## SKETCH OF THE HISTORY

OF

## ELEMENTARY GEOMETRY.

The term Geometry is derived from $\gamma \epsilon \omega \mu \varepsilon \tau \rho i a$, a Greek word, signifying the science of land-measuring. Ancient writers have generally supposed that this science was first cultivated in Egypt, and Herodotus ascribed the origin of Geometry to the time when Sesostris divided the country among the inhabitants. Aristotle attributed the invention to the Egyptian priests, who, living secluded from the world, had abundant leisure for study.

Thales of Miletus, in Asia Minor, who was born about 640 years before Christ, transplanted the sciences, and particularly mathematics, from Egypt into Greece. He resided for some time in Egypt, and formed an acquaintance with its priests. He is said to have measured the height of the Pyramids by means of their shadow, and determined the distance of vessels remote from the shore by the principles of Geometry. On lis return to Greece he founded what has been called the Ionian school, from Ionia, his native country. To him are attributed various discoveries concerning the circle and the comparison of triangles, and he first discovered that all angles in a semicircle are right angles.

One of the disciples of Thales composed an elementary treatise on Ge-ometry-the earliest on record, and he is said to have invented the gnomon, geographical charts, and sun-dials. Anaxagoras, having been cast into prison on account of his opinions relating to Astronomy, employed his time in attempting to square the circle.

Pythagoras was one of the earliest and most successful cultivators of Geometry. He was born about 580 years before Christ, studied under Thales, and traveled in Egypt and India. On his return he settled in Italy, and there founded one of the most celebrated schools of antiquity. He is said to have discovered that in a right-angled triangle the square of the hypothenuse is equal to the sum of the squares on the two legs. He discovered that the circle has a greater area than any other plane figure having an equal perimeter, and that a sphere has a similar property among solids. He also discovered the properties of the regular solids, and the incommensurability of certain lines. One of the pupils of Pythagoras solved the problem of finding two mean proportionals between two straight lines.

Hippocrates, of the island of Chios, who lived about 400 years before Christ, was one of the best geometers of his time. He was the first who effected the quadrature of a curvilinear space by finding a rectilinear one equal to it. He showed that the crescent, bounded by lalf the circumference of one circle, and one fourth the circumference of another, is equal to
an isosceles right-angled triangle whose hypothenuse is the common chord of the two arcs. He also showed that the duplication of the cube depends on the finding of two mean proportionals between two given lines.

One of the most distinguished promoters of science among the Greeks was the celebrated philosopher Plato. He traveled in Egypt and Italy, and, on his return to Greece, made mathematics the basis of his instruction. He put an inscription over the door of his school forbidding any one to enter who did not understand Geometry; and, when questioned concerning the probable employment of the Deity, answered that he geometrized continually. Plato is reported to have invented the geometrical analysis, and the conic sections were first studied in his school.

The problem concerning the duplication of the cube acquired its celebrity about the time of Plato, who gave a solution of the problem himself, and it was also resolved by several other geometers. Another celebrated problem which occupied much attention in the school of Plato was the trisection of an angle. The geometricians of that school failed, as all others have done, in solving this problem by means of elementary Geometry. While they failed in their main object, their exertions were not thrown away, as they made valuable discoveries regarding the conic sections and other branches of Geometry. Eudoxus, a contemporary of Plato, found the measure of the pyramid and cone, and cultivated the theory of the conic sections.

After the time of Plato, the most remarkable epoch in the history of Geometry was the establishment of the school of Alexandria, about 300 years before Christ. It was here that the celebrated geometer Euclid flourished under the first of the Ptolemies. His native place is not known, but he studied at Athens, under the disciples of Plato, before he settled at Alexandria. It is recorded of Euclid that, when Ptolemy asked him whether there was no easier means of acquiring a knowledge of Geometry than that given in his Elements, he replied, "No, sir ; there is no royal road to Geometry." Euclid composed treatises on various branches of the ancient mathematics; but he is best known by his Elements, a work on Geometry and Arithmetic, in thirteen books, under which he has collected all the elementary truths of Geometry which had been found before his time. This work has been translated into the languages of all nations that have made any considerable progress in civilization since it was first published, and has been more generally used for the purposes of teaching than any other work on abstract science that has ever appeared.

Of Euclid's Elements, the first four books treat of the properties of plane figures; the fifth contains the theory of proportion, and the sixth its application to plane figures; the seventh, eighth, ninth, and tenth relate to Arithmetic, and the doctrine of incommensurables; the eleventh and twelfth contain the elements of the geometry of solids, and the thirteenth treats of the five regular solids. Two books more-viz, the fourteenth and fifteenth-on regular solids, have been attributed to Euclid, but are supposed to have been written about two centuries later.

It is only the first six, and the eleventh and twelfth, that are now much used in the schools.

After Euclid comes Archimedes, born at Syracuse about the year 287 B.C. He wrote two books on the sphere and cylinder, containing the discovery that the sphere is two thirds of the circumscribing cylinder, whether we compare their surfaces or solidities. In his book on the measure of the circle, he proves that if the diameter of a circle be reckoned unity, the circumference will be between $3 \frac{10}{70}$ and $3 \frac{10}{71}$. In his treatise on conoids and spheroids, he compares the area of an ellipse with that of a circle; and he proved that the area of any segment of a parabola cut off by a chord is two thirds of the circumscribing parallelogram.

After Archimedes comes Apollonius of Perga, in Pamphylia, born about 250 B.C. He studied in the Alexandrian school under the successors of Euclid, and so highly esteemed were his discoveries that he acquired the name of the Great Geometer. His treatise on the Conic Sections has contributed principally to his celebrity. During the five or six subsequent centuries we find a numerous list of mathematicians, most of whom are chiefly known as cultivators of Astronomy, and some as writers on Geometry. Near the close of the fourth century after Christ, Hypatia, the daughter of Theon, wrote commentaries on Apollonius and Diophantus, and was so learned in Geometry that she was judged worthy to succeed her father in the Alexandrian school. The school of Alexandria ceased in A.D. 640, when that city was taken by the Saracens.

In subsequent centuries the Arabs cultivated Astronomy and Geometry, and, after the revival of learning, the elements of Euclid were first known in Europe through the medium of an Arabic translation. In the fifteenth century, Vieta carried the approximate value of the ratio of the diameter of a circle to its circumference as far as eleven figures, and Adrianus Romanus carried the approximation as far as seventeen decimal figures. In the seventeenth century, Van Ceulen carried this approximation to thirtyfive decimal figures.

Albert Girard, a Flemish mathematician in the seventeenth century, was the first who determined the surface of a spherical triangle, or of a polygon bounded by great circles on the sphere. Kepler was the first to introduce the idea of infinity into the language of geometry. He regarded the circle as composed of an infinite number of triangles, having their vertices at the centre; the cone as composed of an infinite number of pyramids, all having the same vertex as the cone.

The application of Algebra to Geometry by Descartes, in the carly part of the seventeenth century, produced a complete revolution in this science. By bringing Geometry under the dominion of Algebra, the investigations are freed from that cumbrous formality which, however admirable in the elements of science, and however well it may be calculated to discipline the mind, is powerless in the more advanced researches of science. This application of Algebra has been reduced to a systematic form, constituting a separate branch of science, which is generally called Analytic Geometry.

During the present century Geometry has been most successfully cultivated by the French. The treatise on Elementary Geometry which, next to that of Euclid, has been most extensively adopted, is the treatise of Legendre, first published in 1794 , and which has lately received important additions and modifications by Blanchet. The present volume follows substantially the order of Blanchet's Legendre, while the form of the demonstrations is modeled after the more logical method of Euclid.

The problem of the duplication of the cube, or its equivalent, the finding of two mean proportionals between two given magnitudes, is supposed to have first called the attention of mathematicians to the conic sections. If four quantities, as $A, B, C, D$, are in continued proportion, then $\mathrm{A}^{3}: \mathrm{B}^{3}:: \mathrm{A}: \mathrm{D}$; that is, we could find a cube which should have any given ratio to a given cube, provided we could find two mean proportionals between A and D. Thus 24 and 36 are two mean proportionals between 16 and 54 . This problem can not be resolved merely by straight lines and circles-the only lines at first admitied into Geometry, and hence it became necessary to inquire what other lines would afford a solution of this and similar problems, and this investigation led to the study of the Conic Sections. We know little more than the names of the early cultivators of this branch of science, among whom are Aristæus, Euclid, Conon, and Archimedes. Archimedes demonstrated that the area of a parabola is two thirds of that of the circumscribing parallelogram; and he also showed what was the ratio of elliptic areas to their circumscribing circles, and of solids formed by the revolution of the different sections to their circumscribing cylinders.

Apollonius of Perga wrote a work on Conic Sections, consisting of eight books; the first four are supposed to comprehend all that was known on the subject before his time, and the remaining books are supposed to have contained his own discoveries. The first seven books of Apollonius's Conics have been preserved, and the eighth has been restored by Dr. Halley from the hints afforded by the account given of it by Pappus, a writer of the fourth century.

In the early ages of science, the Conic Sections were studied merely as a geometrical theory, but the discoveries of modern times have rendered it the most interesting speculation in Pure Geometry. Galileo showed that the path of a body projected obliquely in a vacuum is a parabola, and Kepler discovered that the planetary orbits are ellipses. Newton demonstrated that a body which revolves under the influence of a central force like gravitation; whose intensity decreases as the square of the distance increases, must move in one of the conic sections-that is, either a parabola, an ellipse, or an hyperbola. These discoveries have incorporated the theory of the Conic Sections with those of Astronomy and the other branches of Natural Philosophy.

## ELEMENTS OF GEOMETRY.

## BOOK I.

## GENERAL PRINCIPLES. <br> Definitions.

1. Every material object occupies a limited portion of space. The portion of space which a body occupies, considered separately from the matter of which the body is composed, is called a Geometrical solic. The material body which occupies the given space is called a Physical solicl. A geometrical solid is, therefore, merely the space occupied by a physical solid. In this treatise, only geometrical solids are considered, and they are called simply solids.

A solid is, then, a limited portion of space.
2. The surface of a solid is the limit or boundary which separates it from the surrounding space.
3. When one surface is cut by another surface, their common section is called a line.
4. When two lines cut each other, their common section is called a point.
5. Although we may derive the idea of a point from the consideration of lines, the idea of a line from the consideration of surfaces, and the idea of a surface from the consideration of a solid, we may conceive of a surface as independent of the space of which it is the boundary; we may conceive of a line as independent of the surfaces of which it is the common section, and as existing separately in space; and we may conceive of a point as independent of the lines of which it is the common section, and as having only position in space.
6. A solid has extension in all directions; but, for the purpose of measuring its magnitude more conveniently, we consider it as having three specific dimensions, called length, breadth, and thickness.
7. A surface has only two dimensions, length and breadth.

A line has only one dimension, viz., length.

A point has no extension, and therefore neither length, breadth, nor thickness.*

8. A straight line is a line which is the shortest path between any two of its points, as ABCD.
 9. A broken line is a line composed of different straight lines, as ABCDEF.
10. A curved line, or simply a curve, is a line no portion of which is straight, as ABC.
For the sake of brevity, the word line is often used to denote a straight line.

11. A plane surface, or simply a plane, is a surface in which, if any two points are taken, the straight line which joins them lies wholly in that surface. $\dagger$
12. A curved surface is a surface no portion of which is plane.
13. A geometrical figure is any combination of points, lines, surfaces, or solids.

Figures formed by points and lines in a plane are called plane figures.
14. Geometry is the science which treats of the properties of figures, of their construction, and of their measurement.
15. Plane geometry treats of plane figures. Geometry of space, or geometry of three dimensions, treats of figures all of whose points are not situated in the same plane.
16. When two straight lines meet together, their mutual inclination, or degree of opening, is called an angle. The point in which the straight lines meet is called the vertex of the angle, and the lines are called the sides of the angle. $\ddagger$

[^0]If there is only one angle at a point, it may be denoted by a letter placed at the vertex, as the angle at A.

But when several angles are formed at the same point by different lines, either of the angles may be denoted by three letters, namely, by one letteron each of its sides, together with one at its vertex, which must be written between the other two.
 Thus the lines CB, CE, CD form three different angles, which are distinguished as $\mathrm{BCE}, \mathrm{ECD}$, and BCD .
17. Angles are measured by degrees. A degree is one of the three hundred and sixty equal parts of the angular space about a point in a plane. (See B. III., Pr. 14.)
18. Angles, like other quantities, may be added, subtracted, multiplied, or divided.

Thus the angle BCD is the sum of the two angles BCE, ECD, and the angle ECD is the difference between the two angles $\mathrm{BCD}, \mathrm{BCE}$.
19. When one straight line meets another so as to make two adjacent angles equal, each of these angles is called a right angle, and the first line is said to be perpendicular to the second.

Thus, if the line CD, meeting the line AB , makes $\overline{\mathbf{A} \quad \mathbf{B}}$ the angles $\mathrm{ACD}, \mathrm{BCD}$ equal, each is a right angle, and the line $C D$ is perpendicular to $A B$.
20. An acute angle is one which is less than a right angle.

An obtuse angle is one which is greater than a right angle.
21. Intersecting lines which are not perpendicular are said to be oblique to each other, and angles which are not right angles are sometimes called oblique.
22. When the sum of two angles is equal to aright angle, each is called the complement of the other. Thus, if BCD is a right angle, BCE is the complement of DCE, and DCE is the complement of BCE.
23. When the sum of two angles is equal to two right angles, each is called the supplement of the other. Thus, if ACE and BCE are together equal to two right angles, then ACE is the supplement of BCE.

B 24. Parallel straight lines are such as are in the same plane, and which, being produced ever so far both ways, do not meet, as $\mathrm{AB}, \mathrm{CD}$.
25. A rectilineal figure, or polygon, is a portion of a plane bounded by straight lines, as ABCDEF. The bounding lines are called the sides of the polygon; and the sides, taken together, form the perimeter of the polygon.
26. A diagonal of a polygon is a line joining the vertices of two angles not adjacent to each other, as AC or AD.
27. The polygon of three sides is the simplest of all, and is called a triangle; that of four sides is called a quadrilateral; that of five, a pentagon; that of six, a hexagon, etc.

28. A triangle is called scalene when no two of its sides are equal, as ABC .

A triangle is called isosceles when tm ) of its sides are equal, as DEF.

A triangle is called equilateral when its three sides are equal, as GHI.

29. A right-angled triangle is one which has a right angle, as ABC , which is right-angled at B . The side AC, opposite to the right angle, is called the hypothenuse.

An obtuse-angled triangle is one which has an obtuse angle. An acute-angled triangle is one which has three acute angles. 30. The base of a triangle is the side upon which it is supposed
 to stand. Any side may be assumed as the base, but in an isosceles triangle that side is called the base which is not equal to either of the others. When any side $A B$ of a triangle haș been adopted as the base, the angle $A C B$ opposite to it is called the vertical angle.
31. Quadrilaterals are divided into classes as follows:

1st. The trapezium, having no two sides parallel, as ABCD.

2d. The trapezoid, which has two sides parallel.
3d. The parallelogram, which has two pairs of parallel sides.

32. Parallelograms are divided into classes as follows:

1st. The rhomboid, whose angles are not right angles, and its adjacent sides are not necessarily
 equal.

2 d . The rhombus, which is an equilateral rhomboid.

3 d . The rectangle, which has all its angles right angles, but all its sides are not necessarily equal.

4th. The square, which is an equilateral rectangle.
33. An equilateral polygon is one which has all its sides equal. An equiangular polygon is one which has all its angles equal.
34. Two polygons are mutually equilateral when the sides of the one are equal to the corresponding sides of the other, each to each, and arranged in the same order, as $\mathrm{ABCD}, \mathrm{EFGH}$. The equal sides are called homologous sides, as AB, EF.

35. Two polygons are mutually equiangular when the angles of the one are equal to the corresponding angles of the other, each to each, and arranged in the same order, as ABCD, EFGH. The equal angles are called homologous angles, as A and E.
36. A convex polygon is such that a straight line, however drawn, can not meet the perimeter of the polygon in more than two points, as ABCDE .

37. A concave polygon is such that a straight line may be drawn meeting the perimeter of the polygon in more than two points, as ABCDEFG. The angle D , contained by two re-entrant sides, is called a re-entrant angle. All the polygons hereafter considered will be understood to be convex, unless the contrary is stated.
38. An axiom is a truth assumed as self-evident.

39. A theorem is a truth which becomes evident by a train of reasoning called a demonstration.
40. A problem is a question proposed which requires a solution.
41. A postulate is a problem so simple that it is unnecessary to point out the method of performing it.
42. A proposition is a general term for either a theorem or a problem.
43. One proposition is the converse of another when the conclusion of the first is made the supposition of the second.
44. A corollary is an immediate consequence deduced from one or more propositions.
45. A scholium is a remark upon one or more propositions, pointing out their connection, their use, their limitation, or their extension.
46. An hypothesis is a supposition made either in the enunciation of a proposition or in the course of a demonstration.

## Axioms.

1. Things which are equal to the same thing, or to equals, are equal to one another:
2. If equals, or the same, be added to equals, the wholes are equal.*
3. If equals, or the same, be taken from equals, the remainders are equal.
4. If equals, or the same, be added to unequals, the wholes are unequal.
5. If equals, or the same, be taken from unequals, the remain ders are unequal.
6. Things which are doubles of the same, or of equals, are equal to one another.
7. Things which are halves of the same, or of equals, are equal to one another.
8. Magnitudes which coincide with one another, that is, which exactly fill the same space, are equal to one another.
9. The whole is greater than any of its parts.
10. The whole is equal to the sum of all its parts.

[^1]11. From one point to another only one straight line can be drawn.
12. Two straight lines which intersect one another can not both be parallel to the same straight line.

## Explanation of Signs.

For the sake of brevity, it is convenient to employ in Geometry some of the signs of Algebra. The following are those which are most frequently employed :
The sign $=$ denotes that the quantities between which it stands are equal; thus the expression $A=B$ signifies that $A$ is equal to $B$.
The sign $>$ or $<$ denotes inequality. Thus $\mathrm{A}>\mathrm{B}$ denotes that $A$ is greater than $B$; and $A<B$ denotes that $A$ is less than $B$.
The sign + is called plus, and indicates addition; thus $\mathbf{A}+\mathrm{B}$ represents the sum of the quantities A and B .
The sign - is called minus, and indicates subtraction; thus A-B represents what remains after subtracting $\mathbf{B}$ from $\mathbf{A}$.
The sign $\times$ indicates multiplication; thus $\mathbf{A} \times \mathbf{B}$ denotes the product of $A$ by $B$. Instead of the sign $\times$, a point is sometimes employed; thus $A . B$ is the same as $A \times B$. The same product is also sometimes represented without any intermediate sign, by AB ; but this expression should not be employed when there is any danger of confounding it with the line $A B$.

A parenthesis () indicates that several quantities are to be subjected to the same operation; thus the expression $\mathrm{A} \times(\mathrm{B}+$ $C-D$ ) represents the product of $A$ by the quantity $B+C-D$.
The expression $\frac{A}{B}$ indicates the quotient arising from dividing A by $B$.

A number placed before a line or a quantity is to be regarded as a multiplier of that line or quantity; thus 3 AB denotes that the line AB is taken three times; $\frac{1}{2} \mathrm{~A}$ denotes the half of A .

The square of the line $A B$ is denoted by $A B^{2}$; its cube by $\mathrm{AB}^{3}$.

The sign $\sqrt{ }$ indicates a root to be extracted; thus $\sqrt{ } 2$ denotes the square root of $2 ; \sqrt{\mathrm{A} \times \mathrm{B}}$ denotes the square root of the product of A and B.
N.B.-The first six books treat only of plane figures, or figures drawn on a plane surface.

## PROPOSITION I. THEOREM.

From a given point in a straight line one perpendicular to that line can be drawn, and but one.

Let AB be a given straight line, and C a given point in it. From the point $C$ one perpendicular can be drawn to the line $A B$, and only one can be drawn.
Suppose that while one extremity of a straight line remains fixed at C , the line itself turns about this point from the position CB to the position CD. In each of its successive positions it makes two different angles with the line AB ; one angle DCB with the portion $C B$, and another angle $A C D$ with the portion AC. While the line revolves from the position CB around to to the position AC , the angle DCB , which begins from zero, is continually increasing; while the angle ACD, which at first is greater than DCB , is continually decreasing until it becomes zero. The angle DCB, which at first was smaller than ACD, becomes at last greater than ACD. There must, therefore, be one position of the revolving line, as CE, where these two angles are equal; and it is evident that there can be but one such position. Therefore, from a given point in a straight line, one perpendicular can be drawn, and but one.*

Corollary. All right angles are equal to each other. Let the straight line DC be perpendicular to AB , and GH to EF ; then will each of the angles $\mathrm{ACD}, \mathrm{BCD}$ be equal to each of the angles $\mathrm{EGH}, \mathrm{FGH}$.

Let the line $A B$ be applied to the line EF so as to coincide with it, and in such a manner that the point $C$ shall fall upon $G$; then will the line CD take the direction GH; otherwise there would be two perpendiculars to the line $A B$ drawn from the same point C, which, by the preceding Proposition, is impossible. There-

[^2]fore the line CD must coincide with the line GH, and the angle ACD will be equal to EGH, and BCD to FGH (Axiom 8), and the four angles will be equal to each other ( Ax .1 ).

PROPOSITION II. THEOREM.
The angles which one straight line makes with another, upon one side of it, are either two right angles, or are together equal to two right angles.

Let the straight line AB make with CD , upon one side of it, the angles $\mathrm{ABC}, \mathrm{ABD}$; these are either two right angles, or are together equal to two right angles.

For if the angle $A B C$ is equal to $\triangle B D$, each of $\overline{C \quad B \quad D}$ them is a right angle (Def. 19) ; but if these angles are unequal, suppose the line BE to be drawn from the point $B$, perpendicular to $C D$; then will each of the angles CBE, DBE be a right angle. Now the angle CBA is equal to the sum of the two angles CBE, EBA. To each of these equals add $\mathbf{c}$
 the angle $A B D$; then the sum of the two angles CBA, ABD will be equal to the sum of the three angles CBE, $\mathrm{EBA}, \mathrm{ABD}(\mathrm{Ax} .2)$.

Again, the angle DBE is equal to the sum of the two angles DBA, ABE. Add to each of these equals the angle EBC; then will the sum of the two angles $\mathrm{DBE}, \mathrm{EBC}$ be equal to the sum of the three angles $\mathrm{DBA}, \mathrm{ABE}, \mathrm{EBC}$. Now things that are equal to the same thing are equal to each other (Ax. 1 ) ; therefore the sum of the angles $C B A, A B D$ is equal to the sum of the angles $\mathrm{CBE}, \mathrm{EBD}$. But $\mathrm{CBE}, \mathrm{EBD}$ are two right angles; therefore $\mathrm{ABC}, \mathrm{ABD}$ are together equal to two right angles. Therefore, the angles which one straight line, etc.

Cor. 1. If one of the angles $\mathrm{ABC}, \mathrm{ABD}$ is a right angle, the other is also a right angle.

Cor.2. If the line $D E$ is perpendicular to $A B$, conversely, AB is perpendicular to DE .

For, because DE is perpendicular to $A B$, the $\bar{\triangle} \quad \mathrm{C} \quad \mathrm{B}$ angle DCA must be equal to its adjacent angle DCB (Def. 19), and each of them must be a right
 angle. But since ACD is a right angle, its adjacent angle, ACE , must also be a right angle (Cor. 1). Hence the angle ACE is equal to the angle ACD (Pr. 1, Cor.), and AB is perpendicular to DE.

Cor. 3. The sum of all the angles BAC, CAD, DAE, EAF, formed on the same side of the line $B F$, at a common point $A$, is equal to two right angles; for their sum is equal $\overline{\mathrm{F}}$ to that of the two adjacent angles BAD, DAF, which, by the Proposition, is equal to two right angles.
proposition iil. theorem (Converse of Prop. II.). If, at a point in a straight line, two other straight lines, upon the opposite sides of it, make the adjacent angles together equal to two right angles, these two straight lines are in one and the same straight line.

At the point $B$, in the straight line $A B$, let the two straight lines $\mathrm{BC}, \mathrm{BD}$, upon the opposite sides of AB , make the adjacent
 angles, $\mathrm{ABC}, \mathrm{ABD}$, together equal to two right angles; then will BD be in the same straight line with CB.

For, if BD is not in the same straight line with CB , let BE be in the same straight line with it; then, because the straight line CBE is met by the straight line $A B$, the angles $A B C, A B E$ are together equal to two right angles (Pr. 2). But, by hypothesis, the angles $\mathrm{ABC}, \mathrm{ABD}$ are together equal to two right angles; therefore the sum of the angles $\mathrm{ABC}, \mathrm{ABE}$ is equal to the sum of the angles $\mathrm{ABC}, \mathrm{ABD}$. Take away the common angle ABC , and the remaining angle ABE is equal (Ax. 3) to the remaining angle ABD ; the less to the greater, which is impossible. Hence BE is not in the same straight line with BC ; and in like manner it may be proved that no other can be in the same straight line with it but BD. Therefore, if, at a point, etc.*

[^3]
## PROPOSITION IV. THEOREM.

Two straight lines, which have two points common, coincide with each other throughout their whole extent, and form but one and the same straight line.

Let there be two straight lines having the points $A$ and $B$ in common; these lines will coincide throughout their whole extent.

It is plain that the two lines must coincide between $A$ and $B$, for otherwise there
 would be two straight lines between $A$ and $B$, which is impossible (Ax. 11).

Suppose, however, that, on being produced, these lines begin to diverge at the point C , one taking the direction CD , and the other CE. From the point $C$ draw the line CF at right angles with AC ; then, since ACD is a straight line, the angle FCD is a right angle (Pr. 2, Cor. 1) ; and, since ACE is a straight line, the angle FCE is also a right angle; therefore (Pr. 1, Cor.) the angle FCE is equal to the angle FCD, the less to the greater, which is absurd. Therefore two straight lines which have, etc.

## PROPOSITION V. THEOREM.

If two straight lines cut one another, the vertical or opposite angles are equal.

Let the two straight lines $\mathrm{AB}, \mathrm{CD}$ cut one another in the point E ; then will the angle AEC be equal to the angle BED, and the angle AED to the angle CEB.

For the angles AEC, AED, which the straight line AE makes with the straight line CD, are to-
 gether equal to two right angles (Pr. 2) ; and the angles AED, DEB , which the straight line DE makes with the straight line AB , are also together equal to two right angles; therefore the sum of the two angles AEC, AED is equal to the sum of the two angles AED, DEB. Take away the common angle AED, and
mences with what has been already admitted or proved to be true, and from this deduces a series of other truths, till it finally arrives at the truth to be proved.

In the indirect demonstration, or, as it is also called, the reductio ad absurdum, a supposition is made which is contrary to the conclusion to be established. On this assumption a demonstration is founded, which leads to a result contrary to some known truth, thus proving the truth of the proposition by showing that the supposition of its contrary leads to an absurd conclusion.
the remaining angle AEC is equal to the remaining angle DEB (Ax. 3).
In the same manner it may be proved that the angle AED is equal to the angle CEB. Therefore, if two straight lines, etc.

Cor. 1. Hence, if two straight lines cut one another, the four angles formed at the point of intersection are together equal to four right angles.

Cor. 2. If any number of straight lines $\mathrm{AB}, \mathrm{AC}$, etc., meet at a point $A$, the sum of all the angles $\mathrm{BAC}, \mathrm{CAD}, \mathrm{DAE}, \mathrm{EAF}, \mathrm{FAB}$, will be equal to four right angles. For if two straight lines are drawn through A perpendicular to each other, the four right angles thus formed will together be equal to the sum of all the angles BAC, CAD, etc., formed about A.

## PROPOSITION VI. THEOREM.

If two triangles have two sides, and the included angle of the one equal to two sides and the included angle of the other, each to each, the two triangles will be equal, their third sides will be equal, and their other angles will be equal, each to each.

Let $\mathrm{ABC}, \mathrm{DEF}$ be two triangles, having the side AB equal to DE , and AC to DF , and also the angle A equal to the angle D ; then will the triangle ABC be equal to the triangle DEF.
For, if the triangle ABC be applied to the triangle DEF , so that the point $A$ may be on $D$, and the straight line $A B$ upon DE , the point B will coincide with the point E , because AB is equal to $\mathrm{DE} ;$ and AB coinciding with $\mathrm{DE}, \mathrm{AC}$ will coincide with DF, because the angle $A$ is equal to the angle D. Hence, also, the point $C$ will coincide with the point $F$, because $A C$ is equal to DF. But the point B coincides with the point E , therefore the base BC will coincide with the base EF (Ax. 11), and will be equal to it. Hence, also, the whole triangle ABC will coincide with the whole triangle DEF, and will be equal to it, and the remaining angles of the one will coincide with the remaining angles of the other, and be equal to them, viz., the angle ABC to the angle DEF, and the angle ACB to the angle DFE. Therefore, if two triangles, etc.

## PROPOSITION VII. THEOREM.

If two triangles have two angles, and the included side of the one equal to two angles and the included side of the other, each to each, the two triangles will be equal, the other sides will be equal each to each, and the third angle of the one to the third angle of the other.
Let ABC, DEF be two triangles having the angle $B$ equal to $E$, the angle $C$ equal to F , and the included sides BC , EF equal to each other; then will the triangle ABC be equal to the triangle DEF.

For, if the triangle ABC be applied to the triangle DEF, so that the point B may be on E , and the straight line BC upon EF , the point C will coincide with the point F , because BC is equal to EF. Also, since the angle B is equal to the angle E, the side BA will take the direction ED , and therefore the point A will be found somewhere in the line DE. And, because the angle C is equal to the angle F , the line CA will take the direction FD , and the point A will be found somewhere in the line DF; therefore the point A , being found at the same time in the two straight lines DE, DF, must fall at their intersection, D. Hence the two triangles $\mathrm{ABC}, \mathrm{DEF}$ coincide throughout, and are equal to each other; also, the two sides $\mathrm{AB}, \mathrm{AC}$ are equal to the two sides DE , DF, each to each, and the angle A to the angle D. Therefore, if two triangles, etc.

## PROPOSITION VIII. THEOREM.

Any side of a triangle is less than the sum of the other two.
Let ABC be a triangle; any one of its sides is less than the sum of the other two, viz., the side $A B$ is less than the sum of $A C$ and $B C$; $B C$ is less than the sum of $A B$ and $A C$; and
 AC is less than the sum of AB and BC .
For the straight line AB is the shortest path between the points $A$ and $B$ (Def. 8); hence $A B$ is less than the sum of $A C$ and $B C$. For the same reason, $B C$ is less than the sum of $A B$ and $A C$, and $A C$ less than the sum of $A B$ and $B C$. Therefore, any two sides etc.

## PROPOSITION IX. THEOREM.

If, from a point within a triangle, two straight lines are drawn to the extremities of either side, their sum will be less than the sum of the other two sides of the triangle.

Let the two straight lines $\mathrm{BD}, \mathrm{CD}$ be drawn from $D$, a point within the triangle $A B C$, to the extremities of the side BC ; then will the sum of BD and DC be less than the sum of $\mathrm{BA}, \mathrm{AC}$, the other two sides of the triangle.

Produce BD until it meets the side AC in E ; and, because one side of a triangle is less than the sum of the other two ( Pr .8 ), the side CD of the triangle CDE is less than the sum of CE and ED. To each of these add DB ; then will the sum of CD and BD be less than the sum of CE and EB.

Again, because the side BE of the triangle BAE is less than the sum of BA and AE , if EC be added to each, the sum of BE and $E C$ will be less than the sum of BA and AC. But it has been proved that the sum of BD and DC is less than the sum of BE and EC; much more, then, is the sum of BD and DC less than the sum of BA and AC. Therefore, if from a point, etc.

## PROPOSITION X. THEOREM.

The angles at the base of an isosceles triangle are equal to one another.

Let ABC be an isosceles triangle, of which the side AB is equal to AC ; then will the angle B be equal to the angle C .

For, conceive the angle BAC to be bisected by the straight line $A D$;* then, in the two triangles $A B D$, ACD , two sides $\mathrm{AB}, \mathrm{AD}$, and the included angle in the one, are equal to the two sides $\mathrm{AC}, \mathrm{AD}$, and the included an-

[^4]gle in the other; therefore (Pr.6) the angle B is equal to the angle C. Therefore the angles at the base, etc.

Cor. 1. Hence, also, the line BD is equal to DC , and the angle ADB equal to ADC ; consequently, each of these angles is a right angle (Def. 19). Therefore the line bisecting the vertical angle of an isosceles triangle bisects the base at right angles; and, conversely, the line bisecting the base of an isosceles triangle at right angles bisects also the vertical angle.

Cor: 2. Every equilateral triangle is also equiangular.
proposition xi. theorem (Converse of Prop. X.).
If two angles of a triangle are equal to one another, the oppo. site sides are also equal.

Let ABC be a triangle having the angle ABC equal to the angle $A C B$; then will the side $A B$ be equal to the side AC.

For if AB is not equal to AC , one of them must be greater than the other. Let AB be the greater, and from it cut off DB equal to AC the less, and join CD.

Then, because in the triangles $\mathrm{DBC}, \mathrm{ACB}, \mathrm{DB}$ is
 equal to AC , and BC is common to both triangles, also, by supposition, the angle DBC is equal to the angle ACB ; therefore the triangle DBC is equal to the triangle ACB (Pr. 6), the less to the greater, which is absurd. Hence AB is not unequal to AC , that is, it is equal to it. Therefore, if two angles, etc.

Cor. Hence every equiangular triangle is also equilateral.

## PROPOSITION XII. THEOREM.

The greater side of every triangle is opposite to the greater angle; and, conversely, the greater angle is opposite to the greater side.

Let ABC be a triangle, having the angle ABC greater than the angle ACB ; then will the side AC be greater than the side AB .

Draw the straight line BD , making the angle DBC equal to C ; then, in the triangle BCD , the side CD
 must be equal to BD (Pr. 11). Add AD to each; then will the sum of $A D$ and $D C$ be equal to the sum of $A D$ and DB . But AB is less than the sum of AD and DB (Pr. 8) ; it is, therefore, less than AC.

Conversely, if the side $A C$ is greater than the side $A B$, then will the angle ABC be greater than the angle ACB .

For if ABC is not greater than ACB , it must be
 either equal to it or less. It is not equal, because then the side AC would be equal to the side AB (Pr. 11), which is contrary to the supposition. Neither is it less, because then the side AC would be less than the side $A B$, according to the former part of this proposition; hence ABC must be greater than ACB . Therefore the greater side, etc.

## PROPOSITION XIII. THEOREM.

If two triangles have two sides of the one equal to two sides of the other, each to each, but the included angles unequal, the base of that which has the greater angle will be greater than the base of the other.

Let ABC, DEF be two triangles, having two sides of the one equal to two sides of the other, viz., AB equal to DE , and AC to DF , but the angle BAC greater than the angle EDF; then will the base BC be greater than the base EF.
Of the two sides DE, DF, let DE be the side which is not greater than the other; and at the point D , in the straight line DE, make the angle EDG equal to BAC ; make DG equal to AC or DF, and join EG.

Because, in the triangles $\mathrm{ABC}, \mathrm{DEG}, \mathrm{AB}$ is equal to DE , and AC to DG ; also, the angle BAC is equal to the angle EDG ; therefore the base BC is equal to the base EG (Pr. 6).

Draw the line DH bisecting the angle FDG, and meeting EG in H , and join FH . Now, because the angle FDH is equal to the angle GDH, also DG is equal to DF, and DH is common to the two triangles FDH, GDH, therefore FH is equal to GH (Pr. 6). Adding EI to each of these equals, we have the sum of EH and HF equal to the sum of EH and HG, or EG. But the sum of EH and HF is greater than EF (Pr. 8). Hence EG, or its equal BC, is greater than EF. Therefore, if two triangles, etc.
proposition xiv. theoren (Converse of Prop. XIII.).
If two triangles have two sides of the one equal to two sides of the other, each to each, but the bases unequal, the angle contained by the sides of that which has the greater base will be greater than the angle contained by the sides of the other.

Let $\mathrm{ABC}, \mathrm{DEF}$ be two triangles having two sides of the one equal to two sides of the other, viz., AB equal to DE , and AC to DF , but the base BC greater than the base EF; then will the angle BAC be greater than the angle EDF.

For if it is not greater, it must be either
 equal to it, or less. But the angle BAC is not equal to the angle EDF, because then the base BC would be equal to the base EF (Pr.6), which is contrary to the supposition. Neither is it less, because then the base BC would be less than the base EF (Pr. 13 ), which is also contrary to the supposition; therefore the angle BAC is not less than the angle EDF, and it has been proved that it is not equal to it; hence the angle BAC must be greater than the angle EDF. Therefore, if two triangles, ctc.

## PROPOSITION XV. TIIEOREM.

If troo triangles have the thrce sides of the one equal to the three sides of the other, each to each, the three angles voill also be equal, each to each, and the triangles themselves vill be equal.

Let ABC, DEF be two triangles having the three sides of the one equal to the three sides of the other, viz., AB equal to $\mathrm{DE}, \mathrm{BC}$ to EF, and AC to DF; then will the three angles also be equal,
 viz., the angle $A^{\prime}$ to the angle $D$, the angle $B$ to the angle $E$, and the angle $\mathbf{C}$ to the angle F .

Suppose the triangle ABC to be placed so that its base BC coincides with its equal EF, but so that its vertex A falls on the opposite side of EF from $D$, as at G. Join DG; and because ED and $E G$ are each equal to $A B$, they are equal to each other, and the triangle EDG is isosceles; therefore the angle EDG is equal to the angle EGD (Pr. 10).

In the same manner it may be shown that the angle FDG is
equal to the angle FGD. Therefore, adding equals to equals, the two angles EDG, FDG are together equal to the two angles EGD, FGD; that is, the angle EDF is equal to the angle EGF. But the angle EGF is, by hypothesis, equal to the angle BAC; therefore also the angle BAC is equal to the angle EDF .

Since the two sides AB and AC are equal to the two sides DE and DF, each to each, and their included angles BAC, EDF are also equal, the two triangles $\mathrm{ABC}, \mathrm{DEF}$ are equal (Pr.6), and their other angles are equal each to each, viz., the angle ABC to the angle DEF, and the angle ACB to the angle DFE. Therefore, if two triangles, etc.

Scholium. In equal triangles, the equal angles are opposite to the equal sides; thus the equal angles A and D are opposite to the equal sides BC, EF.

PROPOSITION XVI. THEOREM.
From a given point without a straight line, only one perpendicular can be drawn to that line.

Let A be the given point, and DE the given straight line; from the point A only one perpendicular can be drawn to DE.

For, if possible, let there be drawn two perpendiculars $\mathrm{AB}, \mathrm{AC}$. Produce the line AB to F , making BF equal to AB , and join CF .

Then, in the triangles $\mathrm{ABC}, \mathrm{FBC}$, because AB is equal to $\mathrm{BF}, \mathrm{BC}$ is common to both triangles, and the angle ABC is equal to the angle FBC, being both right angles (Pr. 2, Cor. 1) ; therefore two sides and the included angle of one triangle, are equal to two sides and the included angle of the other triangle; hence the angle ACB is equal to the angle FCB (Pr. 6).

But, since the angle $A C B$ is, by supposition, a right angle, FCB must also be a right angle; and the two adjacent angles $\mathrm{BCA}, \mathrm{BCF}$, being together equal to two right angles, the two straight lines AC, AF must form one and the same straight line (Pr. 3) ; that is, between the two points A and F , two straight lines, $\mathrm{ABF}, \mathrm{ACF}$, may be drawn, which is impossible (Ax. 11); hence AB and AC can not both be perpendicular to DE . Therefore, from a point, etc.

## PROPOSITION XVII. THEOREM.

If, from a point without a straight line, a perpendicular be drawn to this line, and oblique lines be drawon to different points:
1st. The perpendicular will be shorter than any oblique line.
2d. Two oblique lines, which meet the proposed line at equal distances from the foot of the perpendicular, will be equal.

3d. Of any two oblique lines, that which is further from the perpendicular will be the longer.
Let DE be the given straight line, and A any point without it. Draw AB perpendicular to DE ; draw, also, the oblique lines AC , $\mathrm{AD}, \mathrm{AE}$. Produce the line AB to F , making BF equal to AB , and join $\mathrm{CF}, \mathrm{DF}$.
First. Because, in the triangles $\mathrm{ABC}, \mathrm{FBC}$, AB is equal to $\mathrm{BF}, \mathrm{BC}$ is common to the two
 triangles, and the angle ABC is equal to the angle FBC , being both right angles (Pr. 2, Cor. 1); therefore two sides and the included angle of one triangle are equal to two sides and the included angle of the other triangle; hence the side $\mathbf{C F}$ is equal to the side CA (Pr. 6).
But the straight line ABF is shorter than the broken line ACF (Pr. 8) ; hence AB, the half of ABF, is shorter than AC, the half of ACF. Therefore the perpendicular AB is shorter than any oblique line, AC.

Secondly. Let AC and AE be two oblique lines which meet the line DE at equal distances from the foot of the perpendicular; they will be equal to each other.

For, in the triangles $\mathrm{ABC}, \mathrm{ABE}, \mathrm{BC}$ is equal to $\mathrm{BE}, \mathrm{AB}$ is common to the two triangles, and the angle ABC is equal to the angle ABE, being both right angles (Pr. 1, Cor.) ; therefore two sides and the included angle of one triangle are equal to two sides and the included angle of the other; hence the side AC is equal to the side AE (Pr. 6). Wherefore two oblique lines, equally distant from the perpendicular, are equal.

Thirdly. Let AC, AD be two oblique lines, of which AD is further from the perpendicular than AC ; then will AD be longer than AC . For it has already been proved that AC is equal to CF , and in the same manner it may be proved that AD is equal to DF. Now, by Pr. 9 , the sum of the two lines AC, CF is less than the sum of the two lines $\mathrm{AD}, \mathrm{DF}$. Therefore AC , the half
of ACF , is less than AD , the half of ADF ; hence the oblique line which is furthest from the perpendicular is the longest. Therefore, if from a point, etc.

Cor. 1. The perpendicular measures the shortest distance of a point from a line, because it is shorter than any oblique line. This shortest distance is frequently called the truc distance, or simply the distance.

Cor. 2. It is impossible to draw three equal straight lines from the same point to a given straight line.

PROPOSITION XVIII. THEOREM.
If through the middle point of a straight line a perpendicular is drazon to this line:

1st. Each point in the perpendicular is equally distant from the two extremities of the line.

2d. Any point out of the perpendicular is unequally distant from those extremities.

Let the straight line EF be drawn perpendicular to AB through its middle point, C .

First. Every point of EF is equally distant from the extremities of the line $A B$; for, since $A C$ is equal to CB , the two oblique lines $\mathrm{AD}, \mathrm{DB}$ are equally distant from the perpendicular, and are, therefore, equal (Pr. 17).

So, also, the two oblique lines $\mathrm{AE}, \mathrm{EB}$ are equal, and the oblique lines $\mathrm{AF}, \mathrm{FB}$ are equal; therefore every point of the perpendicular is equally distant from the extremities $\mathbf{A}$ and B .

Secondly. Let I be any point out of the perpendicular. Draw the straight lines $I \mathrm{~A}, \mathrm{IB}$; one of these lines must cut the perpendicular in some point, as D . Join DB; then, by the first case, AD is equal to DB . To each of these equals add ID; then will IA be equal to the sum of $I D$ and $D B$. Now, in the triangle IDB, $I B$ is less than the sum of $I D$ and $D B(\operatorname{Pr} .8)$; it is, therefore, less than IA; hence every point out of the perpendicular is unequally distant from the extremities $A$ and $B$.

Cor. If a straight line have two points, each of which is equally distant from the two extremities of a second line, it will be perpendicular to the second line at its middle point.

## PROPOSITION XIX. THEOREM.

If two right-angled triangles have the hypothenuse and a side of the one equal to the hypothenuse and a side of the other, each to each, the triangles are equal.

Let $\mathrm{ABC}, \mathrm{DEF}$ be two right- A angled triangles, having the hypothenuse AC and the side AB of the one equal to the hypothenuse DF and side DE of the oth-
 er ; then will the side BC be equal to EF , and the triangle ABC to the triangle DEF.

For if BC is not equal to EF , one of them must be greater than the other. Let BC be the greater, and from it cut off BG equal to EF the less, and join AG.

Then, in the triangles $\mathrm{ABG}, \mathrm{DEF}$, because AB is equal to DE , $B G$ is equal to EF , and the angle B equal to the angle E , both of them being right angles, the two triangles are equal (Pr.6), and AG is equal to DF. But, by hypothesis, AC is equal to DF, and therefore $A G$ is equal to $A C$. Now the oblique line $A C$, being further from the perpendicular than $A G$, is the longer $(\operatorname{Pr.} 17)$, and it has been proved to be equal, which is impossible. Hence BC is not unequal to EF ; that is, it is equal to it; and the triangle ABC is equal to the triangle DEF (Pr.15). Therefore, if two right-angled triangles, etc.

## PROPOSITION XX. THEOREM.

Troo straight lines perpendicular to the same straight line are parallel.

Let the two straight lines AC, BD be both perpendicular to AB ; then is AC parallel to BD.

For if these lines are not parallel, being produced, they must
 meet on one side or the other of
AB . Let them be produced, and meet in O ; then there will be two perpendiculars, $\mathrm{OA}, \mathrm{OB}$, let fall from the same point, on the same straight line, which is impossible (Pr.16). Therefore two straight lines, etc.

## PROPOSITION XXI. THEOREM.

If a straight line meeting two other straight lines makes the in. terior angles on the same side together equal to two right angles, the two lines are parallel.

Let the straight line $A B$, which meets the two straight lines $A C, B D$, make the interior angles on the same side, BAC , ABD , together equal to two right angles; then is AC parallel to BD.

From $G$, the middle point of the line AB , draw EFG perpendicular to AC ; it will also be perpendicular to BD.

For the sum of the angles ABD and ABF is equal to two right angles (Pr. 2) ; and, by hypothesis, the sum of the angles ABD and BAC is equal to two right angles. Therefore the sum of ABD and ABF is equal to the sum of ABD and BAC . Take away the common angle ABD , and the remainder, ABF , is equal to BAC ; that is, GBF is equal to GAE.

Again, the angle BGF is equal to the angle AGE (Pr. 5) ; and, by construction, BG is equal to GA; hence the triangles BGF, AGE have two angles and the included side of the one equal to two angles and the included side of the other; they are, therefore, equal (Pr. 7) ; and the angle BFG is equal to the angle AEG. But AEG is, by construction, a right angle, whence BFG is also a right angle ; that is, the two straight lines EC, FD are perpendicular to the same straight line, and are consequently parallel (Pr. 20). Therefore, if a straight line, etc.

Scholium. When two parallel lines AB, CD are cut by a third line EF, called the secant line, the eight angles formed at the points of intersection are named as follows:

1 st. The four angles $1,2,3,4$, without the parallel lines, are called exterior angles.

2 d . The four angles $5,6,7,8$, within the parallel lines, are called interior angles.

3d. The two angles on opposite sides of the secant line, and not adjacent, are called alternate angles, as 1 and 3 , or 2 and 4. Also, 5 and 7 , or 6 and 8 .

## PROPOSITION XXII. THEOREM.

If a straight line intersecting two other straight lines makes the alternate angles equal to each other, or makes an exterior angle equal to the interior and remote upon the same side of the secant line, these two lines are parallel.

Let the straight line EF, which intersects the two straight lines $\mathrm{AB}, \mathrm{CD}$, make the alternate angles AGH, GHD equal to each other; then AB is parallel to CD.

For, to each of the equal angles AGH, GHD, add the angle HGB; then the sum of AGH and HGB will be equal to the sum of GHD and HGB. But AGH and HGB are equal to two right angles (Pr. 2) ; therefore GHD and HGB are equal to two right angles; and hence AB is parallel to CD (Pr. 21).

Again, if the exterior angle EGB is equal to the interior and remote angle GHD, then is AB parallel to CD.

For, the angle AGH is equal to the angle EGB (Pr. 5) ; and, by supposition, EGB is equal to GHD ; therefore the angle AGH is equal to the angle GHD, and they are alternate angles; hence, by the first part of the proposition, AB is parallel to CD. Therefore, if a straight line, etc.

## PROPOSITION XXIII. THEOREM.

 (Converse of Propositions XXI. and XXII.)If a straight line intersect twoo parallel lines, it makes the alternate angles equal to each other; also, any exterior angle equal-to the interior and remote on the same side; and the two interior angles on the same side together equal to two right angles.

Let the straight line EF intersect the two parallel lines $\mathrm{AB}, \mathrm{CD}$; the alternate angles AGH, GHD are equal to each other; the exterior angle EGB is equal to the interior and remote angle on the same side, GIID; and the two interior angles on the same side, BGH, GHD, are together equal to two right angles.

For, if AGH is not equal to GHD, through G draw the line KL, making the angle KGH equal to GHD ; then KL must be B 2
parallel to $\mathrm{CD}(\operatorname{Pr} .22)$. But, by supposition, AB is parallel to CD ; therefore, through the same point, G , two straight lines have been drawn parallel to CD, which is impossible (Ax. 12). Therefore the angles AGH, GHD are not unequal; that is, they are equal to each other.

Now the angle AGH is equal to EGB (Pr. 5), and AGH has been proved equal to GHD ; therefore EGB is also equal to GHD. Add to each of these equals the angle BGH; then will the sum of EGB, BGH be equal to the sum of BGH, GHD. But EGB, BGH are equal to two right angles (Pr. 2) ; therefore, also, BGH, GHD are equal to two right angles. Therefore, if a straight line, etc.

Cor. 1. If a straight line is perpendicular to one of two parallel lines, it is also perpendicular to the other.

Cor, 2. Of the eight angles formed by a line cutting two parallel lines obliquely, the four acute angles are equal to each other , and the four obtuse angles are also equal to each other.

Cor. 3. If two lines, KL and CD, make with EF the two angles KGH, GHC, together less than two right angles, then will KI, and CD meet, if sufficiently produced.

For if they do not meet they are parallel (Def. 24). But they are not parallel; for then the angles KGH, GHC would be equal to two right angles.

It is evident that the two lines KL and CD will meet on that side of EF on which the sum of the two angles KGII, GHC is less than two right angles.

## PROPOSITION XXIV. THEOREM.

Straight lines which are parallel to the same line are parallel to each other.

Let the straight lines $\mathrm{AB}, \mathrm{CD}$ be each of them parallel to the line EF; then will AB be parallel to CD .
For, draw any straight line, as PQR , perpendicular to EF. Then, since AB is parallel to EF, PR, which is perpendicular to EF, will also be perpendicular to AB (Pr. 23, Cor. 1) ; and, since CD is parallel to $\mathrm{EF}, \mathrm{PR}$ will also
be perpendicular to CD. Hence AB and CD are both perpendicular to the same straight line, and are consequently parallel (Pr. 20). Therefore, straight lines which are parallel, etc.

## PROPOSITION XXV. THEOREM.

Tivo parallel straight lines are every where equally distant from each other.

Let $\mathrm{AB}, \mathrm{CD}$ be two parallel straight lines. From any points, $E$ and $F$, in one of them, draw the lines EG, FH perpendicular to AB ; they will also be perpendicular to
 CD (Pr. 23, Cor. 1). Join EH; then, because EG and FH are perpendicular to the same straight line AB , they are parallel ( Pr . 20 ); therefore the alternate angles, EHF, HEG, which they make with HE, are equal (Pr. 23).

Again, because AB is parallel to CD , the alternate angles GHE , HEF are also equal. Therefore the triangles HEF, EHG have two angles of the one equal to two angles of the other, each to each, and the side EH, included between the equal angles, common; hence the triangles are equal ( $\operatorname{Pr} .7$ ) ; and the line EG, which measures the distance of the parallels at the point $E$, is equal to the line FH , which measures the distance of the same parallels at the point F. Therefore, two parallel straight lines, etc.

## PROPOSITION XXVI. THEOREM.

If two angles have their sides parallel each to each, the two angles will either be equal, or supplements of each other.

Let AB be parallel to DE , and BC to EF; then the angle ABC will be equal to the angle DEF, and the angle ABC will be the supplement of the angle DEH.

Produce DE, if necessary, until it meets BC in G. Then, because EF is parallel to GC, the angle DEF is equal to DGC (Pr. 23) ; and, be-
 cause $D G$ is parallel to $A B$, the angle $D G C$ is equal to $A B C$; hence the angle DEF is equal to the angle ABC (Ax. 1). But the angle DEH is the supplement of DEF (Pr. 2). Hence ABC is the supplement of DEH. Therefore, if two angles, etc.

Scholium. Two angles are equal when their sides are not only parallel, but both lie in the same direction, as $\mathrm{ABC}, \mathrm{DEF}$; or both lie in opposite directions, as ABC, HEK. They are supple-
ments of each other when their sides are parallel and two of their sides lie in the same direction, while the other two lie in opposite directions, as $\mathrm{ABC}, \mathrm{DEH}$.

## PROPOSITION XXVII. TIIEOREM.

If one side of a triangle is produced, the exterior angle is equal to the sum of the two interior and remote angles; and the sum of the three interior angles of every triangle is equal to two right angles.

Let ABC be any plane triangle, and let the side $B C$ be produced to $D$; then will the exterior angle ACD be equal to the sum of the two interior and remote angles A and B ; and the D sum of the three angles $\mathrm{ABC}, \mathrm{BCA}, \mathrm{CAB}$ is equal to two right angles.

For, conceive CE to be drawn parallel to the side AB of the triangle; then, because AB is parallel to CE , and AC meets them, the alternate angles BAC, ACE are equal ( Pr . 23).

Again, because AB is parallel to CE , and BD meets them, the exterior angle ECD is equal to the interior and remote angle ABC . But the angle ACE was proved equal to BAC; therefore the whole exterior angle ACD is equal to the two interior and remote angles $\mathrm{CAB}, \mathrm{ABC}$ (Ax. 2). To each of these equals add the angle $A C B$; then will the sum of the two angles $A C D, A C B$ be equal to the sum of the three angles $\mathrm{ABC}, \mathrm{BCA}, \mathrm{CAB}$. But the angles $\mathrm{ACD}, \mathrm{ACB}$ are equal to two right angles (Pr. 2) ; hence, also, the angles $\mathrm{ABC}, \mathrm{BCA}, \mathrm{CAB}$ are together equal to two right angles. Therefore, if one side of a triangle, etc.

Cor. 1. If the sum of two angles of a triangle is given, the third may be found by subtracting this sum from two right angles.

Cor. 2. If two angles of one triangle are equal to two angles of another triangle, the third angles are equal, and the triangles are mutually equiangular.

Cor. 3. A triangle can have but one right angle; for if there were two, the third angle would be nothing. Still less can a triangle have more than one obtuse angle.

Cor. 4. In a right-angled triangle, the sum of the two acute angles is equal to one right angle; that is, each of the acute angles is the complement of the other.

Cor. 5. In an equilateral triangle, each of the angles is one third of two right angles, or two thirds of one right angle.

## PROPOSITION XXVIII. THEOREM.

All the interior angles of a polygon, together with four right angles, are equal to twice as many right angles as the figure has sides.

Let $A B C D E$ be any polygon; then all its interior angles $A, B, C, D, E$, together with four right angles, are equal to twice as many right angles as the figure has sides.

For, from any point, F, within it, draw lines FA, FB, FC, etc., to all the angles. The poly-
 gon is thus divided into as many triangles as it has sides.

Now the sum of the three angles of each of these triangles is equal to two right angles (Pr. 27); therefore the sum of the angles of all the triangles is equal to twice as many right angles as the polygon has sides. But the same angles are equal to the angles of the polygon, together with the angles at the point $F$, that is, together with four right angles (Pr. 5, Cor. 2). Therefore the angles of the polygon, together with four right angles, are equal to twice as many right angles as the figure has sides.

Scholium. When this proposition is applied to concave polygons (Def. 37), each re-entering angle is to be regarded as greater than two right angles.

Cor. The sum of the angles of a quadrilateral is four right angles; of a pentagon, six right angles; of a hexagon, eight, etc.

## PROPOSITION XXIX. THEOREM.

If all the sides of any polygon be produced so as to form an exterior angle at each vertex, the sum of these exterior angles will be equal to four right angles.

Let all the sides of the polygon ABC , etc., be produced in the same direction; that is, so as to form one exterior angle at each vertex ; then will the sum of the exterior angles be equal to four right angles.

For each interior angle ABC , together with its adjacent exterior angle $A B D$, is equal to two right angles (Pr. 2) ; therefore the sum of all the interior and exterior angles is equal to twice as many right angles as there are sides of the polygon; that is, they are equal to all the interior angles of the polygon, together with four right angles. Hence
the sum of the exterior angles must be equal to four right angles (Ax. 3). Therefore, if all the sides, etc.

- PROPOSITION XXX. THEOREM.

The opposite sides and angles of a parallelogram are equal to each other.

Let ABCD be a parallelogram; then will its opposite sides and angles be equal to each other.

Draw the diagonal BD ; then, because AB is parallel to CD , and BD meets them, the alternate angles $\mathrm{ABD}, \mathrm{BDC}$ are equal to each other (Pr. 23).

Also, because AD is parallel to BC , and BD meets them, the alternate angles $\mathrm{BDA}, \mathrm{DBC}$ are equal to each other. Hence the two triangles $\mathrm{ABD}, \mathrm{BDC}$ have two angles, $\mathrm{ABD}, \mathrm{BDA}$ of the one, equal to two angles, $\mathrm{BDC}, \mathrm{CBD}$ of the other, each to each, and the side BD included between these equal angles common to the two triangles; therefore their other sides are equal, each to each, and the third angle of the one to the third angle of the other ( $\operatorname{Pr} .7$ ), viz., the side $A B$ to the side $C D$, and $A D$ to $B C$, and the angle $B A D$ equal to the angle $B C D$.

Also, because the angle ABD is equal to the angle BDC , and the angle CBD to the angle BDA , the whole angle ABC is equal to the whole angle ADC. But the angle BAD has been proved equal to the angle BCD ; therefore the opposite sides and angles of a parallelogram are equal to each other.

Cor.1. Two parallels, $\mathrm{AB}, \mathrm{CD}$, comprehended between two other parallels, $\mathrm{AD}, \mathrm{BC}$, are equal ; and the diagonal BD divides the parallelogram into two equal triangles.

Cor. 2. If one angle of a parallelogram is a right angle, all its angles are right angles, and the figure is a rectangle.

## proposition xxxi. theorem (Converse of Prop. $X X X$.)

If the opposite sides of a quadrilateral are equal, each to each, the equal sides are parallel, and the figure is a parallelogram.

Let ABDC be a quadrilateral, having its opposite sides equal to each other, viz., the side AB equal to CD , and AC to BD ; then will the equal sides be parallel, and the figure will be a parallelogram.
Draw the diagonal BC ; then the triangles $\mathrm{ABC}, \mathrm{BCD}$ have all the sides of the one equal to the corresponding sides of the other,
each to each; therefore the angle ABC is equal to the angle BCD (Pr. 15), and, consequently, the side AB is parallel to CD ( $\mathrm{Pr}: 22$ ). For a like reason, AC is parallel to BD ; hence the quadrilateral ABDC is a parallelogram. Therefore, if the opposite sides, etc.

## PROPOSITION XXXII. THEOREM.

If two opposite sides of a quadrilateral are equal and parallel, the other two sides are equal and parallel, and the figure is a parallelogram.

Let ABDC be a quadrilateral, having the sides $\mathrm{AB}, \mathrm{CD}$ equal and parallel; then will the sides $\mathrm{AC}, \mathrm{BD}$ be also equal and parallel, and the figure will be a parallelogram.

Draw the diagonal BC ; then, because AB is
 parallel to CD , and BC meets them, the alternate angles ABC , BCD are equal ( Pr .23 ).

Also, because AB is equal to CD , and BC is common to the two triangles $\mathrm{ABC}, \mathrm{BCD}$, the two triangles $\mathrm{ABC}, \mathrm{BCD}$ have two sides and the included angle of the one equal to two sides and the included angle of the other; therefore the side AC is equal to BD ( Pr .6 ), and the angle ACB to the angle CBD.

And, because the straight line BC meets the two straight lines $\mathrm{AC}, \mathrm{BD}$, making the alternate angles $\mathrm{BCA}, \mathrm{CBD}$ equal to each other, AC is parallel to $\mathrm{BD}(\mathrm{Pr} .22)$; hence the figure ABDC is a parallelogram. Therefore, if two opposite sides, etc.

PROPOSITION XXXIII. THEOREM.
The cliagonals of every parallelogram bisect each other.
Let ABCD be a parallelogram, whose diagonals $\mathrm{AC}, \mathrm{BD}$ intersect each other in E ; then will AE be equal to EC , and BE to ED .

Because the alternate angles $\mathrm{ABE}, \mathrm{EDC}$ are
 equal (Pr. 23), and also the alternate angles $\mathrm{EAB}, \mathrm{ECD}$, the triangles $\mathrm{ABE}, \mathrm{CDE}$ have two angles in the one equal to two angles in the other, each to each, and the included sides $\mathrm{AB}, \mathrm{CD}$ are also equal; hence the remaining sides are equal, viz., AE to EC , and DE to EB. Therefore the diagonals of every parallelogram, etc.

Cor. If the side AB is equal to AD , the triangles $\mathrm{AEB}, \mathrm{AED}$ have all the sides of the one equal to the corresponding sides of the other, and are consequently equal; hence the angle AEB will equal the angle AED, and therefore the diagonals of a rhombus bisect each other at right angles.

## B O OK II.

## RATIO AND PROPORTION.

## On the Relation of Magnitudes to Numbers.

1. To measure a quantity is to find how many times it contains another quantity of the same kind called the unit.

To measure a line is to find how many times it contains another line called the unit of length, or the linear unit. Thus, when a line is said to be fifteen feet in length, it is to be understood that the line has been compared with the unit of length (one foot), and found to contain it fifteen times.

The number which expresses how many times a quantity contains the unit is called the numerical measure of that quantity.
2. Ratio is that relation between two quantities which is expressed by the quotient of the first divided by the second. Thus the ratio of 12 to 4 is $\frac{12}{4}$. The ratio of $A$ to $B$ is $\frac{A}{B}$. The two quantities compared together are called the terms of the ratio; the first is called the antecedent, and the second the consequent.
3. To find the ratio of one quantity to another is to find how many times the first contains the second; i.e., it is to measure the first by the second taken as the unit. If $B$ be taken as the unit of measure, the quotient $\frac{A}{\bar{B}}$ is the numerical value of $A$ expressed in terms of this unit.

The ratio of two quantities is the same as the ratio of their numerical measures. Thus, if $p$ denotes the unit, and if $p$ is contained $m$ times in A, and $n$ times in B, then

$$
\frac{\mathrm{A}}{\mathrm{~B}}=\frac{m p}{n p}=\frac{m}{n}
$$

4. Two quantities are said to be commensurable when there is a third quantity of the same kind which is contained an exact number of times in each. This third quantity is called the common measure of the two given quantities.

$B$ Thus the two lines $A B, C D$ are commensurable if there is a third line, MN, which is contained an exact number of times in each; $\xrightarrow{M}$ for example, 7 times in AB , and 4 times in CD.

The ratio of two commensurable quantities can therefore be exactly expressed by a number either whole or fractional. The ratio of AB to CD is $\frac{7}{4}$.
5. Two quantities are said to be incommensurable when they have no common measure. Thus the diagonal and side of a square are said to be incommensurable (see B. IV., Pr. 35) ; also the circumference and diameter of a circle (see B.VI., Pr. 11).

Whether A and B are commensurable or not, their ratio is expressed by $\frac{A}{\bar{B}}$.
6. To find the numerical ratio of two given straight lines. Suppose AB and CD are two straight $\mathbf{A} \quad$ E G B lines whose numerical ratio is required.

From the greater line, AB , cut off

a part equal to the less, CD , as many times as possible; for example, twice with a remainder EB less than CD. From CD cut off a part equal to the remainder EB as often as possible; for example, once with a remainder FD. From the first remainder BE cut off a part equal to FD as often as possible; for example, once with a remainder GB. From the second remainder FD cut off a part equal to the third GB as many times as possible. Continue this process until a remainder is found which is contained an exact number of times in the preceding one. This last remainder will be the common measure of the proposed lines; and, regarding it as the measuring unit, we may easily find the values of the preceding remainders, and at length those of the proposed lines, whence we obtain their ratio in numbers.

For example, if we find GB is contained exactly twice in FD, GB will be the common measure of the two proposed lines; for we have $\quad \mathrm{FD}=2 \mathrm{~GB}$;

$$
\begin{aligned}
& \mathrm{EB}=\mathrm{FD}+\mathrm{GB}=2 \mathrm{~GB}+\mathrm{GB}=3 \mathrm{~GB} ; \\
& \mathrm{CD}=\mathrm{EB}+\mathrm{FD}=3 \mathrm{~GB}+2 \mathrm{~GB}=5 \mathrm{~GB} ; \\
& \mathrm{AB}=2 \mathrm{CD}+\mathrm{EB}=10 \mathrm{~GB}+3 \mathrm{~GB}=13 \mathrm{~GB}
\end{aligned}
$$

The ratio of the two lines $A B, C D$ is therefore equal to that of 13 GB to 5 GB , or $\frac{13}{5}$.
7. It is possible that, however far this operation is continued, we may never find a remainder which is contained an exact number of times in the preceding one. In such a case, the two quan-
tities have no common measure ; that is, they are incommensurable, and their ratio can not be exactly expressed by any number, whole or fractional.
8. But, although the ratio of incommensurable quantities can not be exactly expressed by a number, yet, by taking the measuring unit sufficiently small, a ratio may always be found which shall approach as near as we please to the true ratio.

Suppose $\frac{A}{B}$ denotes the ratio of two incommensurable quantities A and B , and let it be required to obtain a numerical expression of this ratio which shall be correct within an assigned measure of precision, say $\frac{1}{100}$. Let B be divided into 100 equal parts, and suppose $A$ is found to contain 141 of these parts, with a remainder less than one of the parts; then we have

$$
\frac{\mathrm{A}}{\mathrm{~B}}=\frac{141}{100} \text { within } \frac{1}{100}
$$

that is, $\frac{141}{100}$ is an approximate value of the ratio $\frac{A}{B}$, within the assumed measure of precision. In the same manner, by dividing B into a greater number of equal parts, the error of our approximate value may be made as small as we please.
9. To generalize this reasoning, let B be divided into $n$ equal parts, and let A contain $m$ of these parts with a remainder less than one of the parts; then we have

$$
\frac{\mathrm{A}}{\bar{B}}=\frac{m}{n} \text { within } \frac{1}{n} ;
$$

and since $n$ may be taken as great as we please, $\frac{1}{n}$ may be made less than any assigned measure of precision, and $\frac{m}{n}$ will be the approximate value of the ratio $\frac{\mathrm{A}}{\mathrm{B}}$, within the assigned limit.
10. The ratio of any two magnitudes A and B is equal to the ratio of two other magnitudes $\mathbf{A}^{\prime}$ and $\mathbf{B}^{\prime}$, when the same number expresses the value of either ratio to the same degree of approximation, however far the approximation may be carried.

Let $\frac{m}{n}$ represent the approximate value of either ratio, and let B be divided into $n$ equal parts; then A will contain $m$ of these parts plus a remainder which is less than one of the parts; that
is, the numerical expression of the ratio $\frac{A}{B}$ will be $\frac{m}{n}$ correct within $\frac{1}{n}$ part. Hence the ratio $\frac{A}{\bar{B}}$ can not differ from the ratio $\frac{A^{\prime}}{\overline{B^{\prime}}}$ by so much as $\frac{1}{n}$. But the measure $\frac{1}{n}$ may be assumed as small as we please; that is, less than any assignable quantity, however small. Hence $\frac{A}{\mathbf{B}}$ can not differ from $\frac{A^{\prime}}{\mathbf{B}^{\prime}}$ by any assignable quantity, however small; that is, the two ratios are equal to each other.
For an application of this principle, see B. III., Pr. 14.
11. A proportion is an equality of ratios. Thus, if the ratio $\frac{A}{B}$ is equal to the ratio $\frac{C}{D}$, the equality

$$
\frac{A}{B}=\frac{C}{\bar{D}}
$$

constitutes a proportion. It may be read, the ratio of $\mathbf{A}$ to $\mathbf{B}$ equals the ratio of C to D ; or A is to B as C to D .

A proportion is often written

$$
\mathrm{A}: \mathrm{B}=\mathrm{C}: \mathrm{D},
$$

or, $\quad \mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
where the notation $\mathrm{A}: \mathrm{B}$ is equivalent to $\mathrm{A} \div \mathrm{B}$. The first and last terms of a proportion are called the two extremes; the second and third terms are called the two means. Of four proportional quantities, the last is called a fourth proportional to the other three taken in order.

$$
\text { Since } \quad \overline{\mathrm{B}}=\frac{\mathrm{C}}{\mathrm{D}},
$$

it is obvious that if A is greater than $\mathrm{B}, \mathrm{C}$ must be greater than D ; that is, if one antecedent is greater than its consequent, the other antecedent must be greater than its consequent; if equal, equal; and if less, less.
12. Three quantities are said to be proportional when the ratio of the first to the second is equal to the ratio of the second to the third; thus, if $A, B$, and $C$ are in proportion, then

$$
\begin{aligned}
& A: B: B: C, \\
& A: B=B: C .
\end{aligned}
$$

In this case the middle term is said to be a mean proportional between the other two, and C is called a third proportional to $A$ and B,
13. Equimultiples of two magnitudes are the products arising
from multiplying those magnitudes by the same number. Thus $7 \mathrm{~A}, 7 \mathrm{~B}$ are equimultiples of A and B ; so also are $m \mathrm{~A}$ and $m \mathrm{~B}$.

Geometers make use of the following technical terms to signify certain ways of changing either the order or magnitude of proportionals, so that they continue still to be proportionals.
14. Alternation is when antecedent is compared with antecedent, and consequent with consequent.

Thus, if

$$
\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D},
$$

then, by alternation, $\quad \mathrm{A}: \mathrm{C}:: \mathrm{B}: \mathrm{D}$.
15. Inversion is when the antecedents are made the consequents, and the consequents the antecedents.

Thus, if
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
then, inversely,
$\mathrm{B}: \mathrm{A}:: \mathrm{D}: \mathrm{C}$.
16. Composition is when the sum of antecedent and consequent is compared either with the antecedent or consequent.

Thus, if

$$
\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}
$$

then, by composition, $\mathrm{A}+\mathrm{B}: \mathrm{A}:: \mathrm{C}+\mathrm{D}: \mathrm{C}$, and

$$
A+B: B:: C+D: D
$$

17. Division is when the difference of antecedent and consequent is compared either with the antecedent or consequent.
Thus, if
$\mathrm{A}: \mathrm{B}: \mathrm{C}: \mathrm{D}$,
then, by division, and

$$
\mathrm{A}-\mathrm{B}: \mathrm{A}:: \mathrm{C}-\mathrm{D}: \mathrm{C}
$$

$$
\mathrm{A}-\mathrm{B}: \mathrm{B}:: \mathrm{C}-\mathrm{D}: \mathrm{D} .
$$

18. When a proportion is said to exist among certain quantities, these quantities are supposed to be represented, or to be capable of being represented by numbers (Art. 3).

