannot devote more than a short time to this object; the time thus afforded is indeed often inadequate, especially in the case of men whose training in the fundamental subjects (anatomy, physiology, bacteriology, and pathology) has always been deficient or has become so from lapse of time. Accordingly there is not time to obtain a proper knowledge of the fundamental data, and without this basis the full benefit to be derived from these short courses may be problematic. (b) A large proportion of the men applying for short courses are "partially prepared clinical specialists," and do so with the object of extending or perfecting their operative technique in general surgery or in some special line of practice.

Most of the applicants for short courses may therefore be regarded as really anxious to obtain a short cut to knowledge. While fully recognizing the difficulty of running these short graduate courses in connexion with undergraduate teaching, the American committee, though expressing their views with great caution, appear to be doubtful if the existing graduate and polyclinic schools, by the provision of lectures, clinical and laboratory demonstrations and training in technique, supply what is wanted; and they urge the university medical schools to give to the better prepared men applying for short courses opportunities for combining diagnosis with treatment. This has perhaps been most fully developed by the University of Harvard, where the medical school offers to graduates the opportunity of taking out courses of varying duration in most of the branches of medicine and surgery. These are termed "practitioners' courses," and mainly consist of classes, restricted to a small number of graduate students, commonly from four to ten. The organization of the graduate division of the medical school of Harvard University is under the direction of Dr. A. S. Begg, the assistant dean, in charge of graduate courses.

THE ROCKEFELLER FOUNDATION GIFTS TO UNIVERSITY COLLEGE AND MEDICAL SCHOOL.

The purpose of the magnificent gifts, amounting together to £1,205,000, made by the Rockefeller Foundation to University College and University College Medical School, is to help in building up in London an ideal medical school, equipped in all departments on the most modern lines, to serve as a model for other schools. The Foundation has encouraged the Clinical Unit System in America, where it has made large grants for the purpose, but this is, so far as we are aware, the first occasion on which it has extended its propaganda to Europe in this very practical form.

The institution chosen as the recipient of these splendid gifts occupies a unique position. For over a century University College has set a high standard in all departments of learning and education in London. It did not lose hope in the worst times, and it is characteristic of its persistent policy of rising to every occasion that when the policy of the Government with regard to the parliamentary grants to university institutions was made known its Medical School at once accepted the plan of Clinical Units, and courageously established two—the one in

medicine and the other in surgery, both fulfilling the conditions laid down by the University Grants Committee as fully set out in the Memorandum published in our columns on June 5th, p. 775.

The Foundation decided to make this gift after full inquiry. Dr. Wickliff Rose, General Director of its International Health Board, and Dr. Pearce, its Adviser in Medical Education, when in London last year, made themselves acquainted with what had been done towards the establishment of clinical units and the difficulties, chiefly financial, which were hampering the full development of the movement. The other medical schools which had started clinical units, St. Bartholomew's and St. Thomas's, were visited, and the conclusion was reached that the medical school most likely to develop the scheme in the best way was that of University College Hospital. In coming to this opinion the two representatives of the Foundation were probably influenced by the fact that the close connexion of the Medical School with University College was a circumstance very favourable to the growth of an institution providing education in all three stages of the curriculum. They found the provision for the preliminary studies satisfactory, and that the Institutes of Physiology and Pharmacology wanted little. It had long been recognized that the third department of the Medical Faculty of the College—Anatomy—was inadequately provided, and that there was need for an Institute of Anatomy in which the Professor, Dr. Elliot Smith, could properly conduct teaching and research work. Part of the offer of the Rockefeller Foundation is to give to the College a sum of £370,000 for an Institute of Anatomy and for additions to the staff of that department, to that of Physiology, and to those of certain others. The sum is allocated as follows:

Institute of Anatomy:	£	£
Site and building	159,800	
Equipment and library	30,000	189,800
Capital sum for Maintenance Fund		180,000
		£359,800

This capital sum is for additional staff—namely:

Anatomy	£5,000 a year
Physiology	£2,500 ..
Other departments	£1,500 ..
	£9,000 ..

The fulfilment of the third part of the plan—the establishment on a permanent basis of three Clinical Units in medicine, surgery, and obstetrics including gynaecology—involved many matters of detail which were finally settled by a conference in America between the Executive Committee of the Rockefeller Foundation of the one part, and the Dean of the Medical School (Dr. Blacker), the Director of the Medical Unit (Dr. T. R. Elliott), the Provost of the College (Sir Gregory Foster), and Professor Elliot Smith of the other. The Executive Committee evinced the greatest interest in the project and indicated that help given would be primarily in the interests of medical education and would extend to the hospital, not as a charity, but as a necessary factor in the teaching at the medical school. So far it had only been found possible to allot 30 or 40 beds apiece to the two directors, instead of the 50 or 100 desired, and provision could not be made for obstetrics. University College Hospital fills an island site, but there is a nursing wing which can be converted into wards for 100 to 120 beds with the necessary clinical laboratories. The plan now adopted is to build on another site a nurses' home, a house for resident officers, and an obstetric annexe for 60 beds. For a new department of biochemistry, and for other additional laboratory accommodation needed a site is available at the back of the present building of the medical school. For these purposes the Foundation has promised £400,000.

It was pointed out that the additional beds would increase the annual expenditure of the hospital and that the school would have to meet additional expenses for the unit, for salaries in the biochemistry department and for augmentation of salaries in the pathological department. The Foundation agreed to give a capital sum of £435,000 to yield an annual income of £21,700 towards meeting these expenses—namely, £1,000 to each unit, £3,100 for salaries, etc., in new laboratories, and £15,600 towards maintenance of new beds.

University College Hospital and Medical School.

Building and Reconstruction:	£	£
Obstetric Department	109,500	
Biochemical Department	50,750	
Reconstruction in Hospital	105,000	
Nurses' Home	103,000	
Residents' Quarters	31,000	400,250
Maintenance... ..		455,000
		835,250

The Rockefeller Foundation, in making grants of capital sums for maintenance, has in this instance departed from its customary policy, which is to make a block grant to begin with and annual grants for a certain number of years, the institution being then expected to continue its work through support received locally. That the Executive Committee was willing to make this departure from practice is evidence of its readiness fully to consider the particular conditions, and of the desire—displayed all through the discussions—to meet needs in a generous spirit. The committee indicated, however, that it did not depart from its policy of looking to the institution benefited to supplement the grants to a considerable extent. It appears that the additional annual expenditure to be met by the Hospital and Medical School when the whole scheme is working will be from £14,000 to £18,000.

At a meeting of the staff and students of University College on June 11th the Provost announced the terms of the offer and read extracts from a report to the Senate of the University, with whom, at its meeting on June 23rd, final acceptance lies. Professor Elliot Smith moved a resolution expressing appreciation of this munificent and spontaneous gift. By endowing the work of the anatomical department, the Rockefeller Foundation would ensure that the requisite facilities for anatomical teaching and research, in close conjunction with those in physiology and pharmacology, would be provided in accordance with the scientific requirements of the time. It had been, he said, the settled policy of University College to restore anatomy to the position which it should occupy, not only in the medical curriculum, but in the field of research. The general scheme of anatomical teaching in this country was curious; there was no equipment for the study of histology in the anatomy department and no facilities for embryological research or teaching, nor for studying the factors which determined the form of the body. Professor J. P. Hill, Vice-Dean of the Faculty of Medical Science and Jodrell Professor of Zoology in University College, said that the new anatomical institute would lead to a great revival of anatomical teaching and research in this country, and he looked forward to the establishment of a corresponding institute of comparative anatomy.

VENEREAL DISEASES.

National Council for Combating Venereal Diseases.

THE fifth annual meeting of the National Council for Combating Venereal Diseases was held at the house of the Royal Society of Medicine on June 7th, with Lord SYDENHAM in the chair, when there was a large attendance. The Chairman announced his retirement from the post of President by reason of advancing years. The Council, he said, had to deal not only with difficult problems in physiology and psychology but with the opposition of ignorance and prejudice. Nevertheless, the movement had never been so vigorous nor so progressive as now. If the Council's teaching were adopted everywhere much would be done to stamp these diseases out of the country. The rural areas presented special difficulties for the overcoming of which the general practitioner's aid was needed. Much money had been spent on clinics in towns, but the results could not be regarded with entire satisfaction, for nearly half of the 175,000 people who attended left before the treatment was completed.

LORD ASTOR said that the importance to the nation of a clean bill of health was increased by our war losses. During the war there was a constant appeal to the imagination; it was needed to stimulate patriotism and to cause the nation to accept irritating control. Imagination had made people realize the ravages of venereal diseases, though it had led to some rash and exaggerated statements. There were no official

figures giving the incidence of these diseases; but there was a far larger attendance for treatment, which would result in reducing the disease. He was not disturbed at the increase in attendances at clinics; he was relieved that the efforts of the Ministry of Health caused people to come to be treated. Deaths from syphilis were not increasing, nor deaths from general paralysis of the insane and locomotor ataxy. But this did not mean that the extent of the disease was not serious, or that it was not a menace. There was much talk of compulsion, of detention, of notification, and of treatment. Before compulsion was even discussed there must be enough facilities for diagnosis and treatment for those affected. The provision was inadequate now. Nor must it be forgotten that compulsion would lead to much concealment and a consequent failure to apply for treatment. Half the people who talked of compulsion had not realized the special difficulties of this disease, and had not studied previous failures. During the war venereal disease was reduced more by women police and drink control than by the D.O.R.A. Regulations 40 D. and 13 A. Flexner had exposed the so-called success achieved on the Continent through their system of inspected houses, which had neither wiped out venereal disease nor produced peoples cleaner in body and mind. Nor must the lack of success of the Contagious Diseases Acts in England be forgotten; venereal disease increased in the army during their operation, and decreased when they were abolished. He had dwelt on past experience because methods had been advocated lately based on the same sort of fallacies as those put forward by the advocates of inspected houses and of the Contagious Diseases Acts. It had been urged that the use of packets should either be officially recommended or at least quietly encouraged. Now, the results achieved by the use of packets in the forces were carefully examined a year ago, and the Ministry of Health decided that the case for packets had not been proved, and that the risk to health and welfare by encouraging their use would be serious. Even if packets had proved an unqualified success in the army it would not necessarily involve their success among the civil population, which was not subject to regular examination, treatment, punishment, and control. Packets would give a false sense of security, and would encourage people to take risk, thereby increasing the very disease they were intended to prevent. Experience showed that the instances of their failure were numerous. The Report of the Interdepartmental Committee, which condemned the official encouragement of packets, had been very well received throughout the country. As to policy, they wanted to stimulate medical education. It was essential to bring the general practitioners more into touch with modern science. They proposed to work through the medical schools and through the V.D. clinics. There were now 172 clinics: this was not enough. Rural areas offered special difficulties, and greater facilities were needed for diagnosis and treatment, with special reference to the needs of pregnant women and of seamen. The Council's propaganda, both for adults and for adolescents, must be continued and increased. But while improving the organizations at home they must not forget the propinquity of nations, the extent of modern travelling, and the special temptations of the seafaring population. He hoped the League of Nations, through its Health Section, would help to solve this as well as many other world problems.

Lord Gorell succeeds Lord Sydenham as President of the National Council.

Society for the Prevention of Venereal Disease.

The first annual general meeting of the Society for the Prevention of Venereal Disease took place at the house of the Royal Society of Medicine on June 3rd with the President, Lord WILLOUGHBY DE BROKE in the chair. In his report the honorary secretary, Dr. H. WANSEY BAYLY, M.C., reviewed the progress made during the seven months of the society's existence and reported a considerable increase in membership. Two public meetings were held in London; a Malay Peninsula branch of the society had been established at Malacca, and requests had been received to open branches in many of the chief provincial towns. The views of the society had been communicated by a deputation to nearly fifty members of the House of Commons, who agreed to form themselves into a Parliamentary Committee to further the aims of the society. Branches of trade unions had shown a keen desire to hear lectures on the prevention of venereal disease, and Dr. Bayly had given many lectures to intelligent and appreciative audiences. The medical officers of health of counties and county boroughs throughout Great Britain were thrice circularized, with the result

that twelve councils had endorsed the Committee's policy and had recommended that the male inhabitants of their boroughs should be given the opportunity of acquiring knowledge of efficient and immediate self-disinfection.

Lord WILLOUGHBY DE BROKE, in his presidential address, said that the origin of the Society was a White Paper, published by the Government some months ago, setting forth the official view with regard to prophylaxis in the treatment of venereal disease. The Government report and the whole complexion and attitude of the official view was against the policy of self-disinfection as a prophylaxis against venereal disease. It was a self-evident proposition that to avoid contagion one should avoid contact; but it was equally true that, in spite of all the exhortation and lecturing, more particularly in the army, with regard to the dangers of promiscuous intercourse, venereal infection was still proceeding at an alarming rate. Thus, moral prevention, although an excellent thing as far as it went, had hitherto failed to achieve the object of stamping out or even lessening the disease. Dr. SALEEBY expressed astonishment that those who now opposed the Society's policy had themselves connived at the confusion between prevention and treatment which the Society desired to make explicit and put an end to. Sir JAMES CRICHTON-BROWNE appealed for the support of the public, and more particularly of employers of labour. Sir FREDERICK MOTT declared that it would be of the greatest value to the Government, both from the point of view of health and of economics, to support the Society's propaganda. Sir W. ARBUTHNOT LANE and Dr. SEQUEIRA also spoke.

VITAL STATISTICS OF ENGLAND AND WALES.

(Continued from p. 802.)

PNEUMONIA.

THE total number of deaths assigned to pneumonia in its various forms during 1918 was 59,666 (33,451 males, and 26,215 females), corresponding to a rate of 2,115 per million of male civilians, 1,350 per million of females, and 1,654 per million of both sexes. These numbers and rates are much in excess of all previous experience, even if the comparison is carried back so far as 1854; they were most nearly approached in 1891, when also influenza was prevalent, and the mortality per million persons was 1,471. The sudden increase in 1918 was due to the great epidemic of influenza. Dr. Stevenson points out that this may be well demonstrated by analysis of the quarterly mortality among females, for whom the figures are scarcely modified by diminution of the civilian population. During the first two quarters of 1918 the mortality from pneumonia conformed very closely to that of the seven preceding quarters, but the third and fourth quarters of 1918 brought increases of 65 per cent. and 169 per cent. respectively. Citing figures from the special report on influenza, Dr. Stevenson estimates that 8,146 deaths of males, and 8,932 of females allocated to pneumonia in 1918, were in reality due to the epidemic of influenza; these increases resemble the increase in influenza in that they were greatest in early adult life, and were practically non-existent in old age. Among females, in addition to these estimated deaths, there were, from June 23rd, 1918, to the end of the year, 41,500 deaths to which both influenza and pneumonia were stated to have contributed. By ascertaining the age distribution of these deaths and comparing it with that of the excess pneumonia deaths of 1918 (that is, the excess of pneumonia deaths during that year over the corrected average of the five preceding years), Dr. Stevenson draws the inference that much of the mortality ascribed to pneumonia in children under 15, and particularly in children under 5, was really of influenzal origin. In normal years pneumonia mortality decreases generally from north to south, and shows a considerable decrease in accordance with decreasing urbanization; these features were not materially modified in 1918, when the influenza epidemic affected all areas with almost equal severity.

DIPHTHERIA AND CROUP.

The 4,801 deaths of civilians in 1918 from diphtheria and croup, of which all but 34 were allocated to diphtheria, correspond to a death rate of 143 per million civilian population, which is a little higher than in 1917, but lower than in the first two years of the war. For children under 15 years of age the mortality rate was 418 per million,

as compared with rates of from 373 to 504 during the preceding eight years. The mortality rate per million living at all ages was 169 in London, 151 in the county boroughs, 150 in other urban districts, and 106 in rural areas. In the north proportionately fewer cases of the disease were notified, but their fatality was very much higher than in the south; in London, on the other hand, the high mortality appears to have been due entirely to the wide prevalence of the disease, its fatality there being lower than in all other areas (82 deaths per 1,000 cases in London, as compared with 118 in the county boroughs, 120 in other urban districts, 107 in rural areas, and 110 in all areas). The distribution of diphtheria mortality among the county boroughs resembles that of scarlet fever in showing exceptional severity in certain Lancashire towns in the neighbourhood of Liverpool.

MEASLES.

During 1918 measles caused 9,787 deaths (including 114 of non-civilians) as compared with 10,538 in 1917. Civilian deaths were 289 per million of the civilian population at all ages, and 867 per million at ages under 15. The mortality was higher in the north and in urban districts. Among the administrative counties the West Riding returned the greatest proportion of deaths, Norfolk, Pembroke, Glamorgan, and London coming next in the order named. The four highest county borough rates occurred in Barnsley, Norwich, Wakefield, and Hull. The Barnsley mortality was extraordinarily high—namely, 4.9 deaths per 1,000 population—a figure which has not been even remotely approached by any county or county borough for at least eight years. At Barnsley all the 233 deaths occurred under the age of 15 years and formed one-third of the total deaths at this age; the majority of the deaths at 2 to 5 years of age were due to measles.

SCARLET FEVER.

Deaths allocated to this disease during 1918 numbered 1,020, including 54 of non-civilians. Civilian deaths corresponded to a rate of 29 per million civilian population at all ages, and of 80 per million at ages under 15; with the exception of those of 1917 both these rates are the lowest recorded in this country. The slight increase for 1918 was entirely due to a rather severe outbreak in and around Liverpool. The mortality from scarlet fever per million living at less than 15 years of age rose from 60 in 1917 to 80 in 1918; the lowest rates previously recorded were 110 in 1916 and 158 in 1911. The mortality is now trifling compared with that prevalent a generation ago; the slight rise above the phenomenally low rate in 1917 is due to the increased severity of the cases, for the number notified fell from 50,661 in 1917 to 49,637 in 1918, the deaths during these years per 1,000 cases notified having been 15.3 and 20.5 respectively per thousand.

WHOOPIING COUGH.

The number of deaths attributed to whooping-cough was 9,892 (4,391 males, and 5,501 females); the corresponding rates of mortality are 296 per million living at all ages, and 893 at ages under 15 years. These rates are the highest for about ten years past, but Dr. Stevenson points out that no rates so low even as these were ever attained during the nineteenth century.

MALARIA.

Deaths from malaria became much more numerous during the latter part of the war, and in 1918 amounted to 197 as against an average of 58 in 1911-14, and 65, 62, and 126 in the three succeeding years respectively. There is good reason to believe that the increase is due almost entirely to deaths in this country of men infected during foreign service. It is reasonable to believe that if the increased mortality were caused in any degree by indigenous infection it would affect both sexes to an approximately equal extent; but of 197 deaths from malaria in 1918, 9 only occurred in females. Confirmatory evidence is obtained by reference to the sex distribution of mortality during periods when malaria acquired in this country still contributed to the English death-rate; deaths from 1881 to 1885 were equally numerous among men and women, but from 1901 to 1910 there were five to ten times as many deaths among men as among women. During the decade

1871-80, 43 per cent. of those dying from "ague" were females, as compared with 4.5 per cent. in 1918. It is noted also that there is no concentration (such as occurred in the partly indigenous malaria of 1871-1890) of the increased mortality to particular counties. Dr. Stevenson states that notwithstanding the recent occurrence of home-bred malaria in some of its old centres—notably Kent—the sharp increase of deaths recorded in late years need occasion no alarm, unless this mortality is found to be concentrated in geographical and diffused in sex incidence. Happily each of these tests yields a negative result. Of the 197 deaths in 1918, 99 were of non-civilian males, and of 89 civilian males 30 were ex-service men and 20 were mariners. Of the 9 females who died from malaria, three were sick nurses, one was the wife of a soldier, two were married to a missionary and a West Coast official respectively, and one was recorded to have suffered from malaria for thirty years.

DYSENTERY.

Deaths attributed to dysentery in 1918 numbered 838 (485 males, and 353 females); in addition, 33 asylum cases were notified as "ulceration of the intestines," and were probably due to dysentery. The 790 cases occurring among civilians yield a death rate of 24 per million (males 32, females 18); these rates are about four times as high as those prevalent before the war. At first sight the possibility is suggested of spread of infection by men returned from foreign service; but this supposition is negated by the fact that of the total registered deaths no less than 81 per cent. occurred in lunatic asylums, which since 1911 have furnished more than half the deaths from dysentery. In the past the deaths of females in asylums have always exceeded those of males, but in 1918 the deaths of males were rather more numerous. This change corresponds with that described for tuberculosis, and, together with the very large increase in the number of asylum deaths from about 150 per annum before the war to 680 in 1918, confirms the surmise¹ that the increase in mortality has been due largely to staff difficulties, which would chiefly affect the male sides of these institutions, though evidently both have suffered. The remaining portion of the increase of deaths from dysentery is traceable to deaths in hospitals; outside asylums and other institutions deaths from this cause were no more abundant than before the war.

(To be continued.)

¹ BRITISH MEDICAL JOURNAL, JUNE 5th, 1920, p. 775.

A MEDICAL school directed by Alexiinsky, of Moscow, has been established at Ekaterinodar in the Caucasus, near the American Red Cross Hospital. The teaching staff consists of professors from the Universities of Petrograd and Moscow who were unwilling to comply with the demands of the new régime.

J. PARISOT (*Rev. méd. de l'Est*, March 1st, 1920) of Nancy, who was consultant to the French Army of Occupation for six months, states that in Germany, and especially in the Rhine provinces, the mortality from tuberculosis before the war was progressively diminishing, and in 1914 did not exceed, and in many cases did not reach, 20 per 10,000 in towns and 15 per 10,000 in country districts. In 1914 the number of deaths from tuberculosis was approximately half of what it was in 1900. On the other hand, the influence of the war on the mortality from tuberculosis was shown by a progressive increase in the death rate, greater and more rapid in the urban than in the rural population. In large towns, such as Mayence and Frankfurt, the tuberculosis mortality in 1918-19 was approximately double what it was in 1914. The mortality from tuberculosis diminished in infants of one year and under (a fact explained by the fall in the birth rate) remained stationary in those aged from 1 to 5 years, and showed a slight increase from 5 to 15 years. The mortality was more than doubled for persons aged from 15 to 30 (327 deaths in 1918 as compared with 144 in 1914 for a population of 400,000), amounted to 534 as compared with 323 in 1914 in those from 30 to 60, and was exactly double (114 as compared with 57) in those above 60. The mortality from tuberculosis was a little higher in men than in women, which is explained by the absence of men on military service, these statistics applying exclusively to the civilian population.

SATURDAY, JUNE 19TH, 1920.

THE ROCKEFELLER FOUNDATION GIFTS.

THERE are several points of particular interest about the Rockefeller gifts to University College, London, and its Medical School. In the first place, it is an act of international courtesy and solidarity very deeply appreciated in this country. Professor Elliot Smith told the meeting of the staff and students of University College on June 11th that the members of the Foundation had impressed upon the representatives of University College who went to New York that the fundamental factor which lay behind the offer was a desire to promote friendly intercourse between their country and ours, and a desire to do something that would bring together the two countries in promoting education throughout the world at large.

Perhaps the most important aspect of the great gift, is the scale it sets and the lesson it reads to the Government and the rich men of this country. When last year Parliament agreed to vote £1,000,000 for universities and colleges in the United Kingdom those of us who remembered what it had been in the habit of doing were almost too surprised to rejoice. Now we have an American endowed fund, knowing very well what it is about since it has had experience in the matter, and after expert inquiry on the spot and full discussion, giving a single medical school more than the House of Commons votes for all the universities and colleges. If we subtract the amount allotted for maintenance—as is proper, since the Parliamentary grant is to be annual—we yet find the Foundation giving £590,000 for construction, so that the units may have buildings sufficiently large and sufficiently well equipped for the work they are to do. The House of Commons last year voted £500,000 to be divided among all universities and colleges to help them to recover time and money and men lost during the war.

The way in which the gift came to be made is interesting. The Rockefeller Foundation considers that the Clinical Unit System is at the present day the best for medicine and medical education, and has encouraged its establishment in universities in the United States. The movement for the establishment of such units in this country dates back to the recommendations made by the Royal Commission on University Education in London in 1913. The fundamental idea is set out in the memorandum of the University Grants Committee published in full in our issue of June 5th (p. 775). It is held necessary for university medical education that the latest advances in the sciences which affect medicine should be continually brought into the teaching of the clinical subjects and applied to the observation and treatment of disease. The second proposition is that, in order to ensure that medical education shall be of this scientific standard, and that students shall come into direct contact with knowledge at its growing point, there is needed a system of instruction by teachers who are actively engaged in scientific research and provided with proper equipment, adequate staff, and sufficient time. The unit system supplements but does not supersede the British system of clinical teaching, the virtues of which were

sung in the memorandum of the University Grants Committee; and clinical instruction will be given as heretofore by other members of the hospital staff who are engaged in private consulting practice and to whom general practitioners are in the habit of referring cases of interest and difficulty.

The essential of the Clinical Unit System is that each university medical school should have at least three units, inter-related and inseparable, dealing respectively with medicine, surgery, and obstetrics (including gynaecology). This does not rule out other units, as for instance neurology. For each unit there should be a professor or director, devoting the greater part of his time to teaching, treatment, and research—one competent to teach, of sound scientific training, and possessing scientific imagination. The director must have an adequate whole-time and part-time staff, the control of wards containing fifty to one hundred beds, a proper out-patient department, ample laboratory accommodation for research and pathological work, and adequate scientific equipment for effective clinical teaching. Representatives of the Rockefeller Foundation, during a visit to London last year, found that these principles were accepted and in part applied at three of the great schools in London, and formed the opinion that it would be proper for the Rockefeller Foundation to provide funds for the development of the system in one school. After due inquiry they came to the conclusion that the school most likely to make the best use of the gift was that of University College Hospital. The recommendation was accepted by the Executive Committee of the Foundation in America, and after consultation there with representatives of the Medical School it was decided to make a gift of £835,000, a part for construction and a part for maintenance, in the manner indicated in the article published this week at p. 834. At the same time the inquiry showed that the Anatomical Department of University College was established on too narrow a basis and ill equipped. Accordingly the Foundation resolved to make a gift of £189,800 for the erection and equipment of an Institute of Anatomy, and of a capital sum of £180,000 to yield an income of £9,000 a year to provide additional staff for the anatomical, the physiological, and certain other departments.

Another point of significance is that in making the gifts to University College the Executive Committee of the Foundation disclaimed any desire to dictate methods to the staff or to lay on the College any other condition than that the proceeds of the endowment should not be used to relieve existing expenditure on medical education and research. The same policy has been pursued with regard to the gift to the Medical School. It is made in order to establish a complete set of clinical units in one medical school in this country to serve as a model for others. The Medical School of University College Hospital had not been able to give to the directors of the medical and surgical units it established a sufficient number of beds, nor to establish a biochemical laboratory, nor to institute an obstetric unit. The Foundation has come forward to supply these deficiencies in the manner indicated at page 835. But while giving large sums for the erection of an obstetrical department and for a new nurses' home and residents' quarter, to liberate part of the existing hospital, as well as a capital sum to yield £21,700 a year, for increases of the staffs of the units and towards the maintenance of the additional beds in the new obstetric department, its purpose has been to assist medical education, and not to maintain hospital

beds; it has therefore considered that the responsibility for making up the deficit on the annual income (some £15,000 or £20,000 a year) may properly be left to this country.

ANTIANAPHYLAXIS IN THE TREATMENT OF CHRONIC DISORDERS.

IN a highly interesting and suggestive essay on the origin, evolution, and treatment of certain non-contagious chronic disorders, Dr. Danysz¹ has propounded a theory of immunity, anaphylaxis, and antianaphylaxis, which is deserving of more than passing attention, for it attempts to throw new light upon both the etiology and the treatment of a number of obscure if commonplace diseases, and gives form and substance to an inchoate mass of opinion. He supports his theory by reports of nearly forty illustrative cases in which the treatment indicated by theory proved successful in practice. He also states that 260 patients have now been treated, on similar lines and with satisfactory results, for a great variety of ailments, such as urticaria, eczema, psoriasis, asthma, neurasthenia, dysmenorrhoea and troubles of the menopause, gastro-intestinal complaints of many varieties, arthritis, rheumatism, albuminuria, not to mention other disorders.

At first sight it may seem that such varied diseases could hardly have a common etiology. But such, nevertheless, is the conclusion drawn by Danysz from the observed fact that they are all capable of cure or amelioration by a single method of treatment. What is the method of treatment? It consists in vaccination with saline suspensions of four or five varieties of bacteria cultivated from the stools, and sterilized by heating to 70° C. for one hour; the particular bacteria selected for use were *B. coli*, enterococci, indeterminate diplococci, very small streptococci, and in some instances also an anaërobe. The mixed vaccine was usually given subcutaneously in doses containing a fraction of a milligram of dried bacterial substance. As a rule numerous doses, at intervals of a few days, were necessary: success seems to have followed the use of either autogenous or heterogenous vaccines. In some cases the vaccine was with success exhibited by the mouth, but in larger doses.

The explanation of how it comes about that so apparently irrelevant a method of treatment as this should cure such a varied collection of diseases is said to lie in the theories of immunity, anaphylaxis, and antianaphylaxis. The diseases are taken to be manifestations of anaphylaxis, or anaphylactic poisoning; the treatment consists of antianaphylaxis by the injection of the poisonous substances (or antigens) responsible for the production of the diseases, and the assumption is made that these poisonous substances are produced by the bacteria growing in the patients' intestines. Before going further, it may be well to offer an explanation of some of the obscure terms used above. An antigen is a poisonous substance, or variety of toxin, that has the property of leading to the production of a specific antibody by the tissues of an experimental animal into which it is injected; the function of the antibody is to neutralize or throw out of action the antigen responsible for its production.² At the end of last century it was found that many antigens when mixed *in vivo* or *in vitro* with their corresponding antibodies gave rise to the formation of a precipitate; and that when this happened, the antigen suddenly became very much more toxic to the

organism producing the antibody, than it was originally. Investigations in this direction led Richet and Portier in 1902 to invent the term anaphylaxis or negation of protection, the opposite of prophylaxis, to indicate the condition of hypersensitiveness to antigens produced in certain phases after their injection. As a typical case of anaphylaxis or anaphylactic shock may be quoted the sudden collapse that sometimes follows immediately and may even prove fatal on the subcutaneous injection of a second dose of some antiserum. Such shock is attributable to the formation of a precipitate in the circulating fluids of the body, the second injection of the antigen—in this instance an antiserum—precipitating the excess of antibody formed in consequence of the first injection of the antigen and still circulating in the blood. Avoidance of these cases of anaphylactic shock is, of course, of the highest importance in institutions where antisera are commonly employed, and is often compassed by the method of antianaphylaxis recommended by Besredka. This consists in giving a minute preliminary injection of the antigen a short time before the main bulk of the second injection of antigen is made. The preliminary injection is too small to give rise to any harmful precipitation in the blood stream, but large enough to neutralize the antibody circulating in it and so to prevent any precipitation by the main bulk of the antigen when it is injected a little later.

Danysz describes bacterial vaccine therapy as depending upon antianaphylaxis for its success. The bacterial vaccine is an antigen, and acts by neutralizing the excess of antibody in the patient's system. "In acute infectious disorders," he says, "the appearance of the symptoms actually coincides with that of the excess of antibodies, and the injection of a suitable dose of the infecting microbes, sterilized or attenuated, results in neutralizing this excess of antibody. At the same time the symptoms of the disease disappear." From this it is to be concluded, as has before been surmised, that the pathological manifestations of the disease are anaphylactic in nature, and not provoked merely by the direct action of a bacterial toxin. Danysz quotes a number of instances to show that antigens are not necessarily specific, but may immunize against many other antigens besides themselves. All antigens are chemically complex substances, and from the physical point of view are to be classed as heterogeneous colloids; none are crystalloids. Antigens given by the mouth are destroyed by the normal processes of digestion, and no more seen or heard of. But if an antigen is introduced into the tissues, whether by experimental injection or by the pathological growth of bacteria there, the organism can get rid of it only by the aid of an antibody produced in the living body *ad hoc*. The antigen and antibody combine together, and this combination is to be regarded as the first phase in a series of reactions ending in its digestion and elimination in crystalloid form. Salts and crystalloids do not act as antigens because the organism can assimilate or eliminate them directly without a previous digestion on the above lines.

So much for theory. To sum up, it may be said that the state of anaphylaxis is one of immunity, guaranteed by the presence in the system of an excess of antibody produced by the cells of some or other tissues in the body. But these cells and tissues may be expected to suffer for their abnormal production of antibody; and, indeed, it is known that experimental animals highly immunized by successive injections of foreign proteins or bacterial growths later are prone

¹ *Origine, Évolution et Traitement des Maladies Chroniques non Contagieuses*. Par J. Danysz. Paris: J. B. Baillière et Fils, 1920. Demy 8vo, pp. 130. Fr. 5 net.)

² BRITISH MEDICAL JOURNAL, 1920, i, 265.

to develop chronic disorders of all sorts. Thus they may show pareses, skin diseases, alopecia, rheumatic affections, progressive wasting, and a lack of resistance to intercurrent infections; their viscera and blood vessels, examined after death, always show grave histological changes. It is argued that the constitutions of such animals have been ruined, not by the toxic substances injected into them, but by the excessive activity of their own cells, which are thereby stimulated to produce antibodies to enable them to deal with such substances. Following Metchnikoff, Danysz holds that all sorts of chronic maladies in human beings have their *fons et origo* in intestinal intoxication. He also indulges in some interesting speculations as to the part that may be played by the central nervous system in the curative actions of bacterial therapy and also therapy by use of the actual cautery. He goes further than Metchnikoff in the development of the antibody theory of disease outlined above; and in his treatment he joins those who believe in the non-specificity of much vaccine therapy. His essay is clearly written and closely argued, and will appeal to the speculative physician, pathologist, and physiologist.

THE ARMY MEDICAL SERVICE IN THE WAR.

ON many matters relating to the war the verdict of history cannot be anticipated: the object of yesterday's or to-day's praise may incur the blame of tomorrow, and vice versa. But if there is one verdict less likely than any other to be reversed by the Court of Historical Appeal it is that which, in popular language, declares that "the R.A.M.C. made good in the war." This phrase is never used in any narrow sense: it means, in the mouths of plain Englishmen, that the doctors as a whole who served in the war deserved more than well of their country, and that the medical service of the armies of Great Britain and her daughter nations played a worthy part in the terrible drama enacted in five theatres of war during almost as many years.

The Medical Department of the War Office has had many critics, and we have been among them: but we know, and have often said, that the Army Medical Department, like the service it administers, came with flying colours through the terrific ordeal of the war. While mistakes, of course, were made, the seeds of reform planted long before bore fruit in the Great War, and for the first time in its history the Army Medical Service won a success not surpassed, if indeed equalled, by any other branch of the army. That success, as we said some two years ago, was due partly to skilful administration, but chiefly to the application of scientific methods to the prevention of disease and the surgical treatment of the wounded. The great merit, we continued, of Sir Alfred Keogh and of Sir Arthur Sloggett, his colleague in France, was that from the first they recognized that their true policy was to give as free a hand as seemed to them possible to the civilian surgeons, physicians, and pathologists who came forward to help the army.

We recorded last week that a dinner was given on June 5th to mark the appreciation felt by statesmen and administrators for the services of the Royal Army Medical Department and of the civilians attached to it during the war. A report appears in another column this week of the memorable speeches made by the chairman, Lord Middleton, by Mr. Winston Churchill, and by Lord Haig, in praise of the services rendered by medicine and by the individual doctor. "The manner of doing things," said Lord Chesterfield

in one of his Letters, "is often more important than the things themselves: and the very same thing may become either pleasing, or offensive, by the manner of saying or doing it." The public tribute paid to the Army Medical Service last week could not have been happier or more graceful. The chairman, speaking with knowledge of the dark past and of the uphill struggle towards the light, eulogized the work of the medical service and its civilian colleagues. He described Sir Alfred Keogh as typifying the administrative genius, the executive efficiency, and the scientific skill which enabled the guests of the evening, not merely to do immense service to the Empire, but to win for Great Britain her position in military medical science. This was no empty compliment, nor was Lord Middleton's surmise that if a review were held of the departments of the army and the award of excellence were given solely for progress since 1900, the King in ordering the parade would place the Army Medical Department on the right of the line. The R.A.M.C., declared the present Secretary of State for War, achieved a better, more humane, more scientific, and more refined treatment than was arrived at by any of the other great nations engaged as deeply in the war. But, he added with equal truth, this could not have been done had the Corps not received an immense reinforcement from the finest scientific brains in the civilian profession. Lord Haig, in words of obvious sincerity, commended the devotion and gallantry of the medical units under his command, the efficiency of the medical administration, and the happy relations that were maintained between the fighting forces and their medical comrades—Regular, Territorial and Temporary alike.

Sir Alfred Keogh, in acknowledging the signal honour done to himself and the medical service, said he regarded the occasion as a triumph for the Army Medical Department after more than sixty years of endeavour to make itself efficient. He insisted, as he has before, on the one-ness of the medical profession, and said that the regular R.A.M.C. officers in past days had always craved for close contact with their civilian brethren. This attitude, so important for the future of British military medicine, is, we need scarcely add, shared by Sir John Goodwin, the present Director-General. He summed up the matter in his own way by saying that it was no longer a question of the civilian profession on the one side and the R.A.M.C. on the other, for all had served together, and had together passed through trials and vicissitudes.

Much has been done; much still remains to do. Reforms are in progress, and the enlightened policy of the Army Medical Department to-day will, we have little doubt, bring forth further measures of reform. It is a great encouragement for those who have at heart the honour and efficiency of the R.A.M.C. to find generous yet discriminating public acknowledgement of what was done by army and civilian doctors working together during the war, and to know that the value of this co-operation is felt not only by the heads of the Army Medical Service, but by public men in high positions.

HONORARY DEGREES AT THE ANNUAL MEETING.

IN connexion with the forthcoming annual meeting of the British Medical Association in Cambridge, the Council of the University Senate propose for the degree of LL.D. *honoris causa* the following distinguished members of the medical profession: Sir T. Clifford Allbutt, K.C.B., Fellow of Gonville and Caius College, Regius Professor of Physic; Dr. Jules Bordet, President of the Faculty of Medicine and

Director of the Pasteur Institute, Brussels; Dr. A. Calmette, Director of the Pasteur Institute, Lille; Dr. Harvey Cushing, Professor of Surgery, Harvard University; Dr. Simon Flexner, Director of Laboratories, Rockefeller Institute for Medical Research; Dr. P. Giacosa, Professor of Materia Medica and Experimental Pharmacology, University of Turin; Major-General William C. Gorgas, President of the American Medical Association and of the American Society of Tropical Medicine; Sir G. H. Makins, G.C.M.G., President of the Royal College of Surgeons of England; Sir Patrick Manson, G.C.M.G.; Sir Norman Moore, Bt., President of the Royal College of Physicians of London, and Honorary Fellow of St. Catharine's College. The degrees will be conferred at a Congregation in the Senate House on Tuesday, June 29th, at 3.30 p.m.

BIOCHEMISTRY IN THE UNIVERSITIES.

THE University of Cambridge has received from the Commercial Union Assurance Company—acting as trustees for the estate of Sir William Dunn—a sum of £165,000 for the establishment of an institute of biochemistry. The university has provided the site, and of the gift it is proposed to spend £60,000 on the erection of suitable buildings and laboratories; for the endowment of the chair £25,000 will be set apart, and £10,000 is to be invested to provide a salary for the second in command. This, it is hoped, will leave something like £3,000 a year for research. It is certain that the best possible use will be made of the gift, for Cambridge has in Dr. Gewlaud Hopkins a professor of biochemistry who has done perhaps more than any one man to put this new department of science on a sound basis through his own contributions and through the work he has stimulated in others. His aim will be to get together groups of workers, trained each year, so as to cover the whole ground of research in metabolism. The intention is to begin with bacteria, yeasts and other micro-organisms, and to go on through the plants and vertebrates to the chemical physiology of the vertebrates. It is hoped at once to start a course of biochemistry distinct from the ordinary course of chemical physiology now given to medical students, but without in any way interfering with it. It was only the other day that Mr. Edward Whitley gave £10,000 towards the endowment of a chair of biochemistry in the University of Oxford, and it has just been announced that, on the donor's nomination, Dr. Benjamin Moore has been appointed the first professor. Dr. Moore, who is a Belfast graduate, was at one time professor of physiology at Yale, afterwards professor of biochemistry at Liverpool, and, until he accepted this new appointment, a member of the staff of the Department of Applied Physiology of the Medical Research Council. The gift of the Rockefeller Foundation will provide the University of London with a biochemical laboratory at University College Hospital Medical School, since it includes a sum of £50,000 for site and buildings, and a capital sum to provide £15,000 a year in salaries. The scheme which Professor Hopkins has in mind is sufficient to show that the new study is still in the early stage; with the means now provided it is reasonable to hope that the progress to be made will before long bring results of increasing value to human physiology and pathology.

MEDICAL REGISTER: CHANGE OF ADDRESS.

WE desire to call the attention of every medical practitioner to the necessity, in his own interest, of notifying the General Medical Council of any change of permanent address; otherwise his name may be erased from the *Medical Register*, and he will be put to considerable trouble in getting it restored, and be required to pay a fee of £1—trouble and expense that may easily be avoided by prompt notification to the Registrar. Section 14 of the Medical Act (1858) is quite clear; under it the onus of keeping his address correct rests upon the practitioner,

and the Registrar is empowered to write a letter to any registered person, addressed to him according to his address on the *Register*, to inquire whether he has ceased to practise or has changed his address. If no answer is returned within six months the Registrar may remove the name from the *Register*. It is recognized that during the war, when so many practitioners left their homes at very short notice to serve their country, an oversight was easy, and special efforts have been made this year to get into communication with practitioners who may have forgotten to notify a change of address to the Council. These efforts have been so far successful that though the number of letters returned through the Dead Letter Office in connexion with the last election of direct representatives was 1,800 in England and Wales alone, communication has been re-established with the majority of them. There remain 500 persons whose last known address was in England or Wales, but with whom all efforts to communicate have so far failed. In addition to this, there are nearly as many more registered in Scotland or Ireland from whom no reply has been received. Any medical practitioner who is in doubt as to the accuracy of his address should send a communication at once, giving his full name, in BLOCK LETTERS, and his usual signature, to the office at which he originally registered. The addresses are as follows: The Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1; The Registrar of the Scottish Branch Council, 20, Queen Street, Edinburgh; The Registrar of the Irish Branch Council, 35, Dawson Street, Dublin.

MILITARY MEDICINE AT THE IMPERIAL WAR MUSEUM.

ON June 9th the Imperial War Museum at the Crystal Palace was opened by the King. The collection comprises upwards of 100,000 exhibits illustrating the military, naval, aerial, and civil labours of men and women throughout the Empire during the war. It is conceived not as a monument of military glory, but as a record of toil and sacrifice, a place of study for the technician and the historian; this intention was strongly emphasized by the King in his sympathetic reply. The greater part of the exhibition, of course, illustrates the combatant services, but a considerable portion is devoted to the Army Medical Section, in which are displayed nearly a thousand pictures illustrating various branches of medical activity in all zones of the war; a large number of these have been given by the Joint Committee of the Red Cross Society and the Order of St. John of Jerusalem. Among the artists whose work is represented are George Pirie, Hadyn R. Mackey, Edward Martin, Austin D. Spare, Sir John Lavery, and Guy Lipscombe. Special mention should be made of J. Hodgson Loble's "Loading Wounded at Boulogne," and Mackey's "In the Wake of the Advance." There are also a noteworthy series of water colours and crayon drawings by David A. Baxter, whose "Dawn: Passchendaele" is grimly interesting, and vivid crayon drawings by Muirhead Bone and Claude Shepperson. The Joint Committee has presented several small statuary groups by Benjamin Clemens. The conditions under which the work of the R.A.M.C. was carried out in France are well illustrated in a number of models of regimental aid posts, advanced dressing stations, divisional baths, incinerators, and "disinfestors." A series of photographs and models shows the methods and results of plastic facial surgery. There are also to be seen samples of the provisional limbs provided by the Joint Committee, and exhibits by manufacturers of artificial legs which combine strength with extreme lightness. There is a very large collection of appliances, bandages, instruments, and dental equipment captured from the Germans, Austrians, and Turks; pewter syringes, lead catheters, and a cotton-wool substitute composed of fine wood shavings may be presumed to illustrate the enemy's shortage of war materials. Transport in all

theatres of war is well illustrated by models and photographs, and there are examples of the camel cacolet, the sand sledge, and the wire sand shoes used in Egypt. The Women's Section includes memorials of work in France and Serbia, together with a large display of hospital exhibits of all kinds. Of the Naval Medical Section we gave an account in our issue of last week (p. 807).

THE JENNER SOCIETY.

THE late Dr. Francis J. Bond of Gloucester, who was most energetic and successful in his efforts to defend vaccination, founded the Jenner Society, whose objects were "to collect, diffuse, and popularize knowledge in regard to the history of small-pox and the value of vaccination as a protection against it; to promote the practice of vaccination in a safe and efficient manner; and to further generally the adoption of those modes of preventing and treating disease which rest upon the foundation of Jenner's inquiry." At a time when few medical men thought it was necessary to defend vaccination against the frequent attacks of organized antivaccinists Dr. Bond fearlessly entered the arena. He knew every weak point in the enemy's "argument," and engaged the writers in the press with striking answers drawn from his enormous stock of accumulated evidence. In writing or editing defensive leaflets and pamphlets Dr. Bond displayed conspicuous ability, and the literature he produced is by no means out of date; it is still being widely circulated. Before his death at an advanced age he was assisted in this work by Dr. Drury of Halifax, to whom, in 1913, the affairs of the society were handed over. Since then Dr. Drury has been carrying on the work almost without assistance, and, like Dr. Bond, has taken care that the case for vaccination shall not go by default when, as so often happens, antivaccinists air their mistaken views in the newspapers and before public bodies. He had already won his spurs by his controversy with Mr. Bernard Shaw in the *Daily News* and with Mr. Arnold Lupton, when M.P. for Sleaford, in the *Yorkshire Post*. Again, in 1914 he gave evidence before the Legislative Council of the Isle of Man in opposition to Dr. Hadwen, the antivaccinist. The result was the unanimous rejection of the conscience clause, so that in this respect the Isle of Man is in advance of England. It had been the intention all along to widen the sphere of influence and activity of the society, but the war and other circumstances delayed the accomplishment of this object. It is now, however, announced that the Jenner Society is in due form affiliated with the Medical Research Society, whose honorary secretary, Mr. Stephen Paget, has been an ardent advocate of the fusion; for the purpose of continuing the work Dr. Drury has been elected a member of the committee of the society. The present recrudescence of small-pox in various parts of the country has brought about an increase in the demand for literature and information on the subject of vaccination. Inquiries should be addressed to Dr. Arthur Drury, Landon House, Halifax.

THE MEDICAL INSURANCE AGENCY.

THE report on the work of the Medical Insurance Agency during 1919, made by the chairman, Dr. G. E. Haslip, to a meeting of the Committee of Management on May 27th, showed that it had again been in a position to make grants, amounting to over £1,000, to medical charities. The financial statement indicated that the business done by the Agency continued to grow steadily. The profit earned by the Agency is divided into two nearly equal parts. The one is disbursed in making rebates on the premiums for insurances effected through it; the amount so returned in 1919 was £960, being £280 more than in 1918. The sums thus returned represent a direct saving to the medical profession and have amounted since the foundation of the Agency to a total of over £7,000. The other moiety of the profits is distributed annually in grants to medical

charities, in accordance with the policy laid down when the Agency was founded in 1907. The suggestion to establish a medical insurance agency arose out of the provisions of the Workmen's Compensation Act which had become law at the end of the previous year. It imposed liabilities on medical men as employers, and it was felt that facilities to insure against the new risks ought to be afforded. From the first, however, the Agency undertook to carry through insurances of all kinds for members of the profession. The Agency transacts business only with first-class offices, and is in a position to advise on the best form of policy to meet the needs of the particular circumstances and as to the company with which it can most advantageously be effected. The sums distributed to medical charities amount to £5,877 10s. The grants made in 1919 were to the Royal Medical Benevolent Fund and the Royal Medical Benevolent Fund Guild, £325 each; to Epsom College Benevolent Fund, £318 5s.; to the Royal Medical Benevolent Fund Society of Ireland, £25; and to the Birmingham Medical Benevolent Society, £25. The balance sheet for 1919, audited by Messrs. Price, Waterhouse and Co., showed marked progress in the amounts received from the three principal sources of business—life, motor car, and accident insurances. Progress was specially evident in the life assurance business, the number of new policies completed during the year having risen to 63, as compared with 25 and 15 in the two previous years. Owing to the increase in the cost of repairs and in the amount of claims for third-party risks, the companies engaged in motor car insurance business have from January 1st this year increased the premiums by 40 to 50 per cent. over rates that prevailed before the war. The expenses of the Agency during 1919 were larger than in previous years. This is due to various causes, among others to increases in salaries and in the cost of printing, stationery, and postage. Although the Agency has made steady progress it might easily be in a position to do more for medical charities if the number of practitioners who do their insurance through it were to increase. They would be benefiting themselves and at the same time the widows and orphans of brethren who have died prematurely. In the hope of stimulating interest a pamphlet setting out the terms and advantages of various forms of life insurance and endowment policies, as well as other kinds of insurance, has been prepared, and will be forwarded on application to the Clerk to the Medical Insurance Agency, 429 Strand, London, W.C.2.

THE NEXT CENSUS.

THE Census Bill, introduced in the House of Lords by Viscount Astor, was read a second time on June 10th. Its proposals indicate a desire on the part of the Ministry of Health to give effect to recommendations made in the past by medical officers of health and others. Although it is safe to assume that a census will be taken in Great Britain at the end of March, 1921, the bill does not specifically provide for this. What it does is to enable an Order in Council to be made directing that a census shall be taken. The Order must prescribe the date on which the census is to be taken, though the intervals between any two enumerations must be at least five years. This possibility, and we trust certainty, of a quinquennial census in the future is satisfactory, and in these days of rapid industrial developments is increasingly needed. A census may, however, be taken at any time for a particular area at the request and at the cost of a county council, a county borough council, or an urban district council. The particulars to be contained in the enumeration returns must include name, sex, age, occupation, nationality, and residence, as well as information with regard to education, infirmity, and condition as to marriage. They may also include, presumably at the discretion of the Ministry of Health, "any other matters with respect to which it is desirable

to obtain statistical information with a view to ascertaining the social or civil condition of the population." The bill will have the approval not alone of statisticians and public health administrators but of all social reformers, for it is drafted on thoroughly democratic lines, and through its local option clause it will be possible for much more detailed local information to be obtained than has hitherto been possible.

CAMBRIDGE.

We print this week at page 845 the seventh and concluding article of the series of descriptive and historical notes on the University and town of Cambridge, which began in our issue of January 3rd. We desire here to acknowledge our indebtedness to Dr. F. J. Allen, honorary secretary of the Cambridge Antiquarian Society, and formerly professor of physiology in Mason's University College, Birmingham, for the very large share he has had in the preparation of the series. Dr. Allen has not only written the text of all the articles, at great cost of time and labour, but many of the beautiful photographs—for instance, those of St. Benet's Church, reproduced a fortnight ago, and the remarkable interior of the Round Church—are from his camera. The learned author has made due acknowledgement to those authorities, living and dead, whom he has consulted, and it only remains for us to thank Dr. Arnold Chaplin for his ready permission to make copies of the portraits of Harvey, Newton, and Young in his collection. We venture to believe that Dr. Allen's notes on Cambridge, representing so much knowledge and research, are not only of interest to the members of the British Medical Association and their guests who are about to visit the university town this month, but will remain of permanent value.

THE Anatomical Society of Great Britain and Ireland has arranged to hold its annual summer meeting at Cambridge on the afternoon of Friday, July 2nd, and on Saturday, July 3rd. The dates have been chosen so as not to clash with the proceedings of the Sections at the Annual Meeting of the British Medical Association. The chief subject for discussion will be the morphology and development of the central nervous system, but papers will be read also on the structure of the earliest land vertebrates, on partial transposition of the mesogastric viscera, and on avian structure as bearing upon problems of bird migration. Further particulars can be obtained from Professor Barclay-Smith, at King's College, Strand, W.C.2.

DR. THOMAS R. BROWN, one of the officers of the League of Red Cross Societies at Geneva, will attend the annual meeting of the British Medical Association as a delegate of that body.

Medical Notes in Parliament.

An Autumn Session is now held by the Government to be "inevitable," and the intention is to adjourn Parliament as near the end of July as possible.

General Medical Council Bill.

The Direct Representatives of the General Medical Council Bill, of which particulars were given in our columns of May 15th, p. 685, was read a second time in the House of Commons on June 14th, and referred to a Standing Committee.

Medicine and Mining Administration.

Our Lobby Correspondent states that the Cabinet had under serious consideration last week a proposal to establish a separate Ministry for Coal Mines. This, however, was rejected on the score of expense and in view of the general feeling against an increase of the bureaucracy. It was then decided to make a Department in the Board of Trade, and that the Bill to be submitted to Sir Robert

Home should provide for an additional Parliamentary Secretary. The intention is that this junior Minister shall deal with all the negotiations and answer for the office in the House of Commons, subject, of course, to decisions on policy by his chief and by the Cabinet. It is further proposed that the new Department shall have the assistance of an advisory council, to include not only representatives of employers and employed and of consumers, but also one or more scientists and one medical man. When the bill is printed it will be found to contain powers for the transfer to the Department of the various medical services in regard to mining which are at present dependent on the Home Office. As the Coal Control Agreement and the Coal Mines Emergency Act lapse on August 31st, legislation is necessary before the summer adjournment of Parliament if the new policy of joint administration is to be adopted.

Dangerous Drugs Bill.

On June 10th, in moving the second reading of the Dangerous Drugs Bill, the purpose of which was fully explained in an article published on May 22nd (p. 714), Major Baird said that it gave effect to the International Opium Convention signed at the Hague on January 23rd, 1912. The purpose of the Convention was to bring under control throughout the world the traffic in opium and cocaine, and the preparations derived from them, restricting their use to medical and other legitimate purposes. The Convention was signed on behalf of all the Powers represented except Turkey and Serbia. Some of the countries, including Germany, failed to ratify the Convention before the outbreak of war, and thus it was not brought into operation. During the war Great Britain found it necessary to act on her own account, owing, first, to the spread of the cocaine habit, and, secondly, to the extensive smuggling of opium carried on in the East; a regulation was made under the Defence of the Realm Act for the control of the manufacture, sale, and distribution of cocaine, and the importation of cocaine and opium was prohibited save under licence of the Secretary of State. These measures were not altogether successful; it was difficult to stop smuggling in the case of an article which could be carried in such small quantities and so easily sold as was opium. The only effective control could come from international co-operation. The Allied Powers attached so much importance to this question that the ratification of the Convention was made one of the conditions of peace: the Convention to be brought into force by legislation without delay, and in any case within twelve months of the treaty coming into force. It was doubly important to pass the bill because of the impending abrogation of the Defence of the Realm Regulations. The bill was limited to carrying out the Convention except in one respect; powers were asked to extend the provision, not only to the derivatives of morphine and cocaine, but to any other alkaloid of opium, and any other drug of any kind which was likely to produce the same injurious effects, and this was contemplated, as might be seen by Article 14 of the Convention. Another reason why the Government was anxious for the powers contained in the bill was that British representatives in China and Japan had referred repeatedly to the disastrous effect of the traffic which was being carried on with China in morphine and cocaine: both China and Japan were signatories to the Convention. Of course, a big measure of this kind affected the interests of large bodies of people at home. Representations had been made by the Pharmaceutical Society and by wholesale dealers, and it was hoped to be able to meet them.

Dr. Murray, after congratulating the Home Secretary on the part he had taken in this matter, and expressing general approval of the bill, said that very often the excuse given by people who were victims of the drug habit was that a doctor had prescribed it, and that after the immediate need for it had passed, the patient had continued the drug until he became a victim. He presumed that what was meant by one of the clauses giving power to the Home Secretary for "regulating the issue by medical practitioners of prescriptions containing any such drug, and the dispensing of any such drugs," was that a chemist who dispensed the prescription containing any of these drugs should not be allowed to dispense it without a renewed prescription from the doctor. He did not know how many times a doctor might allow it to be dispensed without the renewed authority, but there should be some limit. He wished that the Home Secretary had taken power to abolish medicated wine, as in his opinion there was nothing that produced more drinking among women than medicated wines, which were a camouflaged method of

introducing drinking habits. He hoped that any regulation as to keeping books of all drugs sent out would be framed in consultation with the representatives of the medical and pharmaceutical professions. For an offence against this Act a fine of £200 could be imposed. Many thousands of deaths occurred every year from alcoholic poisoning. Deaths also resulted indirectly from it, inasmuch as people were drowned while under the influence of alcohol. The man who sold alcoholic poison which had been the means of killing somebody went free. That was an unfair discrimination against medical men and chemists, who were liable to heavy penalties under the present bill for selling something which was used by victims of the drug habit. The question of penalty needed to be very carefully considered.

Mr. Woolcock, who said that with the exception of the member for South-West Norfolk he was the only M.P. holding a pharmaceutical certificate, raised the question how far the proposal in the bill to allow the sale of specified drugs only by licence would take away the authority given to chemists and druggists under the Poisons and Pharmacy Act. Though they were speaking loosely at the moment of opium, morphine, cocaine, ecgonine, and heroin, they were also dealing with an enormous number of substitutes. He asked for a promise that a pharmacist carrying on business as a chemist should have the right to dispense and retail substances provided for under this Act. The powers to be given to the Home Office should be used only in very serious cases, and anyone found guilty of a breach of the Act or the regulations should have the right of appeal to some court.

Captain Elliot said that the fact that such a bill was necessary was a very striking commentary on the trend of some of our legislation. In America, where they had gone in for prohibition, the drug habit had developed to an extent altogether unknown in our own country. All medical men in the House and the country would like to draw the attention of the Government to the necessity for dealing with patent medicines. Before the war a powerful committee of the House investigated the question thoroughly, and drew up a well thought out and moderate report which, by an unlucky mischance, was presented to the House on the day of the outbreak of the war. Now the war was over he begged the Home Office to confer with the Ministry of Health and introduce legislation along the lines recommended. Very great evils had arisen from people using drugs under conditions in which no medical man or chemist would dare to prescribe them. He hoped the bill was only the beginning of international work for dealing with health problems as a whole; the microbe knew no frontier.

The measure was read a second time and referred to a Standing Committee.

London Hospitals.—Sir Clement Kinloch-Cooke asked the Minister of Health on June 10th if he was aware that the National Hospital for the Paralysed and Epileptic, Queen Square, London, the principal school for the study of nervous diseases, had had to close its doors owing to want of funds, and whether, in view of the urgent public need of keeping open the hospital and the serious loss to medical science involved, the Minister could now make his promised statement with regard to Government assistance to hospitals. Dr. Addison replied: I am not yet in a position to make any general statement, but in the meantime I understand that the King Edward Hospital Fund are prepared to consider the application from this hospital for an immediate emergency grant, an application which reached them this morning, no previous intimation having been given to the Fund that there was any intention of closing the hospital.

Motor Taxation.—In reply to a question, on June 9th, Mr. Neal, Parliamentary Secretary for the Ministry of Transport, said that as the Minister could not recommend a rebate of the proposed taxation on motor vehicles in favour of medical practitioners, no concession could be made to coroners.

The Dentists Bill.—Asked, on June 9th, when legislation would be introduced to carry out the recommendations of the Select Committee on the Dentists Act, 1878, Dr. Addison said that owing to the pressure of other legislation the draft of this bill was not yet complete, and he was unable to say when it would be introduced, though he hoped it would be ready shortly. The question whether it could be carried this session would depend upon whether it was a matter of controversy.

Veterinary Surgeons.—The Veterinary Surgeons Act (1831) Amendment Bill, as amended in the Standing Committee, was read a third time in the House of Commons on June 11th. It provides that every member of the Royal College of Veterinary Surgeons shall pay an annual fee of one guinea to the College, and authorizes the College to conduct examinations, prosecutions and inquiries, and to carry out such other objects as may be considered beneficial to the veterinary profession and necessary for the promotion of the art and science of veterinary surgery. An amendment to leave out the word "prosecution" was resisted by the Parliamentary Secretary to the Ministry of Agriculture, who said that the College had given an undertaking that it did not desire to interfere with the work of unregistered

persons in the performance of operations on or the treatment of animals, provided they did not represent themselves to be qualified veterinary surgeons. It was added that there was nothing in the Bill to give such power. Lieut.-Colonel F. E. Fremantle, while recognizing that the supply of qualified veterinary surgeons was defective, urged that the word "prosecution" should be retained, and the amendment was withdrawn. A clause providing that anything which would be an offence if committed by an individual shall be an offence if committed by a company registered under the Companies Act, was adopted, with the addition moved by Mr. Cautley of the words "or a society registered under the Industrial and Parliamentary Societies Act." In the course of the discussion on the motion for the third reading Captain Elliot said that there was no doubt that from the study of animal pathology much might be learned which would subsequently be of use in human pathology. The investigations into the epidemiology of foot and mouth disease might, he hoped, be of the greatest use in future investigations into influenza. The great institute at Aberdeen for the study of animal diseases had attracted very liberal support from Scottish citizens, and had drawn a professor of physiology from the University of London. Further, many diseases of herds had a bearing on the prosperity of the people. Animal pathology was practically an unexplored science; the fact, for instance, that rickets was of common occurrence amongst sheep and growing pigs showed that if diseases of animals could be investigated by men of scientific training, facts of the utmost importance to children might be discovered. Dental caries was very closely related to diet, and could be studied in animals. Mr. Cautley, speaking on behalf of the promoters, said that its principal features were to give a legal status to the College of Veterinary Surgeons whereby it could set up a teaching school, exercise disciplinary powers over its members, and reserve to these members the title of duly qualified veterinary surgeons. Certain exemptions were made in favour of holders of veterinary certificates of the Highland and Agricultural Society and of others who might be admitted on special terms.

Women and Children Employment Bill.—Major Baird, on behalf of the Home Office, obtained, on June 10th, second reading for the Women, Young Persons and Children (Employment) Bill, which is designed to give effect to an international agreement reached at the recent International Labour Conference in Washington. The operative parts are contained in the schedule, which comprises three conventions. The first fixes 14 years as the minimum age for the admission of children to industrial employment other than that in which only members of the same family are employed. The second convention deals with the night work of young persons employed in industry, and prohibits those under 18 doing night work, save in certain specified undertakings, in which the age is lowered to 16. The third convention deals with the night work of women employed in industry, prohibiting it except in certain specified cases. The definitions of industrial work are given in the schedule, but there is a reservation whereby a competent authority in each country is to settle the line of division which separates industry from commerce and agriculture. There was some little discussion on a qualifying clause in the bill, which lays down that nothing in the Act shall prevent the employment of a child lawfully so employed at present. This has been introduced to meet the case more especially of the Eastern countries, which have not yet sufficient machinery to adopt the two-shift system. Lieut.-Colonel Fremantle took strong objection to Clause II, which would enable women and young persons to be employed in shifts between 6 in the morning and 10 in the evening on any weekday other than Saturday, and said that he hoped, in the interest of public health, the Government would withdraw this clause.

Answers in Brief

The Minister of Health hopes at an early date to lay before Parliament proposals for enabling local authorities to require the immediate utilization of unoccupied dwellings.

The estimated increased cost of giving old age pensions of 10s. weekly to all British citizens of 70 years of age in the United Kingdom, irrespective of their means, would be £15,100,000 a year.

Dr. Macnamara anticipates that, owing to the recent increase in the prices of coal and sugar, the index figure of the cost of living (food, rent, clothing, fuel, light, etc.) will show an advance of 150 per cent. as compared with the level of July, 1914. He mentioned that the figures for December 1st, 1919, showed an advance of 125 per cent., and those for May 1st an increase of 141 per cent.

Sir A. Griffith-Boscawen has stated that in the week ended March 13th, 116 cwt. (1,276 gallons) of fresh milk were received at Harwich from Denmark. There was no official information as to the hygienic conditions in which the milk is produced.

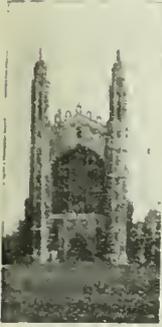

At the outbreak of war three areas had, on representations made by medical officers of health, been declared by the Local Government Board to be insanitary. They comprised 890 houses, occupied by 4,387 persons. In two cases proceedings were deferred owing to the war. A scheme in regard to one has now been submitted, and one for the second of the areas has been promised. In the third a scheme has been made and confirmed.

EIGHTY-EIGHTH ANNUAL MEETING

OF THE

British Medical Association,
CAMBRIDGE, 1920.

PICTURESQUE CAMBRIDGE.

KING'S COLLEGE
CHAPEL.

OF those who know Oxford and Cambridge, few will deny that these are the two most picturesque towns in England—that is, in the matter of man-made picturesqueness resulting from building and planting, for hundreds of towns are more picturesquely situated.

The two towns resemble each other in so far as their beauty depends on fine buildings and luxuriant gardens; but each town has its individual characteristics. Oxford gives the impression of a city, Cambridge of a rambling country town. In one's memory of the two places the stately High Street at Oxford, and the river with the College Backs at Cambridge, will probably leave

the most vivid impressions.

Members attending the Cambridge meeting will naturally wish to make the best of their opportunity to see the local attractions. It has

been arranged to give to each member a copy of the excellent and authoritative *Concise Guide* written by the distinguished local antiquary, J. W. Clark. Those who follow his directions will see Cambridge thoroughly; but many visitors will have only time to see a portion of it, and for those in particular, if not for all visitors, we give the following notes on the most salient features.

Cambridge is the "garden city" of England. Besides the many gardens (for nearly every college has gardens attached to it) there are nearly 300 acres of common land forming open spaces *within* the town as well as *outside* it. All these gardens and playgrounds divide the town into detachments, so that it has no density anywhere, and covers an enormous area for its population, its diameter in any direction being at least four miles.

The College Grounds are open to the public from early morning until dusk, and visitors may walk freely in them, except in those parts which are obviously reserved for private use. It is contrary to rule to take meals in the grounds, or to set up a photographic camera without permission. For obtaining such permission the porter at the

main entrance will give the necessary information. As a rule no objection is made to the unobtrusive use of a hand camera.

THE BACKS.