If, for example, in the proportion

$$
\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D},
$$

$\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$ denote lines, we may suppose one of these lines, or a fifth line, if we please, to be taken as a common measure to the whole, and to be regarded as unity; then $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$ will each represent a certain number of units, entire or fractional, commensurable or incommensurable, and the proportion among the lines $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$ becomes a proportion in numbers. Hence the product of two lines $A$ and $D$ may be regarded as the number of linear units contained in A multiplied by the number of linear units contained in D .

In the proportion $\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
the quantities A and B may be of one kind, as lines, and the quantities C and D of another kind, as surfaces; still, these quantities are to be regarded as represented by numbers. A and B will be
expressed in linear units, C and D in superficial units, and the product of $A$ and $D$ will be a number, as also the product of $B$ and C .

## Axioms.

1. Equimultiples of the same or of equal magnitudes are equal to one another.
2. Those magnitudes of which the same or equal magnitudes are equimultiples are equal to one another.

## PROPOSITION I. THEOREM.

If four quantities are proportional, the product of the two extremes is equal to the product of the two means.

Let $A, B, C, D$ be the numerical representatives of four proportional quantities, so that $A: B:: C: D$; then will $A \times D=B \times C$.

For, since the four quantities are proportional,

$$
\frac{\mathrm{A}}{\overline{\mathrm{~B}}}=\frac{\mathrm{C}}{\mathrm{D}}
$$

Multiplying each of these equal quantities by $B(A x .1)$, we obtain

$$
A=\frac{B \times C}{D}
$$

Multiplying each of these last equals by D , we have

$$
\mathrm{A} \times \mathrm{D}=\mathrm{B} \times \mathrm{C}
$$

Cor: If there are three proportional quantities, the procluct ot the two extremes is equal to the square of the mean.

Thus, if $\mathrm{A}: \mathrm{B}:: \mathrm{B}: \mathrm{C}$,
then, by this proposition, $\mathrm{A} \times \mathrm{C}=\mathrm{B} \times \mathrm{B}$, which is equal to $\mathrm{B}^{2}$.
proposition in. theorem. (Converse of Prop.I.)
If the procluct of two quantities is equal to the product of two others, the one pair may be made the extremes, and the other the means of a proportion.

Thus, suppose we have given

$$
A \times D=B \times C ;
$$

then will $\quad A: B:: C: D$.
For, since $\mathrm{A} \times \mathrm{D}=\mathrm{B} \times \mathrm{C}$, dividing each of these equals by
(Ax. 2), we have

$$
\mathrm{A}=\frac{\mathrm{B} \times \mathrm{C}}{\mathrm{D}}
$$

Dividing each of these last equals by $B$, we obtain

$$
\frac{\mathrm{A}}{\mathrm{~B}}=\frac{\mathrm{C}}{\mathrm{D}}, \text { or, } \mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D} .
$$

## PROPOSITION III, THEOREM.

If four quantities are proportional, they are also proportional when taken alternately.

Let $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}$ be the numerical representatives of four proportional quantities, so that

$$
\begin{aligned}
& A: B:: C: D \\
& A: C:: B: D \\
& A: B:: C: D \\
& A \times D=B \times C \\
& A \times D=B \times C, \\
& A: C:: B: D
\end{aligned}
$$

then, alternately,
For, since
by Pr. 1,
And, since
by Pr. 2,

## PROPOSITION IV. THEOREM.

Ratios that are equal to the same ratio are equal to each other.
Let
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
and
then will
For, since
we have
And, since
we have
$\mathrm{A}: \mathrm{B}:: \mathrm{E}: \mathrm{F}$;
C:D::E:F.
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$.
$\frac{\mathrm{A}}{\mathrm{B}}=\frac{\mathrm{C}}{\mathrm{D}}$.
$A: B:: E: F$,

$$
\frac{\mathrm{A}}{\mathrm{~B}}=\frac{\mathrm{E}}{\mathrm{~F}}
$$

But $\frac{C}{\bar{D}}$ and $\frac{\mathrm{E}}{\mathrm{F}}$, being severally equal to $\frac{\mathrm{A}}{\mathrm{B}}$, must be equal to each other, and therefore

$$
\mathrm{C}: \mathrm{D}:: \mathrm{E}: \mathrm{F} .
$$

Cor. If the antecedents of one proportion are equal to the antecedents of another proportion, the consequents are proportional.

If
and then will

For, by alternation (Pr. 3), the first proportion becomes

$$
A: C:: B: D
$$

and the second, $\quad \mathrm{A}: \mathrm{C}:: \mathrm{E}: \mathrm{F}$.
Therefore, by this proposition,
$B: D:: E: F$.

## PROPOSITION V. THEOREM.

If four quantities are proportional, they are also proportional when taken inversely.

Let
then, inversely,
For, since by Pr. 1, or, therefore, by Pr. 2,

$$
\begin{aligned}
& A: B:: C: D \\
& B: A:: D: C \\
& A: B:: C: D \\
& A \times D=B \times C \\
& B \times C=A \times D ; \\
& B: A:: D: C
\end{aligned}
$$

PROPOSITION VI. THEOREM.
If four quantities are proportional, they are also proportional by composition.

Let
then, by composition,
For, since
by Pr. 1,
To each of these equals add
$A \times C=A \times C ;$
then
or,
Therefore, by Pr. 2, $\mathrm{A}+\mathrm{B}: \mathrm{A}:: \mathrm{C}+\mathrm{D}: \mathrm{C}$.
PROPOSITION VII. THEOREM.
If four quantities are proportional, they are also proportional by division.

Let
then, by division,
For, since
by Pr. 1,
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$;
$A+B: A:: C+D: C$.
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
$\mathrm{B} \times \mathrm{C}=\mathrm{A} \times \mathrm{D}$.
$\mathrm{A} \times \mathrm{C}+\mathrm{B} \times \mathrm{C}=\mathrm{A} \times \mathrm{C}+\mathrm{A} \times \mathrm{D}$,
$(A+B) \times C=A \times(C+D)$.

Subtract each of these equals from $A \times C$;
then,
$A \times C-B \times C=A \times C-A \times D$,
or, $\quad(\mathrm{A}-\mathrm{B}) \times \mathrm{C}=\mathrm{A} \times(\mathrm{C}-\mathrm{D})$.
Therefore, by Pr. 1, $\mathrm{A}-\mathrm{B}: \mathrm{A}:: \mathrm{C}-\mathrm{D}: \mathrm{C}$.
PROPOSITION VIII. TIIEOREM.
If four quantities are proportional, the sum of the first and second is to their difference as the sum of the third and fourth is to their clifference.

Let

$$
A: B:: C: D
$$

then will
By Pr. 6, and by Pr. 7,

By alternation (Pr. 3), these proportions become

$$
A+B: C+D:: A: C
$$

and $\quad \mathrm{A}-\mathrm{B}: \mathrm{C}-\mathrm{D}:: \mathrm{A}: \mathrm{C}$.

$$
\mathrm{A}-\mathrm{B}: \mathrm{C}-\mathrm{D}:: \mathrm{A}: \mathrm{C}
$$

Hence, Pr. 4 ,

$$
\begin{gathered}
A+B: A-B:: C+D: C-D . \\
A+B: A:: C+D: C \\
A-B: A:: C-D: C .
\end{gathered}
$$

$$
\mathrm{A}+\mathrm{B}: \mathrm{C}+\mathrm{D}:: \mathrm{A}-\mathrm{B}: \mathrm{C}-\mathrm{D}
$$

or, alternately,

$$
A+B: A-B:: C+D: C-D
$$

PROPOSITION IX. THEOREM.
If any number of quantities are proportional, any one antecedent is to its consequent as the sum of all the antecedents is to the sum of all the consequents.

Let
then will
For, since
we have
And, since
we have
To these equals add $\quad \mathrm{A} \times \mathrm{B}=\mathrm{A} \times \mathrm{B}$, and we have

$$
A \times B+A \times D+A \times F=A \times B+B \times C+B \times E ;
$$

or, $\quad \mathrm{A} \times(\mathrm{B}+\mathrm{D}+\mathrm{F})=\mathrm{B} \times(\mathrm{A}+\mathrm{C}+\mathrm{E})$.
But $\mathrm{B}+\mathrm{D}+\mathrm{F}$ may be regarded as a single quantity, and $\mathrm{A}+\mathrm{C}+\mathrm{E}$ as a single quantity.

Therefore, by Pr. 1,

$$
\mathrm{A}: \mathrm{B}:: \mathrm{A}+\mathrm{C}+\mathrm{E}: \mathrm{B}+\mathrm{D}+\mathrm{F}
$$

PROPOSITION X. THEOREM.
Equimultiples of two quantities have the same ratio as the quantities themselves.

Let $A$ and $B$ be any two quantities of the same kind, and $m$ any number, entire or fractional, we have the equality

$$
\frac{\mathrm{A}}{\mathrm{~B}}=\frac{m \mathrm{~A}}{m \mathrm{~B}}
$$

or,
Cor. If
$\mathbf{A}: \mathbf{B}:: m \mathbf{A}: m \mathbf{B}$.
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
then
and if

$$
m \mathbf{A}: n \mathbf{B}:: m \mathbf{C}: n \mathbf{D},
$$ then

$$
m \mathbf{A}: n \mathbf{B}:: m \mathbf{C}: n \mathbf{D}
$$

$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$; that is,
If four magnitudes are proportional, we may multiply the ante-
cedents or the consequents, or divide them by the same quantity, and the results will be proportional.

## PROPOSITION XI. THEOREM.

If four quantities are proportional, their squares or cubes are also proportional.

Let
then will
and
For, since
by Pr. 1,

$$
\begin{aligned}
& A: B:: C=D \\
& A^{2}: \mathrm{B}^{2}:: \mathrm{C}^{2}: \mathrm{D}^{2}, \\
& \mathrm{~A}^{3}: \mathrm{B}^{3}:: \mathrm{C}^{3}: \mathrm{D}^{3} \\
& A: B:: C: D, \\
& A \times D=B \times C
\end{aligned}
$$

or, multiplying each of these equals by itself (Ax. 1), we have

$$
\mathrm{A}^{2} \times \mathrm{D}^{2}=\mathrm{B}^{2} \times \mathrm{C}^{2} ;
$$

and multiplying these last equals by $\mathrm{A} \times \mathrm{D}=\mathrm{B} \times \mathrm{C}$, we have

$$
\mathrm{A}^{3} \times \mathrm{D}^{3}=\mathrm{B}^{3} \times \mathrm{C}^{3}
$$

Therefore, by Pr. 2, $\quad \mathrm{A}^{2}: \mathrm{B}^{2}:: \mathrm{C}^{2}: \mathrm{D}^{2}$,
and
$\mathrm{A}^{3}: \mathrm{B}^{3}:: \mathrm{C}^{3}: \mathrm{D}^{3}$.

## PROPOSITION XII. THEOREM.

If there are two sets of proportional quantities, the products of the corresponding terms are proportional.

Let
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
and
then will
For, since
by Pr. 1,
And, since
by Pr. 1 ,
Multiplying together these equal quantities, we have
$\mathrm{A} \times \mathrm{D} \times \mathrm{E} \times \mathrm{H}=\mathrm{B} \times \mathrm{C} \times \mathrm{F} \times \mathrm{G}$;
or, $(\mathrm{A} \times \mathrm{E}) \times(\mathrm{D} \times \mathrm{H})=(\mathrm{B} \times \mathrm{F}) \times(\mathrm{C} \times \mathrm{G}) ;$
therefore, by Pr: 2,

$$
A \times E: B \times F:: C \times G: D \times H
$$

Cor. If
and
$\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$,
B:F::G:H,
then $\quad A: F:: C \times G: D \times H$.
For, by the proposition,

$$
\mathrm{A} \times \mathrm{B}: \mathrm{B} \times \mathrm{F}:: \mathrm{C} \times \mathrm{G}: \mathrm{D} \times \mathrm{H} .
$$

Also, by Pr. 10, $\quad \mathrm{A} \times \mathrm{B}: \mathrm{B} \times \mathrm{F}:: \mathrm{A}: \mathrm{F}$;
hence, by Pr. $4, \quad$ A : $\mathrm{F}:: \mathrm{C} \times \mathrm{G}: \mathrm{D} \times \mathrm{H}$.

PROPOSITION XIII. THEOREM.
If three quantities are proportional, the first is to the third as the square of the first to the square of the second.

Thus, if
then
For, since,
and
therefore, by Pr.12, $\mathrm{A}^{2}: \mathrm{B}^{2}:: \mathrm{A} \times \mathrm{B}: \mathrm{B} \times \mathrm{C}$.
But, by Pr. 10, $\quad \mathrm{A} \times \mathrm{B}: \mathrm{B} \times \mathrm{C}:: \mathrm{A}: \mathrm{C}$;
hence, by Pr. $4, \quad \mathrm{~A}: \mathrm{C}:: \mathrm{A}^{2}: \mathrm{B}^{2}$.
$\mathrm{A}: \mathrm{B}:: \mathrm{B}: \mathrm{C}$,
$A: C:: \mathrm{A}^{2}: \mathrm{B}^{2}$.
$\mathrm{A}: \mathrm{B}:: \mathrm{B}: \mathrm{C}$,
$\mathrm{A}: \mathrm{B}:: \mathrm{A}: \mathrm{B} ;$

## B O OK III.

## THE CIRCLE, AND THE MEASURE OF ANGLES.

## Definitions.

1. A circle is a plane figure bounded by a line, all the points of which are equally distant from a point within, called the centre.

The line which bounds the circle is called its circumference.
2. Any straight line drawn from the centre of the circle to the circumference is called a radius of the circle, as CA, CD.

Any straight line drawn through the centre, and terminated each way by the circumference, is called a ctiameter, as AB.

Cor: All the radii of a circle are equal; also all the diameters are equal, and each is double the radius.
3. An arc of a circle is any portion of its cir-
 cumference, as EGF.

The chord of an are is the straight line which joins its two extremities, as EF.

The are EGF is said to be subtended by its chord EF.
4. A segment of a circle is the figure included between an arc and its chord, as EGF.

Since the same chord EF subtends two arcs EGF, EHF, to the same chord there correspond two segments EGF, EHF. By the term segment, the smaller of the two is always to be understood, unless the contrary is expressed.
5. A sector of a circle is the figure included between an arc and the two radii drawn to the extremities of the arc, as BCD.
6. A straight line is said to be inscribed in a circle when its extremities are on the circumference, as AB .

An inscribed angle is one whose vertex is on the circumference, and which is formed by two chords, as BAC.
7. A polygon is said to be inscribed in a circle
 when all its angles have their vertices on the circumference, as ABC. The circle is then said to be described about the polygon.
8. An angle is said to be inscribed in a segment when it is con-

tained by two straight lines drawn from any point in the arc of the segment to the extremities of the subtending chord. Thus the angles $\mathrm{ACB}, \mathrm{ADB}$ are inscribed in the segment ADCB .

9. A secant is a line which cuts the circumference, and lies partly within and partly without the circle, as DE.
10. A straight line is said to touch a circle when it meets the circumference, and, being produced, does not cut it, as AB.
Such a line is called a tangent, and the point in which it meets the circumference is called the point of contact, as C .

11. Two circumferences are said to touch one another when they meet, but do not cut one another.

12. A polygon is said to be described about a circle when each side of the polygon touches the circumference of the circle.

In this case the circle is said to be inscribed in the polygon.

## PROPOSITION I. THEOREM.

Every diameter divides the circle and its circumference into two equal parts.

Let $A C B D$ be a circle, and $A B$ its diameter; then will the line AB divide the circle and its circumference into two equal parts.

If the figure ADB be turned about AB , and superposed upon the figure $A C B$, the curve line $A C B$ must coincide exactly with the curve line $A D B$. For if any part of the curve $A C B$ were to fall either within or without the curve ADB , there would be points in one or the other unequally distant from the centre, which is contrary to the definition of a circle. Hence the two figures coincide throughout, and are equal in all respects. Therefore every diameter, etc.

## PROPOSITION II. THEOREM.

A straight line can not meet the circumference of a circle ins more than two points.

For, if it be possible, let the straight line ABC meet the circumference of a circle in three points, DBE. Take F, the centre of the circle, and join FD, FB, FE.

Then, because F is the centre of the circle, the three straight lines $\mathrm{FD}, \mathrm{FB}, \mathrm{FE}$ are all equal to each other. Hence three equal straight
 lines have been drawn from the same point to the same straight line, which is impossible (B. I.; Pr. 17, Cor. 2*). Therefore a straight line, etc.

## PROPOSITION III. THEOREM.

In the same circle or in equal circles, equal arcs are subtended by equal chords, and conversely equal chords subtend equal arcs.

Let ADB, EHF be equal circles, and let the arcs AI D, EMH also be equal; then will the chord AD be equal to the chord EH.

For, the diameter AB being equal to the diameter
 EF, the semicircle ADB may be applied exactly to the semicircle EHF, and the curve line AIDB will coincide entirely with the curve line EMHF ( Pr .1 ). But the arc AID is, by hypothesis, equal to the arc EMH ; hence the point D will fall on the point H , and therefore the chord AD is equal to the chord EH (Ax. 11, B. I.).

Conversely, if the chord AD is equal to the chord EH , then the arc AID will be equal to the are EMH.

For, if the radii CD, GH are drawn, the two triangles ACD , EGH will have their three sides equal, each to each, viz., AC to $\mathrm{EG}, \mathrm{CD}$ to GII , and AD equal to EH ; the triangles are consequently equal (B. I., Pr. 15), and the angle ACD is equal to the angle EGH.

[^5]

Let, now, the semicircle ADB be applied to the semicircle EHF, so that AC may coincide with EG; then, since the angle ACD is equal to the angle EGH, the radius CD will coincide with the radius GH, and the point D with the point H. Therefore the arc AID must coincide with the arc EMH, and be equal to it.

If the ares are in the same circle, the demonstration is similar. Therefore, in the same circle, etc.

## PROPOSITION IV. THEOREM.

In the same circle or in equal circles, equal angles at the centre are subtended by equal arcs; and, conversely, equal arcs subtend equal angles at the centre.

Let AGB, DHE be two equal circles, and let $\mathrm{ACB}, \mathrm{DFE}$ be equal angles at their centres; then will the are AB be equal to the arc DE .

Join AB, DE; and, because the circles AGB, DHE are equal, their radii are equal. Therefore the two sides $\mathrm{CA}, \mathrm{CB}$ are equal to the two sides $\mathrm{FD}, \mathrm{FE}$; also, the angle at $C$ is equal to the angle at $F$; therefore the base $A B$ is equal to the base DE (B. I., Pr. 6). And, because the chord AB is equal to the chord DE , the arc AB must be equal to the are DE (Pr. 3).

Conversely, if the arc AB is equal to the arc DE , the angle AC $B$ will be equal to the angle DFE. For, if these angles are not equal, one of them is the greater. Let ACB be the greater, and take ACI equal to DFE; then, because equal angles at the centre are subtended by equal ares, the are AI is equal to the arc DE . But the arc AB is equal to the arc DE ; therefore the arc AI is equal to the arc AB , the less to the greater, which is impossible. Hence the angle ACB is not unequal to the angle DFE, that is, it is equal to it. Therefore, in the same circle, etc.

## PROPOSITION V. THEOREM.

In the same circle, or in equal circles, a greater arc is subtended by a greater chord; and, conversely, the greater chord subtends the greater arc, the arcs being both less than a semi-circumference.

In the circle AEB, let the arc AE be greater than the arc AD; then will the chord AE be greater than the chord AD.

Draw the radii CA, CD, CE. Now, it the $\operatorname{arc} A E$ were equal to the arc $A D$, the angle ACE would be equal to the angle ACD (Pr: 4); hence it is clear that if the arc AE be
 greater than the arc AD , the angle ACE must be greater than the angle ACD. But the two sides AC, CE of the triangle ACE are equal to the two $\mathrm{AC}, \mathrm{CD}$ of the triangle ACD , and the angle ACE is greater than the angle ACD; therefore the third side A E is greater than the third side $\mathrm{AD}(\mathrm{B} . \mathrm{I} ., \mathrm{Pr} .13)$; hence the chord which subtends the greater are is the greater.

Conversely, if the chord AE is greater than the chord AD, the arc AE is greater than the arc AD . For, because the two triangles $A C E, A C D$ have two sides of the one equal to two sides of the other, each to each, but the base AE of the one is greater than the base AD of the other, therefore the angle ACE is greater than the angle ACD (B. I., Pr. 14), and hence the arc AE is greater than the arc $A D$ (Pr.4). Therefore, in the same circle, etc.

Scholium. If the arcs are greater than a semi-circumference, the contrary is true; that is, the greater arc is subtended by a smaller chord.

## PROPOSITION VI, THEOREM.

The diameter which is perpendicular to a chord bisects the chord, and also the arc which it subtends.

Let ABG be a circle, of which AB is a chord, and GE a diameter perpendicular to it; the chord $A B$ will be bisected in D, and the arc AEB will be bisected in E.

Draw the radii CA, CB. The two right-angled triangles $\mathrm{CDA}, \mathrm{CDB}$ have the side AC equal to CB ,
 and $C D$ common; therefore the triangles are equal, and the base AD is equal to the base DB (B. I., Pr. 19).

Secondly. Since the radius $\mathbf{A C}$ is equal to CB , and the line CD

bisects the line $A B$ at right angles, it bisects also the vertical angle ACB (B. I., Pr. 10, Cor. 1). And, since the angle ACE is equal to the angle BCE , the $\operatorname{arc} \mathrm{AE}$ must be equal to the arc BE (B. III., Pr. 4). Hence the diameter GE, perpendicular to the chord AB , divides the arc subtended by this chord into two equal parts in the point $\mathbf{E}$. Moreover, since the semi-circumference GAE is equal to GBE (B. III., Pr. 1), the $\operatorname{arc} A G$ must be equal to $B G$. Therefore the perpendicular, etc.

Corollary. The centre of the circle, the middle point of the chord $A B$, and the middle point of the arc AEB subtended by this chord, are three points situated in a straight line perpendicular to the chord. Now two points are sufficient to determine the position of a straight line; therefore any straight line which passes through two of these points will necessarily pass through the third, and be perpendicular to the chord.

Also, the perpendicular to the chord at its middle point passes through the centre of the circle and through the middle of the arc subtended by the chord.

## PROPOSITION VII. THEOREM.

Through any three points not in the same straight line one circumference may be made to pass, and but one.

Let $A, B, C$ be any three points not in the same straight line; they all lie in the circumference of the same circle. Join $\mathrm{AB}, \mathrm{AC}$, and bisect these lines by the perpendiculars $\mathrm{DF}, \mathrm{E}$ F; DF and EF produced will meet one another.

For, join DE; then, because the angles ADF, AEF are together equal to two right angles, the angles FDE and FED are together less than two right angles; therefore DF and EF will meet if produced (B. I., Pr. 23, Cor. 3). Let them meet in F. Since this point lies in the perpendicular DF, it is equally distant from the two points $A$ and $B$ (B. I., Pr. 18) ; and, since it lies in the perpendicular EF, it is equally distant from the two points $\mathbf{A}$ and $\mathbf{C}$; therefore the three distances FA, FB, FC are all equal; hence the circumference described from the centre $\mathbf{F}$ with the radius $\mathbf{F A}$ will pass through the three given points $\mathrm{A}, \mathrm{B}, \mathrm{C}$.

Secondly. No other circumference can ${ }^{\text {p }}$ pass through the same points. For, if there were a second, its centre could not be out
of the line DF, for then it would be unequally distant from $A$ and B (B. I., Pr. 18) ; neither could it be out of the line FE, for the same reason; therefore it must be on both the lines DF, FE. But two straight lines can not cut each other in more than one point, hence only one circumference can pass through three given points. Therefore, through any three points, etc.

Cor.1. Two circumferences can not cut each other in more than two points; for, if they had three common points, they would have the same centre, and would coincide with each other.

Cor. 2. The perpendicular drawn from the middle of BC will pass through the point F , since this point is equally distant from $B$ and $C$; therefore the three straight lines bisecting the three sides of a triangle at right angles meet in the same point.

## PROPOSITION VIII. THEOREM.

In the same circle or in equal circles, equal chords are equally distant from the centre; and of two rnequal chords, the less is the more remote from the centre.

Let the chords $\mathrm{AB}, \mathrm{DE}$, in the circle AB ED , be equal to one another; they are equally distant from the centre. Take C, the centre of the circle, and from it draw $\mathrm{CF}, \mathrm{CG}$, perpendiculars to $\mathrm{AB}, \mathrm{DE}$.

Join CA, CD; then, because the radius $C F$ is perpendicular to the chord $A B$, it bisects it (Pr. 6). Hence AF is the half of A
 $B$; and, for the same reason, $D G$ is the half of $D E$. But. AB is equal to DE, therefore AF is equal to DG (B.I., Ax. 7). Now, in the right-angled triangles $\mathrm{ACF}, \mathrm{DCG}$, the hypothenuse AC is equal to the hypothenuse DC , and the side AF is equal to the side $D G$; therefore the triangles are equal, and $C F$ is equal to $C$ G (B. I., Pr. 19) ; hence the two equal chords $\mathrm{AB}, \mathrm{DE}$ are equally distant from the centre. ${ }^{-}$

Secondly. Let the chord AH be greater than the chord DE; DE is further from the centre than AH.

For, because the chord $A H$ is greater than the chord $D E$, the arc ABH is greater than the arc DE (Pr. 5). From the arc AB $H$ cut off a part, AB , equal to DE ; draw the chord AB , and let fall CF perpendicular to this chord, and CI perpendicular to AH. It is plain that CF is greater than CK, and CK than CI (B. I., Pr. 17) ; much more, then, is CF greater than CI. But CF is equal
to $C G$, because the chords $\mathrm{AB}, \mathrm{DE}$ are equal; hence CG is greater than CI. Therefore, in the same circle, etc.

Cor. Hence the diameter is the longest line that can be inscribed in a circle.

## PROPOSITION IX. THEOREM.

A straight line perpendicular to a cliameter at its extremity is a tangent to the circumference.

Let ABK be a circle, the centre of which is C , and the diameter AB , and let AD be drawn from $A$ perpendicular to $A B ; A D$ will be a tangent to the circumference.

In AD take any point, E , and join CE ; then, since CE is an oblique line, it is longer than the perpendicular CA (B. I., Pr. 17).
Now CA is equal to CF ; therefore CE is greater than CF, and the point E must be without the circle. But E is any point whatever in the line AD ; therefore AD has only the point A in common with the circumference, hence it is a tangent (Def. 10). Therefore a straight line, etc.

Cor.1. Through the same point, $\mathbf{A}$, in the circumference, only one tangent can be drawn. For, if possible, let a second tangent, $A G$, be drawn; then, since CA can not be perpendicular to $A$ G (B. I., Pr. 1), another line, CH, must be perpendicular to AG, and therefore CH must be less than CA (B. I., Pr. 17); hence the point $H$ falls within the circle, and AH produced will cut the circumference.

Cor.2. A tangent, AD , to a circle at any point, $A$, is perpendicular to the diameter drawn to that point. For, since every point of the tangent except $A$ is without the circumference, the radius CA is the shortest line that can be drawn from the point C to the line AD , and is therefore perpendicular to this line ( B . I., Pr. 17).

PROPOSITION X. THEOREM.

The proposition admits of three cases:
First. When the two parallels are secants, as $\mathrm{AB}, \mathrm{DE}$.

Draw the radius CH perpendicular to AB ; it will also be perpendicular to DE (B.I., Pr.

23, Cor. 1) ; therefore the point H will be at the same time the middle of the arc AHB and of the are DHE (Pr. 6). Hence the arc DH is equal to the arc HE , and the arc AH equal to HB , and therefore the are AD is equal to the are BE (B. I., Ax. 3).

Second. When one of the two parallels is a secant and the other a tangent.

To the point of contact, H , draw the radius CH ; it will be perpendicular to the tangent DE (Pr. 9), and also to its parallel AB . But, since CH is perpendicular to the chord AB , the point H is the middle of the arc AHB (Pr. 6) ; therefore the arcs A $\mathrm{H}, \mathrm{HB}$, included between the parallels AB , DE, are equal.

Third. If the two parallels $\mathrm{DE}, \mathrm{FG}$ are
 tangents, the one at $\mathbf{H}$, the other at K , draw the parallel secant AB ; then, according to the former case, the arc AH is equal to HB , and the arc AK is equal to KB ; hence the whole arc HAK is equal to the whole are HBK (B. I., Ax. 2). It is also evident that each of these arcs is a semi-circumference. Therefore two parallels, etc.

Scholium. The straight line joining the points of contact of two parallel tangents is a diameter.

## PROPOSITION XI. THEOREM.

If two circumferences cut each other, the straight line joining their centres bisects their common chord at right angles.

Let two circumferences cut each other in the points $A$ and $B$; then will the line AB be a common chord to the two circles. Now, if a perpendicular be erect-
 ed from the middle of this chord, it will pass through $C$ and $D$, the centres of the two circles (Pr. 6, Cor.). But only one straight line can be drawn through two given points; therefore the straight line which passes through the centres will bisect the common chord at right angles.

## PROPOSITION XII. THEOREM.

If two circumferences touch each other, either externally or internally, the distance of their centres must be equal to the sum or difference of their radii.

It is plain that the centres of the circles and the point of contact are in the same straight line; for, if possible, let the point of contact, $A$, be without the straight line CD.

From A let fall upon CD, or CD produced, the perpendicular AE , and produce it to B , making BE equal to AE . Then, in the triangles $\mathrm{ACE}, \mathrm{BCE}$, the side AE is equal to $\mathrm{EB}, \mathrm{CE}$ is common, and the angle AEC is equal to the angle BEC; therefore AC is equal to CB (B. I., Pr. 6), and the point B is in the circumference ABF. In the same manner, it may be shown to be in the circumference $A B G$, and hence the point $B$ is in both circumferences. Therefore the two circumferences have two points, $A$ and $B$, in common; that is, they cut each other, which is contrary to the hypothesis. Therefore the point of contact can not be without the line joining the centres; and hence, when the circles touch each other externally, the distance of the centres CD is equal to the sum of the radii CA, DA; and when they touch internally, the distance CD is equal to the difference of the radii $\mathrm{CA}, \mathrm{DA}$. Therefore, if two circumferences, etc.

Scholium. If two circumferences touch each other externally or internally, their point of contact is in the straight line joining their centres.

## PROPOSITION XIII. THEOREM.

If two circumferences cut each other, the distance between their centres is less than the sum of their radii, and greater than their difference.

Let two circumferences cut each other in the point A. Draw the radii CA, DA; then, because any side of a triangle is less than the sum of the other two (B. I., Pr. 8), CD must be less
than the sum of AD and AC. Also, DA must be less than the sum of CD and C A; or, subtracting CA from these unequals (B. I., Ax. 5), CD must be greater than the difference between DA and CA. Therefore, if two circumferences,
 etc.

Scholium. There may be five different positions of two circles with respect to each other :

1st. When the distance between their centres is greater than the sum of their radii, there can be neither contact nor intersection.

2 d . When the distance between their centres is equal to the sum of their radii, the circumferences touch each other externally.

3d. When the distance between their centres is less than the sum of their radii, but greater than their difference, the circumferences intersect.

4th. When the distance between their centres is equal to the difference of their radii, the circumferences touch each other internally.

5th. When the distance between their centres is less than the difference of their radii, there can be neither contact nor intersection.

> PROPOSITION XIV. THEOREM.

In the same circle, or in equal circles, two angles at the centre have the same ratio as their intercepted arcs.

Case first. When the angles are in the ratio of two whole numbers.

Let ABG, DFH be equal circles, and let the angles ACB, DEF at their centres be in the ratio of two whole
 numbers; then will
the angle ACB : angle DEF :: arc AB : arc DF.
Suppose, for example, that the angles ACB, DEF are to each other as 7 to 4 ; or, which is the same thing, suppose that the angle M, which may serve as a common measure, is contained seven times in the angle ACB, and four times in the angle DEF. Draw

radii to the several points of division of the arcs. The seven partial angles into which ACB is divided, being each equal to any of the four partial angles into which DEF is divided, the partial arcs will also be equal to each other ( Pr .4 ), and the entire arc AB will be to the entire arc DF as 7 to 4 . Now the same reasoning would apply if, in place of 7 and 4 , any whole numbers whatever were employed; therefore, if the ratio of the angles $\mathrm{ACB}, \mathrm{DEF}$ can be expressed in whole numbers, the arcs $\mathrm{AB}, \mathrm{DF}$ will be to each other as the angles $\mathrm{ACB}, \mathrm{DEF}$.

Case second. When the angles are incommensurable; that is, their ratio can not be expressed exactly in numbers.

Suppose the angle DEF to be divided into any number $n$ of equal parts; then ACB will contain a certain number $m$ of these parts, plus a remainder which is less than one of the parts. The numerical expression of the ratio $\frac{A C B}{D E F}$ will be $\frac{m}{n}$, correct within $\frac{1}{n}$ part (B.II., Art. 10). Draw radii to the several points of division of the arcs. The arc DF will be divided into $n$ equal parts, and the $\operatorname{arc} \mathrm{AB}$ will contain $m$ such parts, plus a remainder which is less than one of the parts. Therefore the numerical expression of the ratio $\frac{\mathrm{AB}}{\overline{\mathrm{DF}}}$ will also be $\frac{m}{n}$, correct within $\frac{1}{n}$ part. Hence the same number, $\frac{m}{n}$, expresses the value of the ratio $\frac{\mathrm{ACB}}{\overline{\mathrm{DEF}}}$, and of $\frac{\mathrm{AB}}{\mathrm{DF}}$, however small the parts into which DEF is divided. Therefore these ratios must be absolutely equal; and hence, whatever may be the ratio of the two angles, we have the proportion
angle ACB : angle DEF :: arc AB : arc DF.
Therefore, in the same circle, etc.
Scholium. Since the angle at the centre of a circle and the are intercepted by its sides are so related that when one is increased or diminished, the other is increased or diminished in the same ratio, an angle at the centre is said to be measured by its intercepted arc.

It should, however, be observed that, since angles and ares are unlike quantities, they are necessarily measured by different units. The most simple unit of measure for angles is the right angle, and the corresponding unit of measure for ares is a quadrant. An acute angle would accordingly be expressed by some number between 0 and 1 ; an obtuse angle by some number between 1 and 2 .

The unit, however, most commonly employed for angles is an angle equal to $\frac{1}{90}$ th part of a right angle, called a clegree. The corresponding unit of measure for ares is $\frac{1}{90}$ th part of a quadrant, and is also called a degree. An angle or an are is thus numerically expressed by the unit degree and its subdivisions. A right angle and a quadrant are both expressed by 90 degrees. If an angle is $\frac{4}{5}$ ths of a right angle, it is expressed by 72 degrees.

Cor. Since in equal circles sectors are equal when their angles are equal, it follows that in equal circles sectors are to each other as their arcs.

PROPOSITION XV. THEOREM.
An inscribed angle is measured by half the arc included between its sides.

Let BAD be an angle inscribed in the circle BAD. The angle BAD is measured by half the are BD.

First. Let C, the centre of the circle, be within the angle BAD. Draw the diameter AE , also the radii $\mathrm{CB}, \mathrm{CD}$.

Because CA is equal to CB, the angle CAB is equal to the angle CBA (B. I., Pr. 10);
 therefore the angles $\mathrm{CAB}, \mathrm{CBA}$ are together double the angle CAB. But the angle BCE is equal (B. I., Pr. 27 ) to the angles $\mathrm{CAB}, \mathrm{CBA}$; therefore, also, the angle BCE is double of the angle BAC. Now the angle B CE, being an angle at the centre, is measured by the arc BE; hence the angle BAE is measured by the half of BE. For the same reason, the angle DAE is measured by half the are DE. Therefore the whole angle BAD is measured by half the are BD .

Second. Let C, the centre of the circle, be without the angle BAD. Draw the diameter
 AE.

It may be demonstrated, as in the first case, that the angle BAE is measured by half the are BE, and the angle DAE by half the are DE ; hence their difference, BAD , is measured by half of BD. Therefore, an inscribed angle, etc.

Cor. 1. All the angles BAC, BDC, etc., inscribed in the same segment, are equal, for they are all measured by half the same are B EC. (See next fig.)

Cor. 2. An angle BCD at the centre of a circle is double of the angle $B A D$ at the circumference, subtended by the same are.
Cor. 3. Every angle inscribed in a semicircle is a right angle, because it is measured by half a semi-circumference; that is, the fourth part of a circumference.

Cor: 4. Every angle inscribed in a segment greater than a semicircle is an acute angle, for it is measured by half an arc less than a semicircumference.

Every angle inscribed in a segment less than a semicircle in an obtuse angle, for it is measured by half an arc greater than a semi-circumference.

Cor. 5. The opposite angles of an inscribed quadrilateral, ABE $C$, are supplements of each other; for the angle $B A C$ is measured by half the are BEC, and the angle BEC is measured by half the arc BAC; therefore the two angles BAC, BEC, taken together, are measured by half the circumference; hence their sum is equal to two right angles.

## PROPOSITION XVI, THEOREM.

The angle formed by a tangent and a chord is measured by half the arc included between its sides.

Let the straight line BE touch the circumference ACDF in the point A, and from A let the chord AC be drawn; the angle BAC is measured by half the arc AFC.

From the point $A$ draw the diameter $A$ D. The angle BAD is a right angle ( Pr . 9 ), and is measured by half the semi-circumference AFD; also, the angle DAC is
measured by half the arc $\mathrm{DC}(\mathrm{Pr} .15)$; therefore the sum of the angles $\mathrm{BAD}, \mathrm{DAC}$ is measured by half the entire arc AFDC.

In the same manner, it may be shown that the angle CAE is measured by half the arc AGC, included between its sides.

Cor. The angle BAC is equal to an angle inscribed in the segment AGC, and the angle EAC is equal to an angle inscribed in the segment AFC.

## proposition xvir. theorem.

The angle formed by two chords which cut each other is measured by one half the sum of the arcs intercepted between its sides and between the sides of its vertical angle.

Let $\mathrm{AB}, \mathrm{CD}$ be two chords which cut each other at E ; then will the angle AED be measured by one half the sum of the arcs $A D$ and $B C$, intercepted between the sides of AED and the sides of its vertical angle BEC.

Join AC; the angle AED is equal to the sum of
 the angles ACD and BAC (B. I., Pr. 27). But A CD is measured by half the arc AD (B. III., Pr. 15), and the angle BAC is measured by half the arc BC. Therefore AED is measured by half the sum of the arcs AD and BC . Therefore the angle, etc.

## PROPOSITION XVIIT. THEOREM.

The angle formed by two secants intersecting without the circumference, is measured by one half the difference of the intercepted arcs.

Let $\mathrm{AB}, \mathrm{AC}$ be two secants which intersect at $A$; then will the angle. BAC be measured by one half the difference of the arcs BC and DE .

Join CD; the angle BDC is equal to the sum of the angles DAC and ACD (B.I., Pr. 27); therefore the angle $\mathbf{A}$ is equal to the difference of the angles BDC and ACD. But the angle BDC is
 measured by one half the are BC (B. III., Pr. 15), and the angle A CD is measured by one half the are DE. Therefore the angle $\mathbf{A}$ is measured by one half the difference of the arcs BC and DE . Therefore the angle, etc.

## BOOK IV.

## COMPARISON AND MEASUREMENT OF POLYGONS.

## Definitions.

1. The area of a figure is its superficial content. The area is expressed numerically by the number of times that the figure contains some other surface which is assumed for its measuring unit; that is, it is the ratio of its surface to that of the unit of surface. A unit of surface is called a superficial unit. The most convenient superficial unit is the square, whose side is the linear unit, as a square foot or a square yard.
2. Equal figures are such as may be applied the one to the other, so as to coincide throughout. Thus two circles having equal radii are equal; and two triangles having the three sides of the one equal to the three sides of the other, each to each, are also equal.
3. Equivalent figures are such as contain equal areas. Two figures may be equivalent, however dissimilar. Thus a circle may be equivalent to a square, a triangle to a rectangle, etc.
4. Similar polygons are such as have the angles of the one equal to the angles of the other, each to each, and the sides about the equal angles proportional. Sides which have the same position in the two polygons, or which are adjacent to equal angles, are called homologous. The equal angles may also be called homologous angles.

Equal polygons are always similar, but similar polygons may be very unequal.
5. Two sides of one polygon are said to be reciprocally proportional to two sides of another when one side of the first is to one side of the second as the remaining side of the second is to the remaining side of the first.
6. In different circles, similar arcs, sectors, or segments are those

which correspond to equal angles at the centre.

Thus, if the angles A and D are equal, the arc BC will be similar to the arc EF , the sector ABC to the sector DEF, and the segment BGC to the segment EHF.
7. The altitude of a triangle is the perpendicular let fall from the vertex of an angle on the opposite side, taken as a base, or on the base
 produced.
8. The altitude of a parallelogram is the perpendicular drawn to the base from the opposite side.

9. The altitude of a trapezoid is the perpendicular distance between its parallel sides.

PROPOSITION I. THEOREM.
Parallelograms which have equal bases and equal altitudes are equivalent.

Let the parallelograms $\mathrm{ABCD}, \mathrm{ABEF}$ be placed so that their equal bases shall coincide with each other. Let $A B$ be the
 common base; and, since the two parallelograms are supposed to have equal altitudes, their upper bases, DC, FE, will be in the same straight line parallel to AB.

Now, because ABCD is a parallelogram, DC is equal to AB (B. I., Pr. 30). For the same reason, FE is equal to AB , wherefore $D C$ is equal to $F E$; hence, if DC and FE be taken away from the same line DE , the remainders CE and DF will be equal. But AD is also equal to BC , and AF to BE ; therefore the triangles DAF, CBE are mutually equilateral, and consequently equal.

Now if from the quadrilateral $A B E D$ we take the triangle ADF, there will remain the parallelogram ABEF ; and if from the same quadrilateral we take the triangle BCE , there will remain the parallelogram ABCD . Therefore the two parallelograms $\mathrm{ABCD}, \mathrm{ABEF}$, which have the same base and the same altitude, are equivalent.

Cor. Every parallelogram is equivalent to the rectangle which has the same base and the same altitude.

## PROPOSITION II. THEOREM.

Every triangle is half of the parallelogram which has the same base and the same altitucle.

Let the parallelogram ABDE and the triangle ABC have the

same base, AB , and the same altitude; the triangle is half of the parallelogram.

Complete the parallelogram ABFC; then the parallelogram ABFC is equivalent to the parallelogram ABDE , because they have the same base and the same altitude (Pr.1). But the triangle ABC is half of the parallelogram ABFC (B. I., Pr. 30, Cor. 1), wherefore the triangle ABC is also half of the parallelogram ABDE. Therefore every triangle, etc.

Cor. 1. Every triangle is half of the rectangle which has the same base and altitude.

Cor.2. Triangles which have equal bases and equal altitudes are equivalent.

PROPOSITION III. THEOREM.
Tivo vectangles having equal altitudes are to each other as their bases.

Let ABCD, AEFD be two rectangles which have the same altitude $A D$; they are to each other as their bases $\mathrm{AB}, \mathrm{AE}$.

Case first. When the bases are in the ratio of two whole numbers; for example, as 7 to 4 . If AB be divided into seven equal parts, AE will contain four of those parts. At each point of division erect a perpendicular to the base; seven pastial rectangles will thus be formed, all equal to each other, since they have equal bases and altitudes (Pr.1). The rectangle $A B C D$ will contain seven partial rectangles, while AEFD will contain four; therefore the rectangle ABCD is to the rectangle AEFD as 7 to 4 , or as AB to AE. The same reasoning is applicable to any other ratio than that of 7 to 4 ; therefore, whenever the ratio of the bases can be expressed in whole numbers, we shall have

$$
\mathrm{ABCD}: \operatorname{AEFD}:: \mathrm{AB}: \mathrm{AE} .
$$

Case second. When the ratio of the bases can not be expressed exactly in numbers, the proposition may be proved by the same method employed in B. III, Pr.14. Therefore two rectangles, etc.

PROPOSITION IV. THEOREM.
Any two rectangles are to each other as the products of their bases by their altitudes.

Let $A B C D, A E G F$ be two rectangles; the ratio of the rectan-
gle ABCD to the rectangle AEGF is the same with the ratio of the product of AB by AD to the product of AE by AF ; that is, $\mathrm{ABCD}: \mathrm{AEGF}:: \mathrm{AB} \times \mathrm{AD}: \mathrm{AE} \times \mathrm{AF}$.
Having placed the two rectangles so that the angles at $\mathbf{A}$ are vertical, produce the sides GE, CD till they meet in H . The two rectangles ABCD, AEHD have the same altitude AD ; they are, therefore, as their bases $\mathrm{AB}, \mathrm{AE}$ (Pr. 3).

So, also, the rectangles AEHD, AEGF,
 having the same altitude AE, are to each other as their bases AD, AF. Thus we have the two proportions

$$
\begin{aligned}
& \text { ABCD : AEHD }:: \mathrm{AB}: \mathrm{AE} \\
& \text { AEHD }: \text { AEGF }:: \mathrm{AD}: \mathrm{AF} .
\end{aligned}
$$

Hence (B. II., Pr. 12, Cor.), ABCD : AEGF :: AB $\times$ AD $: A E \times A F$.
Scholium. Hence we may take as the measure of a rectangle the product of its base by its altitude, provided we understand by it the product of two numbers, one of which is the number of linear units contained in the base, and the other the number of linear units contained in the altitude.

Thus, if the base of a rectangle contains 6 inches, and the altitude 4 inches, the rectangle can be divided into 24 squares, each equal to one square inch; that is, its area is represented by 24 square inches. If the base of a second
 rectangle contains 9 inches, and its altitude 5 inches, its area is represented by 45 square inches, and the ratio of the two rectangles is that of 24 to 45 .

## PROPOSITION V. THEOREM.

The area of any parallelogram is equal to the product of its base by its altitude.

Let ABCD be a parallelogram, AF its altitude, and $A B$ its base; then is its surface measured by the product of AB by AF. For, upon the base AB , construct a rectangle having the altitude AF; the parallelogram ABCD A. is equivalent to the rectangle ABEF (Pr. 1, Cor.). But the rectangle ABEF is measured by $\mathrm{AB} \times \mathrm{AF}$ (Pr. 4, Sch.) ; therefore the area of the parallelogram ABCD is equal to $\mathrm{AB} \times \mathrm{AF}$.

Cor. Parallelograms having equal bases are to each other as their altitudes, and parallelograms having equal altitudes are to each other as their bases; for magnitudes have the same ratio that their equimultiples have (B. II, Pr. 10).

## PROPOSITION VI. THEOREM.

The area of a triangle is equal to half the product of its base by its altitude.

Let ABC be any triangle, BC its base, and AD its altitude; the area of the triangle ABC is measured by half the product of BC by AD .

For, complete the parallelogram ABCE. The triangle ABC is half of the parallelogram ABCE (Pr. 2) ; but the area of the parallelogram is equal to $\mathrm{BC} \times \mathrm{AD}$ (Pr.5) ; hence the area of the triangle is equal to one half of the product of BC by AD . Therefore the area of a triangle, etc.

Cor.1. Triangles having equal altitudes are to each other as their bases, and triangles having equal bases are to each other as their altitudes.

Cor. 2. Equivalent triangles whose bases are equal have equal altitudes, and equivalent triangles whose altitudes are equal have equal bases.

Scholium. The area of a triangle is equal to half the product of its perimeter by the radius of the inscribed circle. Let $O$ be the
 centre of the inscribed circle. From this point let fall the perpendiculars $\mathrm{OD}, \mathrm{OE}$, OF upon the sides $\mathrm{AB}, \mathrm{BC}, \mathrm{AC}$, and draw the lines $\mathrm{AO}, \mathrm{BO}, \mathrm{CO}$. By this proposition we have triangle $\mathrm{AOB}=\frac{1}{2}(\mathrm{AB} \times \mathrm{OD})$, triangle $\mathrm{AOC}=\frac{1}{2}(\mathrm{AC} \times \mathrm{OF})$, and triangle $\mathrm{BOC}=\frac{1}{2}(\mathrm{BC} \times \mathrm{OE})$. Now the triangle $A B C$ is equivalent to the sum of the triangles $\mathrm{AOB}, \mathrm{AOC}$, and BOC , and the three perpendiculars $\mathrm{OD}, \mathrm{OE}, \mathrm{OF}$ are equal to each other.

Hence

$$
\mathrm{ABC}=\frac{1}{2}(\mathrm{AB}+\mathrm{AC}+\mathrm{BC}) \mathrm{OD}
$$

## PROPOSITION VII. THEOREM.

The area of a trapezoid is equal to the product of its altitude by half the sum of its parallel sides.

Let ABCD be a trapezoid, DE its altitude, AB and CD its parallel sides; its area is measured by half the product of DE by the sum of its sides $\mathrm{AB}, \mathrm{CD}$.

Bisect BC in F , and through F draw GH parallel to AD , and produce DC to H .

In the two triangles BFG, CFH the side BF is, by construction, equal to CF , the vertical angles BFG, CFH are equal (B.I., Pr. 5), and the angle FCH is equal to the alter-
 nate angle FBG, because CH and BG are parallel (B. I., Pr. 23); therefore the triangle CFH is equal to the triangle BFG.

Now if from the whole figure ABFHD we take away the triangle CFH, there will remain the trapezoid ABCD ; and if from the same figure ABFHD we take away the equal triangle BFG , there will remain the parallelogram AGHD. Therefore the trapezoid $A B C D$ is equivalent to the parallelogram $A G H D$, and is measured by the product of AG by DE.

Also, because AG is equal to DH , and BG to CH , therefore the sum of AB and CD is equal to the sum of AG and DH , or twice AG. Hence $A G$ is equal to half the sum of the parallel sides $\mathrm{AB}, \mathrm{CD}$; therefore the area of the trapezoid ABCD is equal to the product of the altitude DE by half the sum of the bases AB , CD.

Cor: If through the point F , the middle of BC , we draw FK parallel to the base $A B$, the point $K$ will also be the middle of AD. For the figure AKFG is a parallelogram, as also DKFH, the opposite sides being parallel. Therefore AK is equal to FG, and DK to HF. But FG is equal to FH, since the triangles BFG, CFH are equal ; therefore AK is equal to DK .

Now, since KF is equal to $A G$, the area of the trapezoid is equal to $\mathrm{DE} \times \mathrm{KF}$. Hence the area of a trapezoid is equal to its altitude multiplied by the line which joins the middle points of the sides which are not parallel.

## PROPOSITION VIII. THEOREM.

If a straight line is divided into any two parts, the square of the whole line is equivalent to the squares of the two parts, together oith twice the rectangle contained by the parts.

Let the straight line $A B$ be divided into any two parts in $C$; the square on AB is equivalent to the squares on $\mathrm{AC}, \mathrm{CB}$, together with twice the rectangle contained by $\mathrm{AC}, \mathrm{CB}$; that is,
$\mathrm{AB}^{2}$, or $(\mathrm{AC}+\mathrm{CB})^{2}=\mathrm{AC}^{2}+\mathrm{CB}^{2}+2(\mathrm{AC} \times \mathrm{CB}$.
Upon $A B$ describe the square $A \overline{B D E}$; take

AF equal to AC ; through F draw FG parallel to AB , and through C draw CH parallel to AE .

The square ABDE is divided into four parts : the first, ACIF, is the square on AC, since AF was taken equal to AC. The second part, IGDH, is the square on $C B$; for, because $A B$ is equal to AE , and AC to AF , therefore BC is equal to EF (B. I., Ax. 3).

But, because BCIG is a parallelogram, GI is equal to BC ; and because DEFG is a parallelogram, DG is equal to EF (B. I., Pr. 30 ) ; therefore HIGD is equal to a square described on BC. If these two parts are taken from the entire square, there will remain the two rectangles BCIG, EFIH, each of which is measured by $\mathrm{AC} \times \mathrm{CB}$; therefore the whole square on AB is equivalent to the squares on $A C$ and $C B$, together with twice the rectangle of $\mathrm{AC} \times \mathrm{CB}$. Therefore, if a straight line, etc.

Cor. The square of any line is equivalent to four times the square of half that line. For, if AC is equal to CB , the four figures $\mathrm{AI}, \mathrm{CG}, \mathrm{FH}, \mathrm{ID}$ become equal squares.

Scholium 1. If $a$ and $b$ denote the numbers which represent the two parts of the line $A B$, this proposition may be expressed algebraically thus: $\quad(a+b)^{2}=a^{2}+2 a b+b^{2}$.

Scholium 2. A rectangle is said to be contained by any two of the straight lines which are about one of the right angles.

## PROPOSITION IX. THEOREM.

The square described on the difference of two lines is equivalent to the sum of the squares of the lines, diminished by twice the rectangle contained by the lines.

Let $\mathrm{AB}, \mathrm{BC}$ be any two lines, and AC their difference; the square described on $\mathbf{A C}$ is equivalent to the sum of the squares on AB and CB , diminished by twice the rectangle contained by $\mathrm{AB}, \mathrm{CB}$; that is,

$$
\mathrm{AC}^{2}, \text { or }(\mathrm{AB}-\mathrm{BC})^{2}=\mathrm{AB}^{2}+\mathrm{BC}^{2}-2 \mathrm{AB} \times \mathrm{BC}
$$

Upon $A B$ describe the square ABKF; take AE equal to AC ; through C draw CG parallel to BK, and through E draw HI parallel to AB , and complete the square EFLI.

Because AB is equal to AF , and AC to AE , therefore CB is equal to EF , and GK to LF. Therefore LG is equal to FK or AB , and hence
the two rectangles CBKG, GLID are each measured by $\mathrm{AB} \times \mathrm{BC}$. If these rectangles are taken from the entire figure $A B K L I E$, which is equivalent to $\mathrm{AB}^{2}+\mathrm{BC}^{2}$, there will evidently remain the square ACDE. Therefore the square described, etc.

Scholium. This proposition is expressed algebraically thus:

$$
(a-b)^{2}=a^{2}-2 a b+b^{2}
$$

PROPOSITION X. THEOREM.
The rectangle contained by the sum and difference of two lines is equivalent to the difference of the squares of those lines.

Let $\mathrm{AB}, \mathrm{BC}$ be any two lines; the rectangle contained by the sum and difference of AB and BC is equivalent to the difference of the squares on AB and BC ; that is,

$$
(\mathrm{AB}+\mathrm{BC}) \times(\mathrm{AB}-\mathrm{BC})=\mathrm{AB}^{2}-\mathrm{BC}^{2}
$$

Upon $A B$ describe the square ABKF, and upon AC describe the square ACDE ; produce AB so that BI shall be equal to BC , and complete the rectangle AILE.

The base AI of the rectangle AILE is the sum of the two lines $A B, B C$, and its altitude AE is the difference of the same lines; there-
 fore AILE is the rectangle contained by the sum and difference of the lines $\mathrm{AB}, \mathrm{BC}$.

But this rectangle is composed of the two parts ABHE and BILH; and the part BILH is equal to the rectangle FGDE, for BH is equal to DE , and BI is equal to EF. Therefore ALLE is equivalent to the figure ABHDGF. But ABHDGF is the excess of the square ABKF above the square DHKG, which is the square of BC ; therefore

$$
(\mathrm{AB}+\mathrm{BC}) \times(\mathrm{AB}-\mathrm{BC})=\mathrm{AB}^{2}-\mathrm{BC}^{2}
$$

Scholium. This proposition is expressed algebraically thus:

$$
(a+b) \times(a-b)=a^{2}-b^{2}
$$

PROPOSITION XI. THEOREM.
In any right-angled triangle the square described on the hypothenuse is equivalent to the sum of the squares described on the other two sides.

Let ABC be a right-angled triangle, having the right angle BAC ; the square described upon the side BC is equivalent to the sum of the squares upon $\mathrm{BA}, \mathrm{AC}$.

On BC describe the square BCED , and on $\mathrm{BA}, \mathrm{AC}$, the squares

$\mathrm{BG}, \mathrm{CH}$; and through A draw AL parallel to BD , and join $\mathrm{AD}, \mathrm{FC}$.

Then, because each of the angles BAC, BAG is a right angle, CA is in the same straight line with AG (B. I., Pr. 3). For the same reason, BA and AH are in the same straight line.

The angle ABD is composed of the angle ABC and the right angle CBD. The angle FBC is composed of the same angle ABC and the right angle ABF ; therefore the whole angle ABD is equal to the angle FBC . But AB is equal to BF , being sides of the same square, and $B D$ is equal to $B C$ for the same reason; therefore the triangles $\mathrm{ABD}, \mathrm{FBC}$ have two sides and the included angle equal; they are therefore equal (B. I., Pr: 6).

But the rectangle BDLK is double of the triangle ABD , because they have the same base BD, and the same altitude BK (Pr. 2, Cor.1); and the square AF is double of the triangle FBC , for they have the same base BF, and the same altitude AB. Now the doubles of equals are equal to one another (B.I., Ax. 6); therefore the rectangle BDLK is equivalent to the square AF.

In the same manner it may be demonstrated that the rectangle CELK is equivalent to the square AI ; therefore the whole square BCED , described on the hypothenuse, is equivalent to the two squares $\mathrm{ABFG}, \mathrm{ACIH}$, described on the two other sides; that is,

$$
\mathrm{BC}^{2}=\mathrm{AB}^{2}+\mathrm{AC}^{2}
$$

Scholium. Tradition has ascribed the discovery of this proposition to Pythagoras (born about 580 B.C.), and hence it is commonly called the Pythagorean theorem.

Cor. 1. The square of one of the sides of a right-angled triangle is equivalent to the square of the hypothenuse, diminished by the square of the other side; that is,

$$
\mathrm{AB}^{2}=\mathrm{BC}^{2}-\mathrm{AC}^{2}
$$

Hence, if the numerical measures of two sides of a right-angled triangle are given, that of the third may be found. For example, if $\mathrm{BC}=5$, and $\mathrm{AB}=4$, then $\mathrm{AC}=$ the square root of $\left(5^{2}-4^{2}\right)=3$.

Also, if $\mathrm{AC}=5$, and $\mathrm{AB}=12$, then $\mathrm{BC}=13$.
Cor. 2. The square BCED, and the rectangle BKLD, having the same altitude, are to each other as their bases BC, BK (Pr. 3). But the rectangle BKLD is equivalent to the square AF ; therefore $\mathrm{BC}^{2}: \mathrm{AB}^{2}:: \mathrm{BC}: \mathrm{BK}$.

In the same manner, $\mathrm{BC}^{2}: \mathrm{AC}^{2}:: \mathrm{BC}: \mathrm{KC}$.
Therefore (B. II., Pr. 4, Cor.),

$$
\mathrm{AB}^{2}: \mathrm{AC}^{2}:: \mathrm{BK}: \mathrm{KC}
$$

That is, in any right-angled triangle, if a line be drawn from the right angle perpendicular to the hypothenuse, the squares of the two sides are proportional to the adjacent segments of the hypothenuse; also, the square of the hypothenuse is to the square of either of the sides as the hypothenuse is to the segment adjacent to that side.

Cor: 3. Let ABCD be a square, and AC its diagonal; the triangle $A B C$ being right-angled and isosceles, we have

$$
\mathrm{AC}^{2}=\mathrm{AB}^{2}+\mathrm{BC}^{2}=2 \mathrm{AB}^{2} ;
$$

therefore the square described on the diagonal of a square is double of the square described on a side.

If we extract the square root of each member of this equation, we shall have $\mathrm{AC}=\mathrm{AB} \sqrt{ } 2$; or $\mathrm{AC}: \mathrm{AB}:: \sqrt{ } 2: 1$.

The square root of 2 is 1.4142136 , correct to seven decimal places. Since the square root of 2 is an incommensurable number, it follows that the diagonal of a square is incommensurable with its side.

## PROPOSITION XII. THEOREM.

In any triangle, the square of the side opposite to an acute angle is less than the squares of the base and of the other side by twice the rectangle contained by the base, and the distance from the acute angle to the foot of the perpendicular let fall from the opposite angle.

Let ABC be any triangle, and the angle at C one of its acute angles, and upon BC let fall the perpendicular $A D$ from the opposite angle; then will

$$
\mathrm{AB}^{2}=\mathrm{BC}^{2}+\mathrm{AC}^{2}-2 \mathrm{BC} \times \mathrm{CD} .
$$

First. When the perpendicular falls within the triangle ABC , we have $\mathrm{BD}=\mathrm{BC}-\mathrm{CD}$, and therefore $\mathrm{BD}^{2}=\mathrm{BC}^{2}+\mathrm{CD}^{2}-2 \mathrm{BC} \times \mathrm{CD}$ (Pr. 9). To each of these equals add $\mathrm{AD}^{2}$; then $\mathrm{BD}^{2}+\mathrm{AD}^{2}$ $=\mathrm{BC}^{2}+\mathrm{CD}^{2}+\mathrm{AD}^{2}-2 \mathrm{BC} \times \mathrm{CD}$.

But in the right-angled triangle $\mathrm{ABD}, \mathrm{BD}^{2}+$ $\mathrm{AD}^{2}=\mathrm{AB}^{2}$; and in the triangle $\mathrm{ADC}, \mathrm{CD}^{2}+$
 $\mathrm{AD}^{2}=\mathrm{AC}^{2}(\operatorname{Pr} .11)$; therefore

$$
\mathrm{AB}^{2}=\mathrm{BC}^{2}+\mathrm{AC}^{2}-2 \mathrm{BC} \times \mathrm{CD}
$$

Secondly. When the perpendicular falls without the triangle ABC , we have $\mathrm{BD}=\mathrm{CD}-\mathrm{BC}$, and therefore $\mathrm{BD}^{2}=\mathrm{CD}^{2}+\mathrm{BC}^{2}-2 \mathrm{CD} \times \mathrm{BC}$ (Pr. 9). To each of these equals add $\mathrm{AD}^{2}$; then $\mathrm{BD}^{2}+\mathrm{AD}^{2}=\mathrm{CD}^{2}+\mathrm{AD}^{2}+\mathrm{BC}^{2}-2 \mathrm{CD} \times \mathrm{BC}$.

But $\mathrm{BD}^{2}+\mathrm{AD}^{2}=\mathrm{AB}^{2}$; and $\mathrm{CD}^{2}+\mathrm{AD}^{2}=\mathrm{AC}^{2}$; therefore $A B^{2}=B C^{2}+A C^{2}-2 B C \times C D$.
Scholium. When the perpendicular AD falls upon AB , this proposition reduces to the same as Pr. 11, Cor. 1.

## PROPOSITION XIII. THEOREM.

In an obtuse-angled triangle, the square of the side opposite the obtuse angle is greater than the squares of the base and the other side by twice the rectangle contained by the base, and the distance from the obtuse angle to the foot of the perpendicular let fall fiom the opposite angle on the base produced.

Let ABC be an obtuse-angled triangle, having the obtuse angle ABC , and from the point $A$ let AD be drawn perpendicular to BC produced; the square of $A C$ is greater than the squares of $A B, B C$ by twice the rectangle $\mathrm{BC} \times \mathrm{BD}$.
For CD is equal to $\mathrm{BC}+\mathrm{BD}$; therefore $\mathrm{CD}^{2}=\mathrm{BC}^{2}+\mathrm{BD}^{2}+2 \mathrm{BC}$ $\times \mathrm{BD}$ (Pr. 8). To each of these equals add $\mathrm{AD}^{2}$; then $\mathrm{CD}^{2}+$ $\mathrm{AD}^{2}=\mathrm{BC}^{2}+\mathrm{BD}^{2}+\mathrm{AD}^{2}+2 \mathrm{BC} \times \mathrm{BD}$.

But $\mathrm{AC}^{2}$ is equal to $\mathrm{CD}^{2}+\mathrm{AD}^{2}$ (Pr. 11), and $\mathrm{AB}^{2}$ is equal to $\mathrm{BD}^{2}+\mathrm{AD}^{2}$; therefore $\mathrm{AC}^{2}=\mathrm{BC}^{2}+\mathrm{AB}^{2}+2 \mathrm{BC} \times \mathrm{BD}$. Therefore, in an obtuse-angled triangle, etc.

Scholium. The right-angled triangle is the only one in which the sum of the squares of two sides is equivalent to the square on the third side; for, if the angle contained by the two sides is acute, the sum of their squares is greater than the square of the epr- ite side; if obtuse, it is less.

## PROPOSITION XIV. THEOREM.

In any triangle, if a straight line is drawn from the vertex to li.: middlle of the base, the sum of the squares of the other two sides isequivalent to twice the square of the bisecting line, together with twice the square of half the base.

Let ABC be a triangle having a line AD drawn from the middle of the base to the opposite angle; the squares of BA and AC are together double of the squares of AD and BD .

From A draw AE perpendicular to BC; then, in the triangle ABD, by Pr. 13,

$$
\mathrm{AB}^{2}=\mathrm{AD}^{2}+\mathrm{DB}^{2}+2 \mathrm{DB} \times \mathrm{DE} ;
$$ and, in the triangle ADC, by Pr. 12,

$$
\mathrm{AC}^{2}=\mathrm{AD}^{2}+\mathrm{DC}^{2}-2 \mathrm{DC} \times \mathrm{DE}
$$

Hence, by adding these equals, and observing that $\mathrm{BD}=\mathrm{DC}$, and therefore $\mathrm{BD}^{2}=\mathrm{DC}^{2}$, and $\mathrm{DB} \times \mathrm{DE}=\mathrm{DC} \times \mathrm{DE}$, we obtain

$$
\mathrm{AB}^{2}+\mathrm{AC}^{2}=2 \mathrm{AD}^{2}+2 \mathrm{DB}^{2}
$$

Therefore, in any triangle, etc.

> PROPOSITION XV. THEOREM.

In every parallelogram, the sum of the squares of the four sides is equal to the sum of the squares of the diagonals.

Let ABCD be a parallelogram, of which the diagonals are AC and BD ; the sum of the squares of AC and BD is equal to the sum of the squares of $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}, \mathrm{DA}$.

The diagonals $A C$ and $B D$ bisect each other in E (B. I., Pr. 33) ; therefore, in the triangle $\mathrm{ABD}(\mathrm{Pr} .14)$,

$$
\mathrm{AB}^{2}+\mathrm{AD}^{2}=2 \mathrm{BE}^{2}+2 \mathrm{AE}^{2}
$$

and, in the triangle BDC ,

$$
\mathrm{CD}^{2}+\mathrm{BC}^{2}=2 \mathrm{BE}^{2}+2 \mathrm{EC}^{2}
$$

Adding these equals, and observing that AE is equal to EC , we have $\quad \mathrm{AB}^{2}+\mathrm{BC}^{2}+\mathrm{CD}^{2}+\mathrm{AD}^{2}=4 \mathrm{BE}^{2}+4 \mathrm{AE}^{2}$.

But $4 \mathrm{BE}^{2}=\mathrm{BD}^{2}$, and $4 \mathrm{AE}^{2}=\mathrm{AC}^{2}$ (Pr. 8, Cor.) ; therefore . $\mathrm{AB}^{2}+\mathrm{BC}^{2}+\mathrm{CD}^{2}+\mathrm{AD}^{2}=\mathrm{BD}^{2}+\mathrm{AC}^{2}$.
Therefore, in every parallelogram, etc.

## proposition xvi. theorem.

If a straight line be drown parallel to the base of a triangle, it will cut the other sides proportionally ; and if the sides be cut proportionally, the cutting line will be parallel to the base of the triangle.

Let DE be drawn parallel to BC , the base of the triangle AB C ; then will $\mathrm{AD}: \mathrm{DB}:: \mathrm{AE}: \mathrm{EC}$.

Join BE and DC; then the triangle BDE is equivalent to the triangle DEC, because they have the same base, DE, and the same altitude, since their vertices $B$ and $C$ are in a line parallel to the base (Pr. 2, Cor. 2).

The triangles $\mathrm{ADE}, \mathrm{BDE}$, whose common vertex is E, having the same altitude, are to each other as their bases AD, DB (Pr. 6, Cor. 1) ; hence

ADE:BDE::AD:DB.
The triangles $\mathrm{ADE}, \mathrm{DEC}$, whose common vertex is D , having the same altitude, are to each other as their bases AE, EC; therefore

$$
\mathrm{ADE}: \mathrm{DEC}:: \mathrm{AE}: \mathrm{EC}
$$

But, since the triangle BDE is equivalent to the triangle DEC , therefore (B. II., Pr. 4),

$$
\mathrm{AD}: \mathrm{DB}:: \mathrm{AE}: \mathrm{EC} .
$$

Conversely, let DE cut the sides $\mathrm{AB}, \mathrm{AC}$, so that $\mathrm{AD}: \mathrm{DB}::$ $\mathrm{AE}: \mathrm{EC}$; then DE will be parallel to BC.

For $\mathrm{AD}: \mathrm{DB}:: \mathrm{ADE}: \operatorname{BDE}$ (Pr. 6, Cor. 1) ; and AE : EC :: AD $\mathrm{E}: \mathrm{DEC}$; therefore (B. II., Pr. 4), ADE : BDE :: ADE : DEC; that is, the triangles BDE, DEC have the same ratio to the triangle ADE ; consequently, the triangles $\mathrm{BDE}, \mathrm{DEC}$ are equivalont, and, having the same base, DE , their altitudes are equal ( Pr . 6, Cor. 2) ; that is, they are between the same parallels. Therefore, if a straight line, etc.

Cor. 1. Since, by this proposition, $\mathrm{AD}: \mathrm{DB}:: \mathrm{AE}: \mathrm{EC}$; by composition, $\mathrm{AD}+\mathrm{DB}: \mathrm{AD}:: \mathrm{AE}+\mathrm{EC}: \mathrm{AE}$ (B. II., Pr. 6), or $\mathrm{AB}::$ $\mathrm{AD}:: \mathrm{AC}: \mathrm{AE}$; also, $\mathrm{AB}: \mathrm{BD}:: \mathrm{AC}: \mathrm{EC}$.

Cor. 2. If two lines be clrawn parallel to the base of a triangle, they will divide the other sides proportionally. For, because FG is drawn parallel to BC, by the preceding proposition, $\mathrm{AF}: \mathrm{FB}:: \mathrm{A}$ G: GC. Also, by the last corollary, because DE is parallel to $\mathrm{FG}, \mathrm{AF}: \mathrm{DF}:: \mathrm{AG}: \mathrm{EG}$. Therefore DF : FB :: EG : GC (B. II., Pr. 4, Cor.).
Also, AD : DF :: AE : EG.

Cor. 3. If any number of lines be drawn parallel to the base of a triangle, the sides will be cut proportionally.

## PROPOSITION XVII. THEOREM.

The line which bisects the vertical angle of a triangle divides the base into two segments, which are proportional to the adjacent sides.