The most attractive feature of Cambridge is the "Backs." Six of the colleges—namely, Queens', King's, Clare, Trinity Hall, Trinity College and St. John's—are situated on the river bank, so that their fronts are towards the streets and their *backs* towards the river, hence the name. Their grounds occupy both sides of the river, and adjoin each other so as to form a continuous garden or park. The combination of river, flowers, trees, many bridges, and college buildings has no parallel anywhere. Visitors will be tempted to take a boat and row through the Backs, but a warning is necessary: pleasant as a row in the Backs may be, their beauty cannot be even imagined in a boat, for the high banks cut off the view on each side. To see the Backs one must walk in the College Grounds and note the view from each of the bridges, especially Garret Hostel Bridge. The so-called "Bridge of Sighs" at St. John's must be seen from St. John's Old Bridge; this is an important hint, for too many visitors cross the Bridge of Sighs and never see it. This bridge was built 1825-30 from a design by Hutchinson, partner of Rickman, the originator of the architectural terms *Early English*, *Decorated*, and *Perpendicular*. The Old Bridge at St. John's, built 1696, is attributed to Wren. These two bridges and that of Clare are the most notable of the college bridges. While in the Backs the visitor should notice the fine wrought-iron work (seventeenth and eighteenth century) of the entrance gates, of which

Trinity College has one, St. John's three, and Clare three.

COLLEGE BUILDINGS.

Of the college buildings, King's Chapel will be the first to arrest attention, forming as it does the central feature of Cambridge, so situated as to be seen to full advantage either from the street, the Backs, or the surrounding country. Its dimensions are of cathedral scale, and it is a product of the most original period of English architecture, the latter half of the sixteenth century, which also produced St. George's Chapel at Windsor Castle and the towers of Merton and Magdalen Colleges, Oxford. The late Francis Bond, a leading authority on the history of architecture, described King's Chapel as "the crowning glory of English art."

Among the other features which no one should omit to see the following are the most important:

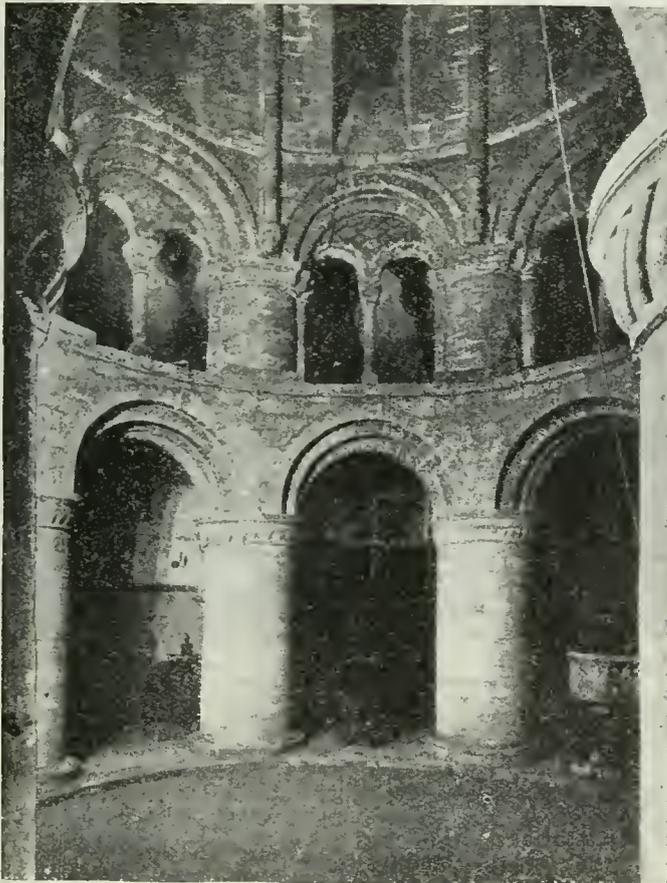

At Queens' College the cloister court, with the beautiful half-timbered house which forms the President's

Lodge; also the view of the College and the Lodge from Erasmus's Walk.

At Caius College the gateways built by John Caius, especially the Gate of Honour.

The Senate House, the interior of which is rich in woodwork of the Grinling Gibbons school.

At Trinity College, the Hall, exterior and interior, and

THE ROUND CHURCH, CAMBRIDGE.

* The previous articles of this series appeared in the JOURNALS of January 3rd, January 24th, March 13th, April 10th, May 8th, and June 5th, 1920.

the Library, the interior of which is one of Wren's most successful achievements. It contains much fine carving by Gibbons. The chapel is a late building, whose chief beauty is in its woodwork, which, like that of the Library, is of the Grinling Gibbons school.

At St. John's, the street front and the interiors of the Hall, Combination Room, and Library. These are the finest mediæval interiors in Cambridge. The Hall has a fine hammer-beam roof and oak-pannelled walls. The Combination Room was formerly the "long gallery," a feature found in several old manor-houses. It may be compared with the long gallery at Aston Hall, Birmingham, which is its contemporary and chief rival. The Library is a wonderful specimen of pseudo-Gothic work of the seventeenth century, with book-cases and roof of richly carved oak.

St. John's Chapel is about the finest work of Sir Gilbert Scott. In spite of the usual defects of modern imitative Gothic work, it is an impressive building, at least internally, and remarkable for its wealth of marble columns. It contains also some good woodwork and monuments transferred from the former chapel.

At Jesus College the Chapel, which is the oldest and, in some respects, the most beautiful chapel in Cambridge, dating from the late twelfth and early thirteenth centuries. It was the church of the nunnery of St. Radegund, the buildings of which were adapted by Bishop Alcock when he founded the college. Other remnants of the nunnery are the doorway of the Chapter House and the Refectory, now used as the Hall. The entrance gateway built by Alcock is one of the finest in Cambridge. Jesus College is farther from the centre of the town than any other college, but the beauty of its buildings makes a visit to it worth a great effort.

At Magdalene, another of the outlying colleges, the Pepysian Library is of interest, both for its books and the beauty of the building in which they are housed.

At Christ's College, which is very centrally situated, the entrance gateway should be noticed, also the Fellows' Buildings, a fine specimen of middle seventeenth century architecture.

Cambridge is notable, in contrast to Oxford, in possessing many brick buildings. They are usually beautiful in design, and present considerable variety. The best instances are St. John's College, Queens' College, Jesus College, and St. Catharine's College.

CAMBRIDGE CHURCHES.

The older part of the town contains many churches, usually within a stone's throw of each other; but the busy visitor need only see three of them which are of peculiar

interest: these are St. Benet's, the Round Church, and Great St. Mary's.

St. Benet's has a Saxon tower of unknown date, but probably about the year 1000. It is one of the best Saxon towers in England, and was doubtless still better when it had four gables and a high pyramidal roof, which have been removed. Internally the tower is supported by a Saxon arch, which is quite impressive in its massive simplicity.

The Round Church is the oldest of the four similar churches still in use in England. The walls or foundations of seven others are also in existence. These churches were built during the Crusades, as reminiscences of the Church of the Holy Sepulchre at Jerusalem. The Cambridge church dates from about 1120. It was much

altered in later mediæval times, and then restored nearly to its original form in 1841. In spite of over-restoration it is a beautiful little building. Its interior is so dark that one cannot appreciate it until the eye becomes accustomed to the gloom.

Great St. Mary's, or the University Church, has a plain exterior, but the interior, though encumbered with great galleries, is a fine and rather ornate specimen of late Perpendicular work.

THE SURROUNDING COUNTRY.

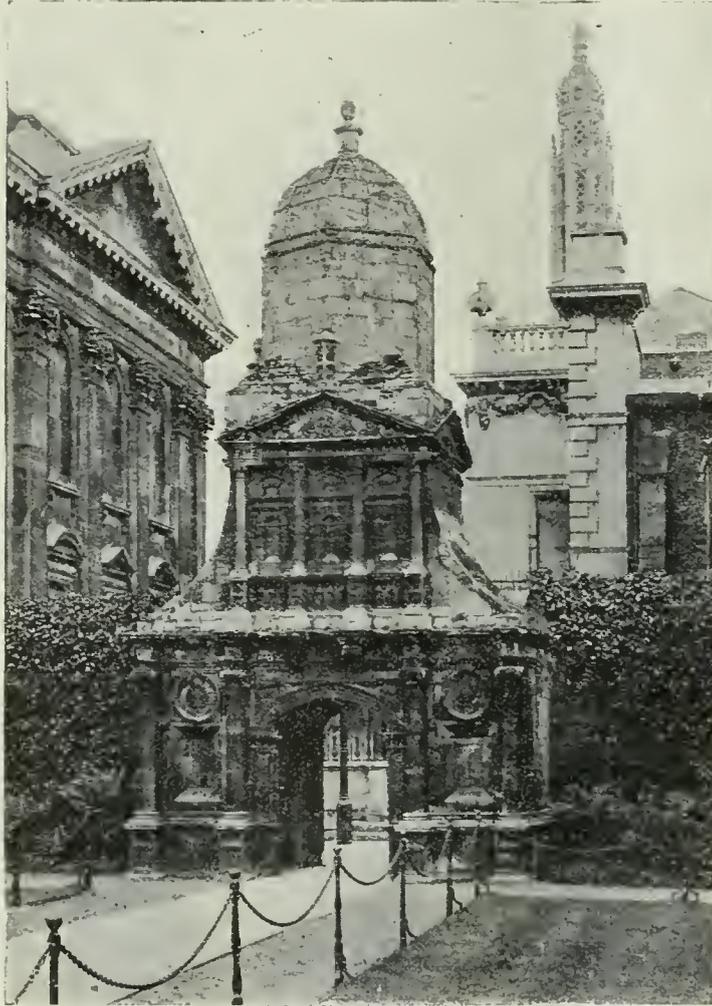

In the immediate neighbourhood of Cambridge the prettiest scenery is at Maddingley and on the upper Cam near Grantchester. Maddingley is situated on the slope of a wooded hill, and has a mediæval mansion in a beautiful park. It would be beautiful in any part of England, and may surprise those who expect to find Cambridgeshire a flat country.

The Cam above Cambridge is a narrow but very pretty river, and all who can find time should have a row as far as Grantchester. Below Cambridge the river is wider. Its prettiest

stretch is that by Fen Ditton, where the boat races are held. Below Ditton the river flows through a flat country, which looks its best as seen from the river. This part of the country, being highly cultivated, has none of the charm of the wild fen, except a small portion, Wicken Fen, which is reserved in its natural state, and forms a happy hunting ground for the botanist and entomologist.

A remarkable feature of the lowlands of Cambridgeshire is the great dykes constructed by the ancient inhabitants for the defence of their territories. They are more wonderful than picturesque, but will give much pleasure to the antiquarian members of the British Medical Association who join the excursion which is being arranged for visiting them.¹

¹ The programme of excursions, etc., is printed in the SUPPLEMENT this week.

GATE OF HONOUR, JESUS COLLEGE; WITH PARTS OF SENATE HOUSE, UNIVERSITY LIBRARY, AND KING'S COLLEGE CHAPEL.

The village churches of Cambridgeshire are of much interest, and are remarkable for the prevalence of fourteenth century work, which is scarce in most other parts of England. The churches of Trumpington, Grantchester, and Cherry Hinton, all very near Cambridge, should be visited by those who are interested in architecture.

ELY.

It is hardly necessary to dilate on the attractions of Ely. The town is picturesquely situated on a low hill commanding the fens, and the cathedral is second to none in England for its architecture and the charm of its surroundings. The interior may justly claim to be the finest in England. The remains of accessory buildings, portions of the

former abbey, add to the interest of the place. One hint concerning Ely is of great importance. The visitor arriving at the railway station should not follow the main road to the cathedral, but should take the turning to the right at the foot of the hill, and afterwards take the footpath to the left, leading across the park. If he fail to do this, he will miss the most beautiful view of the Cathedral—in fact, one of the choicest cathedral views to be found anywhere.

Photo, Cambridge.

BOAT RACING ON THE CAM: VIEW FROM DITTON CORNER.

The Honorary Local Secretaries of the Meeting are Dr. J. F. Gaskell, The Uplands, Great Shelford, near Cambridge, and Dr. G. S. Haynes, 58,

Lensfield Road, Cambridge. Communications should be addressed to them at the Medical Schools, Cambridge.

England and Wales.

MATERNITY HOMES AND HOSPITALS.

The Minister of Health considers it desirable that he should be furnished with annual reports,¹ in respect of maternity homes and hospitals established primarily for normal confinements, showing:

1. The number of cases admitted, with their average duration of stay.
2. The number of cases delivered by midwives and doctors respectively, as well as the number of cases in which the midwife sought medical assistance for special reasons.
3. The number of cases notified as puerperal sepsis, with the results of treatment.
4. The number of cases in which the temperature rose above 100.4 for twenty-four hours, with a rise of pulse rate.
5. The number of notified cases of ophthalmia neonatorum and of "inflammation of the eyes, however slight."
6. The number of infants not entirely breast-fed, with the reasons for this.
7. The number and causes of maternal deaths.
8. The number of cases of fetal stillbirths and deaths.

The authorities of these institutions are asked to keep a register with the purpose of compiling this information. Immediate information is to be sent to the Ministry of every case of maternal mortality and of notified puerperal fever.

SCHOOL MEDICAL OFFICERS' SALARIES.

At a meeting of the Devon Education Committee on June 3rd, at Exeter, the Medical Officer (Dr. Adkins) reported that Dr. C. G. Mathews, who at the last meeting was appointed to fill the vacancy for the Barnstaple district, at a commencing salary of £400 a year, rising by annual increments of £25 to £500, with £175 a year travelling expenses, had sent a telegram the day after his appointment declining to take it up (see BRITISH MEDICAL JOURNAL, May 15th, 1920, p. 686). A temporary arrangement was made whereby Dr. Scott was appointed at 10 guineas a week, with the travelling allowance. The Chairman said the question was whether the Committee would sanction the steps taken. The Medical Officer said that Dr. Mathews was appointed at a salary less than that agreed to by the British Medical Association. To the question whether when the vacancy was advertised women as well as men were invited to become candidates, he replied that he did not think either sex was mentioned. They could not expect women to go about the rural parts of Devonshire in all weathers.

Dr. Mackenzie moved that the Committee ask Dr. Scott to continue the duties at £500 a year. The Medical Officer said the minimum sanctioned by the British Medical Association was £500 a year rising to £650, while the present scale in Devon was £400 rising to £500. In regard to travelling expenses, all the medical men were out of pocket with the present allowance of £175 a year in Devonshire. He suggested the scale of expenses should be £200 a year. Mr. Winder said it seemed to him that it was a fight between the British Medical Association and the Devon Education Committee, and that eventually the Committee would have to give way. He suggested the appointment of Dr. Scott at the increased scale, adding that when the five other district medical men applied to be treated in the same manner—as they would—the Committee should consider the possibility of working the county with a decreased number of doctors. Dr. Mackenzie said it was quite impossible for a man and his wife and family to live and keep up the position required on such a salary as £400 a year. The Medical Officer pointed out that it was not the British Medical Association alone which had intervened in this salary trouble; the Committee had also received communications on the subject from the Ministry of Health, which it had allowed to lie on the table. Dr. Mackenzie said the Committee was not standing by the Medical Officer, but was trying to get him an incapable staff and adding to his other worries. Mr. Stevens urged that the Committee should stand firm and refuse to be dictated to. Mr. Young expressed the view that if "the unions" were to dictate as to what was to be done an Education Committee was a mere sham. It was no use discussing and deciding matters when it was left to their masters to declare what should be done. The proposal was eventually adopted to pay Dr. Scott the same salary as the other district medical officers were receiving. The Medical Officer remarked that that was no good, because it would not be accepted.

PRESENTATION TO DR. BRACKENBURY.

At the monthly meeting of the Middlesex Panel Committee on June 10th Dr. Brackenbury, who has been chairman of the Committee since its inception in 1914, was presented by the members with a silver coffee-pot and sugar-bowl and cream-jug. Before the presentation Drs. Ingram, Cohen, and Shanks commended the skill, diligence, and wisdom Dr. Brackenbury had always displayed in the discharge of his office. The presentation was made by Dr. C. F. T. Scott, Vice-Chairman of the Committee, in a felicitous speech. He attributed the success of the Committee to the able chairmanship of Dr. Brackenbury,

¹ Memo. 19/M.C.W., Ministry of Health, May, 1920.

and dwelt upon Dr. Brackenbury's service to the whole profession, describing him as an example of true statesmanship. History would record that he had obtained an assured place in the esteem of the profession. Dr. Brackenbury, who was enthusiastically received, in expressing his thanks said that in all his work for the profession he had been governed by a single desire to serve the best interests of his fellow insurance practitioners and to promote the public welfare. In so doing he had not only satisfied his sense of duty but had won a great deal of pleasure. Reference was made in the course of the proceedings to the fact that Dr. Brackenbury has been chosen as Liberal candidate for East Walthamstow.

"SAFETY FIRST."

A lecture given by Mr. Gerald Bellhouse, C.B.E., His Majesty's Deputy Chief Inspector of Factories, has been printed by the Manchester University Press. Mr. Bellhouse quotes Home Office figures, which show that 1,384 fatal accidents occurred during 1919; 40,056 accidents were due to machinery and 84,582 to other causes. These figures are slightly lower than usual; accidents which kept the worker away from his work less than one day were not included in the case of machinery accidents or less than seven days in the case of non-machinery accidents. It is calculated that, however well machinery is guarded, not more than a 10 per cent. reduction by this means of the accident rate can be expected; this corresponds very closely with American estimates. Mr. Bellhouse believes that a very large diminution of accidents arising in the course of industrial employment may be expected to follow the organization of a "safety first" movement, such as has been promoted in America during the last six years by a voluntary co-operative association of employers and others. In a steel factory at St. Louis, employing 2,500 men, the number injured was reduced from 769 in 1916, to 124 in 1918; a similar reduction of 60 per cent. was recorded in mines, machine shops, and factories. In one large soap works in England a safety inspector was appointed three years ago, and accidents have been reduced by 60 per cent.; this was accomplished in a works where safety had long been studied, and where the accident rate was already very low. Mr. Bellhouse believes that if success is to be attained by a "safety" organization, five things are essential: (1) Efficient organization in the staff, beginning at the top; the employer or manager must be a thorough believer in "safety first"; (2) the appointment of a part or whole-time safety inspector; (3) willing co-operation of the foremen; (4) a safety committee, with representatives of the management and the workers, meeting regularly at frequent intervals; (5) pictures and stories which show what the workman can do to protect himself should be posted on a "bulletin board." Mr. Bellhouse also recognizes that the accident rate is influenced by lighting, temperature, speed of production and fatigue of the workers, and makes allusion to the inquiry conducted by Dr. Vernon on behalf of the Health of Munition Workers' Committee.¹

Scotland.

SMALL-POX IN SCOTLAND.

CASES of small-pox continue to occur almost daily in Glasgow, but the number of patients under treatment in the Belvidere Hospital had fallen to 125 on June 11th. Dr. Maxwell Williamson, M.O.H., reports that the public in Edinburgh is responding well to the offer of free vaccination and that between 40,000 and 50,000 persons had been vaccinated recently, including the heads of families formerly conscientious objectors. A beginning had, he said, been made with vaccination at the schools, and it was expected that 500 pupils would, with their parents' written consent, be vaccinated daily.

HIGHLANDS AND ISLANDS MEDICAL SERVICE.

The Highlands and Islands Subcommittee met representatives of the Board of Health on June 10th, and discussed with them the representations put forward by the former for improvements in conditions of service of

practitioners serving under the Highlands and Islands scheme. The points dealt with included the following:

- (1) Increase of the guaranteed net income in single practice areas.
- (2) Increase of the present mileage rate.
- (3) Increase in the scale of maximum fees payable by patients.
- (4) Special fees for special services.
- (5) Provision of locumtenents; and
- (6) A pension scheme.

With regard to (1), it was intimated that the Board is in sympathetic agreement with the request for an increase on the original minimum of £300 net, and that advances have actually been made within the limit of the present grant, but that further increases are subject to Treasury sanction, and exceptions may have to be made in the case of small communities which, under no circumstances, could require the full-time services of a doctor. Considerable discussion took place on (2), and the representatives of the Board intimated that they were not in a position to give a final answer, but they accepted the principle that a revision of the terms should be made in the light of the altered conditions of Highlands insurance service, and that the payment should include an allowance for time as well as cost of travel. On (3) doubts were expressed as to the effect of any substantial increase in the direction of restricting the usefulness of the service, and the subcommittee contended that patients themselves frequently expressed surprise at the smallness of the fee charged, and pressed for increase, especially in the midwifery fee. On (4) it was agreed that the question should be examined in the light of the scales fixed in the various distribution schemes under the new Medical Benefit Regulations. With regard to the question of locumtenents (5), it was intimated that arrangements were being made, and that twenty-two doctors in single practice areas had been offered relief this year. The question of further provision was dependent on the available supply of locumtenents. The Board is not prepared at the present stage to consider a pensions scheme.

HOSPITAL AND NURSING SERVICES.

A report by the Scottish Insurance Commission on Hospital and Nursing Services has been presented to Parliament. The report is based upon inquiries made in 1917, and is therefore somewhat out of date. It points out that specialist skill and large general and special hospitals are disposed asymmetrically to the less thickly populated areas dependent upon them. Inaccessibility is the problem of the Highlands and Islands, and in a less degree of the southern uplands. In the former simple treatment, involving little more than appropriate surroundings and nursing care, is often inaccessible, though the institutions providing it are in many cases more than adequate to the calls upon them. The lack of accommodation in voluntary hospitals is mainly on the surgical side, but it extends also to convalescent treatment, neurasthenia, paralysis, epilepsy, chronic affections of the heart and lungs, and incurable diseases generally. No convincing evidence is found that the flow of income to voluntary hospitals has diminished, but it does not grow and the war has aggravated normal difficulties. The fact that the large general and special hospitals work independently of the others and of the rural hospitals is noted, and the opinion expressed that some arrangement might be devised for the classification and admission of patients in order of urgency, taking each large centre with its dependent area as a unit. The fact that the State has made itself responsible for the treatment of pensioners is considered to make possible the growth of a demand for State subventions for others. With regard to nurses, it is said that a revision of the nursing service must be undertaken, but the report does not suggest how this should be carried out.

Ireland.

PRESENTATION TO DR. STANLEY B. COATES.

THE retirement of Dr. Stanley B. Coates from the Belfast Dispensary Medical Service, with which he has been associated for forty-two years, was the occasion of the

¹Cmd. 9046, 1918, or see this JOURNAL, May 18th, 1918, p. 563.

gathering together on May 19th of a large number of his professional brethren. Dr. H. S. Osborne, senior medical officer of the Belfast Union district, who presided, recalled his long association and friendship with Dr. Coates, and dwelt specially upon the kindly interest that Dr. Coates had always shown in the welfare of his brother medical officers; he alluded also to Dr. Coates's long-continued efforts on their behalf and on that of the profession in Ireland in his capacity as representative on the Council of the Irish Medical Association. On behalf of his late colleagues in the Dispensary Medical Service a silver rose bowl of Celtic design, suitably inscribed, was then presented to Dr. Coates. In making the presentation Dr. C. J. Milligan expressed the hope that both Dr. and Mrs. Coates would have a long life of further happiness and continued good health. Dr. Coates replied in suitable terms, and added a few words of advice regarding the prospects of the profession in the future. Complimentary speeches followed from Dr. William Burns, Dr. Irvine, Dr. Munn, and Dr. Longbridge.

PRESENTATION TO DR. JAMES TAYLOR OF TANDRAGEE, ARMAGH.

A presentation was made recently to Dr. James Taylor, J.P., M.O.H. Tandragee Urban and Rural Districts and M.O. to Dispensary Districts. It consisted of an illuminated album containing an address from some two hundred friends and patients in Tandragee and surrounding districts, with facsimiles of their signatures, and a wallet of notes. The address referred in terms of great respect and affection to Dr. Taylor's long service of forty-five years and expressed high appreciation of his personal and professional qualities. The album is bound in blue leather, with Italian ornament, and little water-colour views of the neighbourhood and places in the North of Ireland, painted by the doctor himself, are inset into the illuminated border. The whole forms a rare and beautiful work of art, and a souvenir to one who has spent his life in the service of his fellows. The profession joins in hearty wishes for many years of further activity and much happiness to one of their most honoured brethren in the North of Ireland.

India.

RECRUITING FOR THE INDIAN MEDICAL SERVICE.

THE Secretary of State for India announced last August that 204 medical men were urgently required to fill vacancies in the Indian Medical Service, and it was added that of these two-thirds (136) would be Europeans and the remainder Indians. The appointment of European candidates is to be made by nomination, on the recommendation of a selection committee in England. The Director-General I.M.S. in a recent speech to the Legislative Council said that there was a proposal, in order to facilitate the entry of Indians, to give scholarships or nominations to the most promising Indian medical students who wished to enter the Service. In the former case they would proceed to England to complete their curriculum, and then compete for the Indian Medical Service; in the latter case they would proceed to England only for a further course of instruction. The Indian Medical Service, he said, had been a great asset to India in the past, and had attracted the best intellects from the British medical schools; it would now, he hoped, attract the best from the schools of India as well. Until recent years the Indian Medical Service had never contained more than 7 per cent. of Indians. A Board of Selection has been appointed in India for the recruitment of permanent officers for the I.M.S. in the manner indicated above. The Board consists of the Director-General I.M.S. (president), the Director of Medical Services in India, and an Indian officer I.M.S.; Colonel Sir H. E. Banatvala, C.S.I., is acting in that capacity. Candidates who may be summoned by the Board for interview will, if considered suitable for appointment, be placed in one of two classes—first, those who received their medical education chiefly in England; and secondly, those who do not come within this category. The final recommendation as to the former will be made by the Selection Board in England, while the recommendations as to the latter will be sent direct

from India to the Secretary of State, who will make appointments to fill the vacancies. The Selection Committee in England, in addition to considering applications from India of candidates who have mainly received their education in England, will review those of the candidates in the United Kingdom, but not the recommendations of the Indian Committee in regard to candidates educated in that country.

MEDICAL INSPECTION BY WOMEN.

The first appointment from among the members of the Women's Medical Service of an assistant to the Inspector-General of Civil Hospitals was made in the Punjab in 1914; a similar appointment was made in the United Provinces in 1918. The regular inspection of women's medical institutions by a woman provincial officer is an advantage both to the Government that aids them and to the institutions and staffs concerned. The medical woman inspector is able to organize schemes for maternity relief, and to bring the urgent need for these and other measures to the notice of the inspector-general.

PLAGUE IN THE UNITED PROVINCES DURING 1918-19.

It appears from the annual report of Colonel C. Maclaggart, I.M.S., Inspector-General of Civil Hospitals in the United Provinces, that in the year ending June 30th, 1919, the number of deaths from plague—namely, 17,635—was less than in any previous year since 1903, with the exception of 1908-9, when the number recorded was 14,252. In cities with more than 50,000 inhabitants there were only 21 deaths. The total number of deaths in 1917-18 was 206,190. The mildness of the epidemic of 1918-19 is attributed partly to the existence of "conditions approaching famine," with consequent depletion of the rat population; and partly to the failure of the rains, with decreased atmospheric humidity and consequent diminution in the number of rat fleas. Systematic rat destruction was confined to the district of Azamgarh, where 38,000 rats were killed by a gang of coolies acting under medical supervision. During the severe epidemic of the previous year it was noticed that towns where organized rat destruction had been carried out enjoyed a comparative immunity from plague. Forty thousand protective inoculations were performed, as compared with 140,000 during 1917-18; experience proved that inoculation was only accepted by the people in the actual presence of plague. In one village of a thousand inhabitants in the Mirzapur district half were inoculated and half not; there were no deaths among the former group, but forty-five among the latter. The eighty-seven permanent and twenty-three temporary travelling dispensaries, which had been in use during the previous year, were maintained; they proved a most effective agency for dealing with outbreaks of epidemic disease and have come to be regarded as established institutions in these provinces. Their staff was able to treat 1,200,000 patients and to perform 23,000 operations; through them a large amount of literature dealing with the prevention of epidemic diseases was distributed. It is proposed to use travelling dispensaries in epidemics not only of plague but also of influenza and other diseases. The plague staff consisted of the chief officer (Mr. B. N. Vyas, Rai Bahadur, M.B.), a temporary staff of ten special health officers, the subassistant surgeon in charge of the central plague godown, and the travelling dispensaries.

IN connexion with the Baby Week celebration, conferences of the National Association for the Prevention of Infant Mortality and the Baby Week Council will be held at Leeds on June 30th, at Manchester on July 1st, at Brighton on July 2nd, at Bradford on July 6th, at Wrexham on July 7th, and at Crewe on September 10th. Among the subjects to be discussed are "The care of young children in the home as compared with their care in institutions," "Infant welfare work," and "The decay of parenthood and its menace to the race." After the morning and afternoon sessions a public meeting will be held (in most of the towns) in the evening. The Ministry of Health has sanctioned reasonable expenditure by local authorities in sending delegates to these conferences; the attendance is also invited of delegates of voluntary organizations and of members of the public who are interested in the subjects under discussion. Application for tickets may be addressed to Miss Halford, 4 and 5, Tavistock Square, W.C.1.

Correspondence.

THE TREATMENT OF CANCER OF THE CERVIX UTERI.

SIR,—It is a matter of regret to me that I was unable to be present to hear the interesting communication of Dr. Fletcher Shaw and Dr. Burrows to which you refer in an article in your issue of June 12th.

We are all anxious to learn anything that will help to make cancer of the cervix more curable and more easy to extirpate. At the Liverpool Royal Infirmary we have been fortunate to have a certain amount of radium for some years. At first we applied the tubes to many inoperable cases; but whether our technique was incorrect (we have no facilities for emanations, but have two platinum tubes containing 50 and 30 mg. respectively of radium bromide) or there was some other unknown cause, the results were not satisfactory. I therefore abandoned preliminary applications and, instead, adopted the method of performing a radical operation—the so-called Wertheim technique—in a large majority of all cases (with, as was inevitable in such circumstances, a somewhat large primary mortality) and of laying a container of radium encased in fine rubber tubing on either side of the pelvis at the end of the operation. These tubes are now withdrawn through the vagina at the end of twenty-four hours, for sloughing occurred in several cases when the radium had been left undisturbed for forty-eight hours. I have hoped by this means to destroy cancer cells which might be hidden in the lymphatics and left behind, for it seemed probable that after a radical operation the radium would have the best chance of dealing with outlying cancer cells that might have been left in the tissues. The first time this procedure was carried out was on August 6th, 1916, in a case in which the disease was very advanced. This patient was seen a short while ago, when she was quite well and had put on much flesh. Since this date many other cases have been treated in the same way with, I believe, an improvement in the end-results.

Possibly preliminary emanations followed by operation seven days later with the insertion of radium in the pelvis at the end of the operation may be found to give better results than by either method alone.

There is one more point in the treatment of these patients by which I set considerable store. It is well known, since the work of Benjamin Moore and others in the University of Liverpool, that in all cases of cancer, wherever the disease is situated, the acid secretion of the stomach is absent or deficient. I consider it necessary, therefore, that all patients, after a radical operation for cancer, should take dilute hydrochloric acid three times a day for the rest of their lives. I have been able to demonstrate that in so long a period as ten years after operation hydrochloric acid has still been absent from the stomach.

Until, if ever, we have a specific cure for cancer I think that we should utilize in every case all measures which offer a prospect of benefit in this terrible disease.—I am, etc.,

Liverpool, June 13th.

W. BLAIR BELL.

EXPERIMENTAL INDUCTION OF CANCER.

SIR,—Very interesting indeed and of far-reaching import are the researches of Fibiger on the experimental production of cancer as reported in your issues of May 15th and June 5th. How far these researches will throw light on the origin of cancer the future alone can decide, but it seems to me that they may lend themselves to solving some crucial and much debated points as to the true origin of the cancer cell.

One very important stepping stone in our knowledge of cancer would be reached if we could definitely answer the question: "Can the highly specialized epithelial cell, wherever situated, alone and unaided, be stimulated by a toxin to a state of increased cell division as part of a purely inflammatory process, and then without any qualitative change in the process become cancerous; or does the toxin, by stimulating the reproductive power of the cell beyond endurance, exhaust its energy of cell division and so bring about a state whereby a positive chemiotaxis (a disguised surface energy phenomenon) for original undifferentiated germinal idioplasm is set up, and that it is the union of these two distinct cytological elements that

constitutes the cancer cell?" Undifferentiated germ plasm, which, according to Weismann, is alone supposed to possess potential immortality, is located in the sexual organs—that is, ovary or testis—and is the basic tissue out of which the germ or sperm cells are eventually developed.

Now that the experimental production of cancer is practicable, no doubt the investigation will be taken up in this country, and I would suggest as a crucial experiment to settle this important point some such experiment as the following: Young male rats of a susceptible strain might be fed on the larvae of the *Spiroptera neoplastica*, and an equal number of the same subjected to the same feeding after extirpation of the sexual organs, assuming, of course, that efficient castration is a practical operation. A comparison of the results might determine whether the specialized somatic cell is of itself capable of becoming malignant or not—a point of very great importance; at the same time it might sweep from the lumber room of science some well-worn theories connected with Weismann and his germ plasm.—I am, etc.,

F. B. SKERRITT, M.B., B.Sc.Lond.

London, E., June 11th.

FUTURE PROVISION OF MEDICAL SERVICES.

SIR,—I have been waiting for the last two weeks in the hope that some general practitioner would initiate a correspondence expressing his views on the Report of the Medical Consultative Council. The proposals are so very important and far-reaching that the opinions of all sides of the profession should be sought for and discussed. I have no doubt, however, that the proposed scheme appears to members of the profession so gigantic and all-embracing that they have not yet had time to study and digest it. In the meantime I may be allowed to offer a few comments on some of the points included in the Report, but before doing so it may be said at once that to the ordinary man in the street it appears that the proposed scheme, owing to its vastness and the consequent expense involved, will court destruction if action is persevered in at the present time or the near future.

The Report is based on the assumption that all its provisions are necessary and vital to the public. It is assuming that all, or nearly all, the ailments and diseases of the well-to-do, the working man, and the poor require the attention of the elaborate primary and secondary centres for their treatment. Is that so? I should estimate that something like 80 to 95 per cent. of the illnesses occurring among the public are amply and carefully attended to by general practitioners, and that at most 20 per cent. of the public need the services of consultants and specialists over and above.

If that estimate is near the truth, why should the country be burdened with the enormous expense of the centres for the few? Surely some means could be devised and adopted of a less expensive nature to meet the needs of that part of the public who require, and rightly so, the advantages which are supplied by x rays, baths, massage, electricity, physical culture, etc., of the primary centres, and consultations in medical, surgical, and special cases at the secondary centres. The difficulty might be solved by merging the proposed primary centres, which are unnecessary, in the secondary centres, which could be called consultation centres. Such a method would reduce their number and avoid the multiplication of buildings and staffs, which appears to be inevitable under the scheme of the Council.

Personally I endorse the general principle laid down in the Report, that medical treatment must be both individual and communal—communal treatment being restricted to pre-natal and maternity care, child welfare, school children inspection, dental treatment, and the like; but I do not agree with the proposal to establish at primary centres common consulting rooms for the public, irrespective of their status. Besides, a very large percentage of the public would never consent to such a method of treatment. The primary centre, as shadowed forth by the Consultative Council, may be the ideal one, but human nature being as it is, it is impracticable.

I also heartily approve of domiciliary nursing being available for all illnesses when the doctor deems it necessary. I am sure that every doctor would welcome such assistance—a whole-time nurse when the mother is

ill, and a part-time service to assist and guide the mother when other members of the family are laid aside.

Regarding consultations supplied by the secondary centres, I am afraid that as soon as it is realized that any one can demand a consultation in comparatively ordinary illnesses, the relations between the doctor and the patient would be considerably strained, and I can fancy the feelings and thoughts of the consultant in such cases.

It is to be noted that while consultants would be paid on a part-time basis, with extra fees for special visits, no provision is made for the payment of general practitioners.

"The standard rate of payment at a primary centre would include residence, food, and nursing, but not medical attendance. At the secondary centre the charge would include medical attendance and would be defrayed by moneys allotted to such services. It is suggested that the charges for medical attendance would usually be met by some method of insurance."

There is nothing definite, and the procedure is quite in keeping with that adopted under the Insurance Act.

It is cheering to notice that the Consultative Council is decidedly against the establishment of a salaried State medical service, for good reasons.—I am, etc.,

Edinburgh, June 13th.

MICHAEL DEWAR.

THE TREATMENT OF MENTAL DISORDER.

SIR,—In the Report of the Medical Consultative Council for England (BRITISH MEDICAL JOURNAL, May 29th, 1920, p. 741) it is stated, among other proposals bearing on the future provision of medical services for the whole country, that certain institutional services should be correlated with both primary and secondary health centres—for example, sanatoriums for tuberculosis, convalescent centres, hospitals for curable and incurable mental diseases, institutions for the feeble-minded, for epileptics, etc. May I call attention to a wording which seems to me to be both misleading and unscientific—namely, the classification of mental illness into "curable and incurable"? In the department of mental instability, more, perhaps, than in any other branch of medicine, such a distinction seems inadmissible. The curability of much mental disorder is dependent upon the circumstances surrounding the patient and the nature of the treatment applied, to a degree which is scarcely equalled in any other class of illness. Moreover, the recent advances in therapeutic science seem to make it quite possible that within the lifetime of one generation the "incurable" of to-day may become the "curable" of to-morrow.

Are not the really practical terms for the classification of the various forms of mental illness to divide them into those which require restraint and those for which it is unnecessary, or in which it may even act as an irritant—namely, into the "certifiable" and the "uncertifiable"? For both it is our privilege to provide every possible remedial condition.

Looked at from the institutional point of view, the former belong to the province of the Lunacy Board, and for them our asylums are provided, while for the latter chiefest among remedial agents is an atmosphere of encouragement, reassurance, and hope. This is best given by keeping them absolutely separate from the certifiable lunatic. For such there ought to be hospitals or homes of recovery which they can enter of their own free will, with a full certainty that these are in no way connected with lunacy regulations; and the more definitely they are separate from these the more likely are patients to be willing to come to be treated while their troubles are really curable. In the most excellent *Outline of Preventive Medicine*, issued by Sir George Newman on behalf of the Health Ministry, the greatest stress is laid upon the preventability of illness if treated in natural and appropriate fashion. And this applies *par excellence* to mental cases.

More especially is it desirable that homes of a cheerful nature, with occupational facilities, should be found for the large numbers of invalided soldiers whose nerves have been temporarily unstrung through the severity and stress of war. Most of these, given a fair chance, make short and complete recoveries, and ought not to have their futures clouded by the stigma of having been placed, as they so often are, in institutions connected with certifiable lunacy.—I am, etc.,

London, S.W.1. June 13th

HELEN WEBB.

VACCINAL CONDITION OF SMALL-POX CARRIERS.

SIR,—In your issue for May 29th, under "Medical Notes in Parliament" you report Dr. Addison's reply to a question by Mr. R. Young as to the vaccinal condition of the various small-pox "carriers" in England and Wales during 1919, and this aspect of the vaccination question has hitherto scarcely received adequate attention. The vaccinal condition of the unfortunate persons who contract small-pox in any outbreak is usually reported, but too often but little attention is paid or drawn to the vaccinal condition of the person ("carrier") who is responsible for the outbreak. Yet I venture to assert that this is a very important matter. It will be found that in the vast majority of outbreaks which have occurred in modern times the individual "carrier" responsible for originating an outbreak has been an unrecognized or overlooked case occurring in a vaccinated subject. Moreover, the usual experience is that the "carrier" case has been overlooked because it was of a very mild and modified type. Frequently the case has had but little eruption, and that of a character differing greatly from that usually seen in unmodified small-pox.

The important point I wish to emphasize is that these highly modified easily overlooked "carrier" cases almost invariably occur in vaccinated persons—not recently vaccinated, but vaccinated many years before—and because they had been so vaccinated. When this fact is more generally appreciated than it is at present I think it will be realized that our present system of infantile vaccination which is not followed by systematic revaccination is to a not inconsiderable extent responsible for the spread of small-pox. This may seem a revolutionary suggestion to some, but I submit that if we are to arrive at a just appreciation of the precise advantages to the community of our present system of vaccination we must take the consideration I have referred to into our reckoning.—I am, etc.,

Leicester, June 10th.

C. KILLICK MILLARD.

"A PLEA FOR THE TONSILS."

SIR,—Under this heading the BRITISH MEDICAL JOURNAL (November 1st, 1919, p. 562) reviewed Professor Digby's *Immunity in Health*, and therein confused lymphoid tissue with vestiges. The review has brought from Professor Berry (February 7th, 1920, p. 199) his oft repeated claim that he has discovered that lymphoid tissue did compel the evolution of the vermiform appendix. We are thus confronted with comparisons between the throat and the appendix, an attempt to hide the vestigial nature of the latter, and an endeavour to confer on lymphoid cells a power they do not possess.

Because the throat is in full functional activity surgery is so restricted in its treatment of its associated lymph structures that no surgeon has yet advocated its amputation for tonsillitis, and because the appendix has lost its caecal function the treatment of inflammation of its lymphoid tissues is obliteration. It is as reasonable to think that the tonsils evolved the throat as that lymphoid tissue evolved the appendix, and if thought be permitted on this plan it may be assumed that the red cells of blood coursing through the scapula evolved those vestiges of the coracoid bone—the coracoid processes—for it is certain that the function of lymphoid tissue is as distinct from that of the caecum as the red blood cell from bone.

A plea for the tonsils is based on the service that lymphoid cells render the human organism. Such cells are globular, and the shape they form in mass is that of a ball, except when the shape of the mass is altered by the pressure of other tissues. As amphibia have lymph hearts, and as the human spleen contains muscular tissue, it may be conceded that lymphoid tissue has the power of calling muscular tissue into being, in the same way heart muscle may be evolved to serve the blood. This assumption does not, however, permit us to think that the muscular coats of the gut have been evolved as lymph pumps. Such must be the case if Professor Berry's theory be true.

The implied plea for the appendix rests on the conservation of follicular glands—lymphoid tissue. Professor Berry tells us that "lymphoid tissue is the characteristic feature of the caecal apex." This erroneous statement arose from the rabbit and hare having an enormous collection of lymphoid tissue at the ends of their caeca, and to Sir Richard Owen writing of "the slender termination of the

hare's caecum, which is glandular like the vermiform appendix of man." Whilst much has been made of lymphoid tissue at the end of the rabbit's caecum, the corresponding mass that it contains about the ileo-caecal valve has been ignored and nothing has been said about the comparative absence of lymphoid tissue at the caecal apex of the rat. Right through the mammals—and it applies with equal force to the primates—lymphoid tissue is not the characteristic feature of the caecal apex. Its relationship to that place is casual. The only animal outside the primates that has a vermiform appendix is the marsupial wombat, and its vestige of its ancestral caecum is singularly free from lymphoid tissue. To describe the fully functioning caecum of the rabbit as possessing a vermiform appendix is to deny both form and function.

Professor Berry tells us "as the vertebrate scale is ascended this lymphoid tissue tends to be collected into a specially differentiated portion of the intestinal canal—the vermiform appendix." As the amount of lymphoid tissue in the rabbit's caecal apex is a thousand-fold greater than that in the human or any other vermiform appendix, it is necessary to put the pestiferous and all too prolific rabbit at the top of the vertebrate scale, as he draws it.

To convince one of the vestigial nature of the vermiform appendix it is only necessary to study Treves's four types of human caecum, and to follow the history of man's food. The process is so simple that by the aid of rubber bags and some rubber bands the recession of the caecum can be demonstrated. Few men have had the opportunity as I have had at the courtesy of Mr. Le Souef, director of the Melbourne Zoo, of examining all the dead from a large collection of animals to determine their caecal structure. In this work I became fascinated with the meaning of splits and bands in the digestive tract, and there can be no doubt that in the external muscular coat of the vermiform appendix its history is plain. The vermiform appendix is nothing but a vestige of a large ancestral caecum, and its contained lymphoid tissue in no way affects its vestigial nature.

Professor Berry, after denying that the appendix is a vestige, claims it as a specialized part of the alimentary canal. If this be conceded, we must say that Scarpa's triangle was specially evolved to accommodate lymph glands, that the ileum was evolved for Peyer's patch, that the parotid salivary gland was evolved to contain its lymph gland, and the vertebrae exist to support the thoracic duct. No argument can do away with the fact that the vermiform appendix is typical gut, and until its structure can be denied the lymphoid theory must remain a theory which cannot be permitted to modify surgical practice.—I am, etc.,

WALTER STAPLEY, M.D., D.V.Sc., M.R.C.V.S.

Cambridge, N.Z., May 4th.

Obituary.

DAVID BERRY HART, M.D., F.R.C.P. EDIN.,
Edinburgh.

BRITISH obstetrics and gynaecology would surely have been impoverished had David Berry Hart turned, as he might well have done, to anatomy or to surgery at his graduation as M.B. and C.M. in 1877; but the attention of the late Sir Alexander Simpson was directed to the promising young doctor, and secured him for midwifery by appointing him to be his assistant in that department in the University of Edinburgh, so giving him the opportunity for doing the life work which he so brilliantly accomplished. He carried over into obstetrics and gynaecology the exactness of the anatomist, and in 1880 gained with the M.D. degree a gold medal and the Syme Surgical Fellowship for his thesis on "The structural anatomy of the female pelvic floor." Later in life he added to his anatomical bent the scientifically directed curiosity of the biologist, and explored the early beginnings of vital activity in the ovum and embryo.

Dr. Berry Hart's death took place at his home in Edinburgh on June 10th almost at the very hour when the Library Committee, of which he was convener, was meeting in the Royal College of Physicians. During the winter months he suffered from influenza, and to the sequelae of that disease he attributed the weakness which forced him to cease his lectures at Surgeons' Hall on

May 24th. It was anticipated that a few days' rest would enable him to resume his greatly loved teaching, but signs of more serious trouble became manifest to his doctors, and he passed away in his sixty-ninth year. He was born in Edinburgh, and from his maternal grandfather, Mr. David Berry, builder, came the part of his name which was to distinguish it from others who bore the Hart cognomen.

Dr. Berry Hart received his medical education at the University of Edinburgh between the years 1872 and 1877, displaying then the same originality of thought and enthusiasm of application which marked him in later life. He visited Vienna soon after graduation in 1877, and then settled down to the work of teaching midwifery tutorially in Edinburgh in connexion with Professor Simpson's classes. He was appointed assistant physician to the Royal Maternity Hospital in 1884, and assistant gynaecologist to the Royal Infirmary in 1886, moving on to the senior posts in these two institutions in 1889 and 1901 respectively. In the early nineties he also acted as gynaecologist to Leith Hospital. At the time of his death he was consultant to all these three hospitals. In 1883 Dr. Hart commenced systematic lecturing in the School of Medicine of the Royal Colleges, and gave courses of lectures on midwifery and gynaecology there till within a few weeks of the end. He also collected a large museum of specimens, and gave to their investigation and preservation many hours of his already full life. He was all the while teaching clinically in the various hospitals, was engaged first in a general and later in a specialist practice, and was preparing and publishing many important books and papers. From outside Edinburgh recognition came to him, and he was made an honorary Fellow of the American Gynaecological Society, of the Berlin Obstetrical Society, and a Corresponding Fellow of the Leipzig Obstetrical Society. He opened a debate on placenta praevia at Brussels at the international medical meeting there, and on several occasions he was similarly honoured at the annual gatherings of the British Medical Association. He was secretary of the Edinburgh Obstetrical Society from 1879 to 1883, and became president in 1890. He was examiner in midwifery in the universities of Edinburgh, Oxford, Birmingham, and Liverpool; and he held other appointments of honour and responsibility, such as that of librarian to the Royal College of Physicians of Edinburgh.

Whilst this was the setting, so to say, of Berry Hart's life, there were three directions in which his activities were particularly fruitful—in scientific research, in medical literature, and in teaching; in each of these he revealed the note of distinction and showed the hand of a master. The clinical side of his life was far from featureless; indeed, he performed for the first time in Scotland successfully the operations of Caesarean section for ruptured tubal gestation, and for advanced broad ligament pregnancy; but he was at heart an anatomist, a research scholar, and an inspiring teacher rather than a full-time clinician.

With regard to scientific research, Berry Hart was the first in Scotland to employ the method of frozen sections in anatomical studies, and by this means to throw a flood of light upon the structure of the female pelvic floor and its behaviour in labour, in prolapsus uteri ("sacro-pubic hernia"), in the genu-pectoral position, and during the passage of the Sims speculum. A by-product of Hart's work, although carried out by other hands, was the development of cystoscopy in its modern form. Further, those who in Edinburgh followed him in the Midwifery Department applied, always with fruitful results, the frozen sectional method to the investigation of the anatomy of labour, of the fetus and new-born infant, and of the puerperium; he himself carried it into the study of ectopic pregnancy.

These, however, by no means exhausted the range and scope of Hart's researches; they were, in very truth, only the beginnings. He dealt in turn, and always originally and suggestively, with the mechanism of labour, with the mode of separation of the placenta in the third stage, with the nomenclature of transverse presentations and positions, with the tuberoso-fleshy mole, with the morphology and development of the genito-urinary tract, with hermaphroditism, with the theory of enzygotic twins, and with the kyphotic pelvis. To prove their worth it may be noted that hardly one of these pieces of research failed to arouse

discussion, and some of them excited so much controversy as to give birth to several other researches by Hart himself and by his antagonists. In his later work Dr. Berry Hart roamed almost solitarily (so far as obstetricians were concerned) in the mazes of Mendelism, a subject which, especially in its mathematical aspects, had a strange fascination for him. To explain the various forms of hermaphroditism, to introduce an entirely novel nomenclature, to prove that after all the "free-martin" was not a cow; and to do all this with the help of Mendelian principles was an invigorating exercise to Hart, although to others it seemed nothing less than a *tour de force* of dubious utility. He was head and shoulders above the little thinkers on these matters, and he enjoyed these speculations with his whole soul. Almost his most recent work, an article in the new edition of the *Encyclopaedia Medica* on hermaphroditism in man, illustrates these features of his later work admirably.

Dr. Berry Hart was the writer of nine books and of more than seventy papers, and would therefore demand attention even if the work were not of the high standard it has just been shown to be. He was a literary man. In the first place, his articles, with whatsoever subject they dealt, were invariably written in strong readable English, terse, clear, arresting, forcible. In the second place, he scored two distinct successes with textbooks; the *Manual of Gynaecology* (written in collaboration with Freeland Barbour) has passed through many editions and has been translated into several European languages; and his *Guide to Midwifery* has appealed to the best minds amongst his colleagues and has been already fruitful in many directions. The *Manual* is now, after nearly forty years, quietly accepted as a textbook like many others; but in the year of its publication it stood out alone as a pioneer work establishing gynaecology as a true, self-contained, and scientifically founded speciality. But, in the third place, Hart was successful as the writer of what may justly be termed medical *belles-lettres*. His fascinating book called *Some Phases of Evolution and Heredity* came as a delightful surprise even to many who knew him well. He revealed in it literary grace, a power of epigrammatic description, delicate fancy, brilliant critical instinct, and genuine humour; yet on every page of it real facts of vital importance were being set forth. Take, for instance, his pregnant phrase, "man and woman are equipotential but not equivalent," or his summing up of eugenics. "it is not Nature's way," or his reflection, "in time Cupid, before he shoots, will look up the lovers' dossier," and read his chapter on men (such as Pepys) who have revealed themselves. The whole work teems with what may be called sportive marginalia on the scientific and semi-scientific books and beliefs of the time.

The third direction in which Berry Hart's work was fruitful beyond the average was that of teaching. In part his teaching was through his books and papers, and it was never of the coaching kind, attracting the student whose horizon was coterminous with the walls of the examination hall; but his oral and clinical teaching showed even more the absence of anything approaching the popular style. It appealed rather to the post-graduate or to the under-graduate with the post-graduate mind, who appreciated it to the full, even if for the time being he could not follow out the avenues of thought which were being opened up. The fact that an important but novel matter was not likely to be asked in an examination paper did not deter Hart from giving a whole lecture to it if he thought it deserved it. The desire to teach in this sort of fashion went with Hart to a medical society meeting and gave a sharpness to his criticism of papers read there which some were inclined to resent; but such comments from his tongue were rather to be regarded as compliments than as condemnations. The poor paper he left uncriticized, but for the one that had a spark of originality or of merit in it Hart had a word or two which showed how the spark might be converted into a flame, and he took the author (if he were willing) into the circle of those whom he delighted to engage in combat and measure swords with. It was considerations such as some of these referred to which no doubt led the College of Physicians to bestow upon Dr. Hart in 1918 the Cullen Prize, awarded every four years "for the greatest benefit done to practical medicine," and with that distinction one may suitably close this sketch of his life.

Sides to his life have been left untouched, amongst them

his kindly relations with his patients, his devotion to Liberalism in politics and to his church (the United Free) in religion; but in the main the man, David Berry Hart, was such an one as has been indicated. He has left a widow and four children, two sons and two daughters.

WE regret to record the death of Dr. CLAUDE JOHNSON, which took place from pneumonia on May 15th at King's Heath. Dr. Johnson, who was the second son of Dr. C. J. B. Johnson of King's Heath, near Birmingham, was educated at Birmingham University, where he held office as secretary of the University Medical Society. After graduating M.B., Ch.B. Birmingham, and M.R.C.S., L.R.C.P. Lond. in 1906 he acted as resident medical officer at the Birmingham General Hospital, as assistant obstetric officer at Queen's Hospital, and as house-surgeon to the Meseley Hall Convalescent Hospital for Children. He took the diploma of D.P.H. in 1909. At the outbreak of war he was mobilized as a member of the Special Reserve, and served with the first Expeditionary Force during the retreat from Mons. Subsequently he left his field ambulance to act as sanitary officer in France, and during the latter part of the war he was stationed in India, where he contracted dysentery. After his return to England he joined his father in practice at King's Heath. His death, at the age of 36, is deplored by a wide circle of friends and patients. Great sympathy is felt for his widow, to whom he was married only twelve months ago.

SURGEON-MAJOR RALPH ROBERT SCOTT, R.A.M.C. (retired), died at Bath on June 1st, aged 88. He was born at Kiltegan, county Wicklow, on February 5th, 1832, took the L.R.C.S.I. in 1853, and entered the army as assistant surgeon in the 46th Foot on July 28th, 1854—sixty-six years ago. He became surgeon-major on March 1st, 1873, went on half-pay on July 28th of the same year, and commuted his half-pay three years later. In 1861 he took the L.K.Q.C.P., and the membership of the same college in 1879, after his retirement. He had a varied experience of the army, having served in four regiments—the 46th, 93rd, and 80th Foot, and the 8th Dragoons—as well as four spells on the staff. He served with the 46th Foot in the Crimea from November 8th, 1854, and was present throughout the siege and at the capture of Sebastopol, including the attacks of June 18th and September 8th, receiving the medal with clasp and the Turkish medal. In the Indian Mutiny he served with F Battery, Royal Horse Artillery, at the final capture of Lucknow in 1858, and with the 6th Dragoon Guards (Carabineers), in Sir Hope Grant's column, and in the Trans-Gogra campaign, receiving the mutiny medal with clasp for Lucknow.

THE *Pioneer Mail* reports the death at Lucknow on May 16th of Dr. MOHENDRA NATH OHEDAR, one of the best known medical men in the North-West, now the United Provinces of India. He was 65 years of age, and had served for thirty years in the Provincial Civil Medical Service, holding the post of assistant surgeon of Allahabad for many years, and until he was promoted to the medical charge of a district he served as civil surgeon of Bara Banki, in Oudh. When he retired, about five years ago, he settled at Lucknow, where he speedily acquired a large practice. He was the first Indian to hold a commission in the Volunteers, serving as medical officer of the Allahabad Volunteer Rifles. He received the Indian title of Rai Bahadur for his services in 1892. His death was due to cerebral haemorrhage.

THE first Pan-Hellenic Congress of Hygiene and Demography will be held at Athens from April 25th to April 30th, 1921, under the presidency of Professor Phocas, simultaneously with the celebration of the centenary of Greek independence. There will be six sections represented: Public health, individual hygiene, military and naval hygiene, demography, infantile hygiene, and prophylactic hygiene. An international exhibition of hygiene and medical industry will be opened at the same time as the congress and will continue until June 25th. Further information concerning the congress and exhibition may be obtained from Dr. P. Rondopoulo, 14, Rue Nikiforon, Athens.

Universities and Colleges.

UNIVERSITY OF OXFORD.

DURING Commemoration it will be proposed to confer the honorary degree of D.Sc. upon Lieut.-General Sir Alfred Keogh, G.C.B., Rector of the Imperial College of Science and Technology, and upon his successor in the office of Director-General A.M.S., Lieut.-General Sir John Goodwin, K.C.B.

Captain Philip Walker and Captain Cecil Walker have offered some £2,000 to be added to the balance of the benefaction of the late Philip Francis Walker, and applied by the trustees towards the establishment and maintenance of a studentship in pathology.

The honorary degree of Doctor of Letters has been conferred upon Dr. Teodoro Zammit, C.M.G., professor of chemistry in the University of Malta and curator of the Valletta Museum, in recognition of his great services to the island of Malta by the discovery of antiquities and in the detection of the local causes of fever. Dr. Zammit is a member of the council of the Malta Branch of the British Medical Association.

UNIVERSITY OF CAMBRIDGE.

At a Congregation held on June 12th the recommendation of the General Board of Studies for a University Lectureship in Medical Radiology and Electrology was approved.

The following medical degrees were conferred :

M.D.—A. N. Hooges.
M.B., B.Ch.—J. L. Davies.
M.B.—E. Forrester-Paton, S. H. M. Johns, H. W. Scott, J. H. E. Moore.

The names of those medical men upon whom it is proposed to confer the honorary degree of LL.D. on June 29th are given in another column.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The following have after examination been admitted Fellows of Faculty :

N. S. Bruce, J. A. Conway, J. N. Crnickshank, J. Gracie, S. P. Meighan, J. H. Patterson, D. M.K. Reid, W. R. Snodgrass, I. D. Suttie, G. Young.

UNIVERSITY OF LONDON.

At a meeting of the Senate on May 18th a diploma of psychological medicine open to all registered medical practitioners was instituted. The standard will be approximately that of the University of Cambridge for the corresponding diploma.

Dr. G. Newton Pitt has been appointed representative on the Senate of the City and Guilds of London Institute.

Mr. W. Foster Cross was recognized as a teacher of anaesthetics at St. Bartholomew's Hospital, and Mr. Gwynne E. O. Williams as a teacher of surgery at University College Hospital Medical School.

Dr. V. J. Woolley was appointed a member of the Board of Examiners in Pharmacology for the second examination for medical degrees, Part II.

The following were appointed examiners for the first and second examinations for medical degrees in the session 1920-21, the chairman being indicated by an asterisk :

Chemistry: *Dr. W. B. Tuck and Mr. H. C. H. Candy, or, failing him, Dr. H. R. Le Sueur, together with the external examiners, Dr. H. R. Le Sueur and Professor J. M. Thomson.

General Biology: *Dr. H. W. M. Tims and Dr. F. Drabble, together with the external examiners, Mr. A. Eastwood and Mr. J. T. Cunningham.

Physics: *Mr. W. H. White and Mr. F. Womack, together with the external examiners, Mr. A. Wood and Dr. P. L. Hopwood.

Anatomy: Professor J. E. S. Frazer and Professor W. Wright, together with the external examiners, Dr. W. L. H. Duckworth and Professor G. Elliot Smith.

Pharmacology: Dr. P. Hamill and Dr. V. J. Woolley, together with the external examiners, Professor H. J. Campbell and *Dr. Ransom.

Physiology: Professor J. Mellanby and Professor F. A. Bainbridge, together with the external examiners, Professor M. S. Pembrey and Professor J. S. Macdonald.

Applications for the University Chair of Physiology, tenable at King's College for Women, Household, and Social Science Department (salary of £300 a year), must be received by the Academic Registrar by June 30th, from whom further particulars can be obtained.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An Ordinary Council was held on June 10th, when Sir George Makins, President, was in the chair.

Results of Examinations.

Thirty-eight candidates admitted under the special war conditions passed the examination in anatomy and physiology for the Fellowship, and thirty-six were admitted under the ordinary conditions:

A. J. Abel, H. H. Bailey, J. A. Berry, O. Brechner, R. St. L. Brockman, D. J. Brown, A. G. Bryco, W. P. Christie, E. A. Coldrey, S. H. Cookson, V. M. Coppleson, H. Corsi, R. K. Dadachani,

B. M. Dannatt, W. M. Dickson, T. F. M. Dilworth, C. F. T. East, J. A. W. Ebdon, D. J. Evans, G. I. Evans, W. C. Faull, A. W. Fawcett, L. R. Fifield, W. D. Galloway, A. T. Gibb, J. W. Gilbert, P. K. Gilroy, V. B. Gokhale, E. Grey, A. R. Gunn, S. G. Harrison, F. H. Healey, S. L. Higgs, J. P. Hosford, R. W. P. Hosford, F. Hudson, J. B. Hunter, J. B. Jose, N. J. Judah, G. L. Keynes, J. LeM. Kuebone, E. A. Linell, S. D. Lodge, J. Love, W. M. H. McCullagh, A. C. Macdonie, N. S. Macpherson, W. C. H. Meyer, P. J. Moir, O. G. Morgan, D. F. A. Neilson, R. L. Newell, H. G. Oliver, L. F. O'Shaughnessy, S. T. Parker, E. J. Partridge, D. H. Patey, C. V. Patrick, P. P. Pugh, F. H. Scollson, S. C. Shanks, E. S. S. Snaalpage, J. F. H. Stallman, C. Sturton, C. H. Terry, C. P. Thomas, J. W. T. Thomas, A. H. C. Visick, E. Watson-Williams, H. P. W. White, H. A. B. White Locke, O. H. Williams, A. D. Wright, H. B. Yates.

Diplomas of Fellowship were granted to thirty-nine candidates, of whom Mr. W. E. Le Gros Clark had passed the examination in November, 1919, before attaining the required age of 25 years. The other successful candidates were:

S. Forsdike, N. F. Sinclair, J. W. Adams, G. Gushne-Taylor, B. S. Simmonds, L. N. Reece, W. H. Ogilvie, A. N. Hooper, C. S. L. Roberts, K. H. McMillan, F. A. Williamson, A. C. Perry, H. W. S. Wright, J. R. Griffith, W. T. Warwick, N. J. Wigram, F. C. Mason, J. B. Hume, L. G. Higgins, Muriel E. Landau, J. Joffe, J. Whittingdale, J. Gilmore, W. E. M. Wardill, M. A. W. Moore, R. M. Handfield-Jones, A. L. Buchanan, N. Cantlie, J. H. Col, H. R. Dew, R. Fowler, J. F. Gill, J. N. J. Hartley, R. A. Kerr, T. P. Noble, C. N. Smith, T. L. L. Sandes, M. H. Whiting.

Diplomas for the Licence in Dental Surgery were granted to twenty-one candidates.

Election of Examiners.

The following appointments were made:

FOR THE FELLOWSHIP.—Anatomy: J. Ernest Frazer, W. F. Haslam, Gordon Taylor, A. Ralph Thompson. Physiology: F. A. Bainbridge, J. B. Leathes, H. W. Lyle, A. R. Short.

CONJOINT EXAMINATION.—Elementary Biology: J. P. Hill, T. W. Shore. Anatomy: David Hepburn, F. G. Parsons, Arthur Thompson. Physiology: G. A. Buckmaster, H. E. Roaf. Midwifery: J. S. Fairbairn, Cuthbert Lockyer, G. D. Robinson, G. F. Darwall Smith. Public Health—Part I: Sir Frederick Andrews. Part II: F. N. Kay Menzies. Tropical Medicine and Hygiene: G. C. Low, H. B. G. Newham.

Presentation of Diplomas to Honorary Fellows.

The President reported that the five surgeons who were elected Honorary Fellows of the College on February 12th last would attend to receive their diplomas on Thursday, July 8th, and that the diplomas would be presented to them at 7.30 p.m. on that day, after which they would be entertained to dinner in the College by the Council. The Honorary Fellows are Dr. A. Depage (Brussels), Dr. Gosset (Paris), Dr. P. Duval (Paris), Dr. Finney (Baltimore), Dr. C. Mayo (Rochester, U.S.A.).

The Services.

HONOURS.

C.B.E.

Temporary Lieut.-Colonel Ernest William White, R.A.M., has been appointed C.B.E. (Military Division) in substitution for the award of O.B.E. (Military Division) announced in Supplement to the *London Gazette* of June 3rd, 1919.

Mentioned in Dispatches.

The name of Captain R. C. Clifford, D.S.O., M.C., I.M. attached 24th Punjab, I.A., has been brought to the notice of the Secretary of State for War for gallant and distinguished conduct in the field (dated January 1st, 1919).

A fifth Supplement to the *London Gazette* of June 8th, 1919, published on June 11th, contains further lists of mentions distinguished and gallant services and devotion to duty in fields of operations indicated. The lists contain the following members of the medical profession:

France.—Temporary Lieut.-Colonel C. S. Myers, C.B.E., F.I.R.A.M.C. Captains C. S. O'Neill, O.B.E., R.A.M.C., and R. W. Salmon, O.B.E., R.A.M.C., T.F.

East Africa.—Lieut.-Colonel R. Milner-Smyth, O.B.E., S.A.I. Temporary Lieut.-Colonel J. Grinsell, O.B.E., S.A.M.C. Major (temporary Lieut.-Colonel) W. V. Field, O.B.E., S.A.M.C. Captains (ac Major) S. J. V. Furlong, O.B.E., R.A.M.C.S.R. (acting Lieut.-Colonel) J. D. Kidd, O.B.E., M.C., R.A.M.C., and H. L. Duke, O.B.E., Uga Medical Service.

India.—Lieut.-Colonels P. St. C. More, O.B.E., I.M.S., and J. J. Prescott, D.S.O., O.B.E., R.A.M.C. Temporary Lieut.-Colonel Rajendra Roy, O.B.E., I.M.S. Major and Brevet Lieut.-Colonel (temporary Colonel) P. A. F. Barnado, C.I.E., C.B.E., I.M.S. Major (temporary Lieut.-Colonel) J. K. S. Fleming, O.B.E., I.M.S. G. Franklin, O.B.E., I.M.S., A. T. Frost, O.B.E., R.A.M.C., D. P. J. stone, O.B.E., R.A.M.C., T. W. Minty, O.B.E., I.M.S., R. B. Nichol, O.B.E., M.C., I.M.S., and H. W. Pierpoint, O.B.E., I.M.S. Capt (temporary Major) A. F. Babonau, O.B.E., I.M.S. (temporary Major) F. R. Coppinger, O.B.E., R.A.M.C., W. A. Frost, O.B.E., R.A.M.C., T. B. Heaton, O.B.E., R.A.M.C.(S.R.), C. H. Smith, O.B.E., I.M.S. (temporary Major) J. R. D. Webb, O.B.E., I.M.S. Temp Captains J. Cairns, O.B.E., R.A.M.C., and S. K. Engineer, O.B.I.M.S.

North Russia.—Lieut.-Colonel T. McDermott, O.B.E., R.A.M.C. Captains (acting Major) W. N. W. Kennedy, O.B.E., R.A.M.C.(T) and J. Kenwick, O.B.E., R.A.M.C.

Salonica.—Captain (acting Major) B. L. Davis, O.B.E., R.A.M.C. (T.F.). Temporary Captain (acting Major) F. R. Brown, O.B.R.A.M.C. Drs. (Miss) E. B. Holloway, O.B.E., and (Mrs.) A. M. Livstone-Learnmonth, C.B.E., M.R.C., attached to R.A.M.C.

Siberia.—Major P. J. Collins, O.B.E., C.A.M.C.

Amendments.—In a list of amendments to mentions in dispatches the following are correctly described, and not as printed in the *London Gazette* of the dates indicated: *France*, temporary Lieutenant E. W. Carrington, R.A.M.C. (February 17th, 1915). *Italy*, temporary Captain S. J. Darke, M.C., R.A.M.C. (May 30th, 1918). *Salonica*, Captain T. Carnwath, R.A.M.C.(T.F.) (July 21st, 1917); temporary Captain G. Hardwicke, R.A.M.C., attached 3rd (H.C.) Field Ambulance R.A.M.C.(T.F.) (January 12th, 1920).

FOREIGN DECORATIONS.

The following decorations have been conferred in recognition of valuable and distinguished services rendered during the war:

By the King of Italy.

Order of the Crown of Italy.—Commander: Dr. Alexander Granville, C.M.G., British Red Cross Commissioner, Alexandria.

By the King of the Belgians.

Order of Leopold II.—Commander: Professor G. H. F. Nuttall, M.D., F.R.S. *Médaille du Roi Albert*: Colonel George Abraham Moore, C.M.G., D.S.O.

R.A.M.C. REGULAR OFFICERS' GRATUITY.

A NEW Royal Warrant lays down that Captains of the R.A.M.C. who are given permanent commissions in the corps subsequent to May 25th, 1920, must complete eight and a half years' total commissioned service in order to qualify for the gratuity of £1,000 payable under Article 597 of the Royal Pay Warrant to officers permitted to retire.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL ALFRED ERNEST ROBERTS (retired) died in Guy's Hospital on May 20th, aged 60. He was born on December 3rd, 1859, the son of the late Mr. Andrew Thom Roberts, master printer, of Hackney. He was educated at Aberdeen, where he graduated M.B. and C.M. with honours in 1884, and at the London Hospital. He took the diploma of M.R.C.S. in 1887, and the D.P.H. at Cambridge in 1898. He entered the I.M.S. as surgeon on October 1st, 1887, passing first into and out of the Army Medical School at Netley; he retired as lieutenant-colonel on April 21st, 1908. After four years' military duty he went into civil employ in the North-West, now the United Provinces, in 1891; in May, 1899, he was appointed special health officer of Simla; in April, 1904, statistical officer to the Government of India in the sanitary and medical departments; and in September, 1904, secretary to the Director-General, a post which he held till his retirement. He served on the North-West frontier of India in the Hazara campaign of 1898, receiving the frontier medal with a clasp. He was the author of a short work on *Sanitation in India* (1891), and of a monograph on *Enteric Fever in India* (1906).

Brigade Surgeon Joseph Francis Barter, Madras Medical Service (retired), died at Ealing on June 1st, aged 87. He was the son of William Barter, of Fort William, co. Cork, was born in June, 1832, took the L.R.C.S. Edin. in 1858, and entered the I.M.S. as assistant surgeon on July 27th, 1859, attaining the rank of Brigade Surgeon in 1886, and retired on April 21st, 1890.

Inspector-General George MacLean, R.N.(ret.), died at Hampstead on May 31st. He was educated at Aberdeen, where he graduated M.A. in 1859 and M.B. and C.M. in 1862. Entering the navy soon after, he attained the rank of Inspector-General of Hospitals and Fleet on April 5th, 1898. He had received the Sir Gilbert Blane medal.

Medical News.

THE annual general meeting of the Research Defence Society will be held at the house of the Medical Society of London (11, Chandos Street, Cavendish Square) on Wednesday next at 3.45 p.m. The president, Lord Lamington, will be in the chair, and Lieut.-Colonel R. McCarrison, I.M.S., whose British Medical Association Lecture is published at page 822, will give a short address on vitamins and their relation to health. The attendance of persons interested is invited.

THE Incorporated Society of Trained Masseuses will hold a conference in London on June 24th, 25th, and 26th. The proceedings will be opened by an address on "The art of healing" by Professor Arthur Keith. Sir Charles Ballance will give a lantern demonstration on the healing process in nerves; Mr. H. Chapple, F.R.C.S., will discuss massage and exercises in the puerperium; and Mr. E. B. Clayton, M.B., will give a demonstration on crawling exercises for scoliosis. Particulars can be obtained from the secretary of the society, 157, Great Portland Street, W.1.

THE draft statutory regulations of the Board of Education, dated March 19th, dealing with medical inspections and treatment in secondary schools and other institutions for higher education, have been confirmed. Their chief provisions were summarized in our issue of April 24th (p. 581).

THE annual meeting for the election of officers and council of the Royal Society of Medicine will be held on Wednesday, July 7th. The council has nominated Sir John Bland-Sutton as president, and Dr. A. M. H. Gray, C.B.E., and Mr. W. Girling Ball as honorary secretaries.

THE Society of Tropical Medicine and Hygiene was founded in 1907, with Sir Patrick Manson as president and Sir Ronald Ross as vice-president. The King has now commanded that it shall be known as the Royal Society of Tropical Medicine and Hygiene. The society is not confined to medical men, and there are many veterinary practitioners among its Fellows, who now number 660. The president is Professor W. J. Simpson. The subscription has been raised to £11s. 6d. All particulars can be obtained from the Secretary, 11, Chandos Street, W.1.

DR. DAWSON TURNER has been reappointed extra medical electrician (for radium cases) to the Edinburgh Royal Infirmary for a further period to October, 1922.

THE Rubber Growers' Association offers a number of prizes (the first of £1,000) for the best ideas and suggestions for extending the present uses or encouraging new uses of rubber. Particulars can be obtained from the Secretary, at 38, Eastcheap, London, E.C.3.

THE Ministry of Food and the Ministry of Health announce that on and after June 13th an extra ration of sugar for a child under 2 years of age may be obtained by forwarding to the local food office a medical certificate stating that an extra ration is necessary. Formerly extra sugar could be obtained for such children only as were attending a child welfare centre; it is now available for others, and the certificates may be signed by the medical officer of the centre or by any other duly qualified practitioner.

A VACATION post-graduate course will be held at the North-East London Post-Graduate College (Prince of Wales's General Hospital, Tottenham, N.15) from Monday, July 19th, to Saturday, July 31st, inclusive. It will comprise demonstrations on clinical methods, including laboratory methods of the examination of cases in the mornings, and in the afternoons demonstrations on groups of illustrative cases, general hospital practice in the various departments, and clinical lectures and consultations. On Saturday mornings clinical demonstrations will be given in affiliated special hospitals. The fee for the course is three guineas, or two guineas for either week. Further particulars may be obtained from the Dean at the hospital, or at 19A, Cavendish Square, W.1.

A LECTURE given by Mr. F. L. Hoffman, LL.D., Statistician to the Prudential Assurance Company of America, at a meeting of the American Medical Association, of which he is an associate fellow, has been reprinted under the title *Is Leprosy Increasing?* As the result of a statistical inquiry Dr. Hoffman concludes that in the United States at the present time there are at least 250 cases, and possibly between 400 and 500. This estimate is smaller than the previous ones, but the available evidence seems to justify the conclusion that the disease is very slowly increasing, and that new foci of leprosy are being formed, and constitute a serious menace; during the last four years nearly 250 cases have been reported. Provision has been made by Congress for the erection of a "leprosarium" in Florida, but Dr. Hoffman believes that at least three new institutions are required. It is suggested that the time is opportune for holding another leprosy conference in continuation of the international meetings held at Berlin in 1897, and in Bergen in 1909. In appendices are collated the most recent statistics of leprosy in India, Cuba, Porto Rico, Brazil, Venezuela, Hawaii, and the Panama Canal zone.

A GENERAL meeting of the Tuberculosis Society of Great Britain and Ireland will be held at Cardiff on Saturday, June 26th, when papers will be read by Dr. J. Brownlee, Dr. H. de Carle Woodcock (president), Dr. H. Ellis, and Dr. A. Sandison. There will be a dinner in the evening at which the English members attending will be guests. On the following day members will have an opportunity of visiting the Talgarth Sanatorium, Breconshire, or the Glan Ely Hospital, Cardiff, as may be more convenient. Full particulars can be obtained from Dr. F. J. C. Blackmore, 39, Woodland Terrace, Old Charlton, S.E.7.

A VIOLENT outbreak of plague has occurred at Czernovitz, and many hundred deaths have been reported.

PROFESSOR GIUSEPPE GUICCIARDI of Reggio Emilia has assumed the editorship of the well known journal of psychiatry, *Rivista Sperimentale de Freniatria*, which had been edited for nearly fifty years by the late Professor Augusto Tamburini.

Letters, Notes, and Answers.

ARTHOES desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

AS, owing to printing difficulties, the *JOURNAL* must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

IN order to avoid delay, it is particularly requested that ALL letters on the editorial business of the *JOURNAL* be addressed to the Editor at the Office of the *JOURNAL*.

THE postal address of the *BRITISH MEDICAL ASSOCIATION* and *BRITISH MEDICAL JOURNAL* is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. **EDITOR** of the *BRITISH MEDICAL JOURNAL*, *Aitiology, Westrand, London*; telephone, 2631, Gerrard.
2. **FINANCIAL SECRETARY** AND **BUSINESS MANAGER** (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2620, Gerrard.
3. **MEDICAL SECRETARY**, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the *Scottish Office*, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

"F. W." asks for experience of the use of motor scooters for general practice.

TREATMENT OF SCIATICA.

A CORRESPONDENT has been stimulated by reading Dr. Wilfred Harris's lecture (*BRITISH MEDICAL JOURNAL*, May 22nd, p. 693) on the treatment of trigeminal neuralgia by the injection of alcohol, to ask whether sciatica could be treated by an injection of alcohol or distilled water into the sciatic nerve.

"*." We referred the question to Dr. Harris, who has been good enough to reply as follows: Alcohol must never be used for injection into the sciatic nerve for sciatica, owing to the severe paralysis of all the leg muscles below the knee that it would cause. I sometimes use Lange's method of massive saline injections into the nerve in the neighbourhood of the notch. The saline acts only as a mechanical agent in separating the nerve bundles and breaking down adhesions. 2 per cent. novocain is first injected into the nerve in order to reduce the pain of the saline injection.

INCOME TAX.

W. B. became a director of a limited company in May, 1919, at a fee of £65 a year. He received £65 in May, 1920, and this sum has been assessed to income tax as for the year to April, 1920, and reckoned as part of his income for that year. Is this correct?

"*." Such fees are assessable according to the amount receivable for the year of assessment, and that would be determined by the resolution under which "W. B." received his appointment. For instance, if it provided that he should be appointed as from May 5th, 1919, at a fee of £65 per annum, then the amount of income assessable for the year commencing April 5th, 1919, would be eleven-twelfths of £65—say £60; if the result be to raise the total income above any particular limit, the legal effect is to justify further assessments to adjust the original ones made before the additional income was dealt with by the authorities. "W. B." is liable to include the £65 in his statement of income for 1920-21, but is entitled to have any future assessment restricted to the appropriate proportion of the year if and when he should give up the directorship.

LETTERS, NOTES, ETC.

RATS AND PLAGUE.

WE are indebted to Sir John Tweedy for the following note:—With reference to Lieut.-Colonel R. Cobb's note in the *BRITISH MEDICAL JOURNAL* of June 12th, your readers may be interested to know that in a delightful little book entitled *The Land of the Two Rivers*, by Mr. Edwin Bevan, published two or three years ago, there is the following reference of the destruction of Sennacherib's army:

"On the borders of the desert between Palestine and Egypt the Assyrian army was mowed down by a sudden pestilence. The remnant had to take the homeward road as best it could. Long after, in Egypt, Herodotus was told the story how Sennacherib had come against Egypt, and how Pharaoh prayed to the god Ptah, and a horde of rats had attacked the Assyrian army and gnawed through their straps and bowstrings, so that they had to flee home. He was shown a statue of the Ethiopian Pharaoh holding a rat in his hand. The sculptor may have intended it as a symbol of plague."

In a footnote Mr. Bevan adds: "Apollo Smintheus, the sender of plague, is represented with his foot upon a rat (*Pausanias*, x. 12). When the Philistine cities are visited by the bubonic plague they pacify Yahweh by offering golden rats and golden bubos (*1 Samuel*, vi)."

THE VALUE OF COUNTER-IRRITATION.

DR. W. J. MIDLTON (Bournemouth), in the course of a note on this subject, writes: In support of my view that counter-irritation of the skin promotes destruction and elimination of germs I append notes of the following case: A woman of 44, whose father and two sisters had rheumatic fever and whose mother was consumptive, and who was the fourteenth child of eighteen, was as a girl physically and mentally weak, and did not walk until the age of ten. From infancy the left leg was shorter and weaker than the right, and she had pain in the left hip and knee. After her parents' death she earned her living as a dressmaker, and for five years was treated as an out-patient for (she said) "nervous and bilious attacks." In 1919 the left leg became much weaker, and she could only walk a short distance aided by sticks. She had "nerve storms" and "neuritis," and was wont to cry for hours at a time. When I first saw her on October 20th, 1919, she was thin, pale, and edentulous, with prominent eyes; the left leg was shorter and smaller than the right. The left hip and knee exhibited chronic osteo-arthritis, but were fairly movable. There were no definite physical signs in the lungs, but there was a well-marked systolic murmur. I treated her by making small dots (a few at first, increasing to thirty twice weekly) on the back over and at the sides of the vertebrae. She improved steadily in every way and can now walk two miles without a stick, she sleeps better, the pain and swelling in her knee are nearly gone, and she is able to do her work.

In my small book, *Continuous Counter-irritation in the Treatment of Nervous and other Diseases*, I called attention to the fact that a patient's troubles are by no means over when all the teeth have been removed. There are in the system thousands of small foci impossible to deal with except by general measures. In continuous counter-irritation I have satisfied myself that I have found a very potent means of reaching them. My patient was shown at a meeting of the local medical society on April 14th, 1920.

TREATMENT OF PSOROPTIC MANGE.

DR. J. S. MATTHEWS (Cape Town) writes: May I offer a protest against the unreasonably complicated laboratory method of dealing with the *Psoroptes cuniculi* occurring in rabbits' ears, detailed by Mr. J. E. Mellor on p. 316 of your issue of February 28th? All that is really necessary to effect a complete, painless, and speedy cure is to remove the flakes with forceps and swab thoroughly with 1 per cent. potassium permanganate. This is usually sufficient, as everything will be dead. Inspect a day or two later and remove any flakes which may remain, and reswab merely as a precaution. A third application was never required and the disease never recurred in the same stock. The hutches were disinfected, of course.

DRIED EGGS.

DR. ALETHIA J. BOLTON (Nottingham) writes: In my experience there has been a great increase in the number and severity of cases of indigestion in general practice during the last two or three years. This is attributed by patients to "war bread or margarine, low meat ration," etc.—in my opinion quite erroneously, as the reduced diet has on the whole benefited health. There must, however, be some cause, and I am anxious to know whether the "liquid eggs" so largely used in the manufacture of shop cakes, etc., should be blamed. I understand that the "dried eggs" are not toxic, but should like to know definitely, as I believe it to be a matter of grave importance.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 37, 41, 42, 43, 44 and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 38, 39, and 40.

THE following appointments of certifying factory surgeons are vacant: Buckhaven (Fife), Dulais Valley (Glamorgan), Parkhill (Ayr).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0 7 6
Each additional line...	0 1 3
Whole single column	6 0 0
Whole page	16 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the *British Medical Association* at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive post-*restante* letters addressed either in initials or numbers.

A Lecture

ON THE

EARLY SYMPTOMS AND DIAGNOSIS OF
DISEASES OF THE SPINAL CORD.DELIVERED BEFORE THE PLYMOUTH DIVISION OF THE BRITISH
MEDICAL ASSOCIATION, MAY 1ST, 1920,

BY

SIR F. W. MOTT, K.B.E., M.D., F.R.S.

WHEN the Plymouth Division of the British Medical Association did me the honour of asking me to give an address on the early symptoms and diagnosis of diseases of the spinal cord I readily accepted; but when I came to consider how I could best occupy the time permissible for such an address, I found considerable difficulty—not with what I *could* say on such a very important and extensive neurological subject, but what I could leave out. I will therefore be guided chiefly in the treatment of the subject by the difficulties I have experienced in differentiating early organic from functional disease, especially in the large number of cases which have passed through my hands during the last six years at the War Neurological Clearing Hospital in London.

The cases which presented the greatest difficulty were those in which the patients came under notice for subjective sensory phenomena, many of whom presented no objective signs.

SUBJECTIVE SENSORY SYMPTOMS.

The two subjective sensory symptoms which are the earliest evidence of disease of the spinal cord are pain and paraesthesia or dysaesthesia. They may be the sole symptoms. At first, of severe spinal cord disease, and it should be recognized that a patient who comes to a doctor complaining of localized pain or numbness, tingling, pins and needles, formication, or other abnormal sensations, presents the possibility of early signs of spinal cord disease.

Pain an Early Symptom of Spinal Cord Disease.

Pain is one of the most constant signs of all forms of disease; it is protective, and therefore constitutes an early symptom. When a patient comes complaining of pain in a part, the natural thing to do is to see whether there are any objective signs to account for the cause of the pain in the region where it appears. There may or there may not be signs. For example, a pain in the spine is a very frequent occurrence in the war psychoneuroses. Indeed, in my experience, only a very small percentage of cases complaining of pain in the spine suffered with disease of the spinal cord; and that is true in civil life as well as in military life.

A man may give a history of being blown up or of having fallen and sustained an injury of the back. He complains of pain and tenderness in the spine, which has caused him to lose the use of his legs or to walk with a bent back. Such cases came often under my notice. I will cite one in particular. A conscript had lost the use of his legs and suffered pain in the back following a fall; I examined his spine and told him to tell me exactly the spot where he felt the pain, percussing each spine as I went down. I marked with blue pencil the tender point; at the same time I remarked aloud that this was too low to affect the spinal cord, and he obliged me, when I percussed the spine again, by shifting it higher. Again I suggested that it was too low, and again he shifted it higher. I then tested his reflexes, and finding them normal, suggested that he should get up and walk, which he did.

Nevertheless, although the great majority of cases coming with pain in the spine and tenderness may be functional, occasionally cases occur in which there is organic disease. Thus a good soldier, a sergeant, who had been blown up and buried for three days, complained of pain on pressure over the fifth cervical vertebra on the left side. He had been regarded as a functional case of mild paraplegia. I found, however, a well marked extensor response of the big toe on the left side, absence of the abdominal reflex on that side; and an x-ray examination showed a fracture of the transverse process. I diagnosed

a resulting pachymeningitis. This has since spread, until now he has complete spastic paraplegia. Well, in this case, had his papers been filled up as "functional," he would not have received a gratuity nor an adequate pension.

Localized tenderness on pressure and pain of the spine which cannot be shifted by suggestion, should always be carefully investigated, even in the absence of any deformity and although a neuropathic tendency is obvious. Evidence of pain on movement of the spine in the various directions possible should not be neglected. The exact situation of the tenderness should be noted and the character and localization of the pains or abnormal sensations should be investigated—for this will give important information regarding the anatomical diagnosis. Pain and tenderness on pressure, combined with a localization of pain or paraesthesia in a skin area, corresponding to a segment or segments of the spinal cord, are of great diagnostic importance in caries and new growth of the spine, tumours, aneurysm eroding the spine, and extramedullary tumours affecting posterior roots. An x-ray examination will help to confirm the diagnosis, localize the disease, and indicate the treatment.

Pain in disease of the spinal cord is especially a sign of irritation of the spinal ganglia or sensory roots as they pass through the intervertebral foramina to the cord by a localized or general meningitis.

The Character of the Pain.

The pain due to early spinal cord disease is of a neuralgic character. It varies in severity and from time to time, according to the temperament and general health of the individual. It may be described by the patient as lancinating, boring, cutting, tearing, burning, and so severe may it be as to cause the patient to cry out. It may be continuous, dull, and confusive, with paroxysmal crises of acute pain. It is differentiated from true neuralgia and neuritis by its segmental topographical distribution. In neuralgia there are anatomical points, compression of which gives rise to pain. These neuralgic points are also the seat of pain in the nerve, and seem to be the point of departure of the paroxysms constituting the crises. Pains of a neuralgic type and especially severe, however, arise as a result of compression or irritation of the spinal roots or of the brachial, lumbar, or sacral plexuses. These pains are called *pseudo-neuralgic*, and are met with at the commencement of cases of compression of the spinal cord in caries of the spine, aneurysm of the descending aorta, in the paraplegia dolorosa of cancer, and in cases of irritation of the spinal roots from localized and general meningitis.

The pain of general or local meningitis is frequently associated with general or local muscular spasm and rigidity. This is very obvious when the cervical region is involved. In cervical caries there is local tenderness and rigidity, and if we see a patient supporting his head with both hands owing to pain in the neck, this is almost a sure indication that he is suffering from disease of the cervical vertebrae.

Sooner or later these root pains will be associated with objective sensory disturbances disposed in bands on the trunk and long strips on the limbs. The reason for this is seen in the distribution of the fibres of the posterior spinal ganglion.

Whereas pressure on nerve trunks in peripheral neuritis causes lively pains, this is not so obvious when a nerve is pressed in radiculitis (spinal root inflammation). But severe pain may be caused by sneezing, coughing, blowing the nose, or defaecation. The cause of root pain is a local or general meningitis affecting the posterior sensory roots in some part of their course from the intervertebral foramina to the spinal cord. Not infrequently, especially in syphilis, a diffuse meningitis is associated with the primary local condition, and that this exists is shown by a lymphocytosis of the cerebro-spinal fluid.

Syphilitic Meningitis a Frequent Cause of Root Irritation.

In the greater number of cases of spinal cord disease commencing with symptoms of local root irritation followed by a generalized spinal meningitis (often cerebro-spinal meningitis) syphilis is the cause, and in addition to an abundant lymphocytosis of the cerebro-spinal fluid, a

positive Wassermann reaction of the blood and fluid is obtainable.

The lumbo-sacral region is a frequent seat of root pain, but it may occur in the dorsal or cervical region in syphilis.

The initial lesion of tabes is marked by root pains of a lightning, stabbing, burning character, which are in all probability due to irritation of the rootlets of the posterior spinal ganglion at their entry into the cord. This irritation is probably set up by an inflammatory process in the membranes at the point of entry.

Segmental Pain and Herpes Zoster.

Severe neuralgic pain with a spinal segmental distribution does not always result in symptoms pointing to disease of the spinal cord, and the inflammatory process may affect only the posterior spinal ganglion. When this structure is acutely inflamed, "herpes zoster" appears in the area of distribution of the sensory nerve fibres issuing from the ganglion. The appearance of the eruption is usually followed by a cessation of pain. Intercostal neuralgia and pleurodynia are frequently diagnosed in early rachialgia due to organic disease affecting spinal roots.

Pain in Peripheral Neuritis.

Severe shooting pains in the limbs, especially the lower limbs, followed by objective signs of sensory disturbances, such as hyperaesthesia upon pressure of the calves, associated with anaesthesia to light touch and analgesia, occur in peripheral neuritis, but the history of the case and the distribution of the sensory disturbance will enable a differentiation between this and spinal cord disease to be made.

It must be remembered that in some cases the pains in peripheral neuritis may be of a lightning character and thereby simulate tabes, especially if there are ataxic symptoms and absence of the knee and Achilles jerks, but there is usually an associated motor affection in the form of paresis or paralysis, associated with wasting of the muscles. The pupils are normal, and the Wassermann reaction is negative.

Lightning Pains and Early Symptoms of Tabes.

It is noteworthy that in the pre-ataxic stage of tabes lightning pains occur, and yet Romberg's symptom may be absent and the knee jerks and Achilles jerks present. Hence these pains are often thought by the doctor to be due to rheumatism, muscular rheumatism, or neuritis. I have seen cases of tabes in the pre-ataxic stage where the deep reflexes have disappeared, first on one side and then on the other, after crises of pains. Lightning pains are rarely absent in ataxic patients; they constitute the earliest symptom. Often these pains are for a long time believed by the patient, and even sometimes by the doctor, to be rheumatic or neuritic in origin. It is rare that there is not some pupillary affection in this disease. Unequal pupils, irregular pupils inactive or sluggish to light and active to accommodation—the Argyll Robertson pupil—in conjunction with shooting pains in the limbs, are sufficient evidence to diagnose locomotor ataxy in the pre-ataxic stage. Cases of tabes occur where the knee jerks are present but the Achilles jerks are absent. These cases often show loss of bone sensibility to the vibrations of a tuning-fork.

Painful Visceral Disturbances an Early Symptom in Tabes.

Next to lightning pains bladder troubles are among the earliest and most constant symptoms of tabes; they are not severe, and, according to my experience, the patient does not usually seek the advice of a doctor for this reason. It is only as the result of inquiry, as a rule, that the patient in relating his symptoms mentions difficulties in starting micturition or holding his water.

Bladder crises have been described. They consist of violent pains which occur in the lower part of the belly, radiating to the inner side of the thigh. The patients have an urgent desire to micturate, but are unable; they experience the most severe burning and cutting pains in the urethra. These crises may last a few or many hours. Renal crises have also been described. These crises may simulate passage of a stone or gravel in a patient.

Gastric crises again are not infrequently the earliest symptom of the disease, and the attacks of pain and vomiting may be the cause for which the patient seeks advice. I have seen cases of visceral crises in which the surgeon has been called in with a view to operation for intestinal obstruction, and I have seen two patients, early cases of tabes with visceral crises, upon whom abdominal section had been performed. One patient had pus in the urine, probably owing to cystitis, but the surgeon found the kidneys healthy. Visceral crises may be the sole complaint in tabes of which the patient is conscious.

One patient of mine remained in the pre-ataxic stage twenty years, the sole symptom of the disease of which he was conscious being attacks of severe pain which extended both vertically and transversely between the shoulder blades and over the whole back; as soon as the pain became acute, vomiting would take place and relief would come. He had, however, Argyll Robertson pupils and thoracic anaesthesia to light touch.

Rectal and intestinal crises may also occur and are among the early symptoms of tabes. The patients complain of tenesmus and urgent desire to go to stool, of severe pain in the back passage, like the introduction of a hot iron; sometimes this is accompanied by tenesmus and straining. Laryngeal crises are a rare early symptom and the attacks are not so frequent as visceral crises.

The association of thoracic anaesthesia with visceral crises gives an anatomical explanation of their causation; the afferent visceral sympathetic nerves terminate in the posterior cornua of the spinal cord segments corresponding to the seat of the pain in the skin and the anaesthesia, the irritative inflammatory process that affects the posterior sensory roots innervating the skin irritates the afferent visceral fibres.

Again, painless spontaneous dislocation or fracture may be the first event to bring the patient under medical or surgical observation. Upon inquiry it will generally be found that these patients have had lightning pains which they attributed to rheumatism.

Impotence or satyriasis may be an early symptom of tabes.

The visceral as well as the somatic symptoms depend upon the anatomical seat of the irritative and destructive morbid process.

In all these early manifestations of tabes which bring the patient to the doctor, other signs or symptoms will be revealed by careful examination, the most frequent and important diagnostic clinical sign being the pupil phenomena. The Argyll Robertson pupil shows that a patient has tabes or is a candidate for it, and to me it is as sure a sign of syphilis as the chancre or the secondary eruption.

Girdle Pain an Early Symptom of Chronic Meningo-myelitis.

A girdle pain is common in tabes, but it is also an early symptom of a focal meningitis or meningo-myelitis of slow and progressive evolution, and marks the commencement of the affection.

This early symptom of root affection is very common in syphilitic disease of the spinal cord. The recognition of inflammatory root symptoms—namely, paraesthesia and girdle pains in syphilitic disease of the spinal cord—is a matter of great importance as regards early active treatment being successfully carried out before the inflammation has had time to spread to the spinal cord itself, producing thereby a transverse myelitis, which destroys the nervous structures and leads to ascending and descending degeneration of the tracts conveying sensory and motor impulses to and from the brain. Once this degeneration has occurred a permanent spastic paraplegia is installed, and no amount of specific treatment can restore the destroyed nerve fibres. I have recently seen an ex-service man who had all these warning symptoms, and yet no endeavour had been made to discover by a Wassermann reaction and examination of his fluid the cause of his symptoms and their progress until he became completely paralysed, when he came under my observation.

Syphilitic meningo-myelitis is the most frequent cause of paraplegia in young male adults, and root pains and dysaesthesia are the earliest warning symptoms. If treated in the early stage the results are surprisingly satisfactory. An idea unfortunately still lingers in the profession that affections of the nervous system are a late

tertiary manifestation of syphilis, in spite of the fact that Pournier long ago showed that the severest and largest number of cases of cerebro-spinal syphilis occurred within the first year after infection and diminished in severity and frequency with each successive year. Again, Jonathan Hutchinson pointed out that one-half of the cases of syphilitic paraplegia occurred within the first eighteen months after infection. These facts show how valuable is an examination of the cerebro-spinal fluid as an aid to diagnosis and subsequent treatment in all cases presenting possible symptoms of spinal cord disease. Thus a leucocytosis and discovery of the *Meningococcus intracellularis* is a positive proof of epidemic cerebro-spinal meningitis. A lymphocytosis points to either syphilis or tubercle, but a differential diagnosis is easily effected in a doubtful case by the results of a Wassermann reaction of the blood and fluid and attention to the history of the case, the clinical evidence, and the result of antisyphilitic treatment. I may mention that a lymphocytosis is present in practically every case of untreated syphilis or tabes, but the fluid does not always give a Wassermann reaction, although it may appear after a provocative dose of salvarsan.

DYSAESTHESIA.

Dysaesthesia is a very early symptom of spinal cord disease. Abnormal sensations, such as heaviness of the limbs, numbness, tingling, pins and needles, sensations of heat and cold in some part of the body, especially of the limbs, may bring the patient to the doctor. He may find him a neurasthenic, who has suffered with this symptom on and off for some time, or that it has recently commenced; in any case he should make a careful investigation to ascertain the cause.

The Conditions which Cause Dysaesthesia.

We are all familiar with the unpleasant effects of sitting for some time on a hard seat, thereby compressing the sciatic nerve: upon rising the leg feels heavy, there is a numb feeling associated with pins and needles. This is due to a temporary interruption, by the compression of the nerve, of the normal sensations which are continually contributing subconscious evidence of that part of our personality.

A number of morbid conditions besides compression of a nerve may cause dysaesthesia. They are:

1. Local transitory modifications of the circulation such as are met with in Raynaud's disease and erythromelalgia, due to vasomotor spasm. Also arterial circulatory disturbances in the limbs occasioned by atheroma, arterio-sclerosis, and endarteritis.
2. Reaction to cold.
3. Neuritis of traumatic, toxic, or infective origin.
4. Symptoms of dysaesthesia or, as these objective symptoms are also called, paraesthesia, especially of the extremities (acroparasthesia), are met with in neurasthenics. According to my experience subjective sensory symptoms of numbness and tingling of the extremities is a frequent symptom complained of by neurasthenics.

Having given the causes of dysaesthesia which may occur in other conditions than spinal cord disease, I will now pass on to the subject of dysaesthesia as an early symptom of spinal cord disease.

Dysaesthesia as an Early Symptom of Spinal Cord Disease.

Many of the conditions which give rise to neuralgic pains give rise to abnormal sensations of numbness, tingling, pins and needles—that is, in the prodromal periods of vertebral disease, intramedullary and extramedullary tumour, dysaesthesia may even precede the pain in these affections.

Again, dysaesthesia may be the first symptom in chronic spinal meningitis, acute or chronic myelitis, anterior poliomyelitis, myelomalacia, or thrombotic softening of the spinal cord, transverse syphilitic meningo-myelitis, and disseminated sclerosis. Therefore, when this symptom is complained of, even in the absence of objective signs of disease, it is imperative carefully to investigate the probable causation, look for objective sensory disturbances, examine the condition of the reflexes, and note if there is any evidence of motor weakness.

OBJECTIVE DISORDERS OF SENSIBILITY.

Total anaesthesia in disease of the spinal cord only occurs in cases where there is a complete transverse lesion, such as occurs in fracture dislocation, bullet wound, or severe meningo-myelitis caused by compression or disease; the prognosis is always grave. In meningo-myelitis the subjective sensory symptoms previously described and hyperaesthesia precede the anaesthesia in all cases arising from focal myelitis, or radiculitis, or diffuse myelitis.

Dissociated anaesthesia is more frequent and more important as a diagnostic sign than total anaesthesia in the localization of lesions. By dissociation I mean that all modes of sensation are not affected, or not affected to an equal degree. Superficial sensibility to a light touch with a wisp of cotton-wool, to pricking, and to heat and cold may coexist with unimpaired deep sensibility. An anaesthesia to light touch may be associated with the preservation of pain sensibility, and even so exaggerated that touch sensations are only recognizable as painful (anaesthesia dolorosa). This sensory dissociation may be met with in peripheral neuritis and in cases of compression and irritation of roots. In syringomyelia and haematomyelia, where the grey matter is disorganized, pain, heat and cold sensations are not felt but tactile sensations are.

Diseases of Spinal Cord in which Sensory Phenomena are Transitory or Absent.

There are certain diseases of the spinal cord in which sensory phenomena are transitory or absent.

Anterior poliomyelitis, an infective disease with an acute onset, is ushered in by fever, malaise (frequently vomiting), associated with numbness, tingling, and pins and needles in the limbs, followed in a few hours by a flaccid paralysis of the muscles, proceeding to wasting, with reaction of degeneration and permanent atrophy of some groups. The anatomical lesion is an inflammation affecting especially the anterior horns; the spinal motor neurones are damaged or destroyed, consequently the motor fibres degenerate and with them the muscles they innervate. The posterior spinal ganglia—the trophic centre of the sensory fibres—is not involved; consequently they do not degenerate, and the sensory symptoms are therefore only transitory.

In progressive muscular atrophy there is a progressive and insidious decay and destruction of the spinal motor neurones, and as they degenerate and die, the muscle fibres, which they innervate, degenerate and undergo atrophy. The characteristic fibrillary twitchings in the degenerating muscles is evidence of the increased irritability of the degenerating fibres. There is no sensory disturbance of function in this disease, as the sensory neurones are not affected. Amyotrophic lateral sclerosis is a degenerative disease, not only of the spinal motor neurones innervating the muscles but also of the cortico-spinal neurones which carry voluntary impulses from the brain by the pyramidal tracts to the spinal motor neurones which they control. In this disease also there is no sensory trouble. Both these diseases—progressive muscular atrophy and amyotrophic lateral sclerosis—tend to affect early the small muscles of the hand and shoulder girdle. In amyotrophic lateral sclerosis there is a wasting of muscles associated with exaggerated deep reflexes, patellar and ankle clonus and plantar extensor response; these form the early symptoms of the disease.

Another disease probably infective in origin but of extreme importance is disseminated sclerosis. This disease is easy of diagnosis when such cerebral symptoms are present as intentional tremors, staccato speech, nystagmus, and optic atrophy, but when only spinal cord symptoms are in evidence it is very apt to be mistaken for functional disease. Not infrequently dysaesthesia—namely, numbness, tingling, pins and needles in the limbs—marks the onset of the disease; this is followed in some cases by temporary anaesthesia; the patient then suffers with a spastic condition of the legs associated with a certain amount of paralysis or paresis, inco-ordination and difficulty or awkwardness in gait and station. When these symptoms are accompanied—as they often are in young women—by emotional symptoms, an erroneous diagnosis of hysteria may be made, especially if a systematic examination of the superficial and deep reflexes is not made. Absence of the epigastric and

abdominal reflexes on one or both sides, exaggeration of the knee-jerks, patellar clonus, ankle clonus, and—most important—plantar extensor response of the big toe, with fanning of the other toes, paresis, loss of sense of position, and diminution of bone sensibility show that there is a lesion involving the pyramidal tracts and the posterior column. The superficial sensibility is usually unaffected.

THE IMPORTANCE OF ANATOMICAL DIAGNOSIS IN PROGNOSIS AND IN CASES WHERE SURGICAL INTERFERENCE MAY BE CONTEMPLATED.

The diagnosis of the exact localization of disease of the spinal cord is of great importance from two points of view—namely, in prognosis and in the rare cases where surgical interference is contemplated.

The prognosis is always most grave where there is clinical evidence of extensive diffuse myelitis and where the lesion affects certain regions of the spinal cord owing to dangerous symptoms and complications arising. These lesions in the upper cervical region may affect the phrenic neurones. Again, a lesion in which the symptoms point to a complete transverse myelitis is evident by an absolute loss of sensibility below the lesion paraplegia and loss of control over the sphincters. In such cases cystitis and secondary infective nephritis are liable to occur; also large sacral bedsores, unless great care be taken by the doctor and nurse.

When the lesion affects the lumbo-sacral region and the lower motor neurones are destroyed there is, in addition, atrophy with reaction of degeneration of the muscles of the lower extremities; the sphincter troubles are more serious and bedsores are almost sure to occur in spite of careful treatment and nursing.

Anatomical Diagnosis in Relation to Surgical Interference.

A precise anatomical diagnosis in cases of extramedullary tumour of the spinal cord and meningitis circumscripta is essential before operative interference can even be contemplated. Extramedullary tumour is really a more hopeful surgical operation than cerebral tumour. The difficulty of diagnosis lies, however, in the fact that we cannot always be sure that the tumour is outside the cord. It may be intramedullary. The existence of definite symptoms of root irritation prior to pressure symptoms serves as a means of localization of the situation of the tumour and affords evidence of its extramedullary situation.

The earliest symptom noticed by the patient in extramedullary tumour is pain or paraesthesia, generally on one side and only in the area of distribution of a root and associated with hyperaesthesia of the corresponding skin area. As the tumour increases in size it produces sooner or later a unilateral compression of the spinal cord of the same side, and this causes an interruption of sensory and motor tracts.

Now it frequently happens in these cases that a sensory dissociation known as the Brown-Séguard phenomenon is found—namely, there is loss of sensibility to pain, heat, and cold of the side opposite to the lesion and paralysis and loss of tactile kinaesthetic sense on the same side as the lesion. This can be explained on anatomical grounds. The fibres conveying sensations of heat and cold and pain decussate to the opposite side almost immediately in the grey matter, whereas the fibres conveying tactile kinaesthetic impressions do not decussate until they reach the medulla. The existence of compression in the pyramidal tract fibres is shown by weakness or loss of voluntary power in the limb, dragging of the foot, increase of deep reflexes, ankle clonus, and plantar extensor response. If unrelieved the pressure increases as the tumour grows and a complete paraplegia results.

These cases of slow-growing benign extramedullary tumour may be easily missed in the early stages and the case regarded as functional, unless a very careful and methodical examination is made, and that leads me to say a few words in conclusion regarding the differential diagnosis of spinal cord disease and hysteria in its multiform simulations.

Diagnosis of Functional Diseases.

The experiences of the great war have given us innumerable instances in support of Babinski's view that these

functional disabilities are the result of auto- or hetero-suggestion, and can be cured by suggestion or persuasion.

I do not, however, hold with those authorities who think it unnecessary or undesirable carefully to examine a case to enable them to exclude organic disease. Certainly there is a danger of suggesting to the patient symptoms, especially in respect of sensory disturbances, but after you have made a careful and methodical examination of the superficial and deep reflexes and found them all normal, you are justified in arriving at the conclusion that the contracture, paralysis, or inability to stand or walk (astasia abasia), which may have even existed for months or years, is the result of auto- or hetero-suggestion, and you can then with confidence assure your patient that he can be cured. In these functional cases, moreover, even after prolonged disuse of the limbs, there is little or no wasting, and the muscles all respond normally to electrical stimulation. I would remind you that in long-standing functional cases there is acrocyanosis and coldness of the feet, so that no response occurs to stimulus of the sole. If the foot be warmed the response can be obtained.

The recognition of functional sensory disabilities simulating spinal cord disease is easy: the superficial sensibility to pain, heat and cold, and touch is lost completely; there is no dissociation, neither the anaesthesia nor the pains complained of conform to the anatomical distribution of spinal roots or peripheral nerves. In the limbs the superficial anaesthesia takes the form of a stocking or gaitlet, and can easily be removed by suggestion, the restoration of sensibility being from above downwards. The secret of success in the treatment of these functional cases is faith: consequently, in the first treatment you must not leave the patient until you have established that by bettering or curing the disability. It may take minutes; it may take hours.

However, among the very numerous cases of functional disability there are many cases of organic disease of the spinal cord with a large halo of functional disturbance, which can be removed by various methods of suggestion, by re-education and various other forms of encouragement. But the fact must not therefore be overlooked that such a patient, in spite of the satisfactory results of such treatment, is suffering with a permanent disability, which may progress in spite of improvement by the treatment.

From what I have said it is clearly necessary to decide by examination: First, whether the case is functional or organic. Secondly, if organic, in order to form a correct judgement regarding prognosis and treatment, it is essential to diagnose the pathological nature of the lesion and its anatomical situation.

In conclusion, I would ask you to bear in mind that more mistakes are made from not looking than from not knowing.

THE LABYRINTHINE REACTIONS OF EXPERIENCED AVIATORS.

BY

DAVID RANKEN, M.S.LOND., F.R.C.S.ENG.,
SQUADRON LEADER R.A.F. MEDICAL SERVICE.

This investigation was undertaken in order to ascertain the difference, if any, between the labyrinthine reactions of experienced pilots and those of the average individual of the same age who has done no flying. In the American Air Force the Bárány rotation tests have played a much more important part in the acceptance or rejection of aviation candidates than in our own, and it is stated by Colonel Isaac Jones of the American Air Force, in his book entitled *Equilibrium and Vertigo*, that in addition to the majority of aviation candidates, all experienced pilots so far examined by them have without exception shown normal responses to their routine standards in the turning chair.

As the Aviation Candidates Medical Board, Hampstead, has during the last eighteen months examined several hundreds of experienced pilots for civilian aviation, the present seemed a suitable time for such an investigation. All tests employed have been performed as closely as possible in conformity with the rules laid down for the

American Air Force in order that the results obtained might be strictly comparable.

The points investigated were:

1. (a) The average amount of nystagmus, past-pointing, and vertigo in pilots who have from 100 to 1,000 hours to their credit. (b) As (a), but in pilots who have flown more than 1,000 hours.
2. The difference, if any, between the reaction sensibility of the right and left labyrinths.
3. The reasons for unduly high or low periods or errors.
4. The relation, if any, between these tests and others in use at the Aviation Candidates Medical Board.
5. The value of these tests from the point of view of the medical selection of pilots.

1. *Average Nystagmus Periods.*

(a) The average nystagmus periods of 100 pilots with from 100 to 1,000 hours in the air to their credit were:

- (i) After turning to the right ten times ... 22.6 secs.
- (ii) After turning to the left ten times ... 23 secs.

(b) The average nystagmus periods of 50 pilots with over 1,000 hours to their credit were:

- (i) After turning to the right ten times ... 20.6 secs.
- (ii) After turning to the left ten times ... 21.82 secs.

On comparing these two sets of figures it will be noticed that the first pair is a trifle higher than the second pair, both also being slightly lower than those laid down by the American Air Force—that is, 26 seconds after turning to either the right or the left, as the normal average. It will also be noted that the response in both cases is slightly higher after turning to the left than to the right—that is, after stimulating the right than the left labyrinth, as rotation to the left stimulates and produces impulses mainly from the labyrinth of the opposite side, and vice versa.

Past-Pointing.

The average past-pointing in 50 pilots with 100 to 1,000 hours to their credit was:

- (i) After turning to the right ten times ... 2.5 errors
- (ii) After turning to the left ten times ... 2 errors

In the case of 50 pilots with over 1,000 hours to their credit the figures were:

- (i) After turning to the right ten times ... 2.25 errors
- (ii) After turning to the left ten times ... 1.8 errors

It will again be noticed that the first pair of figures is slightly higher than the second pair. It would seem at first sight also that stimulation of the left labyrinth causes more reaction and consequent error than that of the right. A more probable explanation, however, is that in routine testing all pilots were turned to the right first, and a preliminary education thus gained in pointing errors caused them, consciously or subconsciously, to expect, allow for, and compensate the tendency to such errors on being turned in the opposite direction—that is, to the left. Of all three tests, this would seem the one where erroneous results are most easily obtained, for the above reason.

Vertigo.

It is in the case of the vertigo periods, however, that the most striking results were obtained. The vertigo periods are considered by some to be identical with the nystagmus periods—that is, 26 seconds after turning to the right and 26 seconds after turning to the left.

In the case of 50 pilots with 100 to 1,000 hours to their credit the average vertigo periods were:

- After turning to the right ten times ... 13.5 secs.
- After turning to the left ten times ... 11.7 secs.

In the case of 20 pilots with over 1,000 hours to their credit the average vertigo periods were:

- After turning to the right ten times ... 13.1 secs.
- After turning to the left ten times ... 12.4 secs.

The outstanding feature in these pairs of figures is that they only amount to about half as much as those assumed to be the average for the normal individual. If this assumption were correct one might be justified in believing that the majority of aviators acquire a diminished vertigo period consonant with their flying experience. At a recent examination of cadets for the Air Force, however—youths of about 18 years of age who had never been up in the air—the writer found that the average

vertigo period after turning ten times to the right was 15.4 seconds, and after turning to the left 15.3 seconds. One can only say therefore that in the case of the nystagmus and past-pointing—the average number of errors in the last named is taken to be three after turning to either right or left—there appears to be a very slight gradation of reaction sensibility of the labyrinths, greatest in those who have done no flying and gradually diminishing according to the number of hours done in the air, and that the statement cannot be corroborated that 26 seconds is the average vertigo time of the normal individual or of the experienced pilot.

2. *The Relative Reaction Sensibility of the Right and Left Labyrinths.*

Bearing in mind that turning to the right chiefly stimulates the left labyrinth and vice versa, it is interesting to compare the above nystagmus, past-pointing, and vertigo figures. From them it would seem that stimulation of the right labyrinth produces less past-pointing and vertigo, but a longer nystagmus period than stimulation of the left labyrinth.

The number and extent of the difference are too small for dogma, but it may be stated that a series of cases was taken with the idea of discovering whether there is a guiding labyrinth, and whether it differs in right- and left-handed people.

Out of 71 right-handed pilots it was found on interrogation and after trying to eliminate such influences as training, talk of the machines, etc., that 29 preferred to turn in the air to the left, 12 to the right, and 30 were indifferent whether they turned to the right or left—in other words, the preponderance of right-handed pilots prefer to turn to the left, which act stimulates principally their right labyrinth. Only six genuine left-handed pilots were examined, and it was considered that this number was too small to form any just idea of the preferences of naturally left-handed individuals.

3. *Reasons for Excess or Diminution in the Extent of Labyrinthine Reaction.*

In order to discover whether all experienced pilots satisfy the labyrinthine reactions laid down as standards, the nystagmus times and past-pointing errors of 100 pilots were investigated and compared. In all, therefore, four tests were employed, namely:

1. Nystagmus after turning to the right.
2. Nystagmus after turning to the left.
3. Past-pointing after turning to the right.
4. Past-pointing after turning to the left.

Of 100 experienced pilots three failed to satisfy the standards in all four tests; two failed to satisfy in three tests; seven failed to satisfy in two tests.

A certain number of others failed in one result only. This was always the second past-pointing test and possibly due to previous experience of error as explained above.

Of the seven who did not satisfy in two tests, these were always nystagmus results, and furthermore all were below and none above the time limits save one where the periods were thirty-seven and thirty-nine seconds respectively. It may here be noted that American standards allow anything between sixteen seconds and thirty-six seconds.

Of the two who did not satisfy in three findings—that is, both nystagmus and one past-pointing test—one had suffered during the previous year from nervous debility, and showed signs of it in the other tests performed at the examination. His vision also was defective—right eye $\frac{2}{20}$, left eye $\frac{1}{20}$ —and although no heterophoria was present, the nystagmus periods were not easy to take owing to a seeming difficulty of the eyes to fixate after rotation. He had previously done 3,500 hours in the air, and a recent report from his squadron stated that in practice his vision and flying were satisfactory. He did not wear glasses.

The other, with 800 flying hours to his credit, had normal vision and muscle balance. Four years previously he had spent six weeks in bed with diphtheria. There were apparently no complications, but he was advised by his doctor not to fly for some time. He had consequently flown only once in three years, so that his experience in the air could hardly be called recent; still on rigid standards he would have been rejected as an aviation candidate.

Of the three who failed to satisfy in all four tests, one had done 480 hours between April, 1918, and January, 1919. He had recently suffered from influenza and malaria and was only two weeks out of hospital. He still suffered from headaches. His vision and muscle balance were normal.

The second, who had 5,000 hours in the air to his credit, had just recovered from an attack of jaundice—cause unknown—at the time of examination. He had had a previous attack in 1915. His vision and muscle balance were normal.

The third had suffered from a nervous breakdown one year before, and influenza and pneumonia six months previously. He had recently done 750 hours in the air. His vision and muscle balance were normal and no nervous symptoms were present at the time of examination.

It would seem, therefore, that although definite failure in one or more of these tests is not enough, *per se*, on which to reject a candidate, still a combination of three or four failures is often accompanied by evidence of actual or recent impairment of one or other of the various systems of the body. It is noteworthy also that, in practically every case that could not be said to satisfy rigid standards, failure was due to inability to reach the minimum rather than to exceed the maximum limit, there evidently being a decided tendency towards diminished rather than increased labyrinthine reaction sensibility.

4. Relationship between these Tests and others Used by the Aviation Candidates Medical Board, Hampstead.

In order to see if there is any relationship between the results of these tests and those employed routinely by the Aviation Candidates Medical Board a series of 100 cases was taken and a comparison made. The tests selected for comparison were three in number—namely, tremor of eyelids or hands, self-balancing, and the rod and board test. It was found, however, that a pilot might have what are accepted as normal labyrinthine reactions and yet at the same time perform only moderately or badly one, two, or all three of the above-mentioned tests. Of the pilots discussed under (3), only one of the three with all four labyrinthine reactions unsatisfactory was poor in two tests—namely, self-balancing and the rod and board test; the other two performed all the tests satisfactorily. In addition, in the case of the other pilots discussed under (3), abnormal labyrinthine reactions seemed to bear no relationship at all to the successful execution or otherwise of these three tests. This is perhaps not surprising, as the turning reactions only test the integrity and tone of the cerebro-cerebellar-vestibular tracts, whereas it is well known that many factors may enter into the successful execution of the other tests cited.

5. Value of these Tests from the Point of View of the Medical Selection of Pilots.

At present, and until other and perhaps surer standards are laid down, one is inclined to view the utility of these rotation tests, at all events from the point of view of routine examination, as being problematical. It is true that they may draw attention in certain instances to particular defects which might or might not have been otherwise noted, but, on the other hand, their rigid observance might easily exclude men whose past histories and recent performances are those of perfectly successful pilots. Their value, however, and the data they give to anyone capable of interpreting such information is undoubtedly great in certain instances, as the following two cases recently seen by myself will show:

CASE I.

Lieutenant L. complained of deafness in the left ear incurred in May, 1918. The history was that whilst descending, and about 700 feet from the ground, he felt a tightness in the head and a mist before his eyes. He made a bad landing—"pancake"—was so dizzy on attempting to alight that he could not keep his feet, and had to be taken to his quarters on an ambulance and put to bed. He did not vomit, but things seemed to go round him to the right and he slept badly. During the next few days he was very shaky on his feet when attempting to walk. About two weeks later he was permitted to start flying again. He is now unable to stay long in the air and is always sick should he remain up as long as an hour. Before his accident he was a good stunter, but now either cannot or dare not stunt. On examination he was found to be totally deaf in the left ear, and his nystagmus and past-pointing indicated impairment of the left labyrinth; he was actually sick whilst being tested. The caloric test confirmed the view that his left labyrinth was not functioning, so that here was a pilot with a completely destroyed left labyrinth whose defect had unfortunately not been recognized, and who, being allowed to fly was a constant danger to himself and anyone else who happened to be his observer.

CASE II.

Lieutenant G. was, in May, 1917, in a balloon which was struck by lightning; the telephone receivers were in his ears at the time. The balloon was immediately hauled down, but he felt "overpowered by dizziness," which was accentuated when attempting to walk to his hut after reaching the ground. He also noticed that he was quite deaf in the left ear. After a week's leave he was again put on balloon duty and managed to continue for three months. During this time he always felt uncomfortable and dizzy in the air, though never troubled similarly before the accident. At the end of these three months he was, fortunately for himself, transferred to ground duties. On recent examination for assessment of gratuity,

I found him to be completely deaf in the left ear, and the rotation and caloric tests showed a functionless left labyrinth. Like Case I, this was an undiagnosed case of a destroyed labyrinth, which only careful rotation and caloric tests could demonstrate.

CONCLUSIONS.

1. Experienced pilots have, if anything, a slight tendency towards diminished labyrinthine reactions.
2. Disturbance, present or past, of some other system of the body may affect labyrinthine reactions.
3. Where deafness is present no medical examination of a candidate or pilot is complete without a careful investigation of the functions and reactions of the semicircular canals of both sides.
4. In the absence of a discovery of present or past signs or symptoms pointing to an aural affection, routine examination by means of the Bárány tests is superfluous, provided that a thorough general medical examination is made.

THE EFFECTS OF RADIUM TREATMENT ON WAR INJURIES IN THE NEIGHBOURHOOD OF NERVES.*

BY

WALTER C. STEVENSON, M.D. DUB.,

CAPTAIN R.A.M.C., HOME HOSPITALS RESERVE.

SURGEON TO DR. STEVENSON'S HOSPITAL AND TO THE INCORPORATED ORTHOPAEDIC (CHILDREN'S) HOSPITAL OF IRELAND, DUBLIN.

THAT radium in suitable doses does not injure nerve tissue is shown by the work of Mme. Fabre and Dr. Paul Touchard on five cases of syringomyelia, all of which improved, showing increased mobility of the limbs with diminution of stiffness. One patient's hand had been quite helpless in a *main en griffe* position, but after radium treatment she was able to flex, extend, and separate her fingers. A second was able to resume his work as a draughtsman after six months' disuse of pencil and compasses. Another remarkable fact was the disappearance, in one case, of the trophic disturbances characteristic of Morvan's disease.¹

The conclusion that the powerful physical agent (the gamma rays from radium C) has some effect on injured nerve areas was forced on me, more or less by accident, in the following case:

CASE I.

Pte. S. fell off a transport wagon on March 15th, 1917, fractured the anatomical neck of his left humerus and injured his brachial plexus. When admitted to the Special Military Surgical Hospital, Blackrock, over eight months later, he had limited movement of the shoulder and little power to move his wrist; he was unable to flex his thumb and fingers, especially at the distal joints. Sensation in the hand and wrist, except over the ulnar distribution, was impaired. His first three fingers were discoloured, and there were trophic changes of the nails of the second and third fingers. On December 31st, 1917, graphs of the movements of the wrist and fingers were made with the aid of a strip of lead, as is the routine in this massage department. On January 18th, 1918, with the purpose of increasing the movement in the shoulder-joint, 100 millicuries of radium emanation screened by 2 mm. of lead in a flat applicator, kindly sent me by Dr. Lynham of the London Radium Institute, was applied for two hours in the axilla, and for two hours each on the front and back of the joint. Two days later the masseuse brought the patient to me and asked why he could flex and extend his wrist better and flex his fingers better, and why the discoloration of his fingers was less when radium was only applied to the shoulder. The graphs, which I have before me, taken on January 3rd, 1918, are conclusive evidence of an increase of voluntary movement, which cannot be explained by any change of weather or treatment, nor by suggestion, for it was not expected. The movement in the shoulder was practically unaltered except that voluntary abduction was temporarily reduced from 63 degrees to 59 degrees.

It is difficult to explain the effect of radium in the foregoing and following cases. I can only report the results of careful observations and accurate records in which I have eliminated as far as possible the many sources of error, especially suggestion. The sudden improvement in movements cannot be explained by greater personal attention to a patient, muscle re-education, the recent removal of a splint, or any change of environment or treatment that I am aware of. That radium will within six hours

* Paper read before the Section of Surgery, Royal Academy of Medicine in Ireland, November 21st, 1919.

alter the microscopic appearance of malignant cells has been proved by Morson;² that it will free or loosen scar tissue, and also that in some cases it will act like a charm in removing the pain and tenderness in a scar, I have demonstrated frequently. It has an anaesthetic as well as an analgesic effect.²

Radium cannot be expected to work miracles and materially benefit gross nerve lesions; it would appear, however, to stimulate normal functional activity in nerve tissues which have been injured but are on the road to recovery, either by softening the scar tissue around them, or by some action on the nerve cells themselves, possibly by improving their nutrition. In some cases radiation appears to lessen hyperactivity in a nerve which is being irritated by scar tissue.

When one realizes the number of nerve lesions that have occurred in this war, and the long periods during which one has to wait for recovery after nerve suture, any treatment that presents possibilities of shortening the period of incapacity is worth considering. On this account the following cases are, I believe, worth recording. All the patients except the first were treated by radium emanation supplied by the Royal Dublin Society, Radium Institute. I use a surface applicator of 1.5 mm. thickness of lead, as described in detail elsewhere.³

CASE II.

Pensioner A. fell 30 feet on April 23th, 1916, and fractured the lower part of his spine. On February 13th, 1917, his left leg was flaccid, the right leg spastic; he was incontinent, and could move about with difficulty on crutches. On December 23th there was no response to either current in the right extensor longus hallucis, or in dorsiflexors of foot or peronei on left. January 3rd, 1918: Radium applied to spine. January 7th: Patient stated that for the first time he felt that his feet were cold. A good response to galvanism was obtained in the dorsiflexors and evertors of the left foot and a slight response in the right extensor longus hallucis, ACC > KCC in each case. On January 10th, 1918, the patient could get about more easily on his crutches.

CASE III.

This case, Major B., should perhaps not be included here, as the patient's hand and wrist were radiated as well as the wounded area in the upper arm. He was wounded on February 10th, 1917; the musculo-spiral nerve was freed on May 17th, and the median on June 17th, 1917, by Mr. William Taylor at the Castle Hospital, Dublin, where he attended for massage. During the first six months of treatment he improved greatly, but for three months before I saw him the masseuse informed me there had been little or no improvement in the fingers and wrist. Radium was applied on February 19th, 1918, and I left Dublin a couple of days later. On March 10th the patient wrote: "I believe you have had the diagrams of my hand showing the enormous improvement it made in ten days. I think the results were extraordinarily good." The graphs verify his statements. I applied radium again on April 3rd, 1918, and shortly afterwards he was passed for homeservice.

CASE IV.

Pte. C. The median nerve, partially divided in the lower forearm, was sutured by Major W. S. Haughton on November 12th, 1917. On December 16th radium was applied for prevention of post-operative scar, and on the 17th there was some pain in the palm where it had been anaesthetic; voluntary extension of the wrist and extension and flexion of the fingers, which had been rigid from muscle spasm, now became possible. On January 9th, 1918, there was marked improvement in the movement of the wrist and fingers.

CASE V.

Pte. D. was wounded on the ulnar side of the forearm on December 11th, 1917. Limited voluntary flexion and extension of all joints of the hand. For months any attempt voluntarily to move the fingers had caused violent intention tremors. Radium applied to scar on August 9th, 1918. On the 12th the tremors had markedly diminished, and the patient had a much larger range of voluntary movement.

CASE VI.

Pte. E. was wounded through the left shoulder and chest on October 9th, 1917. He had pain in the scar at the back of the chest, recovering wrist-drop, and hyperextension of the fingers at the metacarpo-phalangeal joints. Radium given on September 21st, 1918, in the front of the shoulder, axilla, and over the scar. Three days later there was some improvement of flexion of the fingers; extension of wrist was much improved. Abduction of the shoulder had increased by 13 degrees, and the scar on the chest was less painful and tender.

CASE VII.

Pte. F., wounded in the left elbow on March 23rd, 1918; brachial artery severed and tied at both ends. Elbow could not be completely extended; hand red and congested, radial artery small. Radium was applied to front of elbow on August 6th, 1918. On the 24th he was seen with Major Haughton, who

agreed that the colour of the hand and the radial pulse were improved; he could extend his elbow completely, and the pronation of the forearm and power of grip were increased as shown by measurements.

CASE VIII.

Pte. G., wounded in right upper arm on July 18th, 1916; trophic changes first and second fingers. Median nerve freed from scar by Lieut.-Colonel W. L. de C. Wheeler on August 9th, 1917. On December 21st, 1917, radium was applied to the operation scar in the upper arm. Next day, opposition of thumb to little finger, which before treatment had been very slowly performed, was now briskly carried out; increase in range of movement of fingers and wrist, except flexion of first interphalangeal joint of first finger, which was limited. A week later further improvement was shown in graphs.

CASE IX.

Pte. H., wounded in left leg, March 16th, 1918; the divided external popliteal nerve was sutured by Major Haughton on August 12th, 1918. *Electric reactions:* Slight response in tibialis anticus to galvanic, none to faradic current; other muscles could not be tested on account of the current causing cramp in the foot. On August 21st radium was applied to the wound and operation scars. Next day the electrical reactions were greatly improved; response to galvanic current and slight flicker of movement to faradic current in the tibialis anticus; no response in other muscles, but no cramp as previously.

CASE X.

L.-Cpl. I., wounded middle left forearm, September 8th, 1916; two inches of median excised and nerve sutured by Major Haughton. On December 15th, 1917, graphs of the finger were taken immediately after massage. On December 16th radium was applied over the sutured nerve to limit the secondary scar of the operation. Next day there was some tenderness in the palm where it had previously been anaesthetic. Graphs taken before massage showed considerable improvement in flexion of fingers, following the application of radium; graphs made immediately after massage showed more than double this range of flexion.

CASE XI.

Pte. J. Wounded in the left shoulder on May 29th, 1917. Operation on median nerve near axilla February 4th, 1918. Hyperaesthesia of hand in region of median nerve distribution. Radium applied March 17th, 1918. Captain Alexander, in charge of the electro-therapeutic department, Alder Hey, reported three days later that there was no improvement in the hyperaesthesia, which had spread to the second finger and also to the radial area. Slight improvement in movement of shoulder.

CASE XII.

Pte. K. Wounded on September 26th, 1917, in the right shoulder, right arm, and immediately above the elbow. Radium was applied in these three localities on April 13th, 1918; the result was diminished tenderness of the scar near the elbow and some improved movement of the fingers. Again treated with radium June 27th, 1918; the movements of fingers before and after were accurately measured by a goniometer. The increase of voluntary and passive movement was as follows:

	Metacarpo-phalangeal Joint.		First Interphalangeal Joint.		Second Interphalangeal Joint.	
	Active.	Passive.	Active.	Passive.	Active.	Passive.
Index finger ...	25°	20°	30°	37°	6°	
Middle finger ...	9°	9°	30°	27°	9°	
Ring finger ...	19°	19°	17°	42°	5°	30°
Little finger ...	20°	13°	16°	20°	5°	

The angles of movement show that after radium treatment the patient could voluntarily flex his fully extended fingers as far as I could force them before radium, while the distance through which I could force them was further increased. For instance, at the index metacarpo-phalangeal joint before radium he could flex voluntarily to 52 degrees and I could force the finger to 72 degrees, while after radium he could voluntarily flex to 77 degrees and I could force it to an angle of 92 degrees. On July 1st, 1918, Captain Lloyd Roberts, neurologist, Alder Hey, examined the hand and noted the improvement in the voluntary movements and pliability of the fingers, though the electrical reactions were not changed since last examined by him on June 22nd; he suggested that the results were due to improved nutrition following radium treatment.

With the exception of a painful bulb in the ulnar nerve, where no improvement was apparent after radium treatment, the above cases include all of this type I can find in my notes of some 300 military patients treated at Black-rock, Alder Hey, and Shepherd's Bush Special Military Surgical Hospitals. Taken separately the cases may not be convincing, but taken collectively the weight of evidence

is that radium treatment serves a very useful purpose in certain types of nerve trauma and in certain stages in the repair of nerve injuries. The conclusions to be drawn from this work with radium in the treatment of war injuries affecting nerves can be summarized as follows:

1. Radium treatment cannot benefit gross nerve lesions; here operative treatment is indicated, to unite severed nerves or free them from dense scar tissue.
2. After a nerve operation, or after milder degrees of nerve trauma, it would appear to aid and to hasten the return of function in a limb.
3. It improves the nutrition in the area supplied by injured nerves.
4. It may be useful as an aid to diagnosis, and in certain cases will indicate or contra-indicate the necessity of operation.
5. It is a valuable adjunct to other forms of treatment.

ON POISONING BY ARSENOBENZOL COMPOUNDS USED IN THE TREATMENT OF SYPHILIS.

BY

ALEXANDER G. R. FOULERTON, F.R.C.S.,

LECTURER ON HYGIENE TO THE LONDON SCHOOL OF MEDICINE FOR WOMEN, AND LECTURER IN THE HYGIENE DEPARTMENT OF UNIVERSITY COLLEGE, LONDON; COUNTY MEDICAL OFFICER OF HEALTH FOR EAST SUSSEX.

BEFORE considering the toxic action of arsenobenzol compounds it will be convenient, since the essential pathological processes appear to be closely similar in either case, to refer to a paper² published in 1918 which dealt with the pathology of another group of cases of poisoning in which what is termed toxic jaundice is a characteristic symptom, and in which there are found after death an infiltration of the liver and kidneys with fat, and in some cases an acute atrophy of the former gland. Six poisons, all of which have a special affinity for fats, were referred to as belonging to this group; three of them—chloroform, ether, and tetrachlorethane—are active fat solvents, and the other three—phosphorus, dinitrobenzene (D.N.B.), and trinitrotoluene (T.N.T.)—are readily soluble in fats.