Let the angle BAC of the triangle ABC be bisected by the straight line AD ; then will

$$
\mathrm{BD}: \mathrm{DC}:: \mathrm{BA}: \mathrm{AC}
$$

Through the point B draw BE parallel to D A, meeting CA produced in E. The triangle A BE is isosceles. For, since AD is parallel to E B , the angle ABE is equal to the alternate angle DAB (B. I., Pr. 23), and the exterior angle
 CAD is equal to the interior and remote angle AEB. But, by hypothesis, the angle DAB is equal to the angle DAC ; therefore the angle $A B E$ is equal to $A E B$, and the side $A E$ to the side $A B$ (B. I., Pr. 11).

And because AD is parallel to BE , the base of the triangle BC $\mathbf{E}$ (Pr. 16), BD:DC::EA:AC.

But $A E$ is equal to $A B$, therefore

$$
\mathrm{BD}: \mathrm{DC}:: \mathrm{BA}: \mathrm{AC} .
$$

Therefore, the line, etc.

## PROPOSITION XVIII. THEOREM.

The line which bisects the exterior angle of a triangle divides the base produced into segments which are proportional to the adjacent sides.

Let BA , one side of the triangle ABC , be produced to E , and let the exterior angle CAE be bisected by the straight line AD , which meets the base produced at D ; then

$$
\mathrm{BD}: \mathrm{DC}:: \mathrm{BA}: \mathrm{AC} .
$$

Through C draw CF parallel to AD, meeting AB at F. Then, because the straight line $A C$ meets the parallels $A D, F C$, the angle ACF is equal to the alternate angle CAD (B.I., Pr. 23). But the angle CAD is, by hypothesis, equal to DAE; therefore DAE is equal to ACF .

Again, because the straight line FAE meets the parallels AD, FC , the exterior angle DAE is equal to the interior and remote angle AFC (B. I., Pr. 23). But DAE has been shown equal to A CF ; therefore ACF is equal to AFC , and therefore AF is equal to AC (B. I., Pr. 11).

And because FC is parallel to AD , one of the sides of the triangle ABD , therefore (B. IV., Pr. 16) $\mathrm{BD}: \mathrm{DC}:: \mathrm{BA}: \mathrm{AF}$. But AF is equal to AC ; therefore

$$
\mathrm{BD}: \mathrm{DC}:: \mathrm{BA}: \mathrm{AC} .
$$

Therefore, the line, etc.
Scholium. By the segments of a line we understand the por-
tions into which the line is divided at a given point. So also by the segments of a line procluced to a given point, we understand the distances between the given point and the extremities of the line.

## PROPOSITION XIX. THEOREM.

Two triangles which are mutually equiangular have their homologous sides proportional, and are similar.

Let ABC,DEF be two triangles which are mutually equiangular, having the angle $\mathrm{A}=\mathrm{D}, \mathrm{B}=\mathrm{E}$, and $\mathrm{C}=\mathrm{F}$; then the homologous sides will be proportional, and we shall have

$$
\mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}:: \mathrm{BC}: \mathrm{EF} .
$$

Take $A G=D E, A H=D F$, and join GH. Then the triangles AGH, DEF are equal, since two sides and the included angle in the one are respectively equal to two sides and the included angle in the other (B.I., Pr. 6). Therefore the angle AGH is equal to the angle $\mathbf{E}$. But, by hypothesis, the angle $\mathbf{E}$ is equal to the angle B ; therefore the angle B is equal to AGH , and therefore GH is parallel to BC (B. I., Pr. 22). Hence (B. IV., Pr. 16) we have $A B: A G:: A C: A H$.

Draw HL parallel to AB ; then BGHL is a parallelogram, and BL is equal to GH.

Also (B. IV:, Pr. 16), we have

$$
\mathrm{AC}: \mathrm{AH}:: \mathrm{BC}: \mathrm{BL} \text { or } \mathrm{GH} .
$$

Since these two proportions contain the same ratio AC:AH, we conclude (B. II., Pr. 4)

$$
\mathrm{AB}: \mathrm{AG}:: \mathrm{AC}: \mathrm{AH}:: \mathrm{BC}: \mathrm{GH},
$$

or, $\quad \mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}:: \mathrm{BC}: \mathrm{EF}$.
Therefore the triangles ABC, DEF have their homologous sides proportional; hence, by Def. 4, they are similar.

Cor. Two triangles are similar when two angles of the one are respectively equal to two angles of the other, for then the third angles must also be equal (B. I., Pr. 27, Cor. 2).

Scholium. In similar triangles the homologous sides are opposite to the equal angles; thus, the angle ACB being equal to the angle DFE, the side AB is homologous to DE , and so with the other sides.

## PROPOSITION XX. TIEOREM.

Two triangles which have their homologous sides proportional are mutually equiangular and similar:

Let the triangles ABC, DEF have their sides proportional, so that
$\mathrm{BC}: \mathrm{EF}:: \mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}$; then will the triangles have their angles equal, viz., the angle A to the an-
 gle $\mathrm{D}, \mathrm{B}$ equal to E , and C equal to F .

Take $\mathrm{AG}=\mathrm{DE}, \mathrm{AH}=\mathrm{DF}$, and join GH. By hypothesis we have $\mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}$;
or, substituting for $D E$ and $D F$ their equals $A G$ and $A I I$, we have $A B: A G:: A C: A H$.
Therefore GH is parallel to BC (B.IV., Pr. 16), and the triangles $\mathrm{ABC}, \mathrm{AGH}$ are mutually equiangular. Hence we have

$$
\mathrm{AC}: A H:: \mathrm{BC}: \mathrm{GH} .
$$

But, by hypothesis, we have

$$
\mathrm{AC}: \mathrm{DF}:: \mathrm{BC}: \mathrm{EF} ;
$$

and, since $\mathrm{AH}=\mathrm{DF}$, we conclude that $\mathrm{GH}=\mathrm{EF}$.
Therefore the triangles AGH, DEF, having the three sides of the one equal to the three sides of the other, are equal, and therefore the angle DEF is equal to AGH , which is equal to ABC ; also, the angle DFE is equal to $\Lambda H G$, which is equal to ACB ; and the angle $D$ is equal to $A$. Hence the triangles $\mathrm{ABC}, \mathrm{DEF}$ are mutually equiangular and similar. Therefore two triangles, etc.

Scholium. It will be seen from the last two propositions that triangles which are mutually equiangular have their homologous sides proportional, and conversely, so that either of these conditions involves the other. -This is not true of figures having more than three sides, for in quadrilaterals we may change the angles without changing the sides; or we may change the proportion of the sides without changing the angles. Thus, if we draw EF parallel to DC, the angles of the quadrilateral ABFE are equal to those of the quadrilateral ABCD , but the proportion of the sides is
 changed. Also, without changing the four sides $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}, \mathrm{DA}$, we may change the angles by moving the point $D$ toward $B$, or from it.

$$
\text { D } 2
$$

## PROPOSITION XXI. THEOREM.

Two triangles are similar when they have an angle of the one equal to an angle of the other, and the sides including those angles proportional.

Let the triangles $\mathrm{ABC}, \mathrm{DEF}$ have the angle $A$ of the one equal to the angle $D$ of the other, and let $\mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}$; the triangle ABC is similar to the triangle DEF.

Take AG equal to DE, also AH equal to DF, and join GH. Then the triangles AGH, DEF are equal, since two sides and the included angle in the one are respectively equal to two sides and the included angle in the other (B. I., Pr. 6). But, by hypothesis,

$$
\begin{aligned}
& \mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF} \\
& \mathrm{AB}: \mathrm{AG}:: \mathrm{AC}: \mathrm{AH}
\end{aligned}
$$

therefore
that is, the sides $A B, A C$, of the triangle $A B C$, are cut proportionally by the line GH ; therefore GH is parallel to BC (Pr. 16).

Hence (B. I., Pr. 23) the angle AGH is equal to $A B C$, and the triangle AGH is similar to the triangle ABC. But the triangle DEF has been shown to be equal to the triangle AGH; hence the triangle DEF is similar to the triangle ABC. Therefore, two triangles, etc.

## PROPOSITION XXII. THEOREM.

Two triangles are similar when they have their homologous sides parallel each to each, or perpendicular each to each.

Let the triangles $\mathrm{ABC}, a b c$, DEF have their homologous sides parallel each to each, or perpendicular each to each, the triangles are similar.

First. Let the homologous sides be parallel each to each. If the side AB is parallel to $a b$, and BC to $b c$, the angle B is equal to the angle $b$ (B. I., Pr. 26) ; also, if AC is parallel to $a c$, the angle C is equal to the angle $c$; and hence the angle A is equal to the angle a. Therefore the triangles ABC , $a b c$ are equiangular, and consequently similar.

Secondly. Let the homologous sides be perpendicular each to
each. Let the side DE be perpendicular to AB , and the side DF to AC. Produce DE to I , and DF to H ; then, in the quadrilateral AIDH, the two angles I and H are right angles. But the four angles of a quadrilateral are together equal to four right angles (B. I., Pr. 28, Cor.) ; therefore the two remaining angles IAH, IDH are together equal to two right angles. But the two angles EDF, IDH are together equal to two right angles (B.I., Pr. 2) ; therefore the angle EDF is equal to IAH or BAC.

In the same manner, if the side EF is also perpendicular to $B$ C , it may be proved that the angle DFE is equal to C , and, consequently, the angle DEF is equal to B ; hence the triangles ABC , DEF are equiangular and similar. Therefore, two triangles, etc.

Scholium. When the sides of the two triangles are parallel to each other, the parallel sides are homologous; but when the sides are perpendicular to each other, the perpendicular sides are homologous. Thus DE is homologous to AB, DF to AC, and EF to BC .

## PROPOSITION XXIII. THEOREM.

In a right-angled triangle, if a perpendicular is drawn from the right angle to the hypothenuse;

1st. The triangles on each side of the perpendicular are similar to the whole triangle and to each other.

2d. The perpendicular is a mean proportional between the segments of the hypothenuse.

3d. Each of the sides is a mean proportional between the hypothenuse and its segment adjacent to that side.

Let ABC be a right-angled triangle, having the right angle $B A C$, and from the angle $A$ let AD be drawn perpendicular to the hypothenuse BC.

First. The triangles $\mathrm{ABD}, \mathrm{ACD}$ are similar
 to the whole triangle ABC , and to each other:

The triangles $\mathrm{BAD}, \mathrm{BAC}$ have the common angle B , also the angle BAC equal to BDA , each of them being a right angle, and, therefore, the remaining angle ACB is equal to the remaining angle BAD (B. I., Pr. 27, Cor. 2) ; therefore the triangles ABC, AB D are equiangular and similar. In like manner, it may be proved that the triangle ADC is equiangular and similar to the triangle ABC ; therefore the three triangles $\mathrm{ABC}, \mathrm{ABD}, \mathrm{ACD}$ are equiangular, and similar to each other.

Secondly. The perpendicular AD is a mean proportional between the segments $\mathrm{BD}, \mathrm{DC}$ of the hypothenuse. For, since the triangle ABD is similar to the triangle ADC , their homologous sides are proportional (Def. 3), and we have

$$
\mathrm{BD}: \mathrm{AD}:: \mathrm{AD}: \mathrm{DC} .
$$

Thirdly. Each of the sides $\mathrm{AB}, \mathrm{AC}$ is a mean proportional between the hypothenuse and the segment adjacent to that side. For, since the triangle BAD is similar to the triangle BAC , we have
$B C: B A:: B A: B D$.
And, since the triangle ABC is similar to the triangle ACD , we have BC:CA: CA:CD.
Therefore, in a right-angled triangle, etc.

Cor. If from a point $A$, in the circumference of a circle, two chords $A B, A C$ are drawn to the extremities of the diameter $B C$, the triangle $B A C$ will be right-angled at A (B. III., Pr. 15, Cor. 3) ; therefore the perpendicular AD is a mean proportional between BD and DC , the two segments of the diameter; that is,

$$
\mathrm{AD}^{2}=\mathrm{BD} \times \mathrm{DC}
$$

## PROPOSITION XXIV. THEOREMI.

Troo triangles, having an angle in the one equal to an angle in the other, are to each other as the rectangles of the sides which contain the equal angles.

Let the two triangles $\mathrm{ABC}, \mathrm{ADE}$ have the angle $A$ in common; then will the triangle $A B C$ be to the triangle ADE as the rectangle $\mathrm{AB} \times \mathrm{AC}$ is to the rectangle $\mathrm{AD} \times \mathrm{AE}$.

Join BE. Then the two triangles $\mathrm{ABE}, \mathrm{ADE}$, having the common vertex E , have the same altitude, and are to each other as their bases $\mathrm{AB}, \mathrm{AD}$ (Pr. 6, Cor. 1); therefore

ABE : ADE::AB:AD.
Also, the two triangles $\mathrm{ABC}, \mathrm{ABE}$, having the common vertex $B$, have the same altitude, and are to each other as their bases $\mathrm{AC}, \mathrm{AE}$; therefore $\mathrm{ABC}: \mathrm{ABE}:: \mathrm{AC}: \mathrm{AE}$.

Hence (B. II., Pr. 12, Cor.)

$$
\mathrm{ABC}: \mathrm{ADE}:: \mathrm{AB} \times A \mathrm{~A}: A D \times A \mathrm{E} .
$$

Therefore two triangles, etc.
Cor. 1. If the rectangles of the sides containing the equal angles are equivalent, the triangles will be equivalent.

Cor: 2. Parallelograms which are mutually equiangular are to
each other as the rectangles of the sides which contain the equal angles.

## PROPOSITION XXV. THEOREM.

Similar triangles are to each other as the squares described on their homologous sides.

Let $\mathrm{ABC}, \mathrm{DEF}$ be two similar triangles, having the angle $A$ equal to $D$, the angle B equal to E , and C equal to F ; then the triangle $A B C$ is to the triangle DEF as the square on BC is to the square
 on EF.

By similar triangles, we have (Def. 4) $\mathrm{AB}: \mathrm{DE}:: \mathrm{BC}: \mathrm{EF}$.
Also, BC:EF::BC:EF.
Multiplying together the corresponding terms of these proportions, we obtain (B. II., Pr. 12),

$$
\mathrm{AB} \times \mathrm{BC}: \mathrm{DE} \times \mathrm{EF}:: \mathrm{BC}^{2}: \mathrm{EF}^{2}
$$

But, by Pr. 24,

$$
\mathrm{ABC}: \mathrm{DEF}:: \mathrm{AB} \times \mathrm{BC}: \mathrm{DE} \times \mathrm{EF} ;
$$

hence (B. II., Pr. 4) ABC : DEF :: $\mathrm{BC}^{2}: \mathrm{EF}^{2}$.
Therefore similar triangles, etc.

## PROPOSITION XXVI. THEOREM.

Two similar polygons may be divided into the same number of triangles, similar each to each, and similarly situated.

Let ABCDE, FGHIK be two similar polygons; they may be divided into the same number of similar triangles. Join AC, AD, FH, FI.

Because the polygon ABCDE is
 similar to the polygon FGHIIK, the angle $B$ is equal to the angle G (Def. 4), and $\mathrm{AB}: \mathrm{BC}:: \mathrm{FG}: \mathrm{GH}$.

And, because the triangles $\mathrm{ABC}, \mathrm{FGH}$ have an angle in the one equal to an angle in the other, and the sides about these equal angles proportional, they are similar ( Pr .21 ) ; therefore the angle BCA is equal to the angle GHF. Also, because the polygons are similar, the whole angle BCD is equal (Def. 4) to the whole angle GHI; therefore the remaining angle ACD is equal to the remaining angle FHI. Now, because the triangles ABC, FGH are similar, $\mathrm{AC}: \mathrm{FH}:: \mathrm{BC}$ : GH.

And, because the polygons are similar (Def. 4),

$$
\begin{aligned}
& \mathrm{BC}: \mathrm{GH}:: \mathrm{CD}: \mathrm{HI} \\
& \mathrm{AC}: \mathrm{FH}:: \mathrm{CD}: \mathrm{HI} ;
\end{aligned}
$$

whence
that is, the sides about the equal angles ACD, FHI are proportional ; therefore the triangle ACD is similar to the triangle FHI (Pr. 21). For the same reason, the triangle ADE is similar to the triangle FIK; therefore the similar polygons ABCDE, FGH IK are divided into the same number of triangles, which are similar each to each, and similarly situated.

Cor. Conversely, if two polygons are composed of the same number of triangles, similar each to each, and similarly situated, the polygons are similar.

For, because the triangles are similar, the angle ABC is equal to FGH ; and because the angle BCA is equal to GHF, and ACD to FHI, therefore the angle BCD is equal to GHI. For the same reason, the angle CDE is equal to HIK, and so on for the other angles. Therefore the two polygons are mutually equiangular.

Moreover, the sides about the equal angles are proportional. For, because the triangles are similar, $\mathrm{AB}: \mathrm{FG}:: \mathrm{BC}: \mathrm{GH}$. Also, $\mathrm{BC}: \mathrm{GH}:: \mathrm{AC}: \mathrm{FH}$, and $\mathrm{AC}: \mathrm{FH}:: \mathrm{CD}: \mathrm{HI}$; hence $\mathrm{BC}: \mathrm{GH}::$ CD : HI.

In the same manner, it may be proved that CD:HI:: DE:IK, and so on for the other sides. Therefore the two polygons are similar.

PROPOSITION XXVII. THEOREM.
The perimeters of two similar polygons are to each other as any two homologous sides, and their areas are as the squares of those sides.

Let ABCDE, FGHIK be two similar polygons, and let AB be the side homologous to FG ; then the perimeter of ABCDE is to the perimeter of FGHIIK as AB is to FG; and the area of ABCDE is to the area of
FGHIK as $\mathrm{AB}^{2}$ is to $\mathrm{FG}^{2}$.
First. Because the polygon ABCDE is similar to the polygon FGHIK (Def. 4),

$$
\mathrm{AB}: \mathrm{FG}:: \mathrm{BC}: \mathrm{GH}:: \mathrm{CD}: \mathrm{HI}, \text { etc. ; }
$$

therefore (B. II., Pr. 9) the sum of the antecedents $\mathrm{AB}+\mathrm{BC}+\mathrm{CD}$, etc., which form the perimeter of the first figure, is to the sum of the consequents $\mathrm{FG}+\mathrm{GH}+\mathrm{HI}$, etc., which form the perimeter of the second figure, as any one antecedent is to its consequent, or as AB to FG .

Secondly. Because the triangle ABC is similar to the triangle FGH , the triangle ABC : triangle $\mathrm{FGH}:: \mathrm{AC}^{2}: \mathrm{FH}^{2}(\mathrm{Pr} .25)$.

And, because the triangle ACD is similar to the triangle FHI, $\mathrm{ACD}: \mathrm{FHI}:: \mathrm{AC}^{2}: \mathrm{FH}^{2}$.
Therefore the triangle ABC : triangle $\mathrm{FGH}:$ : triangle ACD : triangle FHI (B. II., Pr. 4).

In the same manner, it may be proved that

$$
\mathrm{ACD}: \mathrm{FHI}:: \text { ADE : FIK. }
$$

Therefore, as the sum of the antecedents $\mathrm{ABC}+\mathrm{ACD}+\mathrm{ADE}$, or the polygon ABCDE , is to the sum of the consequents $\mathrm{FGH}+$ FHI + FIK, or the polygon FGHIK, so is any one antecedent, as ABC , to its consequent FGH ; or, as $\mathrm{AB}^{2}$ to $\mathrm{FG}^{2}$. Therefore the perimeters, etc.

## PROPOSITION XXVIII. THEOREM.

If two chords in a circle cut each other, the rectangle contained by the parts of the one is equivalent to the rectangle contained by the parts of the other.

Let the two chords $\mathrm{AB}, \mathrm{CD}$, in the circle AC BD , cut each other in the point E ; the rectangle contained by $\mathrm{AE}, \mathrm{EB}$ is equivalent to the rectangle contained by $\mathrm{DE}, \mathrm{EC}$.

Join AC and BD. Then, in the triangles AC $\mathrm{E}, \mathrm{DBE}$, the angles at E are equal, being vertical angles (B.I., Pr. 5) ; the angle A is equal to
 the angle D , being inscribed in the same segment (B. III., Pr: 15, Cor. 1); therefore the angle C is equal to the angle B . The triangles are consequently similar; and hence ( Pr .19 )

$$
\mathrm{AE}: \mathrm{DE}:: \mathrm{EC}: \mathrm{EB}
$$

$\mathrm{AE} \times \mathrm{EB}:: \mathrm{DE} \times \mathrm{EC}$.
or (B. II., Pr. 1) AE $\times \mathrm{E}$
Therefore, if two chords, etc.
Cor. The parts of two chords which cut each other in a circle are reciprocally proportional; that is, $\mathrm{AE}: \mathrm{DE}:: \mathrm{EC}: \mathrm{EB}$.

## PROPOSITION XXIX. THEOREM.

If from a point without a circle a tangent and a secant be drawn, the square of the tangent will be equivalent to the rectangle contained by the whole secant and its external segment.

Let A be any point without the circle BCD , and let AB be a tangent, and AC a secant; then the square of $A B$ is equivalent to the rectangle $\mathrm{AD} \times \mathrm{AC}$.

Join BD and BC. Then the triangles ABD and ABC are similar, because they have the angle A in common; also, the angle ABD , formed by a tangent and a chord, is measured by half the arc BD (B. III., Pr. 16), and the angle C is measured by half the same arc; therefore the angle ABD is equal to C , and the two triangles $\mathrm{ABD}, \mathrm{ABC}$ are mutually equiangular, and consequently similar; therefore (Pr. 19)

$$
\mathrm{AC}: \mathrm{AB}:: \mathrm{AB}: \mathrm{AD} ;
$$

whence (B. II., Pr. I.) $\quad \mathrm{AB}^{2}=\mathrm{AC} \times \mathrm{AD}$.
Therefore, if from a point, etc.
Cor: 1. If from a point without a circle a tangent and a secant be drawn, the tangent will be a mean proportional between the whole secant and its external segment.

Cor. 2. If from a point without a circle two secants be drawn, the rectangle contained by either secant and its external segment will be equivalent to the rectangle contained by the other secant and its external segment; for each of these rectangles is equivalent to the square of the tangent from the same point.

Cor. 3 . If from a point without a circle two secants be drawn, the whole secants will be reciprocally proportional to their external segments.

## PROPOSITION XXX. THEOREM.

If an angle of a triangle be bisected by a line which cuts the base, the rectangle contained by the sides of the triangle is equivalent to the rectangle contained by the segments of the base, together. with the square of the bisecting line.

Let ABC be a triangle, and let the angle BAC be bisected by the straight line AD ; the rectangle $\mathrm{BA} \times \mathrm{AC}$ is equivalent to $\mathrm{BD} \times \mathrm{DC}$, together with the square of AD .

Describe the circle ACEB about the triangle, and produce AD
to meet the circumference in E , and join EC. Then, because the angle BAD is equal to the angle CAE, and the angle ABD to the angle AEC, for they are in the same segment (B. III., Pr. 15, Cor. 1), the triangles ABD, AEC are mutually equiangular and similar; therefore (Pr. 19)

$$
\mathrm{BA}: \mathrm{AD}:: \mathrm{AE}: \mathrm{AC}
$$

 consequently (B. II., Pr. 1),

$$
\mathrm{BA} \times \mathrm{AC}=\mathrm{AD} \times \mathrm{AE}
$$

But $\mathrm{AE}=\mathrm{AD}+\mathrm{DE}$; and multiplying each of these equals by AD , we have (Pr. 3) $\mathrm{AD} \times \mathrm{AE}=\mathrm{AD}^{2}+\mathrm{AD} \times \mathrm{DE}$. But $\mathrm{AD} \times \mathrm{DE}$ $=\mathrm{BD} \times \mathrm{DC}(\mathrm{Pr} .27)$; hence

$$
\mathrm{BA} \times \mathrm{AC}=\mathrm{BD} \times \mathrm{DC}+\mathrm{AD}^{2}
$$

Therefore, if an angle, etc.

## PROPOSITION XXXI. THEOREM.

In any triangle, the rectangle contained by two sides is equivalent to the rectangle contained by the diameter of the circumscribed circle, and the perpendicular let fall upon the third side from the vertex of the opposite angle.

In the triangle ABC , let AD be drawn perpendicular to BC , and let AE be the diameter of the circumscribed circle ; then

$$
\mathrm{AB} \times \mathrm{AC}=\mathrm{AE} \times \mathrm{AD}
$$

For, drawing $E C$, the right angle $A D B$ is equal to the angle ACE in a semicircle (B. III., Pr. 15), and the angle $B$ to the angle $E$ in the
 same segment (B. III., Pr. 15) ; therefore the triangles ABD, AEC are similar, and we have

$$
\begin{gathered}
A B: A E:: A D: A C \\
A B \times A C=A E \times A D
\end{gathered}
$$

and hence
Therefore, in any triangle, etc.

## PROPOSITION XXXII. THEOREM.

The rectangle contained by the diagonals of a quadrilateral inscribed in a circle is equivalent to the sum of the rectangles of the opposite sides.

Let ABCD be any quadrilateral inscribed in a circle, and let the diagonals $\mathrm{AC}, \mathrm{BD}$ be drawn; the rectangle $\mathrm{AC} \times \mathrm{BD}$ is equivalent the sum of the two rectangles $A D \times B C$ and $A B \times C D$.

Draw the straight line BE, making the angle ABE equal to the angle DBC. To each of these equals add the angle EBD ; then will the angle ABD be equal to the angle EBC . But the angle BDA is equal to the angle BCE, because they are both in the same segment (B. III., Pr. 15, Cor. 1) ; hence the triangle ABD is equiangular and similar to the triangle EBC . Therefore we have $\mathrm{AD}: \mathrm{BD}:: \mathrm{CE}: \mathrm{BC}$; and, consequently, $\quad \mathrm{AD} \times \mathrm{BC}=\mathrm{BD} \times \mathrm{CE}$.

Again, because the angle ABE is equal to the angle DBC , and the angle BAE to the angle BDC , being angles in the same segment, the triangle ABE is similar to the triangle DBC ; and hence $\mathrm{AB}: \mathrm{AE}:: \mathrm{BD}: \mathrm{CD}$;
consequently, $\mathrm{AB} \times \mathrm{CD}=\mathrm{BD} \times \mathrm{AE}$. Adding together these two results, we obtain

$$
\mathrm{AD} \times \mathrm{BC}+\mathrm{AB} \times \mathrm{CD}=\mathrm{BD} \times \mathrm{CE}+\mathrm{BD} \times \mathrm{AE},
$$

which equals $\mathrm{BD} \times(\mathrm{CE}+\mathrm{AE})$, or $\mathrm{BD} \times \mathrm{AC}$.
Therefore the rectangle, etc.

## PROPOSITION XXXIII, THEOREMI.

The perpendiculars drawn from the three angles of any triangle to the opposite sides intersect one another in the same point.

If the triangle be right angled, it is plain that all the perpendiculars pass through the right angle. But if it be not right an-
 gled, let ABC be the triangle, and about it describe a circle. Let B and C be two acute angles; draw ADE perpendicular to BC , meeting the circumference in E. Make DF equal to DE ; join BF , and produce it, if necessary, to cut AC, or AC produced, in G; then BG is perpendicular to AC.

Join BE; and, because FD is equal to DE , the angles at D are right angles, and DB is common to the two triangles $\mathrm{FDB}, \mathrm{EDB}$, the angle FBD is equal to EBD (B. I., Pr. 6). But CAD, EBD are also equal, because they are in the same segment (B. III., Pr. 15). Therefore CAD is equal to FBD or GBC. But the angle ACB is common to the two triangles ACD , BCG , and therefore the remaining angles $\mathrm{ADC}, \mathrm{BGC}$ are equal (B.I., Pr. 27). But ADC is a right angle; therefore also BGC is a right angle, and BG is perpendicular to AC .

In the same manner, it may be shown that the straight line CH , drawn through C and F , is perpendicular to AB , and the three perpendiculars all pass through $\mathbf{F}$. Therefore the perpendiculars, etc.

## PROPOSITION XXXIV. THEOREM.

If from any angle of a triangle a perpendicular be drawn to the opposite side or base, the rectangle contained by the sum and difference of the other two sides is equivalent to the rectangle contained by the sum and difference of the segments of the base.

Let ABC be any triangle, and let AD be a perpendicular drawn from the angle $A$ on the base $B C$; then

$$
(\mathrm{AC}+\mathrm{AB}) \times(\mathrm{AC}-\mathrm{AB})=(\mathrm{CD}+\mathrm{DB}) \times(\mathrm{CD}-\mathrm{DB})
$$

From $A$ as a centre, with a radius equal to $A B$, the shorter of

the two sides, describe a circumference BFE. Produce AC to meet the circumference in E , and CB , if necessary, to meet it in F .

Then, because $A B$ is equal to $A E$ or $A G, C E=A C+A B$, the sum of the sides; and $C G=A C-A B$, the difference of the sides. Also, because BD is equal to. DF (B. III., Pr. 6), when the perpendicular falls within the triangle, $\mathrm{CF}=\mathrm{CD}-\mathrm{DF}=\mathrm{CD}-\mathrm{DB}$, the difference of the segments of the base. But when the perpendicular falls without the triangle, $\mathrm{CF}=\mathrm{CD}+\mathrm{DF}=\mathrm{CD}+\mathrm{DB}$, the sum of the segments of the base.

Now, in either case, the rectangle $\mathrm{CE} \times \mathrm{CG}$ is equivalent to $\mathrm{CB} \times \mathrm{CF}$ (Pr. 29, Cor. 2) ; that is,

$$
(\mathrm{AC}+\mathrm{AB}) \times(\mathrm{AC}-\mathrm{AB})=(\mathrm{CD}+\mathrm{DB}) \times(\mathrm{CD}-\mathrm{DB})
$$

Therefore, if from any angle, etc.
Cor. If we reduce the preceding equation to a proportion (B. II., Pr. 2), we shall have

$$
\mathrm{CD}+\mathrm{DB}: \mathrm{AC}+\mathrm{AB}:: \mathrm{AC}-\mathrm{AB}: \mathrm{CD}-\mathrm{DB} ;
$$

that is, the sum of the segments of the base is to the sum of the two other sides as the difference of the latter is to the difference of the segments of the base.

## PROPOSITION XXXV. THEOREM.

The diagonal and side of a square have no common measure.
Let $A B C D$ be a square, and $A C$ its diagonal; $A C$ and $A B$ have no common measure.

In order to find the common measure, if there is one, we must apply CB to CA as often as it is contained in it. For this purpose, from the centre C, with a radius CB, describe the semicircle EBF. We perceive that CB is contained once in AC, with a remainder AE, which remainder must be compared with BC , or its equal AB .

Now, since the angle $A B C$ is a right angle, $A B$ is a tangent to the circumference; and $\mathrm{AE}: \mathrm{AB}:: \mathrm{AB}: \mathrm{AF}$ (Prop. 29, Cor. 1). Instead, therefore, of comparing $A E$ with $A B$, we may substitute the equal ratio of AB to AF . But AB is contained twice in AF , with a remainder $A E$, which must be again compared with $A B$. Instead, however, of comparing $A E$ with $A B$, we may again employ the equal ratio of AB to AF . Hence at each operation we are obliged to compare AB with AF , which leaves a remainder AE; from which we see that the process will never terminate, and therefore there is no common measure between the diagonal and side of a square; that is, there is no line, however small, which is contained an exact number of times in each of them.

The same conclusion was arrived at in Pr. 11, Cor. 3, by a different method.

## B O OK V.

## PROBLEMS.

Hitherto we have assumed the possibility of constructing our figures, although the methods of constructing them have not yet been explained. For the purpose of discovering the properties of figures, we are at liberty to suppose any figure to be constructed, or any line to be drawn, whose existence does not involve an impossibility. We now proceed to show how the figures employed in these demonstrations may be constructed.

All the constructions of Elementary Geometry are supposed to be effected by means of straight lines and circumferences of circles, these being the only lines treated of in the Elements. A straight line is supposed to be drawn by means of a ruler, and a circle by the aid of a pair of compasses. By means of other curves, which are treated of in Higher Geometry, more difficult problems may be constructed, such as to divide any angle into three equal parts; to tind two mean proportionals between two given lines, etc.

## Postulates.

1. A straight line may be drawn from any one point to any other point.
2. A terminated straight line may be produced to any length in a straight line.
3. From the greater of two straight lines, a part may be cut off equal to the less.
4. A circumference may be described from any centre and with any radius.

## PROBLEML 1.

To bisect a given straight line.
Let AB be the given straight line which it is required to bisect.

From the centre A, with a radius greater than the half of $A B$, describe an arc of a circle (Postulate 4) ; and from the centre B, with the same radius, describe apother are inter-

secting the former in D and E . Through the points of intersection draw the straight line DE (Post. 1) ; it will bisect AB in C .

For the two points $D$ and $E$, being each equally distant from the extremities $A$ and $B$, must both lie in the perpendicular, raised from the middle point of AB (B. I., Pr. 18, Cor.). Therefore the line DE divides the line AB into two equal parts at the point C.

## PROBLEM II.

To draw a perpendicular to a straight line from a given point in that line.

Let BC be the given straight line, and A the point given in it ; it is required to draw a straight line perpendicular to BC through the given point A.

In the straight line BC take any point B , and make $A C$ equal to $A B$ (Post. 3). From $B$ as a centre, with a radius greater than $B A$, describe an arc of a circle (Post. 4) ; and from C as a centre, with the same radius, describe another arc intersecting the former in D. Draw AD (Post. 1), and it will be the perpendicular required.

For the points $A$ and $D$, being equally distant from $B$ and $C$, must be in a line perpendicular to the middle of BC (B. I., Pr. 18, Cor.). Therefore AD has been drawn perpendicular to BC from the point A.

Scholium. The same construction serves to make a right angle BAD at a given point A , on a given line BC .

## PROBLEM III.

To draw a perpendicular to a straight line from a given point without it.

Let BD be a straight line of unlimited length, and let $A$ be a given point without it. It is required to draw a perpendicular to BD from the point A.

Take any point $E$ upon the other side of BD , and from the centre A , with the radius AE , describe the are BD , cutting the line BCD in the two points $\mathbf{B}$ and $\mathbf{D}$. From the points B and D as centres, describe two arcs, as in Prob. 2, cutting each other in F. Join AF, and it will be the perpendicular required.

For the two points $A$ and $F$ are each equally distant from the points $B$ and $D$; therefore the line $A F$ has been drawn perpendicular to BD (B. I., Pr. 18, Cor.) from the given point A.

## PROBLEM IV.

At a given point in a straight line, to make an angle equal to a given angle.

Let AB be the given straight line, A the given point in it, and C the given angle; it is required to make an angle at the point A , in the straight line AB ,
 that shall be equal to the given angle $\mathbf{C}$.

With C as centre, and any radius, describe an arc DE terminating in the sides of the angle; and from the point A as a centre, with the same radius, describe the indefinite are BF. Draw the chord DE ; and from B as a centre, with a radius equal to DE , describe an arc cutting the arc BF in G. Draw AG, and the angle BAG will be equal to the given angle C.

For the two arcs BG, DE are described with equal radii, and they have equal chords ; they are, therefore, equal (B. III., Pr. 3). But equal arcs subtend equal angles (B. III., Pr. 4), and hence the angle $A$ has been made equal to the given angle $\mathbf{C}$.

## PROBLEM $V$.

## To bisect a given are or a given angle.

First. Let ADB be the given are which it is required to bisect.

Draw the chord $A B$, and from the centre $C$ draw $C D$ perpendicular to $A B$ (Prob. 3) ; it will bisect the arc ADB (B. III., Pr. 6), because CD is
 a radius perpendicular to a chord.

Secondly. Let ACB be an angle which it is required to bisect. From $C$ as centre, with any radius, describe an arc $A B$; and, by the first case, draw the line CD bisecting the arc ADB. The line CD will also bisect the angle ACB . For the angles $\mathrm{ACD}, \mathrm{BCD}$ are equal, being subtended by the equal ares $\mathrm{AD}, \mathrm{DB}$ (B. III., Pr. 4).

Scholium. By the same construction, each of the halves AD, DB may be bisected; and thus by successive bisections an arc or angle may be divided into four equal parts, into eight, sixteen, etc.

## PROBLEAI VI.

Through a given point to draw a straight line parallel to a given line.

Let A be the given point, and BC the given straight line ; it is required to draw through the point A a straight line parallel to BC .

In BC take any point D , and join AD .
Then, at the point $A$, in the straight line $A D$, make the angle DAE equal to the angle ADB (Prob. 4).

Now, because the straight line $A D$, which meets the two straight lines $\mathrm{BC}, \mathrm{AE}$, makes the alternate angles $\mathrm{ADB}, \mathrm{DAE}$ equal to each other, AE is parallel to BC (B. I., Pr. 22). Therefore the straight line $A E$ has been drawn through the point $A$, parallel to the given line BC.

## PROBLEM VII.

Tuo angles of a triangle being given, to find the third angle.

The three angles of every triangle are together equal to two right angles (B. I., Pr. 27). Therefore, draw the indefinite line ABC . At the point $B$ make the angle $A B D$ equal to one of the given angles (Prob. 4), and the angle DBE equal to the other given angle; then will the angle EBC be equal to the third angle of the triangle.

For the three angles $\mathrm{ABD}, \mathrm{DBE}, \mathrm{EBC}$ are together equal to two right angles (B. I., Pr. 2), which is the sum of all the angles of the triangle.

## PROBLEM VIII.

Two sides and the included angle of a triangle being given, to construct the triangle.

Draw the straight line BC equal to one of the given sides. At the point $B$ make the angle ABC equal to the given angle (Prob. 4), and take $A B$ equal to the other given side. Join AC, and ABC will be the given triangle required. For its sides $\mathrm{AB}, \mathrm{BC}$ are made equal to the given sides, and the included angle $\mathbf{B}$ is made equal to the given angle.

## PROBLEM IX.

One side and two angles of a triangle being given, to construct the triangle.
The two given angles will either be both adjacent to the given side, or one adjacent and the other opposite. In the latter case, find the third angle (Prob. 7), and then the two adjacent angles will be known.
Draw the straight line AB equal to the given side ; at the point A make the angle BAC equal to one of the adjacent angles, and at the point $B$ make the angle ABD equal to the other adjacent angle. The two lines $\mathrm{AC}, \mathrm{BD}$ will cut each other
 in E , and ABE will be the triangle required; for its side $A B$ is equal to the given side, and two of its angles are equal to the given angles.

## PROBLEM X.

The three sides of a triangle being given, to construct the triangle.
Draw the straight line BC equal to one of the given sides. From the point B as a centre, with a radius equal to one of the other sides, describe an arc of a circle; and from the point C as a centre, with a radius equal to the third side, describe another arc cutting the former in $A$. Draw $A B, A C$; then will $A B C$ be
 the triangle required, because its three sides are equal to the three given straight lines.
Scholium. If one of the given lines was equal to or greater than the sum of the other two, the arcs would not intersect each other, and the problem would be impossible; but the solution will always be possible when each side is less than the sum of the other two.

## PROBLEM XI.

Two sides of a triangle and the angle opposite to one of them being given, to construct the triangle.
Draw an indefinite straight line $B C$. At the point $B$ make the angle ABC equal to the given angle, and make BA equal to that side which is adjacent to the given angle. Then from $\mathbf{A}$ as a centre, with a radius equal to the other side, describe an are cutting BC in the points E and F. Join AE, AF.

If the points $E$ and $F$ both fall on the same side of the angle $B$, each of the triangles $A B E$, ABF will satisfy the given conditions; but if they fall on different sides of $B$, only one of them, as ABF , will satisfy the conditions, and therefore this will be the triangle required.

If the points E and F coincide with one another, which will happen when AEB is a right angle, there will be only one triangle, ABD , which is the triangle required.

Scholium. If the side opposite the given angle were less than the perpendicular let fall from A upon BC , the problem would be impossible.

## PROBLEM XII.

Tioo acljacent sides of a parallelogram and their included angle being given, to construct the parallelogram.

Draw the straight line $A B$ equal to one of the given sides. At the point A make the angle BAC equal to the given angle, and take AC equal to the other given side. From the point C as a centre, with a radius equal to AB , describe an are, and from the point B as a centre, with a radius equal to $A C$, describe another are intersecting the former in D . Draw $\mathrm{BD}, \mathrm{CD}$; then will ABDC be the parallelogram required. For, by construction, the opposite sides are equal; therefore the figure is a parallelogram (B. I., Pr. 31), and it is formed with the given sides and the given angle.

Cor. If the given angle is a right angle, the figure will be a rectangle; and if, at the same time, the sides are equal, it will be a square.

## PROBLEM XIII.

To find the centre of a given circumference or of a given arc.

Let $A B C$ be the given circumference or are ; it is required to find its centre.

Take any three points in the are, as $A$. $\mathrm{B}, \mathrm{C}$, and join $\mathrm{AB}, \mathrm{BC}$. Bisect AB in I (Prob. I.), and through D draw DF perpendicular to AB (Prob. 2). In the same manner, draw EF perpendicular to BC at its middle point. The perpendiculars DF, EF
will mect in a point $F$ equally distant from the points $A, B$, and C (B. III., Pr. 7), and therefore F is the centre of the circle.

Scholium. By the same construction, a circumference may be made to pass through three given points, $A, B, C$; and also, a circle may be described about a triangle.

## PROBLEM XIV.

Through a given point, to drawo a tangent to a given circumference.

First. Let the given point $A$ be without the circle BDE ; it is required to draw a tangent to the circumference through the point $A$.

Find the centre of the circle $\mathbf{C}$, and join AC. Bisect AC in D; and, with $D$ as a centre, and a radius equal to AD ,
 describe a circumference intersecting the given circumference in B. Draw AB , and it will be the tangent required.

Draw the radius CB . The angle ABC , being inscribed in a semicircle, is a right angle (B. III., Pr. 15, Cor. 3). Hence the line AB is a perpendicular at the extremity of the radius CB ; it is, therefore, a tangent to the circumference (B. III., Pı: 9).

Secondly. If the given point is in the circumference of the circle, as the point B , draw the radius BC , and make BA perpendicular to BC. BA will be the tangent required (B. III., Pr. 9).

Scholium. When the point A lies without the circle, two tangents may always be drawn; for the circumference, whose centre is $D$, intersects the given circumference in two points.

## Problem xv.

To inscribe a circle in a given triangle.
Let ABC be the given triangle; it is required to inscribe a circle in it.

Bisect any two angles B and C by the lines BD , CD , meeting each other in the point D . From the point of interscction, let fall the perpendiculars $\mathrm{DE}, \mathrm{DF}, \mathrm{DG}$ on the three sides of the trian-
 gle; these perpendiculars will all be equal.

For, by construction, the angle EBD is equal to the angle FBD ; the right angle DEB is equal to the right angle DFB ; hence the third angle $B D E$ is equal to the third angle BDF ( $B$,
I., Pr. 27, Cor. 2). Moreover, the side BD is common to the two triangles $\mathrm{BDE}, \mathrm{BDF}$, and the angles adjacent to this side are equal; therefore the two triangles are equal, and DE is equal to DF .

For the same reason, DG is equal to DF. Therefore the three straight lines $D E, D F, D G$ are equal to each other; and, if a circumference be described from the centre $D$, with a radius equal to DE, it will pass through the extremities of the lines DF, DG. It will also touch the straight lines $\mathrm{AB}, \mathrm{BC}, \mathrm{CA}$, because the angles at the points E, F, G are right angles (B. III., Pr. 9). Therefore the circle EFG is inscribed in the triangle ABC (B. III., Def. 12).

Schotium. The three lines which bisect the angles of a triangle all meet in the same point, viz., the centre of the inscribed circle.

## PROBLEM XVI.

Upon a given straight line, to describe a segment of a circle which shall contain a given angle.

Let AB be the given straight line, upon which it is required to describe a segment of a circle containing a given angle.

At the point $A$, in the straight line $A B$, make the angle $B A D$ equal to the given angle; and from the point $A$ draw $A C$ perpen-

dicular to AD . Bisect AB in E , and from E draw EC perpendicular to AB . From the point C , where these perpendiculars meet, with a radius equal to AC, describe a circle. Then will AGB be the segment required.

For, since $A D$ is a perpendicular at the extremity of the radius AC , it is a tangent (B. III., Pr. 9), and the angle BAD is measured by half the arc AFB (B. III., Pr. 16). Also, the angle AGB, being an inscribed angle, is measured by half the same arc AFB; hence the angle AGB is equal to the angle BAD , which, by construction, is equal to the given angle. Therefore any angle inscribed in the segment AGB is equal to the given angle.

Scholium. If the given angle was a right angle, the required segment would be a semicircle, described on AB as a diameter.

## PROBLEMI XVII.

To divide a given straight line into any number of equal parts, or into parts proportional to given lines.

First. Let AB be the given straight line which it is proposed to divide into any number of equal parts, as, for example, five.

From the point A draw the indefinite
 straight line AC, making any angle with AB. In AC take any point $D$, and set off $A D$ five times upon $A C$. Join $B C$, and draw DE parallel to it; then is AE the fifth part of AB .

For, since ED is parallel to $B C$, we have $A E: A B:: A D: A C$ (B. IV., Pr. 16). But $A D$ is the fifth part of $A C$; therefore AE is the fifth part of $A B$.

Secondly. Let AB be the given straight line, and AC a divided line; it is required to divide $A B$ similarly to $A C$. Suppose AC to be divided in the points D and E . Place $\mathrm{AB}, \mathrm{AC}$ so as to contain any angle; join BC , and through the points D, E draw DF, EG parallel to BC. The line AB will be divided into parts proportional to those of AC.

For, because DF and EG are both parallel to CB, we have AD : AF ::DE : FG :: EC : GB
 (B. IV., Pr: 16, Cor. 2).

## PROBLEM XVIII.

## To find a fourth proportional to three given lines.

From any point A draw two straight lines $\mathrm{AD}, \mathrm{AE}$, containing any angle DAE, and make $\mathrm{AB}, \mathrm{BD}, \mathrm{AC}$ respectively equal to the proposed lines. Join B, C, and through D draw DE parallel to BC ; then will CE be the fourth proportional required.

For, because BC is parallel to DE, we have

$$
\mathrm{AB}: \mathrm{BD}:: \mathrm{AC}: \mathrm{CE}(\mathrm{~B} . \mathrm{IV} ., \operatorname{Pr}, 16) .
$$

Cor. In the same manner may be found a third proportional to two given lines $A$ and $B$, for this will be the same as a fourth proportional to the three lines $\mathrm{A}, \mathrm{B}, \mathrm{B}$.

PROBLEM XIX.
To find a mean proportional between two given lines.

Let $A B, B C$ be the $t$ wo given straight lines; it is required to find a mean proportional between them.

Place $\mathrm{AB}, \mathrm{BC}$ in a straight line; upon AC describe the semicircle ADC , and from the point B draw BD perpendicular to AC . Then will BD be the mean proportional required.

For the perpendicular BD, let fall from a point in the circumference upon the diameter, is a mean proportional between the two segments of the diameter AB, BC (B. IV., Pr. 23, Cor.), and these segments are equal to the two given lines.

## PROBLEM XX.

To divide a given line into two paris such that the greater part may be a mean proportional betwcen the whole line and the other. pow't.

Let AB be the given straight line; it is required to divide it into two parts at the point $F$, such that $A B: A F:: A F: F B$.

At the extremity of the line $A B$ erect the perpendicular $B C$, and make it equal to the half of AB . From C as a centre, with a radius equal to CB , describe a circle. Draw AC cutting the circumference in $D$, and make $A F$ equal to $A D$. The line $A B$ will be divided in the point F in the manner required.

For, since $A B$ is a perpendicular to the radius $C B$ at its extremity, it is a tangent (B. III., Pr. 9) ; and, if we produce AC to E , we shall have $\mathrm{AE}: \mathrm{AB}:: \mathrm{AB}: \mathrm{AD}$ (B. IV., Pr. 29). Therefore, by division (B. II., Pr. 7), AE-AB:AB::AB-AD:AD. But, by construction, AB is equal to DE , and therefore $\mathrm{AE}-\mathrm{AB}$ is equal to $A D$ or $A F$, and $A B-A D$ is equal to $F B$. Hence $A F: A B::$ FB: AD or AF; and, consequently, by inversion (B. II., Pr. 5),

$$
\mathrm{AB}: \mathrm{AF}:: \mathrm{AF}: \mathrm{FB} .
$$

Schol. 1. The line AB is said to be divided in extreme and mean ratio. An example of its use may be seen in Book VI., Pr. 5.

$$
\text { Schol. 2. Let } \mathrm{AB}=a ; \mathrm{AF}=\mathrm{AD}=\mathrm{AC}-\mathrm{CD} . \quad \mathrm{CD}=\frac{a}{2} .
$$

But

$$
\mathrm{AC}=\sqrt{\overline{\mathrm{AB}^{2}+\mathrm{BC}^{2}}}=\sqrt{a^{2}+\frac{a^{2}}{4}}=\sqrt{\frac{5 a^{2}}{4}}=\frac{a}{2} \sqrt{5}
$$

$$
\mathrm{AF}=\frac{a}{2} \sqrt{ } 5-\frac{a}{2}=\frac{a}{2} \times(\sqrt{5}-1)
$$

## PROBLEM XXI.

Through a given point in a given angle, to drazo a straight line so that the parts included between the point and the sides of the angle may be equal.

Let A be the given point, and BCD the given angle; it is required to draw through $\mathbf{A}$ a line BD , so that BA may be equal to AD .

Through the point A draw AE parallel to BC, and take DE equal to CE. Through the points $D$ and $A$ draw the line $B A D$; it will be the
 line required.

For, because AE is parallel to BC, we have (B. IV., Pr. 16) DE: EC :: DA : AB.
But DE is equal to EC ; therefore DA is equal to AB .

## PROBLEM XXII.

To construct a square that shall be equivalent to a given parallelogram or to a given triangle.

First. Let ABCD be the given parallelogram, AB its base, and DE its altitude. Find a mean proportional between AB and DE (Prob. 19), and represent it by $\mathbf{X}$; the square described on $\mathbf{X}$ will
 be equivalent to the given parallelogram ABCD.

For, by construction, $\mathrm{AB}: \mathrm{X}:: \mathrm{X}: \mathrm{DE}$; hence $\mathrm{X}^{2}$ is equal to $\mathrm{AB} \times \mathrm{DE}$ (B. II., Pr. 1, Cor.). But $\mathrm{AB} \times \mathrm{DE}$ is the measure of the parallelogram, and $\mathrm{X}^{2}$ is the measure of the square. Therefore the square described on X is equivalent to the given parallelogram ABCD.

Secondly. Let ABC be the given triangle, BC its base, and AD its altitude. Find a mean proportional between BC and the half of AD , and represent it by $Y$. Then will the square described on Y be
 equivalent to the triangle ABC.

For, by construction, $\mathrm{BC}: \mathrm{Y}:: \mathrm{Y}: \frac{1}{2} \mathrm{AD}$; hence $\mathrm{Y}^{2}$ is equivalent to $\mathrm{BC} \times \frac{1}{2} \mathrm{AD}$. But $\mathrm{BC} \times \frac{1}{2} \mathrm{AD}$ is the measure of the triangle ABC ; therefore the square described on Y is equivalent to the triangle ABC .

## PROBLEII XXIII.

Upon a given straight line, to construct a rectangle equivalent to a given rectangle.

Let AB be the given straight line, and CDFE the given rectangle. It is required to construct on the line AB a rectangle equivalent to CDFE.

Find a fourth proportional (Prob.
18) to the three lines $\mathrm{AB}, \mathrm{CD}, \mathrm{CE}$, and let AG be that fourth proportional. The rectangle constructed on the lines $A B$, $A G$ will be equivalent to CDFE.

For, because $\mathrm{AB}: \mathrm{CD}:: \mathrm{CE}: \mathrm{AG}\left(\mathrm{B} . \mathrm{II}^{2}, \mathrm{Pr} .1\right), \mathrm{AB} \times \mathrm{AG}=\mathrm{CD}$ $\times \mathrm{CE}$. Therefore the rectangle ABHG is equivalent to the rectangle CDFE, and it is constructed upon the given line AB.

## PROBLEM XXIV.

To construct a triangle which shall be equivalent to a given polygon.

Let ABCDE be the given polygon; it is required to construct a triangle equivalent to it.

Draw the diagonal BD , cutting off the triangle BCD. Through the point C draw CF parallel to DB , meeting AB produced in F . Join DF, and the polygon AFDE will be equivalent to the polygon ABCDE .

For the triangles $\mathrm{BFD}, \mathrm{BCD}$, being upon the same base BD , and between the same parallels $\mathrm{BD}, \mathrm{FC}$, are equivalent. To each of these equals add the polygon ABDE ; then will the polygon AFDE be equivalent to the polygon ABCDE ; that is, we have found a polygon equivalent to the given polygon, and having the number of its sides diminished by one.

In the same manner, a polygon may be found equivalent to AFDE, and having the number of its sides diminished by one; and, by continuing the process, the number of sides may be at last reduced to three, and a triangle be thus obtained equivalent to the given polygon.

Scholium. By Prob. 22, any triangle may be changed into an equivalent square, and hence a square can always be found equivalent to any given polygon. This operation is called squaring the polygon, or finding its quadrature.

The problem of the quadrature of the circle consists in finding a square equivalent to a circle whose diameter is given.

## PROBLEM XXV.

To construct a square equivalent to the sum or difference of two given squares.

First. To make a square equivalent to the sum of two given squares, draw two indefinite lines $\mathrm{AB}, \mathrm{BC}$ at right angles to each other. Take $A B$ equal to the side of one of the given squares, and BC equal to the side of the othei. Join AC; it will be the side of the required square.

For the triangle ABC , being right-angled at B , the square on $A C$ will be equivalent to the sum of the squares upon $A B$ and $B C$ (B. IV., Pr. 11).

Secondly. To make a square equivalent to the difference of two given squares, draw the lines $\mathrm{AB}, \mathrm{BC}$ at right angles to each other, and take AB equal to the side of the less square. Then, from $A$ as a centre, with a radius equal to the other side of the square, describe an arc intersecting BC in C ; BC will be the side of the square required, because the square of BC is equivalent to the difference of the squares of AC and AB (B. IV., Pr. 11, Cor. 1).

Scholium. In the same manner, a square may be made equivalent to the sum of three or more given squares; for the same construction which reduces two of them to one will reduce three of them to two, and these two to one.

## problem xxvi.

Upon a given straight line, to construcit a polygon similar to a given polygon.

Let ABCDE be the given polygon, and FG be the given straight line; it is required, upon the line FG, to construct a polygon similar to ABCDE.

Draw the diagonals BD ,
 BE. At the point $F$, in the straight line $F G$, make the angle GFK equal to the angle BAE, and at the point G make the angle FGK equal to the angle ABE. The lines FK, GK will inter* sect in $K$, and FGK will be a triangle similar to ABE.

In the same manner, on GK construct the triangle GKI similar to BED, and on GI construct the triangle GIH similar to BDC. The polygon FGHIK will be the polygon required. For these two polygons are composed of the same number of triangles, which are similar to each other, and similarly situated; therefore the polygons are similar (B. IV., Pr. 26, Cor.).

## PROBLEM XXVII.

Given the area of a rectangle and the sum of two adjacent sides, to construct the rectangle.

Let AB be a straight line equal to the sum of the sides of the required rectangle.

Upon $A B$ as a diameter, describe a semicircle. At the point $A$ erect the perpendicular AC , and make it equal to the side of a square having the given area. Through C draw the line $C D$ parallel to $A B$, and let it meet the circumference in D , and from D draw DE perpendicular to $A B$. Then will $A E$ and $E B$ be the sides of the rectangle required.

For (B. IV., Pr. 23, Cor.) the rectangle $\mathrm{AE} \times \mathrm{EB}$ is equivalent to the square of DE or CA , which is, by construction, equivalent to the given area. Also, the sum of the sides AE and EB is equal to the given line $A B$.

Scholium. The side of the square having the given area must not be greater than the half of $A B$, for in that case the line $C D$ would not meet the circumference ADB .

## problem xxviir.

Given the area of a rectangle and the difference of two adjacent sides, to construct the rectangle.

Let AB be a straight line equal to the dif-
 ference of the sides of the required rectangle.

Upon AB as a diameter describe a circle, and at the extremity of the diameter draw the tangent $A C$ equal to the side of a square having the given area. Through the point C and the centre F draw the secant CE ; then will CD, CE be the adjacent sides of the rectangle required.

For (B. IV., Pr. 29) the rectangle $\mathrm{CD} \times \mathrm{CE}$ is equivalent to the
square of AC , which is, by construction, equivalent to the given area. Also, the difference of the lines $\mathrm{CE}, \mathrm{CD}$ is equal to DE or AB .

## PROBLEM XXIX.

To find two straight lines having the same ratio as the areas of two given polygons.

Since any two polygons can always be transformed into squares, this problem requires us to find two straight lines in the same ratio as two given squares.

Draw two lines, $\mathrm{AC}, \mathrm{BC}$, at right angles with each other, and make AC equal to a side of one of the given squares, and BC equal to a side of the other given square. Join AB , and from C draw
 CD perpendicular to AB . Then (B.IV., Pr.11, Cor. 2) we have $\mathrm{AD}: \mathrm{DB}:: \mathrm{AC}^{2}: \mathrm{CB}^{2}$.
Therefore $A D, D B$ are in the ratio of the areas of the given polygons.

## PROBLEM XXX.

To find a square which shall be to a given square in the ratio of two given straight lines.

Upon a line of indefinite length, take AB equal to one of the given lines, and BC equal to the other line. Upon AC as a diameter describe a semicircle, and at $B$ erect the perpen-
 dicular BD , cutting the circumference in D . Join DA, DC ; and upon DA, or DA produced, take DE equal to a side of the given square. Through the point E draw EF parallel to AC ; then DF is a side of the required square.

For, because EF is parallel to AC (B. IV., Pr. 16), we have DE:DF::DA:DC;
whence (B. II., Pr. 11) $\mathrm{DE}^{2}: \mathrm{DF}^{2}:: \mathrm{DA}^{2}: \mathrm{DC}^{2}$.
Also, because ADC is a right-angled triangle (B.IV., Pr. 11), we have
$\mathrm{DA}^{2}: \mathrm{DC}^{2}:: \mathrm{AB}: \mathrm{BC}$.
Hence
$\mathrm{DE}^{2}: \mathrm{DF}^{2}:: \mathrm{AB}: \mathrm{BC}$.
Therefore the square described on DE is to the square described on DF in the ratio of the two given straight lines.

## PROBLEM XXXI.

To construct a polygon similar to one given polygon, and equivalent to another given polygon.

Let P and Q be two given polygons. It is required to construct a polygon similar to P , and equivalent to Q .

Find M, the side of a square equivalent to $P(\operatorname{Pr} .24$, Schol. $)$, and $N$, the side of a square equivalent to $Q$. Let $A B$ be one side of $P$, and let $C D$ be a fourth proportional to the three lines $M, N, A B$. Upon the side $C D$ homologous to AB , construct the polygon $\mathrm{P}^{\prime}$ similar to $\mathrm{P}(\mathrm{Pr} \cdot 26)$; it will be equivalent to the polygon Q .

For (B. IV., Pr. 27) P: $\mathrm{P}^{\prime}: \mathrm{AB}^{2}: \mathrm{CD}^{2}$.
But, by construction, $\mathrm{AB}: \mathrm{CD}:: \mathrm{M}: \mathrm{N}$,
or $A B^{2}: \mathrm{CD}^{2}:: \mathrm{M}^{2}: \mathrm{N}^{2}$.
Hence $\mathrm{P}: \mathrm{P}^{\prime}:: \mathrm{M}^{2}: \mathrm{N}^{2}$.
But, by construction,

$$
\begin{gathered}
\mathrm{M}^{2}=\mathrm{P}, \text { and } \mathrm{N}^{2}=\mathrm{Q} \\
\mathrm{P}: \mathrm{P}^{\prime}:: \mathrm{P}: \mathrm{Q} .
\end{gathered}
$$

therefore
Hence $\mathrm{P}^{\prime}=\mathrm{Q}$. Therefore the polygon $\mathrm{P}^{\prime}$ is similar to the polygon $P$, and equivalent to the polygon Q .

## PROBLEM XXXII.

To draw a common tangent to two given circles.

Let C and $c$ be the centres of the two given circles. With C as a centre, and a radius CB equal to the difference of the two given radii CA and $c a$, describe a circumference, and from $c$ draw a straight line touching the circle CB in the point B (Prob. 14). Join CB, and produce it to meet the given circumference in $\mathbf{A}$. Draw ca parallel to $\mathbf{C} A$, and join $\mathbf{A} a$. Then $\mathrm{A} a$ is the common tangent to the two given circles.

For, by the construction, $\mathrm{BC}=\mathrm{AC}-a c$; and also $\mathrm{BC}=\mathrm{AC}-$ AB ; whence $a c=\mathrm{AB}$, and $\mathrm{AB} c a$ is a parallelogram (B. I., Pr. 32). But the angle $B$ is a right angle; therefore this parallelogram is a rectangle, and the angles at A and $a$ are right angles. Hence A $\alpha$ is a tangent to both circles.

Since two tangents can be drawn from $c$ to the circle $B C$, there are two common tangents to the given circles, viz., $\mathrm{A} \alpha$ and $\mathrm{D} d$.

Scholium. Two other tangents can be drawn to the two given circles, and their points of contact will lie upon opposite sides of the line joining the centres. For this purpose CB must be taken equal to the sum of the given radii.

## BOOK VI.

REGULAR POLYGONS, AND THE AREA OF THE CIRCLE.

## Definition.

A regular polygon is a polygon which is both equiangular and equilateral.

An equilateral triangle is a regular polygon of three sides; a square is one of four.

## PROPOSITION I. THEOREM.

Regular polygons of the same number of sides are similar figures.

Let ABCDEF, abcclef be two regular polygons of the same number of sides; then will they be similar figures.

For, since the two polygons have the same number of sides, they must have the same number of angles. Moreover, the sum of the angles of the one polygon is equal to the sum of the angles of the other (B.I., Pr. 28) ; and, since the polygons are each equiangular, it follows that the angle $\mathbf{A}$ is the same part of the sum of the angles $\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}$, that the angle $a$ is of the sum of the angles $a, b, c, c l, e, f$. Therefore the two angles $A$ and $a$ are equal to each other. The samre is true of the angles B and $b, \mathrm{C}$ and $c$, etc.

Moreover, since the polygons are regular, the sides $\mathrm{AB}, \mathrm{BC}$, CD, etc., are equal to each other (Def.) ; so, also, are the sides $a b$, $b c, c d$, etc. Therefore $\mathrm{AB}: a b:: \mathrm{BC}: b c:: \mathrm{CD}: c d$, etc. Hence the two polygons have their angles equal, and their homologous sides proportional; they are consequently similar (B. IV., Def. 4). Therefore, regular polygons, etc.

Cor. The perimeters of two regular polygons of the same number of sides are to each other as their homologons sides, and their areas are as the squares of those sides (B. IV., Pr. 27).

Scholium. The magnitude of the angles of a regular polygon is determined by the number of its sides.

## PROPOSITION II. THEOREM.

A circle may be described about any regular polygon, and a circle may also be inscribed within it.

Let ABCDEF be any regular polygon; a circle may be described about it, and another may be inscribed within it.

Bisect the angles $\mathrm{FAB}, \mathrm{ABC}$ by the straight lines $A O, B O$, and, from the point $O$ in which they meet, draw the lines OC,OD, OE, OF to the other angles of the polygon.

Then, because in the triangles OBA, OBC, AB is, by hypothesis, equal to $\mathrm{BC}, \mathrm{BO}$ is common to the two triangles, and the included angles OBA, OBC are, by construction, equal to each other ; therefore the angle OAB is equal to the angle OCB . But OAB is, by construction, the half of FAB , and FAB is, by hypothesis, equal to DCB ; therefore OCB is the half of DCB ; that is, the angle BCD is bisected by the line OC. In the same manner, it may be proved that the angles CDE, DEF, EFA are bisected by the straight lines $\mathrm{OD}, \mathrm{OE}, \mathrm{OF}$.

Now, because the angles $\mathrm{OAB}, \mathrm{OBA}$, being halves of equal angles, are equal to each other, OA is equal to OB (B.I., Pr. 11). For the same reason, $\mathrm{OC}, \mathrm{OD}, \mathrm{OE}, \mathrm{OF}$ are each of them equal to OA. Therefore a circumference described from the centre $O$, with a radius equal to OA , will pass through each of the points $\mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}$, and be described about the polygon.

Secondly. A circle may be inscribed within the polygon ABC DEF.

For the sides $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}$, etc., are equal chords of the same circle; hence they are equally distant from the centre O (B. III., Pr. 8) ; that is, the perpendiculars OG, OII, etc., are all equal to each other. Therefore, if from $O$ as a centre, with a radius $O G$, a circumference be described, it will touch the side BC (B. III., Pr. 9), and each of the other sides of the polygon; hence the circle will be inscribed within the polygon. Therefore a circle may be described, etc.

Scholium 1. In regular polygons, the centre of the inscribed and circumscribed circles is also called the centre of the polygon; and the perpendicular from the centre upon one of the sides, that is, the radius of the inscribed circle, is called the apothegm of the polygon.

Since all the chords $\mathrm{AB}, \mathrm{BC}$, etc., are equal, the angles at the centre, $\mathrm{AOB}, \mathrm{BOC}$, etc., are equal; and the value of each may bo found by dividing four right angles by the number of sides of the polygon.

The angle at the centre of the inscribed equilateral triangle is $\frac{1}{3}$ of four right angles, or $120^{\circ}$; the angle at the centre of the regular inscribed pentagon is $\frac{1}{5}$ of four right angles, or $72^{\circ}$; the angle at the centre of the regular hexagon is $\frac{1}{6}$ of four right angles, or $60^{\circ}$; the angle at the centre of the regular decagon is $\frac{1}{10}$ of four right angles, or $36^{\circ}$.

Sch.2. To inscribe a regular polygon of any number of sides in a circle, it is only necessary to divide the circumference into the same number of equal parts; for, if the arcs are equal, the chords $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}$, etc., will be equal. Hence the triangles $\mathrm{AOB}, \mathrm{BOC}, \mathrm{COD}$, etc., will also be equal, because they are mutually equilateral; therefore all the angles $\mathrm{ABC}, \mathrm{BCD}, \mathrm{CDE}$, etc., will be equal, and the figure $\triangle B C D E F$ will be a regular polygon.

PROPOSITION III. PROBLEM.
To inscribe a square in a given circle.

Let ABCD be the given circle; it is required to inscribe a square in it.

Draw two diameters $\mathrm{AC}, \mathrm{BD}$ at right angles to each other, and join $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}, \mathrm{DA}$.

Because the angles $\mathrm{AEB}, \mathrm{BEC}$, etc., are equal, the chords $\mathrm{AB}, \mathrm{BC}$, etc., are also equal. And because the angles $\mathrm{ABC}, \mathrm{BCD}$, etc., are inscribed in semicircles, they are right angles (B. III., Pr. 15, Cor. 2). Therefore ABCD is a square, and it is inscribed in the circle ABCD.

Cor. Since the triangle AEB is right-angled and isosceles, we have the proportion $\mathrm{AB}: \mathrm{AE}:: \sqrt{ } 2: 1$ (B. IV., Pr. 11, Cor. 3); therefore the side of the inscribed square is to the ractius, as the square root of 2 is to unity.

## PROPOSITION IV. THEOREM.

The side of a regular hexagon is equal to the radius of the circumscribed circle.

Let ABCDEF be a regular hexagon inscribed in a circle whose centre is $O$; then any side, as $A B$, will be equal to the radius AO.

Draw the radius BO. Then the angle AOB is the sixth part of four right angles (Pr. 2, Sich. 1), or the third part of two right angles. Also, because the three angles of every triangle are equal to two right angles, the two angles $\mathrm{OAB}, \mathrm{OBA}$ are together equal to two thirds of two right angles; and since $A O$ is equal to BO , each of these angles is one third
 of two right angles. Hence the triangle AOB is equiangular, and $A B$ is equal to $A O$. Therefore the side of a regular hexagon, etc.

Cor. To inscribe a regular hexagon in a given circle, the radius must be applied six times upon the circumference. By joining the alternate angles $A, C, E$, an equilateral triangle will be inscribed in the circle.

Sch. 1. In the right-angled triangle ACD we have $\mathrm{AC}^{2}=\mathrm{AD}^{2}$ $-\mathrm{DC}^{2}=4 \mathrm{AO}^{2}-\mathrm{AO}^{2}=3 \mathrm{AO}^{2}$. Whence $\mathrm{AC}=\mathrm{AO} \sqrt{ } 3$; that is, the side of an equilateral triangle is equal to the radius of the circumscribed circle multiplied by the square root of 3 .

Sch. 2. The area of the triangle ACE (B. IV., Pr. 6, Sch.) $=\frac{3}{2} \mathrm{AC}$ $\times \mathrm{OH}$.

But

$$
\mathrm{OB}=\frac{\mathrm{AC}}{\sqrt{ } 3}=\frac{\mathrm{AC} \sqrt{ } 3}{3}
$$

Therefore

$$
\mathrm{OH}=\frac{\mathrm{AC} \sqrt{ } 3}{6}
$$

Hence the triangle $\mathrm{ACE}=\frac{3}{2} \mathrm{AC} \times \frac{\mathrm{AC} \sqrt{ } 3}{6}=\frac{\mathrm{AC}^{2}}{4} \sqrt{ } 3$; that is, the area of an equilateral triangle is equal to one fourth the square of one of its sides multiplied by the square root of three.

## PROPOSITION V. PROBLEM.

To inscribe a regular clecagon in a given circle.
Let ABH be the given circle; it is required to inscribe in it a regular decagon.

Take $C$ the centre of the circle; draw the radius AC, and divide it in extreme and mean ratio (B. V., Pr. 20) at the point D. Make the chord AB equal to CD , the greater segment; then will AB be the side of a regular decagon inscribed in the circle.

Join BC, BD. Then, by construction, AC $: C D:: C D: A D ;$ but $A B$ is equal to $C D$; therefore $A C: A B:: A B: A D$. Hence the triangles $\mathrm{ACB}, \mathrm{ABD}$ Lave a common angle A included between proportional sides; they are therefore similar (B. IV., Pr. 21).

And because the triangle ACB is isosceles, the triangle ABD must also be isosceles, and AB is equal to BD . But AB was made equal to CD ; hence BD is equal to CD , and the angle DBC is equal to the angle DCB . Therefore the exterior angle ADB , which is equal to the sum of DCB and DBC , must be double of DCB . But the angle ADB is equal to DAB , therefore each of the angles $\mathrm{CAB}, \mathrm{CBA}$ is double of the angle ACB. Hence the sum of the three angles of the triangle ACB is five times the angle C. But these three angles are equal to two right angles (B.I., Pr. 27) ; therefore the angle C is the fifth part of two right angles, or the tenth part of four right angles. Hence the arc AB is one tenth of the circumference, and the chord AB is the side of a regular decagon inscribed in the circle.

Scholium. $\mathrm{AB}=\mathrm{CD}=\frac{\mathrm{AC}}{2} \times(\sqrt{ } 5-1)$ (see B. V., Pr. 20, Sch. 2); that is; the side of a regular clecagon is equal to half the radius of the circumscribed circle, multiplied by the square root of five, less unity.