The essential process of poisoning in these cases appears to be as follows: The poison, whether swallowed into the stomach or inhaled into the lungs, or fixed in the fatty constituents of the skin and absorbed slowly therefrom—as may be the case with one or other of the six—becomes fixed in the food fat of the circulating blood. This fat, with the poison fixed in it, is carried to the liver for the purposes of normal metabolism, there to be transformed by a process of desaturation of the fatty acids into the "available organic fat" which is believed to be the principal source of energy for the work of various active tissues. The destructive action of the poison thus concentrated in the liver is such that the functional activity of the gland is impaired, with interruption of the process of desaturation of the food fat and, presumably, disorder of function in other directions. The normal metabolism of food fat being checked, engorgement of the liver with fat and a condition of lipaemia, caused by an accumulation of unchanged food fat in the blood, result. In experimental poisoning of the cat and rabbit with trinitrotoluene it was found that considerable quantities of the surplus fat were excreted by the kidneys, being readily demonstrable in the urine. And so the kidneys become engorged with fat in process of excretion; and, as with the liver, there is disturbance of the functional activity of the gland as a result of the direct action of the concentrated fat-fixed poison. The investigation led to the conclusion, therefore, that the fatty changes which occur in the liver in such cases as those of delayed chloroform poisoning and poisoning by trinitrotoluene represent an infiltration with food fat which the gland is unable to transform, and that the similar condition in the kidney is caused by an infiltration with unchanged and useless fat which is in process of excretion from the body. The changes do not represent, as had been supposed hitherto, a fatty degeneration of the parenchyma cells of the gland. The first effect of the direct action of the concentrated poison on the liver, as seen in the earlier stages of experimental poisoning with trinitrotoluene, is a perivascular round-cell infiltration of the connective tissue along the course of the portal circulation. In the areas occupied by the migrating cells the first microscopic evidence of interrupted metabolism is found in the presence of

minute globules of fat which apparently have passed through from the portal capillaries. At a later stage, in human cases, the gradual accumulation of this fat produces the gross fatty infiltration which is the most obvious feature of the group of cases of poisoning. In the more prolonged poisoning of munition workers with trinitrotoluene the tracts of round-cell infiltration become replaced in places by dense fibrotic tissue, so that the parenchyma cells, already damaged by the direct action of the fat-fixed poison, undergo a further destructive degeneration which is secondary to the cirrhotic change.

The fatty changes in the liver and kidneys in fatal cases of poisoning by arsenobenzol compounds appear to be essentially identical with those just described. There is an infiltration of the liver with unchanged fat, resulting from an interference with fat metabolism caused by the direct action of the poison on the tissue of the gland. With this there is an apparently consequent engorgement of the kidney with surplus unchanged circulating food fat. In poisoning with the arsenical compounds, whilst there is not a ready explanation of the concentration of the poison in the liver which in the other cases is afforded by an obvious special affinity for fats, it appears to be possible that some similar fixation of the poison in the fat does in fact occur.

At a time when an investigation into the pathology of poisoning by T.N.T. amongst munition workers was nearly completed, three deaths amongst patients who had been under treatment with arsenobenzol compounds (novarsenobillon and kharsivan) came under observation towards the end of 1917, and were apparently the first cases of the kind recognized in this country. Many other cases followed, but for various reasons it was inexpedient to publish any details at the time: and in the paper quoted on the action of certain poisons which affect fat metabolism only a very brief allusion was made to the subject. The close resemblance between these cases and cases of delayed poisoning by trinitrotoluene was referred to; and it was stated that in an experiment in which a rabbit had been poisoned with arsenobenzol changes in the liver had been produced which were similar to those found after the experimental administration of trinitrotoluene. It had been found that in the rabbit the first appearance of fat was not in the parenchyma cells of the liver, but in areas of round cell infiltration which appeared along the course of the portal capillaries. Also there was evidence of the elimination of fat by the kidneys.

The following table (I) sets out the facts, so far as they were ascertainable, as to the dosage and time of appearance of toxic symptoms in 7 cases which occurred in the practice of six different hospitals, and in which it was possible to make a microscopic examination of the liver and kidneys after death. The table includes similar details which were obtained in an investigation of the circumstances of 9 cases treated in yet another hospital, in which the appearance of jaundice was followed rapidly by death in patients who were either under treatment with kharsivan or for whom the course had already been completed. Nothing is known as to the actual condition of the organs in these last 9 cases.

For purposes of comparison with these 16 cases two other series of cases recorded respectively by Professor Stuart McDonald⁴ and by Drs. Strathy, Smith, and Hannah⁵ may be referred to. The former series included 5 fatal cases which had been treated with "salvarsan," combined with the usual intramuscular injections of mercury. It is stated that in all of the cases the jaundice, which appeared at first without any serious general symptoms, was followed after an interval of from two to eight days by symptoms of severity, increasing jaundice being accompanied by haematemesis, active delirium, and coma, with death in from one to four days. Dr. Strathy and his colleagues refer to a series of 58 cases treated in a military hospital, in which unfavourable symptoms of one kind or another occurred either during or after a course of treatment with either arsenobillon or kharsivan or galyl, combined in each case with intramuscular injections of mercury. Amongst the 58 cases there were 47 in which there was jaundice, and of these 8 died. The number of injections given in the fatal cases varied from four to eleven. The largest amount of the drug given in a fatal case was 6.95 grams and the least amount 2.2 grams. The average interval between the last injection and the onset of symptoms in a fatal case was forty-one days, the longest interval being forty-eight days and the shortest eighteen days. The average interval between the onset of symptoms and death was five days, the longest interval eleven days, and the shortest two days.

Regarded from the clinical point of view the 29 cases, including those recorded by Drs. McDonald and Strathy, which occurred in the practice of nine different hospitals, together with other published cases, appear to fall into

TABLE I.—Sixteen Deaths occurring during the Course of, or after, Treatment with Arsenobenzol Compounds.

Case.	Dose in Grams.	No. of Injections.	Duration of Period of Treatment.	Interval between last Injection and first appearance of Toxic Symptoms.	Interval between appearance of Toxic Symptoms and Death.
1	3.1	8	48 days	44 days	4 days
2	2.8	7	42 "	34 "	3 "
3	3.0	6	83 "	24 "	3 "
4	5.4	6	37 "	42 "	15 "
5	Full course	—	Some weeks	Some weeks	5 "
6	Full course	—	" "	" "	5 "
7	0.9	2	15 days	A few days	2 or 3 days
8	—	7	50 "	15 days	4 days
9	—	7	43 "	10 "	4 "
10	—	7	127 "	16 "	12 "
11	—	6	36 "	13 "	1 day
12	—	6	36 "	8 "	3 days
13	—	6	36 "	17 "	4 "
14	—	4	22 "	9 "	5 "
15	—	3	15 "	9 "	8 "
16	—	—	46 "	9 "	1 day

three groups, according to the rapidity with which definite toxic symptoms follow administration of the drug. There are (1) a few acute cases in which the symptoms appear rapidly after only two or three injections have been given; (2) subacute cases in which symptoms appear at a later date, either during the course of treatment or soon after its completion, and in either case within about ten days after the last injection; and (3) cases of delayed poisoning, in which the symptoms do not appear until from two to seven weeks after the last dose of a completed course, the patient having been in apparently good health during the interval. The factors of dosage and time appear, however, to have quantitatively but little determining influence on the final result. Whether the symptoms appear rapidly after a few doses—as in Case 7, in which only two doses of 0.45 gram each were given—or whether they are delayed for six weeks after the completion of a full course of treatment—as in Case 1, in which 3.1 grams of the drug had been given by eight injections—the final result is the same in a large majority of the fatal cases: jaundice, hæmatemesis, delirium and coma, with death within three, four, or five days.

The Process of Poisoning after Administration of Arsenobenzol Compounds.

The pathological problem presented when these cases were first recognized was one of considerable interest. As the results of earlier investigations it was stated in my previous paper² that it appeared to be probable that the toxic effect of the organic arsenic compounds was influenced materially by the benzene constituent—a conclusion which has been strengthened by subsequent observations. Since then, however, others have suggested that the cases represent an arsenical poisoning pure and simple. Dr. McDonald, on the other hand, considers that the changes in the liver are the effects of an infection by a bacillus of the typhoid-colon group, which he isolated from some of his cases after death.

There would appear at least to be a *prima facie* case for regarding this infection as being the new factor which, acting on livers previously damaged by syphilis, and possibly arsenic plus mercury, has completed the damage to the liver cells and allowed autolysis of the tissue, which appears to be the essential change, to occur.⁴

It being difficult, in view of the general course of these cases, to accept a theory which presupposes a bacterial infection as a determining cause of the illness, which is regarded rather as being simply the direct result of a drug poisoning, some experiments have been carried out in order to determine if possible whether the benzene constituent has any influence in aggravating the toxic effect of the

arsenic. The experiments have included the injection of rabbits subcutaneously with (1) arsenic oxide (As₂O₃), (2) with the benzene constituent (ortho-amido-phenol) with which the drugs are compounded, (3) with arsenobillon, and (4) with kharsivan.

Experiments with Arsenic Oxide.—Altogether 9 rabbits have been injected with toxic doses of arsenic oxide, and, except for Rabbits 1 and 9, the liver and kidneys were examined microscopically after death in every case. The arsenic was injected daily, in approximately equal doses, as shown in Table II.

TABLE II.

No.	Weight of Rabbit in Grams.	No. of Doses.	Average Dose Injected Daily, in Milligrams.	Total Amount in Milligrams.	Result.
1	4 000	1	—	16	Died within 18 hours
2	1 480	4	13.1	52.5	Died on fourth day.
3	3 250	3	10	30	Killed under chloroform on third day. Died on fifth day.
4	3 750	5	9.6	43	Died on fifth day.
5	1 190	5	6.6	33	Died on fifth day.
6	1 500	17	5	85	Died on 17th day; weight, 1,360 grams.
7	1 900	17	5	85	Died on 17th day; weight, 1,670 grams.
8	378	21	1.17	24.75	Died on 21st day; weight, 581 grams.
9	378	23	1.23	29.5	Died on 23rd day; weight, 570 grams.

The cases in which a microscopic examination was made after death may be grouped (1) as cases of acute poisoning (Rabbits 2, 3, 4, and 5) with death within three, four, or five days, and (2) as cases of chronic poisoning (Rabbits 6, 7, and 8) in which death occurred on the seventeenth, or twenty-first day. In all there was evidence of acute nephritis, showing in the more severe instances distension and cellular infiltration of the intertubular connective tissue, with injury to the tubal epithelium which sometimes had been shed. In all there were indications of an interstitial hepatitis, with more or less extensive round cell infiltration of the interlobular connective tissue, and usually an indefinite cloudy sort of change in the parenchyma cells, the outlines of which were often indistinct. Fatty changes were well marked in the liver in all four acute cases, and in the kidneys of Rabbits 2 and 3 which died on the third and fourth days. In Rabbits 2 and 3 there was a fairly heavy infiltration of the liver with fat, which was abundant in the parenchyma cells. There was also an infiltration of the cortical zone of the kidney, the fat appearing mostly in the epithelium of the convoluted portion of the tubules. The appearances, so far, were closely similar to those found in cases of human poisoning with arsenobenzol compounds, except that the actual proportion of fat appeared to be less relatively than in those human cases which had been examined. In Rabbits 4 and 5, which died on the fifth day, the livers showed areas of round cell infiltration along the course of the portal circulation; numerous small fat globules present were confined to the interlobular areas of cell infiltration, and had not reached the parenchyma cells of the lobules. In Rabbit 5 small branches of the portal vein could be seen with small globules of fat in what were apparently chromoblast lengths of the vessels. In these two rabbits there were only traces of fat in the kidneys, present in the form of quite minute globules, and mostly in the tubular epithelium. In Rabbits 6, 7, and 8, in which death was longer delayed, the appearances were again those of acute hepatitis and nephritis. In the livers of Rabbits 6 and 7 there was a fair amount of fat in the form of small globules lying in the areas of cell infiltration, but none was found in the liver of the third animal. In each case the kidneys showed an acute nephritis, with marked interstitial and epithelial changes, but without any fat infiltration.

Experiments with Ortho-amido-phenol.—Two rabbits (No. 10, weighing 1,150 grams, and No. 11, weighing 1,250 grams) received each a daily subcutaneous injection of 1 gram of ortho-amido-phenol, given in a normal soda solution; a third rabbit (No. 12, weighing 1,300 grams) was given a single dose of 0.5 gram. The first two rabbits became drowsy after each dose and died on the third and fourth days respectively; the third rabbit became drowsy on the third day after the single injection and was killed under chloroform. After death, an extensive, dark-brownish, gelatinous infiltration was found about the site of the injections; and the organs generally, and especially the spleen and kidneys, were stained a brownish colour. In Rabbits 10 and 11 there was an intense nephritis, with some disorganization of the kidney structure; no unchanged fat could be seen in the gland. The liver of Rabbit 10 showed an interstitial hepatitis, with some infiltration of the lobules with fat; in Rabbit 11 there were hepatitis and nephritis, but not any microscopic evidence of the presence of fat in either liver or kidney. The ortho-amido-phenol, in the large doses given, appeared to have an actively destructive effect both on parenchyma cells of the liver and on the kidney epithelium.

Experiments with Arsenobillon.—Altogether 7 rabbits were given various doses of arsenobillon injected subcutaneously, the total quantity administered ranging between 0.16 gram given in two doses of 0.8 gram each with a twenty-four hours' interval (Rabbit 14), and a total amount of 3.188 grams given by forty-eight injections, spread over a period of sixty-four days (Rabbit 17). In all the cases the rabbit died from the effects of the drug. The changes in the liver and kidneys were similar, in varying degree, to those found in the rabbits poisoned with arsenic. Thus in the liver of Rabbit 17, as in Rabbits 4 and 5, there were patches of round cell infiltration along the course of the portal circulation, without as yet any passage of the fat into the lobular areas. In other cases there was the appearance of destructive change in the parenchyma cells with, or without, the presence of unchanged fat. In all of the rabbits there was a nephritis of varying intensity.

Experiments with Kharsivan.—Three rabbits were injected with kharsivan, and each died within twenty-four hours of the last injection. Rabbit 18 (weight 1,400 grams) received altogether 0.825 gram subcutaneously by nine injections. Rabbit 19 (2,250 grams) received 1.1 grams by three injections given on consecutive days, and Rabbit 20 (1,900 grams) was given an amount of 1.17 grams by six injections on consecutive days. In all three rabbits there was evidence of nephritis, without any unchanged fat visible in the sections of the kidney. The liver presented the usual indications of an interstitial hepatitis, with in the case of Rabbit 19 small globules of fat amongst the round cell infiltration.

The results of these experiments may be summarized. The action of the arsenic oxide is such that after a comparatively acute poisoning there is an interstitial hepatitis with injury to the parenchyma cells, caused presumably by the direct action of the poison, together with the appearance of considerable quantities of unchanged fat in and amongst the parenchyma cells. In less acute poisoning there is interstitial hepatitis, with fat present in the form of small globules and, as yet, limited to the infiltrated interstitial tissue along the course of the portal circulation. In all of the experimental cases there was a nephritis in addition to the hepatitis. In two of the cases a considerable infiltration of the liver and kidneys with fat had produced an appearance which was comparable exactly with that seen in cases of human poisoning with arsenobenzol drugs. After the injection of ortho-amido-phenol, in the massive experimental doses given, there were acute hepatitis and nephritis, with the presence of unchanged fat in the interstitial tissue of the liver. The action of the poison, in the large amounts, on the parenchyma cells of both liver and kidney, appeared to be severe. The results of poisoning with the two arsenobenzol drugs were comparable histologically with those obtained in the less acute cases of poisoning with arsenic oxide.

In these investigations special attention has been paid to disturbance of fat metabolism as an indication of disorder of function following on damage of the liver tissues caused by the action of various poisons. It is comparatively easy to follow any disturbance of this particular function of the liver, because of the readiness with which unchanged fat can be recognized by histological methods, whilst the biochemical researches of Leathes³ and others after him have given us an understanding of the physiological processes concerned. But of the various functions of the liver that which is concerned with the metabolism of fat is one which may be interfered with, temporarily at any rate, without causing much disturbance of the general health. From the pathological point of view a disorder of other functions which are concerned primarily with the production of urea from nitrogenous waste, and with the elaboration of uric acid from purin bases, are of more importance for the orderly continuance of vital economy. Therefore, whilst the results of the failure of fat metabolism are those which are most clearly obvious on inspection, the concurrent failure of other functions must be looked upon as the more serious and immediate factors in the causation of death. Death with all the symptoms of toxic jaundice, and with fatty infiltration of the liver and kidneys, may follow poisoning with arseniuretted hydrogen gas; so that it appears that the results characteristic of poisoning by arsenobenzol compounds may be produced by the action of arsenic alone. Also the results of my animal experiments show that the fat-metabolizing functions of the liver are directly affected by the action of arsenic oxide in poisonous doses. But in view of the serious damage to the liver and kidney tissues in experimental poisoning with ortho-amido-phenol it is impossible to ignore the probability that the toxic action of the arsenobenzol drugs may be influenced to some extent by the benzene constituent.

Possible Danger in Treatment with Arsenobenzol Drugs.

Three questions of practical importance remain to be considered on the recognition of these cases of poisoning: (1) As to the general risk of poisoning in the treatment of syphilis, malarial infections, and other diseases with arsenobenzol drugs; (2) as to whether the use during the war of other arsenical products in substitution for the "606" of German manufacture, which was in common use before the war, has been in any way responsible for the occurrence of poisoning; and (3) as to whether the so-called "intensive" treatment with arsenobenzol compounds, in combination with intramuscular injections of mercury, which came into vogue during the war, has had any influence in the direction of increasing the risk.

The risk of poisoning inherent in treatment by arsenobenzol drugs cannot be appreciated closely at present. The drugs were used in the treatment of unprecedented numbers of cases during the war, because of the military advantage gained by a shortening of the period during which a man with syphilis has to be kept out of the line; and it is certain that the deaths from poisoning by these drugs which have been recognized and recorded hitherto constitute only a fraction of the number of deaths due to this cause which have occurred during the last six years. This must necessarily be so; because the drug had not been recognized as a possible cause of the toxic symptoms which have been described, and because of the frequency with which a period of apparent good health intervenes between the completion of the treatment and the appearance of those symptoms.

Since these special toxic effects of the arsenobenzol drugs were not recognized during the period when "606" was in common use in this country, it is not possible at present to form any opinion as to whether the arsenical compounds which have been used in succession are more or less toxic than the original drug. As, however, the use of "606" was continued elsewhere during the war, and since the special dangers have come to be recognized, it is possible that some information on this point may be forthcoming later on. But the effects being caused by the essential arsenic, with probably some intensifying action of the benzene constituent, one might, perhaps, infer that when further information has been obtained it will not prove that the precise proportion of the two ingredients has been of material importance in influencing the toxic action of the drug.

With regard to the effect of the "intensive" method of treatment, apart from the conjoined use of mercury, there is not much to be said. It is difficult to trace in recorded cases any correlation between the actual amount of drug administered and either the time of onset of symptoms or the severity of those symptoms. The clinical course of the symptoms appears to be remarkably constant in a large majority of the fatal cases, which are the only ones as to which we have as yet any definite information. In the cases of delayed poisoning the symptoms have occurred usually after the completion of a course of treatment and when a full amount of the drug has been administered; but a precisely similar course of events may intervene during the course of treatment, and after the injection of only two or three comparatively small doses.

The possible effects of the action of mercury on a liver which may be already damaged more or less by the toxic action of the arsenical preparation require special consideration. It is a common belief in therapeutics that mercury has some sort of stimulating effect on the liver cells. The condition of the liver in experimental poisoning with mercury has been described differently by various pathologists. Burmeister and McNally¹ and others describe marked histological changes of a progressive nature in the livers of dogs poisoned with mercuric chloride, but the changes described have not included any of a fatty nature. Practically all observers agree, however, in describing an acute nephritis in experimental mercurial poisoning, with the occurrence of fatty changes in the tubal epithelium.

In a case of human poisoning which I had an opportunity of investigating recently a man, aged 33 years, died on the sixth day after swallowing a tabloid (?1 gram) of mercuric chloride. After death a condition of severe gastro-enteritis was found. Microscopic examination of the liver showed a hepatitis, with a moderate infiltration of the lobules with fat. The examination of the kidneys showed an intense nephritis, without any fat infiltration.

It is evident, therefore, that mercury in large doses has by itself a definite action on the liver tissue, and that its administration in even the moderate doses used with the "intensive" method of treatment may have an injurious effect on a liver already damaged somewhat, with consequent impairment of its functional activity, by the arsenical drug. That such possible unfavourable influence would be of a merely incidental or accessory nature, and not essential, is shown by the fact that mercury had not been administered in at least three out of my series of sixteen cases. Nevertheless it is advisable that the use of mercury in conjunction with arsenic should be discontinued; the more especially so in that it is difficult to understand in what way the additional treatment can have any useful effect under the conditions.

Taking a broad view of the matter in the light of the experience which has accumulated up to the present time, it has to be admitted that there is a certain definite risk in treatment with arsenobenzol compounds. It is impossible to express the risk in any individual case in the terms of a percentage; but the danger is sufficiently real to suggest that a man who is going through a course of treatment should be kept under careful medical regimen throughout the period of administration of the drug and for some weeks afterwards. It is scarcely necessary to say that complete abstinence from alcohol should be compelled; the diet also should be so regulated as to lighten the work of the liver as much as possible. The diet which would appear to be advisable during the course of treatment is the same as that recommended both for the prevention of poisoning by trinitrotoluene amongst munition workers and in the treatment of cases in which symptoms of poisoning have already occurred.

The administration of milk or any other fat food in the course of the treatment of declared poisoning is inadvisable. Whatever may be the exact causation of the disease of the liver two facts are outstanding. In the first place the liver functions become seriously disordered, so that the gland is no longer able to carry out effectively its part in fat metabolism. In the second place, a condition of excessive lipaemia is established. As in preventive treatment sugars should be substituted for fat foods, definite doses of glucose being given together with fruits. The sugar given thus is given not only in substitution for fatty foods, but also because of theoretical considerations which suggest that oxidation of the excessive floating fat will be favoured by its administration. The diet, then, should consist mainly of carbohydrates, with very small quantities of lean meat, or preferably fish—excluding the fatty kinds, such as herring, mackerel, etc.²

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF RINGWORM.

DURING the past twelve months I have successfully dealt with over sixty cases of tinea tonsurans, the majority of cases being cured within a month.

As a preliminary step the affected area of the scalp must be shaved and cleansed with liquid ethereal soap. The part is then gently and carefully rubbed with a piece of lint which has been dipped in liquor potassae and dried with a piece of cotton-wool. Next the part is sprayed with ethyl chloride for about thirty seconds and allowed to dry; it is then painted with tr. iodi mitis. It is unnecessary to repeat the shaving and cleansing with ethereal soap, but the remainder of the procedure should be carried out morning and evening for the first three days and once daily during the subsequent four or five days.

During this time a mild folliculitis occurs, and as a result the infected hairs fall out. Usually a week of such treatment is sufficient to effect a cure, after which it is only necessary to rub ammoniated mercury ointment into the scalp twice daily, keeping the case under observation for about a fortnight or three weeks.

As a rule the folliculitis quickly subsides and healthy hairs soon make their appearance. Other varieties of ringworm can be quickly cured by like treatment.

Coventry. W. P. ELFORD, M.A., M.D.

SIMPLE PAROXYSMAL TACHYCARDIA.

As Dr. Thomas Lewis, in his *Clinical Disorders of the Heart Beat*, states that paroxysmal tachycardia is rare in young children, the following case may be of interest, especially as the boy's mother being similarly affected there is a possibility that heredity played a part.

On April 24th, 1920, I was called in to see a boy, aged 13, who complained of "quick beating of the heart." His mother informed me that he had his first attack when 4 years old, and subsequently one at 6, when convalescent from an ordinary attack of scarlet fever, and at 9, after returning home from tobogganing. During the past winter he had two attacks. He stated that the attacks came on suddenly, without warning or known cause, and after lasting one to three hours stopped as suddenly. He had not had rheumatism; since 8 years of age he had won prizes at the school races, and whilst running had never felt any ill effect. Before the present attack the patient felt quite well. When walking in the house about 9 a.m. he suddenly felt his heart beating fast, and this caused him to sit down; he experienced no pain or breathlessness, and no sickly or faint feeling. When I saw him at 12 noon he was still sitting up, the heart was beating forcibly, and the rate was uncountable. The patient had a slightly pale appearance, and his expression was rather anxious. When he lay down no alteration in the rate of the heart's beat could be detected, but he felt more comfortable. The apex beat was just inside the nipple line, and on percussion no enlargement of the heart was found. Auscultation revealed no murmur; the sounds were tic tac in character. At 1 p.m., although the patient felt hungry, he could not eat much dinner. At 3.30 the beating suddenly stopped, and for a time (he states ten minutes) he felt short of breath; towards the end he had a severe stabbing precordial pain, which disappeared on taking long deep breaths.

I examined him again four days after the attack. No pallor was noticeable and the pulse rate was 74 per minute; in the mitral area a slight presystolic thrill was palpable, and auscultation revealed a short presystolic murmur leading up to a sharp first sound. The second sound in the pulmonary area was reduplicated. The patient stated that since the attack he had not dared to hurry, for fear of bringing on another. I found that his visual acuity was only $\frac{5}{20}$, even with glasses, and he informed me that his sight often became blurred. Dr. Fison kindly estimated his refraction, and found a considerable degree of astigmatism present. He ordered fresh glasses, those in use being unsuitable. As the boy has recently been studying more than usual, the visual defect may account for the attacks occurring so closely together.

His mother is subject to similar attacks, which, in her case, first occurred at 19 years of age, and have since continued at varying intervals. She says that the attack "comes on with a big jump"; she feels the heart beating quickly and the vessels in the neck are seen to beat forcibly. If the attack lasts for any considerable time she feels an aching pain in the upper part of the chest. She is most comfortable lying down, and the attacks end suddenly, after lasting from a few minutes to some hours; they usually come on after over-exertion or too much excitement. On examination of the heart while she was resting no murmur or irregularity was detected. She gave no history of having had Graves's disease, and had no exophthalmos, swelling of thyroid, nor tremor. Her parents are both alive and well, and no history was obtained of cardiac trouble in either.

Harrogate.

A. C. SHARP, M.D. Glas.

OBSTRUCTION DUE TO ADHESIONS OF THE PELVIC COLON.

THE following case is interesting, in that it presented all the general signs and symptoms of increasing obstruction by a malignant growth:

A man of 56 complained of obstinate constipation, which had increased progressively during nine months; for one month he had had diarrhoea every morning, the stools being scanty, slimy, and frothy. He had not noticed blood in them, and was able to pass flatus freely. Two or three similar stools followed the morning stool, and, although he was able to do his work, he almost invariably had one or two "vomiting turns" during the course of the day. He had suffered from rheumatism, and twenty years ago had enteric fever; during the last twelve months he had lost 18 lb. in weight. On abdominal palpation I thought I could detect in the left iliac fossa a small, hard, immovable mass of very ill-defined outline. I was greatly struck with the huge balloon-like cavity shown by rectal examination; the walls of the rectum were felt with difficulty, and were impalpable except in the lowest inch and a half. No tumour was felt. The diagnosis of malignant growth in the lower portion of the pelvic colon was made both by myself, and independently by another surgeon elsewhere.

Assisted by my colleague, Mr. E. A. Guymer, I opened the abdomen by a five-inch incision in the left linea semilunaris. The liver was normal. There were no palpable glands along the course of the large vessels, nor accessory signs of

malignancy. The upper part of the sigmoid was slightly distended; on tracing it downwards the lower six inches presented a remarkable appearance. Along one-half of its circumference it was closely and tightly bound down by old-standing adhesions and scar tissue to the lateral wall of the left iliac fossa. Springing from the lowest inch or two of the sigmoid was a mass of bands which stretched upwards and forwards to the anterior abdominal wall, and the left and upper part of the bladder; it was at this point that the obstruction was most marked; there was a sharp kink in the bowel. The lumen of the rest of the affected portion was also slightly diminished. With some difficulty these adhesions were separated and divided; the gut, which was freed, showed some slight thickening of its wall on that side which had been bound down, but not on the opposing half of the circumference. A rectal examination, made at the close of the operation, gave normal findings.

It is probable that at some time or other at one or more points along one side of the sigmoid there had been inflammatory trouble, which had spread along that side and gradually bound the bowel down in the manner shown at the operation. The origin of this inflammatory process is doubtful; from the condition of things seen it was quite possibly due to inflammatory changes in one or more diverticula on the affected side of the gut, this inflammatory process having spread and then subsided. I should say, therefore, that this was a case of early but arrested diverticulitis; I know of no other pathological condition which could fit in with the findings. The patient made an uninterrupted recovery and he has no further trouble with his bowels.

DONALD M. MACLEOD,
Late Senior House-Surgeon and Resident Surgical Officer,
Norfolk and Norwich Hospital.

Reports of Societies.

FETAL INTRACRANIAL HAEMORRHAGE DURING BIRTH.

At a meeting of the Edinburgh Obstetrical Society, held on June 9th, Dr. WILLIAM FORDYCE, President, in the chair, Dr. EARDLEY HOLLAND read a paper on cranial stress in the fetus during labour, based on *post-mortem* examination of a consecutive series of 168 fresh fetuses. Most of these had undergone breech or forceps delivery, or delivery through contracted pelvis, but a few were born after apparently normal labour. Injuries of the septa of the dura mater were found in 81, or 48 per cent., with subdural cerebral haemorrhage in all but two cases.

The septa of the dura mater were described and shown to form a perfect mechanical system of stress bands and stress lines. The theory was developed that the septa of the dura mater—that is, the tentorium cerebelli, falx cerebri, and falx cerebelli—were, functionally, ligaments of the cranial bone, and limited the alteration in shape or moulding of the head during labour.

During excessive change in shape or moulding of the fetal head excessive strain is thrown on the septa, and they are overstretched and may ultimately tear. The tears occur in the area of greatest stress in the "stress bands"; the usual site is the anterior border of the tentorium at its junction with the falx cerebri. If tearing occurs, the limitation of movement of the cranial bones is removed, and the head is free to undergo an excessive alteration in shape. Further alterations in the relationship of the intracranial contents are thus brought about; the chief of these is kinking and stretching of the vein of Galen. The fixed point of this vein at its entrance into the straight sinus is moved upwards and forwards; the acutely kinked vein becomes engorged and tense, and may rupture. Rupture of the vein of Galen, however, is rare; the vessels that usually give way, and are the cause of subdural haemorrhage, are the tributaries of the vein of Galen coming from the cerebellum and pons Varolii.

The lecturer said that, clinically, tearing of the tentorium cerebelli—an almost non-vascular membrane—was not in itself dangerous; the danger lay in the cerebral haemorrhage which accompanied or followed it. Besides being found in dead-born fetuses, these injuries were extremely common in infants who had died during the first week of life as the result of difficult labour. Their frequency in breech cases suggested that intracranial haemorrhage was the cause of death, and not, as usually described, pressure on the cord, with asphyxia. It was indicated, therefore, to avoid haste and methods likely to cause undue cranial stress. Healed tears might be found in children several

months old, and an example was shown. There could be no doubt that many of these injuries were not immediately fatal; surviving infants might die either in the early days of life or after a few weeks or months. The extent to which these injuries were responsible for infantile cerebral disease, such as spastic paraplegia, mental defects, backwardness, and other similar conditions, formed an interesting speculation.

Dr. J. W. BALLANTYNE and Dr. F. J. BROWNE discussed Dr. Eardley Holland's paper, and showed specimens illustrating head injuries in the newborn fetus. Dr. Ballantyne considered that Dr. Holland's contribution must now be considered as the classical paper on the subject; it seemed evident that tearing of the vessels in the neighbourhood of the tentorium was a common cause of haemorrhage. He and Dr. Browne, however, had more often found haemorrhage in other sites, and in their experience intraventricular haemorrhage was frequent. They were convinced that prematurity was an important factor; asphyxia, post-natal infection, and syphilis were other possible causes. The nature of the haemorrhages seemed to put operative interference out of court. Sir HALLIDAY CROOM said that many years ago, in children after efforts made to resuscitate for asphyxia, he had found lacerations of the liver, intestines, and spleen; one case which he submitted to Professor Cunningham showed a laceration of the tributary vessels of the Galen vein. Dr. HARG FERGUSON emphasized the need for care in the application of forceps in premature children. He referred to the paper of Meyer, who reported 24 cases of tearing of the tentorium in 64 stillbirths; this was a percentage of 37.5 as compared with Dr. Holland's 48 per cent. He believed that in the majority of cases of cephalhaematoma a fracture of the bone took place. Dr. HENDRY said that out of 250 cases in the Glasgow Maternity Hospital they had only had one case of fracture of the cranial bone with cerebral haemorrhage. They had only found injury to the tentorium in 8 out of 250 cases. He pointed out how easy it was to injure the tentorium in the process of examination. Dr. JENKINSON believed that the subject had important clinical bearings, and he was sure that injuries of this sort which were not lethal were important causes of mental defects. The President thought it more likely that the haemorrhages found in breech cases were due to asphyxia and not to stress.

Dr. EARDLEY HOLLAND, in reply, agreed with Dr. Ballantyne that there were many causes of haemorrhage. He himself had focussed his attention on tentorial conditions; the examination rendered the specimens unfit for any further investigation. It was best to make a window in the side of the head and drop the brain out cautiously. His investigations had shown that there was no relation whatever between cerebral haemorrhage and a positive Wassermann reaction.

Reviews.

THE AFTER-TREATMENT OF WOUNDS AND INJURIES.

IN his book on *The After-Treatment of Wounds and Injuries* Mr. R. C. ELSLIE has produced an eminently straightforward practical work. It is the fruit of personal experience gained in a military orthopaedic hospital, and does not pretend to be a complete treatise on the subject. He observes that the principles of military orthopaedics are in no way different from those of civil orthopaedic surgery, though the applications may be new and changing. These principles depend upon what may, after all, be regarded as guiding ideas in all surgery: "a knowledge of pathology, a clear appreciation of mechanics, and the realization that the surgeon's aim is to restore function." Probably the sooner we get rid of the convention that military orthopaedics is a special department in surgery the better. There seems no good reason why any good practical surgeon should not learn to do satisfactory orthopaedic work. Nor is there any reason against the general practitioner making himself familiar with this class of case and endeavouring to cultivate the orthopaedic conscience

¹ *The After-Treatment of Wounds and Injuries*. By R. C. Elmslie, M.S., F.R.C.S. London: J. and A. Churchill, 1919. (Med. 8vo. pp. vii + 325; 144 figures. 15s. net.)

or instinct which will see in the first place that orthopaedic treatment is suitable and in the second quickly decide upon the method to be adopted. Both surgeon and practitioner will obtain plenty of help and sound guidance from this book. There is sufficient pathological and operative detail to satisfy the former, and the latter will find that a great vista is opened up for him full of suggestive work in the directions of both deformity-preventing and deformity-curing.

The first half of the book deals with the principles of treatment, and the remainder with injuries of specific regions, including an account of methods of splinting, the use of plaster-of-Paris, and the various physical methods of treatment, massage, and electricity. The reader will not get far into the book before discovering that the author's demand for rigid asepsis and for thorough eradication of septic foci which continue to lurk in unexpected places is firmly based on his own experience. It was one of the many surprises of war surgery that small pockets of infective granulation tissue and small sequestra could persist for many months in an apparently soundly healed area. With this in view the author gives in detail the description of the technique of radical operation for chronic osteomyelitis.

Rigid conservatism in the surgery of the hand is the best plan. Two of the author's dicta on this subject are worthy of quotation: "A hand of even very little functional utility is better than an artificial hand or appliance"; "a stiff thumb with all the joints ankylosed and all the long tendons lost is better than no thumb at all."

The chapters on nerve lesions—both the discussion of general principles and the detailed description of lesions of individual nerves and their treatment—are exceeding full and very well written. In testing the electrical reaction of muscles Mr. Elmslie advises the surgeon to observe the character of the contraction of the muscle produced by the interrupted galvanic current. When the nerve is intact the contraction produced is both sharp and rapid; when the nerve is interrupted and the lower part is degenerated the contraction is slower and more wave-like. This method of observation he prefers to the expression so long familiar ACC > KCC, the formula resulting from the alteration of polar reactions. The importance of Tinel's sign, "fourmillement" or tingling along the course of the nerve below the point of interruption when that point is lightly percussed with the finger, is properly emphasized; by this sign the gradual progress downwards of the process of regeneration can be watched from time to time. In bridging a gap in a nerve, after all the devices of pulling down and transposing the nerve and posturing the limb have failed, an autogenous graft is, in the author's opinion, the only rational procedure.

Mr. Elmslie's style of writing is didactic, forceful, and clear, but with a tendency to reiteration. The illustrations are well chosen and of good quality. The index is much too scanty. The book is one which can be most heartily recommended as an excellent exposition of a branch of surgery whose range is likely to widen even if, as we all hope, there be no more war.

PULMONARY SYPHILIS.

DURING the last seven years Professor ELIZALDE of Buenos Aires has met with 30 cases of pulmonary syphilis in the *post-mortem* room, finding the *Treponema pallidum* in the lung in each instance. His book on the pathological anatomy and pathogenesis of pulmonary syphilis² contains a detailed histological account of twelve of these cases, illustrated with a large number of microphotographs many of which are excellent; all the thirty patients, it may be added, were adults. The author gives first three cases of pulmonary gumma; no gummatous formation takes place without a preceding endarteritis obliterans, he holds. The next seven cases considered are examples of syphilitic pneumonia; four periods in its development are considered—(1) pulmonary catarrh with early inflammatory growth; (2) sclerosis and gumma formation, with massive filling of the alveoli; (3) sclerosis and gumma formation, bronchiectasis, reopening of the alveoli, and (4) simple sclerosis with shrinkage. Throughout the first two stages there is

a great failure in the production of blood vessels. Among 24 patients with syphilitic pneumonia or bronchopneumonia 18 also exhibited aortic aneurysm, and in 10 of these a greater or less degree of compression of the bronchi was observed; Professor Elizalde is inclined to connect the presence of the pneumonia with this compression. Finally he describes two cases of syphilitic bronchopneumonia, in which all the appearances summed up above are presented on the small scale.

The book is well printed and the numerous illustrations are admirably reproduced; there is, however, no table of contents and no index, though a brief summary of the work in French is appended at the end of the volume.

DIATHERMY.

To the series of manuals issued under the title of "Modern Methods of Treatment" Dr. CLAUDE SABERTON has added *Diathermy in Medical and Surgical Practice*;³ this is an eminently practical and instructive monograph, which should serve a useful purpose as an introduction to the subject, and prove of value to practitioners and students who desire guidance in what has now become an established method of both medical and surgical treatment. It is divided into three parts: the first deals very thoroughly with the technique and methods of application; the apparatus is described in detail, and the various types of diathermy apparatus, with their advantages and disadvantages, are illustrated. The second part is devoted to the medical application of diathermy, including the treatment of diseases of the circulatory system, the nervous system, fibrositis, diseases of joints, and thoracic and other affections. The surgical uses of diathermy are considered in the third part, and, whilst many conditions benefited by this method of treatment are reviewed, its uses in various types of malignant diseases and the method of its application to these diseases are set forth in full detail; the results it is possible to obtain are fairly stated. An extensive bibliography adds to the value of the book and brings it to a conclusion.

The author has used diathermy extensively, and not the least valuable paragraphs are those in which he gives his own experiences and describes his own methods of procedure. The experiences of Mr. Herbert Franking, related on page 107 and the following pages, in the diathermy treatment of papillomata of the bladder and in malignant disease of the tongue show the possibilities of this method in no uncertain manner. Numerous illustrations of both apparatus and methods add to the value of the book and serve to make the author's meaning clear.

NOTES ON BOOKS.

THE man who, while sojourning at Cambridge, desires to add to his John Willis Clark and F. J. Allen a lighter kind of guide may find some amusement from *The Country Cousin at Cambridge*, by LILIAN CLARKE.⁴ This book combines the didactic method of Mrs. Markham with the naïveté of the Young Visitors. The cousin, a man, interrupts the verger-like descriptions of College Halls and Chapels with such remarks as these: "How perfectly sweet!" "The idea of the lady's personal interest in her scholars is charming!" "It is a most elegant aristocratic place!" "How deliciously old-world!" "This is a cosy nest!" There is a thin thread of love interest which comes to an untimely end; and the book is pervaded with the pathetic wistfulness of a Townsman who has missed the crowning glory of cap and gown. We are not made aware of the price of the book, probably because it is one of those works which are best described as priceless!

In his monograph on *Asthma*⁵ Dr. O. H. BROWN develops at full length his theory that the essential feature of the disease is "non-passive expiration," or forced expiration; this leads to a mechanical interference with the circulation in the bronchial blood vessels and lymphatics, with the result that the bronchial mucosa becomes congested and swells up in such a way as to obstruct the passage of air to and from the pulmonary alveoli. He holds that muscle

³ *Diathermy in Medical and Surgical Practice*. By Claude Saberton, M.D. London: Cassell and Co., Ltd. 1920. (Cr. 8vo, pp. 137; 35 figures. 7s. 6d. net.)

⁴ *The Country Cousin at Cambridge*. By Lilian Clarke. 1920. Published by Johnson and Nephew, Cambridge.

⁵ *Asthma*. By Orville Harry Brown, A.B., M.D., Ph.D., formerly Assistant Professor of Medicine, St. Louis University. London: Henry Kimpton. (Med. 8vo, pp. 330; 36 figures.)

² *Anatomía patológica y patogenia de la sífilis pulmonar*. By Dr. Pedro I. Elizalde. Buenos Aires: A. Guidi Buffarini. 1919. (Sup. roy. 8vo, pp. 375; 35 plates.)

spasm does not play more than a contributing part in any case of asthma, and probably exerts an important influence in it but rarely. Opinions will differ as to the value of the author's theory, but his book gives evidence of a very thorough study of the literature of the subject.

Professor ZIELER'S little manual on sexual diseases⁶ contains a short and practical account of the etiology, symptoms, diagnosis, and treatment of gonorrhoea, soft sore, and syphilis. It is designed for the use both of medical practitioners and medical students.

Dr. VAZIFDAR'S *Physiology of the Central Nervous System and Special Senses*⁷ is a compilation from the better known textbooks of physiology, and is designed to help medical students in Bombay and elsewhere through their intermediate examinations by offering them a summary of the subject. The text appears to cover the ground adequately; it contains a number of diagrammatic illustrations, and is by no means free from misprints.

Mr. COMYNS BERKELEY'S *Gynaecology for Nurses and Gynaecological Nursing*⁸ has now reached its third edition. The first part deals with gynaecology proper, and in it the various special diseases to which women are liable are concisely explained; a description of venereal diseases has been added. The second part is concerned with bacteria and immunity; its study will help nurses to understand the importance of asepsis, and the necessity of attending to the small matters which are essential to surgical cleanliness. In the third part all the various methods of treatment the nurse will be required to carry out are fully described, and there are illustrations of the instruments required for operations, and the various positions in which the patient should be placed. Description of operations has been wisely omitted, but the after-treatment and the complications that may arise are fully dealt with.

The series of "Pilgrim's Books" after making an indifferent start with Zimmerman's *Pleasures of Solitude* has recovered itself with the second volume, a selection of sketches from the *Tutler*.⁹ There are three dozen of them, well printed in a small volume which may profitably, as the publisher suggests, be slipped into the pocket on a walking or bicycle tour. The sketches are well chosen, and that every one is gay and shrewd no warranty is needed. In this day, when so much writing is either lipshod or laboured or precious, it is not only a pleasure but an instruction to read a little in this crisp, clean, eighteenth-century English.

WE have received the first number of the *Journal of Neurology and Psycho-pathology*. The editorial secretary is Dr. Carey F. Coombs of Bristol, and the periodical will be published by Messrs. John Wright and Sons of that city. The first number opens with a Note on Suggestion, by Dr. William McDougall of Oxford, and there are papers on the treatment of cerebro-spinal fever by Dr. C. Worster-Drought, on the Freudian explanation of dreams by Dr. Parkes Weber, and on a case of lethargic encephalitis involving the cerebral cortex by Dr. George A. Wilson of Rathill. The number also contains notes and clinical cases, a critical review of vagotonia, editorial articles and abstracts. The periodical will be conducted by an editorial committee consisting, for neurology, of Dr. Kinnier Wilson, Dr. Graham Brown, and Dr. R. M. Stewart, and for psycho-pathology, of Dr. Bernard Hart, Dr. Henry Devine, and Dr. Maurice Nicoll. The price of each number is 8s. 6d.; the annual subscription 30s.

⁶ *Die Geschlechtskrankheiten. Ihr Wesen, ihre Erkennung und Behandlung.* Ein Grundriss für Studierende und Aerzte von Professor Dr. Karl Zeiler, Vorstand der Universitäts- und Poliklinik für Haut und Geschlechtskrankheiten in Würzburg. Leipzig: Georg Thieme, 1920. (Cr. 8vo, pp. viii + 182; 15 figures. M. 5.15.)

⁷ *Physiology of the Central Nervous System and Special Senses.* For the use of students. By N. J. Vazifdar, L.M. and S., Assistant Chemical Analyser to the Government of Bombay. Third edition. Bombay: S. Govind and Co. 1920. (Demy 8vo, pp. 299; 18 figures. Rs. 3.12.)

THE first volume of a new edition of Martindale and Westcott's *Extra Pharmacopoeia* is nearly ready for publication by Messrs. H. K. Lewis. This is the seventeenth edition, the sixteenth was published in January, 1915.

THE REPORT OF THE IRISH PUBLIC HEALTH COUNCIL.

BY

THOMAS HENNESSY, F.R.C.S.I.,

IRISH MEDICAL SECRETARY, BRITISH MEDICAL ASSOCIATION.

THE Report of the Irish Public Health Council was formally laid on the table of the House of Commons on June 14th.

The Irish Public Health Council was appointed by the Chief Secretary for Ireland to formulate proposals with a view to the submission to Parliament of an Irish Public Health Bill which would, *inter alia*, place the public health services on a more comprehensive basis, and, where necessary, make mandatory on the local health authorities the various adoptive and permissive health enactments.

The Council consists of seventeen members, of whom seven are members of the medical profession. The chairman is Dr. E. Coey Bigger, medical commissioner of the Local Government Board for Ireland and chairman of the Central Midwives Board. Three of the seven medical members are, however, departmental officials: Dr. E. F. Stephenson, Acting Medical Commissioner of the Local Government Board; Dr. W. J. Maguire, Medical Commissioner of the Insurance Commission; and Sir William Thompson, F.R.C.P.I., registrar-general of births, deaths, and marriages in Ireland. Dr. R. J. Rowlette and Dr. Alice Barry are the direct representatives in the Council of the Irish medical profession. Sir John William Moore, M.D., president of the Royal Academy of Medicine in Ireland was appointed by the Chief Secretary to represent medical interests generally. The non-medical members of the Council are the Vice-President and a commissioner of the Local Government Board, the Chairman and a commissioner of the Irish Insurance Commission, representatives of approved societies, insurance and tuberculosis committees, veterinary medical associations and nursing institutions.

To people who believe regretfully that, as regards the settlement of most public questions in Ireland, it is too much to expect anything approaching unanimity, the report of the Council should be an agreeable surprise. Apart from some points with regard to the organization of the central health authority, the very important and far-reaching recommendations of the report are signed by all the members of the Council; therefore, on the present occasion the Government cannot refuse to legislate on the plea of the lack of agreement amongst the people most concerned in Irish health questions.

Irish health legislation, on a radical basis, is long overdue. In most respects it is fully fifty years behindhand when compared with England, Scotland, and other European countries. The recent patch-work medical legislation for Ireland has been a complete failure from the want of the necessary local machinery for administration, as has happened, for instance, in the case of the medical inspection of school children. When it came to putting that much-needed Act of Parliament into force it was found practically impossible, as the county councils, which were the bodies for its local administration, had no medical officers of health, nor had they the legal authority to make such appointments. Moreover, whilst Ireland contributes its full amount of the Imperial grants voted in recent times towards the improved medical services for Great Britain it does not share in these improved medical services, as the Government of the day generally excused the exclusion of Ireland on the ground that the economic and other conditions of Ireland differed so much from those of Great Britain that Ireland would best be dealt with by a separate measure. With this contention people in Ireland were in agreement, but somehow the separate measure for Ireland always seemed doomed not to materialize, with the result that an equivalent grant of about a quarter of a million sterling due to Ireland for medical services is unexpended each year by the Treasury. Nor is this equivalent grant spent on any other Irish service. In the circumstances it is to be hoped that not only the unanimity of the recommendations of the Irish Public Health Council, but their general merit, practicability and suitability to the peculiar health needs of Ireland, will secure for them a speedy and calm passage to the statute book.

The Council, during its many sittings, gave every opportunity to all the interests concerned in Irish health questions to put their views before it. It received deputations

from the medical profession and approved societies, and representations were made to it from time to time by public bodies and organizations drawing attention to various defects in the present public health and medical services of Ireland, and suggesting how these defects might be remedied.

The report in its preliminary section lays special stress on the lack of co-ordination and over-lapping, both in the central control and in the local administration of the public health and medical services. As regards the system of central control the report points out that there are several departments in Ireland dealing more or less independently with health matters of a kindred nature, and sometimes actually identical.

The report shows next that there is even a greater lack of co-ordination in local administration. Boards of guardians are, under the Poor Law and Medical Charities Acts, entrusted with the local administration of the union infirmaries and fever hospitals and of the dispensary medical service. The sanitary authorities—for the most part district councils corresponding to the too limited area of the Poor Law unions—are, under the Public Health Acts, vested with the local administration of sanitary enactments and of maternity and child welfare schemes, and also with functions relating to the provision of hospital facilities. Finally, the County Councils are either responsible for, or have certain functions in connexion with, the administration of county infirmaries, sanatoriums, and lunatic asylums. In addition to those functions the County Councils have, by recent legislation, been entrusted with the local administration of schemes for the medical inspection and treatment of school children and for the treatment of tuberculosis and venereal disease. The result is that an enormously complicated system of local health administration has grown up, which few persons, apart from the officials directly concerned, understand, or know from what sources advice or assistance in regard to hospital treatment or to questions pertaining to public health can be obtained. To remove the want of co-ordination and overlapping in the local administration, as well as on the ground of efficiency and economy, the Council urges that all these services should be co-ordinated under one local authority on a county basis.

The report recommends that its proposals might suitably be embodied in a bill comprising five parts :

1. Central health authority.
2. Local health authorities.
3. Medical service.
4. Finance.
5. General.

CENTRAL HEALTH AUTHORITY.

The Council as a first principle recommends that there should be complete co-ordination in the central administration of the medical and public health services in Ireland, and that local (including rating) authorities and professional interests should be represented in the central administration. The Council considers that the advantages of the incorporation of local interests in central administration are twofold. The local bodies and organizations will be placed in a position to advocate directly the needs of the interests which they represent, and at the same time the central authority will be kept fully in touch with, and will be more likely to have the support of, public and professional opinion.

Ministry of Health for Ireland.

The Council recommends the establishment of a Ministry of Health for Ireland, to which should be transferred :

- (a) All the powers and duties of the Local Government Board for Ireland.
- (b) All the powers and duties of the Irish Insurance Commission.
- (c) All the powers and duties of the Registrar-General of Births, Deaths, and Marriages.
- (d) All the powers and duties of the Inspectors of Lunatic Asylums, subject to some specified exceptions.
- (e) The powers and duties of the Chief Secretary for Ireland under the Anatomy Act, 1832, and the Cruelty to Animals Act, 1867.

It is further recommended that power should be given to transfer from time to time to the Ministry, by Order in Council, such powers and duties of other departments as it may be considered desirable so to transfer. Under the category are included (1) the transfer of any powers and duties of the Department of Agriculture and Technical Instruction for Ireland in relation to veterinary services ;

(2) certain medical functions now vested in the Home Office under the Factory Acts ; and (3) the medical functions exercised by the Ministry of Pensions.

As regards the organization of the Ministry there was some difference of opinion. The proposal of the majority for a Ministry was supported by the representatives of the medical profession, and is somewhat as follows :

MINISTER. VICE-PRESIDENT.	Local Government Department	{	Poor Law Branch. Local Government Branch. Housing Branch. Audit Branch, etc.	
	Medical Department	{	Medical Branch. P. H. Branch. Veterinary Branch. Lunacy Branch.	} Health Council
	Health Insurance Department	{	National Health Insurance, etc.	
	Registration Department ...	{	Medical and Vital Statistics. Death Certification, etc.	

Each department should be in charge of a Commissioner who would be responsible for the work of his own department and would have access to the Minister through the Vice-President. In the cases of the Local Government Department, the Medical Department, and the Insurance Department, the report considers it would be necessary that there should be other commissioners (in charge of important branches or groups of branches) associated with and subordinate in each case to the head of the department. The majority of the Council support this scheme.

The alternative proposal of the minority involves the establishment of a central health authority constituted as follows :

PRESIDENT
(The Chief Secretary for Ireland).

A Board of Health, consisting of a Chairman and permanent members to be called Commissioners, transferred from the Departments affected.

The members of the Board of Health recommended by the minority of the Council would have equal standing.

Health Council.

Under either of the systems indicated above the report recommends unanimously the formation of a Health Council. The general policy and principles of administration of the public health and medical services, and of all the activities of the Ministry directly concerning health, should be subject to the general control and direction of the Health Council. As regards the constitution of the Health Council, it is recommended that it might comprise :

- Six representatives of the County or Local Health Boards.
- Four representatives of the medical profession.
- One representative of the dental profession.
- One representative of the veterinary surgeons.
- One representative of nurses ; and two representatives of approved societies.

The Commissioner in charge of the medical departments of the Ministry should be permanent chairman of the Council and should have the right to give a casting vote in case of equality of voting. It will be noted that the county or local health boards and the approved societies have a clear majority over all the other combined interests represented in the Council. This is probably justified on the ground that these two interests will provide a very considerable amount of the moneys for the medical services, etc.

LOCAL HEALTH AUTHORITIES.

The report recommends the county or county borough as the area for local administration for all matters pertaining to health and medical services, and that in each county and in each county borough there should be established a Board of Health, which should be the administrative health authority for the area. The local health boards will consist of members appointed by the county and borough councils, representatives of the medical, veterinary, and dental professions, insured persons, nurses, voluntary health associations, etc. As in the case of the Health Council, the majority of the members of the Local Health Boards will be appointed by the bodies which contribute to the finances—namely, the county council and approved societies.

The County Health Boards would be responsible for the local administration of :

1. The public hospitals, sanatoriums, asylums, etc., in their respective areas of control.
2. The system of medical treatment of insured persons and of those who are unable to pay.
3. Schemes for the medical treatment of expectant and nursing mothers and of young children, and for the inspection and medical treatment of school children.

4. Schemes for the treatment of tuberculosis and other special diseases.

5. The general public health system in their respective areas (with the exception of certain local services in urban areas).

IRISH MEDICAL SERVICE.

The report recommends that the existing dispensary system of providing medical treatment for poor persons should be completely transformed, and that in lieu thereof a system of medical treatment should be provided (as part of the general hospital, etc., system under the control of the local or county health boards):

1. For insured persons on a contributory basis.
2. For those who are admittedly unable to contribute towards the cost of such treatment.

The report lays emphasis on the agreement among the members of the Irish Public Health Council that drastic reforms are necessary with a view to improving the conditions under which the members of the medical profession shall be called upon to carry out the medical treatment of the classes referred to. The report points out that a national medical service was advocated by the Vice-Regal Commission on Poor Law Reform in Ireland, and by the committee appointed in 1913 to consider the extension of medical benefits to Ireland, and that the principle has also been considered and approved by the medical profession, and formed one of the recommendations made last year to the then Chief Secretary by deputations representing the medical profession in Ireland. The report continues:

Accordingly we recommend the establishment of an Irish medical service, the members of which should be appointed by the Ministry as a result of competitive examination and should be eligible for promotion in the service and entitled to superannuation.

At present appointments in the Irish Poor Law medical service are made by election by boards of guardians. Provision will be made that existing officers in the Poor Law medical service will go over to the new service without undergoing the test of a competitive examination. It is also recommended that power should be given in the scheme for the incorporation in the new medical service, without competitive examination, for a limited number of years, of medical men who are now practising amongst the classes who will be entitled to treatment under the new medical scheme. The report states, however, that the introduction of such a scheme may involve difficulties in certain industrial areas with regard to the treatment of insured persons by salaried medical officers, and that it may be necessary, after further discussion with the interests concerned, to exclude temporarily from the application of the scheme certain specified areas.

In connexion with the recommendation of the Irish Public Health Council that the appointments in the new medical service should be made as the result of competitive examination, it is of interest to note that the Irish convention appointed by the Prime Minister in 1917 "to draft a constitution for Ireland which should secure a just balance of all the opposing interests," recommended the formulation of a scheme of competitive examinations for admission to the public service, including all statutory administrative bodies—for example, county councils, etc.

Hospitals.

The report recommends as a very important part of an Irish medical service the co-ordination of the hospital system throughout the country. It is generally admitted that the whole hospital system in Ireland (particularly in the case of the voluntary hospitals in larger cities) requires development and further financial assistance if suitable and adequate hospital treatment is to be available for all classes of the community who are in need of it. Suggestions are made by which the voluntary hospitals can be placed on a firmer financial basis. As regards the county infirmaries, it is recommended they should come under the County Health Boards as part of the hospital system of the Irish medical service, and that all existing financial restrictions should be removed. Finally, the County Health Boards should be entrusted with the local administration of schemes for the medical treatment of expectant and nursing mothers and of young children, as well as of schemes for the medical inspection and treatment of school children. In order that these services may be fully correlated and satisfactorily carried out, the whole system of hospital and institutional treatment of the sick in each county and county borough should be co-ordinated under the County Health Boards.

As regards preventive medicine, the report recommends the appointment of whole-time medical officers of health and the provision of funds for research work.

The report does not deal with the details of the medical service, either as regards its preventive or curative side.

This can be understood, as, apart from making an unanswerable case for a new Irish medical service on a broad basis, the report is content to rest with the suggestion that it would be sufficient if the bill for the establishment of a Ministry of Health for Ireland contained a provision requiring the Ministry to frame a scheme for an Irish medical service centrally appointed and controlled, and entrusted with the duties to which reference has been made above.

THE TREATMENT OF MALARIA.

THE volume of *Observations on Malaria* Sir Ronald Ross has edited for the War Office had its origin in an instruction to the D.S.M.S. of Mesopotamia, Salonica, Egypt, Italy, and France, to obtain reports of scientific observation; on malaria from such officers as were specially qualified to deal with the subject. The result is the eight papers of the present volume, of which four are concerned, directly or indirectly, with treatment, one with an anti-malaria campaign in Italy, two with mosquito surveys and antimalaria work in England, and one with complement fixation in malaria.

The report by Dr. Nierenstein on the excretion of quinine in the urine is based on the examination of 834 specimens from eighty-six malarial patients. It contains a mass of information on the relative value of a number of tests, and quantitative results expressed in tables: it will be consulted by all who are working now or in the future on this subject, which is one for the chemist. It is pointed out that the large amount of work done on the excretion of quinine in dogs is justified by the fact that the dog normally excretes in the urine a substance related to quinoline. He has found a new disintegration product of quinine with haemolytic qualities, provisionally named haemoquinic acid, in the urine of twelve out of thirteen cases of blackwater fever, an observation which may help to throw light on the nature of that lethal disease.

From the military point of view the most interesting contribution is that by Lieut.-Colonel Dalrymple on the treatment of malaria-infected troops in France. The criticism that preventive work on malaria should take precedence of curative may be anticipated by the reflection that in war it must needs be that infections come. It is prefaced by a letter from Field Marshal Earl Haig, which states that the results obtained "were highly satisfactory in bringing about the rapid restoration to the fighting ranks of men who in many cases had previously been for months under treatment without avail."

In June and July, 1918, there arrived in France from Salonica 22 battalions of infantry, every one malaria-infected. It was necessary that they should be fitted for the fighting line with as little delay as possible, for the reinforcement was much needed. From examinations of blood films Colonel Dalrymple estimated that treatment was necessary in from 75 to 85 per cent. of the men. They were formed into two divisions, and the sympathy and co-operation of divisional, battalion, and company commanders, as well as senior non-commissioned officers, were enlisted. The treatment consisted, on the one hand, of a quinine salt systematically administered, 15 gr. daily for fourteen successive days, and then 60 gr. a week for two months; and on the other, of regulated military duty, games, sports, amusements, and the "forward area" ration. A man who relapsed was treated in his own unit. Men who had undergone twenty-eight days' treatment without a relapse were allowed to proceed on leave with fourteen days' supply of quinine tablets. No officer or man escaped treatment, whether he had or had not suffered from malaria: the time factor made this essential. The work done was graduated from four non-consecutive hours up to route marches with full packs, and finally a night in the open without blankets, following such a march; reports were rendered by the regimental medical officer on all such occasions. Sea bathing, which was encouraged under supervision, did not increase the number of relapses. The results of this interesting experiment were excellent: the average duration of treatment was ten weeks, and "two divisions were put in the forward area within three months of commencement almost relapse-free." Moreover, "both divisions distinguished themselves beyond all praise in the front line"; in fact, the success was such that 12,142 men

were sent over from England to undergo the same treatment.

The observations on the pathology and treatment of malaria by Mr. Harold Row, late assistant lecturer in zoology, King's College, London, who unfortunately died from influenza before he had completed his paper, are founded on the study of cases at the 4th London General Hospital between February, 1917, and January, 1919; microscopical examinations were made in each case, as much as a cubic centimetre of blood being scrutinized by the thick film method. The paper deals almost entirely with treatment, first of benign and secondly of subtertian infections, which are so often lumped together to the detriment of sound conclusions. With regard to *P. vivax*, the parasite of benign tertian (about 1,000 cases were studied), the author came to the conclusion that long continued quinine treatment is imperatively necessary to secure even a reasonable freedom from relapse, and that anti-relapse treatment will produce this result in a large proportion of cases. After a number of trials the best form of treatment for the malarial attack was found to be 10 grains of quinine hydrochloride three times a day for at least twenty-one days; of 516 cases so treated it is stated that 30.2 per cent. relapsed, but it appears that most of these were "reported" and not parasitic relapses, and the period for which the cases were under observation is not clear. Moreover, the record does not enable the inquirer to ascertain in what proportion of cases the initial quinine was followed by anti-relapse treatment. This consisted of 10 grains of "quinine" either daily or thrice daily for two days each week. Under this treatment relapses occurred even under hospital conditions, but in the case of men getting 20 or 30 grains daily they were so rare as to call for a personal explanation when they did occur. As "quinine resistance" is quite commonly reported, it is interesting to notice that of 13 men (out of 774) who so relapsed 8 were shown to have avoided swallowing the quinine, or in one instance to have induced vomiting immediately after leaving the medicine room. Mr. Row found that, whereas cases infected with *P. vivax* are liable to relapses for long periods and complete eradication of the infection is difficult, in those due to *P. falciparum*, the parasite of the subtertian variety, the patient will be cured in a large number of cases by the first treatment given, especially if followed by anti-relapse quinine treatment for, say, six months; it should be noted, however, that the number of cases was comparatively small, and the period of observation is not given. Mr. Row saw no essential difference between administration by the mouth and by intramuscular injection, and no advantage in specially timing the dose of quinine; in this he is at variance with such a careful observer as J. D. Thomson, who points out that, especially where the resisting power of the patient is low, success may be obtained with less quinine than would otherwise be needed if its administration is timed so as to secure concentration in the blood at the right stage of the parasitic cycle.

The observations of Captain T. Gardner on the malaria parasites under the influence of various doses of quinine administered by the mouth contain a great deal of statistical information which will well repay study.

Colonel J. C. Robertson, I.M.S., reports on the anti-malarial campaign at Taranto, Southern Italy, during 1918. A large rest camp was formed, and as the district was known to be malarious, "arrangements were made for all the usual anti-malarial operations to be brought into force." But it appears that these were not sufficiently thorough or extensive, and partly owing to an instruction that malaria was not to be diagnosed unless parasites were found in the blood, the reporting of cases was faulty. Indeed, it is stated that many cases were labelled P.U.O., influenza, etc., though they were regarded as malaria and reacted to quinine! Late in the autumn of 1917 the arrival of troops badly infected at Egypt and Salonica was reported, and the extent of the danger may be gauged in some degree by the fact that among 1,573 officers and other ranks of the permanent staff at Taranto there were 220 primary admissions to hospital for malaria, or 14 per cent. The author was sent to Taranto in December of that year. As protection from mosquitoes he asked for huts for the troops, but the type supplied proved difficult to render mosquito-proof, and the wire gauze furnished was of too large a mesh to be effective, so that reliance had to be

placed on destruction of mosquitos—the killing of hibernating adults and the oiling or draining of breeding places and wells. The camp was drained by Major Kenworthy, R.E., at a cost of 186,000 lire, and all operations were well advanced before the breeding season commenced. Of 949 anophelins examined between June and November an infection of the stomach was demonstrated in 74 and an infection of the salivary glands in 12, so that the risk of occurrence of human infection was not negligible. The result of the measures taken was that between April 15 and December only 16 cases of primary infection occurred, and it was doubtful whether more than one of these were contracted in the camp. This result is contrasted with the very unfavourable figures of an Italian anti-aircraft battery hard by the camp.

Major Angus Macdonald, well known in the West Indies, contributes a report on indigenous malaria and malaria work with the troops in England in 1918. After furnishing some account of the control of malaria carriers in England he gives a tabular record of 61 authenticated cases (as against 163 in the previous year) showing the relation of each to carriers and anophelins; in nearly all instances female *Anopheles maculipennis* were found in the huts. The infective foci numbered 29, of which 4 were situated in Kent (42 cases) and the remainder in nine other counties. In the majority the attack occurred in August or September; the onset of three in May is best explained by the "incubation" of infected mosquitos in heated huts, for the malarial cycle in the mosquito in this climate requires summer temperature. In a discussion of the endemicity of malaria in England it is stated that the last epidemic of ague occurred in 1858 to 1860 when the disease was imported by troops from the Crimea. Major Macdonald believes that "the factor definitely determining the occurrence in England is the importation of carriers, and that at the present day there is no evidence to support the belief that malaria is endemic in England." The disappearance of the disease is not, he says, to be attributed to quinine in "its notoriously casual method of administration," nor do the hypotheses of climatic change or "agricultural reorganization" satisfy him. He notes that in 1857 to 1859, besides the carrier importation, the factors of heat and of rainfall were at the optimum. His "chronological entomological record" in tabular form, wherein the findings of anophelins in the adult and larval stages in many places are set down, will, together with a similar table by Captain Parsons, be of value to future workers in this field. Details are furnished of the breeding habits of the species *A. maculipennis* and *bifurcatus*; the latter, as is well known, is a "wild" mosquito, whereas *A. maculipennis* is commonly found, as was pointed out by Grassi, in stables and byres; but *A. bifurcatus*, as an illustration shows, was once found in a farm water-butt. The operations whereby the dykes at Sandwich, Sheppey, and Lydd were rendered inhospitable to larvae are described in detail; resort was not had to oiling. Major Macdonald's paper is effectively illustrated.

Captain A. C. Parsons's contribution on mosquito surveys during 1917 and 1918 of camps and barracks in England where malaria was possible or actually present, is concerned with adult anophelins and the aquatic forms. He found that in a mixed camp anophelins will be discovered, if at all, in the marquees and tents rather than in huts or permanent buildings, and confirms the observation of others that the adults are to be found more thickly in piggeries, stables, and cow byres than in human habitations; indeed, though anophelins as a rule prefer upper stories, in the case of certain cavalry barracks the men's quarters above the stables were singularly free from mosquitos, and other striking instances of the kind are given. Farms are therefore important "test places." It may be here remarked that, in the belief of the French observer Roubaud, domestic animals play a part of first importance in diverting anopheles mosquitos from human habitations, and he deprecates the whitewashing of cowsheds; Colonel James suggested some time ago that it would be better to whitewash dark and dirty corners of human dwelling places.¹ The characters of typical breeding-places are described. *A. maculipennis* was found to dislike water not exposed to the sun, so that ill-considered clearing may encourage this species.

¹ Proceedings of the Special Clinical and Scientific Meeting, British Medical Association, London, 1919.

Lastly, Dr. Gordon Thomson, Protozoologist to the London School of Tropical Medicine, relates his experiments on the complement fixation in malaria with antigens prepared from cultures of malaria parasites. This is pioneer work of prime importance, for if it is possible to perfect the methods employed the results of a complement fixation test will tell us whether and when a malarial infection in any patient has died out, and replace the unsatisfactory uncertainty in which we now stand. The details are of necessity very technical, and at present, Dr. Thomson states, the test is subject to great error.

The volume closes with Provisional Instructions for the Treatment of Cases of Malaria in the United Kingdom, dated August, 1917, and the Interim Report on the Treatment of Malaria, which has been published elsewhere, and, it must be confessed, is calculated rather to befog than to assist the seeker after knowledge.

VITAL STATISTICS OF ENGLAND AND WALES.

(Continued from p. 537.)

ENCEPHALITIS, CEREBRO-SPINAL FEVER, POLIOMYELITIS, POLIOENCEPHALITIS, AND NEURITIS.

The deaths attributed to encephalitis in 1918 numbered 366 (207 males and 159 females), as compared with averages of 184 and 133 respectively for the two sexes in the preceding seven years. Evidence is found, both in the increase of the number and proportions of deaths notified as due to encephalitis, and in the seasonal concentration of these deaths within months in which encephalitis lethargica was prevalent, that the outbreak in the spring of the disease so termed was responsible for a considerable proportion of the deaths recorded as encephalitis. By estimation of this proportion and addition of 101 deaths returned as encephalitis lethargica, polioencephalitis, etc., and 28 deaths ascribed to "botulism," Dr. Stevenson arrives at a total of 180 deaths attributable to encephalitis lethargica.

Cerebro-spinal Fever.—The deaths from cerebro-spinal fever in 1918 numbered 812, as against 1,974, 1,214, and 1,531 in 1915, 1916, and 1917 respectively. Before 1915, the highest recorded numbers (163 and 194) occurred in 1913 and 1914. The figures for 1918 again show a much higher mortality among non-civilians than among civilians and females of the same age-groups.

Poliomyelitis and polioencephalitis were assigned as the cause of death in 268 cases (134 each for males and females) in 1918. These are the highest figures recorded since the adoption of the classification of 1911. The increase represents mainly deaths of adults, and when deaths certified as infantile paralysis or poliomyelitis are distinguished from those attributed to polioencephalitis, is found to concern the latter group only. The number of certificates relating to polioencephalitis was almost twice as great in 1918 as in the whole of the preceding five years. There is therefore little doubt, Dr. Stevenson thinks, that the increased mortality under this heading is to be attributed to deaths from polioencephalitis of epidemic origin; the facts strongly support the view that poliomyelitis is a distinct disease from lethargic encephalitis. The number of deaths recorded as due to poliomyelitis has varied little during the years 1913-18; in the period 1916-18, however, notifications of this disease declined from 704 to 236 annually.

Neuritis.—Deaths from this cause, which averaged 481 a year in 1911-14, fell to 158 in 1918; the decline is much greater for females than for males, and has caused the mortality among females to become less than that recorded for males, although it has previously been twice as great. From 1911-14 the average number of deaths annually assigned to alcoholic neuritis was 26 for males and 70 for females; these numbers have now been reduced to four and three respectively. It seems probable, Dr. Stevenson remarks, that the reduction which has occurred in deaths ascribed to neuritis without mention of alcoholism may be due to the same cause. If this is so, the conclusion is indicated that in the past the majority of cases of fatal neuritis among women have been due to alcoholism, but that there is a residue of cases of neuritis, equally large among men and women, which there is no reason to regard as caused by alcohol.

DEATHS UNDER ANAESTHETICS.

The number of deaths during or in connexion with the administration of an anaesthetic has been very constant

during the last seven years, and in 1918 was 279. In 67 per cent. of the cases the nature of the anaesthetic was stated; of these cases chloroform is recorded in 43 per cent. as the only anaesthetic administered, and in 32 per cent. as administered in combination with some other agent, so that in 25 per cent. only of these cases was chloroform not used. The conditions associated with the greatest mortality in connexion with anaesthetics were: Various forms of violence 40 (including 23 cases of battle wounds), hernia 19, empyema 18, enlarged tonsils and adenoids 18. Status lymphaticus was noted in the case of 23 deaths under anaesthetics. Of these cases 16 were in persons less than 11 years old. In 9 the anaesthetic used was chloroform, in 4 ether, and in 3 chloroform and ether; in the remaining 7 cases the nature of the anaesthetic employed is not stated.

ALCOHOLISM.

During 1918, 81 deaths (61 males and 20 females) were attributed directly to alcoholism. These figures, in accordance with the heading in the International List of causes of death, exclude cases of organic disease attributed to alcoholism. For purposes of comparison all death certificates in which there appeared any mention of alcoholism have been assembled in a special table; the most common associated conditions were cirrhosis of the liver (92), violence (43), lobar pneumonia (31), organic heart disease (24), and influenza (19). The total deaths reckoned in this manner were in 1918 under 400, as compared with 648 in 1917, 1,054 in 1916, 1,551 in 1915, and (in round numbers) from 1,500 to 2,400 annually during the years 1904-14. The alteration of the age-constitution of the male civilian population due to the war has the effect of masking to some extent the full reduction in the death rate, so that this diminution of deaths attributable to or connected with alcoholism is the more striking. In face of so sudden and so great a change (Dr. Stevenson remarks) it is well to bear in mind the possibility that war conditions may in some way have prevented deaths from alcoholic excess from being returned as freely as before, but "in the absence of any adequate explanation of the change on these lines its association with the restrictions on the manufacture and sale of alcoholic liquors entailed by the war appears to be inevitable." On account of difficulties experienced by practitioners in declaring upon an open certificate that death is due to alcoholism, the returns of death from this cause have long been recognized to be unreliable, but this factor of unreliability has been constant. Since the death rate has fallen enormously in conjunction with drastic restriction of the supply of alcohol—this restriction being the one concomitant factor which has obviously changed—"it is difficult to avoid associating the two phenomena as cause and effect."

CIRRHOSIS OF THE LIVER.

Deaths assigned to cirrhosis of the liver in 1918 numbered 1,750 (1,121 males and 609 females); these numbers are very much below those of former years. If the figures are based on the less comprehensive classification (excluding cirrhosis certified to be alcoholic and certain other conditions) which was in use prior to 1911, the deaths for 1918 are reduced to 1,034 males and 545 females; these figures are 26 per cent. below the exceptionally low levels of 1917 and are much the lowest recorded— notwithstanding increase of the population—since the commencement of the record in 1875. The fall in mortality during the war has amounted to about 66 per cent. for females and 50 per cent. for males (those under 45, in whom only 20 per cent. of the mortality occurs, being excluded). Corroboration is found in these figures of the universally held opinion that alcohol causes a certain proportion of the mortality from cirrhosis; and (Dr. Stevenson remarks) "if as a result of increase in the supply and consumption of alcohol in 1919 and subsequent years the death rates under consideration rise once more, the evidence that their fall was due to decreased consumption will be overwhelming." The greater decline in deaths of females has increased the excess of male mortality (normally about 40 per cent.) to 161 per cent. This figure corresponds with the statement usually made in medical textbooks, but has never before been attained in English death certification.

SATURDAY, JUNE 26TH, 1920.

THE ETIOLOGY OF LOBAR PNEUMONIA.

KNOWLEDGE concerning the causation of lobar pneumonia grows apace. It was but recently that American observers¹ succeeded in differentiating the pneumococcus into a number of serologically distinct types, and then determined the frequency of each type in cases of lobar pneumonia. It was found that about 64 per cent. of the cases yielded specimens of either Type I or II, 12 per cent. yielded specimens of Type III, while in 24 per cent. pneumococci were present that could not be identified with any of these types, and were accordingly grouped together as Type IV. An attempt was at once made to apply this new knowledge in order to obtain a rational system of specific therapy for the treatment of cases of lobar pneumonia. From the information available it would seem that the administration of serum prepared against Type I pneumococcus has been of great value in the treatment of cases infected by that strain of the micro-organism. The efficacy of this serum, however, is limited to cases infected by Type I, and according to reports published up to the present time, serum prepared against other types of the pneumococcus has been less successful.

For a long time the pathogenesis of lobar pneumonia has remained obscure, and the experimental studies of Blake and Cecil² carried out in the laboratories of the United States Army Medical School at Washington throw a welcome light upon it; they have succeeded in producing a disease corresponding apparently in all respects with lobar pneumonia in man by introducing the pneumococcus into the trachea of monkeys. The needle of a hypodermic syringe was inserted between the rings of the trachea just below the larynx, and a small dose (1 c.cm.) of a dilution of a broth culture of the pneumococcus introduced in this way into the trachea. The great majority of the monkeys injected in this manner developed lobar pneumonia. In some cases the dose required to produce this result was but one millionth of a cubic centimetre of a broth culture. The monkeys were kept under daily observation, and records were made of the clinical symptoms and physical signs, the temperature, the leucocyte count, and the number of pneumococci developing in cultures from 0.5 c.cm. of their blood. In those that died and in some that were killed at an early stage of the disease a careful histological examination was made of the lungs. It was found that the temperature curves shown by the inoculated monkeys were identical with those of cases of lobar pneumonia in man, presenting the features of sudden onset, sustained elevation throughout the course of the disease, and a fall by crisis on the seventh or eighth day. In some cases the pneumonia remained unresolved, and in others empyema or pericarditis occurred as a complication.

Lobar pneumonia was produced in this way with each of the serological types of the pneumococcus. Out of 31 monkeys injected intratracheally with

Type I lobar pneumonia resulted in 26; of these animals 21 succumbed and 5 recovered. It is of interest to note that while monkeys injected with Types II, III, and IV, also developed pneumonia, they recovered. Although these different specimens of the pneumococcus were alike virulent to mice on intraperitoneal injection, Type I was thus far more virulent than the others to the monkey when introduced into the trachea.

Control experiments were made by injecting monkeys intratracheally in the same way with the same quantity of sterile broth or of broth containing killed pneumococci, with negative result. Attempts to produce pneumonia by instillation of large quantities of virulent pneumococci into the nose and throat of monkeys were also unsuccessful, though the pneumococci thus introduced could be detected in the secretions of the mouth for at least a month. Attempts to produce the disease by subcutaneous or intravenous inoculation of virulent pneumococci also failed; when the animals died, they succumbed to septicaemia.

From their histological observations Blake and Cecil conclude that the pneumococcus, when introduced into the trachea, is absorbed from the bronchi by the lymphatics of the lung, and thus gets into the blood stream. They found that a preliminary leucocytosis began usually within six hours of injection, and reached its apex within twenty-four to forty-eight hours. No relation could be established between the height of the preliminary leucocytosis and the subsequent course of the disease. There is little doubt that it represents an attempt on the part of the body to reinforce the resistance at the site of entry of the pneumococcus. A consistent fall in the leucocyte curve was observed to follow this rise. The rapidity of the fall appears to bear a direct relation to the severity of the disease in the monkey.

In the majority of cases the pneumococcus was recovered from the blood of the monkeys within six to twenty-four hours of its injection into the trachea, and frequently before elevation of temperature or clinical evidence of pneumonia had developed. These observations, therefore, would appear definitely to solve the problem of the pathogenesis of pneumonia, and also to explain the early presence of the pneumococcus in the blood of patients suffering from this disease. It will be of interest to see the further papers promised by these observers, in which they propose to describe the result of introducing other living bacteria into the trachea in the same manner.

THE TREATMENT OF MALARIA.

MALARIA is one of the most widespread diseases, being endemic in probably all parts of the tropics and subtropics and in many regions of the temperate zone. Since, where it is endemic, it is usually very common, the best method of treating it is a question of great importance to large numbers of medical men. During the last half-century the disease had almost ceased to be endemic in this country, but the war has increased the number of malarious persons here who contracted the disease abroad, so that, leaving aside for the moment the question whether the indigenous disease still lingers in some few places in England, treatment has become a subject of greater concern to home practitioners.

Quinine is still the sheet anchor, but there are a great many opinions as to the best way of administering it, a fact to which recent correspondence in this JOURNAL has borne witness. The

¹ Acute Lobar Pneumonia, Monograph No. 7, Rockefeller Institute, N.Y., 1917.

² Blake, F. G., and Cecil, R. C.: Experimental Pneumonia. *Journal of Experimental Medicine*, vol. 31, Nos. 4 and 5, 1920.

Volume on malaria recently issued by the War Office owes much of its value to a discussion on the vast experience gained during the war in the treatment of malaria, and in particular of relapses. We give elsewhere in this issue (p. 872) an account of the principal points elucidated in the volume, and have stated at some length the system recommended by Colonel Dalrymple. The chief value of his paper, however, lies not in the particular mode of administering the quinine he favours—probably other prescriptions would have been equally effective—but in his recognition of the fact that save in recent infections, which as a rule yield to the drug more readily than old, the administration of quinine forms but a part in the management of malaria. As to how great that part is opinions differ, but the chief lessons to be learnt from the experience related is that abundant nutritious food, work graduated to the patient's powers, occupation for the mind, a cheerful environment in a congenial climate, aided by quinine, worked wonders; after a period of at most ninety days practically all the troops had reached such a stage of fitness that they could share the arduous labours of the front area. Perhaps it was fortunate that the treatment was carried out in the summer months, for Dr. J. W. W. Stephens and his colleagues have shown at Liverpool—in a paper that seems to have secured little attention—that the liability to relapse is then at its lowest; in the Liverpool figures the "percentage of cures"—that is, a period of sixty days without relapse—was, in January to April, 10 per cent., but in July to October 60 per cent. or over. It would be interesting, if the figures could be obtained, to learn how many men of Colonel Dalrymple's two divisions relapsed in the succeeding winter and spring. Major Angus Macdonald argues ably in support of his belief that malaria has altogether ceased to be endemic in England; and Nuttall, Cobbett, and Strangeways, writing in 1901, spoke of the disappearance of malaria from Great Britain: this opinion has been generally accepted, although in a table of the distribution of ague in England in the nineteenth century a case at Acle, in Norfolk, is noted. Colonel S. P. James, I.M.S. (retired), now attached to the Ministry of Health, who during the war was concerned especially with malaria among the civil population, found evidence that a certain number of the cases in north-west Kent were indigenous. Of those detected in Sheppey in 1917 some infections were evidently contracted from troops returned from Salonica, but one group, in Queenborough town, could not be ascribed to such an origin; indeed, some infections could be traced to civilian cases which had originated before troops had begun to return from the Eastern Mediterranean. A similar outbreak of true indigenous malaria was observed in the Isle of Grain. "As regards malaria in England," he writes, "we have to deal with two different and as a rule independent conditions: the one arising from the importation of exotic malaria and due to a foreign strain of the parasite, the other being true indigenous malaria due to a parasite which has never entirely disappeared from this country." He finds that with the indigenous variety the cases are mild and relapses are rare. Some of the infections were only discovered during the routine examination of all the inhabitants of a house.

Major Macdonald holds that a large proportion of those infected in one year will for various reasons have ceased to be infective before eleven or twelve months have passed, and that therefore the *Anopheles* biting again after that interval will not become infested with the parasite, so that the chain of infection will be broken. Colonel James, however, shows that

among 20 cases continuously observed from their original attack in 1917 only 6 had no relapse: among the remaining 14 there were 19 relapses, and 9 of these relapses occurred in July to September.

Nevertheless, it is improbable that we shall see any recrudescence of malaria in this country. The contact between man and *Anopheles* was closer in the years of the war than it is likely to be again, and human carriers were more numerous then and in 1919; yet the number of infections was always manageable. Sir William Osler pointed out that in temperate climates districts from which malaria has disappeared have not been reinfected; thus, the progressive fall in the incidence of malaria in Baltimore was not interrupted by the importation of many infected Italians. He attributed a definite rôle in the disappearance of malaria from the great Canadian lakes to the cinchonizing of the inhabitants.

SIR CLIFFORD ALLBUTT'S PORTRAIT.

The presentation to Sir Clifford Allbutt of his portrait, painted by Sir William Orpen, R.A., will be made on Tuesday, June 29th, at 10 p.m., in King's College, Cambridge, after the delivery of his address as President of the British Medical Association. The presentation will be made by Sir Norman Moore, Bt, President of the Royal College of Physicians of London, on behalf of the medical profession.

THE PRODUCTION OF CLEAN MILK.

In our issue of November 8th, 1919 (p. 608), an account was given of the investigations made at the Research Institute in Dairying, University College, Reading, by Freear, Buckley, and Stenhouse Williams, who estimated that for the production of clean milk a charge of 3d. a gallon over and above the market price would meet the increased cost of elaborate apparatus and more careful methods. Bacteriological examinations showed that the main cause of uncleanliness of milk was contamination at the outset; where this contamination had occurred, no subsequent cooling or other manipulations, and no reduction of the length of its journey could remedy matters to any significant extent. Further investigations¹ have now been made at Reading by Knight, Freear, and Stenhouse Williams, who examined systematically the conditions which at the time of milking determine the degree of bacterial concentration subsequently to be found. In the first series of experiments the results of the use of open and covered buckets for milking were compared; on every occasion the number of organisms obtained from the covered bucket was higher than that from the open bucket. The reason for this was revealed when the internal condition of the two buckets was compared; both naked-eye and bacteriological examination showed the internal surface of the covered bucket to be much less clean than that of the closed. When the washing of the buckets, which had hitherto been entrusted to the farm worker, was taken over by the experienced clean milker using the same materials, a great reduction was found in the number of organisms from the milk of the covered bucket. In a third series of experiments both kinds of buckets were steamed for forty minutes, their temperature being raised to 95° C., and kept covered till milking time next morning. Under these conditions the bacterial counts of milk from the covered bucket were much lower than from the open bucket. In the fourth series of experiments it was found that the removal of the long hairs from the udders and the washing of the cows led to a still greater decrease in bacterial contamination. The experiments showed that, given intelligent and

¹ A Study of Factors Concerned in the Production of Clean Milk. Part I. By Edith G. Knight, Kathleen Freear, and R. Stenhouse Williams. London: P. S. King and Son. 1920. (Price 1s.)

interested laborer, it is possible, with comparatively simple equipment in an ordinary cowshed, to produce milk of a high degree of purity. The authors describe the sterilization of buckets as actually carried out on a Grade A milk-producing farm: After being rinsed with cold water and scoured with soap and hot water, then placed in a cold water tank, and finally rinsed with the cold jet from the hose pipe, the buckets are placed in a sterilizing tank, steamed for twenty minutes, and kept in the tank until needed for the next milking. The receiving tank, strainer, and cooler are all carefully washed and treated with current steam in the same way as the buckets. During three years' employment of this method the authors have satisfied themselves by weekly examinations that the cleanliness of the milk has been invariably satisfactory.

RECENT WORK ON HUMAN METABOLISM.

The indefatigable staff of the Carnegie Institute, Washington, have issued two stout volumes¹ discussing important problems of human nutrition. In publication No. 279 Drs. Harris and Benedict subject the data accumulated by many workers with respect to the rate of basal metabolism to a complete statistical analysis. They show that the usual statement, that the caloric output of a resting adult per square metre of body surface is constant, lacks precision. Actually, the basal metabolism of an unknown person can, by means of a linear equation, in which age, body weight, and height are substituted, be predicted with greater average accuracy than is obtained by the usual plan of multiplying body surface by a constant. A table is provided which will save other workers the labour of making calculations. The authors also devote a large number of pages to the criticism of opinions supposed to be entertained by other physiologists, and at times recall to the memory a taunt of Galen: "Such are the opinions of the school of Sabinus, persons who furnish improbable explanations of events which do not happen." Whether Drs. Harris and Benedict have always successfully identified the pupils of Sabinus is perhaps open to question. Publication No. 280 contains 701 large octavo pages and is devoted to an exhaustive study of two experiments upon squads of college students placed for varying periods upon diets low both in the yield of total energy and in the content of protein. The experiments show that it was possible for healthy young men to live the normal life of college students for several months on a diet fully one-third less than ordinarily required, and that, *inter alia*, a new equilibrium of basal metabolism upon a lower plane was temporarily established. In an essay on Tennyson, Walter Bagehot quoted the ten lines which describe Enoch Arden's customary occupation, and added the comment, "So much has not often been made of selling fish." We mean no disrespect to the acute and laborious compilers of publication No. 280 when we say that their 701 pages very often recall Bagehot's comment. We dwell on this because, despite the paper shortage, the habit of printing ill-co-ordinated contents of laboratory notebooks is not declining. In our judgement, the value of this monograph would have been increased had its bulk been reduced by four-fifths. A great many experimental methods which did not in fact lead to any important conclusions are described in detail, to the confusion of the ordinary reader and without any compensating advantage to the expert, since the very small number of physiologists who command the necessary material facilities for such researches would naturally communicate with the workers at the Carnegie Institute before embarking upon a prolonged inquiry on such lines, for even 701 pages cannot contain all the minute details of technique that an experimenter needs to know. There is, again, a lack of the sense of proportion

in writers who, while meticulous in their description of experimental methods, infer from the remarks of twenty-four students in response to questions on the subject of nocturnal emissions, sex feeling, etc., that "our data indicate that Nature demands a rather high metabolic level for the normal functioning of sex in man," and that "these results appear to us of considerable significance." The specialist will find in this volume, particularly perhaps in the part dealing with the excretion of nitrogen, interesting matter; we do not think it either attractive or of particular value to the general medical reader.

COMPLEMENT FIXATION TEST IN SYPHILIS.

The importance officially attached to the complement fixation test in syphilis (commonly known by the name "Wassermann test") is evidenced by the number of reports with regard to it recently issued. Early in 1914 the Local Government Board resolved to make a grant for an investigation into the merits of the various methods of conducting the test. The investigation was to have been carried out in the Military Hospital, Rochester Row, under the direction of Colonel L. W. Harrison, but the scheme was stopped by the outbreak of war. On Colonel Harrison's return to Rochester Row it was revived, and Drs. Eastwood, Griffith, and Scott, pathologists to the Local Government Board, were appointed to work in association with Colonel Harrison. The Medical Research Committee also gave attention to some aspects of the matter and published reports, including two by its Committee on the Standardization of Pathological Methods. The investigation for the Local Government Board was carried on at the same time, and the result is now seen in a volume¹ issued by the Ministry of Health. It contains an introduction by Colonel L. W. Harrison, and two reports, the one by Drs. F. Griffith and W. M. Scott on the technique of the Wassermann reaction, and the other, by Dr. Arthur Eastwood, on the principles involved in the test. The reports of the Medical Research Committee showed that when due precautions are taken the reaction possesses a high degree of reliability. The object Drs. Griffith and Scott had in view was to investigate the behaviour of each agent employed in the reaction. They propose a routine method of applying the test, which they consider free from certain objections; in it the amount of complement containing serum is kept constant. Dr. Eastwood's essay is of a more general character; it contains a very large amount of highly technical information, but the author is far from claiming that all the difficulties are solved; in fact, he winds up both parts of his essay, the one dealing with complement and the other with the "Wassermann substance," by an enumeration of the controversial matters still open.

ANTE-NATAL RESPIRATORY MOVEMENTS.

To many thoughtful obstetricians the reflection must often have come as they watched the first inspiratory efforts of the newborn infant immediately after its expulsion from the canal that these movements were unexpectedly successful and complete if they were, indeed, being performed for the first time and with no preliminary practice. But the question arises whether it is right to assume that no such preliminary respiratory gymnastics (so to say) are undertaken by the unborn infant. Both Ballantyne, in his *Manual of Ante-natal Pathology* (vol. i, pp. 144, 169), and Feldman, in his recent work on *Ante-natal and Post-natal Child Physiology* (p. 146), accept the probability of the explanation that the rhythmic fetal movements which are sometimes felt by the expectant mother and which have been actually seen in tracings by Ahlfeld and Ferroni are thoracic in their nature. It may be taken for granted that they are not sufficiently strong to draw

¹ A Biometric Study of Basal Metabolism. Harris and Benedict. Human Vitality and Efficiency under Prolonged Restricted Diet. Benedict, Miles, Roth, Smith. Carnegie Institute, Washington, 1919. Publications 279 and 280.

liquor amnii into the lungs, although even in this respect it is unwise to limit belief too strictly, and they may be real enough to act as preparatory exercises for post-natal respiration. Ballantyne indeed finds in them "further proof that nature makes no leaps (*non facit saltus*), but prepares beforehand for the transitions of life and even for those of them which seem at first sight so abrupt as does the establishment of pulmonary respiration in place of placental." A curious piece of corroborative evidence has recently been furnished by Hans Jaeger of Zurich (*Korresp. f. Schweizer Aerzte*, No. 39, 1919) in his report of a newborn infant which perished from asphyxia on the second day of life. The ribs showed numerous exostoses, several of which were articulated to each other, and showed signs of displacement in a horizontal direction; some of the exostoses were covered on their surfaces of contact with cartilage, and in a few instances there was a capsule with a joint cavity containing synovial fluid. Similar articulations were detected between exostoses and adjacent ribs. It seems impossible to avoid the conclusion that these intercostal exostoses had been moving upon each other in ante-natal life, for so elaborate an articulating apparatus could hardly have developed during the two days during which the infant made ineffectual efforts to breathe. It is unnecessary to point out the bearing which such new views may have upon some of the current beliefs in medical jurisprudence in relation to infanticide and the proof of live birth. The ambiguous and often discredited phenomenon of *vagitus uterinus* may even be restored again to credence.

AN INSTITUTE OF HYGIENE IN PARIS.

THE University of Paris has come to an understanding with the French Government, through the Minister of Health, and buildings have been found in Paris which can be converted into a large institute of hygiene. It will be under the general direction of the professor of hygiene, Dr. Léon Bernard, but there will be five sections, each with its director. It will have sections of epidemiology, of social hygiene, of food, of industrial hygiene, and of sanitary technology; and a series of laboratories—of bacteriology, chemistry, physics, and physiology—a museum, a library, and lecture rooms. Courses of lectures of two standards will be given, the one elementary, for ordinary students of medicine, and the other advanced, for doctors proposing to specialize in hygiene. Instruction will also be given to persons employed in disinfection and as health and school visitors. It is hoped eventually to extend the opportunities for study by establishing courses for architects, engineers, and statisticians. The food section will comprise three departments, the first dealing with the chemistry of foods and of adulteration, the second with the damage done by parasites and microbes, the third with the physiology of food and nutrition. An institute of hygiene on similar lines is also being established in the University of Strasbourg.

RETROGRADE ABSORPTION BY THE KIDNEY.

THAT the cells of the renal tubules can absorb substances from their lumina is known, or at any rate suspected, but the experiments of Carnot¹ illustrate strikingly this retrograde permeability. He injected 15 c.cm. of melted paraffin into the ureter of dogs, with the result that they developed almost immediately marked progressive dyspnoea and died in three minutes without convulsions. The fatal result was explained by the fact, verified invariably after death, that the paraffin injected into the ureter not only penetrated the calices and tubules of the kidney, but passed, immediately and before solidification, into the veins; in fact, blocks of paraffin were found in the right heart, and the pulmonary arteries at the hilus were injected by a solid mass of paraffin, which completely blocked the circulation and produced immediate death. Histological

examination of the kidney showed how the passage had occurred. The excretory system of the kidney was extensively injected; the paraffin was found not only in the straight tubules, but also in the convoluted tubules, in the glomeruli, and in the efferent veins. The immediate passage of the paraffin from the excretory apparatus to the blood was not due to any traumatic rupture, but must have taken place before solidification had time to occur. These experiments were done with paraffin melting at 50° C., but were repeated with a mixture of paraffin and vaseline melting at 45° C. In the latter case, as solidification was slower death occurred later, the animal surviving for about three-quarters of an hour. At the autopsy the whole excretory apparatus—ureter, pelvis, and calices—was found to be injected; in both sides of the heart there were small blocks of paraffin; masses of hardened paraffin were found at various parts of the lung, where they had produced more or less voluminous emboli. The microscopic examination revealed small fragments of paraffin inside the protoplasm of the tubular epithelial cells, whilst in the lungs, in addition to the arterial emboli, small particles of paraffin were found passing through the alveolar epithelium; finally masses were discovered in large quantity actually within the hepatic cells.

THE FUNDUS OF THE EYE AFTER DEATH.

LITTLE has been published about the changes in the eye after death since Gayet wrote his article in Norris and Oliver's *System of Diseases of the Eye*, now some twenty years old. Würdemann has discussed in the *American Journal of Ophthalmology* for May the external ocular signs of death, and gives two coloured plates of the fundus—the first half an hour after apparent death, the second about four hours after death. He states that about three hours after death the media become somewhat obscured by a lethal film due to the exudation of albumin and to disintegration of the corneal epithelium; the latter factor may be partly eliminated by the instillation of a few drops of water into the conjunctival sac. The changes seen in the fundus picture are due to the cessation of the circulation, the most noticeable being the yellowish discoloration of the eye background, the pallor of the nerve head, the narrowing of the arteries, and the appearance of clear spaces in the lumina of the veins; finally, after some hours the fundus assumes a dirty grey appearance, due to disorganization and infiltration of the retina, which becomes opaque and veils the subjacent choroid. Würdemann's article is interesting from an academic point of view, but we are not disposed to look upon it as of much practical value. The ophthalmic surgeon is very rarely present at death; the results of his handiwork may sometimes lead to blindness, but very rarely indeed to death. People who live in terror of being buried alive are more likely to leave directions to their executors that a surgeon shall be summoned after death to open an artery than an ophthalmologist to give an opinion on the fundus oculi; while many nowadays leave instructions for their cremation, and before that is carried out very stringent regulations establishing the fact of death must be observed.

AN evening concert in aid of the Royal Medical Benevolent Fund Guild will be given at Wigmore Hall, Wigmore Street, W., on Friday, July 2nd, at 8 o'clock. The following artists have kindly promised to assist: Miss Olive Sturgess, Miss Phyllis Lett, Mr. Lloyd Chandos, Mr. R. E. Miles, Miss Elsa Stamford, Miss Gertrude Tomalin, and Mr. Ernest Busby. Tickets (tax included), price 21s., 12s., 5s. 9d. and 3s., may be obtained from Miss M. Ellis Rowell, 49, Beaumont Street, W.1, or from the Box Office, Wigmore Hall. The Guild, a ladies' branch of the Royal Medical Benevolent Fund, was formed some ten years ago to supplement the work of the Fund, by visiting and other personal service, by providing clothes and other necessities, and by assisting in the education and technical training of the younger beneficiaries. This concert is part of an effort to put the Guild on a sound financial basis.

Medical Notes in Parliament.

The Threatened Western Extension of Typhus.

In his statement in the House of Commons on June 17th as to the present position of the League of Nations, Mr. Balfour spoke with satisfaction of the appointment of the permanent Advisory Committee on International Health. It was, he said, a very great advantage—an advantage much more easily obtained through the League of Nations than through any other conceivable machinery—that the nations of the world could appoint to advise them in this great international interest a body of medical experts in which all had confidence and in which all might feel that they were represented. The machinery through which this was being done was a medical conference, originally held in London at the inspiration of the League; he believed that it would contrive to frame an international permanent health committee that would serve an interest which, next to peace, was almost the greatest that he could imagine—the interest of the general health. Of the matters the League of Nations had taken up, in addition to those definitely imposed upon them by treaty obligations, the first was an attempt to deal with the threatened invasion of zymotic disease from the East to the West, especially in Poland. Every one knew that typhus, transported from Russia into Poland, had raged with great severity. Medical authorities were seriously alarmed as to what was going to happen in Central Europe in the coming winter. It was in the winter that typhus occurred with special severity. It was, therefore, during the summer most important to carry out those steps and take those preventive measures by which the population of Europe might be protected from such calamities as those with which our forefathers were only too familiar. Action had been taken through the Red Cross societies and an appeal had been made to the nations forming the union to provide such funds as were necessary for staying the disease. The Polish Government had spent money freely and with great public spirit and skill in doing what it could, but their efforts alone were not sufficient; it would indeed be entirely unfair to throw upon them unassisted the whole burden of acting as the guardians of the health of the West. The League had, therefore, after carefully considering the expert advice, come to the opinion that two million sterling would be sufficient, and that of this sum an immediate expenditure of a quarter of a million was obligatory, or at all events of the very greatest importance. The League had no power to tax the nations, and it was by no means clear if it had the power to say at what rate they should be severally taxed. There were nations who by their geographical position were profoundly and immediately interested in the sanitary condition of Central Europe. Other members of the League of Nations were separated by wide oceans and illimitable spaces from the scene of difficulty, and if an attempt were made to levy on that scale the differences would be very great. It was felt quite impossible to lay down what the nations ought to contribute. The appeal, therefore, would be to generosity, and he could not doubt that when it was made by the League of Nations to its component members it would receive an adequate response. If he were right in that prophecy, he hoped that the action they had taken might really be of first-class importance in preserving Europe from a repetition of such horrors as halved the population about the middle of the fourteenth century, and continued to decimate it for centuries afterwards.

State Grants to Universities.

On June 17th Mr. Inskip asked whether grants to universities would be made in the current year to the amount of £1,000,000; whether it was intended that in future years the grants should not fall below this figure; and whether universities in receipt of aids from rates raised by local authorities would receive grants in accordance with the principle stated by the Prime Minister on August 14th, 1918, to a deputation from the University of Wales. Mr. Chamberlain replied that the permanent State grant to universities was raised in 1919-20 from £468,000 to £1,000,000. The same sum was being provided in the present financial year in addition to certain non-recurrent grants, and would be continued in future years. The responsibility for the distribution of the moneys rested with the Treasury, which had always adopted the advice of the University Grants Committee. As regards the last part of the question, the doubling of the Treasury grant was decided upon some months after the deputation to which Mr. Inskip referred. The grant to the University

of Wales and its constituent colleges was determined by the £ for £ principle, this being in substitution for and not additional to increased grants on the lines of those given to English, Scottish, and Irish universities.

Voluntary Hospitals in London.—In reply to a question, on June 16th, Dr. Addison said that he was aware that the National Hospital for the Paralysed and Epileptic, Queen Square, and two others in London contemplated closing in whole or in part; the question of giving interim assistance to hospitals in serious financial difficulties was under consideration by the King's Fund. The position of many other London hospitals gave ground for anxiety, and he was considering what measures could be taken to meet the situation without prejudicing the voluntary principle and without losing the services of the voluntary workers, to whose co-operation he attached the greatest value. He had never been in favour of nationalizing the voluntary hospitals.

Medical Fees under the Workmen's Compensation Act.—In reply to a question by Sir H. Niell, on June 17th, the Home Secretary said that the question of the revision of the scale of fees to medical referees and assessors under the Workmen's Compensation Act, 1908, would be considered, with due regard to all relevant circumstances, after the Departmental Committee, which had been inquiring into the operation of the Workmen's Insurance Act, had reported.

Blind Welfare Committee.—Asked if he would arrange for a representative of the National League of the Blind to serve on the Blind Welfare Committee, Dr. Addison, on June 17th, said he was anxious not to increase the number of this committee unnecessarily. Its deliberations would extend to various kinds of industrial occupations, and it would no doubt seek the assistance of those competent to speak as regards the conditions in those occupations. He had already decided to ask a representative of the trade unions to serve on the committee.

Neurological Treatment of Pensioners.—Sir Henry Harris asked, on June 17th, whether there were more than 400 cases awaiting in-patient neurological treatment in London and the region immediately surrounding it; and whether, in view of the very serious results of delay and neglect, the Minister was taking steps to provide additional accommodation. Mr. Macpherson accepted the number stated as correct for the whole area covered by London and the south-eastern counties. Every effort was being made to obtain further hospital accommodation. Many difficulties had to be overcome, but he hoped that further facilities would be available at an early date.

Conditions at Kantara Camp.—Lieut.-Colonel Fremantle asked, on June 16th, if the War Secretary was aware of the insanitary condition of the camp at Kantara, Egypt, and of the absence of proper provision against the heat; whether there were in the camp and hospital over 200 officers and 100 nursing sisters who had been awaiting passage home for periods of three months or more; and what prospect could be held out of their return and of immediate improvement in the conditions of living there. Captain R. Terrell had down on the notice paper a similar question, and said that certain words had been omitted by the Clerks at the Table. He had desired to ask what steps are being taken to rectify "these irritating and costly delays." The Speaker reminded the hon. member that adjectives were not admitted into questions. Sir A. Williamson said that he realized the importance of the matter.

Census Bill.—This bill has completed all its stages in the Upper House.

Answers in Brief.

An instruction will shortly be issued that men who have served for six months during the late war will, provided they are otherwise eligible and medically fit, be allowed to join the Territorial Army even though they do not fulfil the physical standard laid down in the regulations.

Alternative pensions have not hitherto been allowed for nurses under the Royal Pensions Warrants. The question of extending the benefits of this class of pensions to nurses is at present under consideration, but Mr. Macpherson is not yet able to make any announcement on the subject.

The number of individuals liable to income tax for the year 1919-20 is estimated at 3,700,000. The number of individuals who will pay income tax for the year 1920-21 under the new Budget proposals is estimated at 2,450,000. These figures do not include individuals whose incomes are above the exemption limit, but who by reason of reliefs and allowances will not be liable to income tax.

Asked whether the Government will introduce a bill to give legislative sanction to the proposals regarding the employment of women before and after childbirth, which were adopted at the Washington International Labour Conference, Dr. Addison has stated that the British representative, acting on his own judgement, refrained from voting on this subject. The extent to which the British Government shall adhere to the recommendations of the Conference is being considered. The matters involved largely affect insurance questions and are being examined.

The Earl of Pembroke, the Earl of Onslow, Earl Beauchamp, Lord Wemyss, and Lord Muir Mackenzie will represent the House of Lords on the Joint Committee of the two Houses to which have been referred the two Criminal Law Amendment Bills that have had second readings. Probably the First Offenders Bill will be referred to the same Committee.

England and Wales.

BRITISH ASSOCIATION AT CARDIFF.

THE eighty-eighth annual meeting of the British Association for the Advancement of Science will begin at Cardiff on August 24th. Professor W. A. Herdman, who holds the chairs of natural history and oceanography in the University of Liverpool, will deliver his inaugural address on the evening of that day. He will give a general survey of the subject of oceanography, and will discuss in detail certain special problems and recent investigations with particular reference to sea fisheries. There will be two evening discourses, one of which, by Sir A. Daniel Hall, K.C.B., F.R.S., to be delivered on August 27th, will deal with "A grain of wheat from the field to the table." There will be twelve sections, which will meet on four days. Professor Karl Pearson, F.R.S., will preside over the section of anthropology; Mr. J. Barcroft, F.R.S., demonstrator in physiology, Cambridge, over that of physiology, and Miss E. R. Saunders over that of botany. On August 25th there will be a conference of delegates of corresponding societies. A general exhibition of specimens will be arranged at the City Hall, and some of the sections will have special exhibitions.

THE CORONERS' SOCIETY.

The annual meeting of the Coroners' Society of England and Wales, held on June 10th, was followed by a banquet at the Holborn Restaurant. Mr. Kelway Pope, coroner for Southampton, the newly-elected president, proposed the loyal toasts. Mr. Brooke Little, who proposed the toast of "The Coroners' Society," said that the office of coroner was very ancient. It was positively known that coroners existed in A.D. 1194 in the reign of Richard I; some people asserted, on the more than doubtful authority of the *Mirror of Justices*, that coroners sat in the time of King Alfred, who was said to have hanged many unjust judges and coroners. In early times coroners were unpaid, and elected for life by the popular vote. In the reign of Henry VII, however, a sum of 13s. 4d.—equivalent to £8 in 1914—was paid to the coroner in cases of murder and manslaughter; this came from the chattels of the accused, if convicted. Under George II the payment of an increased fee and out-of-pocket expenses was ordained for all inquests held upon view of dead bodies. Any recommendations made by the Coroners' Society should carry weight with the Government, especially in respect of contemplated legislation regarding salaries, the granting of adequate pensions, and the extension of fire inquests outside the City of London. At the present time there were over thirty outstanding enactments relating to coroners; he thought they might well be included in one consolidating and amending Act. Mr. Pope, the president, in reply, expressed his agreement with all Mr. Brooke Little's points. Dr. H. R. Oswald, coroner for West London, proposed the toast of "Our Guests." Sir Edward Troup, K.C.B., Permanent Under Secretary of State to the Home Office, in acknowledging the toast, said that the Home Office was not negligent with regard to legislation, and hoped to deal with the question of coroners' juries as soon as possible. The emergency legislation respecting the powers of coroners to dispense with juries held good for six months after the official termination of the war. No complaints regarding this had been received from the general public, except in one case in which a coroner had returned a verdict of *felo de se*. Coroners generally appeared to like the discretionary powers entrusted to them. To say that the election of coroners should be confined to two professions only was evidence of a narrow view; in any case he felt strongly that during the next ten years at least vacancies should be filled by men who had actually seen active military service.

WHOLE-TIME MEDICAL APPOINTMENTS IN WORCESTERSHIRE.

At a meeting of the Worcestershire County Council on June 14th the Chairman (Mr. Willis Band) referred to the efforts which the County Education Committee had made to get assistant medical officers at a salary of £450, but had been prevented from doing so because of the action of the medical papers in refusing to insert the advertisements (see BRITISH MEDICAL JOURNAL, May 8th, 1920, p. 654).

He said that the Committee had advertised in other papers, as they had been authorized, and they got a considerable number of replies, but he was sorry to say that the persons were not suitable. He did not say they were not qualified persons, but the number who were suitable for the job was very small indeed; there was only one that they would be able to appoint. They had a large number of Irishmen and some Scotsmen, but these had not had experience in the class of work which the Ministry of Health required, and he very much doubted whether the Ministry of Health would have approved the appointments. He did not think that they would. If the Council's scheme was to go through, it was absolutely necessary that the appointments should be made, and he could only suggest that the Council should enlarge the resolution and empower the Committee to go beyond the salary offered in certain cases. He suggested that the Committee should be authorized to get the doctors at what salaries they could, but it would have to be more than £450 a year. Mr. Parkes asked why they should do that—because a strong Association demanded and forced their hand? It was obvious that the British Medical Association was at the back of it. The medical officer at Worcester had apologized to the corporation for asking for more; she told them that she did not want more. It had come to something when an Association could force this, and this Association was supported by a Government department. He contended that public officers stood in a position different from the private practitioner because they had no night work and no Sunday duty. Mr. Lane did not think that anything very serious would happen if these appointments were not made. The Chairman said that the Ministry of Health had approved the scheme, and, if the Council did not fill up the appointments they would not make the grants. He agreed with every word Mr. Parkes had said. Mr. Albright asked if the matter had come before the County Councils Association. That was the only way in which they could really resist it—by uniting with other bodies. Dr. H. E. Dixey said that they must realize that several county councils were paying the sums suggested. If they did not appoint officers they would stop the whole medical service of the county. The motion to give the Committee power to go beyond £450 was carried.

INFANTS' AND CHILDREN'S HOMES AND HOSPITALS.

The Ministry of Health has issued a circular letter¹ requiring local authorities and voluntary agencies conducting homes and hospitals for infants and children under five years of age to make records for the purpose of an annual report to the Ministry of:

(1) The number of cases admitted; (2) the average duration of their stay; (3) the reasons for their admission; (4) the number of cases discharged (a) in good health, (b) improved, (c) without improvement; (5) the number of cases of infectious disease, with brief records of any epidemics of measles, whooping-cough, epidemic diarrhoea, or other infectious conditions; (6) the number of deaths, with their date and cause; (7) the number discharged on account of infectious or other illness, with the result (where known) of treatment conducted elsewhere.

Immediate information is to be sent to the Ministry of all deaths from epidemic diarrhoea.

Scotland.

HOSPITAL AND NURSING SERVICES.

WE understand that the report of the Scottish Insurance Commission on hospital and nursing services, to which reference was made last week, has been referred to three of the Consultative Councils in Scotland "to consider whether the present general hospital service is an adequate one for the community, and to make recommendations for its improvement or for the provision and maintenance of an adequate service." A joint committee of the three Councils, with Dr. James R. Drever, Scottish Medical Secretary of the British Medical Association, as chairman, has been appointed. The Insurance Commission's report is now three years old, and is therefore in many respects out of date, particularly in what it has to say about the

¹ Memo. 18/M C.W., Ministry of Health, May, 1920.

financial position of the hospitals. The joint committee of the three Councils will review the present position of the whole question and report in due course.

SMALL-POX IN GLASGOW.

Last week the number of new cases of small-pox in Glasgow slightly increased, as many as eight being admitted on June 16th to the Belvidere Fever Hospital, where, at the end of the week, there were 135 cases under treatment. The Secretary of State for Scotland has stated in the House of Commons that in no patient removed to hospital had vaccination been carried out within six months previous to infection; 29 persons who subsequently developed small-pox were vaccinated either in their own homes or in the reception houses after known exposure to infection, and before the development of the disease. In 7 of these cases vaccination failed; in 22 the disease was in modified form, except in the case of a child of two months who had been exposed to infection at home for seven days before discovery and vaccination; 186 cases of all ages had been vaccinated in infancy; the mortality among these had been 12 per cent.; of these cases 168, and the whole of the deaths had occurred among persons over 16 years of age. In 57 cases of persons who had never been vaccinated the mortality was 35 per cent.; all but six were under the age of 15. In 3 cases the primary vaccination was doubtful; one of these died; these were included in the 186 vaccinated cases. Of the 186 previously vaccinated cases, one had been revaccinated in 1890, five in 1901, one in 1906, and one in 1916; but the two last named showed no evidence of successful revaccination. Among the group vaccinated in infancy only four were under 10 years, and these were mild and modified cases. The Lord Advocate stated that the Scottish Board of Health had from the beginning been daily in consultation with the public health officials in Glasgow, and was satisfied with the measures taken to deal with the outbreak and to prevent the further spread of the disease later in the season. Adequate arrangements had been made from the start for the hospital accommodation of cases, for the isolation of contacts, and for the free vaccination of the general public.

Australia.

FRIENDLY SOCIETIES AND NURSING BENEFITS.

At a recent conference of representatives of the various friendly societies of New South Wales the Premier outlined a plan by which, with the aid of Government assistance, members of these societies might be able to rely upon nursing benefits to supplement the ordinary medical attention now secured by them. It was, he said, now generally admitted that skilled nursing was a necessary adjunct to medical attention. It had been shown that the friendly societies alone were unable to supply nurses, but it was now suggested that the Government might help in this direction. At the present time there was a large number of trained nurses who were unemployed. Many of them had been trained in war service, but the cost of their employment was beyond the limits either of the ordinary workman's income or of the benefits conferred by the friendly societies. The Government statistician had supplied figures showing that if a scheme of district nursing were put into operation the services of a staff of about 680 nurses would be required, and this would mean an expenditure of about £165,000. It had been calculated that if members of friendly societies would pay from 2d. to 3d. a week in addition to their ordinary contributions the scheme could be launched, the Government undertaking to subsidize these payments by 50 per cent., or £ for £ as the case might be. If members of the societies would earmark 3d. a week out of the recent increase given by the Board of Trade they would make provision for skilled nursing of their families. He thought that in the long run the scheme would pay for itself by reason of decreased sickness and the consequent improvement in the general health and efficiency of the workers' families. The delegates agreed to submit the scheme to their respective societies.

FEDERAL CONTROL OF THE PUBLIC HEALTH.

At the recent meeting of the Federal Committee of the Australian Branches of the British Medical Association an important discussion took place on the relation between the Federal Government and the public health. It was decided that a full Commonwealth Department of Public Health ought to be set up with a professional permanent head, and under the control of a minister without other portfolio. Attention was directed to the increasing recognition of the value of preventive medicine to the community, and a proposal in favour of endowing chairs of preventive medicine in the universities of the Commonwealth was endorsed. It was suggested that the policy could best be assisted by local campaigns to demonstrate the efficiency of preventive medicine. These campaigns could be undertaken with the object of elucidating the principal factors in the spread of diphtheria, typhoid fever, and tuberculosis in Australia. The Commonwealth Government is to be asked to extend the scheme of control over venereal diseases, to subsidize State expenditure on infant welfare work and on maternity hospitals and wards, and to undertake a systematic investigation into the causes of infant deaths during the first month after birth. The Committee also considered it desirable in the interests of the public health that there should be a central establishment for the investigation of preventable diseases, working in association with existing State institutions, and that laboratories should be provided at all principal ports and centres, with adequate facilities for the examination of specimens sent by medical practitioners in the surrounding districts, especially for assisting in the diagnosis of cases of quarantinable diseases. There should also be a specially trained staff in field research. These proposals are to be forwarded to the Prime Minister of the Commonwealth.

India.

STATE LEPROSY HOSPITAL, KASHMIR.

DURING 1919 twenty cases of leprosy in the Kashmir State Leprosy Hospital were treated with gynocardate and morrhuate of sodium, as suggested by Sir Leonard Rogers in the BRITISH MEDICAL JOURNAL of February 8th, 1919, p. 147. It is too early to present a final report, but about half appear to have received some benefit, and two have been much improved. The cost of upkeep of this hospital is entirely borne by the Kashmir State, but the staff of the Church Missionary Society act as honorary medical officers.

KASHMIR MEDICAL MISSION.

The annual report for 1919 of the Kashmir Medical Mission contains a memorial notice of the late Dr. Arthur Neve, who was for twenty-four years head of the mission, and from 1903 to 1910 president of the Medical Missionary Association in India; appreciations of his work are quoted from many sources. The secretary of the memorial fund is Mr. Norman Greene, c.o. Messrs. Cox and Co., Srinagar. The Kashmir valley was visited by a severe epidemic of cholera in 1919, and there were 12,000 deaths among 20,000 cases; erysipelas and acute septic cellulitis have also been very prevalent. All forms of tuberculosis are rapidly increasing, but malignant disease, except the special kangri epithelioma, is relatively rare. For the rest, the work of the hospital has to do chiefly with orthopaedic, plastic, and reparative surgery, and with foul wounds and ulcers engendered by extremely dirty and insanitary conditions of life. Carrel's intermittent wound irrigation is much used in the surgical wards: a thousand major and two thousand minor operations were performed in 1919, but the work of the hospital suffers as a consequence of lack of funds. The honorary treasurer in England is Miss S. E. Neve, of 12, Kidbrooke Park Road, Blackheath, S.E.

On September 25th and 26th the Société Belge de Médecine Mentale will celebrate the fiftieth anniversary of its foundation by a congress at Ghent and Brussels which the corresponding societies in the allied countries have been invited to attend. Communications should be sent to the Secretary, Colonie des Aliénés, Lennieux, Brussels.

Correspondence.

FUTURE PROVISION OF MEDICAL SERVICES.

Medicine and the State.

SIR.—The report of the Medical Consultative Council of the Ministry of Health is a momentous document. I have read it side by side with an account of the Gloucestershire Scheme for the Extension of Medical Services, sent me by my valued friend, Dr. J. M. Martin. I trust the profession is going to scrutinize every one of the proposals in each of these documents before committing itself to the great changes which are only vaguely indicated in what we may call their "argument." May I be allowed to suggest some points for consideration?

1. That "part-time service" for the use of all members of the community is "whole-time service," which the report rightly condemns. The original suggestion of "part-time service" naturally presupposed the limitation of such service to those too poor to pay for it. "Income-limit" is an essential condition of "part-time service." The higher the income-limit the nearer such service approximates to whole-time service, with all its grave effects on efficiency when made general throughout the profession.

2. That if the profession is senseless enough to again consider any scheme of reorganization without at the same time having its financial clauses fully and clearly before it, it will deserve to suffer for it, as it certainly will.

3. That the chief secretary of our chief professional defensive body ought to be a business man with legal training, chosen for his proved business ability.

4. That the profession must have an adequate share in its own control. In the Gloucestershire scheme the board of management is practically wholly lay, and therefore quite incompetent for the very responsible position it will occupy. Medical advisory committees have over and over again been shown of small value unless an adequate proportion of the board itself is medical. The appointment of a nearly wholly lay board is retrograde and most undesirable.

5. Special services by consultants should, as usually now, be paid for as "piece work," not by contract. Hospital work might be part-time "contract work," provided a reasonable income limit is imposed.

6. A good deal of misapprehension evidently exists as to the effects of the proposals on

- A, the general practitioners,
- B, the consultants of secondary centres,
- C, the consultants of "teaching schools,"
- D, the public.

A. Effect on General Practitioners.

In the Gloucestershire scheme the lay board appoints the primary centre doctors—that is, it is by no means certain that all the local practitioners will be appointed. Is such a board to override the qualifying powers of universities, licensing bodies, and General Medical Council? If they appoint, they can also dismiss.

It is doubtful if the general practitioner will be stimulated to research by a system which lessens his liberty, ties him to records and red tape—quite valueless, as experience proves in such conditions—supervises him at every turning, and takes away his best cases to the secondary centre, where he has no time to follow them. This in itself is a grave matter, for the general practitioner hitherto has been a noted contributor to research. Edward Jenner was a general practitioner, so was, I think, Withering, who discovered digitalis, so was Sir James Mackenzie, so was Dr. Budd, who at North Tawton discovered "water-borne typhoid."

If the new scheme reduces the general practitioner, as I believe it will, to a sort of *first-aid*, it will do incalculable harm not only to everyday practice but to research. The general practitioner of to-day is a wonderful man, fully justifying Paget's dictum that "general practice is the highest branch of the profession." It is very bad policy to hamper his activities or to degrade his position. The proposals, if carried out, will do both.

B. Secondary Centre Consultants.

What kind of prestige will secondary centre consultants retain when their best cases are taken away to the "higher" sphere of the "teaching centre"?

C. Consultants of "Teaching Schools."

What scale of fees and what safeguards against "hospital abuse" is going to protect these against the "unjustifiably cheap country journey." It has to be remembered that these gentlemen of leisure who occasionally vary their activities by a day in the mines or in the factory are now also men of means! Consultants are generally generous men. But generosity may be abused.

D. The Public.

There is nothing so steadying to fine impulse as financial reflection! What will all this "castle in Spain" cost? Take a primary centre, properly equipped at present building prices (do we lay 300 or 200 bricks a day, now that our best intelligences are in control?), with corresponding scales for fittings of all sorts.

Then how about privacy in illness? Mrs. A. will have the time of her life in the primary centre discovering from the invaluable records what is the matter with Mrs. B. and Miss C.! And how about free choice of doctor when—very reasonably—doctors decline under the new conditions to trouble to go miles to a distant patient in somebody else's district?

And why this enthusiasm about "teaching centres"? Is it to ensure for such schools a larger supply than heretofore of cases to teach from and to examine candidates upon! Do we not nowadays rather need centres for research unhindered by students?

Conclusion.

The proposals seem to me, as I say, to need the most attentive scrutiny, and to be at present uncalled for, except perhaps in view of the financial straits of our medical charities. But the right way to deal with those charities is by requiring small payments from all patients, whilst retaining proper income limits.

It would be difficult to exaggerate the gravity of the proposals before us.

The British medical profession is the magnificent product of industry, intelligence, and public spirit acting in a remarkable atmosphere of individual freedom. Let us beware who handles it. "Facilis est descensus Avernus, sed revocare gradum, hic labor, hoc opus est."—I am, etc.,

Exeter, June 22th.

W. GORDON.

SIR.—The average practitioner has not time to read voluminous reports of Medical Consultative Councils, and, even if he had time, in view of to-day's excessive rents, rates, taxes, cars, and general expenses, he would have no patience to consider further flash and expensive ministries, as neither the ratepayer nor taxpayer will stand much more. Even the small income man—say, £300 a year—is paying £30 per annum to be governed locally and centrally, and as the time he is going to allow this to continue is being measured in months, not years, idealists in medicine who want to bring Harley Street to the pauper's door had better commence with fundamentals—as housing, butter not margarine, bread not husks, meat not dried leather, cloth not shoddy, business not theory. In most middle-class, lower middle-class, and working-class practice it would be an extraordinary year if the times a consultant is required exceeded six, and many practitioners will go a succession of years without requiring their services at all.

Hospitals are now available everywhere for all cases, the motor ambulance having removed that difficulty in poor cases. The difficulties in Canada—where abdominal cases sometimes have to be sent hundreds of miles by rail—do not occur here, yet, from the lack of perspective in these extravagant schemes, it is made to appear that they do. In the cities a consultant could be had at any time, day or night, pre-war for a guinea or two for the masses, and it is very little more now.

For baths, electricity, etc., even the rich have to travel to Buxton, Droitwich, Harrogate, etc., so that it seems rather extravagant (in the absence of a general Communist policy) to bring these to the door of far too many who, for the purposes of legislation and votes, are called poor working classes.

Moderate terms at the nursing homes for small people would be very useful and prevent hospital abuse.—I am, etc.,

Blackburn, June 20th.

J. I. HALSTEAD.

FEEs FOR THE TREATMENT OF SCHOOL CHILDREN.

SIR,—At the Representative Meeting a recommendation will be submitted with reference to the fees for the treatment of school children. Paragraph iii states:

That a fee of not less than one and a half guineas per case (including anaesthetist's fee) be paid for adenoid and tonsil operations involving a general anaesthetic.

In my opinion three guineas is the minimum which should be agreed upon—two guineas for the operator and one guinea for the anaesthetist. The operation is a difficult one. No man who can perform it thoroughly should accept less than two guineas for each case. These cases sometimes die under the anaesthetic. It is of the utmost importance that the anaesthetist should be a specially trained man. A fee of one guinea for his services is moderate.

The Panel Committees have fixed a fee of one guinea for the administration of an anaesthetic. There is a circular to be presented to the Representative Meeting from the Minister of Health recommending a fee of one guinea for the administration of an anaesthetic by a doctor called in by a midwife.

It may be argued that there will be several children to be operated upon at the same time. There will often be only one, and if there are more this does not decrease the difficulty of the operation or the risk which the anaesthetist has to undertake.

The British Medical Association has requested us to increase our fees by 50 per cent. Therefore, in fixing one guinea for operator and half a guinea for anaesthetist, it is the equivalent of 14s. for the operator and 7s. for the anaesthetist at pre-war rates. If governing bodies offered us such fees I maintain that we ought to refuse them, but if they are to be put forward as the considered opinion of our own Association, it will be a retrograde step; it will be derogatory to the profession, and it will decrease the value at which the public have estimated our services.—I am, etc.,

J. LIONEL STRETTON,

Senior Surgeon, Kidderminster Infirmary and Children's Hospital; Chairman, Worcester Division, British Medical Association.

June 19th.

P.S.—I have submitted this letter to a meeting of my Division, and they approve of it.

PANEL PRACTITIONERS AND VACCINATION.

SIR,—I read with personal interest the able account of Dr. Lawson in the SUPPLEMENT of June 19th concerning the dealings which the profession have had with the medical officer of health and the Corporation of Glasgow in regard to vaccination. Sir John Lindsay, the Town Clerk, has now replied that the Corporation intend to abide by their former proposals—namely, "a fee of 2s. for each person vaccinated at the doctors' consulting rooms other than insured persons on the operator's lists, and 2s. 6d. for each person vaccinated in house-to-house visitation."

I shall be pleased if you will allow me, Sir, to deal with another aspect of the question—"vaccination performed by inspectors of the Public Health Department of Glasgow."

At the annual meeting of the West of Scotland Branch it was resolved that the Secretary should write Dr. Chalmers, the medical officer of health, against the employment of sanitary inspectors for carrying out vaccination. In his reply, Dr. Chalmers admitted liability, but intimated that he intended to continue the practice except in the case of infant vaccinations. The Branch Council having met on April 21st to consider the matter resolved to appeal to the Scottish Board of Health, and the following reply was received from the Board, dated May 27th:

With reference to your letter of 21st ultimo regarding the employment of unqualified men for carrying out vaccination, I am directed to say that the Board do not consider any action on their part called for meantime.

The question came up for discussion at a meeting of the Scottish Committee on June 10th, and it was left with Dr. Drever to deal further with the matter.

Why Glasgow should be chosen as the cockpit of Scotland for all the fighting this year is more than we can understand.

In January we had a court of arbitration over the question whether suturing of a tendon is or is not an operation which a general practitioner of ordinary competence and skill can undertake. The Insurance Committee had the

object in view, if it was decided in the affirmative, that other operations, such as appendicitis, would have to be undertaken at the usual rate of remuneration—the capitation grant for insured patients. The result was a signal victory for the profession.

Later we were up against the powers that be over the important question of the limitation of lists, and although in this contest no defeat was sustained, we were not so successful as we hoped to be.

The subject of vaccination is down for discussion at Cambridge, and it seems to me that this opportunity should be accepted by the leaders of the profession to send a strongly worded protest to the Boards of Health that in future all important questions involving the interests of the profession at large should be taken up by central bodies, and not those under local control.—I am, etc.,

A. KENNEDY GLEN,

Secretary Local Medical and Panel Committee,
Honorary Secretary West of Scotland Branch.

Glasgow, June 19th.

SANATORIUM HOSPITAL FOR THE WELL-TO-DO.

SIR,—There is a great need for a sanatorium or clinic for the well-to-do classes in some healthy suburb of London to which patients could be sent for diagnosis, dietetic treatment, convalescence, and rest cures, and where they could live amid cheerful surroundings conducive to restoration to health, the patients being able to undergo medical treatment from their own physicians under suitable conditions, which is an impossibility at home.

There are many such institutions on the Continent, and from my own experiences and observations I know and have seen what a blessing they are to the well-to-do sick. There was before the war—I do not know if it still exists—a very splendid institution in Vienna called the Cottage Sanatorium, known, I feel sure, to many of your readers, where patients were treated under the most perfect conditions, having the medical care and attention of a well organized hospital with the surroundings of one of the best hotels.

I should also like to venture to suggest a block for maternity cases. I was informed whilst in Vienna that most expectant mothers who could afford it went into an institution for their confinement; it was considered far safer, as the mother could get every necessary attention. Confinements thoroughly disorganize a house and do not give a mother a fair chance. Nursing homes with the surroundings of so much illness are depressing for the patient and therefore do not seem proper places for a confinement; as I know from my own personal experience, a confinement in a small nursing home is most disturbing to the other patients.

In this country there is really nowhere for the well-to-do sick except nursing homes, where they are confined to one room, a most distressing existence except when in bed, and there are many sick people who require very careful treatment, though able in all respects to go about the same as the healthy until the end has nearly come. For instance, take diabetics, what a boon such an institution would be to them; they cannot go away for a change to an hotel with satisfactory results owing to the food, and it is the same with many other complaints. Such patients, owing to there being no proper institution in this country, are forced to go on the Continent for treatment which could quite as well be taken in their own country; with other sufferers, circumstances prevent them leaving their country and they have to bear the consequences. If we had such an institution, how many useful lives could be saved or prolonged—lives in many cases most useful to the community? At Banff I understand there is an institution of this nature, but I feel we require such an institution near London within easy reach of our specialists.

The institution in Vienna, I understand, was a company, and should any of your readers wish for any particulars I shall be delighted to do all I can to supply them.—I am, etc.,

10, Calverley Park, Tunbridge Wells,
June 18th.

E. MALCOLM.

THE ROCKEFELLER FOUNDATION GIFTS.

SIR,—May I correct two errors with regard to the Rockefeller Gift which appear in the leading article of the BRITISH MEDICAL JOURNAL of June 19th in an annotation on "Biochemistry in the universities"?

The income from the sum of £435,000 given by the Rockefeller Foundation to the Corporation of University College Hospital as an endowment fund is to be used for the furtherance of medical education and research in the medical school, and a sum, not exceeding £16,000 per annum, to be utilized for the upkeep of the 120 beds allocated to the purposes of the medical and surgical units until such time as money can be otherwise raised for their maintenance, when this income will be restored to its original purpose of helping medical education and research.

For the maintenance of the remaining 60 of the new 180 beds allocated to the obstetric unit, and for the increased charges for upkeep consequent on the increased size of the hospital and nurses' home, the corporation will have to raise the deficit on the annual income—some £15,000 to £20,000 per annum. You will notice that the endowment is for the maintenance of the beds allocated to the medical and surgical units, and not for those allocated to the obstetric unit, as stated in your leader, and the amount to be devoted to the use of the new biochemical laboratory is £1,300 and not £15,000, as stated in your page 84L.—I am, etc.,

G. BLACKER, Dean.

University College Hospital
Medical School, June 21st.

THE POLISH RED CROSS SOCIETY OF GREAT BRITAIN.

SIR.—Your readers are well aware of the serious increase in typhus in Eastern Europe, but few realize that this terrible scourge in the near future may be knocking at our own doors. Adequate assistance must be sent to Poland to deal with the endless stream of refugees pouring through her country.

We, the undersigned, most earnestly appeal for funds to send to Poland a completely equipped unit, armed with all the latest scientific discoveries and fruits of modern research to combat this appalling disease.

It is hardly necessary to add that the need is an urgent one. There are now in Poland itself 250,000 cases of typhus, and this number is increasing daily. Thousands of lives can be saved by sending a unit of this description.