Cor. 1. By joining the alternate angles of the regular decagon, a regular pentagon, AEGIL, may be inscribed in the circle.

Cor. 2. By combining this Proposition with the preceding, a regular pentedecagon may be inscribed in a circle.

For, let AN be the side of a regular hexagon; then the are AN will be one sixth of the whole circumference, and the arc $A B$ one tenth of the whole circumference. Hence the arc BN will be $\frac{1}{6}$ $-\frac{1}{10}$ or $\frac{1}{15}$, and the chord of this arc will be the side of a regular pentedecagon.

Scholium. By bisecting the arcs subtended by the sides of any polygon, another polygon of double the number of sides may be inscribed in a circle. Hence the square will enable us to inscribe regular polygons of $8,16,32$, etc., sides; the hexagon will enable us to inscribe polygons of 12,24 , etc., sides; the decagon will enable us to inscribe polygons of 20,40 , etc., sides; and the pentedecagon, polygons of 30,60 , etc., sides.

The ancient geometricians were unacquainted with any method of inscribing in a circle regular polygons of $7,9,11,13,14,17$, etc., sides, and for a long time it was believed that these polygons could not be constructed geometrically; but Gauss, a German mathematician, has shown that a regular polygon of 17 sides may be inscribed in a circle by employing straight lines and circles only.

## PROPOSITION VI. PROBLEM.

A regular polygon inscribed in a circle being given, to describe a similar polygon about the circle.

Let ABCDEF be a regular polygon inscribed in the circle ABD ; it is required to describe a similar polygon about the circle.

Bisect the $\operatorname{arc} A B$ in $G$, and through $G$ draw the tangent LM. Bisect also the arc BC in H , and through H draw the tangent MN, and in the same manner draw tangents to the middle points of the arcs $\mathrm{CD}, \mathrm{DE}$, etc.
 These tangents, by their intersections, will form a circumscribed polygon similar to the one inscribed.

Find O, the centre of the circle, and draw the radii OG, OH. Then, because OG is perpendicular to the tangent LM (B. III., Pr. 9), and also to the chord AB (B. III., Pr. 6, Cor.), the tangent is parallel to the cloord (B. I., Pr. 20). In the same manner, it may be proved that the other sides of the circumscribed polygoil are parallel to the sides of the inscribed polygon, and therefore the angles of the circumscribed polygon are equal to those of the inscribed one (B. I., Pr. 26).

Since the arcs $B G, B H$ are halves of the equal ares $A G B, B H C$, they are equal to each other; that is, the vertex $B$ is at the middle point of the arc GBH.

Join OM; the line OM will pass through the point B. For the right-angled triangles $\mathrm{OMH}, \mathrm{OMG}$ have the hypothenuse OM common, and the side OH equal to OG; therefore the angle GOM is equal to the angle HOM (B.I., Pr. 19), and the line OM passes through the point $B$, the middle of the arc GBH.

Now, because the triangle OAB is similar to the triangle OLM, and the triangle OBC to the triangle OMN, we have the proportions $\mathrm{AB}: \mathrm{LM}:: \mathrm{BO}: \mathrm{MO}$;
also

$$
\mathrm{BC}: \mathrm{MN}:: \mathrm{BO}: \mathrm{MO} ;
$$

therefore (B. II., Pr. 4) AB : LM :: BC : MN.
But $A B$ is equal to $B C$; therefore $L M$ is equal to MN.

In the same manner, it may be proved that the other sides of the circumscribed polygon are equal to each other. Hence this polygon is regular, and similar to the one inscribed.
Cor: 1. Conversely, if the circumscribed polygon is given, and it is required to form the similar inscribed one, draw the lines OL, OM, ON, etc., to the angles of the polygon; these lines will meet the circumference in the points $A, B, C$, etc. Join these points by the lines $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}$, etc., and a similar polygon will be inscribed in the circle.

Or we may simply join the points of contact $\mathrm{G}, \mathrm{H}, \mathrm{I}$, etc., by the chords GII, HI, etc., and there will be formed an inscribed polygon similar to the circumscribed one.

Cor: 2. Hence we can circumscribe about a circle any regular polygon which can be inscribed within it, and conversely.

Cor. 3. A side of the circumscribed polygon MN is equal to twice MII, or MG + MII.

## PROPOSITION VII. THEOREM.

The area of a regular polygon is equivalent to the product of its perimeter by lalf the radius of the inscribed circle.

Let $A B C D E F$ be a regular polygon, and $G$ the centre of the inscribed circle. From G draw lines to all the angles of the polygon. The polygon will thus be divided into as many triangles as it has sides; and the common altitude of these triangles is GH, the radius of the circle.

Now the area of the triangle BGC is equal to the product of BC by the half of GH (B.IV., Pr. 6), and so of all the other triangles having their vertices in $G$. Hence the sum of all the triangles, that is, the surface of the polygon, is equivalent to the product of the sum of the bases $\mathrm{AB}, \mathrm{BC}$., etc. ; that is, the perimeter of the polygon, multiplied by half of GH, or half the radius of the inscribed circle. Therefore the area of a regular polygon, etc.

## PROPOSITION VIII. THEOREM.

The perimeter's of two regular polygons of the same number of sides are to each other as the radii of the inscribed or circumscribed circles, and their areas are as the squares of these radii.

Let ABCDEF, abcdef be two regular polygons of the same number of sides; let $G$ and $g$ be the centres of the circumscribed circles; and let GH, $g h$ be drawn perpendicular to BC and $b c$; then will the perime-
 ters of the polygons be as the radii $\mathrm{BG}, b g$ of the circimscribed circles; and also as GH, $g h$, the radii of the inscribed circles.

The angle BGC is equal to the angle $b g c$ (Pr. 2, Sch. 1), and, since the triangles BGC, bgc are isosceles, they are similar. So, also, are the right-angled triangles BGH, bgh ; and, consequent$\mathrm{ly}, \mathrm{BC}: b c:: \mathrm{BG}: b g:: \mathrm{GH}: g h$. But the perimeters of the two polygons are to each other as the sides BC, bc (Pr. I., Cor.); they are therefore to each other as the radii $3 \mathrm{G}, \mathrm{bg}$ of the circumscribed circles; and also as the radii GH, gh of the inscribed circles.

The areas of these polygons are to each other as the squares of the homologous sides BC, bc (Pr. 1, Cor.); they are therefore as the squares of $\mathrm{BG}, b g$, the radii of the circumscribed circles, or as the squares of GHI, $g h$, the radii of the inscribed circles.

## PROPOSITION IX. PROBLEM.

The area of a regular inscribed polygon and that of a similar. circumscribed polygon being given, to find the areas of regular inscribed and circumscribed polygons having double the number of sides.

Let AB be a side of the given inscribed polygon; EF , parallel to AB , a side of the similar circumscribed polygon, and C the centre of the circle. Draw the chord AG, and it will be the side of the inscribed polygon having double the number of sides. At the points A and B draw tangents, meeting EF in the points $H$ and $I$; then will HI, which is double of HG, be a side

 of the similar circumscribed polygon ( Pr . 6, Cor. 1).

Let $p$ represent the inscribed polygon whose side is $\mathrm{AB}, \mathrm{P}$ the corresponding circumscribed polygon; $p^{\prime}$ the inscribed polygon having double the number of sides, $\mathrm{P}^{\prime}$ the similar circumscribed polygon. Then it is plain that the space CAD is the same part of $p$ that CEG is of P; also, CAG of $p^{\prime}$, and CAHG of $\mathrm{P}^{\prime}$; for each of these spaces must be repeated the same number of times to complete the polygons to which they severally belong.

First. The triangles $\mathrm{ACD}, \mathrm{ACG}$, whose common vertex is A , are to each other as their bases CD, CG; they a:c also to each ather as the polygons $p$ and $p^{\prime}$; hence

$$
p: p^{\prime}:: \mathrm{CD}: \mathrm{CG} .
$$

Again, the triangles CGA, CGE, whose common vertex is G, are to each other as their bases CA, CE; they are also to each other as the polygons $p^{\prime}$ and $P$; hence

$$
p^{\prime}: \mathrm{P}:: \mathrm{CA}: \mathrm{CE}
$$

But, since $A D$ is parallel to EG , we have $\mathrm{CD}: \mathrm{CG}:: \mathrm{CA}: \mathrm{CE}$; therefore, $p: p^{\prime}:: p^{\prime}: \mathrm{P} ;$
that is, the polygon $\mathrm{p}^{\prime}$ is a mean proportional between the two given polygons.

Secondlly. The triangles CGH, CHE, having the common altitude CG, are to each other as their bases GH, HE. But, since CII bisects the angle GCE, we have (B. IV., Pr. 17) GH:: HE :: CG : CE :: CD : CA, or CG $:: p: p p^{\prime}$.
Therefore CGH : CHE :: $p: p^{\prime}$;
hence (B. II., Pr. 6)
$\mathrm{CGH}: \mathrm{CGH}+\mathrm{CHE}$, or CGE $:: p: p+p^{\prime}$,
or 2CGH: CGE : $: 2 p: p+p^{\prime}$.
But 2 CGH, or CGHA : CGE :: $\mathrm{P}^{\prime}: \mathrm{P}$.
Therefore $\quad \mathrm{P}^{\prime}: \mathrm{P} \because 2 p: p+p^{\prime}$; whence $\mathrm{P}^{\prime}=\frac{2 p \mathbf{P}}{p+p^{\prime}}$;
that is, the polygon $\mathrm{P}^{\prime}$ is found by dividing twice the procluct of the two given polygons by the sum of the two inscribed polygons.

Hence, by means of the polygons $p$ and $P$, it is easy to find the polygons $p^{\prime}$ and $P^{\prime}$ having double the number of sides.

## PROPOSITION X. THEOREM.

A circle being given, two similar polygons can always be found, the one described about the circle, and the other inscribed in it, which shall differ from each other by less than any assignable surface.

Let ACD be the given circle, and the square of X any given surface however small; a polygon can be inscribed in the circle ACD , and a similar polygon be described about it, such that the difference between them shall be less than the square of $\mathbf{X}$.

Bisect $A C$, a fourth part of the circumference; then bisect the half of this fourth, and so continue the bisection until an are is found whose chord AB is less than X . As this are must be contained a certain number of times exactly in the whole circumference, if we apply chords $A B, B C$, etc., each equal to $A B$, the last will terminate at $A$, and a regular polygon, $A B C D$, etc., will be inscribed in the circle.

Next describe a similar polygon about the circle $(\operatorname{Pr} .6)$; the difference of these two polygons will be less than the square of $\mathbf{X}$.

Find the centre G, and draw the diameter AD. Let EF be a side of the circumscribed polygon, and join EG,FG. These lines will pass through the points A and B, as was shown in Pr. 6. Draw GH to the point of contact H ; it will bisect AB in I, and be perpendicular to it (B. III., Pr. 6, cor.). Join also BD.

Let P represent the circumscribed polygon, and $p$ the inscribed polygon. Then, because the polygons are similar, they are as the squares of the homologous sides EF and AB (B. IV., Pr. 27) ; that is, because the triangles EFG, $A B G$ are similar, as the square of $E G$ to the square of $A G$, that is, of HG .

Again, the triangles $\mathrm{EHG}, \mathrm{ABD}$, having their sides parallel to each other, are similar, and therefore

$$
\mathrm{EG}: \mathrm{HG}:: \mathrm{AD}: \mathrm{BD} .
$$

But the polygon $P$ is to the polygon $p$ as the square of EG to the square of $H G$;
hence $\quad P: p:: \mathrm{AD}^{2}: \mathrm{BD}^{2}$, and, by division,

$$
\mathrm{P}: \mathrm{P}-p:: \mathrm{AD}^{2}: \mathrm{AD}^{2}-\mathrm{BD}^{2}, \text { or } \mathrm{AB}^{2} .
$$

But the square of $A D$ is greater than a regular polygon of eight sides described about the circle, because it contains that polygon; and, for the same reason, the polygon of eight sides is greater than the polygon of sixteen, and so on. Therefore $P$ is less than the square of $A D$, and, consequently (B. II., Def. 11), P $-p$ is less than the square of $A B$; that is, less than the given square on X . Hence the difference of the two polygons is less than the given surface.

Cor. Since the circle can not be less than any inscribed polygon, nor greater than any circumscribed one, it follows that a polygon may be inscribed in a circle, and another described about it, each of which shall differ from the circle by less than any assignable surface.

Scholium. A variable quantity is a quantity which assumes successively different values. When the successive values of a variable quantity approach more and more nearly to some constant quantity, so that the difference between the variable and the constant may become less than any assignable quantity, the constant is called the limit of the variable. Thus, if we suppose the number of sides of a regular polygon to increase, the magnitude of each angle will also increase; and if the number of sides be made greater than any finite number, each angle of the polygon will approach indefinitely near to two right angles. Here the variable quantity is the angle of the regular polygon, and the limit toward which its value continually approaches is two right angles. We see, also, that the circle is the limit to which the inscribed and circumscribed polygons approach when the number of their sides is indefinitely increased. When the number of sides of the polygon is greater than any finite number, the difference between the polygon and circle becomes less that any finite quantity; that is, the circle becomes identical with the inscribed polygon, and also with the circumscribed polygon. The circle may therefore be regarded as a regular polygon of an infinite number of sides.

## PROPOSITION XI. PROBLEM.

To compute the area of a circle whose radius is unity.
If the radius of a circle be unity, the diameter will be repre-
sented by 2 , and the area of the circumscribed square will be 4 ; while that of the inscribed square, being half the circumscribed, is 2 .
Now, according to Pr. 9, the area of the inscribed octagon is a mean proportional between the two squares $p$ and P , so that $p^{\prime}=\sqrt{ } 8=2.82843$. Also, the circumscribed octagon $\mathrm{P}^{\prime}=\frac{2 p \mathrm{P}}{p+p^{\prime}}=$ $\frac{16}{2+\sqrt{ } 8}=3.31371$.
Having thus obtained the inscribed and circumscribed octagons, we may in the same way determine the polygons having twice the number of sides. We must put $p=2.82843$, and $\mathrm{P}=$
3.31371, and we shall have $p^{\prime}=\sqrt{p \mathrm{P}}=3.06147$; and $\mathrm{P}^{\prime}=\frac{2 p \mathrm{P}}{p+p^{\prime}}=$ 3.18260 .

These polygons of 16 sides will furnish us those of 32 , and thus we may proceed until there is no difference between the inscribed and circumscribed polygons, at least for any number of decimal places which may be desired. The following table gives the result of this computation for five decimal places:

| Number of Sides. | Inscribed Polygon. | Circumscribed Polygon. |
| :---: | :---: | :---: |
| 4 | 2.00000 | 4.00000 |
| 8 | 2.82843 | 3.31371 |
| 16 | 3.06147 | 3.18260 |
| 32 | 3.12145 | 3.15172 |
| 64 | 3.13655 | 3.14412 |
| 128 | 3.14033 | 3.14222 |
| 256 | 3.14128 | 3.14175 |
| 512 | 3.14151 | 3.14163 |
| 1024 | 3.14157 | 3.14160 |
| 2048 | 3.14159 | 3.1459 |

Now, as the inscribed polygon can not be greater than the circle, and the circumscribed polygon can not be less than the circle, it is plain that 3.14159 must express the area of a circle, whose radius is unity, correct to five decimal places.

After three bisections of a quadrant of a circle we obtain the inscribed polygon of 32 sides, which differs from the corresponding circumscribed polygon only in the second decimal place. After five bisections we obtain polygons of 128 sides, which differ only in the third decimal place; after nine bisections they agree to five decimal places, but differ in the sixth place; after
eighteen bisections they agree to ten decimal places; and thus, by continually bisecting the arcs subtended by the sides of the polygon, new polygons are formed, both inscribed and circumscribed, which agree to a greater number of decimal places.

Vieta, by means of inscribed and circumscribed polygons, carried the approximation to ten places of figures; Van Ceulen carried it to 36 places; Sharp computed the area to 72 places; De Lagny to 128 places; and Dr. Clausen has carried the computation to 250 places of decimals.

By continuing this process of bisection, the difference between the inscribed and circumscribed polygons may be made less than any quantity we can assign, however small.

## PROPOSITION XII. THEOREM.

The area of a circle is equal to the product of its circumference by half the radius.

Let ABE be a circle whose centre is C and radius $C A$ : the area of the circle is equal to the product of its circumference by half of CA:

Inscribe in the circle any regular polygon, and from the centre draw CD perpendicular to one of the sides. The area of the polygon will be equal to its perimeter multiplied by half of CD (Pr. 7).
Conceive the number of sides of the polygon to be indefinitely increased by continually bisecting the arcs subtended by the sides, its perimeter will approach more nearly to the circumference of the circle; and, when the number of sides of the polygon is greater than any finite number, the perimeter of the polygon will coincide with the circumference of the circle; the perpendicular CD will become equal to the radius CA, and the area of the polygon will be equal to the area of the circle (Pr. 10, Schol.). Therefore the area of the circle is equal to the product of its circumference by half the radius.

Cor. The area of a sector is equal to the product of its arc by half its radius.

For the sector ACB is to the whole circle ABD as the arc AEB is to the whole circumference ABD (B. III., Pr. 14, Cor.) ; or, since magnitudes have the same ratio which their equimultiples have (B. II., Pr. 10), as the arc $\mathrm{AEB} \times \frac{1}{2} \mathrm{AC}$ is to the circumference $\mathrm{ABD} \times \frac{1}{2} \mathrm{AC}$.

But this last expression is equal to the area of the circle; therefore the area of the sector ACB is equal to the product of its arc AEB by half of AC.

## PROPOSITION XIII. THEOREM.

The circumferences of circles are to each other as their radii, and their areas are as the squares of their radii.

Let R and $r$ denote the radii of two circles; C and $c$ their circumferences; A and $a$ their areas; then we shall have

$$
\begin{gathered}
\mathrm{C}: c:: \mathrm{R}: r \\
\mathrm{~A}: a:: \mathrm{R}^{2}: r^{2} .
\end{gathered}
$$

and
Inscribe within the circles two regular polygons having the same number of sides. Now, whatever be the number of sides of the polygons, their perimeters will be to each other as the radii of the circumscribed circles ( Pr .8 ). Conceive the arcs subtended by the sides of the polygons to be continually bisected until the number of sides of the polygons becomes indefinitely great, the perimeters of the polygons will approach more nearly to the circumferences of the circles; and when the number of sides of the polygons is greater than any finite number, the perimeters of the polygons will coincide with the circumferences of the circles, and we shall have

$$
\mathrm{C}: c:: \mathrm{R}: r .
$$

Again, the areas of the polygons are to each other as the squares of the radii of the circumscribed circles (Pr. 8). But when the number of sides of the polygons is greater than any finite number, the areas of the polygons become equal to the areas of the circles, and we shall have

$$
\mathrm{A}: a:: \mathrm{R}^{2}: r^{2}
$$

Cor. 1. Similar ares are to each other as their radii, and similar sectors are as the squares of their radii.

For, since the arcs $\mathrm{AB}, a b$ are similar, the angle C is equal to the angle $c(\mathrm{~B}$. IV., Def. 6). But the angle $\mathbf{C}$ is to four right angles as the arc $A B$ is to the whole circumference described with the radius AC (B. III., Pr. 14), and the an-
 gle $c$ is to four right angles as the arc $a b$ is to the circumference described with the radius $a c$. Therefore the $\operatorname{arcs} \mathrm{AB}, a b$ are to each other as the circumferences of which they form a part. But these circumferences are to each other as AC, ac; therefore

$$
\operatorname{arc} \mathrm{AB}: \operatorname{arc} a b:: \mathrm{AC}: a c .
$$

For the same reason, the sectors $\mathrm{ACB}, a c b$ are as the entire circles to which they. belong, and these are as the squares of their radii; therefore

$$
\text { sector } \mathrm{ACB}: \text { sector } a c b:: \mathrm{AC}^{2}: a c^{2}
$$

Cor. 2. Let $\pi$ represent the circumference of a circle whose diameter is unity; also, let $\mathbf{D}$ represent the diameter, $\boldsymbol{R}$ the radius, and $C$ the circumference of any other circle ; then, since the circumferences of circles are to each other as their diameters,

$$
\begin{aligned}
& 1: \pi:: 2 \mathrm{R}: \mathrm{C} \\
& \mathrm{C}=2 \pi \mathrm{R}=\pi \mathrm{D}
\end{aligned}
$$

therefore
that is, the circumference of a circle is equal to the prochuct of its diameter by the constant number $\pi$.

Cor. 3. According to Pr. 12, the area of a circle is equal to the product of its circumference by half the radius.

If we put A to represent the area of a circle, then

$$
\mathrm{A}=\mathrm{C} \times \frac{1}{2} \mathrm{R}=2 \pi \mathrm{R} \times \frac{1}{2} \mathrm{R}=\pi \mathrm{R}^{2}
$$

that is, the area of a circle is equal to the proctuct of the square of its radius by the constant number $\pi$.

Cor.4. When R is equal to unity, we have $\mathrm{A}=\pi$; that is, $\pi$ is equal to the area of a circle rohose radius is unity. According to $\operatorname{Pr} .11, \pi$ is therefore equal to 3.14159 nearly. This number is represented by $\pi$, because it is the first letter of the Greek word which signifies circumference.

## EASY EXERCISES ON THE PRECEDING BOOKS.

A few theorems without demonstrations, and problems without solutions, are here subjoined for the exercise of the pupil. They will be found admirably adapted to familiarize the beginner with the preceding principles, and to impart dexterity in their application. No general rule can be given which will be found applicable in all cases, and infallibly lead to the demonstration of a proposed theorem, or the solution of a problem. The following directions may prove of some service:

## ANALYSIS OF THEOREMS.

1. Construct a diagram as directed in the enunciation, and assume that the theorem is true.
2. Consider what consequences result from this assumption by combining with it theorems which have been already proved, and which are applicable to the diagram.
3. Examine whether any of these consequences are already known to be true or to be false.
4. If the assumption of the truth of the proposition lead to some consequence which is inconsistent with any demonstrated truth, the false conclusion thus arrived at indicates the falsehood of the proposition; and by reversing the process of the analysis, it may be demonstrated that the theorem can not be true.
5. If none of the consequences so deduced be known to be either true or false, proceed to deduce other consequences from all, or any of these, until a result is obtained which is known to be either true or false.
6. If we thus arrive at some truth which has been previously demonstrated, we then retrace the steps of the investigation pursued in the analysis till they terminate in the theorem which was assumed. This process will constitute the demonstration of the theorem.

## ANALYSIS OF PROBLEMS.

1. Construct the diagram as directed in the enunciation, and suppose the solution of the problem to be effected.
2. Study the relations of the lines, angles, triangles, etc., in the diagram, and endeavor to discover the dependence of the assumed solution on some previous theorem or problem in the Geometry.
3. If such can not be found, draw other lines parallel or perpendicular, as the case may seem to require; join given points, or points assumed in the solution, and describe circles if necessary; and then proceed to trace the dependence of the assumed solution on some theorem or problem in Geometry.
4. If we thus arrive at some previously demonstrated or admitted truth, we shall obtain a direct solution of the problem by assuming the last consequence of the analysis as the first step of the process, and proceeding in a contrary order through the several steps of the analysis until the process terminate in the problem required.

## GEOMETRICAL EXERCISES ON BOOK I.

## THEOREMS.

Prop. 1. The difference between any two sides of a triangle is less than the third side. Sce Prop. 8.

Prop. 2. The sum of the diagonals of a quadrilateral is less than the sum of any four lines that can be drawn from any point whatever (except the intersection of the diagonals) to the four angles. See Prop. 8.

Prop. 3. If a straight line which bisects the vertical angle of a triangle also bisects the base, the remaining sides of the triangle are equal to each other.

Demonstration. Produce AD, the bisecting line, making $\mathrm{DE}=$ DA; then in the, etc.

Prop.4. If the base of an isosceles triangle be produced, the exterior angle exceeds one right angle by half the vertical angle. See Prop. 27.

Prop.5. In any right-angled triangle, the middle point of the hypothenuse is equally distant from the three angles.

Dem. From D , the middle point of the hypothenuse, draw perpendiculars upon the two sides of the triangle; then, etc.

Prop. 6. If, on the sides of a square, at equal distances from the four angles, four points be taken, one on each side, the figure formed by joining those points will also be a square. See Prop. 6.

Prop. 7. The parallelogram whose diagonals are equal is rectangular: See Prop. 32.

Prop. 8. If the diagonals of a quadrilateral bisect each other, the figure is a parallelogram. See Props. 6 and 22.

Prop. 9. Any line drawn through the centre of the diagonal of a parallelogram to meet the sides is bisected in that point, and also bisects the parallelogram. See Props. 7 and 29.

Prop. 10. The sum of the three straight lines drawn from any point within a triangle to the three vertices is less than the sum and greater than the half sum of the three sides of the triangle. See Props. 8 and 9.

## PROBLEMS.

Prop. 1. On a given line describe an isosceles triangle, each of whose equal sides shall be double of the base.

Solution. Produce the given base AB both ways, making $\mathrm{AC}=$ $\mathrm{AB}=\mathrm{BD}$. With centre A and radius AD , describe a circle, etc.

Prop. 2. On a given line describe a square, of which the line shall be the diagonal:

Sol. Bisect the given line AB at right angles by DCE , and make $\mathrm{CD}=\mathrm{CE}=\mathrm{CA}$ or CB ; then, etc.

Prop. 3. Divide a right angle into three equal angles.'
Sol. On one of the sides containing the right angle describe an equilateral triangle, etc.

Prop. 4. One of the acute angles of a right-angled triangle is three times as great as the other; trisect the smaller of these.

Sol. The smaller angle is one fourth of a right angle, and its third part is one twelfth of a right angle. May be solved by the method of Prop. 3.

Prop. 5. Construct an equilateral triangle, having given the length of the perpendicular drawn from one of the angles on the opposite side.

Sol. May be solved by the method of Prop. 3.

## EXERCISES ON BOOK II.

1. Find a third proportional to 8 and 12.

Ans. 18.
2. Find a fourth proportional to 12,16 , and 39.

Ans. 52.
3. Find a mean proportional between 24 and 54. Ans. 36.
4. If $\mathrm{A}: \mathrm{B}:: \mathrm{C}: \mathrm{D}$, prove that
$A^{2}+A B+B^{2}: A^{2}-A B+B^{2}:: C^{2}+C D+D^{2}: C^{2}-C D+D^{2}$.

## GEOMETRICAL EXERCISES ON BOOK III.

THEOREMS.
Prop. 1. Every chord of a circle is less than the diameter. See B. I., Pr. 7.

Prop.2. If an arc of a circle be divided into three equal parts by three straight lines drawn from one extremity of the are, the angle contained by two of the straight lines will be bisected by the third. See B. III., Pr. 15.

Prop. 3. Any two chords of a circle which cut a diameter in the same point, and make equal angles with it, are equal to each other. See B. III., Pr. 17.

Prop. 4. The straight lines whieh join toward the same parts the extremities of any two chords in a circle equally distant from the centre, are parallel to each other.

Prop. 5. The two straight lines which join the opposite extremities of two parallel chords intersect in a point in that dimameter which is perpendicular to the chords.

Prop. 6. If two opposite sides of a quadrilateral figure inscribed in a circle are equal, the other two sides will be parallel.

Prop. 7. All the equal chords in a circle may be touched by another circle.

Prop. 8. The lines bisecting at right angles the sides of a triangle all meet in one point. See B. I., Pr. 18.

Prop. 9. If the diameter of a circle be one of the equal sides of an isosceles triangle, the base will be bisected by the circumference. See B. III., Pr. 15, Cor. 2.

Prop. 10. If two circles touch each other externally, and parallel diameters be drawn, the straight line joining the opposite extremities of these diameters will pass through the point of contact. See B. III., Pr. 12, and Pr. 15, Cor. 2.

Prop. 11. The lines which bisect the angles of any parallelogram form a rectangular parallelogram, whose diagonals are parallel to the sides of the former. See B. I., Pr. 27.

Prop. 12. If two opposite sides of a parallelogram be bisected, the lines drawn from the points of bisection to the opposite angles will trisect the diagonal.

## PROBLEMS.

Prop. 1. From a given point without a given straight line, draw a line making a given angle with it. See B. V., Pr. 4.

Prop. 2. Through a given point within a circle, draw a chord which shall be bisected in that point. See B. III., Pr. 6.

Prop. 3. Through a given point within a circle, draw the least possible chord. See B. III., P̂. 6.

Prop. 4. Two chords of a circle being given in magnitude and position, describe the circle. See B. III., Pr. 7.

Prop.5. Describe three equal circles touching one another; and also describe another circle which shall touch them all three.

Sol. Describe an equilateral triangle and bisect its sides.
Prop.6. How many equal circles can be described around another circle of the same magnitude, touching it and one another?

Prop. 7. With a given radius describe a circle which shall pass through two given points. See B. I., Pr. 18.

Prop. 8. Describe a circle which shall pass through two given points and have its centre in a given line. See B. I., Pr. 18.

Prop. 9. In a given circle inscribe a triangle equiangular to a given triangle. See B. III., Pr: 15.

Prop. 10. From one extremity of a line which can not be produced, draw a line perpendicular to it.

Sol. Take any point C without the given line as a centre, and with a radius equal to the distance of $\mathbf{C}$ from the given extremity, describe a circumference, etc.

Prop.11. Divide a circle into two parts, such that the angle contained in one segment shall equal twice the angle contained in the other.

Sol. Inscribe in the circle an equilateral triangle.
Prop.12. Divide a circle into two segments, such that the angle contained in one of them shall be five times the angle contained in the other:

Sol. Inscribe in the circle a regular hexagon.
Prop.13. Describe a circle which shall touch a given circle in a given point, and also touch a given straight line.

Sol. Draw a tangent at A, cutting the given line BC in C; bisect the angle $A C B$ by $C D$, cutting $O A$ in $D$, etc.

Prop. 14. With a given radius, describe a circle which shall pass through a given point and touch a given line.

Sol. Draw AC perpendicular to the given line AB , and make it equal to the given radius. Draw $C D$ parallel to $A B$, etc.

Prop.15. With a given radius, describe a circle which shall touch a given line, and have its centre in another given line.

Sol. Let AB, AC be the two given lines; from any point C in

AC draw CD perpendicular to AC , and equal to the given radius; through D draw, etc.

GEOMETRICAL EXERCISES ON BOOK IV. THEOREMS.
Prop. 1. If from any point in the diagonal of a parallelogram lines be drawn to the angles, the parallelogram will be divided into two pairs of equal triangles. See B.I., Pr. 32, and B.IV., Pr. 2.

Prop. 2. If the sides of any quadrilateral be bisected, and the points of bisection joined, the included figure will be a parallelogram, and equal in area to half the original figure. See B.IV., Pr. 15.

Prop. 3. Show how the squares in Prop. 11, Book IV., may be dissected, so that the truth of the proposition may be made to appear by superposition of the parts.

Prop. 4. In the figure to Prop. 11, Book IV.,
(a.) If BG and CH be joined, those lines will be parallel.
(b.) If perpendiculars be let fall from F and I on BC produced, the parts produced will be equal, and the perpendiculars together will be equal to BC.
(c.) Join GH, IE, and FD, and prove that each of the triangles so formed is equivalent to the given triangle ABC.
(cl.) The sum of the squares of GH, IE, and FD will be equal to six times the square of the hypothenuse.

Prop. 5. The square on the base of an isosceles triangle whose vertical angle is a right angle, is equal to four times the area of the triangle.

Prop. 6. If from one of the acute angles of right-angled triangle a straight line be drawn bisecting the opposite side, the square upon that line will be less than the square upon the hypothenuse by three times the square upon half the line bisected.

Prop. 7. In a right-angled triangle, the square on either of the two sides containing the right angle is equal to the rectangle contained by the sum and difference of the other sides.

Prop. 8. In any triangle, if a perpendicular be drawn from the vertex to the base, the difference of the squares upon the sides is equal to the difference of the squares upon the segments of the base.

Piop.9. The squares of the diagonals of any quadrilateral fig-
ure are together double the squares of the two lines joining the middle points of the opposite sides.

Sol. Compare this Prop. with Prop. 2 above.
Prop. 10. If one side of a right-angled triangle is double the other, the perpendicular from the vertex upon the hypothenuse will divide the hypothenuse into parts which are in the ratio of 1 to 4.

Prop. 11. If two circles intersect, the common chord produced will bisect the common tangent.

Prop. 12. The tangents to a circle at the extremities of any chord contain an angle which is twice the angle contained by the same chord and a diameter drawn from either of the extremities.

Prop. 13. If two circles cut each other, and if from any given point in the straight line produced which joins their intersections two tangents be drawn, one to each circle, they will be equal to one another.

Prop. 14. If from a point without a circle two tangents be drawn, the straight line which joins the point of contact will be bisected at right angles by a line drawn from the centre to the point without the circle.

## PROBLEMS.

Prop. 1. Trisect a given straight line, and hence divide an equilateral triangle into nine equal parts.

Sol. On the given line describe an equilateral triangle; bisect two of its angles, and from the point of intersection of the bisecting lines draw lines parallel to the sides of the triangle, etc.

Prop. 2. Inscribe a circle in a given rhombus.
Sol. Draw the diagonals of the rhombus, etc.
Prop. 3. Describe a circle whose circumference shall pass through one angle and touch two sides of a given square.

Sol. Divide the given angle into four equal parts, etc.
Prop. 4. In a given square, inscribe an equilateral triangle having its vertex in the middle of a side of the square.

Sol. From the middle of a side as centre, with a radius equal to one side of the square, describe a circle, etc.

Prop. 5. In a given square, inscribe an equilateral triangle having its vertex in one angle of the square.

Sol. On two adjacent sides of the square, describe equilateral triangles exterior to the square, and join their vertices with the remote vertex of the square, etc.

Prop.6. If the sides of a triangle are in the ratio of the numbers 2,4 , and 5 , show whether it will be acute-angled or obtuseangled.

Prop. 7. Given the area and hypothenuse of a right-angled triangle, to construct the triangle.

Sol. On half the hypothenuse describe a rectangle equal to the given area, ctc.

Prop. 8. Bisect a triangle by a line drawn from a given point in one of the sides.

Sol. Let $D$ be the given point in the side $A B$, and $A$ the angle nearest to D. Bisect BC in E, and draw AF parallel to DE, etc.

Prop. 9. To a circle of given radius draw two tangents which shall contain an angle equal to a given angle.

Prop. 10. Construct a triangle, having given one side, the angle opposite to it, and the ratio of the other two sides.

Sol. On the given base BC describe a segment containing the given angle; draw DE perpendicular to BC at its middle point, and cutting the remaining segment in E ; divide BC in F in the given ratio; join EF, etc.

Prop. 11. Construct a triangle, having given the perimeter and the angles of the triangle.

Sol. On the line which is equal to the perimeter of the required triangle describe a triangle having its angles equal to the given angles. Bisect the angles at the base, etc.

Prop. 12. Upon a given base describe a right-angled triangle, having given the perpendicular from the right angle upon the hypothenuse.

Sol. Draw any straight line, and erect DC perpendicular to it and equal to the given perpendicular. With centre C and radius equal to the given base, describe a circle cutting the first line in B. At C draw, etc.

Prop. 13: Construct a triangle, having given one angle, a side opposite to it, and the sum of the other two sides.

Sol. On the given side AB describe a segment containing half the given angle, in which segment inscribe AC equal to the given sum. Make the angle CBD equal to BCA, etc.

Prop. 14. Construct a triangle, having criven one angle, an adjacent side, and the sum of the other two sides.

Sol. Make BC the given base, B the given angle, and BD equal to the sum of the two sides; make the angle DCA equal to CDA, etc.

Prop. 15. Inscribe a square in a given right-angled isosceles triangle.

Sol. Trisect the hypothenuse, etc.

## NUMERICAL EXERCISES.

1. If the base and perpendicular of a triangle be 78 and 43 yards respectively, what is the area? Ans. 1677 square yards.
2. Given the hypothenuse of a right-angled triangle equal to 260 feet, and one of the legs equal to 224 feet, to find the other leg.

Ans. 132 feet.
3. Given the legs of a right-angled triangle equal to 765 and 408 yards respectively, to compute the length of the perpendicular from the right angle to the hypothenuse. Ans. 360 yards.
4. If the sides of a triangle are 845,910 , and 975 respectively, what are the lengths of the segments into which they are severally divided by the perpendiculars from the opposite angles?

$$
\text { Ans. }\left\{\begin{array} { l } 
{ 3 5 0 , } \\
{ 4 9 5 , }
\end{array} \left\{\begin{array} { l } 
{ 3 2 5 , } \\
{ 5 8 5 , }
\end{array} \left\{\begin{array}{l}
429, \\
546
\end{array}\right.\right.\right.
$$

5. Given the hypothenuse and one leg of a right-angled triangle equal to 353 and 272 , to find the remaining leg without squaring the given numbers.

Ans. 225.
6. If the base of a triangle be 210 , and the other sides 135 and 105, what is the length of the straight line drawn from the vertical angle to the point of bisection of the base? Ans. 60 .
7. If two adjacent sides and one of the diagonals of a parallelogram be 245,315 , and 280 , what is the length of the other diagonal?

$$
\text { Ans. } 490 .
$$

8. Given the sides of a triangle equal to 147,119 , and 70 yards respectively, to compute the area. Ans. 4116 square yards.
9. If a chord of a circular arc 16 inches in length be divided into two parts of 7 and 9 inches respectively by another chord, what is the length of the latter, one of its segments being 3 inches?

Ans. 24 inches.
10. If the chord of an arc be 720 feet, and the chord of its half be 369 feet, what is the diameter of the circle?

Ans. 1681 feet.
11. If from a point without a circle two secants be drawn whose external segments are 8 inches and 7 inches, while the internal segment of the latter is 17 inches, what is the internal segment of the former?

Ans. 13 inches.
12. From a point without a circular pond two tangents to the
circumference are drawn, forming with each outher an angle of an equilateral triangle, and the length of each tangent is 18 rods, what is the diameter? $\quad A n s .12 \sqrt{ } 3=20.7846$ rods.
13. If the sides of a triangle are 39,42 , and 45 inches respectively, what is the radius of the inscribed circle?

Ans. 12 inches.
14. Given the legs of a right-angled triangle equal to 455 and 1092 respectively, to compute the segments into which the hypothenuse is divided by the perpendicular from the right angle, and to compute also the perpendicular.

Ans. The segments are 175 and 1008, and the perpendicular 420.
15. If the base of a triangle be 246, and the other sides 250 and 160 respectively, what is the length of the line bisecting the vertical angle?

Ans. 160.
16. If two similar fields together contain 518 square rods, what are their separate contents, their homologous sides being as 5 to 7 ? Ans. 175 and 343 square rods.
17. If the sides of a triangle are 104,112 , and 120 respectively, what is the radius of the circumscribed circle? Ans. 65.
18. If the base of a triangle be 54 , and the other sides 75 and 48 respectively, what is the length of the external segment of the base made by a straight line bisecting the exterior angle at the vertex?

Ans. 96.
19. Two chords on opposite sides of the centre of a circle are parallel, and one of them has a length of 48 , and the other of 14 inches, the distance between them being 31 inches; what is the diameter of the circle? Ans. 50 inches.
20. Two parallel chords on the same side of the centre of a circle whose diameter is 50 inches are measured, and found to be the one 24 and the other 7 inches; what is their distance apart? Ans. 17 inches.
21. The area of a rectangle is 18 square feet, and its base is 4.62 feet; what is its altitude?
22. The base of one rectangle is 6 feet and altitude 5 feet; the base of another rectangle is 4 feet and altitude 3 feet; what is the ratio of the two rectangles?

## GEOMETRICAL EXERCISES ON BOOK VI.

## THEOREMS.

Prop. 1. The square inscribed in a circle is equal to half the square described about the same circle.

Prop. 2. Any number of triangles having the same base and the same vertical angle may be circumscribed by one circle.

Prop. 3. If an equilateral triangle be inscribed in a circle, each of its sides will cut off one fourth part of the diameter drawn through the opposite angle.

Prop.4. The circle inscribed in an equilateral triangle has the same centre with the circle described about the same triangle, and the diameter of one is double that of the other.

Prop. 5. If an equilateral triangle be inscribed in a circle, and the arcs cut off by two of its sides be bisected, the line joining the points of bisection will be trisected by the sides.

Prop. 6. The side of an equilateral triangle inscribed in a circle is to the radius as the square root of 3 is to unity.

Prop. 7. The sum of the perpendiculars let fall from any point within an equilateral triangle upon the sides is equal to the perpendicular let fall from one of the angles upon the opposite side.

Prop. 8. If two circles be described, one without and the other within a right-angled triangle, the sum of their diameters will be equal to the sum of the sides containing the right angle.

Prop. 9. If a circle be inscribed in a right-angled triangle, the sum of the two sides containing the right angle will exceed the hypothenuse by a line equal to the diameter of the inscribed circle.

Prop. 10. The square inscribed in a semicircle is to the square inscribed in the entire circle as 2 to 5.

Prop.11. The square inscribed in a semicircle is to the square inscribed in a quadrant of the same circle as 8 to 5 .

Prop. 12. The area of an equilateral triangle inscribed in a circle is equal to half that of the regular hexagon inscribed in the same circle.

Prop. 13. The square of the side of an equilateral triangle inscribed in a circle is triple the square of the side of the regular hexagon inscribed in the same circle.

Prop. 14. The area of a regular hexagon inscribed in a circle is three fourths of the regular hexagon circumscribed about the same circle.

Prop. 15. The triangle, square, and hexagon are the only regular polygons by which the angular space about a point can be completely filled up.

## PROBLEMS.

Prop. 1. Trisect a given circle by dividing it into three equal sectors.

Prop. 2. The centre of a circle being given, find two opposite points in the circumference by means of a pair of compasses only.

Prop. 3. Divide a right angle into five equal parts.
Prop. 4. Inscribe a square in a given segment of a circle.
Prop. 5. Having given the difference between the diagonal and side of a square, describe the square.

Prop.6. Inscribe a square in a given quadrant.
Prop. 7. Inscribe a circle in a given quadrant.
Prop.8. Describe a circle touching three given straight lines.
Prop.9. Within a given circle describe six equal circles touching each other and also the given circle, and show that the interior circle which touches them all is equal to each of them.

Prop.10. Within a given circle describe eight equal circles touching each other and the given circle.

Prop. 11. Inscribe a regular hexagon in a given equilateral triangle.

Prop. 12. Upon a given straight line describe a regular octagon.

## NUMERICAL EXERCISES.

1. What is the circumference of a circle whose diameter is 28 ?
2. What is the diameter of a circle whose circumference is 50 ?
3. What is the area of a circle whose diameter is 19 ?
4. What is the area of a circle whose circumference is 30 ?
5. What is the area of a quadrant of a circle whose radius is 11 ?
6. What is the diameter of a circle whose area is 40 ?
7. What is the circumference of a circle whose area is 35 ?
8. What is the circumference of the earth, supposing it to be a circle whose diameter is 7912 miles?
9. What is the circumference of a circle whose area is 27.45 square rods?
10. What is the area of a sector whose arc is one sixth of the circumference in a circle whose radius is 17 inches?

## GE 0 METRY 0 F SPACE.

## B O OK VII. PLANES AND SOLID ANGLES. Definitions.

1. A straight line is perpendicular to a plane when it is perpendicular to every straight line which it meets in that plane.

Conversely, the plane in this case is perpendicular to the line.

The foot of the perpendicular is the point in
 which it meets the plane.
2. A straight line is parallel to a plane when it can not meet the plane, though produced ever so far.

Conversely, the plane in this case is parallel to the line.
3. Two planes are parallel to each other when they can not meet, though produced ever so far in every direction.
4. The angle contained by two planes which meet one another. is the angle contained by two lines drawn from any point in the line of their common section, at right angles to that line, one in each of the planes.

This angle may be acute, right, or obtuse.
If it is a right angle, the two planes are per-
 pendicular to each other.
5. A solid angle is the angular space contained by more than two planes which meet at the same point, and not lying in the same plane.

To represent a plane in a diagram, we are obliged to take a limited portion of it; but the
 planes treated of in this Book are supposed to be indefinite in extent.

## PROPOSITION I. THEOREM.

One part of a straight line can not be in a plane, and another part without it.

For, from the definition of a plane (B.I., Def. 11), when a straight line has two points common with a plane, it lies wholly in that plane.

Scholium. To discover whether a surface is plane, we apply a straight line in different directions to this surface, and see if it touches throughout its whole extent.

## PROPOSITION II. THEOREM.

Any two straight lines which cut each other are in one plane, and determine its position.

Let the two straight lines $\mathrm{AB}, \mathrm{BC}$ cut each other in $B$; then will $A B, B C$ be in the same plane.

Conceive a plane to pass through the straight line BC, and let this plane be turned about BC until it pass through the point A. Then, because the points $A$ and $B$ are situated in this plane, the straight line AB lies in it (B. I., Def. 11). Hence the position of the plane is determined by the condition of its containing the two lines $A B$, BC ; for if it is turned in either direction about BC, it will cease to contain the point A. Therefore, any two straight lines, etc.

Cor. 1. A triangle ABC , or three points $\mathrm{A}, \mathrm{B}, \mathrm{C}$, not in the same straight line, determine the position of a plane.

Cor. 2. Two parallel lines $\mathrm{AB}, \mathrm{CD}$ deter-

mine the position of a plane. For, if the line EF be drawn, the plane of the two straight lines $\mathrm{AE}, \mathrm{EF}$ will be the same as that of the parallels $A B, C D$; and it has already been proved that two straight lines which cut each other determine the position of a plane.

## PROPOSITION III. THEOREM.

If two planes cut each other, their common section is a straight line.

Let the two planes $\mathrm{AB}, \mathrm{CD}$ cut each other, and let $\mathrm{E}, \mathrm{F}$ be tivo points in their common section. From $E$ to $F$ draw the straight line EF. Then, since the points $\mathbf{E}$ and $\mathbf{F}$ are in the
plane $A B$, the straight line EF which joins them must lie wholly in that plane (B. I., Def. 11). For the same reason, EF must lie wholly in the plane CD . Therefore the straight line EF is common to the two planes $\mathrm{AB}, \mathrm{CD}$; that is, it is their common section. Hence, if two planes, etc.

PROPOSITION IV. THEOREM.
If a straight line be perpendicular to each of two straight lines at their point of intersection, it will be perpendicular to the plane in which these lines are.

Let the straight line $A B$ be perpendicular to each of the straight lines CD, EF which intersect at $\mathrm{B} ; \mathrm{AB}$ will also be perpendicular to the plane MN which passes through these lines.

Through B draw any line BG, in the plane $M N$; let $G$ be any point of this line, and through G draw DGF, so that DG shall be equal to GF (B. V., Pr. 21). Join
 AD, AG, and AF.

Then, since the base DF of the triangle DBF is bisected in $G$, we shall have (B. IV., Pr. 14),

$$
\mathrm{BD}^{2}+\mathrm{BF}^{2}=2 \mathrm{BG}^{2}+2 \mathrm{GF}^{2}
$$

Also, in the triangle DAF,

$$
\mathrm{AD}^{2}+\mathrm{AF}^{2}=2 \mathrm{AG}^{2}+2 \mathrm{GF}^{2}
$$

Subtracting the first equation from the second, we have

$$
\mathrm{AD}^{2}-\mathrm{BD}^{2}+\mathrm{AF}^{2}-\mathrm{BF}^{2}=2 \mathrm{AG}^{2}-2 \mathrm{BG}^{2}
$$

But, because ABD is a right-angled triangle,

$$
\mathrm{AD}^{2}-\mathrm{BD}^{2}=\mathrm{AB}^{2}
$$

and, because ABF is a right-angled triangle,

$$
\mathrm{AF}^{2}-\mathrm{BF}^{2}=\mathrm{AB}^{2}
$$

Therefore, substituting these values in the former equation, we have $\quad \mathrm{AB}^{2}+\mathrm{AB}^{2}=2 \mathrm{AG}^{2}-2 \mathrm{BG}^{2}$;
whence

$$
\begin{aligned}
& \mathrm{AB}^{2}=\mathrm{AG}^{2}-\mathrm{BG}^{2} \\
& \mathrm{AG}^{2}=\mathrm{AB}^{2}+\mathrm{BG}^{2}
\end{aligned}
$$

Wherefore $A B G$ is a right angle (B.IV., Pr. 13, Sch.) ; that is, $A B$ is perpendicular to the straight line $B G$. In like manner, it may be proved that $A B$ is perpendicular to any other straight line passing through $B$ in the plane $\mathbf{M N}$; hence it is perpen-
dicular to the plane MN (Def. 1). Therefore, if a straight line, etc.

Scholium. Hence it appears not only that a straight line may be perpendicular to every straight line which passes through its foot in a plane, but that it always must be so whenever it is perpendicular to two lines in the plane, which shows that the first definition involves no impossibility.

Cor. 1. The perpendicular AB is shorter than any oblique line AD ; it therefore measures the true distance of the point A from the plane MN.

Cor. 2. Through a given point B in a plane, only one perpendicular can be drawn to this plane. For, if there could be two perpendiculars, suppose a plane to pass N through them, whose intersection with the plane MN is BG; then these two perpendiculars would both be at right angles to the line BG, at the same point and in the same plane, which is impossible (B. I., Pr. 1).

It is also impossible, from a given point without a plane, to let fall two perpendiculars upon the plane. For, suppose. $\mathrm{AB}, \mathrm{AG}$ to be two such perpendiculars; then the triangle ABG will have two right angles, which is impossible (B. I., Pr. 27, Cor. 3).

## PROPOSITION V. THEOREM.

Oblique lines drawn from a point to a plane, at equal distances from the perpendicular, are equal; and of two oblique lines unequally distant firom the perpendicular, the more remote is the longer.

Let the straight line AB be drawn perpendicular to the plane MN; and let $\mathrm{AC}, \mathrm{AD}, \mathrm{AE}$ be oblique lines drawn from the point $A$, equally distant from the perpendicular ; also, let AF be more remote from the perpendicular than AE ; then will the lines $\mathrm{AC}, \mathrm{AD}$, N AE all be equal to each other, and AF be longer than AE.
For, since the angles $\mathrm{ABC}, \mathrm{ABD}, \mathrm{ABE}$ are right angles, and $\mathrm{BC}, \mathrm{BD}, \mathrm{BE}$ are equal, the triangles $\mathrm{ABC}, \mathrm{ABD}, \mathrm{ABE}$ have two sides and the included angle equal; therefore the third sides $A C$, $\mathrm{AD}, \mathrm{AE}$ are equal to each other.

So, also, since the distance BF is greater than BE , it is plain that the oblique line AF is longer than AE (B. I., Pr. 17).

Cor. All the equal oblique lines $\mathrm{AC}, \mathrm{AD}, \mathrm{AE}$, etc., terminate in the circumference CDE, which is described from $B$, the foot of the perpendicular, as a centre.

If, then, it is required to draw a straight line perpendicular to the plane MN, from a point A without it, take three points in the plane $C, D, E$, equally distant from $A$, and find $B$, the centre of the circle which passes through these points. Join AB, and it will be the perpendicular required.

Scholium. The angle AEB is called the inclination of the line AE to the plane MN. All the lines AC, AD, AE, etc., which are equally distant from the perpendicular, have thẹ same inclination to the plane, because all the angles $\mathrm{ACB}, \mathrm{ADB}, \mathrm{AEB}$, etc., are equal.

## PROPOSITION VI. THEOREM.

If a straight line is perpendicular to a plane, every plane which passes through that line is perpendicular to the first-mentioned plane.

Let the straight line AB be perpendicular to the plane MN ; then will every plane which passes through $A B$ be perpendicular to the plane MN.

Suppose any plane, as AE, to pass through AB , and let EF be the common section of the planes $\mathrm{AE}, \mathrm{MN}$. In the plane MN, through the point $B$, draw $C D$ perpendic-
 ular to the common section EF.

Then, since the line $A B$ is perpendicular to the plane $M N$, it must be perpendicular to each of the two straight lines CD, EF (Def. 1). But the angle ABD, formed by the two perpendiculars $\mathrm{BA}, \mathrm{BD}$, to the common section EF , measures the angle of the two planes AE, MN (Def. 4), and, since this is a right angle, the two planes must be perpendicular to each other. Therefore, if a straight line, etc.

Scholium. When three straight lines, as $\mathrm{AB}, \mathrm{CD}, \mathrm{EF}$, are perpendicular to each other, each of these lines is perpendicular to the plane of the other two, and the three planes are perpendicular to each other.

## PROPOSITION VII. THEOREM.

If two planes are perpendicular to each other, a straight line drazon in one of them perpendicular to their common section will be perpendicular to the other plane.

Let the plane AE be perpendicular to the plane MN, and let the line $A B$ be drawn in the plane $A E$ perpendicular to the common section EF ; then will AB be perpendicular to the plane MN.

For in the plane MN, draw CD through the point $B$ perpendicular to EF. Then, because the planes AE and MN are perpendicular, the angle ABD is a right angle. Hence the line $A B$ is perpendicular to the two straight lines CD, EF at their point of intersection; it is consequently perpendicular to their plane MN (Pr. 4). Therefore,
if two planes, etc.
Cor. If the plane AE is perpendicular to the plane MN, and if from any point $B$, in their common section, we erect a perpendicular to the plane MN, this perpendicular will be in the plane AE.

For if not, then we may draw from the same point a straight line AB in the plane AE perpendicular to EF , and this line, according to the Proposition, will be perpendicular to the plane MN. Therefore there would be two perpendiculars to the plane MN, drawn from the same point, which is impossible (Pr. 4, Cor. 2).

## PROPOSITION VIII. THEOREM.

If two planes which cut one another are each of them perponsticular to a third plane, their common section is perpendicular to the same plane.

Let the two planes $\mathrm{AE}, \mathrm{AD}$ be each of them perpendicular to a third plane MN, and let AB be the common section of the first two planes; then will AB be perpendicular to the plane MN.

For, fiom the point B, erect a perpendicular to the plane MN. Then, by the Corollary of the last Proposition, this line
must be situated both in the plane AD and in the plane AE ; hence it is their common section AB . Therefore, if two planes, etc.

## PROPOSITION IX. THEOREM.

Two straight lines which are perpendicular to the same plane are parallel to each other.

Let the two straight lines $\mathrm{AB}, \mathrm{CD}$ be each of them perpendicular. to the same plane MN ; then will AB be parallel to CD.

In the plane MN, draw the straight line BD, joining the points $B$ and $D$. Through the lines $\mathrm{AB}, \mathrm{BD}$ pass the plane EF ; it will be perpendicular to the plane $\mathrm{MN}(\mathrm{Pr} .6)$; also, the line CD will lie in this plane, because it is perpendicular to MN (Pr. 7, Cor.).

Now, because AB and CD are both perpendicular to the plane MN, they are per-
 pendicular to the line $B D$ in that plane; and, since $A B, C D$ are both perpendicular to the same line BD , and lie in the same plane, they are parallel to each other (B.I., Pr. 20). Therefore, two straight lines, etc.

Cor.1. If one of two parallel lines be perpendicular to a plane, the other will be perpendicular to the same plane. If $A B$ is perpendicular to the plane MN, then ( $\operatorname{Pr} .6$ ) the plane EF will be perpendicular to MN. Also, AB is perpendicular to BD ; and if CD is parallel to AB , it will be perpendicular to BD , and therefore (Pr. 7) it is perpendicular to the plane MN.

Cor. 2. Two straight lines parallel to the same straight line are parallel to each other. For, suppose a plane to be drawn perpendicular to any one of them; then the other two, being parallel to the first, will be perpendicular to the same plane, by the preceding Corollary; hence, by the Proposition, they will be parallel to each other.

The three straight lines are supposed not to be in the same plane; for in this case the Proposition has been already demonstrated.

## PROPOSITION X. THEOREM.

If a straight line, without a given plane, be parallel to a straight line in the plane, it will be parallel to the plane.

Let the straight line $A B$ be parallel to the straight line $C D$, in the plane MN ; then will it be parallel to the plane MN.

Through the parallels AB, CD suppose a plane $A B D C$ to pass. If the line $A B$ can meet the plane MN, it must meet it in some point of the line CD, which is the common intersection of the two planes. But AB can not meet CD, since they are parallel; hence it can not meet the plane MN ; that is, AB is parallel to the plane MN (Def. 2). Therefore, if a straight line, etc.

PROPOSITION XI. THEOREM.
Two planes which are perpendicular to the same straight line are parallel to each other.

Let the planes $\mathrm{MN}, \mathrm{PQ}$ be perpendicular to the line AB ; then will they be parallel to each other.

For, if they are not parallel, they will meet if produced. Let them be produced and meet in C. Join AC, BC.
Now the line $A B$, which is perpendicular to the plane MN, is perpendicular to the line $A C$ drawn through its foot in that plane. For the same reason, AB is perpendicular to BC . Therefore CA and CB are two perpendiculars let fall from the same point $C$ upon the same straight line $A B$, which is impossible ( $B$. I., Pr. 16). Hence the planes MN, PQ can not meet when produced; that is, they are parallel to each other. Therefore two planes, etc.

## PROPOSITION XII. THEOREM.

If two parallel planes are cut by a third plane, their common sections with it are parallel.

Let the parallel planes $\mathbf{M} N, P Q$ be cut by the plane $A B D C$, and let their common sections with it be $A B, C D$; then will AB be parallel to CD .

For the two lines $A B, C D$ are in the same plane, viz., in the plane $A B D C$ which cuts the planes $\mathrm{MN}, \mathrm{PQ}$; and if these lines were not parallel, they would meet when produced; therefore the planes MN,

PQ would also meet, which is impossible, because they are parallel. Hence the lines $\mathrm{AB}, \mathrm{CD}$ are parallel. Therefore, if two parallel planes, etc.

## PROPOSITION XIII. THEOREM.

If two planes are parallel, a straight line which is perpendicular to one of them is also perpendicular to the other.

Let the two planes MN, PQ be parallel, and let the straight line AB be perpendicular to the plane MN; AB will also be perpendicular to the plane PQ .

Through the point $B$ draw any line $B D$ in the plane $P Q$, and through the lines $A B$,
 $B D$ suppose a plane to pass intersecting the plane MN in AC. The two lines AC, BD will be parallel (Pr. 12).

But the line $A B$, being perpendicular to the plane $M N$, is perpendicular to the straight line AC, which meets it in that plane; it must, therefore, be perpendicular to its parallel BD (B. I., Pr. $23, \mathrm{Cor} .1$ ). But BD is any line drawn through B in the plane. PQ ; and, since AB is perpendicular to any line drawn through its foot in the plane $P Q$, it must be perpendicular to the plane PQ (Def. 1). Therefore, if two planes, etc.

## PROPOSITION XIV. TIIEOREM.

Parallel straight lines included between two parallel planes are equal.

Let $\mathrm{AB}, \mathrm{CD}$ be two parallel straight lines included between two parallel planes MN , PQ ; then will AB be equal to CD .

Through the two parallel lines $\mathrm{AB}, \mathrm{CD}$, suppose a plane ABDC to pass, intersecting the parallel planes in AC and BD. The
 lines $\mathrm{AC}, \mathrm{BD}$ will be parallel to each other (Pr. 12). But AB is, by supposition, parallel to CD ; therefore the figure ABDC is a parallelogram, and, consequently, AB is equal to CD (B. I., Pr. 30). Therefore parallel straight lines, etc.

Cor. Hence two parallel planes are every where equally distant; for if $A B, C D$ are perpendicular to the plane $M N$, they will be perpendicular to the parallel plane $\mathrm{PQ}(\mathrm{Pr} .13)$, and, being both perpendicular to the same plane, they will be parallel to each other (Pr.9), and consequently equal.

## PROPOSITION XV. THEOREM.

If two angles not in the same plane have their sides parallel to each other and similarly situated, these angles will be equal, and their planes will be parallel.

Let the two angles $\mathrm{ABC}, \mathrm{DEF}$, lying in
 different planes $M N, P Q$, have their sides parallel each to each and similarly situated; then will the angle ABC be equal to the angle DEF, and the plane MN be parallel to the plane PQ .

Take AB equal to DE , and BC equal to EF , and join $\mathrm{AD}, \mathrm{BE}, \mathrm{CF}, \mathrm{AC}, \mathrm{DF}$. Then, because AB is equal and parallel to DE , the figure ABED is a parallelogram (B. I., Pr. 32), and AD is equal and parallel to BE .

For the same reason, CF is equal and parallel to BE. Consequently, AD and CF , being each of them equal and parallel to BE, are parallel to each other (Pr. 9, Cor. 2), and also equal; therefore AC is also equal and parallel to DF (B. I., Pr. 32). Hence the triangles $A B C$, DEF are mutually equilateral, and the angle $A_{1} B C$ is equal to the angle DEF (B. I., Pr. 15).

Also, the plane ABC is parallel to the plane DEF. For, if they are not parallel, suppose a plane to pass throngh A parallel to DEF, and let it meet the straight lines BE, CF in the points G and II. Then the three lines AD, GE, HF will be equal (Pr. 14). But the three lines $\mathrm{AD}, \mathrm{BE}, \mathrm{CF}$ have already been proved to be equal ; hence BE is equal to GE , and CF is equal to HF , which is absurd; consequently, the plane ABC must be parallel to the plane DEF. Therefore, if two angles, etc.

Cor. 1 . If two parallel planes $M N, P Q$ are met by two other planes ABED, BCFE, the angles formed by the intersections of the parallel planes will be equal. For the section $A B$ is parallel to the section $\mathrm{DE}(\mathrm{Pr} .12)$, and BC is parallel to EF ; therefore, by the Proposition, the angle ABC is equal to the angle DEF.

Cor. 2. If three straight lines $\mathrm{AD}, \mathrm{BE}, \mathrm{CF}$, not situated in the same plane, are equal and parallel, the triangles $\mathrm{ABC}, \mathrm{DEF}$, formed by joining the extremities of these lines, will be equal, and their planes will be parallel.

For, since AD is equal and parallel to BE , the figure ABED is a parallelogram; hence the side AB is equal and parallel to DE .

For the same reason, the sides BC and EF are equal and parallel, as also the sides AC and DF . Consequently, the two triangles $\mathrm{ABC}, \mathrm{DEF}$ are equal, and, according to the Proposition, their planes are parallel.

PROPOSITION XVI. THEOREM.
If two straight lines are cut by three parallel planes, their corresponding segments are proportional.

Let the straight lines $\mathrm{AB}, \mathrm{CD}$ be cut by M the parallel planes MN, PQ, RS in the points $A, E, B, C, F, D$; then we shall have the proportion

$$
\mathrm{AE}: \mathrm{EB}:: \mathrm{CF}: \mathrm{FD} .
$$

Draw the line BC meeting the plane PQ in $G$, and join $A C, B D, E G, G F$.

Then, because the two parallel planes
 $\mathrm{MN}, \mathrm{PQ}$ are cut by the plane ABC , the common sections AC, EG are parallel (Pr. 12). Also, because the two parallel planes $P Q, R S$ are cut by the plane $B C D$, the common sections BD, GF are parallel. Now, because EG is parallel to AC, a side of the triangle ABC (B. IV., Pr. 16), we have

$$
\mathrm{AE}: \mathrm{EB}: \mathrm{CG}: \mathrm{GB} .
$$

Also, because GF is parallel to BD , one side of the triangle BCD , we have

CG: GB :: CF: FD;
hence (B. II., Pr. 4) AE: EB :: CF:FD.
Therefore, if two straight lines, etc.
proposition xvil. theorem.
If a solid angle is contained by three plane angles, the sum of any troo of these angles is greater than the third.

Let the solid angle at A be contained by the three plane angles $\mathrm{BAC}, \mathrm{CAD}$, DAB ; any two of these angles will be greater than the third.

If these three angles are all equal to each other, it is plain that any two of them must be greater than the third.

But if they are not equal, let BAC be that angle which is not less than either of the other two, and is greater than one of them, BAD. Then, at the point $A$, make the angle BAE equal to the angle BAD ; take AE equal to AD ; through E draw
the line BEC , cutting $\mathrm{AB}, \mathrm{AC}$ in the points B and C , and join DB, DC.

Now, because, in the two triangles $\mathrm{BAD}, \mathrm{BAE}, \mathrm{AD}$ is equal to $\mathrm{AE}, \mathrm{AB}$ is common to both, and the angle BAD is equal to the angle BAE; therefore the base BD is equal to the base BE (B. I., Pr. 6). Also, because the sum of the lines $\mathrm{BD}, \mathrm{DC}$ is greater than BC (B.I., Pr. 8), and BD is proved equal to BE, a part of BC , therefore the remaining line DC is greater than EC.

Now, in the two triangles CAD, CAE, because AD is equal to $\mathrm{AE}, \mathrm{AC}$ is common; but the base CD is greater than the base CE , therefore the angle CAD is greater than the angle CAE (B. I., Pr. 14). But, by construction, the angle BAD is equal to the angle BAE; therefore the two angles BAD, CAD are together greater than BAE, CAE, that is, than the angle BAC. Now BAC is not less than either of the angles BAD, CAD; hence BAC, with either of them, is greater than the third. Therefore, if a solid angle, etc.

PROPOSITION XVIII. THEOREM.
The plane angles which contain any solid angle are together less than four right angles.

Let A be a solid angle contained by any number of plane angles BAC, CAD, DAE, EAF, FAB ; these angles are together less than four right angles.
Let the planes which contain the solid angle at A be cut by another plane, forming the polygon BCDEF, and from any point H within this polygon draw the lines $\mathrm{HB}, \mathrm{HC}, \mathrm{IID}$,
HE, HF.
Now, because the solid angle at $B$ is contained by three plane angles, any two of which are greater than the third (Pr. 17), the two angles $\mathrm{ABC}, \mathrm{ABF}$ are greater than the angle FBC. For the same reason, the two angles ACB, ACD are greater than the angle BCD , and so with the other angles of the polygon BCDEF. Hence the sum of all the angles at the bases of the triangles having the common vertex A is greater than the sum of all the angles at the bases of the triangles whose vertex is $\mathbf{H}$. But the sum of all the angles of the triangles whose vertex is $\mathbf{A}$ is equal to the sum of the angles of the same number of triangles whose vertex is H . Therefore the sum of the angles at A is less than
the sum of the angles at $H$; that is, less than four right angles. Therefore the plane angles, etc.

Scholium. This demonstration supposes that the solid angle is convex; that is, that the plane of neither of the faces, if produced, would cut the solid angle. If it were otherwise, the sum of the plane angles would no longer be limited, and might be of any magnitude.

## PROPOSITION XIX. THEOREM.

If two solid angles are contained by three plane angles which are equal each to each, the planes of the equal angles will be equally inclined to each other.

Let A and $a$ be two solid angles contained by three plane angles which are equal each to each, viz., the angle BAC equal to $b a c$, the angle CAD to $c a d$, and BAD equal to bad; then will the inclination of the planes $\mathrm{ABC}, \mathrm{ABD}$ be equal to the in-
 clination of the planes $a b c, a b d$.

In the line $A C$, the common section of the planes $\mathrm{ABC}, \mathrm{ACD}$, take any point $C$, and through $C$ let a plane $B C E$ pass perpendicular to AB , and another plane CDE perpendicular to AD . Also, take $a c$ equal to AC , and through $c$ let a plane bce pass perpendicular to $a b$, and another plane $c d e$ perpendicular to $a d$.

Now, since the line $A B$ is perpendicular to the plane $B C E$, it is perpendicular to every straight line which it meets in that plane; hence ABC and ABE are right angles. For the same reason, $a b c$ and abe are right angles. Now, in the triangles ABC, $a b c$, the angle BAC is, by hypothesis, equal to $b a c$, and the angles $\mathrm{ABC}, a b c$ are right angles; therefore the angles $\mathrm{ACB}, a c b$ are equal. But the side AC was made equal to the side $a c$; hence the two triangles are equal (B. I., Pr. 7) ; that is, the side AB is equal to $a b$, and BC to $b c$. In the same manner, it may be proved that AD is equal to $a d$, and CD to $c d$.

We can now prove that the quadrilateral ABED is equal to the quadrilateral abed. For, let the angle BAD be placed upon the equal angle $b a d$, then the point $B$ will fall upon the point $b$, and the point D upon the point $d$; because AB is equal to $a b$, and AD to $a d$. At the same time, BE , which is perpendicular to

AB , will fall upon be, which is perpendicular to $a b$; and, for a similar reason, DE will fall upon de. Hence the point E will fall upon $e$, and we shall have BE equal to $b e$, and DE equal to de.

Now, since the plane BCE is perpendicular to the line AB , it is perpendicular to the plane ABD which passes through AB (Pr.6). For the same reason, CDE is perpendicular to the same plane; hence CE, their common section, is perpendicular to the plane ABD (Pr. 8).
In the same manner, it may be proved that $c e$ is perpendicular to the plane $a b d$. Now, in the triangles BCE, $b c e$, the angles BEC , bec are right angles, the hypothenuse BC is equal to the hypothenuse $b c$, and the side BE is equal to be; hence the two triangles are equal, and the angle CBE is equal to the angle cbe. But the angle CDE is the inclination of the planes $\mathrm{ABC}, \mathrm{ABD}$ (Def. 4), and the angle cbe is the inclination of the planes abc, abd; hence these planes are equally inclined to each other. Therefore, if two solid angles, etc.

Scholium 1. The angle CBE is not, properly speaking, the inclination of the planes $\mathrm{ABC}, \mathrm{ABD}$, except when the perpendicular CE falls upon the same side of AB as AD does. If it fall upon the other side of $A B$, then the angle between the two planes will be obtuse, and this angle, together with the angle B of the triangle CBE, will make two right angles. But in this case, the angle between the two planes $a b c, a b d$ will also be obtuse, and this angle, together with the angle $b$ of the triangle $c b e$, will also make two right angles. And, since the angle $\mathbf{B}$ is always equal to the angle $b$, the inclination of the two planes $\mathrm{ABC}, \mathrm{ABD}$ will always be equal to that of the planes $a b c, a b d$.

Scholium 2. If two solid angles are contained by three plane angles which are equal each to each, and similarly situated, the angles will be equal, and will coincide when applied the one to the other.
For we have proved that the quadrilateral ABED will coincide with its equal abed. Now, because the triangle BCE is equal to the triangle bce, the line CE, which is perpendicular to the plane ABED, is equal to the line ce, which is perpendicular
to the plane abed. And, since only one perpendicular can be drawn to a plane from the same point (Pr. 4, Cor. 2), the lines CE , ce must coincide with each other, and the point C coincide with the point $c$. Hence the two solid angles must coincide throughout.

It should, however, be observed, that the two solid angles do not admit of superposition unless the three equal plane angles are similarly situated in both cases. For if the perpendiculars CE, ce lay on opposite sides of the planes ABED, abed, the two solid angles could not be made to coincide. Nevertheless, the Proposition will always hold true, that the planes containing the equal angles are equally inclined to each other.

## BOOK VIII.

## POLYEDRONS.

## Definitions.

1. A polyedron is a geometrical solid bounded by planes. The polygons formed by the mutual intersection of the bounding planes are called the faces of the polyedron.
2. The least number of planes that can form a polyedron is four, for it requires at least three planes to form a solid angle, and it requires a fourth plane to inclose a finite portion of space, or to form a solid. A polyedron of four faces is called a tetraedron ; one of six faces a hexaedron ; one of eight faces an octaedron; one of twelve faces a dodecaedron; and one of twenty faces an icosaedron.
3. The common intersection of two adjacent faces of a polyedron is called an edge of the polyedron. A diagonal of a polyedron is a straight line which joins any two of its vertices not lying in the same face.
4. Similar polyedrons are such as have all their solid angles equal each to each, and are contained by the same number of similar polygons similarly placed.
5. A regular polyedron is one whose solid angles are all equal to each other, and whose faces are all equal and regular polygons.
6. A prism is a polyedron having two faces
 which are equal and parallel polygons, and the others are parallelograms. The equal and parallel polygons are called the bases of the prism; the other faces, taken together, form its lateral or convex surface. The intersections of the lateral faces are called the lateral edges of the prism. The altitude of a prism is the perpendicular distance between the planes of its bases.

7. A right prism is one whose lateral edges are all perpendicular to the planes of its bases. An oblique prism is one whose lateral edges are oblique to the planes of its bases.
8. A prism is triangular, quadrangular, pentagonal, hexagonal, etc., according as its base is a triangle, a quadrilateral, a pentagon, a hexagon, etc.
9. A parallelopiped is a prism whose bases are parallelograms. It is therefore a polyedron, all of whose faces are parallelograms.
10. A right parallelopiped is a parallelopiped whose lateral edges are perpendicular to the planes of its bases. Hence its lateral faces are all rectangles, but its bases may be either rhomboids or rectangles.

A rectangular parallelopiped is a right parallelopiped whose bases are rectangles. Hence it is a parallelopiped all of whose faces are rectangles.
11. A cube is a rectangular parallelopiped whose six faces are all squares.
12. A pyramid is a polyedron bounded by a poly-
 gon called its base, and three or more triangles meeting in a point without the polygon called the vertex of the pyramid. The triangular faces taken together constitute its lateral or convex surface.
13. The altitude of a pyramid is the perpendicular let fall from the vertex upon the plane of the base produced, if necessary.
14. A triangular pyramid is one whose base is a triangle; a quadrangular pyramid is one whose
 base is a quadrilateral, etc. A triangular pyramid is a tetraedron, and any one of its faces may be taken as its base.
15. A regular pyramid is one whose base is a regular polygon, and the perpendicular drawn from its vertex to its base passes through the centre of the base. This perpendicular is called the axis of the pyramid.

The slant height of a regular pyramid is the perpendicular from the vertex to one side of the
 polygon which forms its base.
16. A frustum of a pyramid is a portion of the pyramid included between its base and a section made by a plane parallel to the base. The altitude of a frustum is the perpendicular distance between the two parallel planes.
17. The volume of a polyedron is the numerical measure of its magnitude, referred to some other polyedron as the unit. The polyedron adopted as the unit is called the unit of volume.

- PROPOSITION I. THEOREM.

The lateral surface of a right prism is equal to the product of the perimeter of its base by its altitude.

Let $\mathrm{ABCDE}-\mathrm{K}$ be a right prism; then will its lateral surface be equal to the perimeter of its base (viz., $\mathrm{AB}+\mathrm{BC}+\mathrm{CD}+\mathrm{DE}+\mathrm{EA}$ ) multiplied by its altitude AF.

For the lateral surface of the prism is equal to the sum of the parallelograms $\mathrm{AG}, \mathrm{BH}, \mathrm{CI}$, etc. Now the area of the parallelogram AG is measured by the product of its base AB by its altitude AF (B. IV.; Pr: 4, Sch.). The area of the parallelogram BH is measured by BC $\times \mathrm{BG}$; the area of CI is measured by $\mathrm{CD} \times \mathrm{CI}$, and so of the others. But the lines $\mathrm{AF}, \mathrm{BG}, \mathrm{CH}$, etc., are all equal to each other (B. VII., Pr. 14), and each is equal to the altitude of the prism. Also, the lines $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}$, etc., taken together, form the perimeter of the base of the prism. Therefore the sum of these parallelograms, or the lateral surface of the prism, is equal to the product of the perimeter of its base by its altitude.

Cor. If two right prisms have the same altitude, their convex surfaces will be to each other as the perimeters of their bases.

## PROPOSITION II. THEOREM.

Sections of a prism made by parallel planes are equal polygons.

Let the prism LR be cut by the parallel planes AC, FH; then will the sections ABCDE, FGHIK be equal polygons.

Since $A B$ and $F G$ are the intersections of two parallel planes, with a third plane LMPO, they are parallel. The lines AF, BG are also parallel, being edges of the prism; therefore ABGF is a parallelogram, and $A B$ is equal to $F G$. For the same reason, BC is equal and parallel to $\mathrm{GH}, \mathrm{CD}$ to $\mathrm{IH}, \mathrm{DE}$ to IK, and AE to FK.
Because the sides of the angle ABC are parallel to those of FGH, and are similarly situated, the angle ABC is equal to FGH (B. VII., Pr. 15). In like manner, it may be proved that the angle BCD is equal to the angle GHI, and so of the rest. Therefore the polygons ABCDE, FGHIK being mutually equilateral, and also mutually equiangular, aree equal.

Cor. Any section of a prism made by a plane parallel to the base is equal to the base.

## PROPOSITION III. THEOREM.

Two prisms are equal when they have a solid angle contained by three faces which are equal each to each, and similarly situated.

Let AI, $a i$ be two prisms having the faces which contain the solid angle $\mathbf{B}$ equal to the faces which contain the solid angle $b ;$ viz., the base ABCDE to the base $a b c d e$, the parallelogram AG to the parallelogram ag, and the parallelogram BH to the parallelogram $b h$; then will the prism

 AI be equal to the prism ci i.

Let the prism AI be applied to the prism $a i$, so that the equal bases AD and ad may coincide, the point A falling upon $\alpha, \mathrm{B}$ upon $b$, and so on.

And because the three plane angles which contain the solid angre $B$ are equal to the three plane angles which contain the solid angle $b$, and these planes are similarly situated, the solid angles $B$ and $b$ are equal (B. VII., Pr. 19, Sch. 2). Hence the edge BG will coincide with its equal $b g$, and the point $G$ will coincide with the point $g$.

Now, because the parallelograms AG and $a g$ are equal, the side GF will fall upon its equal $g f$; and, for the same reason, GH will fall upon $g h$. Hence the plane of the base FGHIK will coincide with the plane of the base $f g h i k$ (B. VII., Pr. 2). But, since the upper bases are equal to their corresponding lower bases, they are equal to each other ; therefore the base FI will coincide throughout with $f i$; viz., HI with $h i$, IK with $i k$, and KF with $k f$; hence the lateral faces of the two prisms will coincide each with each, and the prisms coincide throughout, and are equal to each other. Therefore, two prisms, etc.

Cor. Two right prisms, which have equal bases and equal altitudes, are equal.

For, since the side $A B$ is equal to $a b$, and the altitude $B G$ to $b g$, the rectangle ABGF is equal to the rectangle $a b g f$. So, also, the rectangle BGHC is equal to the rectangle $b g h c$; hence the three faces which contain the solid angle $B$ are equal to the three
faces which contain the solid angle $b$; consequently the two prisms are equal.

PROPOSITION IV. THEOREM.
The opposite faces of a parallelopiped are equal and parallel.

Let ABGH be a parallelopiped; then will its opposite faces be equal and parallel.

From the definition of a parallelopiped (Def. 9), the bases AC, EG are equal and parallel; and it remains to be proved that the same is true of any two opposite faces, as $\mathrm{AH}, \mathrm{BG}$.
Now, because $A C$ is a parallelogram, the side $A D$ is equal and parallel to BC . For the same reason, AE is equal and parallel to BF ; hence the angle DAE is equal to the angle CBF (B.VII., Pr. 15), and the plane DAE is parallel to the plane CBF. Therefore also the parallelogram AH is equal to the parallelogram BG. In the same manner, it may be proved that the opposite faces AF and DG are equal and parallel. Therefore, the opposite faces, etc.

Cor. 1. Since a parallelopiped is a solid contained by six faces, of which the opposite ones are equal and parallel, any face may be assumed as the base of a parallelopiped.

Cor. 2. The four diagonals of a parallelopiped bisect each other.

Draw any two diagonals AG, EC; they will bisect each other.

Since $A E$ is equal and parallel to $C G$, the figure AEGC is a parallelogram, and therefore the diagonals AG, EC bisect each other (B.I., Pr. 33). In the same manner, it may be proved that the two diagonals BH and DF bisect each other; and hence the four diagonals mutually bisect each other in a point which may be regarded as the centre of the parallelopiped.

PROPOSITION $V$. THEOREM.
If a parallelopiped be cut by a plane passing through the diagonals of two opposite faces, it will be divided into two equivalent triangular prisms.

Let AG be a parallelopiped, and AC, EG the diagonals of the opposite parallelograms $B D, F H$. Now, because $A E, C G$ are
each of them parallel to BF, they are parallel to each other; therefore the diagonals AC, EG are in the same plane with $\mathrm{AE}, \mathrm{CG}$; and the plane AEGC divides the solid AG into two equivalent prisms.

Through the vertices $\mathbf{A}$ and $\mathbf{E}$ draw the planes AIKL, EMNO perpendicular to AE, meeting the other edges of the parallelopiped in the points $\mathrm{I}, \mathrm{K}, \mathrm{L}$, and in M, N, O. The sections AIKL, EMNO are equal, because they are formed by
 planes perpendicular to the same straight line, and consequently parallel (Pr. 2). They are also parallelograms, because AI, KL, two opposite sides of the same section, are the intersections of two parallel planes $\mathrm{ABFE}, \mathrm{DCGH}$, by the same plane.

For the same reason, the figure ALOE is a parallelogram; so, also, are AIME, IKNM, KLON, the other lateral faces of the solid AIKL-EMNO; hence this solid is a prism (Def. 6) ; and it is a right prism, because AE is perpendicular to the plane of its base. But the right prism AN is divided into two equal prisms ALK-N, AIK-N ; for the bases of these prisms are equal, being halves of the same parallelogram AIKL, and they have the common altitude AE; they are therefore equal (Pr. 3, Cor.).

Now, because AEHD, AEOL are parallelograms, the sides DH, LO, being equal to AE , are equal to each other. Take away the common part DO, and we have DL equal to HO. For the same reason, CK is equal to GN.

Conceive now that ENO, the base of the solid ENGHO, is placed on AKL, the base of the solid AKCDL ; then, the point O falling on L , and N on K , the lines HO , GN will coincide with their equals DL, CK, because they are perpendiculars to the same plane. Hence the two solids coincide throughout, and are equal to each other. To each of these equals add the solid $\mathrm{ADC}-\mathrm{N}$; then will the oblique prism $\mathrm{ADC}-\mathrm{G}$ be equivalent to the right prism ALK-N.

In the same manner, it may be proved that the oblique prism $\mathrm{ABC}-\mathrm{G}$ is equivalent to the right prism AIK-N. But the two right prisms have been proved to be equal; hence the two oblique prisms $\mathrm{ADC}-\mathrm{G}, \mathrm{ABC}-\mathrm{G}$ are equivalent to each other. Therefore, if a parallelopiped, etc.

Cor. Every triangular prism is half of a parallelopiped having the same solid angle, and the same edges $\mathrm{AB}, \mathrm{BC}, \mathrm{BF}$.

Scholium. The triangular prisms into which the oblique parallelopiped is divided can not be made to coincide, because the plane angles about the corresponding solid angles are not similarly situated.

## PROPOSITION VI. THEOREM.

Parallelopipeds upon the same base and of the same altitucte are equivalent.

Case first. When their upper bases are between the same parallel lines.

Let the parallelopipeds AG, AL have the base AC common, and let their opposite bases EG, IL be in the same plane, and between the same parallels EK, HL; then will the solid AG be equivalent to the solid AL.

Because AF, AK are parallelograms, EF and IK are each equal to AB , and therefore equal to each other. Hence, if EF and IK be taken away from the same line EK, the remainders EI and FK will be equal. Therefore the triangle AEI is equal to the triangle BFK.
Also, the parallelogram EM is equal to the parallelogram FL, and AH to BG . Hence the solid angles at E and F are contained by three faces which are equal to each other and similarly situated; therefore the prism AEI-M is equal to the prism BFK-L (Pr. 3).

Now if from the whole solid AL we take the prism AEI-M, there will remain the parallelopiped AL ; and if from the same solid AL we take the prism BFK-I, there will remain the paral-
 lelopiped AG. Hence the parallelopipeds $A L, A G$ are equivalent to one another.

Case second. When their upper bases are not between the same parallel lines.

Let the parallelopipeds AG, AL have the same base $A C$ and the same altitude; then will their opposite bases EG, IL be in the same plane. Also, since the sides EF and

IK are equal and parallel to AB , they are equal and parallel to each other. For the same reason, $F G$ is equal and parallel to KL.

Produce the sides EH, FG, as also IK, LM, and let them meet in the points $N, O, P, Q$; the figure $N O P Q$ is a parallelogram equal to each of the bases EG, IL; and, consequently, equal to ABCD ; and parallel to it.

Conceive now a third parallelopiped AP, having AC for its lower base, and NP for its upper base. The solid AP will be equivalent to the solid AG by the first Case, because they have the same lower base, and their upper bases are in the same plane and between the same parallels, EQ, FP. For the same reason, the solid AP is equivalent to the solid AL ; hence the solid AG is equivalent to the solid $A L$. Therefore parallelopipeds, etc.

## PROPOSITION VII, THEOREM.

Any parallelopiped is equivalent to a rectangular parallelopiped having the same altitude and an equivalent base.

Let AL be any parallelopiped; it is equivalent to a right parallelopiped having the same altitude and an equivalent base.

From the points A, B, C, D draw $\mathrm{AE}, \mathrm{BF}, \mathrm{CG}, \mathrm{DH}$ perpendicular to the plane of the lower base, meeting the plane of the upper base in the points E, F, G, H. Join EF, FG, GH, HE; there will thus be formed the parallelopiped AG, equivalent to AL (Pr. 6); and its lateral faces $\mathrm{AF}, \mathrm{BG}, \mathrm{CH}, \mathrm{DE}$ are rectangles.

If the base ABCD is also a rectan-
 gle, AG will be a rectangular parallelopiped, and it is equivalent to the parallelopiped AL.

But if ABCD is not a rectangle, from $A$ and $B$ draw AI, BK perpendicular to CD, and from E and F draw EM, FL perpendicular to GH, and join IM, KL. The solid ABKI-M will be a rectangular parallelopiped. For, by construction, the bases ABKI and EFLM are rectangles; so, also, are the lateral faces, because the edges $\mathrm{AE}, \mathrm{BF}, \mathrm{KL}, \mathrm{IM}$ are perpendicular to the plane of the base. Therefore the solid AL

is a rectangular parallelopiped. But the two parallelopipeds $A G, A L$ may be regarded as having the same base AF, and the same altitude AI ; they are therefore equivalent. But the parallelopiped $A G$ is equivalent to the first supposed parallelopiped; hence this parallelopiped is equivalent to the rectangular parallelopiped AL , having the same altitude, and an equivalent base. Therefore any parallelopiped etc.

## PROPOSITION VIII. THEOREM.

Two rectangular parallelopipeds having the same base are to each other as their altitudes.

Let AG, AL be two rectangular parallelopipeds having the same base ABCD ; then will they be to each other as their altitudes AE, AI.

Case first. When the altitudes are in the ratio of two whole numbers.

Suppose the altitudes AE, AI are in the ratio of two whole numbers; for example, as seven to four. Divide AE into seven equal parts; AI will contain four of those parts. Through the several points of division let planes be drawn parallel to the base ; these planes will divide the solid AG into seven small parallelopipeds, all equal to each other, having equal bases and equal altitudes. The bases are equal, because every section of a prism parallel to the base is equal to the base (Pr. 2, Cor.) ; the altitudes are equal, for these altitudes are the equal divisions of the edge AE. But of these seven equal parallelopipeds, AL contains four; hence the solid $A G$ is to the solid $A L$ as seven to four, or as the altitude AE is to the altitude AI.

Case second. When the altitudes are not in the ratio of two whole numbers; that is, are incommensurable, the demonstration will be similar to that given in B. III., Pr. 14. Therefore two rectangular parallelopipeds, etc.

## PROPOSITION IX. THEOREM.

Two rectangular parallelopipeds having the same altitude are to each other as their bases.

Let AG, AN be two rectangular parallelopipieds having the same altitude $A E$; then will they be to each other as their bases; that is,
solid AG : solid AN :: base ABCD : base AIKL.
Place the two solids so that their surfaces may have the common angle BAE; produce the plane LKNO till it meets the plane DCGH in the line PR; a third parallelopiped AR will thus be formed, which may be compared with each of the parallelopipeds AG, AN.

The two solids $A G, A R$, having the same
 base AEHD, are to each other as their altitudes $\mathrm{AB}, \mathrm{AL}$ (Pr. 8); and the two solids AR, AN, having the same base ALOE, are to each other as their altitudes AD, AI. Hence we have the two proportions solid AG: solid AR:: AB: AL; solicl AR : solid AN :: AD : AI.
Hence (B. II., Pr. 12, Cor.)

$$
\text { solid } \mathrm{AG}: \text { solid } \mathrm{AN}:: \mathrm{AB} \times \mathrm{AD}: \mathrm{AL} \times \mathrm{AI} \text {. }
$$

But $A B \times A D$ is the measure of the base $A B C D$ (B. IV., Pr. 4, Sch.) ; and $\mathrm{AL} \times \mathrm{AI}$ is the measure of the base AIKI; hence solid AG : solid AN :: base ABCD : base AIKL.
Therefore two rectangular parallelopipeds, etc.
PROPOSITION X. THEOREM.
Any two rectangular parallelopipeds are to each other as the products of their bases by their altitudes.

Let AG, AQ be two rectangular parallelopipeds, of which the bases are the rectangles $\mathrm{ABCD}, \mathrm{AIKL}$, and the altitudes the perpendiculars AE, AP; then will the solid AG be to the solid $A Q$ as the product of $A B C D$ by $A E$ is to the product of AIKL by AP.

Place the two solids so that their surfaces may have the common angle BAE; produce the planes necessary to form the third parallelopiped AN,
 having the same base with $A Q$, and the same altitude with $A G$. Then, by the last Proposition, we shall have
solid AG: solid AN :: ABCD : AIKL.

But the two parallelopipeds AN, AQ, having the same base AIKL, are to each other as their altitudes AE, AP (Pr. 8) ; hence we have solid AN : solid $\mathrm{AQ}:: \mathrm{AE}: \mathrm{AP}$.
Comparing these two proportions (B. II., Pr. 12, Cor.), we have

$$
\begin{aligned}
\text { solid AG: } & \text { solid } \mathrm{AQ}:: \mathrm{ABCD} \times \mathrm{AE}: \\
& \text { AIKL } \times \mathrm{AP} .
\end{aligned}
$$

If, instead of the base $A B C D$, we putits equal $A B \times A D$, and instead of AIKL, we put its equal $A I \times A L$, we shall have solid AG : solid $\mathrm{AQ}:: \mathrm{AB} \times \mathrm{AD} \times \mathrm{AE}$ : $\mathrm{AI} \times \mathrm{AL} \times \mathrm{AP}$.
Therefore any two rectangular parallelopipeds, etc.

Scholium. IIence a rectangular parallelopiped is measured by the product of its base and altitude, or the product of its three dimensions.

It should be remembered that, by the product of two or more lines, we understand the product of the numbers which represent those lines; and these numbers depend upon the linear unit employed, which may be assumed at pleasure. If we take a foot as the unit of measure, then the number of feet in the length of the base, multiplied by the number of feet in its breadth, will give the number of square feet in the base. If we multiply this product by the number of feet in the altitude, it will give the number of cubic feet in the parallelopiped. If we take an inch as the unit of measure, we shall obtain in the same manner the number of cubic inches in the parallelopiped.

## PROPOSITION XI. THEOREM.

The volume of a prism is measured by the proctuct of its base by its altitude.

For any parallelopiped is equivalent to a rectangular parallelopiped, having the same altitude and an equivalent base (Pr. 7). But the volume of the latter is measured by the product of its base by its altitude; therefore the volume of the former is also measured by the product of its base by its altitude.

Now a triangular prism is half of a parallelopiped having the same altitude and a double base (Pr.5). But the volume of the latter is measured by the product of its base by its altitude; hence a triangular prism is measured by the product of its base by its altitude.

But any prism can be divided into as many triangular prisms of the same altitude as there are triangles in the polygon which forms its base.

Also, the volume of each of these triangular prisms is measured by the product of its base by its altitude; and, since they. all have the same altitude, the sum of these prisms will be measured by the sum of the triangles which form the bases, multiplied by the common altitude. Therefore the volume of any prism is measured by the product of its base by its altitude.

Cor. If two prisms have equal altitudes, the products of the bases by the altitudes will be as the bases (B. II., Pr. 10); hence prisms having equal altitudes are to each other as their bases. For the same reason, prisms laving equivalent bases are to each other as their altitudes; and any two prisms are to each other as the products of their bases and altitudes.

## PROPOSITION XII. THEOREM.

Similar prisms are to each other as the cubes of their homologous edges.

Let $\Lambda$ BCDE-F, $a b c d e-f$ be two similar prisms; then will the prism AD F lue to the prism $a d-f$ as $A B^{3}$ to $a b^{3}$, or as $\mathrm{AF}^{3}$ to $a f^{3}$.

For the solids are to each other as the products of their bases and altitudes (Pr. 11, Cor.) ; that is, as ABCDE $\times \mathrm{AF}$ to $a b c d e \times a f$. But, since the prisms are similar, the bases are similar figures, and are to each other as
 the squares of their homologous sides; that is, as $\mathrm{AB}^{2}$ to $a b^{2}$. Therefore we have

$$
\text { solid FD : solid } f d:: \mathrm{AB}^{2} \times \mathrm{AF}: a b^{2} \times a f
$$

But, since BF and $b f$ are similar figures, their homologous sides are proportional; that is,

$$
\mathrm{AB}: a b:: \mathrm{AF}: a f ;
$$

whence (B. II., Pr. 11)

$$
\begin{gathered}
\mathrm{AB}^{2}: a b^{2}:: \mathrm{AF}^{2}: a f^{2} \\
\mathrm{AF}: a f:: \mathrm{AF}: a f .
\end{gathered}
$$

Also,
Therefore (B. II., Pr. 12), $\mathrm{AB}^{2} \times \mathrm{AF}: a b^{2} \times a f:: \mathrm{AF}^{3}: a f^{3}:: \mathrm{AB}^{3}: a b^{3}$.
Hence (B. II., Pr. 4) we have
solid FD : solid $f d:: \mathrm{AB}^{3}: a b^{3}:: \mathrm{AF}^{3}: a f^{3}$.
Therefore similar prisms, etc.

## PROPOSITION XIII. THEOREM.

If a pyramid be cut by a plane parallel to its base, 1 st. The edges and the altitude will be clivided proportionally. 2d. The section will be a polygon similar to the base.

Let A-BCDEF be a pyramid cut by a plane $b c d e f$ parallel to its base, and let AH be its altitude; then will the edges $\mathrm{AB}, \mathrm{AC}, \mathrm{AD}$, etc., with the altitude AH , be divided proportionally in $b, c, d, e, f, h$, and the section $b c d e f$ will be similar to BCDEF.

First. Since the planes $\mathrm{FBC}, f b c$ are parallel, their sections $\mathrm{FB}, f b$, with a third plane AFB, are parallel (B. VII., Pr. 12) ; therefore the triangles AFB, Afb are similar, and we have the proportion

$$
\mathrm{AF}: \mathrm{A} f:: \mathrm{AB}: \mathrm{A} b .
$$

For the same reason, $\mathrm{AB}: \mathrm{A} b:: \mathrm{AC}: \mathrm{Ac}$, and so for the other edges. Therefore the edges $A B, A C$, etc., are cut proportionally in $b, c$, etc. Also, since BH and $b h$ are parallel, we have $\mathrm{AH}: \mathrm{A} h:: \mathrm{AB}: \mathrm{A} b$.

Secondly. Because $f b$ is parallel to $\mathrm{FB}, b c$ to $\mathrm{BC}, c d$ to CD , etc., the angle $f b c$ is equal to FBC (B. VII., Pr: 15), the angle $b c d$ is equal to BCD , and so on. Moreover, since the triangles AFB, $\mathrm{A} f b$ are similar, we have $\mathrm{FB}: f b:: \mathrm{AB}: \mathrm{A} b$.
And because the triangles $\mathrm{ABC}, \mathrm{A} b c$ are similar, we have

$$
\mathrm{AB}: \mathrm{A} b:: \mathrm{BC}: b c
$$

Therefore, by equality of ratios (B. II., Pr. 4),

$$
\mathrm{FB}: f b:: \mathrm{BC}: b c .
$$

For the same reason,

$$
\mathrm{BC}: b c:: \mathrm{CD}: c d, \text { and so on. }
$$

Therefore the polygons BCDEF, bedef have their angles equal each to each, and their homologous sides proportional; hence they are similar. Therefore, if a pyramid, etc.

Cor. 1. If two pyramids having the same altitude, and their bases situated in the same plane, are cut by a plane parallel to their bases, the sections will be to each other as the bases.

Let A-BCDEF, A-MNO be two pyramids having the same altitude, and their bases situated in the same plane; if these pyramids are cut by a plane parallel to the bases, the sections bcdef, mno will be to each other as the bases BCDEF, MNO.

For, since the polygons BC DEF, bcclef are similar, their surfaces are as the squares of the homologous sides $\mathrm{BC}, b c$ (B. IV., Pr. 27). But, by the preceding Proposition, $\mathrm{BC}: b c:: \mathrm{AB}: \mathrm{A} b$.
Therefore
BCDEF : bcclef $:: \mathrm{AB}^{2}: \mathrm{Ab}^{2}$. For the same reason,

MNO : $m n o:: \mathbf{A M}^{2}: \mathbf{A m}^{2}$.

But, since bcclef and mno are in the same plane, we have $\mathrm{AB}: \mathrm{A} b:: \mathrm{AM}: \mathrm{A} m$ (B. VII., Pr: 16); consequently, BCDEF:bcclef::MNO:mno.

Cor. 2. If the bases BCDEF, MNO are equivalent, the sections $b c d e f, m n o$ will also be equivalent.

PROPOSITION XIV. THEOREM.
The lateral sunface of a regular pyramid is equal to the product of the perimeter of its base by half its slant height.

Let $\mathrm{A}-\mathrm{BDE}$ be a regular pyramid whose base is the polygon BCDEF , and its slant height AH ; then will its lateral surface be equal to the perimeter $\mathrm{BC}+\mathrm{CD}+\mathrm{DE}$, etc., multiplied by half of AHI.

The triangles $\mathrm{AFB}, \mathrm{ABC}, \mathrm{ACD}$, etc., are all equal, for the sides $\mathrm{FB}, \mathrm{BC}, \mathrm{CD}$, etc., are all equal (Def. 15) ; and, since the oblique lines AF, $\mathrm{AB}, \mathrm{AC}$, etc., are all at equal distances from the perpendicular, they are equal to each other (B.
 VII., Pr. 5). Hence the altitudes of these several triangles are equal.

But the area of the triangle AFB is equal to FB multiplied by half of AH ; and the same is true of the other triangles ABC , ACD , etc. Hence the sum of the triangles is equal to the sum of the bases $\mathrm{FB}, \mathrm{BC}, \mathrm{CD}, \mathrm{DE}, \mathrm{EF}$ multiplied by half the common altitude AH ; that is, the lateral surface of the pyramid is equal to the perimeter of its base multiplied by half the slant height.

Cor. 1. The lateral surface of a firstum of a regular pyramid is equal to the sum of the perimeters of its two bases multiplied by half its slant height.

Each side of a frustum of a regular pyramid, as $\mathrm{FB} b f$, is a trapezoid ( Pr .13 ). Now the area of this trapezoid is equal to the sum of its parallel sides $\mathrm{FB}, f b$, multiplied by half its altitude $\mathrm{H} h$ (B. IV., Pr. 7). But the altitude of each of these trapezoids is the same; therefore the area of all the trapezoids, or the lateral surface of the frustum, is equal to the sum of the perimeters of the two bases multiplied by half the slant height.
Cor. 2. If the frustum is cut by a plane parallel to the bases, and at equal distances from them, this plane must bisect the edges $\mathrm{B} b, \mathrm{C} c$, etc. (B. IV., Pr. 16) ; and the area of each trapezoid is equal to its altitude multiplied by the line which joins the middle points of its two inclined sides (B. IV., Pr. 7, Cor.). Hence the lateral surface of a frustum of a pyramid is equal to its slant height multiplied by the perimeter of a section at equal distances between the two bases.

## PROPOSITION XV. THEOREM.

Two triangular pyramids having equivalent bases and equal altitudes are equivalent.

Let $\mathrm{A}-\mathrm{BCD}, a-b c d$ be two triangular pyramids having equivalent bases $\mathrm{BCD}, b c d$, supposed to be situated in the same plane,
and having the common altitude TB; then will the pyramid ABCD be equivalent to the pyramid $a-b c d$.

For, if they are not equivalent, let the pyramid $A-B C D$ be the greater, and suppose it to exceed the pyramid $a-b c d$ by a prism whose base is BCD, and altitude BX.

Divide the altitude BT into equal parts, each less than BX; and through the several points of division let planes be made to pass parallel to the base BCD, making the sections EFG, efg equivalent to each other (Pr. 13, Cor. 2) ; also, HIK equivalent to $h i k$, etc.

From the point $C$ draw the straight line $C R$ parallel to $B E$, meeting EF produced in R; and from D draw DS parallel to BE, meeting EG in S. Join RS, and it is plain that the solid BCD-ERS is a prism lying partly without the pyramid.

In the same manner, upon the triangles EFG, HIK, etc., taken as bases, construct exterior prisms, having for edges the parts $\mathrm{EH}, \mathrm{HL}$, etc., of the line AB . In like manner, on the bases efg, hik, lmn, etc., in the second pyramid, construct interior prisms, having for edges the corresponding parts of $a b$.

It is plain that the sum of all the exterior prisms of the pyramid $\mathrm{A}-\mathrm{BCD}$ is greater than this pyramid; and also, that the sum of all the interior prisms of the pyramid $a-b c d$ is smaller than this pyramid. Hence the difference between the sum of all the exterior prisms and the sum of all the interior ones must be greater than the difference between the two pyramids themselves.

Now, beginning with the bases $\mathrm{BCD}, b c d$, the second exterior prism EFG-H is equivalent to the first interior prism efg-b, because their bases are equivalent, and they have the same altitude. For the same reason, the third exterior prism HIK-L, and the second interior prism hik-e are equivalent; the fourth exterior and the third interior, and so on to the last in each series. Hence all the exterior prisms of the pyramid $\mathrm{A}-\mathrm{BCD}$, excepting the first prism $\mathrm{BCD}-\mathrm{E}$, have equivalent corresponding ones in the interior prisms of the pyramid $a-b c d$.

Therefore the prism $\mathrm{BCD}-\mathrm{E}$ is the difference between the sum of all the exterior prisms of the pyramid $A-B C D$, and the sum of all the interior prisms of the pyramid $a-b c d$. But the difference between these two sets of prisms has been proved to be greater than that of the two pyramids; hence the prism $\mathrm{BCD}-\mathrm{E}$ is greater than the prism $\mathrm{BCD}-\mathrm{X}$, which is impossible, for they have the
same base $B C D$, and the altitude of the first is less than $B X$, the altitude of the second. Hence the pyramids $\mathrm{A}-\mathrm{BCD}, a-b c d$ are not unequal in.volume; that is, they are equivalent to each other. Therefore, triangular pyramids, etc.

## PROPOSITION XVI. THEOREM.

Any triangular pyramid is the third part of a triangular prism having the same base and the same altitude.

Let $\mathrm{E}-\mathrm{ABC}$ be a triangular pyramid, and ABC-DEF a triangular prism having the same base and the same altitude; then will the pyramid be one third of the prism.

Cut off from the prism the pyramid $\mathrm{E}-\mathrm{ABC}$ by the plane EAC; there will remain the solid E-ACFD, which may be considered as a quadrangular pyramid whose vertex is E , and whose base is the parallelogram ACFD. Draw the diagonal $C D$, and through the points $\mathrm{C}, \mathrm{D}, \mathrm{E}$ pass a plane, dividing the quadrangular pyramid into two triangular ones $\mathrm{E}-\mathrm{ACD}, \mathrm{E}-\mathrm{CDF}$.

Then, because ACFD is a parallelogram, of which CD is the diagonal, the triangle ACD is equal to the triangle CDF. Therefore the pyramid, whose base is the triangle $A C D$, and vertex the point $\mathbf{E}$, is equivalent to the pyramid whose base is the triangle CDF , and vertex the point E . But the latter pyramid is equivalent to the pyramid $\mathrm{E}-\mathrm{ABC}$, for they have equal bases, viz., the triangles $\mathrm{ABC}, \mathrm{DEF}$, and the same altitude, viz., the altitude of the prism ABC-DEF. Therefore the three pyramids E-ABC, $\mathrm{E}-\mathrm{ACD}, \mathrm{E}-\mathrm{CDF}$, are equivalent to each other, and they compose the whole prism ABC-DEF; hence the pyramid EABC is the third part of the prism which has the same base and the same altitude.

Cor. The volume of a triangular pyramid is measured by the product of its base by one third of its altitude.

## proposition xvit. theorem.

The volume of any pyramid is measured by the product of its base by one third of its altitude.

Let A-BCDEF be any pyramid, whose base is the polygon BCDEF , and altitude AH ; then will the volume of the pyramid be measured by $\mathrm{BCDEF} \times \frac{1}{3} \mathrm{AH}$.

Divide the polygon BCDEF into triangles by the diagonals CF, DF, and let planes pass through these lines and the vertex $A$; they will divide the polygonal pyramid $\mathrm{A}-\mathrm{BCDEF}$ into triangular pyramids, all having the same altitude AH .
But each of these pyramids is measured by the product of its base by one third of its altitude (Pr. 16, Cor.) ; hence the sum of the triargular pyramids, or the polygonal pyramid A-BCDEF, will be measured by the sum of the
 triangles $\mathrm{BCF}, \mathrm{CDF}, \mathrm{DEF}$, or the polygon BCDEF, multiplied by one third of AH. Therefore every pyramid is measured by the product of its base by one third of its altitude.

Cor. 1. Every pyramid is one third of a prism having the same base and altitude.

Cor. 2. Pyramids having equal altitudes are to each other as their bases; pyramids having equivalent bases are to each other as their altitudes; and any two pyramids are to each other as the products of their bases by their altitudes.

Cor. 3. Similar pyramids are to each other as the cubes of their homologous edges.

Scholium. The volume of any polyedron may be found by dividing it into pyramids, by planes passing through its vertices.

PROPOSITION XVIII. THEOREM.
A frustum of a pyramid is equivalent to the sum of three pyramids having the same altitude as the frustum, and whose bases are the lower base of the frustum, its upper base, and a mean proportional between them.

Case first. When the base of the frustum is a triangle.
Let ABC-DEF be a frustum of a triangular pyramid. If a plane be made to pass through the points $\mathrm{A}, \mathrm{C}, \mathrm{E}$, it will cut off the pyramid $\mathrm{E}-\mathrm{ABC}$, whose altitude is the altitude of the frustum, and its base is ABC , the lower base of the frustum.

Pass another plane through the points $\mathbf{C}$, $\mathrm{D}, \mathrm{E}$; it will cut off the pyramid C-DEF, whose altitude is that of the frustum, and its base is DEF, the upper base of the frustum.

To find the magnitude of the remaining
 pyramid E-ACD, draw EG parallel to AD; join CG, DG. Then, because the two triangles AGC, DEF have the angles at A and D equal to each other, we have (B.IV., Pr. 24) AGC:DEF : : AG $\times \mathrm{AC}: \mathrm{DE} \times \mathrm{DF}$,
$:: \mathrm{AC}: \mathrm{DF}$, because AG is equal to DE . Also (B. IV., Pr. 6, Cor. 1),
$\mathrm{ACB}: \mathrm{ACG}:: \mathrm{AB}: \mathrm{AG}$ or DE.
But, because the triangles ABC, DEF are similar (Pr. 13), we have
$\mathrm{AB}: \mathrm{DE}:: \mathrm{AC}: \mathrm{DF}$.
Therefore (B. II., Pr. 4)
$\mathrm{ACB}: A C G:: A C G: D E F ;$
that is, the triangle $A C G$ is a mean proportional between $A C B$ and DEF, the two bases of the frustum.

Now the pyramid $\mathrm{E}-\mathrm{ACD}$ is equivalent to the pyramid $\mathrm{G}-\mathrm{ACD}$, because it has the same base and the same altitude; for EG is parallel to AD , and consequently parallel to the plane ACD . But the pyramid G-ACD has the same altitude as the frustum, and its base ACG is a mean proportional between the two bases of the frustum.

Case second. When the base of the frustum is any polygon.

Let BCDEF-bcdef be a frustum of any pyramid.

Let G-HIK be a triangular pyramid having the same altitude and an equivalent base with the pyramid A-BCDEF, and from it let a frustum HIKhik be cut off, having the same altitude with the frustum BCD EF-bcclef.
The entire pyramids are equivalent ( Pr .17 ), and the small pyramids $\mathrm{A}-b c d e f, \mathrm{G}-h i k$ are also equivalent, for their altitudes are equal, and their bases are equivalent (Pr. 13, Cor. 2). Hence the two frustums are equivalent, and they have the same altitude, with equivalent bases. But the frustum HIK-hik has been proved to be equivalent to the sum of three pyramids, each having the same altitude as the frustum, and whose bases are the lower base of the frustum, its upper base, and a mean proportion-
al between them. Hence the same must be true of the frustum of any pyramid. Therefore a frustum of a pyramid, etc.

Scholium. If $V$ denotes the volume of the frustum, B its lower base, $b$ its upper base, and $h$ its altitude, this proposition is expressed by the formula

$$
\mathrm{V}=\frac{1}{3} h(\mathrm{~B}+b+\sqrt{\mathrm{B} \times b})
$$

## PROPOSITION XIX. THEOREM.

## There can be but five regular polyedrons.

Since the faces of a regular polyedron are regular polygons, they must consist of equilateral triangles, of squares, of regular pentagons, or polygons of a greater number of sides.

First. If the faces are equilateral triangles, each solid angle of the polyedron may be contained by three of these triangles, form-

ing the tetraedron; or by four, forming the octaedron; or by five, forming the icosaedron.

No other regular polyedron can be formed with equilateral triangles; for six angles of these triangles amount to four right angles, and can not form a solid angle (B. VII., Pr. 18).

Secondly. If the faces are squares, their angles may be united three and three, forming the hexaedron or cube.

Four angles of squares amount to four right angles, and can not form a solid angle.

Thirdly. If the faces are regular pentagons, their angles may be united three and three, forming the regular dodecaedron. Four angles of a regular pentagon are greater than four right angles, and can not form a solid angle.

Fourthly. A regular polyedron can not be formed with regular hexagons, for three angles of a regular hexagon amount to four right angles. Three angles of a regular heptagon amount to more than four right angles; and the same is true of any polygon having a greater number of sides.

Hence there can be but five regular polyedrons; three formed with equilateral triangles, one with squares, and one with pentagons.

Scholium. Models of the regular polyedrons may be easily obtained as follows: Let the figures represented below be accurately drawn on card-board and cut out entire. At the lines separating two adjacent polygons let the card-board be cut half through; the edges of the several polygons in each figure may then be brought together so as to represent a regular polyedron, and they may be secured in their place by gluing the edges.

PROPOSITION Xx. PROBLEM.
To compute the volume of a regular tetraedron.

Let $\mathrm{A}-\mathrm{BCD}$ be a regular tetraedron; it is required to determine its volume.

From one angle, A, let fall the perpendicular AE upon the opposite face BCD. By Def. 5 , the faces of the tetraedron are all equal triangles, therefore $\mathrm{AB}, \mathrm{AC}, \mathrm{AD}$ are equal to each other: Hence they are equally distant from the perpendicular (B. VII., Pr. 5, Cor.) ; that is, E is the centre of a circle described about the equilateral triangle BCD . The area of the triangle BCD is equal to $\frac{\mathrm{BC}^{2}}{4} \sqrt{ } 3$ (B. VI., Pr. 4, Sch. 2).

Since EF is one half of EC (B. VI., Pr. 4), it is one third of FC or AF. Then, in the triangle AEF, we have (preceding figure)
$\mathrm{AE}^{2}=\mathrm{AF}^{2}-\mathrm{FE}^{2}=\mathrm{AF}^{2}-\frac{1}{9} \mathrm{AF}^{2}=\frac{8}{9} \mathrm{AF}^{2}$.
Also,

$$
\mathrm{AF}^{2}=\mathrm{CF}^{2}=\frac{3}{4} \mathrm{BC}^{2}
$$

Therefore $\mathrm{AE}^{2}=\frac{8}{9} \times \frac{3}{4} \mathrm{BC}^{2}=\frac{2}{3} \mathrm{BC}^{2}$;
or,
$A E=B C \sqrt{ } \frac{2}{3}$.

Hence the volume of the tetraedron is equal
to

$$
\frac{\mathrm{BC}^{2}}{4} \sqrt{ } 3 \times \frac{1}{3} \mathrm{BC} \sqrt{ } \frac{2}{3}=\frac{1}{12} \mathrm{BC}^{3} \sqrt{ } 2
$$

that is, the volume of a regular tetraedron is equal to the cube of a linectr edge multiplied by one twelfth the square root of two.

Cor. The entire surface of the tetraedron is equal to four times the area of the triangle BCD ; or $\mathrm{BC}^{2} \sqrt{ } 3$; that is, the surface of a regular tetraedron is equal to the square of a linear edge multiplied by the square root of three.

## BOOK IX.

SPHERICAL GEOMETRY.

## Definitions.

1. A sphere is a solid bounded by a curved surface, all the
 points of which are equally distant from a point within called the centre.

A sphere may be conceived to be described by the revolution of a semicircle ADB about its diameter AB , which remains unmoved.
2. A radius of a sphere is a straight line drawn from the centre to any point of the surface. A diameter is any straight line drawn through the centre, and terminated each way by the surface.

All the radii of a sphere are equal; all the diameters are also equal, and each double of the radius.
3. It will be shown (Prop. 1) that every section of a sphere made by a plane is a circle. A great circle is a section made by a plane which passes through the centre of the sphere. A small circle is a section made by a plane which does not pass through the centre.
4. The poles of a circle of a sphere are the extremities of that diameter of the sphere which is perpendicular to the plane of the circle.
5. A plane touches a sphere when it meets the sphere, but, being produced, does not cut it.
6. A spherical polygon is a portion of the surface of a sphere bounded by three or more arcs of great circles, each of which is less than a semi-circumference. These arcs are called the sides of the polygon; and the angles which their planes make with each other are the angles of the polygon.
7. A spherical triangle is a spherical polygon of three sides. It is called right-angled, isosceles, or equilateral in the same cases as a plane triangle.
8. A lune is a portion of the surface of a sphere included between two semi-circumferences of great circles having a common diameter.
9. A spherical ungula or wedge is a portion of a sphere included between the halves of two great circles, and has the lune for its base.
10. A spherical pyramid is a portion of a sphere included between the planes of a solid angle whose vertex is at the centre. The base of the pyramid is the spherical polygon intercepted by those planes.
11. A zone is a portion of the surface of a sphere included between two parallel planes.
12. A spherical segment is a portion of a sphere included between two parallel planes.
13. The bases of the segment are the sections of the sphere made by the parallel planes; the altitude of the segment or zone is the distance between the planes. One of the two planes may touch the sphere, in which case the segment has but one base.
14. When a semicircle, revolving about its diameter, describes a sphere, any sector of the semicircle describes a solid, which is called a spherical sector.

Thus, when the semicircle AEB, revolving about its diameter AB, describes a sphere, any circular sector, as $A C D$ or DCE, describes a spherical sector.

PROPOSITION I. THEOREM.
Every section of a sphere made by a plane is a circle.
Let ABD be a section made by a plane in a sphere whose centre is C. From the point C draw CE perpendicular to the plane ABD ; and draw lines $\mathrm{CA}, \mathrm{CB}, \mathrm{CD}$, etc., to different points of the curve $A B D$ which bounds the section.

The oblique lines CA, CB, CD are equal, because they are radii of the sphere ; there-

fore they are equally distant from the perpendicular CE (B. VII., Pr. 5, Cor.). Hence all the lines $\mathrm{EA}, \mathrm{EB}, \mathrm{ED}$ are equal; and, consequently, the section ABD is a circle, of which E is the centre. Therefore every section, etc.

Cor. 1. If the section passes through the centre of the sphere, its radius will be the radius of the sphere; hence all great circles of a sphere are equal to each other.

Cor: 2. Any two great circles of a sphere bisect each other; for, since they have the same centre, their common section is a diameter of both, and therefore bisects both.

Cor. 3. Every great circle divides the sphere and its surface into two equal parts. For if the two parts are separated and applied to each other, base to base, with their convexities turned the same way, the two surfaces must coincide; otherwise there would be points in these surfaces unequally distant from the centre.

Cor. 4. The centre of a small circle and that of the sphere are in a straight line perpendicular to the plane of the small circle.

Cor: 5 . The circle which is farthest from the centre is the least; for the greater the distance CE , the less is the chord AB , which is the diameter of the small circle $A B D$.

Cor. 6. An arc of a great circle may be made to pass through any two points on the surface of a sphere; for the two given points, together with the centre of the sphere, make three points which are necessary to determine the position of a plane. If, however, the two given points were situated at the extremities of a diameter, these two points and the centre would then be in one straight line, and any number of great circles might be made to pass through them.

## PROPOSITION II. THEOREM.

A plane perpendicular to a diameter at its extremity touches the sphere.

Let ADB be a plane perpendicular to the diameter DC at its extremity $D$, then the plane ADB touches the sphere at the point D .

Let E be any other point in the plane ADB , and join DE, CE Because CD is perpendicular to the plane ADB , it is perpendicu-
lar to the line AB (B. VII., Def. 1) ; hence the angle CDE is a right angle, and the line CE is greater than CD. Consequently, the point $E$ lies without the sphere. Hence the plane ADB has only the point $D$ in common with the sphere; it therefore touches the sphere (Def. 5). Therefore a plane, etc.

Cor. In the same manner, it may be proved that two spheres touch each other when the distance between their centres is equal to the sum or difference of their radii, in which case the centres and the point of contact lie in one straight line.

PROPOSITION III. THEOREM.
Any side of a spherical triangle is less than the sum of the other two.

Let ABC be a spherical triangle; then any side, as AC, is less than the sum of the other two, AB and BC .

Let D be the centre of the sphere, and draw the radii $\mathrm{AD}, \mathrm{BD}, \mathrm{CD}$. Conceive the planes $\mathrm{ADB}, \mathrm{BDC}, \mathrm{CDA}$ to be drawn, forming a solid angle at D . The angles $\mathrm{ADB}, \mathrm{BDC}, \mathrm{CDA}$ will be measured by $\mathrm{AB}, \mathrm{BC}, \mathrm{CA}$, the sides of the
 spherical triangle $A B C$. But when a solid angle is formed by three plane angles, any one of them is less than the sum of the other two (B. VII., Pr. 17) ; hence any one of the arcs AB, BC, CA must be less than the sum of the other two. Therefore any side, etc.

PROPOSITION IV. THEOREM.
The sum of the sides of a spherical polygon is less than the circumference of a great circle.

Let ABCD be any spherical polygon; then will the sum of the sides $\mathrm{AB}, \mathrm{BC}, \mathrm{CD}, \mathrm{DA}$ be less than the circumference of a great circle.

Let E be the centre of the sphere, and join $\mathrm{AE}, \mathrm{BE}, \mathrm{CE}, \mathrm{DE}$. The solid angle at E is contained by the plane angles $\mathrm{AEB}, \mathrm{BEC}, \mathrm{CED}$, DEA, which together are less than four right angles (B. VII., Pr. 18). Hence the sides AB, $\mathrm{BC}, \mathrm{CD}, \mathrm{DA}$, which are the measures of these

H 2
angles, are together less than four quadrants described with the radius AE ; that is, than the circumference of a great circle. Therefore the sum of the sides, etc.

## PROPOSITION V. THEOREM.

All the points in the circumference of a circle of the sphere are equally distant from each of its poles.

Let FGH be any circle of the sphere, and $A B$ any diameter of the sphere which is perpendicular to its plane; then, by the definition (4), A and B are the poles of the circle FGH.

Since $A B$ is perpendicular to the plane of the circle FGH, it passes through $K$, the centre of that circle (Pr. 1, Cor: 4). Hence, if we draw the oblique lines AF, AG, AH, these lines will be equally distant from the perpendicular $A K$, and are therefore equal to each other (B. VII., Pr. 5). Hence all the points of the circumference FGH are equally distant from the pole A. For a similar reason, they are equally distant from the pole B. Therefore all the points, etc.

Cor. 1. All the ares of great circles drawn from a pole of a circle to points in its circumference are equal. For the chords AF, $\mathrm{AG}, \mathrm{AH}$ are all equal, and therefore the arcs $\mathrm{AF}, \mathrm{AG}, \mathrm{AH}$ are equal.

Cor.2. The arc of a great circle $A D$, drawn from the pole to the circumference of another great circle CDE, is a quadrant, for this arc is the measure of the right angle AID.

Cor. 3. If the distance of the point A from each of the points C and D is equal to a quadrant, the point A will be the pole of the arc CD. For, since the arcs $\mathrm{AC}, \mathrm{AD}$ are quadrants, the angles AIC, AID are right angles; therefore the diameter AB is perpendicular to each of the lines CI, DI, and is consequently perpendicular to the plane of the arc CD (B.VII., Pr. 4) ; hence it is the pole of the arc CD.

Cor.4. To find the pole of an arc of a great circle, as CD , at each of the extremities $C$ and $D$ draw the arcs of great circles CA and DA perpendicular to CD; the point of intersection of these arcs will be the pole required.

Scholium. Arcs of circles may be drawn upon the surface of a
sphere with the same ease as upon a plane surface. Thus, by revolving the arc $A F$ around the pole $A$, the point $F$ will describe the small circle FGH; and by revolving the quadrant AC around the pole A , the extremity C will describe the great circle CDE .

If it is required to draw an arc of a great circle through two points $C$ and $D$ on the surface of the sphere, then, from the points C and D as centres, with a radius equal to a quadrant, describe two arcs intersecting in $\mathbf{A}$. The point $\mathbf{A}$ will be the pole of the great circle required; and if from $A$ as a centre, with a radius equal to a quadrant, we describe a circle CDE, it will be a great circle passing through C and D .

## PROPOSITION VI. THEOREM.

The shortest path from one point to another on the surface of a sphere is the smaller of the two arcs of a great circle, joining the two given points.

Let $A$ and $B$ be any two points on the surface of a sphere, and let ADB be the arc of a great circle which joins them; then will the line ADB be the shortest path from $A$ to $B$ on the surface of the sphere.

For, if possible, let the shortest path from A to B pass through $C$, a point situated out of the arc of a great circle $A D B$. Draw $A C, C B$, ares of great circles, and take BD equal to BC .

By Prop. 3, the are ADB is less than $\mathrm{AC}+\mathrm{CB}$. Sub-
 tracting the equal arcs BD and BC , there will remain AD less than AC. Now the shortest path from B to C, whether it be an arc of a circle or some other line, is equal to the shortest path from $B$ to $D$; for, by revolving $B C$ around $B$, the point $C$ may be made to coincide with $D$, and thus the shortest path from $B$ to C -must coincide with the shortest path from B to D . But the shortest path from $A$ to $B$ was supposed to pass through $C$; hence the shortest path from $A$ to $C$ can not be greater than the shortest path from A to D.

Now the arc $A D$ has been proved to be less than $A C$; and therefore, if $A C$ be revolved about $A$ until the point $C$ falls on the arc ADB , the point C will fall between D and B . Hence the shortest path from C to A must be greater than the shortest path from D to A ; but it has just been proved not to be greater, which is absurd. Consequently, no point of the shortest path from $A$ to $B$ can be out of the arc of a great circle $A D B$. Therefore the shortest path, etc

## PROPOSITION VII. THEOREM.

The angle formed by two arcs of great circles is equal to the angle formed by the tangents of those arcs at the point of their intersection, and is measured by the arc of a great circle described from. its vertex as a pole, and included between its sides.

Let BAD be an angle formed by two arcs of great circles; then will it be equal to the angle EAF formed by the tangents
 of these arcs at the point $A$; and it is measured by the arc DB described from the vertex A as a pole.

For the tangent AE, drawn in the plane of the arc $A B$, is perpendicular to the radius AC (B. III., Pr. 9) ; also, the tangent $A F$, drawn in the plane of the arc $A D$, is perpendicular to the same radius AC. Hence the angle EAF is equal to the angle of the planes ACB, ACD (B. VII., Def. 4), which is the same as that of the arcs $A B, A D$.

Also, if the $\operatorname{arcs} \mathrm{AB}, \mathrm{AD}$ are each equal to a quadrant, the lines $\mathrm{CB}, \mathrm{CD}$ will be perpendicular to AC , and the angle BCD will be equal to the angle of the planes $\mathrm{ACB}, \mathrm{ACD}$; hence the arc BD measures the angle of the planes, or the angle BAD.

Cor. 1. Angles of spherical triangles may be compared with each other by means of arcs of great circles described from their vertices as poles, and included between their sides; and thus an angle can easily be made equal to a given angle.

Cor. 2. If two arcs of great circles $\mathrm{AC}, \mathrm{DE}$ cut
 each other, the vertical angles $\mathrm{ABE}, \mathrm{DBC}$ are equal; for each is equal to the angle formed by the two planes ABC, DBE. Also, the two adjacent angles $\mathrm{ABD}, \mathrm{DBC}$ are together equal to two right angles.

## PROPOSITION VIII. THEOREM.

If from the vertices of a given spherical triangle, as poles, arcs of great circles are described, these arcs, by their intersection, form a second triangle, whose vertices are poles of the sides of the given triangle.

Let ABC be a spherical triangle; and from the points $\mathrm{A}, \mathrm{B}, \mathrm{C}$ as poles, let great circles be described intersecting each other in

D, E, and F ; then will the points D, E, and F be the poles of the sides of the triangle ABC.

For, because the point $A$ is the pole of the are EF , the distance from A to E is a quadrant. Also, because the point $C$ is the pole of the arc DE , the distance from C to E is a quadrant. Hence the point E is at a quadrant's distance
 from each of the points $\mathbf{A}$ and C ; it is therefore the pole of the arc AC (Pr. 5, Cor. 3). In the same manner; it may be proved that $D$ is the pole of the arc $B C$, and $F$ the pole of the arc $A B$.

Scholium. The triangle DEF is called the polar triangle of ABC ; and so, also, ABC is the polar triangle of DEF.

Since all great circles intersect each other in two points, the $\operatorname{arcs} \mathrm{DE}, \mathrm{EF}, \mathrm{DF}$, if produced, will form three other triangles; but the triangle which is taken as the polar triangle is the central one, whose vertex $D$, homologous to $A$, is on the same side of $B C$ as the vertex $A$; and so of the other vertices.

> PROPOSITION IX. THEOREM.

In two polar triangles, each angle of either triangle is measured by the supplement of the side lying opposite to it in the other triangle.

Let DEF be a spherical triangle, ABC its polar triangle, then will the side EF be the supplement of the are which measures the angle A, and the side BC is the supplement of the are which measures the angle D .

Produce the sides $\mathrm{AB}, \mathrm{AC}$, if necessary, until they meet EF in G and H. Then, because the
 point $A$ is the pole of the arc GH, the angle A is measured by the arc GH (Pr. 7).

Also, because E is the pole of the arc AH , the are EH is a quadrant; and because $F$ is the pole of $A G$, the arc $F G$ is a quadrant. Hence EH and GF, or EF and GH, are together equal to a semi-circumference. Therefore EF is the supplement of GH, which measures the angle A.

So, also, DF is the supplement of the arc which measures the angle $B$, and $D E$ is the supplement of the arc which measures the angle C. In the same manner, it can be shown that each angle of the triangle DEF is measured by the supplement of the side lying opposite to it in the triangle ABC . Therefore in two poiar triangles, etc.

## PROPOSITION X. THEOREM.

If two triangles on equal spheres are mutually equilateral, they are mutually equiangular.

Let ABC, DEF be two triangles on equal spheres, having the side AB equal to $\mathrm{DE}, \mathrm{AC}$ to DF , and BC to EF ; then will the angles also be equal each to each.

Let the centres of the spheres be $G$ and $H$, and draw the radii GA, GB, GC, HD, HE, HF. A solid angle may be conceived as formed at G by the three plane angles AGB, AGC, BGC ; and another solid angle at H by the three plane angles DHE, DHF, EHF. Then, because the arcs $\mathrm{AB}, \mathrm{DE}$ are equal, the angles $\mathrm{AGB}, \mathrm{DHE}$, which are measured by these arcs, are equal. For the same reason, the angles AGC, DHF are equal to each other; and, also, BGC equal to EHF. Hence $G$ and $H$ are two solid angles contained by three equal plane angles; therefore the planes of these equal angles are equally inclined to each other (B. VII., Pr. 19). That is, the angles of the triangle $A B C$ are equal to those of the triangle DEF, viz., the angle ABC to the angle DEF, BAC to EDF, and ACB to DFE.

Scholium. It should be observed that the two triangles ABC, DEF do not admit of superposition unless the three sides are similarly situated in both cases. Triangles which are mutually equilateral, but can not be applied to each other so as to coincide, are called symmetrical triangles.

## PROPOSITION XI. THEOREM.

If two triangles on equal spheres are mutually equiangular, they are mutually equilateral.

Denote by A and B two spherical triangles which are mutually equiangular, and by $P$ and $Q$ their polar triangles.

Since the sides of $P$ and $Q$ are the supplements of the arcs
which measure the angles of $A$ and $B$ (Pr. 9), $P$ and $Q$ must be mutually equilateral. Also, because $\mathbf{P}$ and $\mathbf{Q}$ are mutually equilateral, they must be mutually equiangular (Pr. 10). But the sides of $A$ and $B$ are the supplements of the ares which measure the angles of $P$ and $Q$, and, therefore, $A$ and $B$ are mutually equilateral.

## PROPOSITION XII. THEOREM.

If two triangles on equal spheres have two sides and the included angle of the one equal to two sides and the included angle of the other each to each, their third sides will be equal, and theirother angles will be equal each to each.

Let $\mathrm{ABC}, \mathrm{DEF}$ be two triangles having the side AB equal to $\mathrm{DE}, \mathrm{AC}$ equal to DF , and the angle BAC equal to the angle EDF ; then will the side BC be equal to EF , the angle ABC to DEF, and ACB to DFE. .

If the equal sides in the two triangles are similarly situated, the triangle ABC may be applied to the triangle DEF in the same manner as in plane triangles (B.I., Pr. 6), and the two triangles will coincide throughout. Therefore all the parts of the one triangle will be equal to the corresponding parts of the other triangle.

But if the equal sides in the two triangles are not similarly situated, then construct the triangle $\mathrm{DF}^{\prime} \mathrm{E}$ symmetrical with DFE, having $\mathrm{DF}^{\prime}$ equal to DF , and $\mathrm{EF}^{\prime}$
 equal to EF. The two triangles DEF', DEF, being mutually equilateral, are also mutually equiangular (Pr. 10).

Now the triangle ABC may be applied to the triangle $\mathrm{DEF}^{\prime \prime}$ so as to coincide throughout, and hence all the parts of the one triangle will be equal to the corresponding parts of the other triangle. Therefore the side BC , being equal to $\mathrm{EF}^{\prime}$, is also equal to EF ; the angle ABC , being equal to $\mathrm{DEF}^{\prime}$, is also equal to DEF ; and the angle ACB , being equal to $\mathrm{DF}^{\prime} \mathrm{E}$, is also equal to DFE. Therefore, if two triangles, etc.

## PROPOSITION XIII. THEOREM.

If two triangles on equal spheres have two angles and the included side of the one equal to two angles and the included side of the other each to each, their third angles will be equal, and their other sides will be equal each to each.

If the two triangles $\mathrm{ABC}, \mathrm{DEF}$ have the angle BAC equal to the angle EDF , the angle ABC equal to DEF , and the included side AB equal to DE , the triangle ABC can be placed upon the triangle DEF, or upon its symmetrical triangle $\mathrm{DEF}^{\prime}$, so as to coincide. Hence the remaining parts of the triangle ABC will be equal to the remaining parts of the triangle DEF ; that is, the side AC will be equal to $\mathrm{DF}, \mathrm{BC}$ to EF , and the angle ACB to the angle DFE. Therefore, if two triangles, etc.

## PROPOSITION XIV. THEOREM.

If two triangles on equal spheres are mutually equilateral, they are equivalent.

Let ABC, DEF be two triangles which have the three sides of the one equal to the three sides of the other each to each, viz., AB to $\mathrm{DE}, \mathrm{AC}$ to DF , and BC to EF ; then will the triangle ABC be equivalent to the triangle DEF.

Let $G$ be the pole of the small circle passing through the three points $\mathrm{A}, \mathrm{B}, \mathrm{C}$; draw the great circle ares $\mathrm{GA}, \mathrm{GB}, \mathrm{GC}$; these ares will be equal to each other (Pr.5). At the point E make the angle DEH equal to the angle $A B G$; make the arc EH equal to the are BG , and join DH, FH.

Because, in the triangles $A B G, D E H$, the sides $D E, E H$ are equal to the sides $\mathrm{AB}, \mathrm{BG}$, and the included angle DEH is equal to ABG , the are DH is equal to $A G$, and the angle DHE equal to AGB (Pr. 12).

Now, because the triangles ABC, DEF are mutually equilateral, they are mutually equiangular (Pr.10) ; hence the angle ABC is equal to the angle DEF. Subtracting the equal angles ABG, DEH, the remainder GBC will be equal to the remainder HEF.

Moreover, the sides $\mathrm{BG}, \mathrm{BC}$ are equal to the sides $\mathrm{EH}, \mathrm{EF}$; hence the arc HF is equal to the arc GC, and the angle EHF to the angle BGC (Pr. 13).

Now the triangle DEH may be applied to the triangle ABG so as to coincide. For, place DH upon its equal BG, and HE upon its equal AG, they will coincide, because the angle DHE is equal to the angle $A G B$; therefore the two triangles coincide throughout, and have equal surfaces.

For the same reason, the surface HEF is equal to the surface GBC, and the surface DFH to the surface ACG. Hence

$$
\begin{gathered}
\mathrm{ABG}+\mathrm{GBC}-\mathrm{ACG}=\mathrm{DEH}+\mathrm{EHF}-\mathrm{DFH} ; \\
\mathrm{ABC}=\mathrm{DEF} ;
\end{gathered}
$$

or,
that is, the two triangles $\mathrm{ABC}, \mathrm{DEF}$ are equivalent. Therefore, if two triangles, etc.

Scholium. The poles G and H might be situated within the triangles $\mathrm{ABC}, \mathrm{DEF}$, in which case it would be necessary to add the three triangles $A B G, G B C, A C G$ to form the triangle ABC , and also to add the three triangles DEH, EHF, DFH to form the triangle DEF, otherwise the demonstration would be the same as above.

Cor. If two triangles on equal spheres are mutually equiangular, they are equivalent. They are also equivalent if they have two sides and the included angle of the one equal to two sides and the included angle of the other each to each, or two angles and the included side of the one equal to two angles and the included side of the other.

PROPOSITION XV. THEOREM.
In an isosceles spherical triangle, the angles opposite the equal sides are equal; and, conversely, if two angles of a spherical triangle are equal, the triangle is isosceles.

Let ABC be a spherical triangle having the side AB equal to AC ; then will the angle ABC be equal to the angle ACB .

From the point $A$ draw the arc $A D$ to the middle of the base BC. Then, in the two triangles $\mathrm{ABD}, \mathrm{ACD}$, the side AB is equal to. $\mathrm{AC}, \mathrm{BD}$ is equal to DC , and the side AD is common; hence the angle ABD is equal to the angle ACD (Pr. 11).

Conversely. Let the angle B be equal to the angle C ; then will the side AC be equal to the side AB .

For if the two sides are not equal to each other, let AB be the greater; take BE equal to AC , and join EC.

Then, in the triangles $\mathrm{EBC}, \mathrm{ACB}$, the two sides $\mathrm{BE}, \mathrm{BC}$ are equal to the two sides $\mathrm{CA}, \mathrm{CB}$, and the included angles EBC, ACB are equal; hence the angle ECB is equal to the angle ABC (Pr. 13). But, by hypothesis, the angle ABC is equal to ACB ; hence ECB is equal to ACB , which is absurd. Therefore AB is not greater than $A C$; and, in the same manner, it can be proved that it is not less; it is, consequently, equal to AC. Therefore, in an isosceles spherical triangle, etc.

Cor. The angle BAD is equal to the angle CAD, and the angle ADB to the angle ADC ; therefore each of the last two angles is a right angle. Hence the arc drawn from the vertex of an isosceles spherical triangle to the middle of the base is perpendicular to the base, and also bisects the vertical angle.

## PROPOSITION XVI. THEOREM.

In a spherical triangle, the greater side is opposite the greater angle, and conversely.

Let ABC be a spherical triangle having the angle $A$ greater than the angle $B$; then will the side BC be greater than the side AC.

Draw the arc AD, making the angle BAD equal to $B$. Then, in the triangle $A B D$, we shall have AD equal to $\mathrm{DB}(\operatorname{Pr} .15)$; that is, $B C$ is equal to the sum of $A D$ and $D C$. But $A D$ and $D C$ are together greater than AC (Pr. 2) ; hence BC is greater than AC .

Conversely. If the side BC is greater than AC , then will the angle $A$ be greater than the angle $B$.

For if the angle $A$ is not greater than $B$, it must be equal to it, or less. It is not equal; for then the side BC would be equal to $\mathrm{AC}(\mathrm{Pr} .15)$, which is contrary to the hypothesis. Neither can it be less, for then the side BC would be less than AC by the first case, which is also contrary to the hypothesis. Hence the angle BAC is greater than the angle ABC. Therefore, in a spherical triangle, etc.

## PROPOSITION XVII. THEOREM.

The sum of the angles of a spherical triangle is greater than twoo, and less than six right angles.

Let $\mathrm{A}, \mathrm{B}$, and C be the angles of a spherical triangle. The arcs which measure the angles $A, B$, and $C$, together with the three sides of the polar triangle, are equal to three semi-circumferences (Pr.9). But the three sides of the polar triangle are less than two semi-circumferences (Pr.4); hence the arcs which measure the angles $\mathrm{A}, \mathrm{B}$, and C are greater than one semi-circumference, and, therefore, the angles $A, B$, and $C$ are greater than two right angles.

Also, because each angle of a spherical triangle is less than two right angles, the sum of the three angles must be less than six right angles.

Cor. A spherical triangle may have two, or even three right angles; also two, or even three obtuse angles.

If a triangle have three right angles, each of its sides will be a quadrant, and the triangle is called a tri-rectangular triangle. The tri-rectangular triangle is contained eight times in the surface of the sphere.*

[^6]
## PROPOSITION XVIII. THEOREM.

The area of a lune is to the surface of the sphere as the angle of the lune is to four right angles.

Let ADBE be a lune, upon a sphere whose centre is C , and the diameter AB ; then will the area of the lune be to the surface of the sphere as the angle DCE to four right angles, or as the arc DE to the circumference of a great circle.

First. When the ratio of the arc to the circumference can be expressed in whole numbers.
Suppose the ratio of DE to DEFG to be as 4 to 25 . Now, if if we divide the circumference DEFG in 25 equal parts, DE will contain 4 of those parts. If we join the pole $A$ and the several points of division by arcs of great circles, there will be formed on the hemisphere ADEFG 25 triangles, all equal to each other, being mutually equilateral. The entire sphere will contain 50 of these small triangles, and the lune ADBE 8 of them. Hence the area of the lune is to the surface of the sphere as 8 to 50 , or as 4 to 25 ; that is, as the arc DE to the circumference.

Secondly. When the ratio of the arc to the circumference can not be expressed in whole numbers, it may be proved, as in $\mathbf{B}$. III., Pr. 14, that the lune is still to the surface of the sphere as the angle of the lune to four right angles.

Cor. 1. On equal spheres, two lunes are to each other as the angles included between their planes.

Cor.2. We have seen that the entire surface of the sphere is equal to eight tri-rectangular triangles (Pr: 17, Cor.). If the area of the tri-rectangular triangle be represented by $T$, the surface of the sphere will be represented by $8^{\prime} \mathrm{T}$. Also, if we take the right angle for unity, and represent the angle of the lune by $A$, we shall have the proportion, area of the lune $: 8 \mathrm{~T}:: \mathrm{A}: 4$.
Hence the area of the lune is equal to $\frac{8 \mathrm{~A} \times \mathrm{T}}{4}$, or $2 \mathrm{~A} \times \mathrm{T}$.
Cor. 3. The spherical ungula, comprehended by the planes $\mathrm{ADB}, \mathrm{AEB}$, is to the entire sphere as the angle DCE is to four right angles. For, the lunes being equal, the spherical ungulas will also be equal; hence, in equal spheres, two ungulas are to each other as the angles included between their planes.

## PROPOSITION XIX. THEOREM.

If twoo great circles intersect each other on the surface of a hemisphere, the sum of the opposite triangles thus formed is equivalent to a lune whose angle is equal to the inclination of the two circles.

Let the great circles ABC, DBE intersect each other on the surface of the hemisphere BADCE; then will the sum of the opposite triangles $\mathrm{ABD}, \mathrm{CBE}$ be equivalent to a lune whose angle is CBE.

For, produce the $\operatorname{arcs} \mathrm{BC}, \mathrm{BE}$ till they meet in F ; then will BCF be a semi-circumference, as also ABC. Subtracting
 BC from each, we shall have CF equal to AB . For the same reason, EF is equal to DB , and CE is equal to AD . Hence the two triangles $\mathrm{ABD}, \mathrm{CFE}$ are mutually equilateral; they are, therefore, equivalent (Pr. 15).

But the two triangles $\mathrm{CBE}, \mathrm{CFE}$ compose the lune BCFE, whose angle is CBE; hence the sum of the triangles $\mathrm{ABD}, \mathrm{CBE}$ is equivalent to the lune whose angle is CBE. Therefore, if two great circles, etc.

## PROPOSITION XX. THEOREM.

The area of a spherical triangle is measured by the excess of the sum of its angles above two right angles multiplied by the tri-rectangular triangle.

Let ABC be any spherical triangle; its surface is measured by the sum of its angles $A, B$, C diminished by two right angles, and multiplied by the tri-rectangular triangle.

Produce the sides of the triangle ABC until they meet the great circle DEG drawn without the triangle. The two triangles ADE, AGH
 are together equal to the lune whose angle is $\mathrm{A}(\mathrm{Pr} .19)$; and this lune is measured by $2 \mathrm{~A} \times \mathrm{T}$ (Pr. 18, Cor. 2). Hence we have

$$
\mathrm{ADE}+\mathrm{AGH}=2 \mathrm{~A} \times \mathrm{T}
$$

For the same reason, $\mathrm{BFG}+\mathrm{BDI}=2 \mathrm{~B} \times \mathrm{T}$; also, $\quad \mathrm{CHI}+\mathrm{CEF}=2 \mathrm{C} \times \mathrm{T}$.