This appeal is issued by the Polish Red Cross Society. Donations should be sent to the Princess Sapielha, 45, Grosvenor Square, W. 1.—We are, etc.,

(Signed)

A. F. LONDON.

June 15th.

Obituary.

DR. ROBERT H. RAINS, of Bexhill, who died last week, received his medical education at Owens College, Manchester, and took the diploma of M.R.C.S. in 1886. He was in practice at Bexhill, and took a temporary commission in the R.A.M.C. during the war. On demobilization a few months ago his health broke down. He took great interest in local affairs at Bexhill, and at one time was a candidate for the borough council.

DR. JAMES MIDDLETON of Peterhead died on March 26th, 1920, at the age of 69. He graduated M.B., C.M. at Aberdeen University in 1882, and for two years acted as assistant to the late Sir John Struthers in the anatomical department. In 1883 he went to Peterhead, where, without neglecting his large practice, he contrived to devote much time to public affairs, which interested him, and to literature, which he loved. His contribution to the *Book of Buchan*—"Men of Literature in the North-East"—is a

well known example of his incisive and scholarly style. Together with Dr. Tocher and Mr. John Gray he was instrumental in beginning the anthropometrical observations of the Buchan Field Club. Dr. Middleton was connected for many years with the volunteer movement, and was Major in the Territorial Force. At the outbreak of war he served for a time at Bedford; subsequently he had charge of the 5th Gordons, at Peterhead. Dr. Middleton was regarded with widespread affection and high esteem, and shortly before his death there were presented to him (privately, on account of his failing health) a series of silver services, which had been purchased by public subscription. Dr. Middleton is survived by a widow, two sons, and two daughters.

It is with deep regret that we have to record the death, on June 16th, of Dr. F. C. SMYTH, I, West Elmwood, Belfast. He was called to an emergency case late on the night of June 15th, and was about to return home when the motor car in which he had been brought suddenly lurched backwards, knocking him down and passing over him. He was conveyed at once to the Royal Victoria Hospital, but despite every care and attention he died in a few hours, without regaining consciousness. Death was due to an extensive fracture of the base of the skull with laceration of the brain. Dr. Smyth, who was only 41 years of age, graduated in the Royal University of Ireland in 1903 and took the M.D. degree in 1908. He was assistant physician to the Ulster Hospital for Children and Women, medical officer to two sections of the Royal Irish Constabulary, and enjoyed a very extensive practice in and around Belfast. He was held in much affection and esteem by his patients, and was popular among his professional brethren, who recognized his great ability and professional skill. He leaves a widow and three young children, with whom and with his brother, Dr. Walter Smyth, co. Antrim Asylum, deep sympathy is felt in their irreparable loss.

The Services.

DEATHS IN THE SERVICES.

SURGEON MAJOR-GENERAL JAMES CLEGHORN, C.S.I., Bengal Medical Service (retired), died at Haslemere, Surrey, on June 14th, aged 79. He was born on May 19th, 1841, educated at the Universities of Edinburgh and Vienna, and took the M.D. of St. Andrews in 1862, and the L.R.C.S. Ed. in 1853. He passed the examination for entrance to the Army Medical Department, and joined at Netley as a surgeon on probation towards the end of 1864. The I.M.S. had then been closed for four years, no new appointments having been made since 1850. In 1865 that service was again thrown open to competition, and at the first examination held in January, 1865, several of the men on probation for the A.M.D. went up, six of them passing. Among them were H. Cook, afterwards Surgeon-General of Bombay, who passed second, Cleghorn was third, and Robert Harvey, who succeeded Cleghorn as Director-General of the I.M.S., was fourth. The list was headed by K. McLeod, who was not one of the candidates from Netley. Entering the I.M.S. as surgeon on April 1st, 1865, Cleghorn reached the administrative grade as surgeon-colonel on August 13th, 1891, and on March 29th, 1895, succeeded the late W. R. Rice as Director-General. He served in the Bhutan campaign of 1865-66, receiving the frontier medal. In 1870 he went into civil employ in the North-West now the United Provinces, and after serving there in several districts, in March, 1885, was appointed to act as surgeon-superintendent of the Presidency European General Hospital, Calcutta. In April, 1886, he was posted to Lucknow, the prize station of the N.W.P., and held that post till his promotion in 1891, when he became Inspector-General of Civil Hospitals in the Punjab. He received a good service pension on April 2nd, 1894, was made C.S.I. on June 22nd, 1897, and was appointed honorary surgeon to the Queen on October 5th, 1898. He retired on October 25th, 1898.

Surgeon Rear-Admiral Sir Daniel J. P. McNabb, K.B.E., C.B., has been appointed naval member of the Medical Consultative Board to the Admiralty.

The name of temporary Captain J. G. M. Molony, R.A.M.C., has been brought to the notice of the Secretary of State for War for valuable services rendered whilst a prisoner of war.

The following are the correct names and ranks of the officers mentioned in the lists of appointments to the Order of the British Empire, and not those as printed in the *London Gazette* of the dates indicated in parenthesis. Captain (temporary Major) George Whiteside Robertson, Union R. of O. (Medic.) attached S.A.M.C. (December 12th, 1919). Lieutenant Raymond Theodore Frederiek Barnett, R.A.M.C.T.F. (March 31st, 1919). Captain Donald Macintyre, R.A.M.C.S.I. (November 18th, 1918, and April 15th, 1919).

Medical News.

DR. VANGHETTI has been awarded the Riberi prize of the Royal Medical Academy of Turin for his work in connexion with the utilization of the muscle of a stump to actuate an artificial limb (the so-called cineplastic operation).

BEFORE the Cavendish Lecture, to be given to the West London Medico-Chirurgical Society by Professor Sherrington on "Posture," at 7.45 p.m., at the Kensington Town Hall, on Friday, June 25th, the society's companion triennial gold medal will be presented to Colonel T. R. Elliott, C.B.E., D.S.O., M.D., F.R.S., for his contributions to the treatment of thoracic injuries in the great war. A conversation and exhibition of medical and surgical appliances and books will follow the lecture.

SIR LEONARD ROGERS will give a lecture on leprosy at the London School of Tropical Medicine, Endsleigh Gardens, N.W., on Monday, June 28th, at 2 p.m.; and on Wednesday, July 14th, at 2 p.m., Colonel S. P. James will deliver a lecture on the prevention of malaria. Members of the medical profession are invited to be present.

A MEETING of the Medical Officers of Schools' Association will be held at 11, Chandos Street, Cavendish Square, W.1, on Monday, June 28th, at 5.15 p.m., when Mr. R. W. Tustin, chairman of the Milk Committee of the Canadian Food Control Board, will give a lecture on milk supply, illustrated by the cinematograph and lantern slides. Any person interested is invited to attend.

A SERIES of film demonstrations will be given at the Royal Society of Medicine on June 29th, July 1st, 5th, 9th, and 12th. The demonstrations have been arranged by the Fellowship of Medicine, but are open to visitors.

A SPECIAL post-graduate course will be held at the National Heart Hospital, Westmoreland Street, London, W.1, during the last two weeks of July. It will include practical instruction in the use of the polygraph and electrocardiograph. Particulars can be obtained from the Dean.

SIR CLIFFORD ALLBUTT has written a preface for a book entitled *Industrial Colonies and Village Settlements for the Consumptive*, by Professor Sir German Sims Woodhead and Mr. P. C. Varrier-Jones, the honorary medical officer of the Cambridge Tuberculosis Colony at Papworth. The book will be published shortly by the Cambridge University Press.

DR. WYNN WESTCOTT, after twenty-six years' service in that office, has resigned the coronership for North-East London.

A CHILD of seventeen months has died in Middlesbrough after accidentally swallowing three pills containing potassium nitrate.

THE new buildings of the University Library at Leyden will be open to the public on July 12th. The official ceremony will take place later.

THE date of the presentation of the cheque, arising out of the generous response to the fund organized for the purpose of marking the very exceptional services of Sir John MacAlister to the Royal Society of Medicine during more than thirty-three years, has been fixed for Wednesday, July 7th, in the Barnes Hall, at 4.30 p.m. The ceremony will be performed by the President, Sir Humphry Rolleston, K.C.B., and will precede the business of the annual meeting, which will be held at 5 p.m. The fund will be finally closed on Saturday, July 2nd.

WE have received from the secretary of the Friends' Emergency and War Victims' Relief Committee (27, Chancery Lane, W.C.2) a circular stating that the population of Vienna has declined from 2,125,000 to 1,750,000. Before the war there were 3,200 doctors; now there are 4,800. It is said that 60 per cent., together with their wives and families, have a hard struggle to earn their daily bread; 20 per cent. are quite unable to get on, and have insufficient nourishment and insufficient warmth; and only 20 per cent. have an income which provides fairly well for themselves and those dependent on them. These conditions are attributable partly to the economic ruin of the middle classes and the extraordinary advance in the cost of living, and partly to the recent extensions of insurance practice in the city; this, it is stated, has reduced doctors' incomes by 90 per cent. Numerous ambulances and welfare centres have been organized, and though their social necessity is by none more highly recognized than by the medical faculty, they have caused its members an enormous material loss.

DR. C. W. WINDSOR of Royston, Herts., has been appointed to the Commission of the Peace for the County of Cambridge.

AT a meeting of the Conference of Delegates of the Metropolitan Medical Schools on March 11th, it was resolved: "That application be made to the Government requesting that a single examination be instituted for admission to the medical services of all Government departments, and that this examination be held at regular intervals." The individual medical schools were invited to consider this question, and at a meeting of the conference held on June 2nd it was resolved that the proposal be approved in principle, and that the departments concerned be informed, and asked to communicate the details of any arrangements which might be formulated if it were decided to institute a single examination.

"KOSOVO DAY," the national day of the Serbians, will be commemorated this year by a concert at the Mansion House on Monday, June 28th, at 3 o'clock, presided over by the Lord Mayor. Admission is by invitation tickets to be obtained from the Secretary, Serbian Red Cross, 8, Queen's Gate Place, S.W.7.

THE Ministry of Health has issued a volume (*Type Plans and Elevations of Houses designed by the Ministry of Health in connexion with State-Aided Housing Schemes*, London, His Majesty's Stationery Office, 1920, price 1s. net) containing thirty-four type plans and elevations for State-aided housing schemes. The designs are not put forward as the "last word in cottage planning," but with the intention of providing a key to the various types for which full working drawings have been prepared. Of the two main groups of houses which it is proposed to construct, class A consists of cottages containing a living room, scullery, three bedrooms, and the necessary offices; Class B contains a parlour in addition. Certain of the plans, however, provide for four bedrooms, the fourth bedroom being rendered possible by the existence of a central passage in a block of four houses. Certain dwellings have been designed with extra long frontages and shallow depths for hilly sites. By adopting type plans local authorities can save a considerable amount of time, and have obtained comparatively satisfactory prices both in open competition and for agreed price contracts. The full sheet working drawings can be obtained by local authorities and public utility societies from the Ministry of Health, Whitehall, or from the Housing Commissioners. A specification has also been issued of cement concrete to be used for approved buildings.

WE have received from Messrs. W. B. Saunders Company (9, Henrietta Street, W.C.2) a catalogue of their medical books, showing the date of publication of each.

Letters, Notes, and Answers.

As, owing to printing difficulties, the JOURNAL must be sent to press earlier than hitherto, it is essential that communications intended for the current issue should be received by the first post on Tuesday, and lengthy documents on Monday.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL.

The postal address of the BRITISH MEDICAL ASSOCIATION and BRITISH MEDICAL JOURNAL is 429, Strand, London, W.C.2. The telegraphic addresses are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone, 4737, Dublin), and of the Scottish Office, 6, Rutland Square, Edinburgh (telegrams: *Associate, Edinburgh*; telephone, 4361, Central).

QUERIES AND ANSWERS.

D. L. asks whether ovarian gland substance has been given in cases of excessive growth of hair on the face in women.

INCOME TAX.

Method of Dealing with Renewals.

A CORRESPONDENT has called our attention to a discrepancy between an answer given on this subject in the BRITISH MEDICAL JOURNAL of January 18th, 1919, and an answer given recently (June 5th, 1920). The earlier answer was founded on what was understood to be the practice of the Inland Revenue Department, but evidence given before the Royal

Commission on Income Tax seems to indicate that the attitude of the department has changed or is changing. In a memorandum presented to the Commission the Board of Inland Revenue suggested the following as an alternative method of estimating allowances for depreciation and obsolescence of plant and machinery, etc.:

"As an alternative to the allowance for wear and tear and obsolescence of plant and machinery, the cost of renewing plant and machinery may be claimed as a deduction in the computation of income tax liability under Schedule D. When this course is preferred by the taxpayer the amount to be allowed is the actual cost of the new plant and machinery (excluding any part of such cost which is attributable to additions or improvements—that is, to an increase in capital) after deducting the scrap value or realized price of the plant and machinery replaced.

"Example (a).—A machine which originally cost £1,000 is worn out and replaced by a machine of similar power or size or capacity which now costs £1,500. The whole of this expense of £1,500 is allowable from the profits of the year in which it is incurred.

"Example (b).—A machine which originally cost £1,000 is worn out and replaced by one of a greater power or size or capacity costing £2,500. The amount to be allowed as an expense is in this case not the full £2,500, but only the cost of replacing the old machine by one of similar power or capacity—say £1,500.

"Although this method of allowance is alternative to the wear and tear allowance for the same class of plant, the two principles may run concurrently for different classes of assets in the same business. For example the wear and tear allowance may apply to fixed machinery, while the renewal method is used for loose plant."

Inasmuch as the whole difficulty will automatically cease if and when the depreciation allowance is made accessible to professional men, it is perhaps unnecessary to pursue the matter further than to say that there seems no reason to assume that the Board will now enforce its early practice as a general rule.

L. A. T. bought a De Dion car for £289 in 1911 and sold it in 1919 for £25, and bought a Ford car in 1913 for £138, which he still uses. Can he claim any deduction for depreciation?

*. As the Income Tax Acts stand at present he has no claim, but if and when he again buys a second car he can claim that expense as a deduction, except to the extent to which the car so purchased represents an improvement. For instance, if the present cost of a similar De Dion car to the one sold be taken as £550, then he can claim when purchasing another car for, say, £x, either £550—£25, or £x—£25, whichever be the smaller.

H. C. P. has been refused by the inspector of taxes a deduction from the amount of his emoluments from the Ministry of National Service in respect of expenses. Apart from the child allowance, H. C. P.'s claim is (a) for hotel expenses, and (b) in respect of the loss incurred by the dissolution of his practice when he accepted a commission.

*. As regards (b), H. C. P. has no legal claim to an allowance, seeing that it is a loss of capital that is in question. The expenses referred to in (a) raise a more difficult question. Assuming that the emoluments are correctly assessed under Schedule E, our correspondent must show that the expenses were wholly, exclusively, and necessarily incurred in the performance of his duties; judicial dicta suggest that a line is drawn between, on the one hand, those obviously allowable expenses, such as the cost of maintaining a car for travelling from place to place to fulfil the conditions of the appointment requiring personal attendance at both places, and on the other hand, those quasi-residential expenses—such as the city man's season ticket—which are necessitated, not by the conditions of the appointment, but by the circumstances of the person who holds it. We fear that to a great extent the expenses which our correspondent has in mind would fall on the wrong side of the line of demarcation. In those circumstances we suggest that he might place the facts before the Board of Inland Revenue, Somerset House, for their consideration; possibly they may be able to exercise some powers of mitigation which the local inspector does not possess.

PUZZLED refers to a recent answer in this JOURNAL which stated that the income tax will be assessed this year under the new regulations; he points out that the forms now being issued by the assessors require a return of profits on a three years' average basis and not on the previous year's basis proposed by the recent Royal Commission.

* The proposals in question—apart from administrative matters—dealt with the methods of calculating the income liable to tax, and with the system to be adopted in assessing that ascertained amount. The latter proposals are embodied in the Finance Bill now before Parliament and will presum-

ably receive statutory effect as for the present financial year, but those proposals which deal with the quantum of income to be assessed are omitted from the Finance Bill, apparently for embodiment in a separate income tax bill to be introduced in the autumn session and to become effective next year. The answer to which our correspondent refers, related to a question in which the quantum of the income was assessed, and therefore one which turned on the application of the new proposals to this year's tax. We may perhaps add that the assessors' forms are apparently printed some months before the Finance Bill is introduced.

SUNBURNT POTATOES.

DR. JOHNSON SMYTH (Bournemouth) asks for an explanation of the intensely disagreeable taste of a boiled sunburnt potato. Is the taste due to some alkaloid developed at the same time as the chlorophyll? The potato belongs to the Solanaceae; is it possible that it may develop solanine or atropine in association with the chlorophyll?

LETTERS, NOTES, ETC.

THE PREVENTION OF INFLUENZA.

DR. J. LEON JONA (Melbourne, Victoria) writes to express the hope that Sir Thomas Horder's address, recorded in the BRITISH MEDICAL JOURNAL of November 29th, 1919, will lead the profession to consider the adoption of a practical scheme for anticipating and dealing with epidemics of influenza. The first important step, Dr. Jona considers, would be to make notification compulsory. While it has been stated that influenza did not exist in an epidemic form in Melbourne in October, 1918, yet at that time those engaged in general medical practice met many cases of the disease. The second factor is, he thinks, rather economic than purely medical; in influenza the infectivity is highest in the early catarrhal stage, and it is not sufficient to isolate those patients only who are seriously ill. These are comparable to criminals who have been caught and placed out of harm's way; it is the criminal at large—the promiscuous sneezer, cougher, or kisser—who is the menace to public safety and requires to be dealt with, but here that in civil life difficulties begin. The man who feels off-colour reports to a doctor only if it pleases him; he must pay out of his own pocket. If the doctor advises treatment in bed or isolation, the patient must lose his wages, or even perhaps his post. Men with dependants and mothers of families (and it was among the latter that the mortality was highest in the recent epidemic) are particularly reluctant to "report sick." Dr. Jona continues: I suggest that in every city district medical inspectors should be appointed to whom any employee feeling ill could be sent, and at whose discretion the patient would be sent home or into isolation; the payment of his wages should be continued. Provision for this could be made by a scheme similar to that employed for insurance under the Workmen's Compensation Act. The isolated patient should be periodically examined by the medical inspector; a staff of domestic assistants should also be organized. Such a system may perhaps appear complicated and expensive, but if it pays the army to keep, say, one M.O. per ten thousand men for sanitary services and preventive medicine, the system that I advocate should prove a sound economic proposition. It is the duty of the profession to take active steps in this matter.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 43, 44, 45, 46, 47, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 41, 42, and 43.

The following appointments of certifying factory surgeons are vacant: Stokesley (York, North Riding), Truro (Cornwall).

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Six lines and under	0	7	6
Each additional line	0	1	3
Whole single column	6	0	0
Whole page	16	0	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Tuesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE: It is against the rules of the Post Office to receive post-restelete letters addressed either in initials or numbers.

CURRENT NOTES.

Temporary I.M.S. Commissions.

I.M.S. officers whose leave is long overdue will be glad to note that, owing to the efforts of the British Medical Association, a special endeavour is being made by the India Office to obtain temporary reliefs in order that it may be possible to grant leave. This offer, which appears in the *JOURNAL* this week (p. 35), is based on the proposals put forward by the British Medical Association in November. In considering the financial aspect, however, intending candidates would do well not to be carried away by the specious interpretation placed upon the offer by a lay contemporary. It gives a false idea to speak of money paid in rupees, and spent as such in India, in terms of its English equivalent. A rupee in India is of no more value to-day than it was ten years ago, despite the rise in exchange; indeed, its purchasing value has gone down and is still going down instead of up, for the cost of living in India has risen greatly. The only fair way of comparing this pay with the pay of a medical man in England is to convert the amount which can be sent home and spent at home at the value of the rupee in England, and to convert the rupee spent in India at the Government rate—namely, 1s. 4d.—that is, 15 rupees to the sovereign. An officer without wife and family should be able to live on 400 rupees a month in India; this at 15 rupees to the £1 amounts to £320 a year. The balance of 300 rupees a month sent home and valued at 2s. 4d. per rupee is £420 a year, so that the value of the annual pay may be reckoned as £740, and not £930, as has been stated elsewhere.

Fees for Medical Examination for Life Assurance.

The Contract Practice Subcommittee of the British Medical Association recently met representatives of the Life Offices Association, an organization representing all the Life Insurance Offices of the United Kingdom, and discussed the fees now paid for medical examinations. The subject was thoroughly debated and an agreed report of the proceedings will be placed before the Medico-Political Committee at its meeting in January, after which it is hoped that a report may be placed before the Divisions. As central action is being taken, there should be no local collective effort to alter the present fees, for experience shows that merely local action is of little use, and in any case will embarrass those who are trying to arrive at an agreement which will cover the whole country.

Fee for Notification of Infectious Disease.

The Ministry of Health has given notice that the provisions of the Local Government (Emergency Provisions) Act, 1916, will lapse on the date of termination of the war as fixed by Order in Council, after which date the fee to be paid to a medical practitioner for the notification of a case of infectious disease will be restored to 2s. 6d.

THE BRITISH MEDICAL ASSOCIATION:

ITS WORK AND ITS CRITICS.

BY

ALFRED COX, O.B.E.,

MEDICAL SECRETARY TO THE BRITISH MEDICAL ASSOCIATION.

It is the immemorial right of the Englishman to grumble; objects for the exercise of this right are never far to seek, but the chief honours are, I think, shared by the weather and "the Government." The former was intended by Providence for the purpose: the latter—a thing made by and for ourselves, but impersonal, remote, and yet all-pervading—is irresistibly tempting. The British Medical Association stands in a similar relation to the medical profession. It is big, it is all-pervading in medical matters, it represents ourselves as an organized body, it is made by and for ourselves, but, like the Government, it is impersonal and remote. At one point the analogy breaks down: we cannot get out of contributing to the Government however much we may grumble at it; but we may have all the luxury of damning the Association though we may never have paid a penny or raised a finger to help it.

Just as Ministers have to take the platform at times to defend the Government and attempt to show that, though it may not be perfect, it is composed of men of the same flesh and blood as ourselves, struggling with difficulties but inspired by ideals, making mistakes but not unwilling to learn, and, above all, anxious for the support and confidence of those who put them in their position—so it is not unfitting that from time to time those who are responsible for the central work of the Association should make a similar appeal to our constituents. It is for that purpose that I am here to-day to speak about the work of the Association and to face its critics.

I have just finished reading the life of the man who, in my opinion, did more than any other to make the Association what it is to-day—Sir Victor Horsley. One part of it is not pleasant reading for those who regard ingratitude as probably the meanest of human failings, for there is no doubt that his unique services to the Association and the profession were rewarded by treatment which, however stoically he might conceal it, cut him to the heart. I will not pursue the painful subject—Horsley himself would have been the last to allow an injury to an individual to obscure general principles; but I want you to hear what Horsley thought the work of the Association should be. Stephen Paget, his biographer, says:

The Association stood for the resistance of his profession against autocracy and bureaucracy; he looked for its strength to tell on the nation, the Government, and public institutions of education and of health; it was democratic, in touch with the present, not bound by traditions; it could do what the Royal Colleges and the General Medical Council were not doing; it

* An address delivered before a meeting of the Leicester and Rutland Division at Leicester on December 9th, 1919.

could make people hear what it said to them. He had constantly in his mind the power which the Association might attain on these lines, as the one great intermediary between the State and his profession, the one system in which the doctors would be united to defend themselves from injustice, to provide a better service for the nation, and to enforce proper rates of payment of their work.

These were the ideals of a great man and a devoted believer in the Association, and though we failed, as he believed, to live up to them at a critical time, we can honour his memory and help the Association and the profession of which he was such a brilliant ornament by examining them and trying to follow them.

As Others See Us.

The value of the work of the Association may fairly be gauged by what public opinion thinks about us. It is a better test on the whole than the opinion of members of the profession itself, because the perspective is better. *Municipal Engineering*, a technical journal of considerable standing, in discussing our recommendations concerning the Ministry of Health, in August, 1917, said the recommendations showed:

that the medical profession is not only a very powerful body, but one of the strongest "trade unions" in the country. As a consequence of their unity of purpose and of organization they are able to wield, not only at the Local Government Board and in Parliament, but in the country, a power which no other professional body of men can approach.

The *Daily Telegraph* of October 26th, 1917, speaking of the Joint Industrial Councils under the Whitley Scheme, said:

That is to say, the Councils will acquire a distinct authoritative status similar to that enjoyed in respect of the medical profession by the British Medical Association. Whenever any Government department wishes to know anything about a particular industry it will apply direct to the new Council; if it desires to negotiate with an industry it will automatically choose the Council as that industry's recognized mouthpiece.

When the civil servants in 1918 formed their Society of Civil Servants they said in their circular that their endeavour would be

To establish the administration of the public service as a science and a profession . . . to found an Institute of Civil Servants which will provide for the service a medium for expression and for corporate action similar to that which is furnished for their members by the British Medical Association and other professional bodies.

Another testimonial, to which I attach great importance as being written by one of our most thoughtful and brilliant students of social and political affairs, is to be found in an article on "Progress in Industry," by Mr. A. E. Zimmern, Professor of International Politics in the University of Wales. Speaking of the ideals of the more thoughtful of the younger trade union leaders, he said:

Trade unionism does not exist merely to raise wages or to fight the capitalist any more than the British Medical Association exists merely to raise fees and to bargain with the Government. They exist to supply a professional need: to unite men who are doing the same work and to promote the welfare and the dignity of that work. . . . Professional organizations are, and are bound to be, conservative; their conservatism is honourable and to their credit, for they are the transmitters of a great tradition.

Finally, I would quote some remarks of Mr. Justice McCaig in his judgement in the Coventry case—remarks which are not the less valuable because that judgement was against us on the issues then at stake:

The British Medical Association is a powerful body. . . . The Association has performed for many years and in several directions a great and beneficent work in matters of interest and importance to the medical profession and the public.

The View of the Profession.

So much for public opinion—not always so favourably expressed, I admit, as in the passages I have quoted, but invariably respectful of the power of the Association and its public influence. What is the opinion of the members of the profession for which and through which it works? What is the opinion of the medical man or woman who has taken some trouble to find out the facts? On the whole, and naturally, they are inclined to dwell on the weaknesses and failures of the Association, but disposed to admit, in spite of disappointments, that any work that has been done for the benefit of the profession generally has been done, at any rate in the main, by the Association, because there is no other body to do it. The average

medical man knows that the Association has for many years, and to an ever-increasing extent, taken an active part in moulding legislation bearing on the health of the nation or on the prospects and status of the medical profession; that it has cultivated the pursuit of the medical sciences in every direction—through its JOURNAL, its annual meetings, its Branch and Division meetings; that it has brought members of the profession together socially and has thereby encouraged the growth of that good-fellowship which does so much to sweeten any kind of work; and that it has to the best of its powers and judgement tried to elevate the status and improve the pecuniary position of its members and of the profession in general.

These are elementary facts and undoubtedly we all ought to know them; but it is painfully impressed on me that comparatively few do know them, and it may be useful to spend a little time in considering some of them in more detail.

The Association's Scientific Work.

During the war many of our usual scientific activities have been perforce in abeyance. But our JOURNAL kept the flag flying, and received many well-deserved compliments from those in the best position to judge for the way in which it dealt with the medical and surgical discoveries and developments the publication of which was of inestimable value to us and our allies. The Special Clinical Meeting held in the spring was admitted on all hands to be a triumph for the Association, proving once again how it can always rely on the services of the best men for an effort of this kind. Our Annual Meetings will revive again next year, when, under the presidency of a man honoured throughout the world of medicine—Sir Clifford Allbutt—Cambridge will show us what an Annual Meeting can and should be. And our Branches and larger Divisions are showing a growing appreciation of their duties and capabilities in the way of directing the scientific activities of the profession in their neighbourhood. It is not generally known that for many years the Association has spent some £700 or £800 of its income in scholarships and grants to scientific workers. We were pioneers in this field long before the Government realized—as it has done only imperfectly now—that scientific workers need encouragement. Looking down the list of those who have had these grants, one is surprised and delighted to see how many men now in the first rank had their scientific enthusiasm encouraged by the Association at a time when such help was most valuable to them.

Its Social Usefulness.

The service performed by the Association in merely bringing its members together is so much taken for granted that it is rarely recognized as being probably the most useful and necessary of all its work. Useful not only to the profession but also to the public, for whatever makes for ease in professional intercourse and the breaking down of professional misunderstandings and jealousies is undoubtedly a public gain. Many a man owes to the Association meetings some of his best friendships and most cherished recollections. Even a formidable rival may be seen to have his good points in the convivial atmosphere of a Branch or Division dinner.

Its Influence on Remuneration and Status.

Since its reconstruction in 1902 the Association has spent much of its activities and of its income on questions of remuneration and conditions of service. Indeed some of our older, more prosperous, or more conservative members think we have paid too much attention to an aspect of our work which seems to them rather sordid. It is not that the Association is devoting less of its energies to the scientific and social side, but that it has enormously developed its work for the "honour and interests of the medical profession" in response to a demand which was insistent. The man who did not know the Association twenty years ago cannot possibly realize the extent of this development. Social and political tendencies have compelled our profession to come into relations with the State and public bodies in ways that were undreamt of twenty years ago. We cannot resist those tendencies. We must either accept them without question or try to mould them in a way which seems to us consistent both with our interests and those of the community we serve. We have had to lay down minimum scales of salaries for all kinds

of public medical officers and to enforce them through our JOURNAL and through our Divisional machinery. We have backed up our Divisions in laying down local rates of pay for contract and other kinds of work and in fighting for them. We have fought the Government, with varying success, with respect to the National Insurance system. We have extracted, and are continuing to extract, equitable terms for those doctors who are in the Services of the Crown. We have fought and won the battle of equal remuneration for the same work, for medical men and women.

It would take me far longer than either you or I can spare to enter in detail into the matters I have just sketched in a few words. But there is one object lesson of the Association's ability to determine and improve rates of remuneration so outstanding and so irrefutable that I submit it to you.

Mr. Lloyd George's first offer of remuneration for work under the Insurance Act was 6s., inclusive of cost of drugs. The final offer was 9s., and the difference was due entirely to the action of the Association, which in the three years 1910 to 1913 spent £30,000 of its own money, in addition to moneys subscribed to a voluntary fund, in organizing the profession to refuse the offer of the Government and to improve the Insurance Act from our point of view. Now there are, roughly speaking, 14 million insured persons and the extra 3s. has been paid for six years. It is therefore easy to show that from 1913 to 1919 the sum of £12,600,000 has been paid to the profession which they would not have had unless the Association had done the work referred to. As there are, roughly, 14,000 insurance practitioners, the average extra amount put into the pocket of each during the past six years is £900, not to mention the war bonuses and grants for practice expenses also secured by the work of the Association. Not a bad return for a yearly subscription of two guineas.

Its War Work.

The status of any body of men in the community is governed not only by their financial position, but, I am glad to think to an increasing extent, by the usefulness to the community of their work. Judged by this test we need fear no comparisons. But even a profession with a record like ours must show from time to time that it is not living on its reputation, but can make a special effort when great occasions arise. From such a test the profession and our Association have recently emerged triumphant. I believe that when we are far enough away from it to see it in the right perspective we shall regard the establishment and successful conduct of the Central and Local Medical War Committees as the finest single achievement of our Association. I fully recognize that without the co-operation of non-members of the Association that work would have been far harder and far less successful than it was, but it was only rendered possible because we had the necessary central and local machinery. It was carried through mainly by the enthusiasm, patriotism, and unselfish devotion of our members, and it was paid for by the Association, which spent about £15,000 over it, the Government, however, in recognition of the great national usefulness of the work, contributing the sum of £5,000. This work, which enabled the services of the profession to be made available for military purposes with the minimum of inconvenience to the public, will always redound to the honour of the Association, and give infinite satisfaction in retrospect to those who were privileged to take part in it.

Collective Bargaining: An Example.

A recent achievement of the Association, through its Insurance Acts Committee, also deserves attention, not only for its certain effects on the remuneration and conditions of service of those who are doing National Insurance work, and thereby indirectly on all forms of medical remuneration, but also because it may serve as an object lesson in the way negotiations between reasonable people should be carried out. In these days we hear much of differences between employers and employed. We suffer, along with the rest of the nation, by the "direct action" and "lightning strike" methods of people who have not yet risen to the conception that we are "all members of one body," and that each of us owes a duty to that body. We all believe that ways should and will be found of settling such disputes in a reasonable way, extreme action only being

resorted to under the stress of a conviction that there is no other way of obtaining justice. I claim that the procedure adopted by the Ministry of Health and the Insurance Acts Committee is an object lesson of how points of difference may be reduced to a minimum by reasonable discussion. For over a year the two parties have discussed the conditions of service of National Insurance with the one object of finding out the defects in the present system and the ways in which they can be remedied. In all such discussions there must be differences of opinion, because each side looks at the questions in debate from a different angle. But when each side is anxious to convince the other and not to overhear it, the result is bound to be a large measure of agreement. And so we found it. The new Regulations differ greatly from the first draft we considered; they contain many points that we have been asking for years; they largely increase the responsibility of medical bodies for the working of the system and the amount of local option given to the areas; they are, in my opinion, a great improvement over the present Regulations. Of course they contain restrictions and innovations that we would prefer omitted, and at least one which I think is a mistake from the point of view both of the public and the profession as being unnecessary. But the method was sound and the result on the whole good, and if we can only manage to conduct the negotiations on the last remaining point—remuneration—in the same spirit, I am convinced we shall not only satisfy the average member of our profession, but will have set an example which might well be copied in the industrial world.

Ideals and Methods.

Like most men who have worked for long in the political and organizing spheres, I have had reluctantly to drop many of the ideas and theories with which I began. But some of the articles of my original creed are still held as ardently and tenaciously as ever. For example, I believe that in the long run—sometimes, I admit, a very long run—reason always prevails. This belief sustains me in the face of many of the criticisms that are brought against our Association. When I am told that the only way to get things done is to use force, bluster, and strong language, I disagree, because daily experience shows me that that is not the way in which you and I generally get what we desire, or as much of it as is good for us. The man who approaches us with the pistol at our heads and loud threats of what he intends to do unless he gets his "demands," finds a resistance which probably would not have been there had he made his approach on the assumption that he was dealing with an honest and reasonable person. This particularly applies when we know the said pistol is not loaded, or is handled by a person so clumsy as to be much more likely to damage himself than anybody else. Of course, the wise man will always contrive to have some special means of persuasion up his sleeve in case reason does not prevail, but seeing that the medical profession always has such means and that the other party always knows it, it is as well to keep them up our sleeve and out of sight until we are sure that all other means have failed. The profession in the last resort can always refuse service on the terms offered, or, what is quite as effective, if slower, it can prove that a grudging and unwilling service is worth nobody's while.

I believe most profoundly in democracy, and in our Association because it is democratic. "Government of the people, for the people, and by the people" is a motto which runs through every article and by-law of our Association. Democracy as a form of government has its defects, of course. It is subject to mistakes, but so are autocracy and oligarchy, and the beauty of democracy is that the people who make the mistakes are also the people who suffer by them and are therefore all the more ready and willing to profit by them. The cure for the faults of democracy is more democracy, more insistence on the acceptance of responsibility on the part of the people who elect their representatives to govern them. The whole tendency of the present day is to put more and more responsibility on the separate parts of the kingdom, on the local authorities, and even on each calling, so that each may work together for the good of the whole.

Our Association has made its mistakes, and it will make many more; the full value of democracy can only be learnt by using it. As a writer in *The Times* said the other day, "Democracy is not an automatic process like

the beating of the heart, but a highly advanced faculty that only functions properly by virtue of continued exercise." So to our critics I freely admit that we are not perfect, that we are frequently slow in action and too late in coming to decisions, that we are sometimes timid when we ought to be bold, often claiming that we know what the profession wants when the event proves that we did not know. But is the remedy to remain outside and act simply as a unit, or to seek to set up some other body yet untried—a process which would take many years without any certainty of gaining by the change—or to improve on the organization we have got? I reject entirely the theory of those who imagine that by adopting the trade union form of organization we should find a short cut out of all our troubles. There is no short cut, and all experience forbids us to look for it in any mere variation of the form of organization. It is the spirit that counts—the burning enthusiasm, the faith in a good cause, the feeling of pride in the dignity of our high calling. With these our Association can do anything the profession demands of it. Without them any form of organization would be sterile.

I will not waste your time by discussing a criticism of the Association which is in favour just now with a certain school. They say, "Oh, the Association is all right as a scientific body, but it is useless for protective purposes. You ought to let some other body, preferably a trade union, do that kind of thing for you." The man who can say that is fully ignorant of the history of the Association during the last twenty years. If he really knew that history, and was still capable of believing his theory, he would be capable of believing anything.

I believe there is a great future before our Association and that the efforts and accomplishments of the past are nothing compared with what we can and will do in the future. There is an immediate task before us which will test our organization, our capacity for usefulness, and our public spirit to the utmost. The Minister of Health tells us he expects next year to bring in a great bill dealing with the extension and improvement of the medical service of the country. It will be the profession's duty and its privilege to guide that legislation into channels which seem to it consistent with the great traditions of the profession as well as with the interests of the people. No Minister can do this without the assistance of our profession: the profession cannot help him properly unless it is organized: it has no organization except the British Medical Association.

Some of you may have expected, from the title of my address, to find me in an apologetic mood. I never felt less reason for apologies. On the contrary, I ask you to feel pride in our past history and strong hope and determination for our future.

Meetings of Branches and Divisions.

NORFOLK BRANCH.

British Medical Association Lecture.

A MEETING of the Norfolk Branch was held in the Norfolk and Norwich Hospital on December 19th, 1919, when the President, Dr. F. W. BURTON-FANNING, F.R.C.P., was in the chair. About fifty members of the Association and non-members residing in Norfolk were present.

Sir HUMPHRY ROLLESTON, K.C.B., M.D., F.R.C.P., Emeritus Physician, St. George's Hospital, President of the Royal Society of Medicine, gave an address on the dyspeptic and other referred symptoms associated with disease of the gall bladder and of the appendix, which will be published in a subsequent issue of the JOURNAL. The lecturer discussed the symptoms and signs referred to the gastro-intestinal, cardiac, nervous, and locomotor systems as the result of gall bladder and appendix disease; also the diagnosis, by means of x rays, of disease in these organs, and the spread of disease in the biliary passages to the pancreas.

Dr. MUIR EVANS, Dr. A. J. CLEVELAND, Mr. S. H. BURTON, and Mr. A. J. BLAXLAND discussed various points raised in the address.

On the motion of Sir HAMILTON BALLANCE, seconded by Dr. ARTHUR BURTON, a vote of thanks was accorded to Sir Humphry Rolleston, to which he replied.

METROPOLITAN COUNTIES BRANCH: HARROW DIVISION.

A MEETING of the Division, to which all non-members engaged in general practice were invited, was held on December 12th, 1919. The ethical rules were adopted.

The subject of increase of medical fees was discussed, and the following resolutions were unanimously adopted:

That this meeting of the medical practitioners in the area of the Harrow Division adopt the recommendation of the Council of the British Medical Association that all fees should be increased by at least 50 per cent. over pre-war rates to meet the increased cost of living and expenses, and expects that every practitioner in the Division, while reserving his right to meet cases requiring special consideration, will agree to carry out loyally the recommendation of the Council, as is being done all over the country.

That the honorary secretary be instructed to send a copy of the above resolution to each practitioner in the area, to the honorary secretaries of the adjacent Divisions, and to the newspapers in the area.

The feeling was strongly expressed that the fee payable for a full life insurance examination, including examination of urine, should be at least one guinea, whatever the amount covered by the insurance, and that the Council of the British Medical Association should urge this matter on insurance offices.

With reference to the National Insurance Act New Regulations, it was resolved to inform practitioners by circular:

That a meeting of all panel practitioners should be summoned to discuss the new terms offered by the National Insurance Commissioners as soon as these were made known, and asking them to refrain from signing the new agreement until after this meeting had been held.

Association Notices.

MEETING OF COUNCIL.

THE next Meeting of Council will be held on Wednesday, February 18th, in the Council Room, 429, Strand, London, W.C. 2.

SUGGESTED CHANGES OF AREAS.

Tunbridge Wells Division.

NOTICE is hereby given to all concerned of the following proposal made by the Kent Branch:

That the urban and rural districts of Sevenoaks and the civil parishes of Stansted, Shipbourne, and Ightham be included in the area of the Tunbridge Wells Division of the Kent Branch, and that the present Sevenoaks Division be discontinued.

The matter will be determined in due course by the Council. Any member affected by the proposed change and objecting thereto is requested to write, giving reasons therefor, to the Medical Secretary, 429, Strand, London, W.C. 2, not later than March 3rd, 1920.

BRANCH AND DIVISION MEETINGS TO BE HELD.

KENT BRANCH: MAIDSTONE DIVISION.—Dr. A. C. Black, Honorary Secretary (Strettit Place, East Peckham, Paddock Wood, Kent), gives notice that a meeting of the Division will be held at the West Kent Hospital, Maidstone, on January 5th, at 3.15 p.m., when an address will be given by Mr. N. Bishop Harman, F.R.C.S., on some ocular conditions causing "pink eye."

NOTTINGHAM DIVISION.—The Nottingham Division cordially invites members of the Midland Branch of the Association to be present at a British Medical Association lecture to be given at 64, St. James's Street, Nottingham, on Wednesday, January 7th, 1920, at 4 p.m. Dr. Bernard Hart, Physician for Mental Diseases, University College Hospital, London, will lecture on modern methods of treatment in functional nervous disorders.

INSURANCE.

INSURANCE ACTS SUBCOMMITTEE, SCOTLAND.

AT a meeting of the Subcommittee held in the Scottish Office of the British Medical Association, 6, Rutland Square, Edinburgh, on December 9th, 1919, Dr. C. Nairn (Greenock) was elected chairman and Dr. M. Dewar (Edinburgh) deputy-chairman of the Subcommittee.

The Draft Medical Benefit Regulations (Scotland) were considered, and it was resolved to make representations to the Board of Health with regard to several of them. It was also resolved to hold a conference of representatives of Scottish Local Medical and Panel Committees as soon as convenient after the Regulations are in the hands of the Committees.

On December 9th representatives of the Subcommittee met the Board in conference with representatives of Insurance Committees, and discussed the draft Regulations. It is understood that the Regulations will be issued to practitioners early in January.

A SUCCESSFUL INSURANCE APPEAL.

ON an appeal undertaken by the London and Counties Medical Protection Society for one of its members against a decision of the East Sussex Insurance Committee, a point of interest to insurance practitioners arose under Article 21, Subsection 1, of the Medical Benefit Regulations, which sets out the manner in which the Insurance Committee, with the approval of the Commissioners, shall require an insured person to select a practitioner.

The manner of making application required by the Committee and approved by the Commissioners was set out in the contract between the doctor and the Committee, which incorporated the Regulations. The scheme adopted by the Committee as set out in the contract with the doctor was made under Article 21, Subsection 4 of the Regulations, which is as follows :

In any case in which an application from an insured person to be placed on the list of a practitioner, either by the presentation of a medical card or in such other manner as the Insurance Committee shall, from time to time, prescribe, is rejected by the practitioner, it shall be the duty of the practitioner, (a) if the applicant is in urgent need of treatment, to provide such treatment as the case may require, and (b) in every case to inquire whether the insured person wishes to apply to another practitioner on the panel, or whether he wishes to apply to be assigned by the Committee to a practitioner on the panel.

The facts, as stated at the inquiry, were that in this case the insured person had caused to be posted an application to be placed upon the doctor's panel, which application had, in fact, never come to the doctor's notice, and had neither been accepted nor rejected by him. When the patient required medical attendance and sent for the doctor the application was then discovered for the first time by the doctor, who refused to attend on the ground that the patient was not in his area.

The question arose whether the posting of the application by an insured person to a doctor constituted a presentation within the meaning of Article 21, Subsection 4, of the Regulations. It was argued by Mr. Croom-Johnson, instructed by Messrs. Le Brasseur and Oakley, the society's solicitors, on behalf of the doctor, that the word "present" in its natural and ordinary meaning meant a presentation in person, and that a construction which would enable applications to be made by post would not only place a serious additional burden of clerical work on insurance doctors, but would lead to a number of administrative difficulties.

After a very lengthy discussion the Committee found in favour of the doctor on appeal, holding that the presentation of an application by an insured person to be placed upon a doctor's panel must be made either by the applicant in person, or at least by an agent in the position to answer such inquiries as the doctor might require to put to him and to convey such message relating to the application as the doctor might require to be sent to the applicant.

CORRESPONDENCE.

The Panel Conference.

SIR,—The minutes (M. 32) of the annual Conference held at the Memorial Hall, Farringdon Street, should be printed in letters of gold and sent to the Minister of Health. To him it will be an epoch-making document. The Local Medical and Panel Committees, through their representatives, have proclaimed him autocrat in medical affairs. Against his ruling there is no appeal, against his penalties no remedy, his word is law. He is the second Englishman who has been raised to this position. Alexander Selkirk was the first.

It is true that the Conference carried the motion : "That any person aggrieved by the removal of his name from the list may appeal to the High Court, and on any such appeal the High Court may give such directions in the matter as it thinks proper," etc. That this was carried, however, was not the fault of the Conference. We were authoritatively told by a private member that neither Dr. Addison nor the representatives could alter the law of the land nor curtail the power of His Majesty's judges. Our hands were therefore tied. The Conference remained as loyal as it could to the Minister. Every motion that gave the smallest hint of interfering with his autocratic powers was immediately either ruled out of order or was by a little adroit manoeuvring withdrawn. Dr. Addison's position was made secure when a resolution to organize the profession to refuse service under certain contingencies was dropped as unthinkable. For do we not admit that no greater calamity could befall us than removal from the medical list? We agree that whatever the capitation fee may be our services are certain. We are so enamoured with our work that we are

clamouring for more. We insist that the bargain (what bargain nobody seems to know) will continue for three years. To make ourselves thoroughly docile throughout the whole of our working lives we intend to negotiate with the Government for a pension scheme. We must then work or lose our pension.

The same fate befell any attempt to assert the right of the panel practitioner, for it was made abundantly clear that the practitioner has no rights. The following motions were unceremoniously thrown out : (a) That attendance on insured persons after labour shall not be required until twenty-eight days after delivery ; (b) that a person must produce evidence of his being an insured person—that is, a medical card—before he can claim treatment ; (c) that the liability of an insurance practitioner for the acts and omissions of his deputy be defined. In spite of weighty objections, his list must be limited to 3,000. When there are sufficient practitioners to go round it must be further reduced to 2,000, for surely one can give more time and attention to 2,000 than to 3,000. But lest he has too much time to spare, he must place himself at the beck and call, day and night, of any one who can bluff him for treatment. If he employs an assistant he must obtain the consent of the Insurance Committee and agree to the terms the Committee impose. The patients whom he attracts by his ability, affability, and tact are not his, but belong to the State. Such is democracy and nationalization. He can be dismissed at a moment's notice, with or without a hearing, but this is as it should be, for God's scales of justice are placed in the Minister's hands.

What resolutions, then, did the Conference pass? The non-committal ones. "That the conference maintains the opinion that 13s. 6d. is the lowest capitation fee that can properly be accepted for an effective service." It is a pious opinion qualified by an adverb and an adjective. That the week should be defined as from Saturday midnight to Saturday midnight instead of from Sunday midnight to Sunday midnight was carried unanimously, and will no doubt receive the Minister's hearty approval.

Medical men throughout these islands will receive with pleasurable surprise, eclipsed only by that of the Minister, the news "That the Conference do express a general approval of the new Regulations for 1920." The representatives themselves were staggered at their own hardihood.

In this encounter we have lost. The Ministry has won. This is as I expected. The Association must admit that it is powerless. The wisest course now, in my opinion, is to let the profession drift to its doom. Thorough humiliation and decay will precede regeneration.—I am, etc.,

Exeter, Dec. 11th, 1919.

J. PEREIRA GRAY.

* * We have thought it right to submit a proof of Dr. Pereira Gray's letter to the Chairman of the Insurance Acts Committee, who replies as follows :

SIR,—Dr. Pereira Gray's letter reveals him as the obstinate twelfth jurymen. To maintain this attitude it is necessary either to pervert the facts, or to attribute to other minds one's own psychological imperfections. Dr. Gray does both. It appears to be the general opinion that the recent Conference of representatives of Local Medical and Panel Committees was the most successful of the series because (1) relatively full opportunity was given for the discussion of all important matters, (2) the items were as far as possible taken in what seemed to the meeting their order of importance, (3) after full discussion it was possible to arrive at unanimous or almost unanimous decisions to present to the Ministry of Health. That Dr. Gray does not agree with these decisions does not prove that they were foolish. He should not, however, misrepresent them or give, as he does, an entirely erroneous impression of the character of the Conference. He appears to have seen merely what he looked for. He tells us, "This is as I expected." He certainly regards all the other eleven jurymen as fools.

Dr. Gray's letter consists of the expression of a series of opinions sandwiched between what purport to be statements of fact. It is sometimes a little difficult to separate the one from the other, but almost every sentence which purports to be a statement of fact is either false or misleading. I quote seriatim the most important :

1. "The Local Medical and Panel Committees, through their representatives, have proclaimed him"—the Minister of Health—"autocrat in medical affairs."
2. "A resolution to organize the profession to refuse service under certain contingencies was dropped as unthinkable."
3. "We intend to negotiate with the Government for a pension scheme. We must then work or lose our pension."
4. "When there are sufficient practitioners to go round it"—the practitioner's list of insured persons—"must be further reduced to 2,000."

5. The insurance practitioner "must place himself at the beck and call, day and night, of anyone who can bluff him for treatment."

6. "If he employs an assistant he must . . . agree to the terms the Committee impose."

7. "The patients whom he attracts . . . are not his, but belong to the State."

8. "He can be dismissed at a moment's notice, with or without a hearing."

Not one of these statements is true; and the truth of others must not be assumed because I have refrained from quoting them. Such being the state of affairs with regard to the facts, there is no need for me to examine any opinions based upon them. I would ask Dr. Gray and others interested to read again the minutes of the Conference to which he refers, and your admirable report of the proceedings. Dr. Gray has, of course, a right to hold whatever opinions he chooses both as to matters of medical politics and as to the actions of the chosen representatives of the profession in this connexion, but before offering these opinions to the public he should verify his facts, and be should refrain from attributing improper motives to his colleagues, all of whom have the honour and interests of the profession at heart to at least as great a degree as he has, I doubt not, himself.—I am, etc.,

London, N., Dec. 27th.

H. B. BRACKENBURY.

The Capitation Fee.

SIR,—The letters appearing under this heading each week seem to miss the real point. Your correspondents labour to prove (what is already sufficiently obvious) that the demands of the profession, far from being unreasonable, claim less than what is just; and they continue to waste time appealing for fair play and consistency.

Surely the whole disreputable history of the Insurance Act should have taught them that at bottom what really counts with a politician is not justice or consistency or fair play, but simply expediency. Why does Dr. Addison refuse to accept the very moderate capitation fee claimed by the representatives of the profession? Because acceptance would mean a slight increase in the weekly contributions of the insured, and such an increase might be unpopular, and therefore inexpedient. Convince him that the hostility of a united profession is a far more serious menace to the success of the proposed new service than the unpopularity he fears, and all difficulties about granting the capitation fee will magically vanish.

But to effect this we must be united and organized. Dr. Addison will not listen to our representatives. Very well. Break off negotiations and let all panel practitioners be invited to send in their resignations from the panel to the Local Medical Committees by a certain date, a formal guarantee being given that these shall be returned if less than 75 per cent. respond to the call.

If the profession is really in earnest in its determination to resist further exploitation, a response far exceeding this figure may be anticipated. (If it is *not* in earnest, it will have to submit, deservedly, to any terms the Minister of Health may choose to impose.)

Should the rank and file support their representatives properly, Dr. Addison would be confronted with an argument the cogency of which he could not disregard. Expediency would now beckon him in a different direction, and his present shortsighted and provocative policy would be dropped.—I am, etc.,

Okehampton, Devon,
Dec. 2. th, 1919.

T. STRETHILL WRIGHT.

Payments for 1918.

SIR,—Whilst I have read each week various letters concerning the National Insurance Act and the capitation fee required to work it, I have been struck by the fact that none of your correspondents have mentioned that as far as 1918 was concerned we have not been paid at the rate of either 7s. or 8s. 9d. per head.

In the statement presented to me the following figures are of interest: The amount of the individual doctors' credit is £230,835 8s. 9d., but the amount available to pay that sum is only £187,799 1s. 7d., or 81.356 per cent. Therefore, without any apology, the Insurance Committee state that instead of paying me the full amount to which I am entitled, and for which we contracted to work, they will only pay 81 per cent. In other words, instead of receiving £252 12s. 3d., I only receive £205 10s. 4d., a matter of £47 less.

Is there any body of men in the country other than doctors who would stand this? It amounts really to a bankrupt paying his creditors 15s. in the £ instead of 20s., as I think you will admit 81 per cent. really means we are paid 5s. 6d. per head instead of 7s.

The Government can well afford to give us a 15 per cent. war bonus when they can pay us 19 per cent. short of the money legally due to us.—I am, etc.,

M. C. S. LAWRENCE.

Earlestown, Lancs, Dec. 13th, 1919.

Arbitration.

SIR,—I advocate a further 50 per cent. increase of all fees by July 1st, 1920, making a total increase of 125 per cent. above pre-war figures.

As the Health Ministry has not accepted our figures, I suppose the matter will now go to arbitration. I submit that the arbitration board should consist of three members: one appointed by the Panel Conference, one appointed by the Health Ministry, and a chairman (appointed by the King) who shall have both legal and medical qualifications.

Other points, besides remuneration, that might well go before the arbitration board are: Records; transference of patients on death of panel practitioner; expenses of doctors summoned before Medical Service Subcommittee; limitation of liability of panel practitioner to personal attendance on his own panel patients; free choice of patient by doctor; no alteration of Regulations without consent of Panel Committee; payment of fees for unallocated persons since 1913; liability of Health Ministry to pay full quarterly fees for insured persons remaining uncanceled on practitioner's list over the first day of each quarter; liability of Health Ministry to provide each insured person with a medical card within one month of such person becoming entitled to medical benefit.—I am, etc.,

GEOFFREY PRICE, M.R.C.S., L.R.C.P.

Kineton, Warwick, Dec. 27th, 1919.

Insurance Terms and Conditions.

"GENERAL PRACTITIONER" writes: I ventured to suggest in a letter written while the matter was still unsettled—but for which you were unable to find room—that our ultimate financial reward was already decided and that the acceptance of the objectionable clauses in the new agreement would not increase that reward. Now, when we are told that the modest figure asked for is quite unthinkable, I suggest that since the acceptance of these clauses did not provide the profitable lever we were told it would, we should try if the still more modest sum offered by the Government could not be used as a lever to get rid of these clauses. Take the "emergency" clause. There it is admitted that a doctor cannot possibly attend to even an insured person on every conceivable occasion, yet his capitation fee is made liable for each time he fails to do so. His brother practitioners are bound to drop all and run to the insured person who considers his case an emergency. Should he happen to be an epileptic, say, he may soon figure as a minus quantity in his doctor's books. And since the principle of deduction is to be accepted, how long will it be before the hospitals also charge us when they treat our patients, or before "police calls" are made recoverable from the panel doctor? On the other hand, any reward we may get for attending an emergency must be dearly bought at the loss of our personal freedom. At a time when workers all the world over are claiming and obtaining more liberty and freedom we are surrendering ours and accepting duties which are likely to give rise to friction amongst ourselves and ultimately to reduce our incomes.

STANDARDS OF VISION FOR MOTOR DRIVERS.

THE Council of British Ophthalmologists almost a year ago appointed a Committee to inquire into the visual requirements of persons licensed to drive mechanically propelled vehicles on public roads. The Council was impressed by the growing number of accidents caused by motor traffic, and wished to ascertain how far these might be due to defective vision on the part of drivers. At present the only qualification required for obtaining a licence to drive a motor vehicle other than a public conveyance is that the applicant must be 17 years of age; and it is stated as a fact that a blind man has obtained a licence. The problem to which the Council addressed itself was to ascertain the types of visual defect which may interfere with, or delay, a driver's power of avoiding accidents, and to determine as far as possible a standard which would not exclude the driver whose visual defect does not interfere with his capacity for driving with safety.

Report.

The Committee, to which Mr. Elmore Brewerton acted as Secretary, has recently reported to the Council, which has now issued a report,¹ divided into five parts: the first

¹ Report on the Visual Requirements of Persons Licensed to Drive Mechanically Propelled Vehicles on Public Roads. London: G. P. Man and Sons, Ltd. Price 1s.

gives a summary of the existing conditions under which licences are granted to drivers of various forms of mechanically propelled vehicles in this and other countries. The second part shows, in tabular form, the number of accidents occasioned by motor vehicles in London during the years 1912-17 inclusive, arranged in two groups—fatal and non-fatal. The number of accidents of both kinds grew each year up to 1915, and then declined, but during 1916-17 the number of hackney carriages plying for hire was much less. A striking feature of the tables is the steady increase in the number of accidents, both fatal and non-fatal, caused by trade and commercial cars during the whole period dealt with—even in the last two years, when the total number of accidents decreased. It is supposed that less care has been taken with the choice of drivers for this class of vehicle than for any other. While the accidents are, of course, attributable to a variety of causes, the defective sight of the drivers must be one cause.

The third part of the report takes up the kinds of visual defects in motor drivers from which accidents may arise, under the following heads: (1) Blindness in, or loss of, one eye; (2) conditions necessitating the habitual use of spectacles; (3) defective acuity of vision both with and without spectacles; (4) restricted fields of vision, night blindness; (5) the presence of diplopia or squint. Blindness in, or the loss of, one eye, limits the field of vision, and objects cannot be seen stereoscopically. But compensatory adjustments occur, as is well known, and one-eyed drivers are positive in believing themselves fully competent to drive with safety to themselves and others, though all admit that a foreign body in the sound eye might disable them. Discussing the hindrances to driving caused by spectacles, it is observed that obscuration of spectacles from without by mist, rain, dust, or mud can to some extent be guarded against by adaptable screens. The evidence collected from drivers does not seem to show that the restriction of the field of vision caused by using ordinary spectacles has proved a source of danger; it would in any case be much less than that due to the use of goggles. As regards acuity of vision generally, and the degree of this needed for safe motor driving, it is noted that the standard of central acuity laid down for army chauffeurs by an Army Council Instruction in 1918 was without glasses, in one eye $\frac{1}{15}$, and in the other $\frac{1}{20}$, no distinction being made as to which eye should have the better vision. It is not, however, considered that this army war standard, when there was a shortage of labour, can be taken as suitable for motor drivers of public vehicles in civil life, in time of peace, when there is an ample supply. Under (4) it is remarked that for the quick perception of oncoming traffic, or of objects approaching from either side, a full field of vision is the most important factor, rather than acute form sense in the centre of the field such as is tested by Snellen's test types.

The fourth part puts forward a scheme of vision testing for licences. Although desirable, it is held to be impracticable to subject to a satisfactory sight test every applicant for the issue or renewal of a licence. Obviously the standards of vision necessary for motor driving are not the same for all classes of drivers. Thus, one who drives his own car (unless he is a country doctor) can choose his time, route and pace, but not so (in theory, at least) a taxi-driver. Again, the responsibilities of a motor omnibus driver for instance are especially great, because he carries many passengers and moves along fixed routes at set times, while the vehicle he steers is large and heavy, and he is ill protected from mist, rain, and dust. The Council states emphatically that no person who from any cause has double vision should be granted a licence. The recommendation is made that certificates of sight for motor drivers be instituted, stating the visual fitness of the driver to drive certain classes of motor vehicles after having had his sight tested by an ophthalmic surgeon appointed for that purpose. In setting up standards for hackney cab drivers it is recognized that some persons have a greater capacity than others for overcoming the disadvantages due to visual defect. As a rough practical test of rapidity of response to visual stimuli the Council recommends a daylight trial trip as well as the direct vision test, and further, that some leniency may be shown as to the standard of central acuity required for renewal of licences to hackney cab drivers of long experience.

Recommendations.

The fifth part gives a summary of the Council's recommendations as follows:

I. That before a licence is granted by a county or borough council to an applicant to drive a mechanically propelled vehicle along the public roads such applicant be required to show his ability to steer a motor car round corners and to avoid obstacles.

II. That before such a licence be renewed the applicant be required to sign a statement that since the licence was granted he has not suffered from any physical disability likely to interfere with his driving capacity.

III. That if a licensed driver who suffers from some visual defect meet with an accident attributable in any way to that defect, he shall be liable to have his licence taken from him, or endorsed, as may be considered desirable in accordance with the circumstances of the case.

IV. That special sight test certificates for drivers of motor vehicles be instituted, and granted to applicants whose sight has been tested by ophthalmic surgeons appointed for the purpose, these certificates to be of three grades: Grade A, certifying the holder's visual capacity to drive any kind of motor vehicle; Grade B, certifying the holder's visual capacity to drive any kind of motor vehicle other than a motor omnibus or tramcar; Grade C, certifying the holder's visual capacity to drive a motor tramcar.

For Grade A certificate:

1. Every applicant, in addition to manifesting his ability to steer a motor car satisfactorily in daylight, should be required, in a trial trip at night, to show himself capable of driving in dim light and under varying degrees of illumination.

2. In an examination by an ophthalmic surgeon he should show: (a) Visual acuity of $\frac{3}{8}$ in one eye and $\frac{3}{4}$ in the other eye without the aid of glasses. (b) A full field of vision in each eye. (c) No manifest squint. (d) No double vision.

For Grade B certificate:

1. Every applicant, in addition to manifesting his ability to steer a motor car satisfactorily in daylight, should be required, in a trial trip at night, to show himself capable of driving in dim light and under varying degrees of illumination.

2. In an examination by an ophthalmic surgeon he should show: (a) Visual acuity of $\frac{3}{8}$ in one eye and $\frac{3}{4}$ in the other eye with glasses if necessary; (b) a full field of vision in each eye; (c) no double vision.

For Grade C certificate:

1. Every applicant should be required in a trial trip to show himself capable of driving a motor tramcar by day and by night under varying degrees of illumination.

2. In an examination by an ophthalmic surgeon he should reach the same visual standards as for a Grade A certificate.

V. That an applicant for a licence to drive a mechanically propelled hackney carriage be required to obtain the appropriate sight test certificate before such licence be granted.

An applicant for a renewal of licence to drive a hackney motor cab who is an experienced driver might, however, be granted such a renewal with a lower standard of central acuity of vision, namely, $\frac{1}{15}$ in one eye and $\frac{1}{20}$ in the other, with or without glasses.

VI. That owners of mechanically propelled vehicles, other than hackney carriages, be strongly advised to employ as drivers only those who have obtained a Grade A or Grade B certificate.

VII. That temporary permits be granted to those learning to drive mechanically propelled vehicles. When driving motor cars along the public roads the holders of such permits must be accompanied by a licensed driver.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Surgeon Commanders: T. W. Philip to the *Centurion*, and to the *Ajax* on re-commissioning; N. S. Meiklejohn, D.S.O., to Plymouth Hospital; J. S. McGrath to the *Woodcock*, J. G. Stevens to the *Stuart*, J. D. Bangay to the *Cornflower*, H. P. Turnbull to the *Superb*. Surgeon Lieutenant-Commander G. F. Sym to R.N. College, Dartmouth. Surgeon Lieutenants: R. F. Quinton to R.N. Hospital, Plymouth; N. B. de M. Greenstreet to the *Ark Royal*, H. W. Fitzroy-Williams to the *Teal*, G. L. Stanley to HMAS, A. G. McKee to the *Feron*, J. M. Moran to the *Columbine* for Port Edgar Base, G. E. Heath to the *Hollyhock* on commissioning. Surgeon Lieutenants (temporary): J. D. Milligan to the *Blake*, H. M. Scott to the *Inflexible*, T. W. Robbins to the *Camellia*, additional, for duty with sloops.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel S. G. Butler, D.S.O., relinquishes the acting rank of Colonel on ceasing to be specially employed.

The following relinquish the acting rank of Lieutenant-Colonel: Major M. F. Grant, Major F. Casement, D.S.O. (on ceasing to command a medical unit). On ceasing to be specially employed: Majors H. E. J. A. Howley and R. V. Cowry, D.S.O. Temporary Captain W. N. Parker, D.S.O.

To be acting Lieutenant-Colonels whilst specially employed: Major and Brevet Lieut.-Colonel C. R. Sylvester-Bradley, Captain and Brevet Major F. T. Dowling.

The following relinquish the acting rank of Major: Captain E. A. Strachan (December 15th, 1913, substituted for notification in the *London Gazette*, March 13th, 1913). Temporary Captain C. E. Waldron. On ceasing to be specially employed: Captains J. A. J. Wilson, J. B. Hepper. Temporary Captains: S. S. Dunn, E. T. C. Milligan, O. B. E., T. M. Bellows, G. Marshall, N. Reader, C. J. L. Patch, M.C., St. G. E. Harris, E. J. Maxwell, R. McKee.

To be acting Majors whilst specially employed: Captains W. T. Graham, O. B. E., (Brevet Major) W. F. Christie (from February 5th to July 23rd, 1919). Temporary Captains H. B. G. Russell, C. S. Wynne, M.C. (from October 14th to November 20th, 1919), E. Kidd (from September 1st to October 23rd, 1919).

Captain A. Watson, D.S.O., is seconded for service with the Egyptian Army.

To be Captains, but not to reckon for pay or allowances prior to December 1st, 1919: Captain E. C. Linton from S.R., March 19th, 1913, precedence next below R. H. Leigh; Captain J. C. Denvir from T.F., November 4th, 1913, precedence next below W. Russell.

Lieutenant (temporary Captain) G. E. Spicer, M.C., resigns his commission.