But the sum of these six triangles exceeds the surface of the hemisphere by twice the triangle ABC , and the hemisphere is represented by 4 T ; hence we have

$$
4 \mathrm{~T}+2 \mathrm{ABC}=2 \mathrm{~A} \times \mathrm{T}+2 \mathrm{~B} \times \mathrm{T}+2 \mathrm{C} \times \mathrm{T} ;
$$

or, dividing by 2 , and then subtracting 2 T from each of these equals, we have

$$
\begin{gathered}
\mathrm{ABC}=\mathrm{A} \times \mathrm{T}+\mathrm{B} \times \mathrm{T}+\mathrm{C} \times \mathrm{T}-2 \mathrm{~T}, \\
\mathrm{ABC}=(\mathrm{A}+\mathrm{B}+\mathrm{C}-2) \times \mathrm{T} .
\end{gathered}
$$

or
Hence every spherical triangle is measured by the sum of its angles diminished by two right angles, and multiplied by the trirectangular triangle.

Cor. If the sum of the three angles of a triangle is equal to three right angles, its surface will be equal to the tri-rectangular triangle; if the sum is equal to four right angles, the surface of the triangle will be equal to two tri-rectangular triangles; if the sum is equal to five right angles, the surface will be equal to three tri-rectangular triangles, etc.

## PROPOSITION XXI. THEOREM.

The area of a spherical polygon is measured by the sum of its angles, diminished by as many times two right angles as it has sides less two, multiplied by the tri-rectangular triangle.

Let ABCDE be any spherical polygon. From the vertex $B$ draw the arcs $B D, B E$ to the opposite angles; the polygon will be divided into as many triangles as it has sides minus two.

- But the surface of each triangle is measured by the sum of its angles minus two right angles, multiplied by the tri-rectangular triangle. Also, the sum of all the angles of the triangles is equal to the sum of all the angles of the polygon; hence the surface of the polygon is measured by the sum of its angles, diminished by as many times two right angles as it has sides less two, multiplied by the tri-rectangular triangle.

Cor. If the polygon has five sides, and the sum of its angles is equal to seven right angles, its surface will be equal to the trirectangular triangle; if the sum is equal to eight right angles, its surface will be equal to two tri-rectangular triangles; if the sum is equal to nine right angles, the surface will be equal to three tri-rectangular triangles, etc.

## BOOK X.

## MEASUREMENT OF THE THREE ROUND BODIES.

## Definitions.

1. A cylinder is a solid described by the revolution of a rectangle about one of its sides, which remains fixed. The bases of the cylinder are the circles described by the two revolving opposite sides of the rectangle.
2. The axis of a cylinder is the fixed straight line about which the rectangle revolves. The opposite side of the rectangle describes the lateral or convex
 surface.
3. A cone is a solid described by the revolution of a right-angled triangle about one of the sides containing the right angle, which side remains fixed. The base of the cone is the circle described by that side containing the right angle which revolves.
4. The axis of a cone is the fixed straight line about which the triangle revolves. The hypothe-
 nuse of the triangle describes the lateral or convex surface. The side of the cone is the distance from the vertex to the circumference of the base.
5. A frustum of a cone is the part of a cone next the base, cut off by a plane parallel to the base.
6. Similar cones and cylinders are those which have their axes and the diameters of their bases proportionals.

## PROPOSITION I. THEOREM.

The convex surface of a cylinder is equal to the product of its altitude by the circumference of its base.

Let ACE-G be a cylinder whose base is the circle ACE, and altitude AG; then will its convex surface be equal to the product of $A G$ by the circumference $A C E$.

In the circle $A C E$ inscribe the regular polygon $A B C D E F$, and upon this polygon let a right prism be constructed of the same altitude with the cylinder.

The edges $A G, B H, C K$, etc., of the prism, being perpendicular to the plane of the base, will be contained in the convex surface of the cylinder. The convex surface of this prism is equal to the product of its altitude by the perimeter of its base (B. VIII., Pr. 1).

Let, now, the arcs subtended by the sides $A B$, $B C$, ctc., be bisected, and the number of sides of the polygon be indefinitely increased, its perimeter will approach the circumference of the circle; and when the number of sides of the polygon becomes - greater than any finite number, its perimeter will become equal to the circumference of the circle (B.VI., Pr. 10), and the convex surface of the prism will become equal to the convex surface of the cylinder.

But, whatever be the number of sides of the prism, its convex surface is equal to the product of its altitude by the perimeter of its base; hence the convex surface of the cylinder is equal to the product of its altitude by the circumference of its base.

Cor. If $H$ represent the altitude of a cylinder, and $R$ the radius of its base, the circumference of the base will be represented by $2 \pi$ R (B. VI., Pr. 13, Cor. 2), and the convex surface of the cylinder by $2 \pi$ RH.

## PROPOSITION II. THEOREM.

The volume of a cylinder is equal to the product of its base by its altitude.

Let ACE-G be a cylinder whose base is the circle ACE, and altitude AG; its volume is equal to the product of its base by its altitude.

In the circle $A C E$ inscribe the regular polygon ABCDEF , and upon this polygon let a right prism be constructed of the same altitude with the cylinder. The volume of this prism is equal to the product of its base by its altitude (B. VIII., Pr. 11).

Let, now, the number of sides of the polygon be indefinitely increased; its area will become equal to that of the circle, and the volume of the prism becomes equal to that of the cylinder. But, whatever be the number of sides of the prism, its volume is equal to the product of its. base by its altitude;
hence the volume of a cylinder is equal to the product of its base by its altitude.

Cor. 1. If H represent the altitude of a cylinder, and $R$ the radius of its base, the area of the base will be represented by $\pi \mathrm{R}^{2}$ (B. VI., Pr. 13, Cor. 3), and the volume of the cylinder will be $\pi \mathrm{R}^{2} \mathrm{H}$.

Cor: 2. Cylinders of the same altitude are to each other as their bases, and cylinders of the same base are to each other as their altitudes.

Cor.3. Similar cylinders are to each other as the cubes of their altitudes, or as the cubes of the diameters of their bases.

For the bases are as the squares of their diameters; and, since the cylinders are similar, the diameters of their bases are as their altitudes (Def. 6). Therefore the bases are as the squares of the altitudes, and hence the products of the bases by the altitudes, or the cylinders themselves, will be as the cubes of the altitudes.

## PROPOSITION III. THEOREM.

The convex surface of a cone is equal to the product of half its side by the circumference of its base.

Let $\mathrm{A}-\mathrm{BCDEFG}$ be a cone whose base is the circle $B D E G$, and its side $A B$; then will its convex surface be equal to the product of half its side by the circumference of the circle BDF .

In the circle BDF inscribe the regular polygon BCDEFG , and upon this polygon let a regular pyramid be constructed having A for its vertex. The edges of this pyramid will lie in the convex surface of the cone. From $A$ draw
 AH perpendicular to CD , one of the sides of the polygon. The convex surface of the pyramid is equal to the product of half the slant height AH by the perimeter of its base (B. VIII., Pr. 14).

Let, now, the arcs subtended by the sides BC, CD, etc., be bisected, and the number of sides of the polygon be indefinitely increased, its perimeter will become equal to the circumference of the circle, the slant height AH becomes equal to the side of the cone $A B$, and the convex surface of the pyramid becomes equal to the convex surface of the cone.

But, whatever be the number of faces of the pyramid, its convex surface is equal to the product of half its slant height by the perimeter of its base; hence the convex surface of the cone is
equal to the product of half its side by the circumference of its base.

Cor. If S represent the side of a cone, and R the radius of its base, then the circumference of the base will be represented by $2 \pi \mathrm{R}$, and the convex surface of the cone by $2 \pi \mathrm{R} \times \frac{1}{2} \mathrm{~S}$, or $\pi \mathrm{RS}$.

## PROPOSITION IV. THEOREM.

The convex surface of a frustum of a cone is equal to the product of its side by half the sum of the circumferences of its two bases.

Let BDF-bdf be a frustum of a cone whose bases are $\mathrm{BDF}, b d f$, and $\mathrm{B} b$ its side; its convex surface is equal to the product of $\mathrm{B} b$ by half the sum of the circumferences $\mathrm{BDF}, b d f$.

Complete the cone $\mathrm{A}-\mathrm{BDF}$ to which the frustum belongs, and in the circle BDF inscribe the regular polygon BCDEFG, and upon this polygon let a regular pyramid be constructed having $\mathbf{A}$ for its vertex. Then will BDF-bdff be a frustum of a regular pyramid, whose convex surface is equal to the product of its slant height by half the sum of the perimeters of its two bases (B. VIII., Pr. 14, Cor. 1).
Let, now, the number of sides of the polygon be indefinitely increased, its perimeter will become equal to the circumference of the circle, and the convex surface of the pyramid will become equal to the convex surface of the cone. But, whatever be the number of faces of the pyramid, the convex surface of its frustum is equal to the product of its slant height by half the sum of the perimeters of its two bases. Hence the convex surface of a frustum of a cone is equal to the product of its side by half the sum of the circumferences of its two bases.

Cor. It was proved (B. VIII., Pr. 14, Cor. 2) that the convex surface of a frustum of a pyramid is equal to the product of its slant height by the perimeter of a section at equal distances between its two bases; hence the convex surface of a frustum of a cone is equal to the product of its side by the circumference of a section at equal distances between the two bases.

## PROPOSITION V. THEOREM.

The volume of a cone is equal to one third of the product of its base by its altitude.

Let $\mathrm{A}-\mathrm{BCDF}$ be a cone whose base is the circle BCDEFG, and AH its altitude; the volume of the cone will be equal to one third of the product of the base BCDF by the altitude AH.

In the circle BDF inscribe a regular polygon BCDEFG, and construct a pyramid whose base is the polygon BDF, and having its vertex in A. The volume of this pyramid is equal to one third of the product of the polygon BCDEFG by its
 altitude AH (B. VIII., Pr. 17).

Let, now, the number of sides of the polygon be indefinitely increased; its area will become equal to the area of the circle, and the volume of the pyramid will become equal to the volume of the cone. But, whatever be the number of faces of the pyramid, its volume is equal to one third of the product of its base by its altitude; hence the volume of the cone is equal to one third of the product of its base by its altitude.

Cor. 1. Since a cone is one third of a cylinder having the same base and altitude, it follows that cones of equal altitudes are to each other as their bases; cones of equal bases are to each other as their altitudes; and similar cones are as the cubes of their altitudes, or as the cubes of the diameters of their bases.

Cor: 2. If H represent the altitude of a cone, and R the radius of its base, the volume of the cone will be represented by $\pi R^{2} \times$ $\frac{1}{3} \mathrm{H}$, or $\frac{1}{3} \pi \mathrm{R}^{2} \mathrm{H}$.

## PROPOSITION VI. THEOREM.

A frustum of a cone is equivalent to the sum of three cones having the same altitude with the frustum, and whose bases are the lower base of the frustum, its upper base, and a mean proportional between them.
Let $\mathrm{BDF}-b d f$ be any frustum of a cone. Complete the cone to which the frustum belongs, and in the circle BDF inscribe the regular polygon.BCDEFG, and upon this polygon let a regular pyramid be constructed having its vertex in A .

Then will BCDEFG-beclefg be a frustum of a regular pyramid whose volume is equal to three pyramids having the same alti-

tude with the frustum, and whose bases are the lower base of the frustum, its upper base, and a mean proportional between them (B. VIII., Pr. 18).

Let, now, the number of sides of the polygon be indefinitely increased, its area will become equal to the area of the circle, and the frustum of the pyramid will become the frustum of a cone. Hence the frustum of a cone is equivalent to the sum of three cones having the same altitude with the frustum, and whose bases are the lower base of the frustum, its upper base, and a mean proportional between them.

Proposition vir. theoren.
The surface of a sphere is equal to the product of its diameter by the circumference of a great circle.

Let ABDF be the semicircle by the revolution of which the sphere is described. Inscribe in the semicircle a regular semi-polygon ABCDEF, and from the points $\mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}$ let fall the perpendienlars BG, CII, DK, EL upon the diameter AF.
If, now, the polygon be revolved about $A F$, the lines $\mathrm{AB}, \mathrm{EF}$ will describe the convex surface of two cones, and $\mathrm{BC}, \mathrm{CD}, \mathrm{DE}$ will describe the convex surface of frustums of cones.

From the centre I draw LM perpendicular to BC; also draw MN perpendicular to AF, and BO
perpendicular to CII. Let circ. MN represent the circumference of the circle described by the revolution of MN. Then the surface described by the revolution of BC will be equal to BC multiplied by circ. MN (Pr. 4, Cor.).

Now the triangles IMN, BCO are similar, since their sides are perpendicular to each other (B.IV., Pr. 22); whence

$$
\begin{aligned}
\mathrm{BC}: \mathrm{BO} \text { or } \mathrm{GH} & :: \mathrm{IM}: M \mathrm{MN}, \\
& :: \text { circ. IM:circ. MN. }
\end{aligned}
$$

Hence (B. II., Pr. 1)

$$
\mathrm{BC} \times \text { circ. } \mathrm{MN}=\mathrm{GH} \times \text { circ. } \mathrm{IM} .
$$

Therefore the surface described by BC is equal to the altitude GH multiplied by circ. IM, or the circumference of the inscribed circle.

In like manner, it may be proved that the surface described by CD is equal to the altitude IIK multiplied by the circumference of the inscribed circle; and the same may be proved of the other sides. Hence the entire surface described by ABCDEF is equal to the circumference of the inscribed circle multiplied by the sum of the altitudes AG, GH, HK, KL, and LF ; that is, the axis of the polygon.
Let, now, the arcs $\mathrm{AB}, \mathrm{BC}$, etc., be bisected, and the number of sides of the polygon be indefinitely increased, its perimeter will coincide with the circumference of the semicircle, and the perpendicular IM will become equal to the radius of the sphere; that is, the circumference of the inscribed circle will become the circumference of a great circle. Hence the surface of a sphere is equal to the product of its diameter by the circumference of a great circle.

Cor. 1. The area of a zone is equal to the product of its altitude by the circumference of a great circle.
For the surface described by the lines $\mathrm{BC}, \mathrm{CD}$ is equal to the altitude GK multiplied by the circumference of the inscribed circle. But when the number of sides of the polygon is indefinitely increased, the perimeter $\mathrm{BC}+\mathrm{CD}$ becomes the are BCD , and the inscribed circle becomes a great circle. Hence the area of the zone produced by the revolution of BCD is equal to the product of its altitude GK by the circumference of a great circle.

Cor. 2. The area of a great circle is equal to the product of its circumference by half the radius (B. VI., Pr. 12), or one fourth of the diameter; hence the surface of a sphere is equivalent to four of its great circles.

Cor. 3. The surface of a sphere is equal to the convex surface of the circumscribed cylinder.
For the latter is equal to the product of its altitude by the circumference of its base. But its base is equal to a great circle of the sphere, and its altitude to the diameter; hence the convex surface of the cylinder is equal to the product of its diameter by the circumference of a great circle, which is also the measure of the surface of a sphere.

Cor. 4. Two zones upon equal spheres are to each other as their altitudes, and any zone is to the surface of its sphere as the altitude of the zone is to the diameter of the sphere.

Cor: 5. Let R denote the radius of a sphere, D its diameter, C
the circumference of a great circle, and $S$ the surface of a sphere; then we shall have

$$
\begin{gathered}
\mathrm{C}=2 \pi \mathrm{R}, \text { or } \pi \mathrm{D}(\mathrm{~B} . \mathrm{VI} ., \operatorname{Pr} .13, \mathrm{Cor} .2) . \\
\mathrm{S}=2 \pi \mathrm{R} \times 2 \mathrm{R}=4 \pi \mathrm{R}^{2}, \text { or } \pi \mathrm{D}^{2} .
\end{gathered}
$$

Also
If H represents the altitude of a zone, its area will be $2 \pi \mathrm{RH}$.

## PROPOSITION VIII. THEOREM.

The volume of a sphere is equal to one third the product of its surface by the radius.

Let ACEG be the semicircle by the revolution of which the sphere is described. Inscribe in the semicircle a regular semi-polygon ABCDEFG, and draw the radii $\mathrm{BO}, \mathrm{CO}, \mathrm{DO}$, etc.

The solid described by the revolution of the polygon ABCDEFG about AG is composed of the solids formed by the revolution of the triangles $\mathrm{ABO}, \mathrm{BCO}, \mathrm{CDO}$, etc., about AG.

First. To find the value of the solid formed by the revolution of the triangle ABO.

From O draw OH perpendicular to AB , and from $B$ draw $B K$ perpendicular to $A O$. The two triangles ABK, BKO, in their revolution about AO, will describe two cones having a common base, viz., the circle whose radius is BK.

The solid described by the triangle ABO will then be represented by $\frac{1}{3} \pi \mathrm{R}^{2} \mathrm{H}$, or $\frac{1}{3} \pi \mathrm{BK}^{2} \times \mathrm{AO}$ (Prop. 5, Cor. 2).
But, by similar triangles,

$$
\begin{aligned}
& \mathrm{BK}: \mathrm{BA}:: \mathrm{HO}: \mathrm{AO} \\
& \mathrm{BK} \times \mathrm{AO}=\mathrm{HO} \times \mathrm{AB}
\end{aligned}
$$

therefore
or, multiplying by $\frac{\pi}{3} \mathrm{BK}$, we have

$$
\frac{1}{3} \pi \mathrm{BK}^{2} \times \mathrm{AO}=\frac{1}{3} \mathrm{HO} \times \pi \mathrm{AB} \times \mathrm{BK} .
$$

But the surface described by $\mathrm{AB}=\pi \mathrm{AB} \times \mathrm{BK}$ (Prop. 3, Cor:.).
Hence the solid described by the triangle $A B O$ is equal to $\frac{1}{3} \mathrm{HO} \times$ the surface described by AB .

Secondly. To find the value of the solid formed by the revolution of the triangle BCO.

Produce BC until it meets AG produced in L. It is evident, from the preceding demonstration, that the solid described by the triangle LCO is equal to
$\frac{1}{3} \mathrm{OM} \times$ surface described by LC;
and the solid described by the triangle LBO is equal to
$\frac{1}{3} \mathrm{OM} \times$ surface described by LB;
hence the solid described by the triangle BCO is equal to
$\frac{1}{3} \mathrm{OM} \times$ surface described by BC.
In the same manner, it may be proved that the solid described by the triangle CDO is equal to $\frac{1}{3} \mathrm{ON} \times$ surface described by CD , and so on for the other triangles. But the perpendiculars $\mathrm{OH}, \mathrm{OM}, \mathrm{ON}$, etc., are all equal; hence the solid described by the polygon ABC DEFG is equal to the surface described by the
 perimeter of the polygon multiplied by $\frac{1}{3} \mathrm{OH}$.

Let, now, the number of sides of the polygon be indefinitely increased, the perpendicular OH will become the radius OA , the perimeter ACEG will become the semi-circumference ADG, and the solid described by the polygon becomes a sphere; hence the volume of a sphere is equal to one third of the product of its surface by the radius.

Cor. 1. The volume of a spherical sector is equal to the proctuct of the zone which forms its base by one third of the radius of the sphere.

For the solid described by the revolution of BCDO is equal to the surface described by $\mathrm{BC}+\mathrm{CD}$ multiplied by $\frac{1}{3} \mathrm{OM}$.

But when the number of sides of the polygon is indefinitely increased, the perpendicular OM becomes the radius OB, the quadrilateral BCDO becomes the sector BDO , and the solid described by the revolution of BCDO becomes a spherical sector. Hence the volume of a spherical sector is equal to the product of the zone which forms its base by one third of the radius of the sphere.

Cor. 2. Let R represent the radius of a sphere, D its diameter, $S$ its surface, and Vits volume ; then we shall have

$$
\begin{gathered}
\mathrm{S}=4 \pi \mathrm{R}^{2}, \text { or } \pi \mathrm{D}^{2}(\text { Pr. } 7, \text { Cor. } 5) . \\
\mathrm{V}=\frac{1}{3} R \times S=\frac{4}{3} \pi \mathrm{R}^{3}, \text { or } \frac{1}{6} \pi \mathrm{D}^{3} ;
\end{gathered}
$$

Also
hence the volumes of spheres are to each other as the cubes of their radii.

If we put H to represent the altitude of the zone which forms the base of a sector, then the volume of the sector will be represented by $\quad 2 \pi \mathrm{RH} \times \frac{1}{3} \mathrm{R}=\frac{2}{3} \pi \mathrm{R}^{2} \mathrm{H}$.

Cor. 3. Every sphere is two thirds of the circumscribed cylinder:

For, since the base of the circumscribed cylinder is equal to a great circle, and its altitude to a diameter, the volume of the cylinder is equal to a great circle multiplied by the diameter (Pr. 2).

But the volume of a sphere is equal to four great circles multiplied by one third of the radius, or one great circle multiplied by $\frac{4}{3}$ of the radius, or $\frac{2}{3}$ of the diameter. Hence a sphere is two thirds of the circumscribed cylinder.

## PROPOSITION IX. TIIEOREM.

A spherical segment with one base is equivalent to half of a cylinder having the same base and altitudle, plus a sphere whose diameter is the altitude of the segment.

Let BD be the radius of the base of the segment, AD its altitude, and let the segment be generated by the revolution of the circular half segment AEBD about the axis AC. Join CB, and from the centre C draw CF perpendicular to AB .

The solid generated by the revolution of the segment AEB is equal to the difference of the solids generated by the sector ACBE and the triangle ACB . Now the solid generated by the sector ACBE is equal to

$$
\frac{2}{3} \pi \mathrm{CB}^{2} \times \mathrm{AD}(\mathrm{Pr} .8, \mathrm{Cor} .2)
$$

And the solid generated by the triangle ACB , by Pr. 8 , is equal to $\frac{1}{3} \mathrm{CF}$ multiplied by the convex surface described by AB , which is $2 \pi \mathrm{CF} \times \mathrm{AD}$ (Pr. 7), making, for the solid generated by the triangle $\mathrm{ACB}, \quad \frac{2}{3} \pi \mathrm{CF}^{2} \times \mathrm{AD}$.
Therefore the solid generated by the segment AEB is equal to

$$
\frac{2}{3} \pi \mathrm{AD} \times\left(\mathrm{CB}^{2}-\mathrm{CF}^{2}\right),
$$

or
that is, $\frac{2}{3} \pi \mathrm{AD} \times \mathrm{BF}^{2}$; $\frac{1}{6} \pi \mathrm{AD} \times \mathrm{AB}^{2}$,
because $\mathrm{CB}^{2}-\mathrm{CF}^{2}$ is equal to $\mathrm{BF}^{2}$, and $\mathrm{BF}^{2}$ is equal to one fourth of $\mathrm{AB}^{2}$.

Now the cone generated by the triangle ABD is equal to

$$
\frac{1}{3} \pi \mathrm{AD} \times \mathrm{BD}^{2} \text { (Pr. 5, Cor. 2) }
$$

Therefore the spherical segment in question, which is the sum of the solids described by AEB and ABD , is equal to

$$
\begin{aligned}
& \frac{1}{6} \pi \mathrm{AD}\left(2 \mathrm{BD}^{2}+\mathrm{AB}^{2}\right) ; \\
& \frac{1}{6} \pi \mathrm{AD}\left(3 \mathrm{BD}^{2}+\mathrm{AD}^{2}\right),
\end{aligned}
$$

that is,
because $A B^{2}$ is equal to $\mathrm{BD}^{2}+\mathrm{AD}^{2}$.
This expression may be separated into the two parts

$$
\frac{1}{2} \pi \mathrm{AD} \times \mathrm{BD}^{2}, \text { and } \frac{1}{6} \pi \mathrm{AD}^{3} .
$$

The first part represents the volume of a cylinder having the same base with the segment and half its altitude (Pr.2); the other part represents a sphere, of which AD is the diameter (Pr. 8, Cor. 2). Therefore a spherical segment, etc.

Cor. The volume of the spherical segment of two bases generated by the revolution of BCED about the axis AE may be found by subtracting that of the segment of one base generated by ABD from that of the segment of one base generated by ACE.

## EXERCISES ON THE PRECEDING PRINCIPLES.

1. What is the entire surface of a triangular prism whose base is an equilateral triangle, having each of its sides equal to 17 inches, and its altitude 5 feet?
2. What is the entire surface of a regular triangular pyramid whose slant height is 15 feet, and each side of the base 4 feet?
3. What is the convex surface of the frustum of a square pyramid whose slant height is 14 feet, each side of the lower base being $3 \frac{1}{2}$ feet, and each side of the upper base $2 \frac{1}{2}$ feet?
4. What is the volume of a triangular prism whose height is 12 feet, and the three sides of its base 4,5 , and 6 feet?
5. What is the volume of a triangular pyramid whose altitude is 25 feet, and each side of the base 4 feet?
6. What is the volume of a piece of timber whose bases are squares, each side of the lower base being 14 inches, and each side of the upper base 12 inches, the altitude being 25 feet? 2
7. What is the entire surface of a cylinder whose altitude is 17 feet, and the diameter of its base 3 feet?
8. What is the entire surface of a cone whose side is 24 feet, and the diameter of its base 5 feet?
9. What is the entire surface of a frustum of a cone whose side is 18 feet, and the radii of the bases 5 feet and 4 feet?
10. 
11. What is the volume of a cylinder whose altitude is 16 feet, and the circumference of its base 5 feet?
12. What is the volume of a cone whose altitude is 13 feet, and the circumference of its base 7 feet?
13. What is the volume of a frustum of a cone whose altitude is 22 feet, the circumference of its lower base 18 feet, and that of the upper base 14 feet?
14. What is the surface of a sphere, the circumference of its great circle being 40 feet?
15. What is the area of the surface of the earth, supposing it to be a sphere whose diameter is 7912 miles?
16. What is the convex surface of a zone whose altitude is 13 inches, upon a sphere whose diameter is 40 inches?
17. What is the volume of a sphere whose diameter is 17 inches? 25
18. What is the volume of the earth, supposing it to be a sphere whose diameter is 7912 miles?
19. What is the volume of a spherical segment with one base, the diameter of the sphere being 12 feet, and the altitude of the segment 3 feet?
20. What is the surface of a regular tetraedron whose edge is 7 feet?
21. What is the volume of a regular tetraedron whose edge is 9 feet?
22. What is the edge of a regular tetracdron whose volume is 20 cubic feet?
23. The base of a rectangular parallelopiped is 3.42 feet by 4.36 feet, and its volume is 100 cubic feet; what is its altitude?
24. The volume of a parallelopiped is 366.4 cubic feet, and its altitude is 23.4 feet; what is the area of its base?

24 . The sides of the base of a tetraedron are 13,15 , and 17 feet, and its altitude is 11 feet; required its volume.
25. What is the volume of a frustum of a regular triangular pyramid having a side of one base equal to 4 feet, and a side of the other base 3 feet, and the lateral edge equal to $3 \frac{1}{2}$ feet? $/ 8.43$
26. The volume of a sphere is 1870 cubic feet; required its radius.

27 . The edge of a cube is 30 inches; required the volume of the circumscribing sphere.
28. The side of a right cone is 22 feet, and its altitude 15 feet; required its lateral surface.
29. A stone obelisk has the form of a regular quadrangular pyramid, having a side of its base equal to 4 feet, and its slant height 13 feet. The density of the stone is 2.5 times that of water; what is its weight, assuming that a cubic foot of water weighs $62 \frac{1}{2}$ pounds.
30. Supposing the earth to be a sphere, and that a quadrant is equal to $32,800,000$ feet, it is required to determine the radius of the earth, the area of its surface, its volume, and its weight, the mean density of the earth being 4.5 times that of water.

## CONIC SECTIONS.

There are three curves whose properties are extensively ap plied in Astronomy and many other branches of Natural Philosophy, which, being the sections of a cone made by a plane in different positions, are called the Conic Sections. These are

> The Parabola,
> The Ellipse, and
> The Hyperbola.

## P A R A B OLA.

## Definitions.

1. A parabola is a plane curve, ever'y point of which is equally distant from a given fixed point and a given straight line.
2. The fixed point is called the focus of the parabola, and the given straight line is called the directrix.

Thus, if a straight line BC, and a point without it, $F$, be given in position in a plane, and the point $A$ be supposed to move in such a manner that AF, its distance from the given point, is always equal to AD , its perpendicular distance from the given line, the point A will describe a curve called a parabola.
3. Any straight line perpendicular to the directrix, terminated at one extremity by the parabola, and produced indefinitely within the curve, is called a diameter.

The vertex of a diameter is the point in which it meets the parabola.

Thus, through any point of the curve, as A, draw a line DE perpendicular to the directrix $\mathrm{BC} ; \mathrm{AD}$ is a diameter of the par- C
 abola, and the point $A$ is the vertex of this diameter.
4. The axis of the parabola is the diameter which passes through the focus, and the vertex of the axis is called the principal vertex.

Thus, through the focus F draw GH perpendicular to the directrix; GV is the axis of the parabola, and the point V, where the axis meets the curve, is called the principal vertex of the parabola, or simply the vertex.
It is evident, from Def. 1, that $\mathrm{FV}=\mathrm{VH}$; that is, a perpendicular drawn from the focus to the directrix is bisected at the vertex of the axis.
5. A tangent to the parabola is a straight line which meets the curve in one point only, and every where else falls without the curve.
6. An ordinate to a diameter is a straight line drawn from any point of the curve to meet that diameter, and is parallel to the tangent at its vertex.

Thus, let $A C$ be a tangent to the parabola at B , the vertex of the diameter BD , and from any point E of the curve draw EGH parallel to $A C$; then is EG an ordinate to the diameter BD.

It is proved in Prop. 12 that EG is equal to GH; hence the entire line EH is sometimes called a double ordinate.
7. An abscissa is the part of a diameter intercepted between its vertex and an ordinate.

Thus BG is the abscissa of the diameter BD corresponding to the ordinate EG, and also to the point E of the curve.
8. A subtangent is that part of a diameter produced which is included between a tangent and an ordinate drawn from the point of contact.

Thus, let EL, a tangent to the curve at E, meet the diameter BD in the point L , and let the ordinate EG meet the same diameter in $G$; then $L G$ is the subtangent of BD corresponding to the point E.
9. The parameter of a diameter is the double ordinate which passes through the focus.

Thus, through the focus $F$ draw IK parallel to $A C$, which tonches the curve at the vertex of the diameter BD; then is IK the parameter of the diameter BD.
10. The parameter of the axis is called the principal parameter, or latus rectum.
11. A normal is a line drawn perpendicular to a tangent from the point of contact, and terminated by the axis.
12. A subnormal is the part of the axis included between the normal and an ordinate drawn from the same point of the curve.

Thus, let $A B$ be a tangent to the parabola at any point A. From A draw AC perpendicular to AB , and draw AD an ordinate to the axis VC ; then AC is the normal, and DC is the subnormal corresponding to
 the point A.*

PROPOSITION I. PROBLEA.
The focus and directrix of a parabola being given, to describc the curve.

First method. By points.
Let $F$ be the focus, and $B b$ the directrix of a parabola. Through F draw DC perpendicular to $\mathrm{B} b$, and bisect FD in V ; then, since $\mathrm{DV}=\mathrm{VF}, \mathrm{V}$ is a point on the curve, and CV is the axis of the parabola.

To find other points of the curve, draw any number of lines $\mathrm{A} a, \mathrm{~A}^{\prime} a^{\prime}, \mathrm{A}^{\prime \prime} a^{\prime \prime}$, etc., perpendicular to CD ; then, with the distances DC , $\mathrm{DC}^{\prime}, \mathrm{DC}^{\prime \prime}$, etc., as radii, and the focus F as a centre, describe arcs intersecting the perpendiculars in $A, A^{\prime}, A^{\prime \prime}$, etc. The points $A, A^{\prime}, A^{\prime \prime}$, etc., in which the arcs cut the perpendiculars, are points of the curve.
For

$$
\mathrm{FA}=\mathrm{DC}=\mathrm{AB}(\mathrm{Def} .1)
$$

We may thus determine as many points on the curve as we please, and the curve line which passes through all the points $V$, $\mathrm{A}, \mathrm{A}^{\prime}, \mathrm{A}^{\prime \prime}$, etc., will be the parabola whose focus is F , and directrix $\mathrm{B} b$.

Cor. The same radius determines two points of the curve, one above and one below the axis; and, since $\mathrm{AF}=a \mathrm{~F}, \mathrm{FC}$ is common

[^7]to the two triangles $\mathrm{AFC}, \alpha \mathrm{FC}$, and the angles at C are right angles; therefore $A C=a C$; that is, every straight line terminated by the curve, and perpendicular to the axis, is bisected by it; and, consequently, the parabola consists of two equal branches similarly situated with respect to the axis.

Moreover, since the radius FA is always greater than FC, the arc described with $F$ as a centre will always intersect the corresponding perpendicular, and there is therefore no limit to the distance to which the curve may extend on both sides of the axis.

Second method. By continuous motion.

Let BC be a ruler whose edge coincides with the directrix of the parabola, and let DEG be a square. Take a thread equal in length to EG, and attach one extremity of it at $G$, and the other at the focus F. Then slide the side of the square DE along the ruler $B C$, and at the same time keep the thread continually stretched by means of the point of a pencil $A$ in contact with the square; the pencil will describe one part of the required parabola. For, in every position of the square, $A F+A G=A E+A G ;$
and hence $\mathrm{AF}=\mathrm{AE} ;$
that is, the point $A$ is always equally distant from the focus $F$ and the directrix BC.

If the square be turned over and moved on the other side of the point $F$, the other part of the same parabola may be described.

## PROPOSITION II. THEOREM.

The distance of any point without the parabola from the focus is greater than its distance from the directrix ; and the distance of any point within the parabola from the focus is less than its distance from the directrix.

Let AVH be a parabola, of which $F$ is the focus, and $B C$ the directrix; and let $D$ be a point without the curve, that is, on the same side of the curve as the directrix. Then, if DF be joined, and BD be drawn perpendicular to BC, DF will be greater than DB.

For, as DF necessarily cuts the curve, let A be the point of section. Draw AE perpendic-
ular to the directrix, and join DE . Then, because A is a point in the parabola, $\mathrm{AE}=\mathrm{AF}$ (Def. 1) ; therefore $\mathrm{DF}=\mathrm{DA}+\mathrm{AE}$; but $\mathrm{DA}+\mathrm{AE}$ is greater than DE (B. I., Pr. 8), and therefore still greater than DB (B. I., Pr. 17). Therefore DF is greater than DB.

Again, let G be a point within the parabola. Then GF, a line drawn to the focus, is less than GE, a perpendicular to the directrix. The perpendicular GE necessarily cuts the curve; let A be the point of section, and join AF. Then AF=AE (Def. 1), and $G A+A F=G E$. But $G F$ is less than $G A+A F$, therefore GF is less than GE.

Cor. A point is without or within the parabola according as its distance from the focus is greater or less than its distance from the directrix.

## PROPOSITION III. THEOREM.

The straight line which bisects the angle contained by two lines drawon from the same point in the curve, the one to the focus and the other perpendicular to the directrix, is a tangent to the parabola at that point.

Let $A$ be any point of the parabola $A V$, from which draw the line AF to the focus, and AB perpendicular to the directrix, and draw AC bisecting the angle BAF ; AC is a tangent to the curve at the point $A$.

Let $D$ be any other point in the line $A C$, from which draw $\mathrm{DB}, \mathrm{DF}$. Also draw DE perpendicular to the directrix, and join BF . Since, in the two triangles, $\mathrm{ACB}, \mathrm{ACF}, \mathrm{AF}$
 is equal to AB (Def. 1), AC is common to both triangles, and the angle CAB is, by supposition, equal to the angle CAF ; therefore CB is equal to CF , and the angle ACB to the angle ACF .

Again, in the two triangles $\mathrm{DCB}, \mathrm{DCF}$, because BC is equal to CF , the side DC is common to both triangles, and the angle DCB is equal to the angle DCF ; therefore DB is equal to DF . But DB is greater than DE (B. I., Pr. 17) ; therefore the distance of the point $D$ from the focus is greater than its distance from the directrix ; hence that point is without the parabola (Pr. 2, Cor.). Therefore every point of the line DC, except A, is without the curve ; that is, DC is a tangent to the curve at A (Def. 5).

Cor. 1. Since the angle BAF continually increases as the point A moves toward $V$, and at $V$ becomes equal to two right angles,
the tangent at the principal vertex is perpendicular to the axis. The tangent at the vertex $V$ is called the vertical tangent.

Cor. 2. Since an ordinate to any diameter is parallel to the tangent at its vertex, an ordinate to the axis is perpendicular to the axis.

PROPOSITION IV. THEOREM.
The latus rectum is equal to four times the distance from the focus to the vertex.

Let AVB be a parabola, of which F is the focus, and $V$ the principal vertex; then the latus rectum $A F B$ will be equal to four times $F V$.

Let CD be the directrix, and let AC be drawn perpendicular to it; then, according to Def. 1, AF is equal to AC or DF , because ACDF is a parallelogram. But DV is equal to VF; that is, DF is equal to twice VF. Hence AF is equal to twice VF. In the same manner, it may be proved that BF is equal to twice VF ; consequently, AB is equal to four times VF. 'Therefore the latus rectum, etc.

PROPOSITION V. THEOREM.
If a tangent to the parabola cut the axis produced, the points of contact and of intersection are equally distant from the focus.

Let AB be a tangent to the parabola GAII at the point A , and let it cut the axis produced in $B$; also, let $A F$ be drawn to the focus; then will the line AF be equal to BF.

Draw AC perpendicular to the directrix ; then, since $A C$ is parallel to $B F$, the angle BAC is equal to ABF . But the angle BAC is equal to $\mathrm{BAF}(\operatorname{Pr} .3)$; hence the angle $A B F$ is equal to $B A F$, and, consequently, AF is equal to BF. Therefore, if a tangent, etc.

Cor. 1. Let the normal AD be drawn. Then, because BAD is a right angle, it is equal to the sum of the two angles $\mathrm{ABD}, \mathrm{ADB}$, or to the sum of the two angles BAF, ADB. Take away the common angle BAF, and we have the angle DAF equal to ADF. Hence the line AF is equal to FD. Therefore, if a circle be clescribed with the centre F and radius FA , it will pass through the three points $\mathrm{B}, \mathrm{A}, \mathrm{D}$.

Cor. 2. The normal bisects the angle made by the diameter at the point of contact with the line drawn from that point to the focus.

For, because BD is parallel to CE, the alternate angles ADF, DAE are equal. But the angle ADF has been proved equal to DAF; hence the angles DAF, DAE are equal to each other.

Scholium. It is a law in Optics that the angle made by a ray of reflected light with a perpendicular to the reflecting surface is equal to the angle which the incident ray makes with the same perpendicular. Hence, if GAII represent a polished surface whose figure is that produced by the revolution of a parabola about its axis, a ray of light falling upon it in the direction EA would be reflected to F . The same would be true of all rays parallel to the axis. Hence the point F , in which all the rays would intersect each other, is called the focus, or burning point.

## PROPOSITION VI. THEOREM.

The sultangent to the axis is bisected by the vertex.
Let AB be a tangent to the parabola $A D V$ at the point $A$, and $A C$ an ordinate to the axis; then will BC be the subtangent, and it will be bisected at the vertex V .

For BF is equal to AF (Pr. 5), and AF is equal to CE , which is the distance of the point A from the directrix. That is,
$\mathrm{BF}=\mathrm{CE}$.
But
 Therefore the remainder $\mathrm{BV}=$ the remainder CV .

Cor. 1 . Hence the tangent at D , the extremity of the latus rectum, meets the axis in E, the same point with the directrix. For, by Def. 8, EF is the subtangent corresponding to the tangent DE.

Cor. 2. Hence, if it is required to draw a tangent to the curve at a given point A, draw the ordinate AC to the axis. Make BV equal to VC ; join the points $\mathrm{B}, \mathrm{A}$, and the line BA will be the tangent required.

## PROPOSITION VII. THEOREM.

The subnornal is equal to half the latus rectum.
Let AB be a tangent to the parabola AV at the point A ; let

AC be the ordinate, and AD the normal from the point of contact; then $C D$ is the subnormal, and is equal to half the latus rectum.

For the distance of the point $A$ from the focus is equal to its distance from the directrix, which is equal to $\mathrm{VF}+\mathrm{VC}$, or $2 \mathrm{VF}+\mathrm{FC}$; that is,

$$
\mathrm{FA}=2 \mathrm{VF}+\mathrm{FC}
$$

But
Hence

$$
\mathrm{FA}=\mathrm{FD}(\operatorname{Pr} .5, \operatorname{Cor} .1)
$$

$\mathrm{FD}=2 \mathrm{VF}+\mathrm{FC}$.
Taking away the common part FC , the remainder $\mathrm{CD}=2 \mathrm{VF}$, which is equal to half the latus rectum ( Pr .4 ).

## PROPOSITION VIII. THEOREM.

If a perpendicular be drawn from the focus to any tangent, the point of intersection will be in the vertical tangent.

Let AB be any tangent to the parabola AV , and FC a perpendicular let fall from the focus upon AB ; join VC ; then will the line VC be a tangent to the curve at the vertex V .

Draw the ordinate AD , to the axis. Since FA is equal to FB (Pr. 5), and FC is drawn perpendicular to $A B$, it divides the triangle AFB into two equal parts, and therefore AC is equal to BC . But BV is equal to $\mathrm{VD}(\mathrm{Pr} .6)$; hence BC: CA::BV:VD,
and therefore CV is parallel to $A D$ (B.IV., Pr. 16). But AD is perpendicular to the axis BD ; hence CV is also perpendicular to the axis, and is a tangent to the curve at the point V (Pr. 3, Cor. 1). Therefore, if a perpendicular, etc.

Cor. 1. Because the triangles FVC, FCA are similar, we have

$$
\mathrm{FV}: F C:: F C: F A
$$

that is, the perpendicular from the focus upon any tangent is a mean proportional between the distances of the focus from the vertex and from the point of contact.

Cor. 2. From Cor. 1 we have $\mathrm{FC}^{2}=\mathrm{FV} \times \mathrm{FA}$.
But FV remains constant for the same parabola; therefore the square of the perpendicular from the focus to any tangent varics as the distance from the focus to the point of contact.

## PROPOSITION IX. THEOREM.

The square of an ordinate to the axis is equal to the product of the lutus rectum by the corresponding abscissa.

Let AVC be a parabola, and A any point of the curve. From A draw the ordinate AB ; then is the square of AB equal to the produet of VB by the latus rectum.

Draw the tangent AT and the normal AD . Since TAD is a right angle, and AB perpendicular to TD,

$$
\mathrm{AB}^{2}=\mathrm{TB} \times \mathrm{BD}(\text { B. } \mathrm{IV} ., \mathrm{Pr} .23) .
$$

But
and
Therefore
or
Cor. 1. Sine the lation latur (Pr:
Cor. 1. Since the latus rectum is constant for the same parabola, the squares of ordinates to the axis are to each other as their corresponding abscissas.

Cor.2. The preceding demonstration is equally applicable to ordinates on either side of the axis; hence $A B$ is equal to BC , and $A C$ is called a double ordinate. The curve is composed of two branches of unlimited extent, which recede continually from the axis as well as from the directrix.

## PROPOSITION X. THEOREM.

If two tangents to the parabola intersect each other, and lines be drawon from the focus to the points of contact and to the point of intersection, the two triangles thus formed will be similar to each other.

Let two lines which touch the parabola at A and $a$ intersect each other at $T$; from the focus draw FA, FT, and $\mathrm{F} a$; the two triangles TFA, TF $a$ are similar.

Draw AB and $a b$ perpendicular to the directrix $\mathrm{B} b$, and join $\mathrm{TB}, \mathrm{T} b$, and BF . The two triangles $\mathrm{ACB}, \mathrm{ACF}$ are equal to each other, since AB is equal to $\mathrm{AF}, \mathrm{AC}$ is common to the two tri-

angles, and the angle CAB is equal to CAF (Pr. 3) ; therefore the augles at C are right angles, and BC is equal to CF.

Also, the two triangles TCB, TCF are equal, since BC is equal to CF , TC is common to both triangles, and the angles at C are equal; therefore TF is equal to TB.
In the same manner, it may be proved that TF is equal to $\mathrm{T} b$, the angle $\mathrm{FT} a$ is equal to $b \mathrm{~T} a$, and a circle described from the centre T , with radius TF , will pass through $B$ and $b$.
The angle $\mathrm{FB} b$ is equal to the angle CAB , since each is the complement of ABC; also, the angle BAC is equal to FAC (Pr. 3) ; therefore the angle FAC is equal to $\mathrm{FB} b$. But the angle $\mathrm{FB} b$ is half the angle $\mathrm{FT} b$ (B. III., Pr. 15, Cor. 2), and is therefore equal to the angle FTa. Therefore the angle FAT is equal to the angle $\mathrm{FT} a$.
In the same manner, it may be proved that the angle ATF is equal to $\mathrm{F} a \mathrm{~T}$. Therefore the remaining angle TFA is equal to the angle $\mathrm{TF} a$, and the triangle AFT is similar to the triangle $a \mathrm{FT}$.

## PROPOSITION XI. THEOREM.

If two tangents to a parabola be dravon at the extremities of a chord, the diameter which passes through their point of inter'section will bisect the chord.

Let two lines which touch the parabola at A and $a$ intersect each other at T , and from T let TC be drawn perpendicular to the directrix $\mathrm{B} b$, meeting the chord $\mathrm{A} a$ in C ; then $\mathrm{A} a$ will be bisected in C.

Draw $\mathrm{AB}, a b$ perpendicular to the directrix ; join TB, Tb, and let TC mect $\mathrm{B} b$ in D .

The two triangles TDB, TD $b$ are equal, since TB is equal to Tb (Pr. 10), TD is common to the two triangles, and the angles at D are right angles; therefore BD is equal to $b \mathrm{D}$.

Because the lines $\mathrm{AB}, \mathrm{CD}, a b$ are parallel, we have $\mathrm{AC}: \mathrm{C} a:: \mathrm{BD}: \mathrm{D} b$.
But $\mathrm{BD}=\mathrm{D} b$; therefore $\mathrm{AC}=\mathrm{C} a$; that is, $\mathrm{A} \alpha$ is bisected in C .

## PROPOSITION XII. THEOREM.

If two tangents to a parabola be drawn at the extremities of a chord, and a diameter be drawn through their point of intersection, the tangent at its vertex will be parallel to the chord.

If from a point T two tangents TA , $\mathrm{T} a$ be drawn to a parabola, and TC be drawn parallel to the axis, meeting the parabola in C , the tangent $\mathrm{BC} b$ will be parallel to the chord $\mathrm{A} a$.

Let the tangent $\mathrm{BC} b$ meet $\mathrm{TA}, \mathrm{T} a$ in B and $b$. Join $A C$, and draw BD parallel to the axis, meeting AC in D.

Because BD is parallel to TC, we
 have TB: BA :: CD :DA. But $\quad \mathrm{CD}=\mathrm{DA}(\mathrm{Pr} .11)$; therefore $\mathrm{TB}=\mathrm{BA}$. For the same reason, $\mathrm{T} b=b a$.

Therefore $\mathrm{TB}: \mathrm{BA}:: \mathrm{T} b: b a$, and $\mathrm{B} b$ is parallel to $\mathrm{A} a$ (B. IV., Pr. 16).

Cor. 1. Since AE is parallel to the tangent BC , it is an ordinate to the diameter CE; and since $\mathrm{A} a$ is bisected in E (Pr. 11), $\mathrm{A} \alpha$ is a double ordinate to CE. Hence every diameter bisects its clouble ordinates.

Cor. 2. Since BC is parallel to AE , we have
TC : CE :: TB : BA.

But $\mathrm{TB}=\mathrm{BA}$; therefore $\mathrm{TC}=\mathrm{CE}$; that is, the subtangent upon any diameter is bisected at the vertex of that diameter.

## PROPOSITION XIII. THEOREM.

The square of an ordinate to any diameter is equal to four times the product of the corresponding abscissa by the clistance from the vertex of that cliameter to the focis.

Let AE be an ordinate to the diameter CE ; then

$$
\mathrm{AE}^{2}=4 \mathrm{CE} \times \mathrm{CF}
$$

Produce AE to meet the parabola in $\alpha$, and draw the tangents TA, Ta, meeting CE produced in the point $\mathrm{T}(\mathrm{Pr} .12)$. Let the tangent at C meet TA in B , and join $\mathrm{FA}, \mathrm{FB}$, and FC .

Now, since from the point B two tangents $\mathrm{BA}, \mathrm{BC}$ are drawn

to the parabola, the triangle BCF is similar to the triangle BFA (Pr. 10) ; therefore the angle CBF is equal to BAF. But BAF is equal to BDF (Pr: 3 ), which equals BTC ; therefore the angle CBF is equal to BTC. Also, the angle FCb is equal to $\mathrm{TC} b$; therefore their supplements are equal ; that is, FCB is equal to $\mathrm{BCr}^{r}$. Therefore the remaining angle BFC is equal to the remaining angle $C B T$, and the triangle $B C F$ is similar to BCT. Hence $\mathrm{CF}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CT}$,
or $\quad \mathrm{CB}^{2}=\mathrm{CT} \times \mathrm{CF}=\mathrm{CE} \times \mathrm{CF}(\mathrm{Pr} .12, \mathrm{Cor} .2)$.
Also, since AE is parallel to BC , we have
$\mathrm{AE}: \mathrm{BC}:: \mathrm{ET}: \mathrm{CT}$.
But $\quad \mathbf{E T}=2 \mathrm{CT}(\operatorname{Pr} .12$, Cor. 2) ; therefore $\mathrm{AE}=2 \mathrm{BC}$;
and $\quad \mathrm{AE}^{2}=4 \mathrm{BC}^{2}=4 \mathrm{CE} \times \mathrm{CF}$.
PROPOSITION XIV. THEOREM.
The parameter of any diameter is equal to four times the clistance from its vertex to the focus.

Let BAD be a parabola, of which F is the focus, AC is any diameter, and BD its parameter; then is BD equal to fomr times AF.

Draw the tangent AE; then, since AE FC is a parallelogram, AC is equal to EF , which is equal to AF ( Pr .4 ).

Now, by Pr. $13, \mathrm{BC}^{2}$ is equal to $4 \mathrm{AF} \times$ AC ; that is, to $4 \mathrm{AF}^{2}$. Hence BC is equal to twice AF , and BD is equal to four times AF. Therefore the parameter of any diameter, etc.

Cor. Hence the square of an ordinate to any diameter is equal to the product of its parameter by the corresponding abseissa (Pr.13).

> PROPOSITION XV. THEOREM.

If a cone be cut by a plane parallel to its side, the section is a párabola.

Let ABGCD be a cone cut by a plane VDG parallel to the slant side $A B$; then will the section DVG be a parabola.

Let $A B C$ be a plane section through the axis of the cone, and perpendicular to the plane VDG; then VE, which is their common section, will be parallel to AB (B. VII., Pr.12). Let $b g c d$ be a plane parallel to the base of the cone; the intersection of this plane with the cone will be a circle.

Since the plane ABC divides the cone into two equal parts, BC is a diameter of the circle BGCD , and $b c$ is a diameter of the circle bgect. Let DEG, cleg be the common sections of the plane VDG with the planes BGCD,
 $b y c d$ respectively. Then DG is perpendicular to the plane ABC (B. VII., Pr. 8), and, consequently, to the lines VE, BC. For the same reason, $d g$ is perpendicular to the two lines VE, $b c$.

Now, since be is parallel to BE , and $b \mathrm{~B}$ to $e \mathrm{E}$, the figure $b \mathrm{BE} e$ is a parallelogram, and $b e$ is equal to BE. But, because the triangles Vec, VEC are similar, we have

$$
e c: \mathrm{EC}:: \mathrm{Ve}: \mathrm{VE} ;
$$

and, multiplying the first and second terms of this proportion by the equals be and BE , we have

$$
b e \times e c: \mathrm{BE} \times \mathrm{EC}:: \mathrm{Ve}: \mathrm{VE} .
$$

But, since $b c$ is a diameter of the circle $b g c d$, and de is perpendicular to $b c$ (B. IV., Pr. 23, Cor.), $b e \times e c=d e^{2}$.
For the same reason, $\quad \mathrm{BE} \times \mathrm{EC}=\mathrm{DE}^{2}$.
Substituting these values of $b e \times e c$, and $\mathrm{BE} \times \mathrm{EC}$ in the preceding proportion, we hare

$$
d e^{2}: \mathrm{DE}^{2}:: \mathrm{Ve}: \mathrm{VE} ;
$$

that is, the squares of the ordinates are to each other as the corresponding abscissas, and hence the curve is a parabola whose axis is VE (Pr. 9, Cor. 1). Hence the parabola is called a conic section, as mentioned on page 203.

Schol. 1. The conclusion that DVG is a parabola would not be legitimate unless it was proved that the property that "the squares of the ordinates are to each other as the corresponding abscissas" is peculiar to the parabola. That such is the case appears from the fact that, when the axis and one point of a parabola are given, this property will determine the position of every
 other point of the curve. Thus, let VE be the axis of a parabola,
and $g$ any point of the curve, from which draw the ordinate $g e$. Take any other point in the axis, as E , and make GE of such a length that $\mathrm{Ve}: \mathrm{VE}:: g e^{2}: \mathrm{GE}^{2}$.

Since the first three terms of this proportion are given, the fourth is determined, and the same proportion will determine any number of points of the curve..

Schol.2. AB, AC, the sides of the cone, may be conceived to be indefinitely extended, until the height of the cone $A B C$ is infinite. If the plane DVG be also indefinitely extended, the two branches of the parabola DVG will extend to an infinite distance from V , and will also recede to an infinite distance from the axis, as stated in Prop. 9, Cor. 2.

PROPOSITION XVI. THEOREM.
A segment of a parabola cut off by a double ordinate to the axis is two thircls of its circumscribing rectangle.

Let AVD be a segment of a parabola cut off by the straight line $A D$ perpendicular to the axis. Through $V$ draw the tangent BC ; also, draw $\mathrm{AB}, \mathrm{CD}$ parallel to the axis; then will the parabolic segment AVD be two thirds of the rectangle ABCD.

Let $H$ be a point of the curve near to $A$, and through $A$ and II diaw the secant line AHE. Also, through H draw KL perpendicular, and MN parallel to the axis.

The area of the trapezoid AHLG is equal to $\frac{1}{2}(A G+H L) H N$, (B.IV., Pr. 7) ; and the area of the trapezoid ABMH is equal to $\frac{1}{2}(\mathrm{AB}+\mathrm{MH}) \mathrm{AN}$. Hence we have

AHLG: ABMH :: $(\mathrm{AG}+\mathrm{HL}) \mathrm{HN}:(\mathrm{AB}+\mathrm{MH}) \mathrm{AN}$, $::(\mathrm{AG}+\mathrm{HL}) \mathrm{EG}:(\mathrm{AB}+\mathrm{MH}) \mathrm{AG}$,
because EG: AG::HN:AN.
If, now, we suppose the point $H$ to moze toward $A$, the secant line AIIE will approach the position of a tangent to the curve at A, and will coincide with the tangent when $H$ coincides with $A$. When this takes place, $A G$ will be equal to $H L$, and $A B$ to $M H$; also, EG will be double of VG or AB (Pr.6). We shall then have

$$
\frac{\mathrm{AHLG}}{\mathrm{ABMH}}=\frac{2 \mathrm{AG} \cdot \mathrm{EG}}{2 \mathrm{~A}} \overline{\mathrm{~B} \cdot \mathrm{AG}}=\frac{\mathrm{EG}}{\mathrm{AB}}=2 .
$$

Hence the portion of the parabola included between two ordinates indefinitely near is double of the corresponding portion of the external space ABV. The same may be proved for every point of the curve, and hence the whole space AVG is double the space ABV. Whence AVG is two thirds of ABVG, and the parabolic segment AVD is two thirds of the circumscribing rectangle ABCD. Therefore a segment, etc.

## EXERCISES ON THE PARABOLA.

1. The diameter of the circle described about the triangle AVB is equal to 5 FV . (See fig., Pr. 4.)
2. If from the point $\mathrm{D}, \mathrm{DE}$ be drawn at right angles to FA , then AE is equal to 2VF. (See fig., Pr: 7.)
3. If the triangle ADF is equilateral, then AF is equal to the latus rectum. (See fig., Pr. 7.)
4. If AB is a common tangent to a parabola, and the circle described on the latus rectum as a diameter, prove that AF and BF make equal angles with the latus rectum.
5. If the tangent AC meets the directrix in G , prove that AC . $A G=\mathrm{AF}^{2}$, and that $A C . C G=A F . F V$. (See fig., Pr. 3.)
6. If AE be drawn at right angles to AV, meeting the axis in E, then CE is equal to 4 VF . (See fig., Pr. 7.)
7. The tangent at any point of a parabola meets the directrix and latus rectum produced in points equally distant from the focus.
8. Prove that $\mathrm{BC}=\mathrm{CD}$, and that BA.BC=BF.BD. (See fig., Pr. 8.)
9. If a circle be described about the triangle AFC, the tangent to it from $V$ is equal to one half AC. (See fig., Pr. 7.)
10. If the ordinate of a point $A$ bisect the subnormal of a point B , the ordinate of A is equal to the normal of B .
11. If from any point on the tingent to a parabola a line be drawn touching the parabola, the angle between this line and the line to the focus from the same point is constant.
12. If the diameter AC meets the directrix in $G$, and the chord drawn through the focus parallel to the tangent at $\mathbf{A}$ in $\mathbf{C}$, prove that $\mathrm{AC}=\mathrm{AG}$. (See fig., Pr. 14.)
13. Required the area of a segment of a parabola cut off by a chord 15 inches in length, perpendicular to the axis, the corresponding abscissa of the axis being 21 inches.
14. An ordinate to the axis of a parabola is 9 inches, and the corresponding abscissa is 10 irches; Tequired the latus rectum.
15. An ordinate to a diameter of a parabola is 12 inches, and the corresponding abscissa is 5 inches; required the parameter of that diameter.
16. The latus rectum of a parabola is 20 inches; required the area of the segment cut off by a double ordinate to the axis when the corresponding abscissa is 30 inches.
17. The latus rectum of a parabola is 9 . What is the ordinate to the axis corresponding to the abscissa 4 ?
18. The latus rectum of a parabola is 10 inches. Find the ordinate to the axis corresponding to that point of the curve from which, if a tangent and normal be drawn, they will form with the axis a triangle whose area is 36 inches.
19. The latus rectum of a parabola is 15 , and a tangent is drawn through the point whose ordinate to the axis is 4. Determine where the tangent line meets the axis produced.
20. The latus rectum of a parabola is 12 , and a tangent is drawn through the point whose ordinate to the axis is 7. Determine where the normal line passing through the same point meets the axis.

## ELLIPSE.

## Definitions.

1. An ellipse is a plane curve traced out by a point which moves in such a manner that the sum of its distances from two fixed points is always the same.
2. The two fixed points are called the foci of the ellipse.

Thus, if F and $\mathrm{F}^{\prime}$ are two fixed points, and if the point $D$ moves about $F$ in such a manner that the sum of its distances from F and $\mathrm{F}^{\prime}$ is always the same, the point D will describe an ellipse, of which $F$ and $F^{\prime}$ are the foci.
3. The centre of the ellipse is the mid-
 dle point of the straight line joining the foci.
4. The eccentricity is the distance from either focus to the centre.

Thus, let F and $\mathrm{F}^{\prime}$ be the foci of the ellipse $\mathrm{ABA}^{\prime} \mathrm{B}^{\prime}$. Draw the line $\mathrm{FF}^{\prime}$, and bisect it in C . The point C is the centre of the ellipse, and CF or $\mathrm{CF}^{\prime}$ is the eccentricity.
5. A diameter is any straight line passing through the centre, and terminated on both sides by the curve.

6. The extremities of a diameter are called its vertices.

Thus, through $\mathbf{C}$ draw any straight line $\mathrm{DD}^{\prime}$ terminated by the curve ; $\mathrm{DD}^{\prime}$ is a diameter of the ellipse; D and $\mathrm{D}^{\prime}$ are the vertices of that diameter.
7. The major axis is the diameter which passes through the foci.
8. The minor axis is the diameter which is perpendicular to the major axis.

Thus, produce the line $\mathbf{F F}^{\prime}$ to meet the curve in $\mathbf{A}$ and $\mathbf{A}^{\prime}$, and through C draw $\mathrm{BB}^{\prime}$ perpendicular to $\mathrm{AA}^{\prime}$; then is $\mathrm{AA}^{\prime}$ the major axis, and $\mathrm{BB}^{\prime}$ the minor axis.
9. A tangent to an ellipse is a straight line which meets the curve in one point only, and every where else falls without it.
10. An ordinate to a diameter is a straight line drawn from any point of the curve to the diameter, and is parallel to the tangent at one of its vertices.

Thus, let $\mathrm{DD}^{\prime}$ be any diameter, and $\mathrm{TT}^{\prime}$ a tangent to the ellipse at D. From any point $G$ of the curve draw $\mathrm{GKG}^{\prime}$ parallel to $\mathrm{TT}^{\prime}$, and cutting $\mathrm{DD}^{\prime}$ in K ; then is GK an ordinate to the diameter $\mathrm{DD}^{\prime}$. It is proved in Pr. 7 that the tangents at D and $\mathrm{D}^{\prime}$ are parallel.

It is proved in Pr. 21, Cor. 1, that GK is equal to $\mathrm{G}^{\prime} \mathrm{K}$; hence the entire line $\mathrm{GG}^{\prime}$ is called a double ordinate.
11. Each of the parts into which a diameter is divided by an ordinate is called an abscissa.

Thus, DK and $\mathrm{D}^{\prime} \mathrm{K}$ are the abscissas of the diameter $\mathrm{DD}^{\prime}$ corresponding to the ordinate GK, or to the point $G$.
12. One diameter is said to be conjugate to another when it is parallel to the ordinates of the other diameter.

Thus, draw the diameter $\mathrm{EE}^{\prime}$ parallel to GK, an ordinate to the diameter $\mathrm{DD}^{\prime}$, in which case it will, of course, be parallel to the tangent $\mathrm{TT}^{\prime}$; then is the diameter $\mathrm{EE}^{\prime}$ conjugate to $\mathrm{DD}^{\prime}$.

13. The latus rectum is the double ordinate to the major axis which passes through one of the foci.

Thus, through the focus $\mathbf{F}^{\prime}$ draw $\mathrm{LL}^{\prime}$, a double ordinate to the major axis; it will be the latus rectum of the ellipse.
14. A subtangent is that part of an axis produced which is included between a tangent and the ordinate drawn from the point of contact.

Thus, if $\mathrm{TT}^{\prime}$ be a tangent to the curve at D , and DG an ordinate to the major axis, then GT is the corresponding subtangent.
15. The directrix of an ellipse is

G a straight line perpendicular to the major axis produced, and intersecting it in the same point with the tangent drawn through one extremity of the latus rectum.

Thus, if LT be a tangent drawn
through one extremity of the latus rectum $\mathrm{LL}^{\prime}$, meeting the axis produced in T, and GT be drawn through the point of intersection perpendicular to the axis, it will be the directrix of the ellipse.

The ellipse has two directrices, one corresponding to the focus F , and the other to the focus $\mathrm{F}^{\prime}$.

## PROPOSITION I. THEOREMS.

The sum of the two lines drawn from any point of an ellipse to the foci is equal to the major axis.

Let $\mathrm{ADA}^{\prime}$ be an ellipse, of which F , $\mathbf{F}^{\prime}$ are the foci, $\mathrm{AA}^{\prime}$ is the major axis, and D any point of the curve; then will $\mathrm{DF}+\mathrm{DF}^{\prime}$ be equal to $\mathrm{AA}^{\prime}$.

For, by Def. 1, the sum of the distances of any point of the curve from
 the foci is equal to a given line. Now, when the point D arrives at $\mathrm{A}, \mathrm{FA}+\mathrm{F}^{\prime} \mathrm{A}$, or $2 \mathrm{AF}+\mathrm{FF}^{\prime}$ is equal to the given line. And when $D$ is at $\mathbf{A}^{\prime}, \mathrm{FA}^{\prime}+\mathrm{F}^{\prime} \mathrm{A}^{\prime}$, or $2 \mathrm{~A}^{\prime} \mathrm{F}^{\prime}+$ $\mathrm{FF}^{\prime}$ is equal to the same line. Hence

$$
2 \mathrm{AF}+\mathrm{FF}^{\prime \prime}=2 \mathrm{~A}^{\prime} \mathrm{F}^{\prime}+\mathrm{FF}^{\prime} ;
$$

consequently, $\quad \mathrm{AF}$ is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime}$.

Hence $\mathrm{DF}+\mathrm{DF}^{\prime}$, which is equal to $\mathrm{AF}+\mathrm{AF}^{\prime}$, must be equal to $\mathrm{AA}^{\prime}$. Therefore the sum of the two lines, etc.

Cor. The major axis is bisected in the centre. For, by Def. 3, CF is equal to $\mathrm{CF}^{\prime}$; and we have just proved that AF is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime}$; therefore AC is equal to $\mathrm{A}^{\prime} \mathbf{C}$.

## proposition in. problem.

The major axis and foci of an ellipse being given, to describe the curve.

First method. By points.
Let $\mathrm{AA}^{\prime}$ be the major axis, and $\mathrm{F}, \mathrm{F}^{\prime}$ the foci of an ellipse. Take E any point between the foci, and from F and $\mathrm{F}^{\prime}$ as centres, with the distances $\mathrm{AE}, \mathrm{A}^{\prime} \mathrm{E}$ as radii, describe two circles cutting each other in the point $\mathrm{D} ; \mathrm{D}$ will be a point on the ellipse. For, join FD,
 $\mathrm{F}^{\prime \prime} \mathrm{D}$; then $\mathrm{DF}+\mathrm{DF}^{\prime}=\mathrm{EA}+\mathrm{EA}^{\prime}=\mathrm{AA}^{\prime}$; and, at whatever point between the foci E is taken, the sum of DF and $\mathrm{DF}^{\prime}$ will be equal to $\mathrm{AA}^{\prime}$. Hence, by Def. $1, \mathrm{D}$ is a point on the curve; and, in the
same manner, any number of points in the ellipse may be determined.

Cor. The same circles determine two points of the curve $D$ and $\mathrm{D}^{\prime}$, one above and one below the major axis. It is also evident that these two points are equally distant from the axis ; that is, the ellipse is symmetrical with respect to its major axis, and is bisected by it.

## SECOND METHOD. By continuous motion.

Take a thread equal in length to the major axis of the ellipse, and fasten one of its extremities at $F$, the other at $\mathrm{F}^{\prime}$. Then let a pencil be made to glide along the thread, so as to keep it always stretched; the curve described by the point of the pencil will be an ellipse. For in every position of the pencil the sum of the distances $\mathrm{DF}, \mathrm{DF}^{\prime}$ will be the same, viz., equal to the entire length of the string.

Scholium. The ellipse is evidently a continuous and closed curve.

## PROPOSITION III. TIIEOREM.

The sum of two lines drawn from any point without the ellipse to the foci is greater than the major axis; and the sum of two lines drawn from any point within the ellipse to the foci is less than the major axis.

Let $\mathrm{ADA}^{\prime}$ be an ellipse, of which $\mathrm{F}, \mathrm{F}^{\prime}$ are the foci, and $\mathrm{AA}^{\prime}$ the major axis; and let E be a point without the ellipse. Join EF, EF'; the sum of EF and $\mathrm{EF}^{\prime \prime}$ will be greater than $\mathrm{AA}^{\prime}$.

Let EF', which must meet the ellipse, meet it in D ; then $\mathrm{DE}+\mathrm{EF}$ is greater than DF (B. I., Pr. 8). Adding $\mathrm{DF}^{\prime}$ to these unequals, we have $\mathrm{EF}+\mathrm{EF}^{\prime}$ greater than $\mathrm{DF}+\mathrm{DF}^{\prime}$; that is, than $\mathrm{AA}^{\prime}$.

Again, let G be a point within the ellipse ; then GF $+\mathrm{GF}^{\prime}$ will be less than AA'.

Let $F^{\prime \prime} G$, which must meet the curve if produced beyond $G$, meet it in D, and join DF. The line GF is less than $\mathrm{DG}+\mathrm{DF}$ (B. I., Pr. 8). Adding GF $^{\prime}$ to these unequals, we have GF $+\mathrm{GF}^{\prime}$ less than $\mathrm{DF}+\mathrm{DF}^{\prime}$; that is, less than $\mathrm{AA}^{\prime}$. Therefore the sum, etc.

Cor. A point is without or within the ellipse according as the sum of two lines drawn from it to the foci is greater or less than the major axis.

PROPOSITION IV. THEOREM.
Every cliameter of an ellipse is bisected in the centre.
Let D be any point of an ellipse; join $\mathrm{DF}, \mathrm{DF}^{\prime}$, and $\mathrm{FF}^{\prime \prime}$. Complete the parallelogram $\mathrm{DFD}^{\prime} \mathrm{F}^{\prime}$, and join $\mathrm{DD}^{\prime}$.

Now, because the opposite sides of a parallelogram are equal, the sum of DF and $\mathrm{DF}^{\prime}$ is equal to the sum of $\mathrm{D}^{\prime} \mathrm{F}$ and
 $\mathrm{D}^{\prime} \mathrm{F}^{\prime}$; hence. $\mathrm{D}^{\prime}$ is a point in the ellipse. But the diagonals of a parallelogram bisect each other ; therefore $\mathrm{FF}^{\prime}$ is bisected in C ; that is, C is the centre of the ellipse, and $\mathrm{DD}^{\prime}$ is a diameter bisected in C. Therefore every diameter, etc.

## PROPOSITION V. THEOREM.

The distance from either focus to the extremity of the minor axis is equal to half the major axis.

Let F and $\mathrm{F}^{\prime}$ be the foci of an ellipse, $\mathrm{AA}^{\prime}$ the major axis, and $\mathrm{BB}^{\prime}$ the minor axis; draw the straight lines $\mathrm{BF}, \mathrm{BF}^{\prime}$; then $\mathrm{BF}, \mathrm{BF}^{\prime}$ are each equal to AC .

In the two right-angled triangles $\mathrm{BCF}, \mathrm{BCF}^{\prime}, \mathrm{CF}$ is equal to $\mathrm{CF}^{\prime}$, and BC is common to both triangles;
 hence BF is equal to $\mathrm{BF}^{\prime}$. But $\mathrm{BF}+\mathrm{BF}^{\prime \prime}$ is equal to $2 \mathrm{AC}(\mathrm{Pr}$. 1) ; consequently, BF and $\mathrm{BF}^{\prime}$ are each equal to AC . Therefore the distance, etc.

Cor. 1. Half the minor axis is a mean proportional between the parts into which either focus divides the major axis.

For $\mathrm{BC}^{2}$ is equal to $\mathrm{BF}^{2}-\mathrm{FC}^{2}$ (B. IV., Pr. 11), which is equal to $\mathrm{AC}^{2}-\mathrm{FC}^{2}$ (Pr. 5). Hence (B. IV., Pr. 10)

$$
\begin{aligned}
\mathrm{BC}^{2} & =(\mathrm{AC}+\mathrm{FC}) \times(\mathrm{AC}-\mathrm{FC}) \\
& =\mathrm{AF}^{\prime} \times \mathrm{AF} ; \text { and, therefore }, \\
& \mathrm{AF}: \mathrm{BC}:: \mathrm{BC}: \mathrm{FA}^{\prime} .
\end{aligned}
$$

Cor. 2. The square of the eccentricity is equal to the difference of the squares of the semi-axes.

For $\mathrm{FC}^{2}$ is equal to $\mathrm{BF}^{2}-\mathrm{BC}^{2}$, which is equal to $\mathrm{AC}^{2}-\mathrm{BC}^{2}$.

## PROPOSITION VI. THEOREM.

A tangent to the ellipse makes equal angles with straight lines draun from the point of contact to the foci.

Let $\mathrm{F}, \mathrm{F}^{\prime}$ be the foci of an ellipse, and D any point of the curve; if through the point D the line $\mathrm{TT}^{\prime}$ be drawn, making the angle TDF equal to $\mathrm{T}^{\prime} \mathrm{DF}^{\prime}$, then will 'TT' be a tangent to the ellipse at D.
Let E be any point in the line $\mathrm{TT}^{\prime}$ different from D. Produce $F^{\prime} D$ to $G$, making DG equal to DF , and join $\mathrm{EF}, \mathrm{EF}^{\prime}, \mathrm{EG}$ and FG .

Now, in the two triangles DFH, DGH, because DF is equal to DG, DH is common to both triangles, and the angle FDH is, by supposition, equal to $\mathrm{F}^{\prime} \mathrm{DT}^{\prime}$, which is equal to the vertical angle GDH; therefore HF is equal to HG, and the angle DHF is equal to the angle DHG. Hence the line 'TT' is perpendicular to FG at its middle point; and, therefore, EF is equal to EG. Hence $\mathrm{EF}+\mathrm{EF}^{\prime}$ is equal to $\mathrm{EG}+\mathrm{EF}^{\prime}$. But $\mathrm{EG}+\mathrm{EF}^{\prime}$ is greater than $\mathrm{GF}^{\prime}$; that is, greater than $\mathrm{FD}+\mathrm{F}^{\prime} \mathrm{D}$, which is equal to the major axis of the ellipse; therefore $\mathrm{EF}+\mathrm{EF}^{\prime}$ is greater than the major axis, and hence the point E is without the ellipse (Pr. 3, Cor.). Therefore every point of the line TT' except D is without the curve; that is, $\mathrm{TT}^{\prime}$ ' is a tangent to the curve at D .

Cor.1. As the point $D$ moves toward A, each of the angles FDT, F'DT' increases, and at A becomes a right angle. Hence the tangents at the vertices of the major axis are perpendicular to that axis. Also, since the angle FBC is equal to $\mathrm{F}^{\prime} \mathrm{BC}$ (Pr. 5), the tangents at the vertices of the minor axis are perpendicular to that axis, and hence an ordinate to either axis is perpendicular to that axis.

Cor. 2. If 'TT' represent a plane mirror, a ray of light proceeding from F in the direction FD would be reflected in the direction $\mathrm{DF}^{\prime}$, making the angle of reflection equal to the angle of incidence. And, since the ellipse may be regarded as coinciding with a tangent at the point of contact, if rays of light proceed from one focus of a polished concave surface whose figure is that
produced by the revolution of an ellipse about its major axis, they will all be reflected to the other focus. For this reason, the points $\mathrm{F}, \mathrm{F}^{\prime}$ are called the foci, or burning points.

## PROPOSITION VII. THEOREM.

Tangents to the ellipse at the vertices of any cliameter are parallel to each other.

Let $\mathrm{DD}^{\prime}$ be any diameter of an ellipse, and $\mathrm{TT}^{\prime}, \mathrm{VV}^{\prime}$ tangents to the curve at the points $\mathrm{D}, \mathrm{D}^{\prime}$; then will they be parallel to each other.

Join $\mathrm{DF}, \mathrm{DF}^{\prime}, \mathrm{D}^{\prime} \mathrm{F}, \mathrm{D}^{\prime} \mathrm{F}^{\prime}$; then, by the preceding Proposition, the angle FDT is equal to $\mathrm{F}^{\prime} \mathrm{DT}^{\prime}$, and the angle $\mathrm{FD}^{\prime} \mathrm{V}$ is equal to $F^{\prime} D^{\prime} V^{\prime}$. But, by Pr. 4 ,
 $\mathrm{DFD}^{\prime} \mathrm{F}^{\prime}$ is a parallelogram ; and, since the opposite angles of a parallelogram are equal, the angle $\mathrm{FDF}^{\prime}$ is equal to $\mathrm{FD}^{\prime} \mathrm{F}^{\prime}$; therefore the angle FDT is equal to $\mathrm{F}^{\prime} \mathrm{D}^{\prime} \mathrm{V}^{\prime}$ (B. I., Pr. 2). Also, since FD is parallel to $\mathrm{F}^{\prime} \mathrm{D}^{\prime}$, the angle $\mathrm{FDD}^{\prime}$ is equal to $\mathrm{F}^{\prime} \mathrm{D}^{\prime} \mathrm{D}$; hence the whole angle $\mathrm{D}^{\prime} \mathrm{DT}$ is equal to $\mathrm{DD}^{\prime} \mathrm{V}^{\prime}$; and, consequently, $\mathrm{TT}^{\prime}$ is parallel to $V V^{\prime}$. Therefore tangents, etc.

Cor. If tangents are drawn through the vertices of any two diameters, they will form a parallelogram circumscribing the ellipse.

PROPOSITION VIII. THEOREM.
If from the vertex of any diameter straight lines are drazon through the foci, meeting the conjugate cliameter, the part intercepted by the conjugate is equal to half the major axis.

Let $\mathrm{EE}^{\prime}$ be a diameter conjugate to $\mathrm{DD}^{\prime}$, and let the lines $\mathrm{DF}, \mathrm{DF}^{\prime}$ be drawn, and produced, if necessary, so as to meet $\mathrm{EE}^{\prime}$ in H and K ; then will DH or DK be equal to AC.

Draw FG parallel to $\mathrm{EE}^{\prime}$ or $\mathrm{TT}^{\prime}$. Then the angle DGF is equal to the alternate angle $\mathrm{F}^{\prime} \mathrm{DT}^{\prime}$, and the angle DFG is equal to FDT. But the
 angles $\mathrm{FDT}, \mathrm{F}^{\prime} \mathrm{DT}^{\prime}$ are equal to each other (Pr. 7); hence the angles $D G F, D F G$ are equal to each other, and $D G$ is equal to $D F$.

Also, because CH is parallel to FG , and CF is equal to $\mathrm{CF}^{\prime}$, therefore HG must be equal to $\mathrm{HF}^{\prime}$.

Hence $\mathrm{FD}+\mathrm{F}^{\prime} \mathrm{D}$ is equal to $2 \mathrm{DG}+2 \mathrm{GH}$ or 2 DH . But $\mathrm{FD}+$ $\mathrm{F}^{\prime} \mathrm{D}$ is equal to 2 AC . Therefore 2 AC is equal to 2 DH , or AC is equal to DH .
Also, the angle DHK is equal to DKH, and hence DK is equal to DH or AC. Therefore, if from the vertex, etc.

PROPOSITION IX. THEOREM.
Perpendiculars drawn from the foci upon a tangent to the ellipse meet the tangent in the circumference of a circle whose diameter is the major axis.

Let $\mathrm{TT}^{\prime}$ be a tangent to the ellipse at $D$, and from $F^{\prime}$ draw $F^{\prime} E$ perpendicular to $\mathrm{T}^{\prime \prime} \mathrm{T}$; the point E will be in the circumference of a circle described upon $\mathrm{AA}^{\prime}$ as a diameter.

Join CE, FD, $\mathrm{F}^{\prime} \mathrm{D}$, and produce $\mathrm{F}^{\prime} \mathrm{E}$ to meet FD produced in G .

Then, in the two triangles $\mathrm{DEF}^{\prime}$, DEG, because DE is common to both triangles, the angles at E are equal, being right angles; also, the angle $\mathrm{EDF}^{\prime}$ is equal to FDT (Pr. 6), which is equal to the vertical angle $E D G$; therefore $\mathrm{DF}^{\prime}$ is equal to DG, and $\mathrm{EF}^{\prime}$ is equal to EG .

Also, because $\mathrm{F}^{\prime} \mathrm{E}$ is equal to EG , and $\mathrm{F}^{\prime} \mathrm{C}$ is equal to $\mathrm{CF}, \mathrm{CE}$ must be parallel to FG, and, consequently, equal to half of $F G$.

But, since DG has been proved equal to $\mathrm{DF}^{\prime}, \mathrm{FG}$ is equal to $\mathrm{FD}+\mathrm{DF}^{\prime}$, which is equal to $\mathrm{AA}^{\prime}$. Hence CE is equal to half of $\mathrm{AA}^{i}$ or AC ; and a circle described with C as a centre, and radius CA, will pass through the point $E$.

The same may be proved of a perpendicular let fall upon TT' from the focus F . Therefore perpendiculars, etc.

Cor. CE is parallel to DF ; and, if CH be joined, CH will be parallel to $\mathrm{DF}^{\prime}$.

> PROPOSITION X. THEOREM.

The product of the perpendiculars let fall from the foci upon a tangent is equal to the square of half the minor axis.

Let $\mathbf{T T}^{\prime}$ be a tangeat to the ellipse at any point $\mathbf{E}$, and let the
perpendiculars FD, $\mathrm{F}^{\prime} \mathrm{G}$ be drawn from the foci ; then will the product of FD by $\mathrm{F}^{\prime} G$ be equal to the square of $B C$.

On $\mathrm{AA}^{\prime}$ as a diameter, describe a circle; it will pass through the points $D$ and $G(P r .9)$.

Produce $\mathrm{GF}^{\prime}$ to meet the circle in $\mathrm{D}^{\prime}$, and join $\mathrm{DD}^{\prime}$; then, since the angle at $G$ is a right angle, $\mathrm{DD}^{\prime}$ passes through the centre $\mathbf{C}$.
 Because FD and $\mathrm{D}^{\prime} \mathrm{G}$ are perpendicular to the same straight line, they are parallel to each other, and the alternate angles CFD, $\mathrm{CF}^{\prime} \mathrm{D}^{\prime}$ are equal. Also, the vertical angles $\mathrm{DCF}, \mathrm{D}^{\prime} \mathrm{CF}^{\prime}$ are equal, and CF is equal to $\mathrm{CF}^{\prime}$. Therefore DF is equal to $\mathrm{D}^{\prime} \mathrm{F}^{\prime}$; hence $\mathrm{DF} \times G \mathrm{~F}^{\prime}$ is equal to $\mathrm{D}^{\prime} \mathrm{F}^{\prime} \times G \mathrm{~F}^{\prime}$, which is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime} \times \mathrm{F}^{\prime} \mathrm{A}$ (B. IV., Pr. 28), which is equal to $\mathrm{BC}^{2}$ (Pr. 5, Cor. 1).

Cor. The triangles FDE, $F^{\prime} G E$ are similar; hence

$$
\mathrm{FD}: \mathrm{F}^{\prime} \mathrm{G}:: \mathrm{FE}: \mathrm{F}^{\prime} \mathrm{E} ;
$$

that is, perpendiculars let fall from the foci upon a tangent are to each other as the distances of the point of contact from the foci.

PROPOSITION XI. THEOREM.
If a tangent and ordinate be drawon from the same point of an ellipse, meeting either axis produced, half of that axis will be a mean proportional between the distances of the two intersections from the centre.

1st. For the major axis.
Let TT' be a tangent to the ellipse, and DG an ordinate to the major axis from the point of contact; then we shall have

$$
\mathrm{CT}: \mathrm{CA}:: \mathrm{CA}: \mathrm{CG} .
$$

From F draw FH perpendicular to $\mathrm{TT}^{\prime}$; join $\mathrm{DF}, \mathrm{DF}^{\prime}, \mathrm{CH}$ and GH . Then, by Pr. 9, Cor., CH is parallel to $\mathrm{DF}^{\prime}$. Also, since DGF, DHF are both right angles, a circle described on DF as a diameter will pass through the points $G$ and $H$. Therefore the angle HGF is equal to the angle HDF (B. III., Pr. 15, Cor. 1),

angles are equiangular, and we have $\mathrm{C}^{\prime} \mathrm{F}: \mathrm{CH}:$ : CH:CG.
But CH is equal to CA ( Pr .9 ) ; therefore

$$
\mathrm{C}^{\prime}: \mathrm{CA}:: \mathrm{CA}: \mathrm{CG} .
$$

## 2d. For the minor axis.

Let the tangent $\mathrm{TT}^{\prime}$ meet the minor axis in $\mathrm{T}^{\prime}$, and let $\mathrm{DG}^{\prime}$ be an ordinate to the minor axis from the point of contact; then we shall have

$$
\mathrm{CT}^{\prime}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CG}^{\prime} .
$$

Draw DH perpendicular to
 TT', and it will bisect the angle $\mathrm{FDF}^{\prime \prime}$ (Pr. 6). Hence $\mathrm{HF}^{\prime}: \mathrm{HF}:: \mathrm{DF}^{\prime}: \mathrm{DF}$
:: TF ${ }^{\prime}$ : TF (Pr. 10, Cor.). Therefore (B. II., Pr. 8) $2 \mathrm{CF}: 2 \mathrm{CH}:: 2 \mathrm{CT}: 2 \mathrm{CF}$. Whence $\mathrm{CT} \times \mathrm{CH}=\mathrm{CF}^{2}$.

But we have proved that
$\mathrm{CT} \times \mathrm{CG}=\mathrm{CA}^{2}$.
Subtracting the former from the latter, we have

$$
\mathrm{CT} \times \mathrm{GH}=\mathrm{CA}^{2}-\mathrm{CF}^{2}=\mathrm{CB}^{2}
$$

Because the triangles DGH and $\mathrm{CTT}^{\prime}$ are similar, we have CT: C' ${ }^{\prime}:: D G: G H$.
Whence
Therefore
$\mathrm{CT} \times \mathrm{GH}=\mathrm{CT}^{\prime} \times \mathrm{DG}=\mathrm{CT}^{\prime} \times \mathrm{CG}^{\prime}$.
$\mathrm{CT}^{\prime} \times \mathrm{CG}^{\prime}=\mathrm{CB}^{2}$, or

$\mathrm{C}^{\prime} \mathrm{T}^{\prime}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CG}^{\prime}$.
Cor: By this Proposition, $\mathrm{CA}^{2}=\mathrm{CG} . \mathrm{CT}$.
If a second ordinate $d g$, and tangent $d t$, be drawn, we shall also have

$$
\mathrm{CA}^{2}=\mathrm{C} g \cdot \mathrm{C} t
$$

Whence
$\mathrm{CG} . \mathrm{CT}=\mathrm{C} g . \mathrm{C} t$
$\mathrm{GC}: \mathrm{C} g:: \mathrm{C} t: \mathrm{CT}$.

## PROPOSITION XII. THEOREM.

The subtangent of an ellipse is equal to the corresponding subtangent of the circle described upon its major axis.

Let AEA' be a circle described on $\mathrm{AA}^{\prime}$, the major axis of an ellipse, and from any point E in the circle draw the ordinate EG, cutting the ellipse in D. Draw DT touching the ellipse at D, and join ET; then will ET be a tangent to the circle at E .

Join CE. Then, by the last Proposition,
CT:CA::CA:CG;
or, because $C A$ is equal to $C E$,
CT: CE :: CE : CG.
Hence the triangles CET, CGE, having the angle at C common, and the sides about this angle proportional, are similar (B.IV., Pr. 21). Therefore the angle CET, being equal to the angle CGE, is a right angle; that is, the line ET is perpendicular to the radius CE , and is, consequently, a tangent to the circle ( B . III., Pr. 9). Hence GT is the subtangent corresponding to each of the tangents DT and ET. Therefore the subtangent, etc.

Cor. A similar property may be proved of a tangent to the ellipse meeting the minor axis.

## PROPOSITION XIII. THEOREM.

The square of either axis is to the square of the other as the rectangle of the abscissas of the former is to the square of their ordinate.

1st. For the major axis.
Let DE be an ordinate to the major axis from the point $D$; then we shall have
$\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{AE} \times \mathrm{EA}^{\prime}: \mathrm{DE}^{2}$.
Draw TT ${ }^{\prime}$ a tangent to the ellipse at D ; then, by Pr. 11, CT:CA::CA:CE.
Hence (B. II., Pr. 13)
CT: CE:: $\mathrm{CA}^{2}: \mathrm{CE}^{2}$;
 and by division (B. II., Pr. 7),

$$
\begin{equation*}
\mathrm{CT}: \mathrm{ET}^{\prime}: \mathrm{CA}^{2}: \mathrm{CA}^{2}-\mathrm{CE}^{2} \tag{1}
\end{equation*}
$$

Again, by Pr. 11,
$\mathrm{CT}^{\prime}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CE}^{\prime}$ or DE . Hence $\mathrm{CT}^{\prime}: \mathrm{DE}:: \mathrm{CB}^{2}: \mathrm{DE}^{2}$. But, by similar triangles, $\mathrm{CT}^{\prime}: \mathrm{DE}:$ : $\mathrm{CT}: \mathrm{ET}$;
Therefore

$$
\begin{equation*}
\mathrm{CT}: \mathrm{ET}:: \mathrm{CB}^{2}: \mathrm{DE}^{2} \tag{2}
\end{equation*}
$$

Comparing proportions (1) and (2), we have $\quad \mathrm{CA}^{2}: \mathrm{CA}^{2}-\mathrm{CE}^{2}:: \mathrm{CB}^{2}: \mathrm{DE}^{2}$.
But $\mathrm{CA}^{2}-\mathrm{CE}^{2}$ is equal to $\mathrm{AE} \times \mathrm{EA}^{\prime}$ (B.IV., Pr. 10).
Hence

$$
\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{AE} \times \mathrm{EA}^{\prime}: \mathrm{DE}^{2}
$$

2d. For the minor axis.
Let $\mathrm{DE}^{\prime}$ be an ordinate to the minor axis; then we shall have $\mathrm{CB}^{2}: \mathrm{CA}^{2}:: \mathrm{BE}^{\prime} \times \mathrm{E}^{\prime} \mathrm{B}^{\prime}: \mathrm{DE}^{\prime 2}$.
We have already proved that

$$
\mathrm{CA}^{2}: \mathrm{CA}^{2}-\mathrm{CE}^{2}:: \mathrm{CB}^{2}: \mathrm{DE}^{2}\left(=\mathrm{CE}^{\prime 2}\right) ;
$$

therefore, by division,

$$
\mathrm{CA}^{2}: \mathrm{CE}^{2}:: \mathrm{CB}^{2}: \mathrm{CB}^{2}-\mathrm{CE}^{\prime 2}
$$

or

$$
\mathrm{CB}^{2}: \mathrm{CA}^{2}:: \mathrm{CB}^{2}-\mathrm{CE}^{\prime 2}: \mathrm{DE}^{\prime 2}
$$

But $\quad \mathrm{CB}^{2}-\mathrm{CE}^{\prime 2}$ is equal to $\mathrm{BE}^{\prime} \times \mathrm{E}^{\prime} \mathrm{B}^{\prime}$ (B.IV., $\mathrm{Pr}: 10$ ).
Hence

$$
\mathrm{CB}^{2}: \mathrm{CA}^{2}:: \mathrm{BE}^{\prime} \times \mathrm{E}^{\prime} \mathrm{B}^{\prime}: \mathrm{DE}^{\prime 2}
$$

Cor. 1. $\quad \mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CA}^{2}-\mathrm{CE}^{2}: \mathrm{DE}^{2}$.
Cor. 2. The squares of the ordinates to either axis are to each other as the rectangles of their abscissas.

PROPOSITION XIV. THEOREM.
If a circle be described on either axis, then any ordinate in the circle is to the corresponding ordinate in the ellipse as the axis of that ordinate is to the other axis.

Let a circle be described on $\mathrm{AA}^{\prime}$ as a diameter, and let DE , an ordinate to the axis, be produced to meet the circle in $G$; then

GE : DE :: AC : BC.
For (Pr. 13) $\mathrm{AC}^{2}: \mathrm{BC}^{2}:: \mathrm{AE} \times \mathrm{EA}^{\prime}: \mathrm{DE}^{2}$.
But $\mathrm{AE} \times \mathrm{EA}^{\prime}$ is equal to $\mathrm{GE}^{2}$ (B.IV., Pr. 23, Cor.)
Therefore
$\mathrm{AC}^{2}: \mathrm{BC}^{2}:: \mathrm{GE}^{2}: \mathrm{DE}^{2}$, or
AC : BC : : GE : DE.

Also, if a circle be described on $\mathrm{BB}^{\prime}$ as a diameter, and the ordinate $\mathrm{DE}^{\prime}$ be drawn meeting the circle in $\mathrm{G}^{\prime}$, then

$$
\mathrm{G}^{\prime} \mathrm{E}^{\prime}: \mathrm{DE}^{\prime}:: \mathrm{BC}: \mathrm{AC} .
$$

## PROPOSITION XV. THEOREM.

The latus rectum is a third proportional to the major and minor axes.

Let LL' be a double ordinate to the major axis passing through the focus F ; then we shall have

$$
\mathrm{AA}^{\prime}: \mathrm{BB}^{\prime}:: \mathrm{BB}^{\prime}: \mathrm{LL}^{\prime} .
$$

Because LF is an ordinate to the major axis,

$$
\begin{aligned}
& \mathrm{AC}^{2}: \mathrm{BC}^{2}:: \mathrm{AF} \times \mathrm{FA}^{\prime}: \mathrm{LF}^{2}(\mathrm{Pr} .13) . \\
& \\
& \\
& \\
& \text { Hence } \\
& \text { or }
\end{aligned}
$$

Therefore the latus rectum, etc.

## PROPOSITION XVI. THEOREM.

If one diameter of an ellipse is conjugate to another, and if from the vertices of these two diameters ordinates be drawn to either axis, the sum of the squares of these ordinates will be equal to the square of half the other axis.
Let the diameter $\mathrm{EE}^{\prime}$ be conjugate to $\mathrm{DD}^{\prime}$; and let DG and EH, ordinates to the major axis, be drawn from their vertices; in which case CG and CH will be equal to the ordinates of the minor axis drawn from the same points; then we shall have

$\mathrm{CG}^{2}+\mathrm{CH}^{2}=\mathrm{CA}^{2}$;
$\mathrm{DG}^{2}+\mathrm{EH}^{2}=\mathrm{CB}^{2}$.
and
er describe the circle $\mathrm{AMA}^{\prime}$, and produce Upon $A A^{\prime}$ as a diameter circumference in $M$ and $N$. Draw the
$D G$ and $E H$ to cut the coll tangents at D and M , which will meet each other in T , in the axis produced (Pr. 12). Join CM and CN.

Since DT is parallel to EC, the triangles DTG and ECII are similar, and therefore

## CH:GT :: EH:DG <br> :: NH: MG. By Pr. 14.

Hence the triangle NHC is similar to MGT, and it is also similar to MCG (B.IV., Pr. 23). But the hypothenuse $\mathrm{CM}=\mathrm{CN}$; therefore $\mathrm{MG}=\mathrm{CH}$; and, consequently,

$$
\mathrm{CG}^{2}+\mathrm{CH}^{2}=\mathrm{CG}^{2}+\mathrm{G} \mathrm{M}^{2}=\mathrm{CM}^{2}=\mathrm{CA}^{2} .
$$

Secondly. By Pr. 14,

$$
\begin{aligned}
\mathrm{AC}^{2}: \mathrm{BC}^{2}: & : \mathrm{NH}^{2}: \mathrm{EH}^{2} \\
& :: \mathrm{MG}^{2}: \mathrm{DG}^{2} \\
& :: \mathrm{NH}^{2}+\mathrm{MG}^{2}: \mathrm{EH}^{2}+\mathrm{DG}^{2} \text { (B. II., Pr. } 6 \text { ) } . \\
& \mathrm{NH}^{2}+\mathrm{MG}^{2}=\mathrm{NH}^{2}+\mathrm{CH}^{2}=\mathrm{CN}^{2}=\mathrm{AC}^{2} ; \\
& \quad \mathrm{EH}^{2}+\mathrm{DG}^{2}=\mathrm{BC}^{2} .
\end{aligned}
$$

But
therefore
Therefore, if one diameter, etc.
Cor. 1. Since $\mathrm{CG}^{2}=\mathrm{NH}^{2}$, we have

$$
\mathrm{AC}^{2}: \mathrm{BC}^{2}:: \mathrm{CG}^{2}: \mathrm{EH}^{2}
$$

Cor. 2. If one diameter of an ellipse is conjugate to another, the second is conjugate to the first. For if the tangent $\mathbf{E T}^{\prime}$ be drawn, it will be parallel to $\mathrm{DD}^{\prime}$.

Draw $\mathrm{NT}^{\prime}$; it will be tangent to the circle at N , and the triangle $\mathrm{NT}^{\prime} H$ will be similar to NHC; that is, to CGM.
Hence
T'H:CG: : NH:MG
: : EH:DG.
Therefore the triangles $\mathrm{ET}^{\prime} H$ and DCG are similar, and $\mathrm{ET}^{\prime}$ is parallel to CD.

Cor. 3. Since

$$
\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{MG}^{2}: \mathrm{DG}^{2},
$$

and

$$
\mathrm{MG}^{2}=\text { CG.GT (B. IV., Pr. 23, Cor.), }
$$ we have $\mathrm{CA}^{2}: \mathrm{CB}^{2}:$ : CG.GT: $\mathrm{DG}^{2}$.

If a second ordinate $d g$, and tangent $d t$ be drawn, we shall have $\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{C} g \cdot g t: d g^{2}$.
Hence CG.GT: C $g \cdot g t:: \mathrm{DG}^{2}: \operatorname{cl}^{2}$.

PROPOSITION XVII. THEOREM.
The sum of the squares of any two conjugate diameters is equal to the sum of the squares of the axes.

Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be any two conjugate diameters; then we shall have $\quad \mathrm{DD}^{\prime 2}+\mathrm{EE}^{\prime 2}=\mathrm{AA}^{\prime 2}+\mathrm{BB}^{\prime 2}$.

Draw DG, EH ordinates to the major axis. Then, by the preceding Proposition, $\quad \mathrm{CG}^{2}+\mathrm{CH}^{2}=\mathrm{CA}^{2}$,
and $\quad \mathrm{DG}^{2}+\mathrm{EH}^{2}=\mathrm{CB}^{2}$.

## Hence

$\mathrm{CG}^{2}+\mathrm{DG}^{2}+\mathrm{CH}^{2}+\mathrm{EH}^{2}=\mathrm{CA}^{2}+\mathrm{CB}^{2}$,
or $\mathrm{CD}^{2}+\mathrm{CE}^{2}=\mathrm{CA}^{2}+\mathrm{CB}^{2}$;
that is

$$
\mathrm{DD}^{\prime 2}+\mathrm{EE}^{\prime 2}=\mathrm{AA}^{\prime 2}+\mathrm{BB}^{\prime 2}
$$

Therefore the sum of the squares, etc.

PROPOSITION XVIII. THEOREM.
The parallelogram formed by drawing tangents through the vertices of twoo conjugate diameters is equal to the rectangle of the axes.

Let $\mathrm{DED}^{\prime} \mathrm{E}^{\prime}$ be a parallelogram formed by drawing tangents to the ellipse through the vertices of two conjugate diameters $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$; its area is equal to $\mathrm{AA}^{\prime} \times \mathrm{BB}^{\prime}$.

Let the tangent at D meet the major axis produced in $T$; join $\mathrm{E}^{\prime} \mathrm{T}$, and draw the ordinates DG, $\mathrm{E}^{\prime} \mathrm{H}$.
Then, by Pr. 16, Cor. 1, we have
$\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CG}^{2}: \mathrm{E}^{\prime} \mathrm{H}^{2}$, or $\mathrm{CA}: \mathrm{CB}:: \mathrm{CG}: \mathrm{E}^{\prime} \mathrm{H}$.

But
hence
CT:CA::CA:CG (Pr. 11);
or
$\mathrm{CA} \times \mathrm{CB}$ is equal to $\mathrm{CT} \times \mathrm{E}^{\prime} \mathrm{H}$,
which is equal to twice the triangle CE'T, or the parallelogram $\mathrm{DE}^{\prime}$; since the triangle and parallelogram have the same base $\mathrm{CE}^{\prime}$, and are between the same parallels.

Hence $4 \mathrm{CA} \times \mathrm{CB}$ or $\mathrm{AA}^{\prime} \times \mathrm{BB}^{\prime}$ is equal to $4 \mathrm{DE}^{\prime}$, or the parallelogram DED'E'. Therefore the parallelogram, etc.
proposition xix. theorem.
If from the vertex of any diameter straight lines are drawn to the foci, their product is equal to the square of half the conjugate diameter.

Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be two conjugate diameters, and from D let lines be drawn to the foci; then will $\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}$ be equal to $\mathrm{EC}^{2}$.

Draw a tangent to the ellipse at D , and upon it let fall the perpendiculars $\mathrm{FG}, \mathrm{F}^{\prime} \mathrm{H}$; draw, also, DK perpendicular to $\mathrm{EE}^{\prime}$.

Then, because the triangles DFG, DLK, $\mathrm{DF}^{\prime} \mathrm{H}$ are similar, we have FD:FG::DL:DK. Also, $F^{\prime} D: F^{\prime} H:: D L: D K$. Whence (B. II, Pr. 12)
$\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}: \mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}:: \mathrm{DL}^{2}: \mathrm{DK}^{2}$. (1) But, by Pr. 18, $\mathrm{AC} \times \mathrm{BC}=\mathrm{EC} \times \mathrm{DK} ;$
whence

$$
\begin{gather*}
\mathrm{AC} \text { or } \mathrm{DL}: \mathrm{DK}:: \mathrm{EC}: \mathrm{BC}, \\
\mathrm{DL}^{2}: \mathrm{DK}^{2}:: \mathrm{EC}^{2}: \mathrm{BC}^{2} . \tag{2}
\end{gather*}
$$

and
Comparing proportions (1) and (2), we have

$$
\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}: \mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}:: \mathrm{EC}^{2}: \mathrm{BC}^{2}
$$

But $\mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}$ is equal to $\mathrm{BC}^{2}(\mathrm{Pr} .10)$; hence $\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}$ is equal to $\mathrm{EC}^{2}$. Therefore, if from the vertex, etc.

> PROPOSITION XX. THEOREM.

If a tangent and ordinate be ḋrawn from the same point of an ellipse to any diameter, half of that diameter will be a mean proportional between the distances of the two intersections from the centre.

Let a tangent EG and an ordinate EH be drawn from the same point E of an ellipse, meeting the diameter CD produced; then we shall have $\quad \mathrm{CG}: \mathrm{CD}:: \mathrm{CD}: \mathrm{CH}$.

Produce EG and EH to meet the major axis in K and L ; draw DT a tangent to the curve at the point D, and draw DM parallel to GK. Also, draw the ordinates EN, DO.
By similar triangles we have

> OM:NK::DO:EN,
and also OT:NL::DO:EN.
Multiplying together the terms of these proportions (B. II., Pr. 12), we have

OM.OT :: NK.NL ::DO2 $: \mathrm{EN}^{2}::$ CO.OT : CN.NK (Pr. 16, Cor: 3). Omitting the factor OT in the antecedents, and NK in the consequents of this proportion (B. II., Pr. 10, Cor.), we have OM: NL::CO:CN,
and, by composition, CO:CN ::CM:CL. But, by Pr. 11, Cor., CO:CN :: CK:CT. Whence
But and hence Therefore, if a tangent, etc.

## PROPOSITION XXI. THEOREM.

The square of any diameter is to the square of its conjugate as the rectangle of its abscissas is to the square of their ordinate.

Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be two conjugate diameters, and GH an ordinate to $\mathrm{DD}^{\prime}$; then
$\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{GH}^{2}$.
Draw 'TT' a tangent to the curve at the point G, and draw GK an ordinate to EE'. Then, by Pr. 20,

$$
\mathrm{CT}: \mathrm{CD}:: \mathrm{CD}: \mathrm{CH},
$$

and $\mathrm{CD}^{2}: \mathrm{CH}^{2}:: \mathrm{CT}: \mathrm{CH}$ (B.II., Pr. 13);
whence, by division,

$$
\begin{equation*}
\mathrm{CD}^{2}: \mathrm{CD}^{2}-\mathrm{CH}^{2}:: \mathrm{CT}: \mathrm{HT} . \tag{1}
\end{equation*}
$$

$\mathrm{CT}^{\prime}$ : CE::CE:CK,

Also, by Pr. 20, and
$\mathrm{CE}^{2}: \mathrm{CK}^{2}:: \mathrm{CT}^{\prime}: \mathrm{CK}$ or GH , :: CT:HT.

Comparing proportions (1) and (2), we have
$\mathrm{CD}^{2}: \mathrm{CE}^{2}:: \mathrm{CD}^{2}-\mathrm{CH}^{2}: \mathrm{CK}^{2}$ or $\mathrm{GH}^{2}$,
$\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{GH}^{2}$.
or
Therefore the square, etc.
Cor. 1. In the same manner, it may be proved that $\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}$ $:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{G}^{\prime} \mathrm{H}^{2}$; hence GH is equal to $\mathrm{G}^{\prime} \mathrm{H}$, or every cliameter bisects all chords parallel to the tangents at its vertices.

Cor.2. The squares of the ordinates to any diameter are to each other as the rectangles of their abscissas.

## PROPOSITION XXII. THEOREM.

If a cone be cut by a plane, making an angle with the base less than that made by the side of the cone, the section is an ellipse.

Let ABC be a cone cut by a plane DE GH, making an angle with the base less than that made by the side of the cone; the section $\mathrm{DeEGH} h$ is an ellipse.

Let ABC be a section through the axis of the cone, and perpendicular to the plane DEGH. Let EMHO, emho be circular sections parallel to the base; then EH , the intersection of the planes DEGH, EMHO will be perpendicular to the plane ABC , and, consequently, to each of the lines $\mathrm{DG}, \mathrm{MO}$. So, also, eh will be perpendicular to DG and mo.

Now, because the triangles DNO, Dno are similar, as also the triangles GMN, Gmn, we have the proportions
NO : no::DN:Dn,
and

$$
\mathrm{MN}: m n:: \mathrm{NG}: n \mathrm{G} .
$$

Hence, by B. II., Pr. 12,

$$
\mathrm{MN} \times \mathrm{NO}: m n \times n o:: \mathrm{DN} \times \mathrm{NG}: \mathrm{D} n \times n \mathrm{G} .
$$

But, since MO is a diameter of the circle EMHO, and EN is perpendicular to MO, we have (B. IV., Pr. 23, Cor.)

$$
\begin{aligned}
\mathrm{MN} \times \mathrm{NO} & =\mathrm{EN}^{2} . \\
m n \times n o & =e n^{2} .
\end{aligned}
$$

For the same reason,
Substituting these values of $\mathrm{MN} \times \mathrm{NO}$ and $m n \times n o$ in the preceding proportion, we have

$$
\mathrm{EN}^{2}: e n^{2}:: \mathrm{DN} \times \mathrm{NG}: \mathrm{D} n \times n \mathrm{G} ;
$$

that is, the squares of the ordinates to the diameter $D G$ are to each other as the products of the corresponding abscissas. Therefore the curve is an ellipse (Pr. 13, Cor. 2), whose major axis is DG. Hence the ellipse is called a conic section, as mentioned on page 203.

Scholium. The conclusion that the curve DEGH is an ellipse would not be legitimate unless the property above demonstrated were peculiar to the ellipse. That such is the case appears from the fact that when the major axis and one point of an ellipse are given, this property will determine the position of every other point of the curve, in the same manner as was shown in the corresponding Proposition for the parabola, p. 215.

## PROPOSITION XXIII. THEOREM.

The area of an ellipse is a mean proportional between the two circles described on its axes.

Let $\mathrm{AA}^{\prime}$ be the major axis of an ellipse $\mathrm{ABA}^{\prime} \mathrm{B}^{\prime}$. On $\mathrm{AA}^{\prime}$ as a diameter describe a circle; inscribe in the circle any regular polygon $\mathrm{AEDA}^{\prime}$, and from the vertices $\mathrm{E}, \mathrm{D}$, etc., of the polygon draw perpendiculars to $\mathrm{AA}^{\prime}$ '. Join the 'points $\mathrm{B}, \mathrm{G}$, etc., in which these perpendiculars intersect the ellipse, and there will be inscribed in the ellipse a polygon of an equal number of sides.

Now the area of the trapezoid CEDH is equal to $(\mathrm{CE}+\mathrm{DH}) \times$ CH $\times \frac{\mathrm{CH}}{2}$. These trapezoids are to each other as $\mathrm{CE}+\mathrm{DH}$ to $\mathrm{CB}+\mathrm{GH}$, or as AC to BC (Pr. 14).

In the same manner, it maybe proved that each of the trapezoids composing the polygon inscribed in the circle is to the corresponding trapezoid of the polygon inscribed in the ellipse as AC to BC. Hence the entire polygon in-
 scribed in the circle is to the polygon inscribed in the ellipse as AC to BC .

Since this proportion is true, whatever be the number of sides of the polygons, it will be true when the number is indefinitely increased; in which case one of the polygons coincides with the circle, and the other with the ellipse. Hence we have

$$
\text { area of circle: area of ellipse :: } \mathrm{AC}: \mathrm{BC} \text {. }
$$

But the area of the circle is represented by $\pi \mathrm{AC}^{2}$; hence the area of the ellipse is equal to $\pi \mathrm{AC} \times \mathrm{BC}$, which is a mean proportional between the two circles described on the axes.

PROPOSITION XXIV. THEOREM.
The distance of any point in an ellipse from either focus is to its distance from the corresponding directrix as the eccentricity to half the major axis.

Let D be any point in the ellipse; let $\mathrm{DF}, \mathrm{DF}^{\prime}$ be drawn to the two foci, and DG, DG' perpendicular to the directrices; then DF : DG :: $\mathrm{DF}^{\prime}: \mathrm{DG}^{\prime}:: \mathrm{CF}: \mathrm{CA}$.

Draw DE perpendicular to the major axis, and take H , a point in the axis, so that $\mathrm{AH}=\mathrm{DF}$, and consequently $\mathrm{HA}^{\prime}=\mathrm{DF}^{\prime \prime}$; then CH is half the difference between $\mathrm{A}^{\prime} \mathrm{H}$ and AH , or $\mathrm{DF}^{\prime}$ and DF , and CE is half the difference between FE and F'E. By B. IV., Pr. 34, $\mathrm{FF}^{\prime \prime}: \mathrm{DF}^{\prime}+\mathrm{DF}:: \mathrm{DF}^{\prime \prime}-\mathrm{DF}: \mathrm{F}^{\prime} \mathrm{E}-\mathrm{FE}$.
Dividing each term by two, we have CF:CA::CH:CE.
But, by Pr. 11, CA: CT::CF:CA.
Therefore
$\mathrm{CA}: \mathrm{CT}:$ : $\mathrm{CH}: \mathrm{CE}$.
Hence (B. II., Pr. 7)
$\mathrm{CA}-\mathrm{CH}: \mathrm{CT}-\mathrm{CE}:: \mathrm{CA}: \mathrm{CT}$,
or
that is, $\quad \mathrm{DF}: \mathrm{DG}:: \mathrm{CF}: \mathrm{CA}$.
In the same manner, it may be proved that

$$
\mathrm{DF}^{\prime}: \mathrm{DG}^{\prime}:: \mathrm{CF}: \mathrm{CA} .
$$

## EXERCISES ON THE ELLIPSE.

1. If a series of ellipses be described having the same major axis, the tangents at the extremities of their latera recta will all meet the minor axis in the same point.
2. The foci of an ellipse being given, it is required to describe an ellipse touching a given straight line.
3. If the angle $\mathrm{FBF}^{\prime \prime}$ be a right angle, prove that $\mathrm{CA}^{2}=2 \mathrm{CB}^{2}$. (See fig., Pr. 5.)
4. If a circle be described touching the major axis in one focus, and passing through one extremity of the minor axis, AC will be a mean proportional between $B C$ and the diameter of this circle. (See fig., Pr. 5.)
5. If, on the two axes of an ellipse as diameters, circles be described, and a line be drawn cutting the larger circle in H and $\mathrm{H}^{\prime}$, and the smaller circle in K and $\mathrm{K}^{\prime}$, then $\mathrm{HK} . \mathrm{H}^{\prime} \mathrm{K}=\mathrm{CF}^{2}$. (See fig., Pr. 14.)
6. If $D G$ produced meet the tangent at the extremity of the latus rectum in $K$, then $K G=D F$. (See fig., Pr. 11.)
7. A tangent to the ellipse makes a greater angle with a line drawn from the point of contact to one of the foci than with the perpendicular on the directrix. (See fig., Pr. 24.)
8. If from C one line be drawn parallel, and another perpendicular to the tangent at D , they inclose a part of $\mathrm{DF}^{\prime}$ equal to DF . (See fig., Pr. 9.)
9. If the tangent at the vertex $A$ cut any two conjugate diameters in T and $t$, then AT.A $t=\mathrm{BC}^{2}$. (See fig., Pr. 16.)
10. What is the area of an ellipse whose axes are 46 and 34 feet?
11. An ordinate to the major axis of an ellipse is 7 inches, and the corresponding abscissas are 5 and 20 inches; required the latus rectum.
12. The latus rectum of an ellipse is 11 inches, and the major axis 26 inches; required the area of the ellipse.
13. The eccentricity of an ellipse is 10 inches, and its latus rectum 12 inches; required the area of the ellipse.
14. Supposing a meridional section of the earth to be an ellipse whose major axis is 7926 miles, and its minor axis 7900 miles, what is the area of the section?
15. What is the latus rectum of the terrestrial ellipse, and what is its eccentricity?
16. What is the distance of the directrix of the terrestrial ellipse from the nearest vertex of the major axis?
17. If the axes of an ellipse are 60 and 100 feet, what is the radius of a circle described to touch the curve, when its centre is in the major axis at the distance of 16 feet from the centre of the ellipse?

Ans. 27.495 feet.
18. If the axes of an ellipse are 60 and 80 feet, what are the areas of the two segments into which it is divided by a line perpendicular to the major axis at the distance of 10 feet from the centre? . Ans. 1291.27 and 2478.65 feet.
19. The minor axis of an ellipse is 8 inches, the latus rectum 5 inches, and an ordinate of 3 inches is drawn to the major axis; determine where the tangent line drawn through the extremity of this ordinate meets the major axis produced.
20. Determine where the tangent line in the last example meets the minor axis produced.

## H Y P E R B O L A.

## Definitions.

1. An hyperbola is a plane curve traced out by a point which moves in such a manner that the difference of its distances from two fixed points is always the same.
2. The two fixed points are called the foci of the hyperbola.

Thus, if F and $\mathrm{F}^{\prime}$ are two fixed points,
 and if the point D moves about F in such a manner that the difference of its distances from $F$ and $F^{\prime}$ is always the same, the point D will describe an hyperbola, of which F and $\mathrm{F}^{\prime}$ are the foci.

If the point $\mathrm{D}^{\prime}$ moves about $\mathrm{F}^{\prime}$ in such a manner that $\mathrm{D}^{\prime} \mathrm{F}-\mathrm{D}^{\prime} \mathrm{F}^{\prime}$ is always equal to $\mathrm{DF}^{\prime}-\mathrm{DF}$, the point $\mathrm{D}^{\prime}$ will describe a second branch of the curve similar to the first. The two branches are called branches of the hyperbola.
3. The centre of the hyperbola is the middle point of the straight line joining the foci.
4. The eccentricity is the distance from either focus to the centre.

Thus, let F and $\mathrm{F}^{\prime}$ be the foci of an hyperbola. Draw the line $\mathrm{FF}^{\prime}$, and bisect it in C . The point C is the centre of the hyperbola, and CF or $\mathrm{CF}^{\prime}$ is the eccentricity.
5. A diameter is any straight line passing through the centre, and terminated on both sides by opposite branches of an hyperbola.
6. The extremities of a diameter are called its vertices.

Thus, through C draw any straight line $\mathrm{DD}^{\prime}$ terminated by the opposite curves; $\mathrm{DD}^{\prime}$ is a diameter of the hyperbola; D and $\mathrm{D}^{\prime}$ are the vertices of that diameter.
7. The transverse axis is the diameter which, when produced, passes through the foci.
8. The conjugate axis is a line drawn through the centre perpendicular to the transverse axis, and terminated by the circum-
ference described from one of the vertices of the transverse axis as a centre, and with a radius equal to the eccentricity.

Thus, through C draw $\mathrm{BB}^{\prime}$ perpendicular to $\mathrm{AA}^{\prime}$, and with A as a centre, and with CF as a radius, describe a circumference cutting this perpendicular in B and $\mathrm{B}^{\prime}$; then $\mathrm{AA}^{\prime}$ is the transverse axis, and $\mathrm{BB}^{\prime}$ the conjugate axis.

If, on $\mathrm{BB}^{\prime}$ as a transverse axis, opposite branches of an hyperbola are described, having $\mathrm{AA}^{\prime}$ as their conjugate axis, this hyperbola is said to be conjugate to the former.
9. A tangent to an hyperbola is a straight line which meets the curve in one point only, and every where else falls without it.
10. An ordinate to a diameter is a straight line drawn from any point of the curve to meet the diameter produced, and is parallel to the tangent at one of its vertices.

Thus, let $\mathrm{DD}^{\prime}$ be any diameter, and $\mathrm{TT}^{\prime}$ a tangent to the hyperbola at D . From any point $G$ of the curve draw GKG' parallel to $\mathrm{TT}^{\prime}$, and cutting $\mathrm{DD}^{\prime}$ produced in K ; then is GK an ordinate to the diameter $\mathrm{DD}^{\prime}$.

It is proved in Pr. 21, Cor. 1, that GK is equal to $\mathrm{G}^{\prime} \mathrm{K}$; hence the entire
 line $\mathrm{GG}^{\prime}$ is called a double ordinate.
11. The parts of the diameter produced, intercepted between its vertices and an ordinate, are called its abscissas.

Thus, DK and D'K are the abscissas of the diameter $\mathrm{DD}^{\prime}$ corresponding to the ordinate GK.
12. When the ordinates of a diameter of an hyperbola are parallel to a diameter of the conjugate hyperbola, the latter diameter is said to be conjugate to the former.

Thus, draw the diameter EE' parallel to GK, an ordinate to the diameter $\mathrm{DD}^{\prime}$, in which case it will, of course, be parallel to the tangent $\mathrm{TT}^{\prime}$; then is the diameter $\mathrm{EE}^{\prime}$ conjugate to $\mathrm{DD}^{\prime}$.
13. The latus rectum is the donble ordinate to the transverse axis which passes through one of the foci.

Thus, through the focus $\mathrm{F}^{\prime}$ draw $\mathrm{LL}^{\prime}$, a double ordinate to the transverse axis; it will be the latus rectum of the hyperbola.

14. A subtangent is that part of an axis produced which is included between a tangent and the ordinate drawn from the point of contact.
Thus, if ' $\mathrm{TT}^{\prime}$ ' be a tangent to the curve at D , and DG an ordinate to the transverse axis, then GT is the corresponding subtangent.
15. The directrix of an hyperbola is a straight line perpendicular to the transverse axis, and intersecting it in the same point
 with the tangent to the curve at one extremity of the latus rectum.

Thus, if LT be a tangent drawn through one extremity of the latus rectum LL', meeting the axis in T, and, through the point of intersection, $\mathrm{GG}^{\prime}$ be drawn perpendicular to the axis, it will be the directrix of the hyperbola.
The hyperbola has two directrices, one corresponding to the focus F , and the other to the.focus $\mathrm{F}^{\prime}$.

PROPOSITION I. THEOREM.
The difference of the two lines drawn from any point of an hyperbola to the foci is equal to the transverse axis.

Let $F$ and $F^{\prime}$ be the foci of two opposite hyperbolas, $\mathrm{AA}^{\prime}$ the transverse axis, and D any point of the curve; then will $\mathrm{DF}^{\prime}-\mathrm{DF}$ be equal to $\mathrm{AA}^{\prime}$.

For, by Def. 1, the difference of the distances of any point of the curve from the foci is equal to a given line. Now when the point $D$ arrives at $A, F^{\prime} A$ FA , or $\mathrm{AA}^{\prime}+\mathrm{F}^{\prime} \mathrm{A}^{\prime}-\mathrm{FA}$, is equal to the given line. And when $D$ is at $\mathrm{A}^{\prime}, \mathrm{FA}^{\prime}-\mathrm{F}^{\prime} \mathrm{A}^{\prime}$, or $A \mathrm{~A}^{\prime}+\mathrm{AF}-\mathrm{A}^{\prime} \mathrm{F}^{\prime}$, is equal to the same line. Hence $\mathrm{AA}^{\prime}+\mathrm{AF}-\mathrm{A}^{\prime} \mathrm{F}^{\prime}=\mathrm{AA}^{\prime}+\mathrm{F}^{\prime} \mathrm{A}^{\prime}-\mathrm{FA}$,
or

$$
2 \mathrm{AF}=2 \mathrm{~A}^{\prime} \mathrm{F}^{\prime} ;
$$

that is, AF is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime}$.
Hence $\mathrm{DF}^{\prime}-\mathrm{DF}$, which is equal to $\mathrm{AF}^{\prime \prime}-\mathrm{AF}$, must be equal to AA'. Therefore the difference of the two lines, etc.

Cor. The transverse axis is bisected in the centre. For, by Def. 3, CF is equal to $\mathrm{CF}^{\prime}$; and we have just proved that AF is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime}$; therefore AC is equal to $\mathrm{A}^{\prime} \mathrm{C}$.

## PROPOSITION II. PROBLEM.

The transverse axis and foci of an hyperbola being given, to clescribe the curve.

First method. By points.
Let $A A^{\prime}$ be the transverse axis, and $F, F^{\prime}$ the foci of an hyperbola. In the transverse axis $\mathrm{AA}^{\prime}$ produced, take any point E , and from F and $\mathrm{F}^{\prime}$ as centres, with the distances $A E, A^{\prime} E$ as radii, describe two circles cutting each other in the point D ; D will be a point in the hyperbola. For, join FD, $F^{\prime} D$; then
 $\mathrm{DF}^{\prime \prime}-\mathrm{DF}=\mathrm{EA}^{\prime}-\mathrm{EA}=\mathrm{AA}^{\prime}$; and at whatever point of the transverse axis produced E is taken, the difference between $\mathrm{DF}^{\prime}$ and DF will be equal to AA'. Hence, by Def. $1, \mathrm{D}$ is a point on the curve ; and, in the same manner, any number of points in the hyperbola may be determined. In a similar manner the opposite branch may be constructed.

Cor. The same circles determine two points of the curve D and $\mathrm{D}^{\prime}$, one above and one below the transverse axis. It is also evident that these two points are equally distant from the axis; that is, the hyperbola is symmetrical with respect to its transverse axis.

Second method. By continuous motion.
Take a ruler longer than the distance $\mathrm{FF}^{\prime}$, and fasten one of its extremities at the point $\mathbf{F}^{\prime}$. Take a thread shorter than the ruler, and fasten one end of it at F , and the other to the end H of the ruler. Then move the ruler $\mathrm{HDF}^{\prime}$ about the point $\mathrm{F}^{\prime}$, while the thread is kept constantly
 stretched by a pencil pressed against the ruler; the curve described by the point of the pencil will be a portion of an hyperbola. For, in every position of the ruler, the difference of the lines $\mathrm{DF}, \mathrm{DF}^{\prime}$ will be the same, viz., the difference between the length of the ruler and the length of the string.

If the ruler be turned, and move on the other side of the point $F$, the other part of the same branch may be described.

Also, if one end of the ruler be fixed in F, and that of the thread in $\mathrm{F}^{\prime}$, the opposite branch may be described.

It is evident that each portion of each branch will extend to an indefinitely great distance from the foci and centre.

PROPOSITION III. THEOREM.
The difference of the two lines ctrawn to the foci from any point without the hyperbola is less than the transverse axis, and the difference of the two lines drawn to the foci from any point within the hyperbola is greater than the transverse axis.

Let $F$ and $\mathrm{F}^{\prime}$ be the foci of an hyperbola; let AA' be the transverse axis, and $E$ any point without the curve. Join $\mathrm{EF}, \mathrm{EF}^{\prime}$; the difference of $\mathrm{EF}^{\prime}$ and EF will be less than $\mathrm{AA}^{\prime}$.

Let $\mathbf{F}$ be the focus nearest to $\mathbf{E}$; the line EF must cut the curve in some point D ; then $\mathrm{EF}^{\prime}$ is less than $\mathrm{ED}+\mathrm{DF}^{\prime}$ (B.I., Pr. 8). Subtracting EF, or $\mathrm{ED}+\mathrm{DF}$, from these unequails, we have $\mathrm{EF}^{\prime}-\mathrm{EF}$ less than $\mathrm{DF}^{\prime}-\mathrm{DF}$; that is, than $\mathrm{AA}^{\prime}$.

Again, let.G be a point within either branch of the hyperbola, and let $F$ be the nearer focus; then $F^{\prime} G$ will cut the nearer branch of the curve in H . Join FH ; then $\mathrm{FG}<\mathrm{HG}+\mathrm{HF}$. Subtract each from $F^{\prime} G$, and we have
$\mathrm{F}^{\prime} \mathrm{G}-\mathrm{FG}>\mathrm{F}^{\prime} \mathrm{G}-\mathrm{HG}-\mathrm{HF}$, which equals $\mathrm{F}^{\prime} \mathrm{H}-\mathrm{FH}$;
that is, $\quad \mathrm{F}^{\prime} \mathrm{G}-\mathrm{FG}>\mathrm{AA}^{\prime}$.
Cor. A point is without or within the hyperbola according as the difference of two lines diawn from it to the foci is less or greater than the transverse axis.

## PROPOSITION IV. THEOREM.

 Every diameter of an hyperbola is bisected in the centre.

Let D be any point of an hyperbola; join DF , $\mathrm{DF}^{\prime}$, and $\mathrm{FF}^{\prime}$. Complete the parallelogram $\mathrm{DFD}^{\prime} \mathrm{F}^{\prime}$, and join $\mathrm{DD}^{\prime}$.

Now, because the opposite sides of a parallelogram are equal, the difference between DF and $\mathrm{DF}^{\prime}$ is equal to the difference between $D^{\prime} F$ and $D^{\prime} \mathrm{F}^{\prime}$; hence $\mathrm{D}^{\prime}$ is a point in the opposite branch of the hyperbola. But the diagonals of a parallelogram bisect each other; therefore $\mathrm{FF}^{\prime}$ is bisected in C ; that is, C is the centre of the hyperbola, and $\mathrm{DD}^{\prime}$ is a diameter bisected in C. Therefore every diameter, etc.

## PROPOSITION V. THEOREM.

Half the conjugate axis is a mean proportional between the clistances from one of the foci to the vertices of the transverse axis.

Let $F$ and $F^{\prime}$ be the foci of an hyperbola, $\mathrm{AA}^{\prime}$ the transverse axis, and $\mathrm{BB}^{\prime}$ the conjugate axis; then will $B C$ be a mean proportional between $A F$ and $A^{\prime} F$.

Join $A B$. Now $B C^{2}$ is equal to $\mathrm{AB}^{2}$ $\mathrm{AC}^{2}$, which is equal to $\mathrm{FC}^{2}-\mathrm{AC}^{2}$ (Def. 8).
 Hence (B. IV., Pr. 10)

$$
\begin{aligned}
\mathrm{BC}^{\prime} & =(\mathrm{FC}-\mathrm{AC}) \times(\mathrm{FC}+\mathrm{AC}) \\
& =\mathrm{AF} \times \mathrm{A}^{\prime} \mathrm{F} ; \\
& \mathrm{AF}: \mathrm{BC}:: \mathrm{BC}: \mathrm{A}^{\prime} \mathrm{F} .
\end{aligned}
$$

and hence
Cor. 1. The square of the eccentricity is equal to the sum of the squares of the semi-axes.

For $\mathrm{FC}^{2}$ is equal to $A \mathrm{~B}^{2}$ (Def. 8), which is equal to $\mathrm{AC}^{2}+$ $\mathrm{BC}^{2}$.

Cor. 2. The eccentricity of an hyperbola and of its conjugate are equal, and a circle described from C as a centre and CF as a radius will pass through the four foci of the two hyperbolas.

## PROPOSITION VI. THEOREM.

A tangent to the hyperbola bisects the angle contained by lines drawn from the point of contact to the foci.

Let $\mathrm{F}, \mathrm{F}^{\prime}$ be the foci of an hyperbola, and $D$ any point of the curve; if, through the point D , the line $\mathrm{TT}^{\prime}$ be drawn bisecting the angle $\mathrm{FDF}^{\prime}$, then will $\mathrm{TT}^{\prime}$ be a tangent to the hyperbola at D.

Let E be any point in the line $\mathrm{TT}^{\prime}$ different from D , and let F be the focus nearest to E . On DF' take DG
 equal to DF, and join $\mathrm{EF}, \mathrm{EF}^{\prime}, \mathrm{EG}$, and FG .

Now, in the two triangles DFH, DGH, because DF is equal to $\mathrm{DG}, \mathrm{DH}$ is common to both triangles, and the angle FDH is, by supposition, equal to GDH; therefore HF is equal to HG, and the angle DHF is equal to the angle DHG. Hence the line TT' is perpendicular to FG at its middle point, and therefore EF is equal to EG.

T. Hence $\mathrm{EF}^{\prime}-\mathrm{EF}$ is equal to $\mathrm{EF}^{\prime}$ EG. But EF ${ }^{\prime}$ - EG is less than GF ${ }^{\prime}$ (B. I., Pr. 8) ; that is, less than the difference of $\mathrm{DF}^{\prime}$ and DF , which is equal to $\mathrm{AA}^{\prime}$; therefore $\mathrm{EF}^{\prime}-\mathrm{EF}$ is less than the transverse axis, and hence the point E is without the hy: perbola (Pr. 3, Cor.). Therefore every point of the line $T T^{\prime}$ except $D$ is without the curve; that is, 'TT' is a tangent to the curve at D .

Cor.1. As the point D moves toward $A$, each of the angles $\mathrm{FDT}^{\prime}, \mathrm{F}^{\prime} \mathrm{DT}^{\prime}$ increases, and at A becomes a right angle. Hence the tangents at the vertices of the transverse axis are perpendicular to that axis.

Cor. 2. If $\mathrm{TT}^{\prime}$ represent a plane mirror, a ray of light proceeding from $F$ in the direction $F D$ would be reflected in a line which, if produced backward, would pass through $\mathrm{F}^{\prime}$, making the angle of reflection equal to the angle of incidence. And, since the hyperbola may be regarded as coinciding with a tangent at the point of contact, if rays of light proceed from one focus of a polished surface whose figure, whether concave or convex, is that produced by the revolution of an kyperbola about its transverse axis, they will be reflected in lines diverging from the other focus. For this reason, the points $\mathrm{F}, \mathrm{F}^{\prime}$ are called the foci.

PROPOSITION VII. THEOREM.
Tangents to the hyperbola at the vertices of any diameter are parallel to each other.

Let $\mathrm{DD}^{\prime}$ be any diameter of an hy-
 perbola, and $\mathrm{TT}^{\prime}, \mathrm{VV}^{\prime}$ tangents to the curve at the points $\mathrm{D}, \mathrm{D}^{\prime}$; then will they be parallel to each other.

Join DF, DF', D'F, D'F'. Then, by Pr. 4, FDF ${ }^{\prime} \mathrm{D}^{\prime}$ is a parallelogram; and, since the opposite angles of a parallelogram are equal, the angle $\mathrm{FDF}^{\prime}$ is equal to $\mathrm{FD}^{\prime} \mathrm{F}^{\prime}$. But the tangents TT', $\mathrm{V} \mathrm{V}^{\prime}$ bisect the angles at D and $\mathrm{D}^{\prime}$ ( $\operatorname{Pr} .6$ ) ; hence the angle $\mathrm{F}^{\prime} \mathrm{DT}^{\prime}$,
or its alternate angle $F T^{\prime} D$, is equal to $F D^{\prime} V$. But $E T^{\prime} D$ is the exterior angle opposite to $\mathrm{FD}^{\prime} \mathrm{V}$; hence $\mathrm{TT}^{\prime}$ is parallel to $\mathrm{VV}^{\prime}$. Therefore tangents, etc.

Cor. If tangents are drawn through the vertices of any two diameters, whether of the same or of conjugate hyperbolas, they will form a parallelogrant.

## proposition viil. theorem.

If through the vertex of any diameter straight lines are drawn from the foci, meeting the conjugate diameter, the purt intercepted by the conjugate is equal to half of the transverse axis.

Let $\mathrm{EE}^{\prime}$ be a diameter conjugate to $\mathrm{DD}^{\prime}$, and let the lines $\mathrm{DF}, \mathrm{DF}^{\prime}$ be drawn, and produced, if necessary, so as to meet $\mathrm{EE}^{\prime}$ in H and K ; then will DH or DK be equal to AC.

Draw $\mathrm{F}^{\prime} \mathrm{G}$ parallel to $\mathrm{EE}^{\prime}$ or $\mathrm{TT}^{\prime}$, meeting FD produced in G. Then the angle $\mathrm{DGF}^{\prime}$ is equal to the exterior angle $\mathrm{FDT}^{\prime \prime}$, and the angle $\mathrm{DF}^{\prime} \mathrm{G}$ is equal to the alternate angle $\mathrm{F}^{\prime \prime} \mathrm{DT}^{\prime}$. But the angles FDT', $\mathrm{F}^{\prime} \mathrm{DT}^{\prime}$ are equal to each other (Pr. 6);
 hence the angles $\mathrm{DGF}^{\prime}, \mathrm{DF}^{\prime} \mathrm{G}$ are equal to each other, and DG is equal to $\mathrm{DF}^{\prime}$. Also, because CK is parallel to $\mathrm{F}^{\prime} \mathrm{G}$, and CF is equal to $\mathrm{CF}^{\prime \prime}$, therefore FK must be equal to KG.

Hence $\mathrm{F}^{\prime} \mathrm{D}-\mathrm{FD}$ is equal to $\mathrm{GD}-\mathrm{FD}$ or $\mathrm{GF}-2 \mathrm{DF}$; that is, $2 \mathrm{KF}-2 \mathrm{DF}$ or 2 DK . But $\mathrm{F}^{\prime} \mathrm{D}-\mathrm{FD}$ is equal to 2 AC . Therefore 2 AC is equal to 2 DK , or AC is equal to DK .

Also, the angle DHK is equal to DKH, and hence DH is equal to DK or AC. Therefore, if through the vertex, etc.

## PROPOSITION IX. THEOREM.

Perpendicular's drawn from the foci upon a tangent to the hyperbola meet the tangent in the circumference of a circle whose diameter is the transverse axis.
Let $\mathrm{TT}^{\prime}$ be a tangent to the hyperbola at D , and from F draw FE perpendicular to $\mathrm{TT}^{\prime}$; the point E will be in the circumference of a circle described upon $\mathrm{AA}^{\prime}$ as a diameter.

Join CE, FD, $F^{\prime} D$, and produce $F E$ to meet $F^{\prime} D$ in $G$.
Then, in the two triangles DEF, DEG, because DE is common to both triangles, the angles at E are equal, being right angles;
also, the angle EDF is equal to EDG (Pr. 6) ; therefore DF is equal to DG, and EF to EG.

Also, because FE is equal to EG , and CF is equal to $\mathrm{CF}^{\prime}$, CE must be parallel to $F^{\prime} G$, and, consequently, equal to half of $F^{\prime} G$.

But, since $D G$ has been proved equal to $\mathrm{DF}, \mathrm{F}^{\prime} \mathrm{G}$ is equal to $\mathrm{F}^{\prime} \mathrm{D}-\mathrm{FD}$, which is equal to $\mathrm{AA}^{\prime}$. Hence CE is equal to half of $\mathrm{AA}^{\prime}$ or AC , and a circle described with $\mathbf{C}$ as a centre, and radius CA, will pass through the point $\mathbf{E}$.
The same may be proved of a perpendicular let fall upon 'TT' from the focus $\mathrm{F}^{\prime}$. Therefore perpendiculars, etc.

PROPOSITION X. THEOREM.
The product of the perpencliculars from the foci upon a tangent is equal to the square of half the conjugate axis.

Let $\mathrm{TT}^{\prime}$ be a tangent to the hyperbola at any point $E$, and let the perpendiculars FD, $\mathrm{F}^{\prime} \mathrm{G}$ be drawn from the foci ; then will the product of $F D$ by $F^{\prime} G$ be equal to the square of 13 C .

On $\mathrm{AA}^{\prime}$ as a diameter describe a circle; it will pass through the points $D$ and $G$ (Pr. 9). Let $\mathrm{GF}^{\prime}$ meet the circle in $\mathrm{D}^{\prime}$, and join $\mathrm{DD}^{\prime}$; then, since the angle at G is a right angle, $\mathrm{DD}^{\prime}$ passes through the centre C. Because $F D$ and $F^{\prime} G$ are perpendicular to the same straight line $\mathrm{TT}^{\prime}$, they are parallel to each other, and the alternate angles $\mathrm{CFD}, \mathrm{CF}^{\prime} \mathrm{D}^{\prime}$ are equal. Also, the vertical angles $\mathrm{DCF}, \mathrm{D}^{\prime} \mathrm{CF}^{\prime}$ are equal, and CF is equal to $\mathrm{CF}^{\prime}$. Therefore DF is equal to $\mathrm{D}^{\prime} \mathrm{F}^{\prime}$; hence $\mathrm{DF} \times \mathrm{GF}^{\prime}$ is equal to $\mathrm{D}^{\prime} \mathrm{F}^{\prime} \times \mathrm{GF}^{\prime}$, which is equal to $\mathrm{A}^{\prime} \mathrm{F}^{\prime} \times$ $\mathrm{F}^{\prime} \mathrm{A}$ (B. IV., Pr. 29, Cor. 2), which is equal to $\mathrm{BC}^{2}$ (Pr. 5).

Cor. The triangles FDE, $\mathrm{F}^{\prime} \mathrm{GE}$ are similar; hence

$$
\mathrm{FD}: \mathrm{F}^{\prime} \mathrm{G}:: \mathrm{FE}: \mathrm{F}^{\prime} \mathrm{E} ;
$$

that is, perpendiculars let fall from the foci upon a tangent are to each other as the distances of the point of contact from the foci.

## PROPOSITION XI. THEOREM.

If a tangent and ordinate be drawn from the same point of an hyperbola, meeting either axis produced, half of that axis will be a mean proportional between the distances of the two intersections from the centre.

1st. For the transverse axis.
Let DT be a tangent to the hyperbola, and DG an ordinate to the transverse axis from the point of contact; then we shall have CT: CA::CA : CG.

From $\mathbf{F}$ draw $\mathbf{F H}$ perpendicular to DT , and join $\mathrm{DF}, \mathrm{DF}^{\prime}, \mathrm{CH}$, and GH . Then, by Pr. 9, CH is parallel to $\mathrm{DF}^{\prime}$. Also, since DGF, DHF are both right angles, a circle described on DF as a diameter will pass through the points G and H. Therefore the angle CGH or FGH is equal to the angle HDF (B. III., Pr. 15, Cor. 1), which is equal to $\mathrm{F}^{\prime} \mathrm{DT}$ or CHT. That is, the angle CGH is equal to CHT; and, since the angle $\mathbf{C}$ is common to the two triangles CGH, CHT, these triangles are equiangular, and we have

CT:CH::CH:CG.
But CH is equal to CA (Pr. 9) ; therefore
CT:CA: CA:CG.
2d. For the conjugate axis.
Let the tangent $\mathrm{DTT}^{\prime}$ meet the conjugate axis in $\mathrm{T}^{\prime}$, and let $\mathrm{DG}^{\prime}$ be an ordinate to the conjugate axis from the point of contact; then we shall have

$$
\mathrm{CT}^{\prime}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CG}^{\prime} .
$$

Draw DH perpendicular to DT, and it will bisect the exterior angle of the triangle $\mathrm{FDF}^{\prime}$. Hence (B. IV., Pr. 18)

$$
\begin{array}{r}
\mathrm{HF}^{\prime}: \mathrm{HF}:: \mathrm{DF}^{\prime}: \mathrm{DF} \\
\\
:
\end{array}: \mathrm{TF}^{\prime}: \mathrm{TF} .
$$

Therefore (B. II., Pr. 8)
 $2 \mathrm{CF}: 2 \mathrm{CH}:: 2 \mathrm{CT}: 2 \mathrm{CF}$.

## Whence <br> $\mathrm{CT} \times \mathrm{CH}=\mathrm{CF}^{2}$.

But we have proved that $\mathrm{CT} \times \mathrm{CG}=\mathrm{CA}^{2}$.
Subtracting the latter from the former, we have

$$
\mathrm{CT} \times \mathrm{GH}=\mathrm{CF}^{2}-\mathrm{CA}^{2}=\mathrm{CB}^{2}
$$

Because the triangles DGH and CTT" are similar, we have CT: $\mathrm{CT}^{\prime}:: \mathrm{DG}: \mathrm{GH}^{2}$

Whence
Therefore or

$$
\mathrm{CT} \times \mathrm{GH}=\mathrm{CT}^{\prime} \times \mathrm{DG}=\mathrm{C}^{\prime} \mathrm{T}^{\prime} \times \mathrm{CG}^{\prime} .
$$

$\mathrm{CT}^{\prime} \times \mathrm{CG}^{\prime}=\mathrm{CB}^{2}$, $\mathrm{CT}^{\prime}: \mathrm{CB}:$ : $\mathrm{CB}: \mathrm{CG}^{\prime}$. Cor. By this Proposition, $\mathrm{CA}^{2}=\mathrm{CG} \times \mathrm{CT}$.
If a second ordinate $d y$, and tangent $d t$ be drawn, we shall also have $\mathrm{CA}^{2}=\mathrm{C} g . \mathrm{C} t$.
Whence $\quad \mathrm{CG} \times \mathrm{CT}=\mathrm{C} g . \mathrm{Ct}$, or CT: $\mathrm{C} t:: \mathrm{C} g: \mathrm{CG}$.

PROPOSITION XII. THEOREM.
The subtangent of an hyperbola is equal to the corresponding subtangent of the circle described upon its transverse axis.

Let AEA' be a circle described on $\mathrm{AA}^{\prime}$, the
 transverse axis of an hyperbola, and from any point E in the circle draw the ordinate ET. Through T draw the line DT touching the hyperbola in D , and from the point of contact draw the ordinate DG. Join GE; then will GE be a tangent to the circle at E .
Join CE. Then, by the last Proposition, CT: CA::CA:CG;
or, because CA is equal to CE ,

> CT: CE :: CE: CG.