D. C. Smalzer to be temporary Captain.

The following officers relinquish their commissions: Temporary Major E. P. G. Causton, O.B.E., and retains the rank of Major. Temporary Captains and are granted the rank of Major: J. S. Lloyd, V. H. Masou, M.C. (on account of ill health caused by wounds), G. B. Warburton. Temporary Captains and retain the rank of Captain: N. P. L. Lamb, O.B.E., F. J. McCarthy, T. Readman, S. P. Pollard, L. G. Reynolds, S. Potter, W. E. Cooke, D. B. Spence, H. V. Swindale, R. L. Jones, A. G. Morris, A. F. Fraser, W. J. D. Smyth, C. C. Twort, A. R. Gnon, W. G. Gordon, J. Hewat, C. H. Phillips, H. W. Garden, T. G. Evans, T. C. B. Watson, V. R. Hirsch, G. W. Beresford, O.B.E., J. W. Potter, V. C. W. Vickers, G. H. Sinclair, A. Murdoch, A. E. Inseow, R. G. Morshead, M.C., W. W. Stacey, J. Dickson, M.C., T. L. Jones, R. Adam, R. K. Robertson, H. L. Attwater, J. M. Sheridan, W. Niccol, E. H. Good, V. C. James, L. G. Jacob, F. G. Beatty, V. Wallace, C. St. A. Vivian, S. G. Gordon, A. Brenner, E. J. Selby, O.B.E., C. W. Aikman, J. M. MacKay, M.C., T. Jones, D. Bird, C. Sherris, E. J. Sluckey, O.B.E., A. V. Ledger, C. Murray, R. Jamison, W. Robertson, J. N. G. Nolan, I. Hodgkinson, J. A. Thom, W. C. Stevenson (on ceasing to serve with the Home Hospitals Reserve), J. W. Brown, H. D. Matthews, H. M. Godfrey (on account of ill health caused by wounds). Temporary Lieutenant J. Black, and retains the rank of Lieutenant.

ROYAL AIR FORCE.
MEDICAL BRANCH.

Major E. C. Clemeals (R.A.M.C.T.F.) is granted a temporary commission as Major on seconding to R.A.F.
Flying Officers to be Flying Lieutenants: J. T. X. Canton, P. McDiarmid.
Transferred to the unemployed list: Captains A. Kirkhope, C. J. Milner, P. C. Parr, Lieutenant W. J. S. Cameron.
The notification in the *London Gazette* of August 19th concerning Flying Officer L. C. Proughon-Hoad is cancelled.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captains relinquish the acting rank of Major on ceasing to be specially employed: R. D. Cameron, G. E. Kidman, D. G. Stoute.
Captain M. D. Vint relinquishes his commission on account of ill health contracted on active service, and retains the rank of Captain.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Captain (acting Major) F. Scroggie, M.C., relinquishes the acting rank of Major on ceasing to be specially employed.
Captain W. C. D. Hills relinquishes his commission on account of ill health contracted on active service and retains the rank of Captain.
3rd Scottish General Hospital.—Captain J. Patrick is restored to the establishment on ceasing to hold a temporary commission in the R.A.M.C.
1st Southern General Hospital.—Captain J. W. Stratton is restored to the establishment.
1st Western General Hospital.—Captain (acting Major) C. T. Holland relinquishes the acting rank of Major on ceasing to be specially employed.

VOLUNTEER FORCE.

Bedfordshire R.A.M.C.(F.).—Temporary Captain F. W. B. Phillips relinquishes his commission, and is granted the honorary rank of Captain.
Essex R.A.M.C.(F.).—Temporary Captain A. L. Curror relinquishes his commission, and is granted the honorary rank of Captain.
Merseyside R.A.M.C.(F.).—Temporary Captain J. Adam relinquishes his commission, and is granted the honorary rank of Captain.
Northamptonshire R.A.M.C.(F.).—Temporary Lieutenant A. Leitch relinquishes his commission, and is granted the honorary rank of Lieutenant.

EXCHANGE.

R.A.M.C. Lieut.-Colonel, at present at home on leave, wishes to hear from an officer of his own rank serving in the British Isles who is willing to proceed to India to complete a term of duty, ending in June, 1925. Address Lieut.-Col. J. G. Gill, R.A.M.C., Junior United Service Club, London.

APPOINTMENTS.

DOUGAL, Daniel, M.C., M.D., Honorary Assistant Surgeon, St. Mary's Hospitals for Women and Children, Manchester.
DYER, Charles Harold, M.D., C.M.Aberd., D.P.H. Vict., Medical Officer to the Tunbridge Wells Post Office.
EDMOND, William Square, F.R.C.S., Honorary Surgeon to the Royal Naval Infirmary.
HERZFELD, Miss Gertrude, M.B., Ch.B., Assistant Surgeon to the Royal Hospital for Sick Children, Edinburgh.
TROTTER, G. Clark, M.D. Edin., Medical Officer of Health for Deptford.
KING'S COLLEGE HOSPITAL AND MEDICAL SCHOOL.—The following new appointments to the staff are announced: H. W. Wiltshire, D.S.O., O.B.E., M.D., F.R.C.P., Physician in Charge of the Cardiological Department, Lecturer on Cardiology, and Vice-Dean of the Medical School. F. W. Tunnicliffe, M.D., M.R.C.P., Physician in Charge of the Therapeutics and Applied Pharmacology Department, and Lecturer on Therapeutics and Applied Pharmacology. A. C. D. Firth, M.D., M.R.C.P., Junior Physician and Demonstrator of Clinical Medicine. R. H. Steen, M.D., M.R.C.P., Out-patient Physician for Psychological Medicine. S. A. Klunier Wilson, M.D., F.R.C.P., Junior Neurologist and Lecturer on Neurology. J. W. Thomson Walker, O.B.E., M.B., Ch.B., F.R.C.S., Senior Urologist and Lecturer on Urology. H. A. T. Fairbank, D.S.O., M.S., F.R.C.S., Senior Orthopaedist and Lecturer on Orthopaedics. John Everidge, O.B.E., F.R.C.S., Junior Urologist and Junior Surgeon; Lecturer on Surgical Applied Anatomy. C. Jennings Marshall, M.D., M.S., F.R.C.S., Junior Orthopaedist and Junior Surgeon; Lecturer on Surgical Applied Anatomy. W. J. R. Simpson, C.M.G., M.D., F.R.C.P., D.P.H., Lecturer on Tropical Medicine. W. d'Este Finlay, M.D., B.Sc., M.R.C.P., Pathologist, Director of Pathological Department, and Lecturer on General Pathology. B. R. Clayton, M.B., B.Ch., Physio-therapist and Director of the Physio-therapeutic

Department. L. M. Moody, M.D., B.S., M.R.C.P., Bacteriologist and Lecturer on Bacteriology. G. A. Harrison, M.R.C.S., Bio-chemist and Lecturer on Medical Chemistry. Helen Ingleby, M.B., B.S., M.R.C.P., Pathological Registrar and Lecturer on Morbid Anatomy. H. A. Burrigide, M.B., Lecturer on Forensic Medicine and Toxicology. J. H. Sheldon, M.B., B.S., Sambrooke Medical Registrar and Medical Tutor. C. P. G. Wakeley, M.R.C.S., Sambrooke Surgical Registrar and Surgical Tutor. A. C. McAllister, M.B., B.S., Obstetric Registrar and Obstetric Tutor.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—Honorary Assistant Physician: William Y. Woodburn, M.D. Honorary Assistant Anaesthetist: William Carling, M.B., B.Ch.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 6s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

IRVINE.—On the 21st December, 1919, at 36, Salisbury Terrace, Devonport, the wife of Major A. E. S. Irvine, R.A.M.C., of a son.
PRITCHARD.—On December 22nd, 1919, to the wife of Dr. Norman P. Pritchard, M.C., Carfew House, Chertsey, Surrey—a son (Gordon Alford).

MARRIAGES.

DONOGHUE-ANDERSON.—At Chapel Royal, Savoy, on December 20th, 1919, by the Rev. Hugh Chapman, Surgeon-Lieutenant, William O'G. Donoghue, Royal Navy, to Grace Turnbull Anderson, M.B., Ch.B., second daughter of the late Thomas Anderson, A.M.Inst.C.E., Royal Indian Marine, and Mrs. Anderson, of 9, Belzelo Park, London, N.W.
LYNN-THOMAS-MACRAE.—On the 9th December, 1919, at St. George's U.F. Church, Edinburgh, by the Rev. Prof. H. P. MacKintosh, Charles Ivao Lynn-Thomas, formerly Lieutenant of 1st South Wales Borderers, son of Sir John Lynn-Thomas, K.B.E., C.B., C.M.G., and Lady Lynn-Thomas, R.R.C., of Greenclawn, Penylan, Cardiff, to Dorothy Guthrie Macrae, daughter of Duncan Macrae, Ruthven, Kingussie.
SINCLAIR-DANIEL.—On the 30th December, 1919, at Saint Anne's Church, Sale, Manchester, William Sinclair to Stephanie Patricia Daniel, M.B., B.S., M.R.C.S.

DEATHS.

FORREST.—On 18th ult., at a private nursing home, Glasgow, Robert Wardrop Forrest, M.D., F.R.F.P.S.G., aged 79, of Westwood, 60, Dalziel Drive, Pollokshields, Glasgow.
JOHN.—On December 27th, 1919, at 15, Albion Road, Hampstead, William John, M.R.C.S.Eng., L.M., late of Haverfordwest, aged 78 years.
ROSS.—On the 25th December, 1919, at "Roslyn," 153, Brigstock Road, Thornton Heath, Surrey, William George Ross, M.D., formerly of the 8th, "The King's," Regiment and Army Medical Department, aged 79. (15th May, 1840.)
SCALLON.—On December 23rd, 1919, Ethel Bache, wife of Ernest O. over Scallon, M.D., of Romsey, Hampshire, and daughter of the late John Senior, of New Inn and Dalwich.

DIARY FOR THE WEEK.

ROYAL SOCIETY OF MEDICINE.—Section of Surgery—Subsection of Orthopaedics: Tuesday, 5 p.m., Cases. Section of Surgery—Subsection of Proctology: Wednesday, 5.30 p.m., Discussion on Diverticulitis to be opened by Dr. Maxwell Telling, and continued by Professor A. Keith, Mr. Lockhart-Mummery, Dr. E. I. Spriggs, Mr. McAdam Eccles, Mr. Grey Turner, Mr. Rutherford Morison, Mr. Hamilton Drummond, Mr. Garnett Wright, Mr. James Berry, Mr. R. P. Rowlands, Mr. Maynard Smith, Mr. H. S. Clogg, Dr. A. C. Jordan, Mr. Ivor Back, Mr. Peter Daniel, Mr. L. E. C. Norbury, Mr. W. E. Miles, Dr. de Bac Turtle, Sir C. Gordon Watson, Dr. Herniman Johnson, Mr. Sampson Handley. A collection of specimens illustrating the subject of discussion will be on view from 2.30 p.m. Following the meeting on January 7th the Annual Dinner of the Subsection will be held at Oddenino's Restaurant, 60, Regent Street. Members of the Subsection are entitled to invite one guest, but must intimate their intention to Mr. Sampson Handley before January 3rd. Section of Neurology: Thursday, 8.30 p.m., Dr. F. M. R. Walshe: Peripheral Neuritis among the Egyptian Expeditionary Force, 1915-19. Clinical Section: Friday, 5.30 p.m., Sir Anthony Bowlby: The Application of War Methods to Civil Practice. Exhibition of Cases.

DIARY OF THE ASSOCIATION.

Date.	Meetings to be Held.
JANUARY.	
5 Mon.	Maidstone Division, West Kent Hospital, 3.15 p.m.
6 Tues.	London: Scrutiny Subcommittee of Organization Committee, 2.30 p.m.
7 Wed.	Nottingham Division, 64, St. James's Street, Nottingham, 4 p.m., Lecture by Dr. Bernard Hart: Modern Methods of Treatment in Functional Nervous Disorders.
8 Thur.	London: Territorial Force Subcommittee, 4 p.m.
15 Tues.	London: Maternity and Child Welfare Subcommittee, 2.30 p.m.
17 Wed.	London: Propaganda Subcommittee, 2.15 p.m.
27 Tues.	London: Public Health Committee.
28 Wed.	London: Medical-Political Committee.
29 Thur.	London: Organization Committee.
30 Fri.	London: Ethical Committee.
FEBRUARY.	
18 Wed.	London: Council.

CURRENT NOTES.

The New Insurance Regulations and Remuneration.

WE believe there is little likelihood of the decision of the Government being announced this week, owing to the continuance of the pressure of matters of great national and international importance which are within the knowledge of all. The matter is, we understand, receiving the direct attention of the Government. The Minister of Health is seeking to obtain an early decision, which will be communicated to the Insurance Acts Committee at the earliest possible moment.

The Association in Victoria.

WE have received from Melbourne the annual report of the Council of the British Medical Association (Victorian Branch) and the Medical Society of Victoria for the year ending December 3rd, 1919. The Council held twenty-five meetings in all, apart from meetings of the trustees and of various subcommittees. The number of members on the roll showed an increase of 36. The war record shows that of the 966 members of the Association in Victoria, 407 enlisted for whole-time military service; of these, 304 have returned, 73 are still abroad, and 40 gave their lives for the empire. It is proposed to hang in the Medical Society's hall an Honour Board inscribed with the names of those who fell. Ethical matters occupied a good deal of the Council's attention during the year. It considered the attempt by certain insurance societies to discredit the obligation of professional secrecy on the part of medical men towards their patients. Insurance companies had inserted a clause whereby the insurer consented to his medical adviser divulging certain professional confidences usually kept secret. The Council decided that members should disregard such attempt, and should preserve strictly the ethical duty of professional secrecy. A great deal of time and care was devoted by the Council and its Organization Committee to the dispute with the friendly societies. Some account of this matter was given in a letter from the officers of the Victorian Branch to the Chairman of the Council of the Association, printed in the SUPPLEMENT of December 27th, 1919, and a note appeared also in the JOURNAL of the same date (p. 854). The loyalty and solidarity of the members of the Branch have been well shown all through this long-drawn-out dispute. It appears that the friendly societies are now trying to obtain in this country 100 doctors to act as medical officers, and in other ways to outflank the medical profession of Victoria. Before accepting any

medical posts in Australia doctors are therefore urged to apply for information to the Medical Secretary of the British Medical Association, 429, Strand. With regard to legislation, the principal medico-political matters considered by the Council of the Victorian Branch were the proposed State Health Bill, the question of unqualified medical practitioners, the patent medicines question, and the general question of the extent of State and Federal medical services. Various recommendations have been made on behalf of the medical profession of Victoria in these matters. In response to a request from the Federal Committee to all the Branches, the Council appointed a subcommittee to draw up a report on the nationalization of medicine, with Sir Harry Allen as its chairman. In addition to using its influence in obtaining resident hospital appointments for medical men returning from military service, the Council arranged with the Melbourne hospitals and the medical school and Federal Serum Institute for the holding of a post-graduate course; this was attended by ninety practitioners, most of whom had been on active service. Ten meetings were held during the year for the discussion of papers on clinical and scientific subjects.

Pensions for Senior Medical Officers, R.N.

AS recorded in the SUPPLEMENT of November 15th, 1919, the Naval and Military Committee of the British Medical Association recently instructed a special subcommittee to examine and report on the new regulations for pay and retirement of naval medical officers. The most pressing matter before the subcommittee was the position of certain senior surgeon commanders under the new scheme. The pension allowed by the new regulations to senior surgeon commanders is less than 10 per cent. greater than the old rate fixed more than forty years ago. Further, this increase is in certain contingencies subject to a deduction of 20 per cent., giving a final reduction of pension of about 10 per cent. Another matter which has formed the subject of representations to the Admiralty is the new age for compulsory retirement and the consequent loss of full pay service and chances of promotion to higher rank. On the instruction of the Naval and Military Committee a letter was sent to the Admiralty on December 2nd, 1919, drawing attention to the way in which senior surgeon commanders are adversely affected by the recent regulations. A request was made for an early reply. The Lords Commissioners of the Admiralty have now informed the British Medical Association by letter that the subject referred to in the Medical Secretary's letter of December 2nd—namely, the retirement of senior surgeon commanders R.N.—is receiving careful consideration, and that a reply, it is hoped, will be sent at an early date.

Colonial Medical Services.

It was announced in this column on November 22nd, 1919, that the British Medical Association would shortly give evidence before the Colonial Medical Services Committee recently appointed by the Secretary of State for the Colonies. The terms of reference of this Committee are as follows:

To consider the position of the medical services of the various colonies and dependencies, with a view to maintaining and increasing the supply of candidates, and to securing contentment within the service; and to consider whether the principle of assimilating the medical service of neighbouring colonies may usefully be extended, and, if so, how far and by what means.

The Colonial Office has agreed to the suggestion that representatives of the Association should be invited to give evidence, and has intimated that the Colonial Medical Services Committee would like to have a *précis* of the points which the British Medical Association desires to bring forward. In our last reference to this matter medical officers belonging to, or with recent experience of, any of the colonial medical services were invited to communicate with the Medical Secretary of the Association.

Association Notices.**MEETING OF COUNCIL.**

THE next Meeting of Council will be held on Wednesday, February 18th, in the Council Room, 429, Strand, London, W.C. 2.

BRANCH AND DIVISION MEETINGS TO BE HELD.

DUNDEE BRANCH.—Drs. R. C. Buist and G. H. S. Milln, Honorary Secretaries (166, Nethergate, Dundee), give notice that the second address on after-war conditions will be delivered in the Physiology Department, University College, Dundee, at 5 p.m. on Wednesday, January 14th, by Dr. Arthur Hurst, Physician to Guy's Hospital, who has chosen as his subject the functional element in diseases—medical, surgical, gynaecological, genito-urinary, ophthalmic, and oto-laryngological. The address will be illustrated by cinematograph and lantern demonstrations.

KENT BRANCH: TUNBRIDGE WELLS DIVISION.—Dr. A. F. Hurst, Physician to Guy's Hospital, will give a lecture to the Division, at the General Hospital, Tunbridge Wells, on Tuesday, January 20th, on new views on the pathology, diagnosis, and treatment of gastric and duodenal ulcer.

Meetings of Branches and Divisions.**LANCASHIRE AND CHESHIRE BRANCH: ST. HELENS DIVISION.**

At a meeting on December 9th, 1919, it was decided to adopt the recommendation of the Council of the British Medical Association to increase medical fees by 50 per cent. over pre-war prices, and to advertise this decision in the local newspapers, it being always understood that the individual doctor will use his discretion when dealing with the individual patient.

PERTH BRANCH.

A MEETING of the Perth Branch was held at Perth on December 19th, 1919, when Dr. FERGUSON WATSON was in the chair, and sixteen members were present.

The TREASURER (Dr. Hume) read his report, and stated that Dr. Parker Stewart became treasurer in accordance with the resolution passed at the meeting of the Branch on September 25th, 1919. A vote of thanks was unanimously accorded to Dr. Hume for the services he had rendered to the Branch as treasurer. The meeting approved the insertion of a report of the meeting in the newspapers stating that after careful consideration it was resolved to increase medical fees by 50 per cent. to cover increased cost of living.

The meeting, after discussion, expressed approval of the usual monthly circular to honorary secretaries of Divisions and Branches, issued from the head office, regarding the activities of the Association. With reference to the paragraph regarding the lending facilities of the library, several members intimated that they would willingly pay postage to be enabled to have books placed at their disposal by the library.

At a meeting of the medical profession of Bournemouth and district held on November 29th, 1919, it was unanimously resolved, in view of the increased cost of living and of working expenses by at least 100 per cent., and the general depreciation in the value of money, to recommend that the pre-war rate of fees be increased by 50 per cent.

INSURANCE.**CORRESPONDENCE.***Insurance Remuneration.*

SIR,—I feel that my "pride in the dignity of our high calling" is diminished now that the purely personal relation between doctor and patient has been lost and we are journeymen working under contract. Still, this need not close the door on common sense. What other body of workers has been content to carry on on pre-war pay?

We have not embarrassed the Government by strikes. In fairness the Government should see that any readjustment of insurance payments should be retrospective.

The essence of all "bargaining" is that each side is prepared to give way. Dr. Addison recognizes this, and, though he knows that all our expenses have gone up more than 125 per cent., he is not ashamed to suggest a capitation fee of 10s. (or will it be 81 per cent. of 10s.?) as a basis of bargaining.

We, ashamed to embarrass a bankrupt Act, make our mistake of 1912 over again by timidly putting forward our modest minimum as a starting point of bargaining. Very decent of us, but very bad business.—I am, etc.,

Husbands Bosworth, Rugby, Jan. 4th.

J. A. NOBLE.

The Profession and the Government.

SIR,—No medical practitioner, whether he has worked the panel or not, can fail to be interested in the present condition of things in the medical world, and to view with considerable uneasiness the great changes taking place in the business life of the profession to which he devoted time and money to enter.

I am chiefly interested in the stand made for a certain fixed capitation fee. For an ununited body of men to presume to dictate for one moment to a Government autocrat appears to me foolish in the extreme. It is customary for a slave to approach his lord in a spirit of meekness, and what we see is a body of conscripts dictating terms to an individual whose powers are enormous and who regards himself as only a shade lower than the Deity.

I think it most probable that the Minister of Health will out of charity allow his slaves a slight increase in the present fee, recognizing how utterly they are at his mercy, but further than that he will not budge, but rush the profession into compliance by forwarding agreements to be signed and returned by a certain date, probably four days, under the threat that unless received duly signed the practitioner will be deemed to have left the panel service. No time for remonstrance, bargaining, or meetings.

It should be remembered that many curious creatures, called, for the sake of propriety, conscientious Coniberts, are now emerging from their war nests and are ready and willing to support any scheme or adopt any tactics ensuring a living, and that by earning the good opinions of the slave driver they will creep and crawl into some better post when matters have been settled.

There is only one hope for the future of the medical man, and that is an amalgamation of the three D's—doctors, dentists, and druggists—and the sooner that comes the better.

I write quite impartially, as I have never adopted the panel, and only starvation would make me do so, but I have seen and know what it is and what it threatens to become.—I am, etc.,

COLLINGWOOD FENWICK, M.D.

Wallingford, Dec 29th, 1919.

The Panel Conference.

SIR,—As Dr. Braeklenbury, in his comments on my letter, says that almost every sentence which purports to be a statement of fact is either false or misleading, I must ask for space for a reply.

A Conference that gives its approval to regulations which declare the decisions of the Minister to be final, that objects to an appeal to a court of law, that connives at the fact that the Minister may be both accuser and judge, that rejects clear-cut motions such as those from Stockport, Portsmouth, and Cheshire, and passes the assuasive motion from Brighton, proclaims the Minister autocrat in the strictest sense of the term. "Speaking generally, what is resented more than anything else in the new Regulations," says the BRITISH MEDICAL JOURNAL, "is the autocratic element which permeates them."

Over and over again, at the conferences, objection was raised to the limitation of lists as curtailing the liberty of the medical man, interfering with his practice, and abrogating a first principle—free choice of doctor. Two years ago seventy areas voted for no limitations, as against

thirty-three in favour of them. Yet the Bournemouth resolution to limit lists to 3,000 was passed, although the chairman informed us that he had ruled out of order motions contrary to the decisions of the July conference. A further limitation to 2,000 is a logical deduction.

I said a resolution to organize the profession to refuse service under certain contingencies was dropped as unthinkable. The minutes record that an amendment from York, "and instructs the Insurance Committee to endeavour by all means to secure the refusal of all insurance practitioners to take service at any less sum," was lost. The reason given at the Conference was that refusal was unthinkable. So to this day the Minister cannot make up his mind about the fee. If an insurance practitioner is responsible for all persons who have been accepted by him, for those who have left him and are perhaps out of benefit but who have not been notified to him by the committee as having ceased to be on his list, and for all accidents and emergencies pending their acceptance by somebody else, I say that he is at the beck and call, night and day, of anyone who can bluff him for treatment.

A practitioner shall not employ a permanent assistant to attend his insured patients without the previous consent of the committee to the employment of such an assistant. The committee is requested to be reasonable. Before consenting to the employment by a practitioner of more than one assistant the committee shall obtain the approval of the Minister. In spite of these regulations the practitioner is after all responsible for all acts and omissions of any practitioner acting as his deputy or assistant. It is an old shibboleth that State money means State control. But in this case we have State control without State money.

I said that the patients whom a doctor attracts are not his but belong to the State. If the Minister confiscate Dr. Brackenbury's watch it belongs to the Minister, as there is no appeal. The BRITISH MEDICAL JOURNAL has not minced words: "The Ministry of Health has stated its determination to alter the present Regulations about transfers. Practitioners, for their part, are equally determined not to submit to any confiscation of the goodwill in their panel practices."

A pension scheme was literally sprung upon us a day or two before the Conference. It was a red herring drawn across the trail. It was a daring move on the part of those who are out for a State service. It was resolved "that this Conference is in favour of a pension scheme for insurance practitioners, to be managed by the practitioners themselves, and authorizes the Insurance Acts Committee to negotiate with the Government concerning such a scheme." Resolved also "that the question of a pension scheme for insurance practitioners be referred to Local Medical and Panel Committees."

At the Conference three names were added to the Association's nominees to form a deputation to the Minister. They had to inform him definitely that 13s. 6d. was the irreducible minimum that the profession would accept as a capitation fee. The interview with the Minister is published in the BRITISH MEDICAL JOURNAL of December 13th. The usual arguments for better payment were advanced. That money had depreciated during the war, that the cost of living had increased, that more work meant more pay, that greater responsibility entailed greater consideration, were theories new to him. His stereotyped reply reads: "That he could not see any case made out for any increased rate of remuneration."

The Ministry has taken the measure of our Conference delegates. Our motions, whether passed or rejected, are entirely ignored at the Ministry. Since our Conference the following most objectionable regulations were inserted in the latest draft Regulations:

Range of practitioner's duties. (13) A practitioner is required—(a) To furnish in writing to the medical officer any information which the latter may require with regard to the case of any patient to whom the practitioner has issued, or declined to issue, a medical certificate of incapacity for work.

(b) To meet the medical officer, when the latter so requires, for the purpose of examining, in consultation, any patient in respect of whom the practitioner has sought the advice of the medical officer.

(c) To afford to the medical officer, or to such other person as he may appoint for the purpose, access at all reasonable times to any records kept by the practitioner under these terms of service, and to furnish the medical officer with any such records, or with any necessary information with regard to any entry therein, as he may require; and

(d) To answer any inquiries of the medical officer with regard to any prescription issued by the practitioner, or to any statement made in any report furnished by him under these terms of service.

Is it possible to consider insurance practice reputable after this? Fortune may render us unhappy, it is only ourselves that can make us despicable.

We were once medical practitioners. We were members of a learned profession. Now by the terms of our service we are insurance practitioners. We have, in the commissioners' own words, to safeguard the interests of the approved societies. We are agents in a business undertaking; for heaven's sake, then, let us learn business methods.—I am, etc.,

Exeter, Jan. 3rd.

J. PEREIRA GRAY.

** We have printed above *in italics* the words stated by Dr. Pereira Gray to have been used by the Minister of Health. We print below extracts from the official report of the Minister's reply published in the SUPPLEMENT:

"Dr. Addison said that, quite frankly, the case for a 13s. 6d. capitation fee was not, in his view, made out. . . . He was quite sure that the Government could not give 13s. 6d. . . . He did not see how it could be possible for the Government to accept such a proposal. . . . He concluded by saying that he was satisfied that there was a case for a substantial increase over the pre-war fee, and that the new fee to be fixed must be one which would give a good average general practitioner, fairly doing his duty, what he himself would feel would pay him properly for treatment—in other words, something like the same payment that he would expect for his patients generally, other than the more wealthy patients."

(SUPPLEMENT, December 13th, 1919, p. 157.)

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Surgeon Commander L. Warren, O.B.E., to the *President*, additional for service with Subcommission of Inter-Allied Commission of Control. Surgeon Lieutenant Commander J. S. Elliott to the *Crescent*. Surgeon Lieutenants: J. C. Sinclair to the *Bluebell*, on commissioning; N. A. H. Barlow to the *Foxglove*, on commissioning; J. C. Kelly, D.S.C., to the *Godetia*, on commissioning; O. J. M. Kerrigan to the *Cicala*, on commissioning. Surgeon Lieutenant (temporary) J. F. Ainley to the *Grenville*.

ARMY MEDICAL SERVICE.

Colonel G. Dansey-Brownrigg, C.B.E., is placed on the half-pay list. Temporary Colonel E. F. Buzzard (Captain R.A.M.C.T.F.) relinquishes his temporary commission on re-posting.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel C. J. O'Gorman, D.S.O., relinquishes the temporary rank of Colonel, March 31st, 1919 (substituted for the notification in the *London Gazette*, November 4th, 1919).

Major E. L. Moss, C.M.G., M.C., relinquishes the acting rank of Colonel.

The following relinquish the acting rank of Lieutenant-Colonel: Major G. H. Stevenson, D.S.O., Major C. W. Bowle (on ceasing to command a medical unit), Major E. D. Caddell, M.C.

To be acting Lieutenant-Colonels: Temporary Captain L. D. Shaw, D.S.O. (from July 22nd, 1918, to March 14th, 1919), Major E. B. Lathbury, O.B.E. (whilst commanding a medical unit from August 15th to October 5th, 1919).

Major W. M. Power, from the half-pay list, retires on retired pay on account of ill health, October 5th, 1919 (substituted for notification in the *London Gazette*, October 4th, 1919).

H. E. L. Canney, late temporary Major, to be temporary Major, seniority from June 25th, 1915.

The following relinquish the acting rank of Major: Captain H. A. Rowell, M.C.; temporary Captain E. Biddle, M.C., September 17th, 1919 (substituted for notification in the *London Gazette*, December 2nd, 1919).

Major E. L. Moss, C.M.G., M.C., relinquishes the acting rank of Colonel.

Captain G. S. Parkinson, D.S.O., to be temporary Major whilst specially employed.

Captain H. A. Rowell, M.C., to be acting Major from August 15th to October 5th, 1919.

The following are seconded for service with the Egyptian Army: Brevet Major W. E. Marshall, M.C., J. Biggani, M.C. (substituted for notification in the *London Gazette*, December 9th, 1919), K. P. Mackenzie (substituted for notification in the *London Gazette*, November 8th, 1919).

Temporary Captain J. Higgins to be Captain, March 1st, 1918, but not to reckon for pay and allowances prior to November 1st, 1919, with precedence next below A. L. Roberts (substituted for notification in the *London Gazette*, December 4th, 1919).

Lieutenants (temporary Captains) to be Captains: W. E. Hodgins, T. S. Law.

Late temporary Captains to be temporary Captains: A. Vella (seniority from November 21st, 1915), G. Fleming (seniority from November 16th, 1915), J. N. G. W. McMorris (seniority from June 6th, 1916).

Temporary Lieutenant A. P. Cullen to be temporary Captain.

Lieutenant E. H. W. Elkington, from C.A.M.C., to be Lieutenant, and to be temporary Captain, April 17th, 1918, but not to reckon for pay or allowances prior to December 15th, 1919, with precedence next below M. C. Paterson.

W. H. Stevenson to be temporary Lieutenant.

The following officers relinquish their commissions:—Temporary honorary Lieut.-Colonel M. Gamble, on ceasing to serve with the Withington War Hospital, and retains the honorary rank of Lieutenant-Colonel. Temporary Captain (acting Major) F. G. W. Deane, and is granted the rank of Lieutenant-Colonel. Temporary Captains and are granted the rank of Major: D. B. Fuscald (November 13th, 1919; substituted for notification in the *London Gazette*, December 5th, 1919), A. S. K. Anderson, D.S.O., M.C., E. G. Dingley, G. H. B. Purce, M.C., G. W. R. Rudkin, M.C., M. Bates, J. S. Doyie, J. B. Hayercraft, M.C., F. de S. McManamin, M.C., W. Martin, E. McCulloch,

Temporary Captains and retain the rank of Captain: F. J. Strachan, M.C., E. Gray, A. J. Will, R. Thomson, N. S. Sherrard, J. D. Wright, R. H. Thomson, M.C., R. Ward, H. A. Ash, A. Renshaw (March 26th, 1917, substituted for notification in the *London Gazette*, June 13th, 1917), W. E. Hopkins, M.C. (November 9th, 1917, substituted for notification in the *London Gazette*, December 4th, 1919), H. J. Burke, M.C., C. G. Harmer, L. Hutchinson, A. Gregory, J. F. Allan, P. S. Marshall, V. St. L. Pinnock, W. T. Currie, J. H. Murray, R. W. Murphy, E. T. Glenn, J. A. Macarthur, T. Forsyth, J. Paxton, B. P. Parmiter, L. M. Mayers, A. L. E. F. Coleman, M.C., E. Morison, N. Reader, B. J. Cusack, S. Murray, J. Dunlop, L. W. Bain, W. J. Macdonald, M.C., H. Richmond, A. E. Schokman, R. McLean, J. A. P. Cullen, S. P. Rowlands, I. C. MacKenzie, J. Porter, J. I. Eoright, J. Avery, S. J. Darke, M.C., T. W. Bayne, H. P. Fairlie, J. D. MacEwen, J. C. Koox, D. S. Campbell, M.C., R. M. McMillan, R. Brown, W. L. Cassels, S. P. Stoker, M.C., S. A. Furlong (on account of ill health), P. D. Magowan, H. L. Fliot, J. C. McWalter, R. S. Harvey, W. J. Poole, C. E. Sharp, O. R. Allison, J. C. Robb, H. G. Oliver, D. Malloch, M.C., J. P. Dee, D. L. Spence, W. Howat, A. R. Moore, A. E. Foerster, J. H. D. Phelps, D. Denlop, J. Meozias, S. E. Y. Elliott, H. Mortimer, R. A. Fuller, M.C., G. Habgood, N. H. Smith, V. M. Coates, M.C., F. Newey, O.B.E. Temporary Captains: A. Anderson. Temporary Lieutenant and retains the rank of Lieutenant: P. J. F. Lynch.

ROYAL AIR FORCE. MEDICAL BRANCH.

Transferred to unemployed list:—Captains: W. L. Scott (February 13th, 1919 (substituted for notification in the *London Gazette*, April 4th, 1919), R. W. Meller (March 20th, 1919), J. E. Lascelles (April 14th, 1919), L. A. Walker (May 20th, 1919), H. Y. Riddell (December 5th, 1919), C. H. Browne (December 13th, 1919), (acting Major) L. C. McL. Wedderburn (December 19th, 1919).

INDIAN MEDICAL SERVICE.

The promotion to his present rank of Captain U. J. Bourke has been antedated from May 30th, 1917, to July 17th, 1916. Major H. Crossle was posted as Joint Civil Surgeon, Peshawar, for September 29th, 1919.

Lieut.-Colonel C. A. Lane, M.D., has been permitted to retire from the service, with effect from October 25th, 1919. The Hon. Major-General W. R. Edwards, C.B., C.M.G., K.H.P., I.M.S., has been elected an honorary Fellow of the Royal College of Surgeons of Edinburgh.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain J. B. Hanna relinquishes the acting rank of Major. Lieutenants to be Captains: W. E. P. Briggs, G. Winter, G. S. Lewis, W. Oats.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel W. B. Mackay, C.M.G., relinquishes his commission on account of ill health contracted on active service and retains the rank of Lieut.-Colonel.

The following officers relinquish the acting rank of Lieut.-Colonel on ceasing to be specially employed: Major (acting Lieut.-Colonel) W. A. Thompson (July 7th, 1918), Captain (acting Lieut.-Colonel) F. G. Dobson, D.S.O. (June 30th, 1919, substituted for notification in the *London Gazette*, August 5th, 1919).

The following Captains (acting Majors) relinquish the acting rank of Major on ceasing to be specially employed: D. C. Bremner, J. Everidge, O.B.E. (March 21st, 1919, substituted for notification in the *London Gazette*, October 16th, 1919), F. W. K. Tough, A. P. Thomson, M.C. (May 13th, 1919, substituted for notification in the *London Gazette*, June 4th, 1919), L. N. Reece.

Captain F. Ellis, M.C., relinquishes his commission on account of ill health caused by wounds, and is granted the rank of Major.

1st *London Sanitary Company*.—Lieutenant J. T. A. Walker to be Captain.

1st *Northern General Hospital*.—Captain N. Hodgson is restored to the establishment.

TERRITORIAL FORCE RESERVE.

ARMY MEDICAL SERVICE.

Lieut.-Colonel Sir H. Davy, K.B.E., C.B., from 4th Southern General Hospital, to be Colonel.

ROYAL ARMY MEDICAL CORPS.

The announcement regarding Major G. Black, T.D., which appeared in the *London Gazette*, October 30th, 1918, is cancelled.

VOLUNTEER FORCE.

Kincardine R.A.M.C.(V).—Temporary Lieutenant C. Aymer relinquishes his commission and is granted the honorary rank of Lieutenant.

QUEEN MARY'S ARMY AUXILIARY CORPS.

Auxiliary Section, R.A.M.C. attached.—Medical Controller E. E. Bourne, M.D., relinquishes her appointment.

EXCHANGE.

R.A.M.C. Lieut.-Colonel, at present at home on leave, wishes to hear from an officer of his own rank serving in the British Isles who is willing to proceed to India to complete a term of duty ending in June, 1922. Address Lieut.-Col. J. G. Gill, R.A.M.C., Junior United Service Club, London.

APPOINTMENTS.

ALPHEON, G. G., M.B., B.Ch., F.R.C.S. Eng., Surgeon to the Coventry and Warwickshire Hospital.

BARNEA, E. W., L.R.C.P.I., L.R.F.P.S. Glasg., Public Vaccinator for the Central District of Liverpool.

FARDON, A. H., M.D., Medical Officer, Dorking Union Institution.

HEATH, T. L., M.R.C.S., L.R.C.P., Assistant Medical Officer, Poplar and Stepney Sick Asylum District.

MACDONALD, D. M., M.D., Medical Referee under Workmen's Compensation Act for County Court Circuit No. 3, and to be attached more particularly to the Barrow-in-Furness, Ulverston, Ambleside, Kendal, Kirkby Lonsdale, and Settle County Courts, vice Dr. Mathews, deceased.

POLLARD, H. D., M.B., B.S. Lond., F.R.C.S., Medical Officer, Bedford Union Institution.

SMURTHWAITE, Henry, M.D., B.S. Durh., Assistant Surgeon to the Gloucestershire Royal Infirmary and Eye Institution, and will be in charge of the Ear, Nose, and Throat Department.

DISTRICT MEDICAL OFFICERS: E. M. Brown, M.B. (Berkhamsted Union); A. Budd, M.B., B.S. Durh. (Lancaster Union); C. E. Droup, M.B., B.Ch. (Gainsborough Union); E. A. C. Fagan, M.R.C.S., L.R.C.P. (Titchmarsh Union); W. E. Gammell, M.B. (Aitcham Union); B. G. Gutteridge, M.R.C.S., L.R.C.P. (Shardlow Union); J. T. Hall, M.B., Ch.B. (Ashbourne Union); F. A. Hepworth, M.B., B.Ch., F.R.C.S. (Saffron Walden Union); W. J. Johnson, M.D. (Biggleswade Union).

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 6s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

BULSTRODE.—On the 22nd December, 1919, at Southleigh Park, Havant, the wife of C. V. Bulstrode, D.S.O., M.D., of Hampton-in-Arden, a son.

JUBB.—On December 22nd, 1919, at 7, Wentworth Street, Wakefield, the wife of A. Armitage Jubb, M.D., D.Sc., a daughter.

WARWICK.—On the 1st January, at 94, Regent's Park Road, to A. Macgregor Warwick, M.C., M.B., and his wife—a daughter.

MARRIAGE.

NICOL—MURRAY.—On 18th December, 1919, at British Embassy Chapel, Constantinople, by the Rev. Lieut.-Colonel J. L. Findlay, D.S.O., Chalmers Nicol, Major R.A.S.C., son of the late Alexander Nicol, St. Helens, Aberfeldy, to Mary Doroche Murray, M.B. Ch.B., eldest daughter of the Rev. John Murray, Cupar, Fife.

DEATH.

LYLE.—On the 30th December, 1919, suddenly, at Speldhurst, Elmfield Road, Bromley, Kent, in her 48th year, Annie Seaton, the dearly loved wife of Herbert Willoughby Lyle, M.D. Lond., F.R.C.S., and only daughter of the late E. W. Winton, of Speldhurst, Tunbridge Wells, and of Mrs. Winton, of Etherton House, Widmore Road, Bromley.

DIARY FOR THE WEEK.

ROYAL SOCIETY OF MEDICINE.—*Section of Psychiatry*: Tuesday, 5 p.m., Dr. E. W. Scripture: Nature of Epilepsy; Dr. H. Crichton Miller: Endocrines in the Production of Mental Disorder. *Section of History of Medicine*: Wednesday, 5 p.m., Mr. S. P. Vivian: Thomas Campanon, Doctor of Physic, 1557-1620; Canon Westlake: The Guild of Our Lady of Rouncival. *Section of Dermatology*: Thursday, 4.30 p.m., Cases. *Section of Otolaryngology*: Friday, 5 p.m., Dr. A. A. Gray: Anatomy of the Vestibule. Cases and specimens. *Section of Electro-therapeutics*: Friday, 8.30 p.m., Mr. C. Thurstan Holland: Lessons of the War.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, II, Chandos Street, W. 1, Friday, 8.30 p.m.—Discussion on Bacillary Dysentery, to be opened by Dr. Manson-Bahr. Fleas as the Probable Carriers of Rheumatic Fever, Dr. Tertius Clarke (Pouang). Treatment of Malaria and Blackwater Fever, Dr. F. Roux.

POST-GRADUATE COURSES AND LECTURES.

MANCHESTER ROYAL INFIRMARY.—Tuesday, 4.30 p.m., Mr. E. D. Telford: Treatment of Spinal Curves.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N. 15.—Tuesday, 4.30 p.m., Sir Humphry Rolleston, K.C.B., M.D., opening address of spring session: The Uses and Methods of Application of Post-graduate Teaching.

DIARY OF THE ASSOCIATION.

Date.	Meetings to be Held.
JANUARY.	
13 Tues.	London: Maternity and Child Welfare Subcommittee, 2.30 p.m.
14 Wed.	London: Propaganda Subcommittee, 2.15 p.m. Dundee Branch: University College, Dundee. Second address on After-War Conditions, by Dr. Arthur Hurst, Physician to Guy's Hospital, 5 p.m.
16 Fri.	North of England Branch, Royal Victoria Infirmary, Newcastle-upon-Tyne. Demonstrations: 2.30 p.m., Occupational Phthisis. 3.0 p.m., Trigeminal Neuralgia. 3.30 p.m., Difficult Labour. 4.15 p.m., Ophthalmic Cases. 4.45 p.m., Carcinoma of the Colon.
20 Tues.	London: Scrutiny Subcommittee, 2.30 p.m. Tunbridge Wells Division, Tunbridge Wells General Hospital. Lecture by Dr. A. F. Hurst: New Views on the Pathology, Diagnosis, and Treatment of Gastric Duodenal Ulcer.
22 Thur.	London: Naval and Military Committee, 2.30 p.m.
27 Tues.	London: Public Health Committee.
28 Wed.	London: Medical-Political Committee.
29 Thur.	London: Organization Committee.
30 Fri.	London: Central Ethical Committee, 2 p.m.

British Medical Association.

CURRENT NOTES.

Insurance Remuneration: the Government's Decision.

On Wednesday, January 14th, the Minister of Health received the members of the Insurance Acts Committee and informed them of the Government's decision as to remuneration for insurance medical practitioners under the new terms and conditions of service. Dr. Addison stated that the Government, after full and close discussion, had agreed to an annual capitation fee of 11s., which, subject to certain conditions, should take effect from January 1st, 1920. He expressed the hope that insurance practitioners would accept this offer and give loyal service under the new Regulations. The Chairman of the Insurance Acts Committee reminded the Minister that the Panel Conference had resolved unanimously that 13s. 6d. was the lowest capitation fee that could properly be accepted for an effective service, and that the Committee had no power to accept any less fee. The Chairman stated that the Committee would advise their constituents not to accept the 11s. He added that the Committee had a discretion—in the event of a lower sum than 13s. 6d. being offered by the Government—to make a proposal for arbitration. This suggestion was carefully examined, and an agreement was eventually arrived at on this basis, which is set out in the letter from the Ministry printed in the SUPPLEMENT at p. 15.

Action by Panel Committees and Insurance Practitioners.

The Insurance Acts Committee wishes to impress on every Panel Committee and on every insurance practitioner the importance of combined and uniform action at the present juncture. Acting in accordance with the scheme approved by the Panel Conference, the Committee has advised every Panel Committee, and through them every insurance practitioner, what action it is proposed to take. Panel Committees are urged to do nothing which will prevent or confuse this combined action, and insurance practitioners are strongly recommended to await the advice of the Insurance Acts Committee before taking any action which may be advised by any other body.

The Representative Body.

All members of the Association should study the notices published at page 14 with regard to preparations for the Annual Representative Meeting, which will begin at Cambridge on the morning of Friday, June 25th. Representatives and their deputies must be elected by May 28th, and their names notified to the Medical Secretary by June 4th. The members of each constituency are free to decide for themselves whether these elections shall be carried out by general meeting or by postal vote. Notices of motion affecting either the constitution of the Associa-

tion or its policy on large issues must reach the Medical Secretary by April 10th, so that they may be published in the JOURNAL not later than April 24th. By decision of the Council every Oversea Division and Division-Branch that has an honorary secretary and the necessary organization is now an independent constituency for electing to the Representative Body. During the Cambridge meeting the Annual Conference of Honorary Secretaries of Branches and Divisions will be held; honorary secretaries, like representatives, are paid their first-class travelling expenses within the United Kingdom.

Individual Aid.

The attention of the Naval and Military Committee of the Association was recently called to the case of a senior I.M.S. officer, who wrote to say that, far from getting more pay under the new adjustment known as the 33½ per cent. increase, he was actually being paid less than before. When the new scale came into force he had just reached the maximum of Rs.1500 per mensem possible under the old scale, and should have begun at once to draw Rs.1800 a month. It is difficult for anyone not conversant with the intricacies of calculating pay adopted by the Government of India to understand by what process of reasoning the authorities arrived at the conclusion that this officer, instead of drawing an increase of Rs.300 a month, was to take a few steps back and begin again at Rs.1340 a month. However, that was the decision arrived at and made known to him. In accordance with Mr. Montagu's promise that he would inquire into any cases of this kind that were brought to his notice, details were at once submitted by the British Medical Association to the India Office, and it is most satisfactory to note that the officer's pay has been readjusted and that he is getting exactly what he asked the Association to obtain for him. The officer, it may be added, has written a letter cordially thanking the Association for its successful efforts on his behalf.

Association Notices.

ELECTION OF REPRESENTATIVE BODY OF THE ASSOCIATION, 1920-21.

Constituencies in Representative Body.

THE list of provisional Home Constituencies for election of the Representative Body, 1920-21, was sent by the Council to all the Home Divisions and Branches in November. Copies can be had by members on application to the Medical Secretary.

As intimated to all the Oversea bodies, the Council has made each Oversea Division and Division-Branch, possessing an Honorary Secretary and the necessary organization, an independent Constituency.

Election of Representatives and Deputy-Representatives.

The Representatives and Deputy-Representatives in the Representative Body require to be elected not later than

May 28th, and their names to be notified to the Medical Secretary not later than June 4th.

The Council draws special attention to the fact that it is entirely within the discretion of each Constituency to decide whether the election of its Representative(s) and Deputy-Representative(s) shall be carried out by general meeting of the Constituency, or by postal vote.

Date of Annual Representative Meeting at Cambridge.

The Annual Representative Meeting at Cambridge will begin on Friday, June 25th, at 10 a.m.

Motions for the Annual Representative Meeting.

Notices of Motion by Divisions, Constituencies, or Branches for the consideration of the Annual Representative Meeting, proposing to make any addition to, or any amendment, alteration or repeal of any Regulation or By-law, or to make any new Regulation or By-law, or proposing material alteration of the policy of the Association in matters relating to the honour and interests of the profession or of the Association, must be published in the *JOURNAL* not later than April 24th, and for this purpose should be received by the Medical Secretary **not later than April 10th.**

ELECTION OF COUNCIL OF THE ASSOCIATION, 1920-21.

The list of the Groups of Branches in the United Kingdom for election of twenty-four members of the Council, 1920-21, and **Nomination Forms**, will appear in the *SUPPLEMENT* of January 24th.

The list of the Groups of Oversea Branches was published in the *SUPPLEMENT* of October 11th, 1919, p. 79.

ANNUAL CONFERENCE OF SECRETARIES AT CAMBRIDGE.

The Annual Conference of Honorary Secretaries of Divisions and Branches will be held in connexion with the Annual Representative Meeting at Cambridge. Particulars of the date and hour of the Conference will be announced later. Honorary Secretaries are reminded that, as in the case of Representatives, the first-class travelling expenses, within the United Kingdom, of the Honorary Secretary of a Division or Branch attending the Conference are payable from the central funds of the Association.

BRANCH FOR NYASALAND.

The following change has been made in accordance with the articles and by-laws, and takes effect as from the date of publication of this notice:

That a Nyasaland Branch of the Association be formed, coterminous with the Protectorate of Nyasaland.

Representation in Representative Body.—Under the arrangements made by the Council, the Branch will be entitled to independent representation in the Representative Body, 1920-21, to return one Representative.

BRANCH AND DIVISION MEETINGS TO BE HELD.

KENT BRANCH: TUNBRIDGE WELLS DIVISION.—Dr. A. F. Hurst, Physician to Guy's Hospital, will give a lecture to the Division, at the General Hospital, Tunbridge Wells, on Tuesday, January 20th, on new views on the pathology, diagnosis, and treatment of gastric and duodenal ulcer.

METROPOLITAN COUNTIES BRANCH: MARLBORNE DIVISION.—Messrs. N. Bishop Harman (108, Harley Street, W.1) and C. Edward Wallis (13, Queen Anne Street, W.1), Honorary Secretaries, give notice that a debate will be held this day Friday, January 16th, at 5 p.m., at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, to discuss 'The Future of the Medical Profession under a salaried, whole-time State Medical Service.' The chair will be taken by Dr. C. O. Hawthorne, and the discussion will be opened by Professor Benjamin Moore, D.Sc., F.R.S. of the State Medical Service Association, and Sir Wilmot Herringham, K.C.M.G., C.B., M.D.

SOUTH MIDLAND BRANCH: BUCKINGHAMSHIRE DIVISION.—Dr. Arthur E. Larking, Honorary Secretary (17, The Woodlands, Uxesham Bois), gives notice that a meeting of the Division will be held to-day Friday, January 16th, at 3.30 p.m., at the Crown Hotel, Aylesbury. Tea will be provided. Agenda: Monthly Report of Medical Secretary. List of Members and Non-members. Resolution to be proposed: "That the New Ethical Rules be adopted for the area of the Bucks Division." Suggested scale of minimum fees. Discussion: "On the Present Outlook for the General Practitioner" introduced by the Secretary.

IRISH MEDICAL COMMITTEE.

A MEETING of the Irish Medical Committee was held in the Royal College of Surgeons, Dublin, on January 6th, when Mr. R. J. JOHNSTONE, F.R.C.S., was in the chair. There were also present: Drs. Darling, P. J. Hamilton, M. R. J. Hayes, McCann, McGrath, McKenna, Conor Maguire, M. McQuaid, Meagher, Morris, W. W. Murphy, J. J. O'Connor, W. O'Sullivan, J. Power, B. C. Powell, J. V. Ryan, R. J. Rowlette, E. C. Thompson, H. T. Warnock, D. Walshe, and the secretaries. Apologies for absence were received from Drs. Costelloe, Doolin, Giusani, Henry, and W. J. O'Sullivan.

Irish Public Health Council.

The following letter was received from Dr. E. Coey Bigger, chairman of the Irish Public Health Council:

I beg to inform you that the Irish Public Health Council, at their meeting of December 9th, had under consideration the question of the reform of the medical service in Ireland, and decided to recommend to the Irish Government the establishment of an Irish Medical Service, appointed by competitive examination, with fixed scales of salaries, rights to pension, study leave, etc.

Consequent on this recommendation, the Council also considered the functions and duties to be entrusted to and performed by the medical officers belonging to the service, but before coming to any conclusion in the matter the Council thought it would be of considerable assistance to their deliberations to have the benefit of the advice and help of the representatives of the medical profession in Ireland. With this object they directed me to request that the Irish Medical Committee would be so good as to nominate a few representatives who would attend the next meeting of the Irish Public Health Council, which will be held at the above office on Wednesday, January 7th, 1920, at 12.15 p.m.

The Council are anxious to have the opinions of the representatives generally on the services to be provided by the members of the Irish Medical Service, and particularly with reference to what classes of the community would be entitled to medical and surgical attendance in connexion with the service. The Council very much regret that they are not in a position to recoup expenses to the representatives for the attendance at the meeting.

The letter was discussed at considerable length, and the following decisions were unanimously arrived at:

That the medical service proposed by the Irish Public Health Council should include all residents in the administrative areas whose individual incomes do not exceed £150 per annum; that the minimal salary for medical officers should be £650 per annum with progressive increments; their offices ordinarily be pensionable on the attainment of 60 years, and subject to compulsory retirement at 65.

The following members were appointed as a deputation to wait upon the Irish Public Health Council on January 7th: Drs. Darling, Day, Johnstone, Morris, Murphy, O'Connor, O'Sullivan, Power, Thompson, and Warnock. The members of the deputation were also appointed to form a standing subcommittee to look after the interests generally of the medical profession with regard to the legislative proposals put forward by the Irish Public Health Council, and to report when necessary to the Irish Medical Committee.

A warm vote of thanks was passed to Dr. Rowlette for his services in the Irish Public Health Council.

Medical Treatment for Discharged Disabled Men.

In connexion with the scheme for the medical treatment of discharged disabled soldiers the following resolution was unanimously passed, and directed to be forwarded to the Irish Insurance Commission:

That the scheme in existence for the medical attendance on discharged disabled soldiers and sailors has proved unsatisfactory both as to the inadequacy of the remuneration and to its method of distribution.

Medical Certification under the Insurance Act.

A letter, stating that the question of increased remuneration for medical certifiers would engage their early attention, was read from the Insurance Commissioners in reply to a communication on behalf of the Irish Medical Committee drawing attention to the inadequacy of the remuneration for certification and the urgent necessity for increasing its amount. The resolution recently passed by the co. Wexford Local Medical Committee was, on the motion of Dr. W. W. MURPHY, unanimously adopted:

That the remuneration for certification under the Insurance Act is insufficient, and should be increased by the sum which is returned unexpended each year to the Treasury out of the Equivalent Grant. That as Ireland has to pay one year with another her full quota towards the administrative expenditure of the Act in England, Scotland, and Wales, we consider it grossly unfair that the Irish medical profession should be deprived of their money.

Medical Attendance on the Royal Irish Constabulary.

A letter addressed to the Medical Secretary, with regard to the position of medical officers of the police, was read from the Deputy Inspector-General, who stated that the question of medical attendance on the Royal Irish Constabulary was at present before the Treasury, and that an early decision in the matter was expected. The letter also stated that the Inspector-General could find no ground for the suggestion that medical attendants were removed from the service without any specific reasons being assigned. The invariable rule was to send to the medical attendant concerned copies of any complaints made by the members of the force against him, and to ask for his observations on the subject. If the occasion so required, an inquiry was held by a superior officer of the Royal Irish Constabulary and no action was ever taken in such a case without consultation with the surgeon of the force.

Some members of the Irish Medical Committee, who are police medical attendants, stated that they were not aware that the procedure outlined by the Inspector-General was usually followed.

Payments for Attendance on Post Office Employers.

A letter was read from Dr. W. J. O'Sullivan stating that the medical practitioners in the Limerick area refused the capitation fee for medical treatment of post office employees, and were now working a scheme under which they received 10s. a visit, exclusive of medicines. This arrangement was considered by the Irish Medical Committee quite satisfactory, and some members expressed a view that if such arrangements did not exist elsewhere, it was entirely due to the failure of the profession to organize on lines similar to those adopted in Limerick.

INSURANCE REMUNERATION.**TERMS OF SETTLEMENT.**

THE following letter, embodying the terms of the settlement arrived at late on the evening of Wednesday, January 14th, has been addressed by the Ministry of Health to the Secretary of the Insurance Acts Committee:

Ministry of Health,
14th January, 1920.

SIR.—I am directed by the Minister of Health to refer to the correspondence and interviews which have taken place with your Committee on the subject of the remuneration of insurance practitioners, and to the deputation received to-day. The results were as follows:

The Minister stated that the representations which had been put forward had received the fullest consideration by the Government, and that the Government were prepared to seek the authority of Parliament for the supplementation of insurance funds by an Exchequer grant to the extent necessary to provide for the calculation of the Central Practitioners' Fund on the basis of an increased yearly capitation fee of eleven shillings (11s.), together with a Mileage Fund of £300,000 per annum for distribution amongst practitioners engaged in practice in rural areas in England and Wales.

The Insurance Acts Committee stated that, as the Conference of Panel Committees had resolved on a capitation fee of 13s. 6d., they would feel bound to recommend their constituents not to accept the 11s. capitation fee, and requested that the amount of the fee should be referred to arbitration. This was fully discussed, and after an adjournment the Minister announced that the Government acceded to this request, it being agreed that the award should be binding on both sides; that the Government would accordingly recommend Parliament to give effect to it when made; and that the Insurance Acts Committee and the Panel Committees would do all in their power to secure from the practitioners throughout the country a full and efficient service, with goodwill, under this settlement as a whole, including the terms of the award.

The reference to the arbitrators will be, in substance, to advise the Government as to what capitation rate will afford to insurance practitioners fair remuneration for the time and services required to be given in connexion with the attendance and treatment of insured persons under the conditions of the proposed Medical

Benefit Regulations, 1920, as published in December last. It is understood on both sides that the investigation by the arbitrators is to be kept within the limits above stated, and it is hoped that it may be completed within four weeks. Any revision of the capitation payment, made as a result of the arbitrators' award, will operate, in every Insurance Committee area in which an adequate and satisfactory medical service is forthcoming, as from April 1st, 1920 (that being the date on which the new terms and conditions of service generally come into operation).

The request which had been previously made by the Insurance Acts Committee that the increased capitation rate asked for should operate (subject to certain understandings) as from January 1st, 1920, was specially considered in the light of the new position created by the reference to arbitration. The Government agreed that the Central Practitioners' Fund should be calculated from January 1st, 1920 (until the award of the arbitrators comes into operation) on the basis of the capitation fee of 11s., subject to the understanding (agreed by your Committee) that the whole of the new financial arrangements embodied in the 1920 Regulations shall come into operation, except as regards payment for invalided sailors and soldiers, from that date, and subject to the further understanding that the Panel Committees will co-operate effectively in such action as is necessary to enable the new Regulations to come into full operation on April 1st, 1920. This entails in particular that the schemes under Articles 15 and 21 of the Regulations should be determined in time to be embodied in the formal notice to the individual practitioners, which notice must be sent out by Insurance Committees at latest by February 3rd. As regards invalided sailors and soldiers, it is agreed, as most convenient to all concerned, that the present arrangement for payment on an attendance basis should be continued until March 31st, 1920, the accounts for that period constituting, of course, a first charge on the Central Practitioners' Fund, since this Fund will include the necessary funds to cover the estimated cost of treatment of these men. Insurance and Panel Committees are being advised accordingly.

In view of the general conditions under which it has been necessary for the Government to take the present decision with regard to the question of insurance practitioners' remuneration, and of the possibility of future legislation, whether as affecting health insurance contributions or otherwise, it is considered desirable that the arrangements above set out should not be entered upon for a defined term of years, the Government undertaking not to make any alteration except after consultation with the representatives of insurance practitioners and after an adequate period of notice.

I am, Sir, your obedient servant.

R. W. HARRIS.

CORRESPONDENCE.*Insurance Remuneration.*

SIR.—The Minister of Health recently stated (as reported in the SUPPLEMENT of December 13th, 1919) that "the new fee to be fixed must be one which would give a good average general practitioner, fairly doing his duty, what he himself would feel would pay him properly for treatment."

In settling the fee for treatment there are two factors: First, the average amount of work done; and secondly, the increase due to the extra cost of living.

In 1917 an interesting pamphlet was written by Mr. W. M. Marshall, Clerk to the County of Lanark Insurance Committee and Secretary to the Scottish Association of Insurance Committees; it was entitled "Medical Benefit in Scotland."¹ In an appendix he gives details as to the services rendered during the year 1916 by certain doctors in Lanarkshire, three of the practices being rural, two rural and industrial, and ten industrial.

Taking the averages of all those practices, there were 2.01 visits and 2.42 consultations per person on the panel lists for the year. The Ministry of Health allow 2s. 6d. per visit and 2s. for each consultation in the case of temporary residents and invalided soldiers.

If we take this scale for our estimate of the payment due it will be found that 2.01 visits amount to 5.25s., and

¹ Reviewed in BRITISH MEDICAL JOURNAL, December 15th, 1917.

2.42 consultations amount to 4.84s., the total amounting to 10.09s., or 10s. 1d., approximately, for which we are at present paid the sum of 7s.

If we add 50 per cent. on to this amount for the increased cost of living, the new fee should be 15s. 13d., or if the lower rate of only 33½ per cent. is taken, the new fee would be 13s. 5d. (neglecting fractions), which is very nearly the same as the sum for which the British Medical Association are asking (13s. 6d.), and which shows the moderation of their demands.—I am, etc.,

Builth Wells, Jan. 10th.

W. BLACK JONES.

A Call to Order.

SIR,—Judging by the subjective symptoms of Dr. Pereira Gray's jaundiced letter, I would suggest to him that his disease is not decline and death of his body politic, but that it is his liver which is out of order, and that the remedy is a blue pill of knowledge coated with accuracy, and followed by a deep draught of the saline, common sense. After a vigorous course of this treatment I am quite sure he will see and think clearly, and never again say that Alexander Selkirk was an Englishman.

Unfortunately Dr. Pereira Gray is not the only member of the profession who suffers from this malady. Judging by the number and character of the letters appearing in the SUPPLEMENT, there seems to be an epidemic at present characterized chiefly by an inability to see the subject under discussion from any standpoint but the writer's own.

O wad some pow'r the giftie gie us
To see ourselves as others see us!
It wad frae monie a blunder free us,
And foolish notion.

is as pregnant with truth to-day as when it was written, and I do wish my professional brethren would wake up to the fact that there are other people in the world as well as medical men, and then surely they would not talk and write "through their hats" as they do now. We are not "monarchs of all we survey." The man in the street does exist, and he is by no means a blithering idiot.

A prominent public man who is in no way unfriendly to the profession said to me recently, "Well, I hope your profession will do as well out of this deal as they did out of the last one." You cannot bluff a man when he sees your cards, so "let us cut the cackle and come to the horses."

Whatever we do, however, do not let us think we can help our cause by slinging mud at each other, especially at those placed in positions by ourselves to conduct our business for us. I do not agree with everything the Insurance Acts Committee have done, and will probably disagree with them again, but I recognize they have been chosen by us constitutionally, and I think it is the greatest folly as well as the basest ingratitude to write as some men do imputing motives and making innuendoes. For heaven's sake! if they have not the confidence of the majority fling them out neck and crop; but personally I am quite sure, however I may disagree with them, that our leaders are actuated by one motive only—that is, the greatest good of the greatest number of their professional brethren.

"Tis not in mortals to command success," but Dr. Brackenbury, the Insurance Acts Committee, and our officials, have done better, they have deserved it; and they have placed us all, including the grouseers, under a deep debt of gratitude, which I hope in due season—but that is another matter.—I am, etc.,

Auchincruir, Jan. 5th.

J. CROMIE.

APPOINTMENTS.

- BRASH, J. W., M.R.C.S., L.R.C.P., Medical Officer Children's Home, Parish of Paddington.
- HOLDEN, Oscar, M.D., D.P.H., Medical Officer of Health of the County Borough of Dewsbury.
- LEETL, Mason, M.B., B.S.Durb., Assistant Medical Officer of Health, Borough of Birkenhead.
- SMITH, W. A., M.B., C.M.Aberd., Certifying Factory Surgeon for the Darwen District.
- TURNER, R. T., M.D., D.P.H.Vict. Manch., Certifying Factory Surgeon for Nantwich, co. Cheshire.
- WATSON, C. Riley, M.B., Ch.B.Loeds, Medical Officer for the Bubwith District of the Howden Union.
- WRIGHT, P. P., M.D., Assistant Medical Officer, West Derby Union Infirmary.
- DISTRICT MEDICAL OFFICERS: H. C. Billings, M.R.C.S., L.R.C.P. (Dorking Union); N. Daly, M.R.C.S., L.R.C.P. (Basinstoke Union); C. E. Droop, M.B. (East Retford Union).

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 6s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

- ANDERSON.—At 39, Chalmers Street, Edinburgh, on January 5th, the wife of Surgeon Lieutenant G. A. Melville Anderson, M.B., Royal Navy, a daughter.
- BRUNTON.—On January 12th, at Purey Cust Nursing Home, York, to Lucy M. Brunton M.B., the wife of G. L. Brunton, M.D., a son.
- SHARRARD.—At Elmhurst, The Avenue, Lincoln, on December 26th, to Dr. W. and Mrs. Sharrard (née Winifred H. Wells), M.B., M.R.C.S., D.P.H., a daughter.
- SUDLOW.—On January 12th, at Penton House, Stoke-on-Trent, the wife of George Wray Sudlow, of a son (Gordon Wray).

DEATH.

- NISBET.—At St. Ishmaels, Newton Abbot, S. Devon, Dr. A. T. Nisbet.

DIARY FOR THE WEEK.

- HARVEIAN SOCIETY, 11, Chandos Street, W., Thursday, 8.15 p.m.—Annual Meeting.
- LONDON DERMATOLOGICAL SOCIETY, 49, Leicester Square, W.C.2.—Tuesday, 4.0 p.m., Cases.
- ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C., Monday, Wednesday, and Friday, 5 p.m.—Professor Arthur Keith, F.R.S.: John Hunter's Observations and Discoveries in Anatomy and Surgery.
- ROYAL SOCIETY OF MEDICINE.—Occasional Lecture: Wednesday, 5 p.m., Surgeon Commander K. Digby Bell, R.N.: The Medical Profession and National Physical Education. Section of Therapeutics and Pharmacology: Tuesday, 4.30 p.m., Discussion: "On the Therapeutic Uses of Oxygen," to be opened by Mr. G. Barcroft, C.B.E., F.R.S., Colonel Cummins, C.B., C.M.G., Dr. C. J. Douglas, Dr. J. S. Haldane, F.R.S., Dr. P. Hamill, Dr. G. H. Hunt, Dr. R. H. Peters, Dr. Ryle, Dr. F. Shufflebotham, and Dr. G. H. Sowry will speak. Section of Pathology: Tuesday, 8.30 p.m., Imperial Cancer Research Laboratories, 8, Queen Square, W.C.1. Mr. W. H. Woglom: Industrial and Experimental Pitch Warts; Mr. A. H. Drew: Oxidation Process in Normal Tissues and Cancer; Mr. W. E. Gye and Dr. B. R. G. Russell: Conditions of Survival of Tumour Cells in *in vitro*; Dr. W. Cramer: Action of Uranium Salts on Tumour Cells; Dr. J. A. Murray: Return-autologous Grafting of Tumours after Transplantation in Normal Animals. Section of Study of Disease in Children: Friday, 4.40 p.m., Cases. Section of Epidemiology and State Medicine: Friday, 8.30 p.m., Dr. F. G. Crookshank: Principles of Epidemiology; Dr. Cleland and Dr. Campbell: Epidemiology of Acute Encephalo-myelitis. Dinner will be provided at the Welbeck Palace Hotel at 7 p.m. (price 7s. 6d.). Those intending to dine are asked to inform Dr. Major Greenwood, Lister Institute, Chelsea, S.W.1, not later than Wednesday, January 21st.
- SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague Street, W.C., Friday, 5 p.m.—Dr. John Robertson, C.M.G., O.B.E.: Sinus and their Regeneration.

POST-GRADUATE COURSES AND LECTURES.

- FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.1.—Tuesday and Thursday, noon, Dr. S. A. Kionier-Wilson: Cerebral Localization.
- MANCHESTER ROYAL INFIRMARY.—Tuesday, 4.30 p.m., Dr. A. Ramsbottom: Chorea.
- NEWCASTLE-UPON-TYNE: ROYAL VICTORIA INFIRMARY.—Friday, 2.30 p.m., Professor Rutberford Morison: Abdominal Emergencies; 3.15 p.m., Professor T. Beattie: Early Diagnosis of Pulmonary Tuberculosis; 4.30 p.m., Professor R. A. Bolam: Venereal Diseases.
- SHEFFIELD ROYAL HOSPITAL.—Monday, 3.30 p.m., Dr. Nutt: Demonstrations of X-ray Apparatus. Tuesday and Friday, 4.0 p.m., Dr. Hay: Examination of Eye. Wednesday, 3.30 p.m., Dr. Wilkinson: Common Forms of Sore Throat. Thursday, 3.30 p.m., Dr. Skinner: General Considerations in Dermatology.

DIARY OF THE ASSOCIATION.

Date.	Meetings to be Held.
JANUARY.	
16 Fri.	North of England branch, Royal Victoria Infirmary, Newcastle-upon-Tyne. Demonstrations: 2.30 p.m., Occupational Phtthisis. 3.0 p.m., Trigeminal Neuralgia. 3.30 p.m., Difficult Labour. 4.15 p.m., Ophthalmic Cases. 4.45 p.m., Carcinoma of the Colon.
	Buckinghamshire Division, Crown Hotel, Aylesbury, 3.30 p.m.
	Marylebone Division, Rooms of Medical Society of London, 11, Chandos Street. Discussion on the Future of the Medical Profession under a Salaried, Whole-time, State Medical Service, 5 p.m.
20 Tues.	London: Scrutiny Subcommittee, 2.30 p.m.
	Tunbridge Wells Division, Tunbridge Wells General Hospital. Lecture by Dr. A. F. Hurst: New Views on the Pathology, Diagnosis, and Treatment of Gastric Duodenal Ulcer.
21 Wed.	London: Hospitals Committee, 3 p.m.
22 Thur.	London: Naval and Military Committee, 2.30 p.m.
23 Fri.	London: Ministry of Health Committee, 2.30 p.m.
27 Tues.	London: Public Health Committee.
28 Wed.	London: Medico-Political Committee.

INSURANCE REMUNERATION.

THE following is the authorized report of the conference on January 14th, 1920, between the Minister of Health and the Insurance Acts Committee, on medical remuneration. We have introduced cross headings.

Dr. ADDISON, in opening the proceedings, stated that since the last occasion on which this matter had been discussed with representatives of the Insurance Acts Committee the case put forward on behalf of the insurance practitioners for a capitation fee of 13s. 6d. had received the most careful consideration by himself and his colleagues in the Government. He regretted that there had been unavoidable delay in arriving at a decision. This was due to the fact that other matters of pressing national importance had been engaging the attention of the Government, and wider proposals and possible developments relating to Poor Law and other kindred issues had inevitably complicated the issue. Further, the Government were pledged to large expenditure of public money on old age pensions, unemployment insurance, and increased cash benefits, which made it necessary to review the case submitted by the profession in the light of other national commitments. He felt, however, in view of pledges given to the medical profession during the war, that a decision on the narrower issue of remuneration could no longer be delayed.

THE GOVERNMENT'S OFFER.

Any settlement on this question must necessarily take into account separate items, which had hitherto formed part of the insurance practitioners' remuneration, but which must in future be consolidated in the revised capitation fee. He referred in particular to the "floating sixpence" and payments in respect of invalided soldiers. These would in future be absorbed in the new basis of payment, and, as the deputation were aware, under the new system of calculating the central pool in advance, the amount for each area would be definitely known and paid quarterly to the medical men in the area in accordance with the local scheme of distribution. In considering the case for increased remuneration, it was obvious to him that medical men had suffered, with other classes of the community, from the general rise in the cost of living, and had also incurred increased practice expenses; but the argument which had been put forward in favour of increased remuneration on account of increased work, had not, in his view, been so fully substantiated. He referred in this connexion to the Manchester figures quoted by the Committee at his previous interview with them, and emphasized the importance, both from the point of view of the Government and of the profession, of securing that insured persons received treatment of the same quality as that which a doctor would give to his private patients. It had to be stated quite frankly that a feeling existed in the mind of the public that this was not, at present, the case in many districts. Impressions

of this kind, although based on a limited number of cases which came unduly into prominence, certainly increased the difficulties of the examination of the case for increased remuneration. He hoped to see a great improvement in this respect as a result of the new Regulations, and he anticipated that the system of referee-consultants which it was proposed to establish, would meet the long-expressed wishes of the profession, and generally prove of value in improving the standard of insurance practice.

Dealing with the question of the actual amount of remuneration, Dr. Addison said that the Government had provided no less a sum than £300,000 as a mileage fund for England and Wales as against a pre-war figure of £34,000, and said that this would be an immense help in meeting the difficulties of the rural practitioners. This mileage fund, together with the payments for drugs and appliances supplied by practitioners, would stand outside and be additional to the new capitation fee.

The case for 13s. 6d. had been most carefully examined, and he regretted to say that the Government were not convinced of the necessity for such a large increase. The pre-war payment of 7s. 3d., including the floating sixpence, had been increased by war bonus to 8s. 9d., and it had been urged upon him from many quarters that the new capitation fee should not exceed 10s. The Government, however, had decided that this was not sufficient, and came to the conclusion that a fair figure would be 11s. When this arrangement came into operation, the total cost of medical benefit in Great Britain would be £10,000,000, some £2,000,000 of which was represented by the increased payments to doctors now being agreed to by the Government over and above what had been given by way of war bonus. The Government felt that a capitation fee of 11s. would give a fair remuneration to a practitioner using his best efforts in carrying out the obligations laid upon him under the new Regulations, and they sanctioned this amount only on the distinct understanding that the services to insured persons were to be materially improved and that there would be the fullest co-operation of the profession in securing a high standard of service.

It had been necessary, in dealing with this matter, to take into account the large expenditure on other public health services, and it was impossible to avoid the fact that public opinion might demand that every possible avenue should be explored with a view to determining whether the best possible results were being obtained in return for the heavy expenditure which would be incurred. The sum of 10 million pounds was an enormous item, and he therefore appealed to the profession to justify the cost by improved working of the medical services of the country.

The increased capitation payment would be available in every Insurance Committee area where an adequate and satisfactory service was forthcoming, and would date from January 1st, 1920, on the understanding, of course, that the new financial arrangements operated as a whole from that date. These would embrace the new basis of constitution of the central pool, the new basis of distribution, the disappearance of the floating sixpence, and all liability for treatment of temporary residents and invalided soldiers, in respect of which different methods of payment operated at present.

The Government did not feel able to acquiesce in the Committee's request that the new arrangement should be for a particular term of years, but were prepared to agree that no alteration would be made at any time except after consultation with the insurance practitioners and after an adequate period of notice. The new proposals would require legislation, which the Government would submit to Parliament in due course.

In conclusion, Dr. Addison said: "I have tried to put the case fairly before you. I appeal to you to use your good efforts to assist us in this matter; the Government has not seen its way to grant your full demands, and I do not expect as practical men you expected that it would. I do not wish to conceal the fact that it is only after the most prolonged and difficult consideration of this proposal that the decision has been arrived at, that the Government feel that it has dealt with the case not on any narrow arithmetical issue, but broadly and generously, because it feels that it is above all things necessary to secure, if we can, your friendly goodwill and co-operation in promoting improved developments not only in insurance services but in other directions, and from that point of view it is, in my opinion, one of the most justifiable items of public expenditure. I am sure that no comprehensive and steady policy for securing an improvement in our medical services can be carried through without the goodwill and assistance of fair-minded representatives of the medical profession, and I feel sure that you will realize that I have put the case frankly before you without any attempt to disguise the facts as they are, but at the same time in a whole-hearted endeavour to secure the development of improved medical services in this and in other respects, and to obtain your goodwill and help in furthering them. It is with these purposes and in that spirit that the Government has decided to put this proposal before Parliament in due course.

"It was necessary, of course, as a part of our undertaking that I should communicate it to you as soon as possible. I am very sorry it was not possible to do so earlier. I can assure you that it was due to no lack of energy on my part, but it was due partly to the great anxieties which had had to be attended to in all parts of the world, and which have necessarily engaged the attention of heads of many of the Government departments, and it was also due to the complexity of the case itself, and due finally to the prolonged and careful consideration which it received."

THE COMMITTEE'S REPLY.

Dr. BRACKENBURY said that Dr. Addison would appreciate that, before giving any sort of answer to the offer he had put before the deputation on behalf of the Government, consultation would be necessary; that would be done as quickly as possible. Meanwhile, he proposed to offer a few general observations arising out of the remarks of the Minister, without committing himself or his colleagues on the particular offer made. In the first place, he wished to express the thanks of himself and his colleagues for the extreme care and attention the Minister had given to the case which had been put before him in what must have been at times extremely anxious negotiations with his colleagues and others, and for the Minister's personal attitude towards this matter, and the way in which he had considered it and presented it. The deputation also appreciated fully the two difficulties which had been put before them: first of all, the economic situation and the other large commitments which the Government had to satisfy. At the same time, that did not appeal very much to the deputation as an argument against the granting of the demand which had been made; because although these commitments were great they were very largely in consequence of other classes of the community, other trades and occupations, having asked for increases in their remuneration; and it did not seem to be a satisfactory state of things that the Government had committed itself to that additional expenditure on account of the demands made by other classes of the community, and that that should present a difficulty in granting the demand which insurance practitioners in their turn had belatedly made. They also appreciated the difficulty the Minister had had with his colleagues about what might be called the prejudices in the minds of laymen as to the inefficiency of the existing service. It was because the deputation recognized that there were some doctors in many places, and perhaps a good many doctors in a few places, who had not lived up to what the deputation would desire them to regard as their professional reputation in connexion with this service, that the profession wanted to improve the service and get it on a right basis so that there should be no excuse for anybody to do work of any other than the highest type. The existence of that prejudice was recognized and that

there was a certain basis for that prejudice. As the Minister had said, it loomed much larger than it ought to do because those deficiencies had been revealed to the public eye, while the good work done by the great bulk of the profession had not come to the public view at all.

Dr. Brackenbury thought the Minister and his colleagues had entirely misunderstood the inferences that the deputation drew from the Manchester figures. He did not wish to enter upon a controversy about those figures, but it seemed to him that what was brought out more obviously in the Manchester figures than any others was that when the remuneration was paid over at the end of the first year or the second year, it was brought home to the individual doctor, not consciously, but unconsciously, that he was not being adequately remunerated for the services which, in fact, he gave. It might have been in that first year, owing to the payment by attendance, that a few doctors in Manchester paid unnecessary visits and gave unnecessary attention at the very beginning, because they thought by so doing they would get a greater amount of payment out of the pool. But apart from that, and assuming all the men gave thoroughly good work through that first year, they discovered at the end that their remuneration was not adequate therefore; and in consequence, not by any collective arrangement but by the semi-conscious effect of that remuneration upon their minds, they minimized their services, they gave what they conceived to be safe and adequate but not superabundant services. Also they felt justified in using whatever means of treatment there were available for the community in Manchester and Salford in order that they themselves might not have to give services which were not properly paid for. In this way the medical man of Manchester did to some extent adjust the services which he rendered to the insured population to the amount of remuneration he received, in exactly the same way as he might quite legitimately do in his private practice.

Appreciating the Minister's difficulties, the object of the deputation was to get the service on the proper administrative and professional level. It was because of that that the request for 13s. 6d. was made. They wanted the general practitioner service improved in some form or another. Whether under the National Insurance scheme or in any other, the most important medical service must be the general practitioner service, for it was the foundation of all. Because it was so strongly felt that that service must be put in its proper administrative and professional place as the foundation of all the services of the Ministry of Health they believed they were justified in asking for the remuneration which was asked for, because, as the Minister himself had agreed, good service must be adequately paid for. That proposition might, with equal truth, be reversed. In order to get good service it was necessary to offer adequate payment, and that aspect of it should be well considered. It was agreed that some of the service which had been given in the existing state of affairs had not been adequate and would not in some individual cases, perhaps, justify the remuneration now asked for. But they did not want to offer any excuse for the perpetuation of that kind of thing. Unless remuneration on a scale such as that asked for was offered it would be difficult to say to every doctor, "You have no excuse whatever for giving anything else than your very best and most abundant energy and skill, because the remuneration is enough to justify that being asked for." If the remuneration were inadequate they could only expect a continuation of a service upon the present lines with a good many doctors doing less than their best, because they felt that their very best was not being paid for by the State. The profession was tremendously anxious to avoid that state of things. If that went on, the existing system would be damned, and there was the danger that a worse kind of system than this could be at its best might be substituted for it. There should be no excuse for the panel system offering less than the very best the whole body of general practitioners could offer. In order to attain that very best, one of the prime necessary conditions was that remuneration ought to be adequate so that all possible pressure could be brought to bear upon the profession for them to give the best that they had it in them to give.

On the purely economic side he must emphasize that the request for 13s. 6d. was not made as an offer which they expected to have to compromise upon. It was made, after the fullest consideration, as what was believed to be a reasonable minimum offer; they believed, rightly or wrongly, that they could justify it—that the 13s. 6d. was a sum which would stand cross-examination, and that it was the least for which the type of service could be offered which ought to be required. Since the request was made economic matters had not improved, and medical men had begun to realize in a way that many had not previously done,

what the real economic situation was. During the last two months they had had opportunities of thinking more in the new values of money than ever before, because although they had recognized that there was an altered value, they had scarcely got out of the habit of thinking in the old values of money. Not only had the economic condition worsened since the request was made, but experience had emphasized the moderation of the request.

Dr. BRACKENBURY concluded by again thanking the Minister for the consideration which he had given to the case, and asked that the deputation might consult together before announcing its attitude.

The MINISTER agreed to this course, but he thought it right to say that he was not authorized by the Government to enter into a course of bargaining. The figure of 11s. was that which the Government had decided should be submitted to Parliament.

THE PROPOSAL FOR ARBITRATION.

On resumption of the Conference after an interval, Dr. BRACKENBURY explained what the position and actual powers of the deputation were in regard to the offer which had been made. They had no power whatever to accept any offer of less than 13s. 6d.; there was, however, a discretion given by the Conference in case of an offer of less than 13s. 6d. to make the suggestion that the whole question should be submitted to a suitable board of arbitration. They had been considering whether that discretion should be exercised, and had decided that it should. They were quite unable to accept the 11s., would advise their constituents not to accept it, and would like to know whether arbitration could be accepted by the Minister on behalf of the Government.

Dr. ADDISON replied that this suggestion would need consideration, and it would be necessary for him to consult his colleagues before any reply could be given, but the first point which occurred to him was, What would be the question to be submitted to arbitration? Was their position that the question of payment should be inquired into, or would the inquiry include investigation into the character of the service?

Dr. BRACKENBURY said the inquiry would assume that the new Regulations would be enforced and properly worked, and that the inquiry would be limited to the question of what would be the proper remuneration of the medical practitioner, given the type of service indicated in the Regulations.

Dr. ADDISON said such an inquiry should not be on a hypothetical basis, nor should it assume a state of affairs other than that which existed at present. The inquiry would open up the questions of what were the deficiencies of the service, how they had arisen, and to what extent they would be removed by the new Regulations, or whether any other system would give a better result.

Dr. BRACKENBURY said they could not agree to arbitration on any such wide issues as those. He added that it was essential that the arbitration should be concluded quickly. On being reminded that the award might be for a smaller figure than 11s., he replied that he felt sure that he could take the responsibility of saying that their constituents would abide by the award if they could have a corresponding guarantee on the part of the Government, should the figure in the award be higher.

Dr. ADDISON said that, if arbitration were agreed to, the Ministry would of course abide by the award, but the sanction of Parliament was needed, and no pledge could be given beyond his promise to recommend Parliament to carry out the award. He personally had no objection to an inquiry, but he did not at present see how it could be confined to the narrow issue.

Dr. BRACKENBURY said that in that case, as the Committee had no power to accept any figure lower than 13s. 6d., and if arbitration on the narrow issue was really impracticable, they must report the situation to their constituents, and as they were fully convinced of the moderation and propriety of their demands, they had unanimously decided to use their influence to get the insurance practitioners throughout the country not to accept the offer of 11s.

Dr. ADDISON said that the position as he understood it was that the Committee desired arbitration on the narrow issue of the proper amount of the capitation payment, and could not accept at this stage an inquiry into the larger questions. He would put this proposition to the Chancellor of the Exchequer. The Conference would be resumed in the evening, to allow time for both sides to consider the matter in all its bearings.

ARBITRATION ACCEPTED.

On the discussion being resumed, Dr. ADDISON stated that he had conferred with the Chancellor of the Exchequer, who shared his opinion that it would be difficult to limit the arbitration to the narrow issue proposed; but in order that no opportunity of a friendly adjustment should be lost, he had expressed the view, with which the Chancellor concurred after much hesitation, that the Government should agree to refer the matter to arbitration on the lines requested by the Insurance Acts Committee. The Chancellor, however, wished it to be conveyed to the deputation that this proposal was only sanctioned with considerable misgivings, and that the Government might feel bound to consider subsequently whether, in view of the large sums of public money required, it could not be expended to greater advantage in some other way. It would be part of the understanding that, if arbitration took place, the Insurance Acts Committee would use their good offices to secure an efficient service in the interim at the rate of 11s., the Government undertaking to use their best endeavours to secure the consent of Parliament to the adoption of the arbitrators' award. It must also be agreed that, as the arbitration was on the narrow issue, if it should appear to the Government as a result of the award of the arbitrators on the question of remuneration that a wider inquiry became subsequently necessary into the medical services of the community, insured or otherwise, the loyal co-operation of the medical profession could be relied upon for the purpose of such further inquiry.

Dr. BRACKENBURY replied that as regards the wider inquiry they did not consider that the time was suitable, so soon after the war, which had necessarily interfered seriously with all medical services at home, for an investigation into the adequacy of the existing services, nor could they approve of such an inquiry being entrusted to the body which they would regard as suitable for the purpose of arbitration on the narrow question of the amount of the remuneration.

After further discussion an agreed statement was drawn up, and was afterwards embodied in the official reply on the whole matter sent the same day to the Insurance Acts Committee and printed in last week's SUPPLEMENT and issued to all Panel Committees.

A preliminary discussion followed with regard to the constitution of the Arbitration Board, and the Conference then concluded.

THE SETTLEMENT.

The details as to the arbitrators and the precise terms of reference have yet to be arranged, but the information will be published as soon as possible. The arrangements made for carrying on the work, pending the result of the arbitration, devolve certain duties on the Panel Committees. The request of the Insurance Acts Committee that the remuneration accepted by the profession, whatever it might be, should date back to January 1st, has been met by the Government agreeing to pay 11s. between January 1st and March 31st, 1920. The fee as settled by arbitration will come into operation on April 1st, 1920, or, should the results of the arbitration not be known by April 1st, the new fee will be retrospective to April 1st.

The payment of the 11s. during the interval before the new Regulations come into force involves also the acceptance of the other new financial arrangements, including the new method of setting up the Central Pool, the new method of distribution of the Central Pool, and the inclusion in the Local Pool of the money for discharged disabled sailors and soldiers and temporary residents. But it has been decided that during the quarter January 1st to March 31st accounts on an attendance basis shall continue to be rendered and paid for as a first charge on the Central Practitioners Funds so far as concerns the disabled service men only.

The Model Schemes.

The Insurance Acts Committee has undertaken to urge Panel Committees to co-operate with the Insurance Committees in order that the two model schemes—allocation and distribution—may be sent up as soon as possible to the Ministry, so that they may be finally printed and distributed locally to the individual practitioners by January 31st. The decision of the Panel Conference to accept arbitration, and necessarily, therefore, to accept whatever fee may be awarded by the arbitrators, relieves Panel Committees from the difficulty they have hitherto

had of dealing with these schemes until they knew the money that was to be given.

The latest date by which notice of the conditions of service (including the schemes) must be sent to the individual practitioners is February 3rd, and the individual practitioner will have until February 17th to make up his mind whether he will go off the panel.

Mileage and Drugs.

In considering the remuneration which will be in operation both this quarter and after the result of the arbitration is known, insurance practitioners should bear in mind the concessions that have been made as regards mileage and the payment for drugs. The amount of the mileage grant for *England and Wales*, which is altogether apart from the capitation fee, is £300,000 as compared with the pre-war grant of £34,000. The mileage grant for Scotland is not yet known, but there is no reason to suppose that the claims of rural practitioners in Scotland will be treated less fairly than those in England and Wales.

The additional capitation fee to insurance practitioners who supply drugs and appliances will be uniform throughout the country—namely, 2s. per annum—and practitioners will not have to supply the more expensive drugs and appliances specified in a list as to which the Insurance Acts Committee was consulted.

The Regulations.

The foregoing information, together with an analysis of the present position of the Regulations as affected by the decisions of the Panel Conference, has been sent by the Medical Secretary to the honorary secretaries and chairmen of Local Medical and Panel Committees in Great Britain, and to the honorary secretaries of Divisions and Branches of the British Medical Association.

Scotland.

The provisional settlement reached on January 14th between the Minister of Health and the Insurance Acts Committee does not apply to Scotland, Dr. Addison being unable to speak for the Scottish Board of Health. The Committee, however, relies on Scottish practitioners to insist that the remuneration accepted in Scotland is not less than that settled by arbitration. In the meanwhile the Scottish Subcommittee of the Insurance Acts Committee is in negotiation with the Scottish Board of Health.

STATEMENT BY THE MINISTRY OF HEALTH.

The letter from the Ministry of Health to the Secretary of the Insurance Acts Committee, conveying the substance of the terms of settlement arrived at on January 14th, 1920, was published in last week's SUPPLEMENT at p. 15. The Ministry on January 15th issued the following statement to the press:

On Wednesday, January 14th, the Minister of Health received a deputation of members of the Insurance Acts Committee of the British Medical Association—representing the Conference of Local Medical and Panel Committees—on the subject of remuneration of insurance medical practitioners. The results of the negotiations have been embodied in an official communication from the Ministry of Health to the Insurance Acts Committee, which is appearing in the *British Medical Journal* of this week.

Dr. Addison stated to the deputation that the Government were prepared to seek the authority of Parliament for the provision of funds necessary to pay insurance doctors on the basis of an increased yearly capitation fee of 11s., together with a mileage fund of £300,000 per annum for rural doctors in England and Wales. The doctors' representatives stated that, as the Conference had resolved on 13s. 6d., they would feel bound to recommend their constituents not to accept the 11s. capitation fee; but they were empowered to ask for arbitration, which they now did. This was fully discussed, and, after an adjournment, the Minister announced that the Government acceded to this request and would recommend Parliament to give effect to the finding of the arbitrators. The Insurance Acts Committee on their part undertook that they and the Panel Committees throughout the country would co-operate in securing from the practitioners throughout the country a full and efficient service, with goodwill, under the settlement as a whole, including the terms of the award. The arbitrators' award will operate as from

April 1st, 1920, the Government agreeing to pay in the meantime a capitation fee of 11s. as from January 1st.

The Minister stated that, in view of the general conditions under which it had been necessary for the Government to take the decision above described and of the possibility of future legislation, no particular term of years would be specified for the duration of the arrangements, the Government undertaking not to make any alteration except after consultation with the representatives of insurance practitioners and after an adequate period of notice.

The Minister also stated that the Government reserved its freedom to institute, at a subsequent date, any inquiry which might be then thought desirable in the light of the award and the cost of its working, into the question whether as good or better a service could be secured with the same or less expenditure of money under some other system.

NEW INSURANCE CONTRIBUTIONS AND BENEFITS.

THE Ministry of Health issued the following announcement on January 15th:

The Government have arrived at a decision as to the revision of the contributions and benefits under the National Health Insurance scheme, and a bill to give effect to their proposals is to be introduced into Parliament at the first opportunity.

The weekly contributions are to be increased by 3d. in the case of both men and women, 2d. of which is to fall on the employer and 1d. on the employed person. The normal rate of sickness benefit is to be increased to 15s. in the case of men and 12s. in the case of women. Disablement benefit is to be at the rate of 7s. 6d. a week for both men and women, and maternity benefit is to be increased from 30s. to £2.

Sanatorium benefit is to be removed from the Acts, the treatment (other than domiciliary) of tuberculosis, both among the insured and the uninsured, being recognized as falling within the province of the local authorities. A State system of medical referees is to be established, towards the cost of which the societies will make a small contribution by way of payment per case referred.

The increased contributions above described, together with the consequential increase in the Exchequer contributions, will, in addition to providing for the above increases in the rates of cash benefits, enable a larger sum than hitherto to be made available towards meeting the increased cost of medical benefit.

The above changes relate to England and Wales and Scotland. In the case of Ireland there are some modifications, the principal of these being that sanatorium benefit will remain in the Act. The rates of the cash benefits are to be the same as in Great Britain, but the weekly contributions in Ireland are to be increased by 2½d. (employer 1½d., and employed person 1d.) instead of 3d.

CORRESPONDENCE.

The New Regulations and Arbitration.

SIR,—In 1912 our Representatives, accepting the calculation of our Council that a capitation of 8s. 6d. would yield but 1s. 5d. per attendance, insisted upon this, and threw away an unparalleled opportunity to fix a wage limit for all contract work; also they antagonized the Chancellor and all his supporters and split our ranks beyond repair. Yet the calculation which did such mischief proved entirely wrong, and positively more is received on a capitation of 7s. than was expected from 8s. 6d. Statistics of 25 burghs and 31 counties of Scotland, covering three years and comprising between four and five million attendances per annum, show but 3.16 attendances annually per unit, and even if one allows an error of over 10 per cent.—a large one for a Scot in a matter of business—and calls it 3.5, this yields, on a capitation of 7s., 2s. per attendance.

Now, had 7s. been accepted on trial, as it surely would have been had 2s. per attendance been expected from it, and our still united forces been solidly thrown into battle with the then new-formed and hesitating Insurance Committees over the limit of wage, can it be doubted that we should have won? The abomination of educated doctors attending plutocratic munitioners, with fur coats and grand pianos at home, at 7s. a year would then never have been perpetrated, and administrative expenses would have been greatly reduced. Further, we should have co-operated in shaping Regulations and records, and the monstrous things

¹ Report of the Administration of National Health Insurance, 1914-17, pp. 294 and 295.

foisted upon us would never have been produced. Above all, we should have remained a united, victorious, and formidable body, whom no one would have dared to affront again. Because at that time estimated attendances at 3.75, yielding 1s. 10½d. each on a 7s. capitation, predicted that panel practices would prove most saleable of all, warned my colleagues that we should "go down like a pack of cards" if we struck, and strenuously, both at meetings and in the JOURNAL,² advocated precisely the above course as our only hope, I venture now to criticize the present action of our Committee.

Once more, learning nothing from that deplorable and most avoidable fiasco, we are throwing away opportunities, perhaps our last, to obtain solid improvements in hope, probably vain, to gain higher pay. On a capitation of 11s. a panel of 3,000 yields £1,650 a year, without expense of collection, bad debts, or bill for drugs, and private practice is allowed besides, the dependants of the insured being estimated at 1.5 to 1. To this is added £300,000 for rural doctors. Will any court of arbiters give us more? On the other hand, we are neglecting far more essential matters once again. The raising of the wage limit of non-manual workers to £250, logical in itself, should have been seized on as pretext to limit manual workers in like way. I do not think they would resent it. The new Regulations are unintelligible to me in this matter, but as our Committee do not mention it, I presume it is not done. The inequitable contract should have been revised, allowing no change without mutual consent. The powers of the Insurance Commissioners, already too considerable, should have been curtailed; instead, being vested in a single man, they are infinitely more dangerous to us. How shall we stand when he is nominee of a Labour Cabinet, and perhaps definitely hostile, or pledged to State service? The emergency regulation should have been fought, and the scope of "reports" defined and restricted. The liability for expenses in case of complaint should have been imposed equally upon societies with ourselves, or else upon neither. Finally, the old regulation as to transfer should have been left, but safeguarded on the lines suggested by Mr. Anderson, a layman of practical experience whom I quoted in my letter of December 20th, 1919.

Now, I maintain that there is not one of these questions which could not be fully understood and appreciated by a court of intelligent laymen, and not one but might be brought before them with good hope of redress. Surely it had been better had our Committee insisted that all of them be submitted to arbitration. Is it too late even now to repair this omission? I earnestly hope that some effort in this direction may yet be made.—I am, etc.,

Chichester, Jan. 18th.

G. C. GARRATT.

SIR,—At the last Panel Conference it was agreed to submit the amount of the capitation fee to arbitration if necessary, but it was not agreed that such arbitration should go further and involve at the same time the acceptance of the whole of the Regulations, which now appears to be the intention of the Government.

There are two vital principles embodied in the Regulations which, if allowed, would affect not only panel practitioners but also the whole of the community, namely:

(a) The taking away of goodwills without purchase or compensation.

(b) The taking away from all British subjects their inherent right of appeal to the Courts of Law in the event of being unjustly penalized.

These two vital principles stand absolutely outside arbitration and no attempt must be made to smuggle them in under cover of any kind of award.—I am, etc.

Stalybridge, Jan. 18th.

ADAM FOX, L.R.C.P., L.R.C.S.

Remuneration.

SIR,—It is very noticeable in the letters on this subject that the bulk of the complaints come from those who have small panels, especially those (as in country practices) where the possible total is strictly limited.

This is what any business man would expect. A large number, concentrated in a small area, where the transport to and from the place of business (the doctor's house) is easy, always greatly cuts down expenses of management. Patients, for instance, will come three miles or more in a ramcar, whereas in the country they would demand a visit, and telegraph for it, too.)

There may be objections, and I suppose in any case the suggestion is now too late, but would it not be possible and

more equitable to grade up the capitation fee according to the smallness of the practitioner's panel—say an extra sixpence a head for every hundred under, say, a thousand? At present the small panels—country ones, anyway—are either negative or a loss.—I am, etc.,

Newton Ferrers, S. Devon, Jan. 9th. W. F. BENSTED-SMITH.

Association Notices.

MEETING OF COUNCIL.

THE next Meeting of Council will be held on Wednesday, February 18th, in the Council Room, 429, Strand, London, W.C. 2.

ELECTION OF REPRESENTATIVE BODY OF THE ASSOCIATION, 1920-21.

Constituencies in Representative Body.

A LIST of the provisional Home Constituencies for election of the Representative Body, 1920-21, is appended (see (I) below).

As intimated to all the Oversea bodies, the Council has made each Oversea Division and Division-Branch, possessing an Honorary Secretary and the necessary organization, an independent Constituency.

Election of Representatives and Deputy-Representatives.

The Representatives and Deputy-Representatives in the Representative Body must be elected not later than May 23th, and their names notified to the Medical Secretary not later than June 4th.

The Council draws special attention to the fact that it is entirely within the discretion of each Constituency to decide whether the election of its Representative(s) and Deputy-Representative(s) shall be carried out by General Meeting of the Constituency, or by postal vote.

Date of Annual Representative Meeting at Cambridge.

The Annual Representative Meeting at Cambridge will begin on Friday, June 25th, at 10 a.m.

Motions for the Annual Representative Meeting.

Notices of Motion by Divisions, Constituencies, or Branches for the consideration of the Annual Representative Meeting, proposing to make any addition to, or any amendment, alteration or repeal of any Regulation or By-law, or to make any new Regulation or By-law, or proposing material alteration of the policy of the Association in matters relating to the honour and interests of the profession or of the Association, must be published in the JOURNAL not later than April 24th, and for this purpose should be received by the Medical Secretary not later than April 10th.

ELECTION OF COUNCIL OF THE ASSOCIATION, 1920-21.

A LIST of the Groups of Branches in the United Kingdom for election of twenty-four members of the Council, 1920-21, and Nomination Form, are appended (I) and (II) below, p. 22).

The list of the Groups of Oversea Branches was published in the SUPPLEMENT of October 11th, 1919, p. 79.

(I) HOME CONSTITUENCIES FOR ELECTION OF THE REPRESENTATIVE BODY.

(Divisions bracketed together form one Constituency.)

(III.) FORM FOR NOMINATION

BY A DIVISION, OR BY THREE MEMBERS OF A BRANCH, IN THE GROUP, OF A CANDIDATE FOR ELECTION AS ONE OF THE TWENTY-FOUR MEMBERS OF THE COUNCIL, 1920-21, TO BE ELECTED BY THE GROUPED HOME BRANCHES.

* By instruction of the Division I (* or Wc, the undersigned Members of the Branch) hereby nominate

.....
 of

as a Candidate for Election by the Branches in Group as a Member of the Council of the Association.

..... Honorary Secretary.*
 Division.*
 (..... Member.*
 Member.*
 Member.*)

I hereby declare my willingness to serve, if elected, as a Member of the Council for the year 1920-21.

Candidate's Signature

N.B.—Nominations should be sent to the Medical Secretary, 429, Strand, London, W.C.2.

* Please omit words not required.
 { The Group should be indicated by filling in the index letter (as above).

British Medical Association.

CURRENT NOTES.

Appointments on Pensions Boards.

It has come to the notice of the Medical Secretary of the British Medical Association that some medical men who have served during the war are apparently not familiar with the method by which they can, if they so desire, secure work on the local pensions board. The policy of the Ministry is to give preference for this work to practitioners who have served, and any such doctor who is living in the neighbourhood of a pensions board but who is not a member of it should apply to the Deputy Commissioner of Medical Services of the district, whose name and address will be given to him by the chairman of the board or can be obtained by writing to the Medical Department of the Ministry of Pensions, Great Smith Street, S.W.1. The appointments are made by the Ministry, but the applications must go through the D.C.M.S.

The Representative Body.

We would again draw the attention of members to the notices published at page 21 with regard to preparations for the Annual Representative Meeting, which will begin at Cambridge on Friday, June 25th. Representatives and their deputies must be elected by May 28th, and their names notified to the Medical Secretary by June 4th. The members of each constituency are free to decide for themselves whether these elections shall be carried out by general meeting or by postal vote. Notices of motion affecting either the constitution of the Association or its policy on large issues must reach the Medical Secretary by April 10th, so that they may be published in the JOURNAL not later than April 24th. By decision of the Council every Oversea Division and Division-Branch that has an honorary secretary and the necessary organization is now an independent constituency for electing to the Representative Body. The Annual Conference of Honorary Secretaries of Branches and Divisions will be held during the Cambridge meeting; honorary secretaries, like representatives, are paid their first-class travelling expenses within the United Kingdom.

BRANCH AND DIVISION MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.—Mr. Albert E. Morison, Honorary Secretary (1, St. George's Square, Sunderland), gives notice that the annual meeting of the Division will be held at the Royal Infirmary, Sunderland, on Thursday, January 29th, at 4.30 p.m. At 7 p.m. a complimentary dinner will be given to those members who have returned from active service, at the Burnville Café, Fawcett Street.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following announcements are notified by the Admiralty:—Surgeon Commanders (retired) E. Cooper, G. T. Bishop, and H. W. Gordon-Green, O.B.E., have been promoted to the rank of Surgeon Captains (retired), seniority January 1st. Surgeon Commanders F. Cook to the *Eagle*, additional; C. Ross to R.N. Hospital, Simons-town; R. W. Stanistreet to the *Orión*, J. H. Ferguson to the *Pembroke* for Chatham Hospital; J. H. L. Page to the *Victory*, for Haslar Hospital; P. M. Rivaz to the *Pembroke*, for the Medical Ambulance Train; P. F. Woodruff-Minet to the *Danae*, G. D. Walsh to the *Erebus*, W. W. D. Chilcott to the *Vivid* for R.N. Barracks, C. K. Bushe, O.B.E., to the *President*, additional, for Medical Department as Assistant to Medical Director-General, A. McCloy to R.N. Hospital, Plymouth. R. Kennedy to H.M. Hospital Ship *Berbice*, F. G. Goble to the *Centaur*, D. C. Given to the *Woolwich*, Surgeon Lieutenant Commanders D. P. H. Pearson to the *Crescent*, for R.N. Sick Quarters, South Queensferry; K. H. Hole to the *Agadir*, A. M. Henry to the *Valiant*, J. T. D. S. Higgins to the *Shakespeare*, H. F. Briggs to the *Berbice*, Surgeon Lieutenants H. C. C. Veitch to the *Wallace*, R. R. Shaw to the *Barham*, E. Heffernan to the *Royal Oak*, R. P. Ninnis to the *Queen Elizabeth*, J. D. Brown to the *King George V*, W. P. Vicary to the *Cornflower*, J. J. Baugay to the *Europa*, additional, to 3rd Royal Marine Battalion, Mudros, N. B. de M. Greenwood to the *Ladybird*, Surgeon Lieutenants (temporary) R. N. B. McCord to the *Hercules*, J. H. Bennett to the *Blake*, temporarily, J. A. Watson to the *Woolwich*, on re-commissioning.

ARMY MEDICAL SERVICE.

Major-General Sir H. N. Thomson, K.C.M.G., C.B., D.S.O., is placed on the half-pay list, November 18th, 1919 (substituted for notification in the *London Gazette*, December 8th, 1919).
Temporary Colonel Sir H. J. Stiles, K.B.E. (Brevet Lieut.-Colonel R.A.M.C.) relinquishes his temporary commission on reposting.
The following officers retire on retired pay: Major-General H. Carr, C.B., Colonel F. W. Begbie, C.B.E., and Colonels G. T. Rawnsley, C.B., C.M.G., and T. B. Beach, C.M.G., C.B.E. from the half-pay list.

Temporary Colonel C. M. Weyman, C.M.G., C.B.E., relinquishes his commission and retains the rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel D. J. Collins to be temporary Colonel whilst A.D.M.S., April 7th, 1916 (substituted for notification in the *London Gazette*, July 14th, 1916).

The following officers relinquish the acting rank of Lieutenant-Colonel: Majors P. E. Rowan-Robinson, J. H. R. Wiader, D.S.O., R. W. D. Leslie, O.B.E., E. G. French; Captain E. W. Wade, D.S.O.

To be acting Lieutenant-Colonels: Major C. H. Denyer, M.C. (from September 25th to November 19th, 1919); temporary Major W. E. Home, O.B.E. (whilst commanding troops on a hospital ship).

Major E. G. R. Lithgow is restored to the establishment.
Temporary Major C. V. Mackay to draw the pay and allowances of his temporary rank from March 26th to June 6th, 1918 (inclusive), and from August 3rd to September 26th, 1918 (inclusive).

Temporary Major E. Ligertwood, D.S.O., relinquishes the temporary rank of Lieutenant-Colonel on reposting, November 30th, 1916 (substituted for notification in the *London Gazette*, January 22nd, 1917).

Captain L. C. Hayes to be temporary Major whilst specially employed.

The following relinquish the acting rank of Major: Captains J. S. McCombe, D.S.O., W. T. Hare, M.C., E. C. Lambkin, D.S.O., A. Jackson, W. K. Campbell, D.S.O., M.C., J. F. Bourke, M.C. Temporary Captains R. Nichol, J. Porter, W. Brown.

Captain and Brevet Major J. D. Kidd, O.B.E., M.C., to be acting Major.

To be acting Majors: Temporary Captains J. T. Gubb, from November 10th to December 7th, 1918 (substituted for notification in the *London Gazette*, September 10th, 1919); J. E. P. Shera, from November 25th, 1918, to May 8th, 1919.

Captain P. H. Wells, M.C., resigns his commission.
Temporary Captain R. Jamison relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed (October 18th, 1919, substituted for the notification in the *London Gazette*, December 9th, 1919).

Temporary Captain (acting Major) W. M. Oakden to draw the pay and allowances of his acting rank (June 18th, 1919).

Temporary Captain (acting Major) D. O. Riddell, D.S.O., relinquishes the pay and allowances of his acting rank.

Captain T. E. B. Beatty, from Special Reserve, to be Captain, August 16th, 1919, but not to reckon for pay or allowances prior to December 1st, 1919, with precedence next below W. L. A. Harrison.

The notifications regarding temporary Captains William G. Gordon, Roland B. Radcliffe, and Rae McRae, published in the *London Gazette* of December 19th, May 30th, and December 22nd, 1919, respectively, are cancelled.

To be temporary Captains: J. A. Martin. Temporary Lieutenants: P. Johnson, W. L. Young, J. H. Rodgers, C. K. T. Hewson, P. P. Galea, P. C. S. Bradbury, H. G. Walters, H. H. McClelland.

Temporary honorary Lieutenant C. E. Backus (since deceased) to be temporary honorary Captain, October 10th, 1919.

H. P. Hodge to be temporary Lieutenant.
Late temporary Captains to be temporary Captains: L. C. E. Murphy (seniority December 18th, 1916), J. A. Cowan (seniority December 20th, 1916), and P. J. Waldmeier (seniority September 21st, 1917).

The following officers relinquish their commissions:—Temporary Major F. C. Purser, O.B.E., and retains the rank of Major. Temporary Captain and Brevet Major S. P. Hodgkinson, and retains the Brevet rank of Major. Temporary Captain W. N. Parker, D.S.O., and is granted the rank of Lieutenant-Colonel. Temporary Captains and are granted the rank of Major: D. C. Ogilvie, M.C., J. P. Davidson, M.C., R. B. Roe, F. H. Moxon, O.B.E., E. T. C. Milligan, O.B.E., J. W. McKinney, R. S. S. Statham, O.B.E., G. Jackson, S. S. Dunn, R. Jamison (November 18th, 1919, substituted for notification in the *London Gazette*, December 20th, 1919), W. Gemmill, J. G. Duncanson, T. M. Bellow, W. H. Alderton, M.C., P. J. Lane, M.C., R. MacDonald, O.B.E. Temporary Captains and retain the rank of Captain: C. Murphy, E. T. Jameson, E. G. D. Murray, O.B.E., R. R. K. Patou, C. A. O'Driscoll, K. D. Falcoer, M.C., A. Gastou, M.C., W. J. Moir, A. G. H. Geyer, R. W. Miller, C. J. C. Macquarie, H. B. McCaskie, D. R. Adams (on account of ill health contracted on active service), C. Harris, A. C. MacKay, J. R. Stott, O.B.E., C. W. Macpherson, M. Sommerville, M.C., H. N. Crossley, W. A. Alexander, R. N. Thomson, W. Campbell, J. G. Lessey, M. Rust, T. M. Anderson, S. C. R. Flaxman, W. J. Symes, C. F. Davey, C. C. Harrison, M.C., A. G. Howson, J. F. Penman, M. H. Watney, A. P. Green, W. Hornsby, W. H. Bush, A. J. Dempsey, J. Russell, E. D. F. Hayes, P. J. Montgomery, A. Dick, A. Cott, E. D. Wortley, O.B.E., P. Wilson, W. K. Connell, J. McPolin, I. S. James, S. J. Cowell, E. R. Denny, E. Gordon, M.C., S. J. Graham (on ceasing to serve with the Belfast War Hospital), J. B. Mason, J. A. Frost, R. J. Wilson, (acting Major) J. A. Moraes (on ceasing to serve with the Ceylon Sanitary Company), A. T. Gibb (on account of ill health contracted on active service), J. R. Pate, R. G. Barlow, J. Campbell, M.C., O. G. Evans (on account of ill health), C. L. Stewart, B. E. Laurence, B. Dunlop, A. Davidson, J. P. McGreehin, R. W. L. Todd, P. C. Cole. Temporary Captain A. Peden. Temporary Lieutenants and retain the rank of Lieutenant: J. A. Martin, (acting Captain) F. G. Stevens, and T. C. Vau-der-Ziel on ceasing to serve with the Ceylon Sanitary Company.

ROYAL AIR FORCE.

MEDICAL BRANCH.

Wing Commander J. St. J. Murphy (Surgeon Commander R.N.) and Flight Lieutenant E. Heffernan (Surgeon Lieutenant R.N.) relinquish their temporary R.A.F. commissions on return to naval duty.

Squadron Leader E. G. R. Lithgow (Major R.A.M.C.) relinquishes his temporary R.A.F. commission on return to army duty.

J. D. Keir (Surgeon Commander R.N.) is granted a temporary commission as Lieutenant-Colonel, October 1st, 1918, seniority from April 1st, 1918 (substituted for notification in the *London Gazette*, November 26th, 1918).

H. J. Swan (late Flying Officer R.A.F.) is granted a temporary commission as Flight Lieutenant.

Flying Officers to be Flying Lieutenants: D. Cromie, J. B. Barnett, C. H. Young.

Transferred to Unemployed List: Captains A. B. Rooke (March 30th, 1919), J. S. Dockhill (May 3rd, 1919), J. Paxton (February 21st, 1919), J. R. Adam (February 28th, 1919), J. H. Cooke, M.B.E. (December 6th,

1919). J. A. Johnson (November 12th, 1919), S. A. Neild-Paulkner (December 20th, 1919), H. Munro (March 5th, 1919), Lieutenant J. Gorsky (December 17th, 1919).

INDIAN MEDICAL SERVICE.

Lieut.-Colonel E. V. Hugo, C.M.G., M.D., F.R.C.S., appointed to be Professor of Surgery, and Major R. H. Bott, M.B., F.R.C.S., Professor of Operative Surgery at the King Edward Medical College, Lahore, October 11th, 1919.

Lieut.-Colonel G. P. T. Gronba has been permitted to retire from the service in consequence of ill health, October 7th, 1919.

Lieut.-Colonel C. A. Lane, M.D., has been permitted to retire from the service with effect from October 25th, 1919.

Captain H. K. Rowntree, M.C., appointed to be additional Assistant Director-General, Indian Medical Service, January 6th, 1920.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain A. G. McColl relinquishes his commission on account of ill health contracted on active service and retains the rank of Captain.

Captain W. Donald, M.C., relinquishes the acting rank of Major.

Captain G. H. Gidlow-Jackson relinquishes his commission on account of ill health and retains the rank of Captain.

Lieutenant A. B. Grant to be Captain.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Major (acting Colonel) C. H. Lindsay, C.M.G., D.S.O., relinquishes the acting rank of Colonel on vacating the appointment of A.D.M.S.

The following Captains (acting Majors) relinquish the acting rank of Major on ceasing to be specially employed: N. W. Kidston, K. I. S. Smith, E. A. Houchin, M. Coplans, O.B.E., D.S.O. (March 8th, 1919, substituted for notification in the *London Gazette*, April 25th, 1919), acting Lieut.-Col. C. H. J. Fagan, O.B.E.

Captain V. T. Ellwood is restored to the establishment.

1st *Eastern General Hospital*.—Major H. B. Rolrick, O.B.E., T.D., is seconded for service with the Cambridge University (Medical Unit) Senior Division, O.T.C.

2nd *Eastern General Hospital*.—Major F. G. Busbneil is restored to the establishment.

1st *London Sanitary Company*.—Lieutenant F. C. Cook to be Captain.

2nd *London Sanitary Company*.—Captain H. Jessop relinquishes his commission on account of ill health contracted on active service, and retains the rank of Captain; Lieutenant S. Shaw to be Captain.

Supernumery for Service with the O.T.C..—Lieutenant (temporary Captain) W. L. H. Duckworth ceases to serve with the Cambridge University Contingent (Medical Unit), Senior Division, and relinquishes the temporary rank of Captain.

VOLUNTEER FORCE.

The following temporary Majors relinquish their commissions and are granted the honorary rank of Major: H. L. Rutler, J. Harrison, M. Bruce, J. P. Philip.

The following temporary Captains relinquish their commissions and are granted the honorary rank of Captain: A. A. Angelis, T. Halliwell, B. A. Richmond, and J. F. Sarjeant (City of London R.A.M.C.V.), G. W. Brumwell (Cumberland R.A.M.C.V.), W. F. Clowes (Essex R.A.M.C.V.), C. H. Evers, A. H. Hobbs, D. Revic, C. G. Henderson, B. Younger, A. A. Martin (Northumberland R.A.M.C.V.), G. C. Grant (Bantshire R.A.M.C.V.), R. M. Hugo and G. M. Wilcockson (Surrey R.A.M.C.V.), E. J. Jerome (Cornwall R.A.M.C.V.), J. R. Leeson (Middlesex R.A.M.C.V.), T. Wood (Midlothian R.A.M.C.V.).

The following temporary Lieutenants have relinquished their commissions and are granted the honorary rank of Lieutenant: E. H. Andrews, G. F. Cooper, and F. Isdell (Essex R.A.M.C.V.), L. C. Burrell (Surrey R.A.M.C.V.), J. Cromie (Kirkcubright R.A.M.C.V.), G. Duffus (Surrey R.A.M.C.V.), T. Gilchrist (Linlithgowshire R.A.M.C.V.), H. S. Grace and A. Payne (Northumberland R.A.M.C.V.), J. Heard (City of London R.A.M.C.V.), R. Inch (Midlothian R.A.M.C.V.), D. R. Macdonald (Haddingtonshire R.A.M.C.V.), F. McKenna (Ayrshire R.A.M.C.V.), R. S. Penman (Renfrewshire R.A.M.C.V.), G. E. Sawdon (Derbyshire R.A.M.C.V.), E. I. H. White and J. R. H. Dubourg (Lancashire R.A.M.C.V.).

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 6s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

PRIOR.—On January 16th, at 22, Hampstead Way, N.W.4, to Dr. and Mrs. E. S. S. Prior—a daughter.

SHAUD.—On Sunday, January 18th, 1920, at 307, Gillett Road, Edgbaston, Birmingham, the wife of G. E. Shaud, M.D. (Aberd.), D.P.H., of a daughter.

STRANGE.—On January 16th, 1920, at The Queen Victoria Nursing Institute, Wolverhampton, to the wife of Ernest W. Strange, M.D.—a son.

MARRIAGE.

EVANS—HARRIS.—On January 8th, 1920, at St. Mathew's Church, Rugby, by the Rev. Dr. Middleton, Dr. T. Garnold Evans, M.D. (Lond.), son of the late Captain John Evans, Aberayron, to Catherine Macintyre Harris, second daughter of Mr. Alfred Harris, 68, Dunchurch Road, Rugby.

DEATHS.

DAVY.—On January 12th, 1920, suddenly at a nursing home, David Henry Davy, M.R.C.S., L.R.C.P., 84, Beverley Road, Hull, in his 67th year.

DUNN.—On January 12th, Edwin Lindsay Dunn, M.B., Medical Superintendent, Berkshire County Asylum, only son of the late Robert Dunn and Mary B. Lindsay Dunn of Dunfield, Londonderry.

British Medical Association.

OFFICES AND LIBRARY, 429, STRAND, LONDON, W.C.2.

Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 5 p.m., Saturdays 10 to 1.

LENDING LIBRARY: Members are entitled to borrow books, which will be forwarded by post, if desired, on application to the Librarian.

DIARY OF SOCIETIES AND LECTURES.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Monday, 8.30 p.m., Demonstration of Pathological and Medico-legal Specimens.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Monday, Wednesday, and Friday, 5 p.m., Professor Arthur Keith, F.R.S.: John Hunter's Observations and Discoveries in Anatomy and Surgery.

ROYAL SOCIETY OF MEDICINE.—Social evening, Friday, 8.30 p.m., Sir D'Arcy Power will speak on The Fees of Our Predecessors, with illustrations. Objects of interest will be exhibited in the Library. Music and light refreshments. *Section of Odontology*: Monday, 8 p.m., Mr. S. F. St. J. Steadman: Dental Sepsis in Children. *Section of Medicine*: Tuesday, 5.30 p.m., Dr. W. H. Willcox: Typhus and Relapsing Fever in Mesopotamia and Northern Persia. Dr. Arkwright and Dr. Ledingham will speak on Bacteriology. *Section of Bacteriology and Climatology*: Thursday, 5.30 p.m., Discussion on Merits and Defects of British Health Resorts, to be opened by Dr. Neville Wood.

POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.1.—Tuesday, noon, Mr. C. H. S. Frankau, C.B.E., D.S.O.: Simple Enlargements and Tumours of the Thyroid Gland. Wednesday, noon: Intestinal Obstruction. Thursday, noon, Dr. A. E. Gow: Intravenous Protein Therapy.

MANCHESTER: ANCOATS HOSPITAL.—Thursday, 4.30 p.m., Mr. Douglas: Clinical Demonstrations.

MANCHESTER ROYAL INFIRMARY.—Tuesday, 4.30 p.m., Mr. Wilson H. Hey: Surgical Treatment of Incurable Cancer.

NEWCASTLE-UPON-TYNE: ROYAL VICTORIA INFIRMARY.—1 p.m., Mr. A. M. Martin: Operations. 3.15 p.m., Professor T. Beattie: Early Diagnosis of Pulmonary Tuberculosis. 4.30 p.m. (at College of Medicine), Dr. J. D. Lickley: Anatomy of the Thorax and Abdomen.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Tuesday, 2 p.m., Dr. J. Metcalfe: X-ray Treatment of Diseases of the Thyroid Gland (demonstration). 4.30 p.m., Lieut.-Colonel R. H. Elliot: Treatment of Glaucoma (lantern lecture).

SHEFFIELD ROYAL HOSPITAL.—Monday, 5.30 p.m., Dr. Nutt: Localization of Foreign Bodies. Tuesday, 4 p.m., Dr. Hay: Examination of Eye. Wednesday, 3.30 p.m., Dr. Wilkinson: Enlarged Testis and Adenoids. Thursday, 3.30 p.m., Dr. Skinner: Urticaria, Purpura, etc. Friday, 4 p.m., Dr. Hay: Ocular Sequelae of General Diseases.

WEST LONDON POST-GRADUATE COLLEGE, Hammersmith, W.—Friday (January 23rd), 5 p.m., Professor W. M. Bayliss, F.R.S.: Acidosis. Saturday, 10 a.m., Dr. Arthur Saunders: Medical Diseases of Children. Monday, 5 p.m., Mr. Addison: Club Foot. Tuesday, 5 p.m., Mr. Bankz Davis: Common Affections of Middle ear.—Treatment. Wednesday, 5 p.m., Mr. Souttar: Clinical Surgery. Thursday, 5 p.m., Dr. Grainger Stewart: Encephalitis Lethargica. Friday, 5 p.m., Mr. MacMahon: Functional and Organic Affections of Voice and Speech.

APPOINTMENTS.

HILLIER, R. J., M.R.C.S., L.R.C.P., Anaesthetist to Jessop Hospital for Women, Sheffield.

SALMOND, R. W. A., O.B.E., M.D., Ch.M., Honorary Radiologist to University College Hospital and Lecturer in Radiology at the Medical School.

WARD, H. G., M.D., D.P.H. (Vict.), Medical Officer of Health for the Warwickshire United Districts.

WILSON, J. I. P., M.D., Medical Superintendent, Mile End Old Town Hamlet Infirmary.

INSURANCE REMUNERATION.

THE BOARD OF ARBITRATORS.

The following gentlemen have consented to act as arbitrators on the question of the remuneration of insurance practitioners:

- F. GORE-BROWNE, Esq., K.C. (a Master of the Bench of the Inner Temple), Chairman;
- Sir RICHARD VASSAR-SMITH, Bt. (President of the Council of the Institute of Bankers, Chairman of Lloyd's Bank, Ltd.); and
- J. C. STAMP, Esq., C.B.E., D.Sc., Fellow Royal Statistical Society (Secretary to Explosives Trades, Ltd., Member of the Royal Commission on Income Tax).

TERMS OF REFERENCE.

The terms of the reference to the arbitrators are as follows:

"To advise the Government what should be the amount of the capitation fee (per insured person per annum) on the basis of which the Central Practitioners Fund under Article 19 (i) of the Medical Benefit Regulations, 1920, should be calculated, so as to afford fair remuneration for the time and services required to be given by general practitioners, under the conditions set out in those Regulations, in connexion with the medical attendance and treatment of insured persons.

"This capitation fee is not to include any payment in respect of the supply of drugs and appliances (such payments being met out of the Drug Fund under Article 22) nor any payments to meet those special conditions of practice in rural and semi-rural areas which are covered by the payments to be made out of the Central Mileage Fund under Article 19 (ii)."

British Medical Association.

CURRENT NOTES.

Reconstruction of the Territorial Medical Force.

The Naval and Military Committee of the British Medical Association and its Territorial Force Subcommittee have for some time past had under consideration from various aspects the future organization of the medical service of the Territorial Force. In view, however, of the announcement that the Secretary of State for War would shortly meet representatives of the Territorial Force Association for the purpose of expounding the policy of the Government in relation to the future of the Territorial Force as a whole, it has been deemed inadvisable to take action until the general policy proposed with regard to the Territorial Force is made known, since the constitution of the medical service must be largely determined by that of the force. The Naval and Military

Committee, however, having examined the subject in its various aspects, will be in a position to consider the proposals of the Government from the medical point of view and to offer advice with regard to the reconstruction of the Territorial Medical Service, and on the relation of that service to the civil profession both in peace and in war. The matter will be very closely watched.

Election of Council.

The attention of members is called to the notice printed in last week's SUPPLEMENT, at p. 21, with regard to the election of twenty-four members of the Council of the Association for 1920-21, by the grouped Home Branches. This election is carried out at the head office of the Association by a postal vote of all the members in each group. The list of groups was printed at p. 22, together with the form for nomination of candidates. Nominations should reach the Medical Secretary by May 17th next. All members of the Association are eligible for election. The SUPPLEMENT for January 24th contained also notices as to election of the Representative Body for the ensuing year, and gave a list of the home constituencies for the purpose of these elections, which may be carried out by a general meeting, or by postal vote, at the discretion of the members of each constituency. It is intended that the Annual Report of the Council for 1919-20 shall be published in the SUPPLEMENT of April 24th.

Degrees for London Medical Students.

The Council of the Metropolitan Counties Branch of the British Medical Association at its last meeting discussed the question of degrees for London medical students and the establishment of a teaching university in London, and took steps to appoint a committee to advise what action, if any, should be taken. The Branch is thus resuming at an opportune moment its consideration of a subject upon which it presented a very valuable report in 1885, when the late Mr. Macnamara was its president. One outcome of its action at that time was the appointment of a Royal Commission, which found that the case for a teaching university in London was made out, but by a majority advised that there should be one university for London, and not two. A minority, consisting of Lord Kelvin, Sir Gabriel Stokes, and Dr. Weldon, expressed their preference for a new teaching university for London, leaving the existing university untouched. Mr. McAdam Eccles, who is now president of the Branch, briefly related to the Council the subsequent history of the movement, and the work of the various Royal Commissions on the subject; he drew attention to the recommendations of the most recent Commission with regard to the establishment of university hospital units in London, a recommendation now being put into force, with the assistance of the University Grants Committee, at St. Bartholemew's, St. Thomas's, and University College Hospital. The last Royal Commission (the Haldane Commission), which reported in 1913, admitted the grievance of London medical students, in that so many of them, in spite of the fact that they had received medical education in the capital of the empire, could not obtain a

university degree. The Commission considered that the proper course was to advise what in the medical faculty, as in others, was essential to a real university education, and to draft recommendations which would result in adequate provision being made in London to render this education open to all able to profit by it. "The degree," it was said, "would follow in the ordinary course, and the grievance should naturally disappear." The Metropolitan Counties Branch, therefore, can quote the opinion of the Royal Commission in favour of steps being taken which will lead to the disappearance of the grievance.

Fee for Administration of Gas to Pensioners.

The attention of the Association was recently called to the fact that no definite fee was provided for the administration of nitrous oxide gas in cases where medical men were called in by dentists under arrangement with the Ministry of Pensions. It was represented to the Ministry of Pensions that a special fee should be provided in these cases. The Ministry of Pensions replied that a fee of 5s. had been provided in addition to the 5s. allowed to the dentist in cases of extraction under gas. A further letter was sent to the Ministry of Pensions, pointing out that the Association could not possibly consider a fee of 5s. adequate for this service, and expressing the hope that a fee of at least 10s. 6d. would be provided. A reply has been received stating that the fee has been reconsidered, and that in future the sum of 10s. 6d. will be paid to the medical man for the administration of this anaesthetic.

R.A.M.C.: Retired Pay.

As was shown in a leading article in the JOURNAL of October 18th, 1919 (p. 503), an examination of the new scale of retired pay for officers of the Royal Army Medical Corps brought to light the extraordinary fact that, whereas in pre-war days a major of twenty years' service could retire with a pension of £1 a day, he will in future receive but £321 a year. A letter was addressed by the British Medical Association to the War Office calling attention to this fact and expressing the hope that this figure would be reconsidered. In a reply received on January 16th it is stated that the rates of retired pay granted to officers in the R.A.M.C. are at present under consideration and that the point raised by the Association will not be lost sight of.

Meetings of Branches and Divisions.

DUNDEE BRANCH.

ON January 14th Dr. A. F. HURST, Physician to Guy's Hospital, delivered an address on the functional element in diseases—medical, surgical, gynaecological, genito-urinary, ophthalmic, and oto-laryngological. Professor MACLEWAN presided over a large audience. The address was very interesting, and Dr. Hurst gave some account of the results of the psychic and re-educative treatment of cases at Netley and Seale Hayne. The address was illustrated by a series of excellent slides and cinematograph films, this being the first public exhibition of medical films in the district. Dr. W. B. DRUMMOND conveyed the thanks of the audience to Dr. Hurst.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.

A GENERAL meeting of the local medical profession called by the South-West Wales Division was held at Carmarthen on January 16th. The meeting was addressed by Dr. ALFRED COX, Medical Secretary of the Association, who gave a *résumé* of what had taken place in the negotiations between the Insurance Acts Committee and the Minister of Health two days earlier.

He said that the profession had asked for 13s. 6d. as a capitation fee, or, failing that, for arbitration, and the latter had been granted. The Minister, on being asked whether the Government would accept the results of arbitration, said he was in a position to bind the Government, and asked whether the Insurance Acts Committee could speak as confidently for its constituents. Dr. Cox thought the question a very pertinent one in view of the notoriously undisciplined action of certain sections of the profession, but he said they had assured the Minister that the profession were honourable men and sportsmen, and, having asked for arbitration, would abide loyally by the result. He pointed out how the negotiations had completely contradicted their friends who tried to make them believe that no body that was not a trade union could carry on negotiations in a matter of this kind. The fact was that it did not matter to

the Government whether a body negotiating with it called itself a "trade union" or a "brotherhood," or a "boys scouts brigade"—what the Government wanted to know was whether the negotiators could "deliver the goods." It was because they believed that the British Medical Association was in a better position to do this than any other body that they negotiated with it, knowing that it had taken a great deal of trouble to get a mandate from a representative conference.

He specially directed the attention of his audience, most of whom were rural practitioners, to the great achievement that had been effected on their behalf, a sum of £300,000 having been allotted for mileage purposes as against the old amount of £34,000. This was in his opinion a handsome but richly deserved recognition of the important services of the rural practitioner to the community. Insurance practitioners generally and rural practitioners in particular owed a deep debt of gratitude to the men who had been mainly instrumental in carrying through this great improvement—namely, Drs. Williams-Freeman, A. Linnell, Lewys-Lloyd, and Brackenbury.

Dr. Cox then referred to the general work of the Association and urged the younger members of the Association to take an active part in its work. The Association, like all organized bodies, needed a constant influx of new blood and new ideas, and it was hopeless if the younger men contented themselves with criticism instead of lending a hand. He also referred to the formation of the Welsh Committee and to the useful work he believed it was destined to perform in regard to specially Welsh medical interests.

The meeting closed with a hearty vote of thanks to Dr. Cox and the Chairman, Dr. Owen Williams.

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.

AT a largely attended meeting of the practitioners resident in the area of the Kensington Division, Mr. HERBERT TANNER presiding, it was unanimously resolved:

That this meeting of medical practitioners resident in Hammersmith, Kensington, and Paddington agrees that, owing to the altered value of money, it is necessary that the fees for professional work be increased by at least 50 per cent. on the fees prevailing before the war, and calls upon all practitioners resident in these areas to loyally carry out this recommendation, as is being done in all parts of London and the provinces; it being understood that in cases (known to the practitioner) where such an increase would be the infliction of a hardship, he will use his own estimate of the fees to be demanded in these circumstances.

SUFFOLK BRANCH; SOUTH SUFFOLK DIVISION.

AT a meeting of the South Suffolk Division the following resolutions as to increase of private fees and fees for life insurance examinations were adopted:

At a meeting held in Ipswich on December 5th, 1919, the medical practitioners in the area of the South Suffolk Division of the British Medical Association, comprising both members and non-members of the Association, decided, in view of the increased cost of living and expenses of carrying on practice, to raise their private fees by not less than 50 per cent., but they will continue to show the same consideration they have habitually extended to those unable to pay the recognized fees.

This meeting is of opinion that the time has come when fees for examinations for life insurance should be not less than 21s., and that insurance companies should be circularized to that effect, and that doctors practising in the area should be informed.

WORCESTERSHIRE AND HEREFORDSHIRE BRANCH: WORCESTER DIVISION.

A SPECIAL meeting of the Worcester Division, to which non-members were invited, was held at the Worcester General Infirmary on January 7th, when Dr. J. LIONEL STRETTON was in the chair.

The MEDICAL SECRETARY addressed the meeting, and dealt with the following matters: (1) Fees for the notification of infectious diseases. (2) Criticism of members of the Insurance Acts Committee by members and non-members of the British Medical Association. (3) Present position of negotiations for alterations in draft Regulations: (a) Sale of practices; (b) question of appeal to the High Court; (c) capitation fee for supply of drugs; (d) certificates; (e) remuneration. (4) Fees for medical examination for life assurance. (5) The numerous certificates required by ex-service men when claiming a pension. (6) Fees for operations, etc., undertaken on behalf of public authorities on school children.

On the motion of the CHAIRMAN, seconded by Dr. POLLARD, a hearty vote of thanks was accorded to Dr. Alfred Cox for his address.