Hence the triangles CET, CGE, having the angle at C common, and the sides about this angle proportional, are similar (B.IV., Pr. 21). Therefore the angle CEG, being equal to the angle CTE, is a right angle; that is, the line GE is perpendicular to the radius CE , and is, consequently, a tangent to the circle (B. III., Pr. 9). Hence GT is the subtangent corresponding to each of the tangents DT and EG. Therefore the subtangent, etc.

## PROPOSITION XIII. THEOREM.

The square of the transverse axis is to the square of the conjugate as the rectangle of the abscissas of the former is to the square of their ordinate.

Let DE be an ordinate to the transverse axis from the point D ; then we shall have

$$
\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{AE} \times \mathrm{EA}^{\prime}: \mathrm{DE}^{2} .
$$

Draw DTT' a tangent to the hyperbola at D; then, by Pr. 11,

$$
\mathrm{CT}: \mathrm{CA}:: \mathrm{CA}: \mathrm{CE} .
$$

Hence (B. II., Pr. 13)

$$
\mathrm{CT}: \mathrm{CE}:: \mathrm{CA}^{2}: \mathrm{CE}^{2} ;
$$

and, by division (B. II., Pr. 7),

$$
\begin{equation*}
\mathrm{CT}: \mathrm{ET}:: \mathrm{CA}^{2}: \mathrm{CE}^{2}-\mathrm{CA}^{2} \tag{1}
\end{equation*}
$$

Again, by Pr. 11, $\mathrm{CT}^{1}: \mathrm{CB}:: \mathrm{CB}: \mathrm{CH}$ or DE. Hence $\mathrm{CT}^{\prime}: \mathrm{DE}^{2}: \mathrm{CB}^{2}: \mathrm{DE}^{2}$. But, by similar triangles,

$$
\begin{equation*}
\mathrm{CT}^{\prime}: \mathrm{DE}:: \mathrm{CT}: \mathrm{ET} ; \tag{2}
\end{equation*}
$$

therefore $\quad \mathrm{CT}:{\mathrm{ET}:: \mathrm{CB}^{2}: \mathrm{DE}^{2} \text {. }}_{\text {. }}$
Comparing proportions (1) and (2), we have

$$
\mathrm{CA}^{2}: \mathrm{CE}^{2}-\mathrm{CA}^{2}:: \mathrm{CB}^{2}: \mathrm{DE}^{2}
$$

But $\mathrm{CE}^{2}-\mathrm{CA}^{2}$ is equal to $\mathrm{AE} \times \mathrm{EA}^{\prime}$ (B. IV., Pr. 10).
Hence $\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{AE} \times \mathrm{EA}^{\prime}: \mathrm{DE}^{2}$.
Cor. 1.
$\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CE}^{2}-\mathrm{CA}^{2}: \mathrm{DE}^{2}$.
Cor.2. The squares of the ordinates to the transverse axis are to each other as the rectangles of their abscissas.

Cor. 3. Produce DE to meet the conjugate hyperbola in $\mathrm{D}^{\prime}$, and draw $\mathrm{D}^{\prime} \mathrm{E}^{\prime}$ at right angles to $\mathrm{CE}^{\prime}$; then, since the conjugate hyperbola is described with $\mathrm{BB}^{\prime}$ as transverse axis and $\mathrm{AA}^{\prime}$ as conjugate axis, we shall have

$$
\mathrm{CB}^{2}: \mathrm{CA}^{2}:: \mathrm{CE}^{\prime 2}-\mathrm{CB}^{2}: \mathrm{D}^{\prime} \mathrm{E}^{\prime 2}
$$

## PROPOSITION XIV. THEOREM.

If a circle be described on the transverse axis of an hyperbola, an ordinate to this axis is to a tangent to the circle drawn from the foot of the ordinate as the conjugate axis is to the transverse.

Let a circle be described on $\mathrm{AA}^{\prime}$ as a diameter; draw the ordinate DE , and from E draw EG tangent to the circle; then ED:EG:: BC:AC.
For, by Pr. 13,

$$
\mathrm{ED}^{2}: \mathrm{AE} \times \mathrm{EA}^{\prime}:: \mathrm{CB}^{2}: \mathrm{CA}^{2}
$$

But $\mathrm{AE} \times \mathrm{EA}^{\prime}$ is equal to $\mathrm{EG}^{2}$ (B. IV., Pr. 29).
Therefore

$$
\begin{gathered}
\mathrm{ED}^{2}: \mathrm{EG}^{2}:: \mathrm{CB}^{2}: \mathrm{CA}^{2} ; \\
\mathrm{ED}: \mathrm{EG}:: \mathrm{CB}: \mathrm{CA} .
\end{gathered}
$$

## PROPOSITION XV. THEOREM.

The latus rectum is a third proportional to the transverse and conjugate axes.

Let LL' be a double ordinate to the transverse axis passing through the focus F ; then we shall have

$$
\mathrm{AA}^{\prime}: \mathrm{BB}^{\prime}:: \mathrm{BB}^{\prime}: \mathrm{LL}^{\prime} .
$$

Because LF is an ordinate to the transverse axis,

$$
\begin{aligned}
& \mathrm{AC}^{2}: \mathrm{BC}^{2}:: \mathrm{AF} \times \mathrm{FA}^{\prime}: \mathrm{LF}^{2}(\mathrm{Pr} .13) \\
&:: \mathrm{BC}^{2}: \mathrm{LF}^{2}\left(\mathrm{Pr}^{5}\right) . \\
& \mathrm{AC}^{\prime}: \mathrm{BC}^{\prime}:: \mathrm{BC}^{:} \mathrm{LF}, \\
& \mathrm{AA}^{\prime}: \mathrm{BB}^{\prime}:: \mathrm{BB}^{\prime}: \mathrm{LL}^{\prime} .
\end{aligned}
$$

Hence
Therefore the latus rectum, etc.

## PROPOSITION XVI. THEOREM.

If a cliameter of the hyperbola is conjugate to a cliameter of the conjugate hyperbola, and if ordinates be drawn to either axis from the vertices of the two diameters, the difference of their squares will be equal to the square of half the other axis.

Let $\mathrm{DD}^{\prime}$ be a diameter of an hyperbola, and DT a tangent at the point D; and let $\mathrm{EE}^{\prime}$ be a diameter of the conjugate hyperbola parallel to DT. Let DG and EH be ordinates to the axis $\mathrm{AA}^{\prime}$; then we shall have $\quad \mathrm{CG}^{2}-\mathrm{CH}^{2}=\mathrm{CA}^{2}$, and $\mathrm{EH}^{2}-\mathrm{DG}^{2}=\mathrm{CB}^{2}$.
Through E draw the tangent ET'; then, by Pr. 13, Cor. 3,

$$
\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CH}^{2}: \mathrm{EH}^{2}-\mathrm{CB}^{2},
$$

and, by composition,

$$
\begin{aligned}
\mathrm{CA}^{2}+\mathrm{CH}^{2}: \mathrm{EH}^{2} & : \mathrm{CA}^{2}: \mathrm{CB}^{2} \\
& \left.:: \mathrm{CG}^{2}-\mathrm{CA}^{2}: \mathrm{DG}^{2} \text { (Pr. 13, Cor. } 1\right) .
\end{aligned}
$$

But $\mathrm{CA}^{2}+\mathrm{CH}^{2}=\mathrm{CH} . \mathrm{CT}^{\prime}+\mathrm{CH}^{2}=\mathrm{CH} . \mathrm{HT}^{\prime}(\operatorname{Pr} .11)$,
and
Hence

$$
\mathrm{CG}^{2}-\mathrm{CA}^{2}=\mathrm{CG}^{2}-\mathrm{CG} . \mathrm{CT}=\mathrm{CG} . \mathrm{GT} .
$$

$$
\text { CH.HT' }: \text { CG.GT }:: \mathrm{EH}^{2}: \mathrm{DG}^{2}
$$

$:: \mathrm{CH}^{2}: \mathrm{GT}^{2}$, by sim. triangles.
Hence, B. II., Pr. 10, Cor.,

$$
\mathrm{HT}^{\prime}: \mathrm{CG}:: \mathrm{CH}: \mathrm{GT}:: \mathrm{EH}: \mathrm{DG}
$$

Therefore the triangles $\mathrm{EHT}^{\prime}$ and DGC are similar, and $\mathrm{ET}^{\prime}$ is
parallel to $\mathrm{DD}^{\prime}$. Hence the triangles $\mathrm{ECT}^{\prime}$ and DCT are similar,
and we have
But
Hence
or

CT: CT': : GT: CH.
CT: CT' $:$ : CH:CG (Pr: 11, Cor.).
GT: CH: : CH:CG,
$\mathrm{CH}^{2}=$ CG.GT.

Subtract each of these equals from $\mathrm{CG}^{2}$, and we have

$$
\mathrm{CG}^{2}-\mathrm{CH}^{2}=\mathrm{CG}^{2}-\mathrm{CG} \cdot \mathrm{GT}=\mathrm{CG} \cdot \mathrm{CT}=\mathrm{CA}^{2} .
$$

Also, since $\mathrm{ET}^{\prime}$ is parallel to $\mathrm{DD}^{\prime}$, the diameter $\mathrm{DD}^{\prime}$ is conjugate to $\mathrm{EE}^{\prime}$, and we have $\mathrm{EH}^{2}-\mathrm{DG}^{2}=\mathrm{CB}^{2}$.
Therefore, if a diameter, etc.
Cor. 1.
$\mathrm{CA}^{2}+\mathrm{CH}^{2}=\mathrm{CG}^{2}$;
$\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CG}^{2}: \mathrm{EH}^{2}$.
Cor. 2. If a diameter of an hyperbola is conjugate to a diameter of the conjugate hyperbola, the second diameter is conjugate to the first; for it has been proved that if $\mathrm{EE}^{\prime}$ be parallel to the tangent $\mathrm{DT}, \mathrm{DD}^{\prime}$ will be parallel to the tangent $\mathrm{ET}^{\prime}$.

Cor. 3. $\mathrm{CG}^{2}-\mathrm{CA}^{2}=\mathrm{CG} . \mathrm{GT}$;
hence $\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CG} \times \mathrm{GT}: \mathrm{DG}^{2}$.
If a second ordinate $d g$, and tangent $d t$ be drawn, we shall have
$\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{C} g \times g t: d g^{2}$.
Hence $\mathrm{CG} \times \mathrm{GT}: \mathrm{C} g \times g t:: \mathrm{DG}^{2}: d g^{2}$.

## PROPOSITION XVII. THEOREM.

The difference of the squares of any two conjugate diameters is equal to the difference of the squares of the axes.
Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be any two conjugate diameters; then we shall have

$$
\mathrm{DD}^{\prime 2}-\mathrm{EE}^{\prime 2}=\mathrm{AA}^{\prime 2}-\mathrm{BB}^{\prime 2}
$$

Draw DG, EH ordinates to the transverse axis. Then, by the preceding Proposition, $\quad \mathrm{CG}^{2}-\mathrm{CH}^{2}=\mathrm{CA}^{2}$,
and
Hence

$$
\mathrm{EH}^{2}-\mathrm{DG}^{2}=\mathrm{CB}^{2} .
$$

$$
\begin{gathered}
\mathrm{CG}^{2}+\mathrm{DG}^{2}-\mathrm{CH}^{2}-\mathrm{EH}^{2}=\mathrm{CA}^{2}-\mathrm{CB}^{2}, \\
\mathrm{CD}^{2}-\mathrm{CE}^{2}=\mathrm{CA}^{2}-\mathrm{CB}^{2} ; \\
\mathrm{DD}^{\prime 2}-\mathrm{EE}^{\prime 2}=\mathrm{AA}^{\prime 2}-\mathrm{BB}^{\prime 2} .
\end{gathered}
$$

Therefore the difference of the squares, etc.

## PROPOSITION XVIII. THEOREM.

The parallelogram formed by drawing tangents through the vertices of two conjugate diameters is equal to the rectangle of the axes.

Let $\mathrm{DED}^{\prime} \mathrm{E}^{\prime}$ be a parallelogram formed by drawing tangents to the conjugate hyperbolas through the vertices of two conjugate diameters $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$; its area is equal to $\mathrm{AA}^{\prime} \times \mathrm{BB}^{\prime}$.

Let the tangent at D meet the transverse axis in T ; join ET, and draw the ordinates DG, EH.

Then, by Pr. 16, Cor. 1, we have $\mathrm{CA}^{2}: \mathrm{CB}^{2}:: \mathrm{CG}^{2}: \mathrm{EH}^{2}$,

or CA:CB::CG:EH.
But CT:CA::CA:CG (Pr. 11);
hence CT:CB::CA:EH, or $\mathrm{CA} \times \mathrm{CB}$ is equal to $\mathrm{C} \mathrm{T} \times \mathrm{EH}$, which is equal to twice the triangle CTE, or the parallelogram DE; since the triangle and parallelogram have the same base CE, and are between the same parallels.
Hence $4 \mathrm{CA} \times \mathrm{CB}$ or $\mathrm{AA}^{\prime} \times \mathrm{BB}^{\prime}$ is equal to 4 DE , or the parallelogram DED'E' Therefore the parallelogram, etc.

> proposition xix. theorem.

If from the vertex of any diameter straight lines are drawn to the foci, their product is equal to the square of half the conjugate diameter.

Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be two conjugate diameters, and from D let lines be drawn to the foci; then will $\mathrm{FD} \times$ F'D be equal to $\mathrm{EC}^{2}$.
Draw a tangent to the hyperbola at D , and upon it let fall the perpendiculars FG, F'H; draw, also, DK perpendicular to EE'. $^{\prime}$.
Then, because the triangles DFG, DLK, $\mathrm{DF}^{\prime} H$ are similar, we have
FD : FG::DL:DK.
Also,
F'D : $\mathrm{F}^{\prime} \mathrm{H}:$ : DL : DK.
Whence (B. II., Pr. 12)
$\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}: \mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}:: \mathrm{DL}^{2}: \mathrm{DK}^{2}$.

But, by Pr. 18, whence and Comparing proportions (1) and (2), we have $\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}: \mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}:: \mathrm{EC}^{2}: \mathrm{BC}^{2}$.
But $\mathrm{FG} \times \mathrm{F}^{\prime} \mathrm{H}$ is equal to $\mathrm{BC}^{2}(\mathrm{Pr} .10)$; hence $\mathrm{FD} \times \mathrm{F}^{\prime} \mathrm{D}$ is equal to $\mathrm{EC}^{2}$. Therefore, if from the vertex, etc.

## PROPOSITION XX. THEOREM.

If a tangent and ordinate be drawn from the same point of an hyperbola to any diameter, half of that diameter will be a mean proportional between the clistances of the two intersections from the centre.

Let a tangent EG, and an ordinate EH, be drawn from the same point $E$ of an hyperbola, meeting the diameter CD produced; then we shall have

$$
\mathrm{CG}: \mathrm{CD}: \text { : CD : CH. }
$$

Produce GE and HE to meet the transverse axis in K and L ; draw DT a tangent to the curve at the point D , and draw DM parallel to GK. Also draw the ordinates EN, DO.

By similar triangles we have

> OM : NK : : DO : EN,
and also OT:NL: : DO : EN.

Multiplying together the terms of these proportions (B.II., Pr. 12), we have

$$
\begin{aligned}
& \mathrm{OM} \times \mathrm{OT}:: \mathrm{NK} \times \mathrm{NL}:: \mathrm{DO}^{2}: \mathrm{EN}^{2}:: \mathrm{CO} \times \mathrm{OT}: \mathrm{CN} \times \mathrm{NK} \\
& \text { (Pr: } 16, \mathrm{Cor} .2) .
\end{aligned}
$$

Omitting the factor OT in the antecedents, and NK in the consequents of this proportion (B. II., Pr. 10, Cor.), we have

$$
\mathrm{OM}: \mathrm{NL}:: \mathrm{CO}: \mathrm{CN},
$$

and, by division, But, by Pr. 11, Cor.,

Whence
But and hence

CO : CN : : CM : CL.
CO:CN: CK: CT.
CK : CM : : CT : CL.
CK:CM: CG:CD,
CT:CL::CD:CH;
$\mathrm{CG}: \mathrm{CD}:$ : CD:CH.

Therefore, if a tangent, etc.
Cor. If a tangent to the hyperbola meet a conjugate diameter, and from the point of contact an ordinate be drawn to that diameter, it may be proved that half of that diameter is a mean proportional between the distances of the two intersections from the centre.

## PROPOSITION XXI. THEOREM.

The square of any diameter is to the square of its conjugate as the rectangle of its abscissas is to the square of their ordinate.

Let $\mathrm{DD}^{\prime}, \mathrm{EE}^{\prime}$ be two conjugate diameters, and GH an ordinate to $\mathrm{DD}^{\prime}$; then
$\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{GH}^{2}$.
Draw GTT' a tangent to the curve at the point G, and draw GK an ordinate to $\mathrm{EE}^{\prime}$. Then, by Pr. 20, CT:CD: CD: CH, and $\mathrm{CD}^{2}: \mathrm{CH}^{2}:: \mathrm{CT}: \mathrm{CH}$ (B. II., Pr. 13),
whence, by division, $\mathrm{CD}^{2}: \mathrm{CH}^{2}-\mathrm{CD}^{2}:: \mathrm{CT}: \mathrm{HT}$.
Also, by Pr. 20, Cor., CT ${ }^{\prime}$ : CE : : CE : CK, and $\mathrm{CE}^{2}: \mathrm{CK}^{2}:: \mathrm{CT}^{\prime}: \mathrm{CK}$ or GH , : : CT : HT

Comparing proportions (1) and (2), we have $\mathrm{CD}^{2}: \mathrm{CE}^{2}:: \mathrm{CH}^{2}-\mathrm{CD}^{2}: \mathrm{CK}^{2}$ or $\mathrm{GH}^{2}$,

## or

 $\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{GH}^{2}$.Therefore the square, etc.
Cor. 1. In the same manner, it may be proved that $\mathrm{DD}^{\prime 2}: \mathrm{EE}^{\prime 2}$ $:: \mathrm{DH} \times \mathrm{HD}^{\prime}: \mathrm{G}^{\prime} \mathrm{H}^{2}$; hence GH is equal to $\mathrm{G}^{\prime} \mathrm{H}$, or every diameter bisects all chords parallel to the tangents at its vertices.

Cor.2. The squares of the ordinates to any diameter are to each other as the rectangles of their abscissas.

Scholium. If $\mathrm{DD}^{\prime}$ be produced beyond $\mathrm{D}^{\prime}$, and ordinates be drawn in the opposite branch of the hyperbola, all the propositions which refer to the ordinates of the diameter $\mathrm{DD}^{\prime}$ will apply indiscriminately to ordinates of either or both branches.

Thus, let $\mathrm{DD}^{\prime}$ be produced to $h$, and draw the ordinate $g h$; then, by Cor. 2, DH.D'H : D $h . \mathrm{D}^{\prime} h:: \mathrm{GH}^{2}: g h^{2}$.
Also, produce $\mathrm{EE}^{\prime}$ beyond $\mathrm{E}^{\prime}$ to $k$, and draw the ordinate $k l$; then EK.E'K : Ek.E' $k:: \mathrm{KL}^{2}: k i^{2}$.

## PROPOSITION XXII. THEOREN.

If a cone be cut by a plane not passing through the vertex, and making an angle with the base greater than that made by the side of the cone, the section is an hyperbola.

Let ABC be a cone cut by a plane DGH, not passing through the vertex, and making an angle with the base greater than that made by the side of the cone, the section DHG is an hyperbola.

Let ABC be a section through the axis of the cone, and perpendicular to the plane HDG. Let bged be a section made by a plane parallel to the base of the cone; then DE , the intersection of the planes HDG , BGCD , will be perpendicular to the plane ABC , and, consequently, to each of the lines $\mathrm{BC}, \mathrm{HE}$. So, also, de will be perpendicular to $b c$ and HE. Let AB and HE be produced to meet in L .

Now, because the triangles LBE, Lbe are
 similar, as also the triangles HEC, Hec, we have the proportions

> BE : be : : EL : eL,
> $\mathrm{EC}: e c:: \mathrm{HE}: \mathrm{He}$.

Hence, by B. II., Pr. 12,
$\mathrm{BE} \times \mathrm{EC}: b e \times e c:: \mathrm{HE} \times \mathrm{EL}: \mathrm{He} \times \mathrm{eL}$.

But, since BC is a diameter of the circle BGCD , and DE is perpendicular to BC , we have (B. IV., Pr. 23, Cor.)

$$
\mathrm{BE} \times \mathrm{EC}=\mathrm{DE}^{2}
$$

For the same reason,

$$
b e \times e c=d e^{2} .
$$

Substituting these values of $\mathrm{BE} \times \mathrm{EC}$ and $b e \times e c$ in the preceding proportion, we have $\mathrm{DE}^{2}: d e^{2}:: \mathrm{HE} \times \mathrm{EL}: \mathrm{He} \times \mathrm{eL} ;$
that is, the squares of the ordinates to the diameter HE are to each other as the products of the corresponding abscissas. Therefore the curve DHG is an hyperbola (Pr. 13, Cor. 2) whose transverse axis is LH. Hence the hyperbola is called a conic section, as mentioned on page 203.

Schol. 1. The conclusion that the curve DHG is an hyperbola would not be legitimate unless the property above demonstrated were peculiar to the hyperbola. That such is the case appears from the fact that, when the transverse axis and one point of an hyperbola are given, this property will determine the position of every other point of the curve in the same manner as shown in the corresponding Proposition for the parabola, p. 215.

It will be noticed that this property of the hyperbola differs from the corresponding property of the ellipse in this particular, that the ordinate of the hyperbola falls upon the axis procluced, while in the ellipse it falls upon the axis itself.

Schol. 2. The surface of the cone may be regarded as extending indefinitely below the base BGC, and hence the curve will extend indefinitely in the same direction.

The surface of the cone is described by the motion of the line AB (B. X., Def. 3). If the portion of AB produced toward $L$ be regarded as describing a second portion of the conical surface, the intersection of the plane DHGE with this second portion will be the opposite branch of the hyperbola DHG.

## PROPOSITION XXIII. THEOREM.

The distance of any point in an hyperbola from either focus is to its clistance from the corresponding directrix as the eccentricity to half the transverse axis.

Let D be any point in the hyperbola; let $\mathrm{DF}, \mathrm{DF}^{\prime}$ be drawn to the two foci, and $D G G^{\prime}$ perpendicular to the directrices; then
$\mathrm{DF}: \mathrm{DG}:: \mathrm{DF}^{\prime}: \mathrm{DG}^{\prime}:: \mathrm{CF}: \mathrm{CA}$.
Draw DE perpendicular to the transverse axis, and take $H$ a point in the axis, so that $\mathrm{AH}=\mathrm{DF}$, and, consequently, $\mathrm{HA}^{\prime}=\mathrm{DF}^{\prime}$; then CH is half the sum of AH and $\mathrm{A}^{\prime} \mathrm{H}$, or DF and $\mathrm{DF}^{\prime}$; and CE is half the sum of FE and $\mathrm{F}^{\prime} E$.

By B. IV., Pr. 34,

$$
\mathrm{FF}^{\prime}: \mathrm{DF}^{\prime}-\mathrm{DF}^{\prime}:: \mathrm{DF}^{\prime}+\mathrm{DF}: \mathrm{F}^{\prime} \mathrm{E}+\mathrm{FE}
$$

Dividing each of these equals by two, we have
CF : CA: : CH:CE.
By Pr. 11,
CF : CA : : CA: CT.
Therefore
CH: CE : : CA : CT.
Hence (B. II., Pr. 7)
$\mathrm{CH}-\mathrm{CA}: \mathrm{CE}-\mathrm{CT}:: \mathrm{CA}: \mathrm{CT} ;$
$\mathrm{AH}: \mathrm{ET}:: \mathrm{CA}: \mathrm{CT}:: \mathrm{CE}: \mathrm{CA} ;$
$\mathrm{DF}: \mathrm{DG}:: \mathrm{CF}: \mathrm{CA}$.

In the same manner, it may be proved that

$$
\mathrm{DF}^{\prime}: \mathrm{DG}^{\prime}:: \mathrm{CF}: \mathrm{CA} .
$$

Scholium 1. We have seen that, in the parabola, the distance of any point of the curve from the focus is equal to its distance from the directrix, while in the ellipse and hyperbola these distances are in the ratio of the eccentricity to half the major or transverse axis. In the ellipse the eccentricity is less than the semi-major axis, while in the hyperbola it is greater than the semi-transverse axis. In each of these three curves the two distances have to each other a constant ratio. In the parabola this ratio is unity; in the ellipse it is less than unity; while in the hyperbola it is greater than unity.

Scholium 2. Astronomers generally regard the semi-major axis of a planetary orbit as unity, in which case the eccentricity of the ellipse will be less than unity. It we regard the semi-transverse axis of an hyperbola as unity, its eccentricity will be greater than unity. The parabola may be regarded as an ellipse whose major axis is infinite, and in which the eccentricity is equal to the semi-major axis; that is, the eccentricity is unity. In Astronomy, therefore, the eccentricity of a parabola is considered as unity; that of an ellipse is less than unity; and that of an hyperbola is greater than unity. In each case the value of the eccentricity expresses the ratio of the distances of any point of the curve from the focus and directrix.

## OF THE ASYMPTOTES.

Definition. If tangents to two conjugate hyperbolas be drawn through the vertices of the axes, the diagonals of the rectangle so formed, being indefinitely produced, are called asymptotes to the hyperbolas.

## PROPOSITION XXIV. THEOREM.

If an ordinate to the transverse axis be produced to meet the asymptotes, the rectangles of the segments into which it is divided by the curve will be equal to the square of half the conjugate axis.

Let $\mathrm{AA}^{\prime}, \mathrm{BB}^{\prime}$ be the axes of two conjugate hyperbolas, and through the vertices $A, A^{\prime}, B, B^{\prime}$ let tangents to the curve be drawn, and let CE, $\mathrm{CE}^{\prime}$, the diagonals of the rectangle thus formed, be indefinitely produced, they will be asymptotes to the curves.
From any point $D$ of ore of the curves draw the ordinate DG to the transverse axis, and produce it to meet CE in II, and $\mathrm{CE}^{\prime}$ in $\mathrm{H}^{\prime}$. Then, from Pr. 13, Cor. 1, we shall have

$$
\mathrm{CA}^{2}: \mathrm{CB}^{2}\left(=\mathrm{AE}^{2}\right):: \mathrm{CG}^{2}-\mathrm{CA}^{2}: \mathrm{DG}^{2}
$$

$:: \mathrm{CG}^{2}: \mathrm{GH}^{2}$, by similar triangles.

## Hence

$$
\mathrm{CG}^{2}: \mathrm{GH}^{2}:: \mathrm{CG}^{2}-\mathrm{CA}^{2}: \mathrm{DG}^{2},
$$

and by division,

$$
\mathrm{CG}^{2}: \mathrm{GH}^{2}:: \mathrm{CA}^{2}: \mathrm{GH}^{2}-\mathrm{DG}^{2} \text {, or as } \mathrm{CA}^{2}: \mathrm{AE}^{2} .
$$

Since the antecedents of this proportion are equal to each other, the consequents must be equal ; that is,

$$
\mathrm{AE}^{2} \text { or } \mathrm{BC}^{2} \text { is equal to } \mathrm{GH}^{2}-\mathrm{DG}^{2},
$$

which is equal to $\mathrm{HD} \times \mathrm{DH}^{\prime}(\mathrm{B} . \mathrm{IV}$., Pr. 10).
Cor. 1. Since the rectangle contained by HD and $\mathrm{DH}^{\prime}$ remains constant, while $\mathrm{HDH}^{\prime}$ is removed from C , and the line $\mathrm{DH}^{\prime}$ consequently increases, DH must diminish; and, by taking H sufficiently far from C, DII may be made less than any assignable magnitude. The line CH , therefore, approaches nearer and nearer to the hyperbola the farther it is produced, though it never actually reaches it at any finite distance from C. When the distance of H from C becomes infinitely great, DH becomes less than any assignable quantity, and the asymptote may therefore be considered as a tangent to the curve at a point infinitely distant from the centre.

The asymptote $\mathrm{CH}^{\prime}$, in the same manner, approaches nearer and nearer to the other branch of the hyperbola the farther it is produced.

Cor. 2. The line AB , joining the vertices of the two axes, is bisected by one asymptote, and is parallel to the other.

Cor. 3. If DL be drawn perpendicular to the conjugate axis, and meet the asymptotes in K and L , and the conjugate hypeibola in $\mathrm{D}^{\prime}$, it may also be proved that $\mathrm{CA}^{2}=\mathrm{D}^{\prime} \mathrm{K} \times \mathrm{D}^{\prime} \mathrm{L}$. The asymptote CH , therefore, continually approaches the conjugate hyperbola, and becomes tangent to it at an infinite distance from the centre.

Cor: 4. If $\mathrm{KK}^{\prime}$ be drawn parallel to $\mathrm{HH}^{\prime}$, then $\mathrm{KM} \times \mathrm{MK}^{\prime}=\mathrm{HD}$ $\times \mathrm{DH}^{\prime}$, for each of them is equal to $\mathrm{BC}^{2}$; that is, if two ordinates to the transverse axis be produced to meet the asymptotes, the rectangles of the segments into which these lines are divided by the curve are equal to each other.

## PROPOSITION XXV. THEOREM.

All the parallelograms formed by drawing lines from any point of an hyperbola parallel to the asymptotes are equal to each other.
Let CH, $\mathrm{CH}^{\prime}$ be the asymptotes of an hyperbola; let the lines $\mathrm{AK}, \mathrm{DL}$ be drawn parallel to $\mathrm{CH}^{\prime}$, and the lines $\mathrm{AK}^{\prime}, \mathrm{DL}^{\prime}$ parallel to CHE; then will the parallelogram CLDL' be equal to the parallelogram CKAK'.
Through the points A and D draw $\mathrm{EE}^{\prime}, \mathrm{HH}^{\prime}$ perpenidicular to the transverse axis; then, because the triangles AEK, DHL are similar, as also the triangles $\mathrm{AE}^{\prime} \mathrm{K}^{\prime}, \mathrm{DH}^{\prime} \mathrm{L}^{\prime}$, we have the proportions

AK : AE :: DL : DH.
Also, $\mathrm{AK}^{\prime}: \mathrm{AE}^{\prime}:: \mathrm{DL}^{\prime}: \mathrm{DH}^{\prime}$.
Hence (B. II., Pr. 12)
$\mathrm{AK} \times \mathrm{AK}^{\prime}: \mathrm{AE}^{2} \mathrm{AE}^{\prime}:: \mathrm{DL} \times \mathrm{DL}^{\prime}:$
$\mathrm{DH}^{2} \times \mathrm{DH}^{\prime}$.
But, by Pr. 24, Cor. 4, the consequents of this proportion are equal to each
 other ; hence $\quad \mathrm{AK} \times \mathrm{AK}^{\prime}$ is equal to $\mathrm{DL} \times \mathrm{DL}^{\prime}$.

But the parallelograms CA, CD, being equiangular, are as the rectangles of the sides which contain the equal angles (B. IV., Pr. 24, Cor. 2 ); hence the parallelogram CD is equal to the parallelogram CA.

## EXERCISES ON THE HYPERBOLA.

1. In an hyperbola, the tangents at the vertices of the trans'verse axis will meet the asymptotes in the circumference of the circle described on $\mathrm{FF}^{\prime}$ as a diameter.
2. If DM be drawn parallel to CG (fig., Pr. 14), meeting the transverse axis in $M$, then $M E=B C$.
3. If an hyperbola and an ellipse have the same foci, they cut one another at right angles.
4. If DG (fig. 2d, Pr. 11) be the ordinate of a point D , and GK be drawn parallel to AD to meet CD in K , then AK is parallel to the tangent at $D$.
. 5. If from any point of the hyperbola lines be drawn parallel to, and terminating in the asymptotes, the parallelogram so formed will be equal to one eighth of the rectangle described on the axes.
5. An ordinate to the transverse axis of an hyperbola is 43 inches, and the corresponding abscissas are 30 and 85 inches; required the latus rectum.
6. If the axes of an hyperbola are 65 and 54 inches, what is the radius of a circle described to touch the curve, when its centre is in the transverse axis produced, at the distance of 112 inches from the centre of the hyperbola?
7. If the axes of an hyperbola are 65 and 54 inches, what is its latus rectum, and what is the position of its directrix?
8. The conjugate axis of an hyperbola is 52 inches, the latus rectum 42 inches, and an ordinate of 36 inches is drawn to the transverse axis ; determine where the tangent line drawn through the extremity of this ordinate meets the transverse axis.
9. Determine where the tangent line in the last example meets the conjugate axis.

## PLANE TRIGONOMETRY.

1. Trigonometry is that branch of Mathematics which teaches how to determine the several parts of a triangle by means of others that are given. In a more enlarged sense, it embraces the investigation of the relations of angles in general.
Plane Trigonometry treats of plane angles and triangles; Spherical Trigonometry treats of spherical triangles.
2. In every triangle there are six parts: three sides and three angles. These parts are so related to each other that when any three of them are given, provided one of them is a side, the remaining parts can be determined.
3. In order to subject angles to computation, they must be expressed by numbers. The units by which angles are expressed are the degree, minute, and second, designated by the characters ${ }^{\circ}, ',{ }^{\prime}$.
A degree is the 90 th part of a right angle, or the 360 th part of the whole angular space about a point. A right angle is expressed by $90^{\circ}$; two right angles by $180^{\circ}$; and the whole angular space about a point by $360^{\circ}$.
A minute is an angle equal to the 60th part of a degree. Therefore one degree $=60^{\prime}$.
A second is an angle equal to the 60th part of a minute. Therefore one minute $=60^{\prime \prime}$.
Angles less than a second are expressed as decimal parts of a second. Thus $\frac{1}{7}$ th of four right angles will be expressed by

$$
51^{\circ} 25^{\prime} 42 . .^{\prime \prime} 86
$$

4. Since angles at the centre of a circle are proportional to the ares intercepted between their sides, these ares may be taken as the measures of the angles. An angle may therefore be measured by the number of units of arc intercepted on the circumference.
The units of are are also the degree, minute, and second. They are the arcs which subtend angles of a degree, a minute, and a second respectively at the centre. The quadrant is therefore expressed by $90^{\circ}$; the semi-circumference by $180^{\circ}$; and the whole circumference by $360^{\circ}$.

The radius of the circle employed in measuring angles is arbi-
trary, and, for convenience, is generally taken as unity. When this is not done, it is denoted by its initial letter R .
5. The circumference of a circle whose diameter is unity is 3.14159. If the radius be unity, the semi-circumference, or an arc of $180^{\circ}$, will be 3.14159 . Hence the length of an arc of $1^{\circ}$ will be $\quad 0.01745$; and the length of an arc of $1^{\prime}$ will be 0.00029 , etc.
6. The complement of an arc or angle is the remainder obtained by subtracting the are or angle from $90^{\circ}$. Thus the complement of $25^{\circ} 15^{\prime}$ is $64^{\circ} 45^{\prime}$. Since the two acute angles of a right-angled triangle are together equal to a right angle, each of them must be the complement of the other.

In general, if we represent any arc by $A$, its complement is $90^{\circ}$ - A. Hence, if an arc exceeds $90^{\circ}$, its complement must be negative. Thus the complement of $113^{\circ} 15^{\prime}$ is $-23^{\circ} 15^{\prime}$. See Art. 79.
7. The supplement of an are or angle is the remainder obtained by subtracting the arc or angle from $180^{\circ}$. Thus the supplement of $25^{\circ} 15^{\prime}$ is $154^{\circ} 45^{\prime}$. Since in every plane triangle the sum of the three angles is $180^{\circ}$, either angle is the supplement of the sum of the other two.

In general, if we represent any arc by $A$, its supplement is $180^{\circ}-A$. Hence, if an arc is greater than $180^{\circ}$, its supplement must be negative. Thus the supplement of $200^{\circ}$ is $-20^{\circ}$.
8. The sine of an arc is the perpendicular let fall from one extremity of the arc upon the diameter passing through the other extremity.

Thus FG is the sine of the arc AF, or of the angle ACF.

Every sine is half the chord of clouble the arc. Thus the sine FG is the half of FH, which is the chord of the are FAH, double of FA. The chord which subtends the sixth part of the circumference, or the chord of $60^{\circ}$, is equal to the radius (Geom., B. VI., Pr. 4); hence the sine of $30^{\circ}$ is equal to half of the radius.
9. The tangent of an arc is the line which touches the circle at one extremity of the arc, and is limited by a line drawn from the centre through the other eatrenity.

Thus AI is the tangent of the arc AF, or of the angle ACF.
10. The secant of an arc is the line drawn from the centre of the circle through one extremity of the arc, and is limited by the tangent drawn through the other extremity.

Thus CI is the secant of the arc AF, or of the angle ACF.
In the preceding definitions of sine, tangent, and secant, the radius of the circle has been assumed as unity. In a circle of any other radius, we must suppose these lines to be divided by that radius.
11. The cosine of an are is the sine of the complement of that arc.

Thus the are DF, being the complement of AF, FK, or its equal CG , is the sine of the are DF , or the cosine of the arc AF .

The cotangent of an arc is the tangent of the complement of that arc. Thus DL is the tangent of the arc DF , or the cotangent of the arc AF.

The cosecant of an arc is the secant of the complement of that arc. Thus CL is the secant of the arc DF, or the cosecant of the arc AF.

In general, if we represent any angle by A,

$$
\begin{array}{r}
\cos . A=\operatorname{sine}\left(90^{\circ}-A\right) \\
\cot A=\operatorname{tang} \cdot\left(90^{\circ}-A\right) \\
\operatorname{cosec} A=\sec .\left(90^{\circ}-A\right)
\end{array}
$$

Since in a right-angled triangle either of the acute angles is the complement of the other, the sine, tangent, and secant of one of these angles is the cosine, cotangent, and cosecant of the other.
12. The versed sine of an arc is that part of the diameter intercepted between the extremity of the arc and the foot of the sine.

Thus GA is the versed sine of the arc AF, or of the angle ACF.
The versed sine of an acute angle ACF is equal to the radius minus the cosine CG. The versed sine of an obtuse angle BCF is equal to radius plus the cosine $C G$; that is, to BG.
13. The sine, tangent, and secant of any arc are equal to the sine, tangent, and secant of its supplement.

Thus FG is the sine of the arc AF, or of its supplement BDF.
AI, the tangent of the arc AF , is equal to BM , the tangent of the are BDF.

And CI, the secant of the arc AF, is equal to CM, the secant of the are BDF.
14. Fundamental formulce. The relations of the sine, cosine, -etc., to each other may be derived from the proportions of the

sides of similar triangles. Thus the triangles CGF, CAI, CDL being similar, we have

1. $\mathrm{CG}: \mathrm{GF}:: \mathrm{CA}: \mathrm{AI}$; that is, representing the arc by A , and the radius of the circle by $R$, we have

$$
\cos . A: \sin . A:: R: \operatorname{tang} . A .
$$

Whence tang. $\mathrm{A}=\frac{\mathrm{R} \sin . \mathrm{A}}{\cos . \mathrm{A}}$.
2. $\mathrm{CG}: \mathrm{CF}:: \mathrm{CA}: \mathrm{CI}$; that is, $\cos . A: R:: R: s e c . A$.
Whence $\sec . A=-\frac{R^{2}}{\cos . A}$.
3. $\mathrm{GF}: \mathrm{CG}:: \mathrm{CD}: \mathrm{DL}$; that is, $\sin . \mathrm{A}: \cos . \mathrm{A}:: \mathrm{R}: \cot . \mathrm{A}$.

Whence

$$
\cot . A=\frac{R \cos . A}{\sin . A}
$$

4. GF : CF $:: \mathrm{CD}: \mathrm{CL}$; that is, $\sin . \mathrm{A}: \mathrm{R}:: \mathrm{R}: \operatorname{cosec} . \mathrm{A}$.

Whence

$$
\operatorname{cosec} . A=-\frac{R^{2}}{\sin . A} .
$$

5. AI : AC :: CD $: D L$; that is, tang. $A: R:: R: c o t$. $A$.

Whence

$$
\operatorname{tang} . A=\frac{\mathrm{R}^{2}}{\cot . A} .
$$

The preceding formulæ will be frequently referred to hereafter. 15. Given the sine of an angle, to find the cosine, tangent, etc.

In the right-angled triangle CGF , we find $\mathrm{CG}^{2}+\mathrm{GF}^{2}=\mathrm{CF}^{2}$; that is, $\sin .^{2} \mathrm{~A}+\cos ^{2}{ }^{2} \mathrm{~A}=\mathrm{R}^{2}$, where $\sin .^{2} \mathrm{~A}$ signifies " the square of the sine of A." When radius is taken as unity, we have

$$
\cos \cdot A=\sqrt{1-\sin .^{2} A}=\sqrt{(1+\sin . A)(1-\sin \cdot A)} .
$$

When the sine and cosine of an angle have been determined, the tangent may be found by Eq. 1, Art. 14,

$$
\operatorname{tang} . A=\frac{\sin . A}{\cos . A^{\prime}}
$$

and the cotangent by Eq. 3, Art. 14,

$$
\cot . A=\frac{\cos . A}{\sin . A}
$$

Also the secant by Eq. 2, Art. 14,

$$
\sec . A=\frac{1}{\cos \cdot A^{2}}
$$

and the cosecant by Eq. 4, Art. 14,

$$
\operatorname{cosec} . A=\frac{1}{\sin . A}
$$

Hence we see that if we had a table of sines for every degree and minute of the quadrant, we could easily obtain the cosines, tangents, cotangents, etc.

Ex. 1. Compute the cosine, tangent, etc., of $30^{\circ}$.
Ex. 2. Given the tangent of $20^{\circ}$, equal to 0.364 , to find the secant of $20^{\circ}$. Find also the sine, etc., of the same angle.

Ex. 3. The tangent of $45^{\circ}$ is unity. Compute the sine and secant of $45^{\circ}$.

Ex. 4. The sine of $40^{\circ}$ is 0.643 . Compute the cosine, tangent, etc.
16. A table of natural sines, tangents, etc., is a table giving the lengths of those lines for different angles in a circle whose radius is unity.

Thus, if we describe a circle with a radius of one inch, and divide the circumference into equal parts of ten degrees, we shall find that

| sine | $10^{\circ}=0.174$ | sine $50^{\circ}=0.766$ |  |
| :---: | :---: | :---: | :---: |
| " | $20=0.342$ | " | $60=0.866$ |
| " | $30=0.500$ | " | $70=0.940$ |
| " | $40=0.643$ | " $80=0.985$ |  |
| " | $45=0.707$ | " $90=1.000$ |  |

If we draw the tangents of the same arcs,
 we shall find that
tangent $10^{\circ}=0.176$
$\begin{array}{ll}" & 20=0.364 \\ " & 30=0.577 \\ " & 40=0.839 \\ " & 45=1.000\end{array}$
tangent $50^{\circ}=1.192$
" $60=1.732$
" $\quad 70=2.747$
" $80=5.671$
" $90=$ infinite.

Also, if we draw the secants of the same arcs, we shall find that
secant $10^{\circ}=1.015 \mid$ secant $50^{\circ}=1.556$

| " | $20=1.064$ |
| :--- | :--- |
| " | $30=1.155$ |
| " | $40=1.305$ |
| " | $45=1.414$ |$\quad$ " $\quad 70=20=2.000=5.759$

17. The following table, pages 268-9, gives the sines and tangents between $0^{\circ}$ and $90^{\circ}$ for every ten minutes to four places of figures. For angles less than $45^{\circ}$, look for the degrees in the first vertical column,
 and for the minutes at the top of one of the six following columns; and for angles greater than $45^{\circ}$, look

|  | o |  |  |  |  | 50 |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  | 46 |  |  |  |  |  |  |
|  |  |  |  |  |  |  | 47 |  | 1 | 3 |  |  |  |
| 3 | -5 |  |  |  |  |  | 48 |  |  |  |  |  |  |
| 4 |  |  | 0756 |  |  | -84 | 49 |  |  |  |  |  |  |
| 5 |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 6 |  |  |  | 1132 | I 16 |  | 5 |  |  |  |  |  |  |
| 7 |  |  |  |  |  |  | 52 |  |  |  |  |  |  |
| 8 |  |  |  | 1 |  | I 536 | 53 | 79 |  |  |  |  |  |
|  |  |  |  |  |  |  |  |  |  |  |  |  |  |
|  |  |  |  |  |  |  | 55 |  |  |  |  |  |  |
|  |  |  |  |  |  |  | 50 |  |  |  | 8339 |  |  |
|  |  |  | 6 |  |  |  |  |  |  |  | 8434 |  |  |
|  | 22 |  |  |  |  |  | 58 | 84 | 849 |  |  |  |  |
|  |  |  |  | 25 | 532 | 2560 |  |  |  | 8601 | 8616 | 863 I |  |
|  |  |  |  |  |  |  | 60 |  |  |  |  |  |  |

|  | - $0^{\prime}$ | 10 | 20 | $3 \mathrm{o}^{\prime}$ | $40^{\prime}$ | $50^{\prime}$ |  | $\mathrm{o}^{\prime}$ | $10^{\prime}$ | $20^{\prime}$ | $30^{\prime}$ | $40^{\prime}$ |  |

for the degrees in the eighth vertical column, and for the minutes at the top of one of the six following columns. Upon the same horizontal line with the degrees, and under the given number of minutes at the top of the page, will be found the sine or tangent required. Since the radius of the circle is supposed to be unity, the sine of every arc below $90^{\circ}$ is less than unity. The sines are expressed in decimal parts of radius; and, although the decimal point is not written in the table, it must always be prefixed. Thus

$$
\text { the sine of } 25^{\circ} 10^{\prime} \text { is } 0.4253 \text {; }
$$

$$
\text { " } \quad 51 \quad 30 \text { is } 0.7826 .
$$

So also the tangent of $31^{\circ} 40^{\prime}$ is 0.6168 ;

$$
65 \quad 20 \text { is } 2.1770 .
$$

If the cosine of an angle is required, we must look for the sine of the complement of that angle. Thus
the cosine of $16^{\circ} 40^{\prime}$ is the sine of $73^{\circ} 20^{\prime}$, or 0.9580 ;
" $67 \quad 20 \quad$. $\quad 2240$, or 0.3854 .
The cotangents are found in the same manner.
It is not necessary to extend the tables beyond a quadrant, because the sine of an angle is equal to that of its supplement, Art. 13.

Thus the sine of $116^{\circ} 10^{\prime}$ is the same as the sine of $63^{\circ} 50^{\prime}$.
cosine of $132 \quad 40 \quad$ " sine of 4240 ;
Co tangent of $143 \quad 20 \quad$ " $\quad$ tangent of $36 \quad 40$;
cotangent of $151 \quad 50$ " tangent of 6150 .
18. If a sine is required for an angle containing a number of minutes not given in the table, it must be found by interpolation. This interpolation is based upon the assumption that the differences of the sines are proportional to the differences of the angles; and, although this assumption is not strictly correct, the error is generally so small that it may be neglected. Thus the sine of $40^{\circ} 20^{\prime}$ is 0.6472 ;
" $\quad 40 \quad 30$ is 0.6494 .
The difference of the sines corresponding to ten minutes of are is .0022 , which is called the tabular difference.

The correction for $1^{\prime}$ is therefore .00022 ; for $2^{\prime}$ it is .00044 ; for $3^{\prime}$ it is .00066 , etc.

As the tables only extend to four decimal places, we omit the fifth decimal, and, when the fraction omitted exceeds a half, we increase the preceding figure by unity. Thus we find
the sine of $40^{\circ} 21^{\prime}$ is 0.6474 ;

| $"$ | 40 | 22 | $0.6476 ;$ |
| :--- | :--- | :--- | :--- |
| " | 40 | 23 | 0.6479, etc. |

Thus we see that the correction for the odd minutes is found by multiplying the tabular clifference by the number of minutes, and dividing the product by 10.

In this manner we find

$$
\begin{aligned}
& \text { the sine of } 27^{\circ} 17^{\prime} \text { is } 0.4584 ; \\
& \text { cosine of } 45 \quad 23 \text { is } 0.7024 ; \\
& \text { the tangent of } 63 \quad 32 \text { is } 2.0090 ; \\
& \text { cotangent of } 81 \quad 48 \text { is } 0.1441 \text {; }
\end{aligned}
$$

19. To find the number of degrees and minutes belonging to a given sine or tangent.

If the given sine is found exactly in the table, the corresponding degrees will be found in the first or eighth vertical column, and the minutes at the top of the page. But when the given number is not found exactly in the table, look for the sine or tangent which is next less than the proposed one, and take out the corresponding degrees and minutes. The additional minutes may be found by reversing the process described in the preceding article.

Find the difference between the given number and the one next less in the table; multiply this difference by 10 , and divide the result by the tabular difference. The quotient will be the additional minutes required.

Ex. Required the arc whose sine is 0.5060 .
The next less sine in the table is 0.5050 , which corresponds to $30^{\circ} 20^{\prime}$. The difference between this sine and the given sine is .0010 , which, multiplied by 10 and divided by the tabular difference .0025 , gives 4 , the additional minutes required. The required are is therefore $30^{\circ} 24^{\prime}$.

In the same manner we find the are whose tangent is 1.750 is $60^{\circ} 15^{\prime}$.
If the arc corresponding to a cosine or a cotangent is required, first find the arc corresponding to the same number regarded as a sine or tangent, and take the complement of this arc. Thus
the are whose cosine is 0.8264 is $34^{\circ} 16^{\prime}$;
6
cotangent is 0.7146 is $54^{\circ} 27^{\prime}$.

## LOGARITHMS.

20. Logarithms are numbers designed to diminish the labor of multiplication and division by substituting in their stead addition and subtraction. All numbers are regarded as powers of some one number; which is called the base of the system; and the.
exponent of the power to which the base must be raised in order to be equal to a given number is called the logarithm of that number.

The base of the common system of logarithms (called, from their inventor, Briggs's Logarithms) is the number 10. Hence all numbers are to be regarded as powers of 10 . Thus, since

$$
\begin{array}{lrr}
10^{0}=1 & \text { we have logarithm of } 1 & =0 ; \\
10^{1}=10 & " & 10=1 ; \\
10^{2}=100 & " & 100=2 ; \\
10^{3}=1000 & " & 1000=3, \text { etc. }
\end{array}
$$

Whence it appears that in Briggs's system the logarithm of any number between 1 and 10 is some number between 0 and 1 ; that is, it is a fraction less than unity, and is generally expressed as a decimal. The logarithm of any number between 10 and 100 is some number between 1 and 2 ; that is, it is equal to 1 plus a decimal. The logarithm of any number between 100 and 1000 is some number between 2 and 3 ; that is, it is equal to 2 plus a decimal ; and so on.
21. The same principle may be extended to fractions by means of negative exponents. Thus, since

| $10^{-1}=\frac{1}{10}$, | or 0.1, | -1 is the logarithm of $0.1 ;$ |  |
| :--- | :--- | :--- | :--- |
| $10^{-2}=\frac{1}{100}$, | or 0.01, | -2 | " |
| $10^{-3}=\frac{1}{1000}$, | or $0.001,-3$ | " | $0.01 ;$ |
| $10^{-4}=\frac{1}{10000}$, | or $0.0001,-4$ | " | $0.001 ;$ |
| 10 | $0.0001, ~ e t c$. |  |  |

Hence it appears that the logarithm of any number between 1 and 0.1 is some number between 0 and -1 , or may be represented by -1 plus a decimal. The logarithm of any number between 0.1 and 0.01 is some number between -1 and -2 , or may be represented by -2 plus a decimal. The logarithm of any number between 0.01 and 0.001 is some number between -2 and -3 , or may be represented by -3 plus a decimal, and so on.
22. Hence we see that the logarithms of most numbers must consist of two parts, an integral part and a decimal part. The integral part is called the characteristic or index of the logarithm. The characteristic may always be determined by the following

## RULE.

The characteristic of the logarithm of any number is equal to the number of places by which the first significant figure of that number is removed from the unit's place; and is positive when this figure is to the left of the unit's place, negative when it is to the right, and zero when it is in the unit's place.

Thus the characteristic of the logarithm of 397 is +2 , and that of 4673 is +3 , while the characteristic of the logarithm of 0.0046 is -3 .
23. Since powers of the same quantity are multiplied by adding their exponents, the logarithm of the product of twoo or more numbers is equal to the sum of the logarithms of those numbers. Also, since powers of the same quantity are divided by subtracting their exponents, the logarithm of the quotient of two numbers is equal to the logarithm of the dividend diminished by that of the divisor.

Since the logarithm of 10 is 1 , if. a number be multiplied or divided by 10 , its logarithm will be increased or diminished by 1 , the decimal part remaining unchanged. Hence

The decimal part of the logarithm of any number is the same as that of the number multiplied or divided by $10,100,1000$, etc.

Thus, if we denote the decimal part of the logarithm of 3456 by $m$, we shall have logarithm of $3456=3+m$; logarithm of $.3456=-1+m$;

|  | $345.6=\mathcal{L}+m ;$ | " | $.03456=-2+m ;$ |
| :---: | :---: | :---: | :---: |
| 6 | $34.56=1+m ;$ |  | . $003456=-3+m$; |
|  | $3.456=0+m$; |  | $.0003456=-4+m$. |

## Table of Logarithms.

24. A table of logarithms usually contains the logarithms of the entire series of natural numbers from 1 up to 10,000 , and the larger tables extend to 100,000 or more. In the smaller tables the logarithms are usually given to five or six decimal places; the larger tables extend to seven, and sometimes eight or more places.

In the accompanying table, the logarithms of the first 100 numbers are given, with their characteristics; but for all other numbers, only the decimal part of the logarithm is given, while the characteristic is left to be supplied according to the rule in Art. 22.

To find the Logarithm of any Number between 1 and 100.
25. Look on the first page of the accompanying table, along the column of numbers under N., for the given number, and against it, in the next column, will be found the logarithm, with its characteristic. Thus
opposite 13 is 1.113943 , which is the logarithm of 13 ;
" 65 is 1.812913 , " 65.

## To find the Logarithm of any Number consisting of three

Tigures.
Look on one of the pages of the table from 322 to 342 , along the left-hand column, marked N., for the given number, and against it, in the column headed 0 , will be found the decimal part of its logarithm. To this the characteristic must be prefixed, according to the rule in Art. 22. Thus

As the first two figures of the decimal are the same for several successive numbers in the table, they are not repeated for each logarithm separately, but are left to be supplied. Thus the decimal part of the logarithm of 339 is .530200 . The first two figures of the decimal remain the same up to 347 ; they are therefore omitted in the table, and are to be supplied.

## To find the Logarithm of any Number consisting of four

Figures.
Find the three left-hand figures in the column marked N., as before, and the fourth figure at the head of one of the other columns. Opposite to the first three figures, and in the column under the fourth figure, will be found four figures of the logarithm, to which two figures from the column headed 0 are to be prefixed, as in the former case. The characteristic must be supplied according to Art. 22. Thus
the logarithm of 3456 is 3.538574 ;

$$
\text { " " } \quad 8765 \text { is } 3.942752 \text {. }
$$

In several of the columns headed $1,2,3$, etc., small dots are found in the place of figures. This is to show that the two figures which are to be prefixed from the first column have changed, and they are to be taken from the horizontal line directly below. The place of the dots is to be supplied with ciphers. Thus the logarithm of 2045 is 3.310693 ;
"
9777 is 3.990206 .
The two leading figures from the column 0 must also be taken from the horizontal line below, if any dots have been passed over on the same horizontal line. Thus
the logarithm of 1628 is 3.211654 .

## To find the Logarithm of any Number containing more than four Figures.

26. By inspecting the table, we shall find that the differences of the logarithms are nearly proportional to the differences of their corresponding numbers. Thus
the logarithm of 7250 is 3.860338 ;

| " | " | 7251 is 3.860398 ; |
| :--- | :--- | :--- |
| " | " | 7252 is 3.860458 ; |
| " | " | 7253 is 3.860518 . |

Here the difference between the successive logarithms, called the tabular difference, is constantly 60 , corresponding to a difference of unity in the natural numbers. If, then, we suppose the differences of the logarithms to be proportional to the differences of their corresponding numbers (as they are nearly), a difference of 0.1 in the numbers should correspond to a difference of 6 in the logarithms; a difference of 0.2 in the numbers should correspond to a difference of 12 in the logarithms, etc. Hence
the logarithm of 7250.1 must be 3.860344 ;

| " | " | 7250.2 | " | 3.860350 ; |
| :--- | :--- | :--- | :--- | :--- |
| " | 7250.3 | " | 3.860356 . |  |

In order to facilitate the computation, the tabular difference is inserted on page 338 in the column headed D., and the proportional part for the fifth figure of the natural number is given at the bottom of the page. Thus, when the tabular difference is 60 , the corrections for $.1, .2, .3$, etc., are seen to be $6,12,18$, etc.

If the given number was 72501 , the characteristic of its logarithm would be 4 , but the decimal part would be the same as for 7250.1 .

If it were required to find the correction for a sixth figure in the natural number, it is readily obtained from the Proportional Parts in the table. The correction for a figure in the sixth place must be one tenth of the correction for the same figure if it stood in the fifth place. Thus, if the correction for .5 is 30 , the correction for .05 is obviously 3 .

Required the logarithm of 452789.
The logarithm of 452700 is 5.655810 .
The tabular difference is 96 .
Accordingly, the correction for the fifth figure, 8 , is 77 , and for the sixth figure, 9 , is 8.6 , or 9 nearly. Adding these corrections to the number before found, we obtain 5.655896 .

The preceding logarithms do not pretend to be perfectly exact,
but only the nearest numbers limited to six decimal places. Accordingly, when the fraction which is omitted exceeds half a unit in the sixth decimal place, the last figure must be increased by unity.

Required the logarithm of 8765432.
The logarithm of 8765000 is $\quad 6.942752$
Correction for the fifth figure, $4, \quad 20$

| " | " | sixth figure, 3 , | 1.5 |
| :---: | :---: | :---: | :---: |
| " | " | seventh figure 2 , | 0.1 |

Therefore the logarithm of 8765432 is 6.942774 .
Required the logarithm of 234567.
The logarithm of 234500 is 5.370143
Correction for the fifth figure, 6, 111
" " sixth figure, 7, 13
Therefore the logarithm of 234567 is $\overline{5.370267}$.

## To find the Logarithm of a Decimal Fraction.

27. According to Art. 23, the decimal part of the logarithm of any number is the same as that of the number multiplied or divided by $10,100,1000$, etc. Hence, for a decimal fraction, we find the logarithm as if the figures were integers, and prefix the characteristic according to the rule of Art. 22.

## EXAMPLES.

|  |  |  | is 2.538574 ; |
| :---: | :---: | :---: | :---: |
| " | " | 87.65 | is 1.942752 ; |
| " | " | 2.345 | is 0.370143 ; |
| " | " | . 1234 | is $\overline{1} .091315$; |
| " | " | . 005 | s $\overline{3} .75419$ |

The minus sign is here placed over the characteristic, to show that that alone is negative, while the decimal part of the logarithm is positive.

## To find the Logarithm of a Vulgar Traction.

28. We may reduce the vulgar fraction to a decimal, and find its logarithm by the preceding article; or, since the value of a fraction is equal to the quotient of the numerator divided by the denominator, we may, according to Art. 23, subtract the logarithm of the denominator from that of the numerator ; the difference will be the logarithm of the fraction.

Ex. 1. Find the logarithm of $\frac{3}{16}$, or 0.1875 .

$$
\begin{array}{ll}
\text { From the logarithm of } 3, & 0.477121, \\
\text { Take the logarithm of } 16, & \frac{1.204120}{} \\
\text { Leaves the logarithm of } \frac{3}{16} \text {, or } .1875,1.273001 .
\end{array}
$$

Ex. 2. The logarithm of $\frac{4}{55}$ is $\overline{2} .861697$.
Ex. 3. The logarithm of $\frac{1}{8} \frac{23}{6}$ is $\overline{1} .147401$.

## To find the Natural Number corresponding to any Logarittum.

29. Look in the table, in the column headed 0 , for the first two figures of the logarithm, neglecting the characteristic; the other four figures are to be looked for in the same column, or in one of the nine following columns; and if they are exactly found, the first three figures of the corresponding number will be found opposite to them in the column headed N., and the fourth figure will be found at the top of the page. This number must be made to correspond with the characteristic of the given logarithm by pointing off decimals or annexing ciphers. Thus the natural number belonging to the log. 4.370143 is 23450 ;

$$
\text { " " " " } 1.538574 \text { is } 34.56 \text {. }
$$

If the decimal part of the logarithm can not be exactly found in the table, look for the nearest less logarithm, and take out the four figures of the corresponding natural number as before; the additional figures may be obtained by means of the Proportional Parts at the bottom of the page.
Required the number belonging to the logarithm 4.368399. On page 328 we find the next less logarithm .368287 .
The four corresponding figures of the natural number are 2335. Their logarithm is less than the one proposed by 112. The tabular difference is 186 ; and, by referring to the bottom of page 328 , we find that, with a difference of 186 , the figure corresponding to the proportional part 112 is 6 . Hence the five figures of the natural number are 23356 ; and, since the characteristic of the proposed logarithm is 4 , these five figures are all integral.

Required the number belonging to the logarithm 5.345678 .

The next less logarithm in the table is
Their difference is
345570.

The first four figures of the natural number are 2216.
With the tabular difference 196, the fifth figure, corresponding to 108 , is seen to be 5 , with a remainder of 10 . To find the sixth figure corresponding to this remainder 10 , we may multiply it by

10, making 100 , and search for 100 in the same line of Proportional Parts. We see that a difference of 100 would give us 5 in the fifth place of the natural number. Therefore a difference of 10 must give us 5 in the sixth place of the natural number. Hence the required number is 221655.

In the same manner we find the number corresponding to the $\log .3 .538672$ is 3456.78 ;

| " | " | " | ".994605 is |
| :--- | :--- | :--- | :--- |
| " | $98.7654 ;$ |  |  |
|  |  |  | 1.647817 is |
|  | .444444. |  |  |

## MULTIPLICATION BY LOGARITHMS.

30. According to Art. 23, the logarithm of the product of two or more factors is equal to the sum of the logarithms of those factors. Hence, for multiplication by logarithms, we have the following

## RULE.

Add the logarithms of the factors; the sum will be the of their product.

Ex. 1. Required the product of 57.98 by 18 .
The logarithm of $57.98 \quad$ is 1.763278

The logarithm of the product 1043.64 is 3.018551 .
Ex. 2. Required the product of 397.65 by 43.78 .

$$
\text { Ans. } 17409.117
$$

Ex. 3. Required the continued product of $54.32,6543$, and 12.345.

The word sum in the preceding rule is to be understood in its algebraic sense; therefore, if any of the characteristics of the logarithms are negative, we must take the difference between their sum and that of the positive characteristics, and prefix the sign of the greater. It should be remembered that the decimal part of the logarithm is invariably positive; hence that which is carried from the decimal part to the characteristic must be considered positive.

Ex. 4. Multiply 0.00563 by 17.
The logarithm of 0.00563 is $\overline{3} .750508$
17 is 1.230449
Product, 0.09571 , whose logarithm is 2.980957 .
Ex. 5. Multiply 0.3854 by 0.0576 .

$$
\begin{aligned}
& \text { The logarithm of } 0.3854 \text { is } \overline{1} .585912 \\
& \text { " " } 0.0576 \text { is } \overline{2} .760422
\end{aligned}
$$

Product 0.022199 , whose logarithm is $\overline{2} .346334$.
Ex. 6. Multiply 0.007853 by 0.00476 . Ans. 0.00003738 .
Ex. 7. Find the continued product of $11.35,0.072$, and 0.017 .
31. The logarithm of a negative number is an imaginary quantity. If, therefore, it is required to multiply negative numbers by means of logarithms, we must multiply the equal positive numbers, and give to the product the sign required by the rule of signs in Multiplication. To distinguish the negative sign of a natural number from the negative characteristic of a logarithm, we append the letter $n$ to the logarithm of a negative factor. Thus for -56 we write the logarithm $1.748188 n$.
Ex. 8. Multiply 53.46 by -29.47 .
The logarithm of $\quad 53.46$ is 1.728029
For -29.47 we write the logarithm $1.469380 n$. Product, $-1575.47, \log . \overline{3.197409} n$.
Ex. 9. Find the continued product of $372.1,-.0054$, and -175.6.
Ex. 10. Find the continued product of $-0.137,-7.689$, and -. 0376 .

## DIVISION BY LOGARITHMS.

32. According to Art. 23, the logarithm of the quotient of one number divided by another is equal to the difference of the logarithms of those numbers. Hence, for division by logarithms, we have the following

## RULE.

From the logarithm of the dividend subtract the logarithm of the divisor; the difference will be the logarithm of the quotient.

Ex. 1. Required the quotient of 888.7 divided by 42.24 .

> The logarithm of 888.7 is 2.948755 42.24 is 1.625724 $"$

The quotient is 21.039 , whose $\log$. is $\overline{1.323031}$.
Ex. 2. Required the quotient of 3807.6 divided by 13.7. Ans. 277.927.
The word difference, in the preceding rule, is to be understood in its algebraic sense; therefore, if the characteristic of one of the logarithms is negative, or the lower one is greater than the
upper, we must change the sign of the subtrahend, and proceed as in addition. If unity is carried from the decimal part, this must be considered as positive, and must be united with the characteristic before its sign is changed.

Ex. 3. Required the quotient of 56.4 divided by 0.00015.

| The logarithm of | 56.4 is 1.751279 |
| ---: | ---: |
| " | 0.00015 is $\overline{4} .176091$ |

The quotient is 376000 , whose logarithm is $\overline{5.575188}$.
This result may be verified in the same way as subtraction in common arithmetic. The remainder, added to the subtrahend, should be equal to the minuend. This precaution should always be observed when there is any doubt with regard to the sign of the result.

Ex. 4. Required the quotient of .8692 divided by 42.258.
Ex. 5. Required the quotient of .74274 divided by .00928 .

| The logarithm of | 0.74274 is $\overline{1} .870837$ |
| :---: | :--- |
| " | 0.00928 is $\overline{3} .967548$ |

The quotient is 80.037 , whose logarithm is 1.903289 .
Ex. 6 . Required the quotient of 24.934 divided by .078541.
If the divisor or dividend, or both, be negative, we perform the division by logarithms by using the equal positive numbers, and prefixing to the quotient the sign required by the rule of signs in Algebra.

Ex. 7. Required the quotient of -79.54 divided by 0.08321 .
Ex. 8. Required the quotient of -0.4753 divided by -36.74 .

## INVOLUTION BY LOGARITHMS.

33. It is proved in Algebra, Art. 398, that the logarithm of any power of a number is equal to the logarithm of that number multiplied by the exponent of the power. Hence, to involve a number by logarithms, we have the following

RULE.
Multiply the logarithm of the number by the exponent of the power required.

Ex. 1. Required the square of 428.
The logarithm of 428 is 2.631444
Square, $183184, \log . \overline{5.262888}$.

Ex. 2. Required the 20th power of 1.06 .
The logarithm of 1.06 is 0.025306
20
20 th power, $3.2071, \log . \overline{0.506120}$.
Ex. 3. Required the 5 th power of 2.846.
It should be remembered that what is carried from the decimal part of the logarithm is positive, whether the characteristic is positive or negative.

Ex. 4. Required the cube of .07654.
The logarithm of .07654 is $\overline{2} .883888$
Cube, .0004484, log. $\overline{\overline{4} .651664}$.
Ex. 5. Required the fourth power of 0.09874.
Ex. 6. Required the seventh power of 0.8952 .

## EVOLUTION BY LOGARITHMS.

34. It is proved in Algebra, Art. 399, that the logarithm of any root of a number is equal to the logarithm of that number divided by the index of the root. Hence, to extract the root of a number by logarithms, we have the following

## RULE.

Divide the logarithm of the number by the index of the root required.

Ex. 1. Required the cube root of 482.38 .
The logarithm of 482.38 is 2.683389 .
Dividing by 3 , we have 0.894463 , which corresponds to 7.842 , which is therefore the root required.

Ex. 2. Required the 100th root of 365. Ans. 1.0608.
When the characteristic of the logarithm is negative, and is not divisible by the given divisor, we may increase the characteristic by any number which will make it exactly divisible, provided we prefix an equal positive number to the decimal part of the logarithm.

Ex. 3. Required the seventh root of 0.005846 .
The logarithm of 0.005846 is $\overline{3} .766859$, which may be written $\overline{7}+4.766859$.

Dividing by 7 , we have $\overline{1} .680980$, which is the logarithm of .4797 , which is, therefore, the root required.

This result may be verified by multiplying $\overline{1} .680980$ by 7 ; the result will be found to be $\overline{3} .766860$.

Ex. 4. Required the fifth root of 0.08452 .
Ex. 5. Required the tenth root of 0.007815 .

## PROPORTION BY LOGARITHMS.

35. The fourth term of a proportion is found by multiplying together the second and third terms, and dividing by the first. Hence, to find the fourth term of a proportion by logarithms,

Add the logarithms of the second and third terms, and from their sum subtract the logarithm of the first term.

Ex. 1. Find a fourth proportional to $72.34,2.519$, and 357.48.

$$
\text { Ans. } 12.448 .
$$

36. When one logarithm is to be subtracted from another, it is sometimes more convenient to convert the subtraction into an addition, which may be done by first subtracting the given logarithm from 10 , adding the difference to the other logarithm, and afterward rejecting the 10 .
The difference between a given logarithm and 10 is called its complement; and this is easily taken from the table by beginning at the left hand, subtracting each figure from 9 , except the last significant figure on the right, which must be subtracted from 10.
To subtract one logarithm from another is the same as to add its complement, and then reject 10 from the result. For $a-b$ is equivalent to $10-b+a-10$.

To work a proportion, then, by logarithms, we must
Add the complement of the logarithm of the first term to the logarithms of the second and third terms.

The characteristic must afterward be diminished by 10.
Ex. 1. Find a fourth proportional to 6853,489 , and 38750.
The complement of the logarithm of 6853 is 6.164119
The logarithm of 489 is 2.689309
" " 38750 is 4.588272
The fourth term is 2765 , whose logarithm is $\overline{3.441700}$.
One advantage of using the complement of the first term in working a proportion by logarithms is, that it enables us to exhibit the operation in a more compact form.

Ex. 2. Find a fourth proportional to $73.84,658.3$, and 4872.
Ans.

Ex. 3. Find a fourth proportional to $5.745,781.2$, and 54.27 .

## LOGARITHMIC SINES AND TANGENTS.

37. When the natural sines, tangents, etc., are used in proportions, it is necessary to perform the tedious operations of multiplication and division. It is therefore generally preferable to employ the logarithms of the sines; and, for convenience, these numbers are arranged in a separate table, called logarithmic sines, etc. Thus

$$
\text { the natural sine of } 32^{\circ} 30^{\prime} \text { is } 0.5373 \text {. }
$$

Its logarithm, found from page 335 , is $\overline{1} .730217$.
The characteristic of the logarithm is negative, as must be the case with all the sines, since they are less than unity. To avoid the introduction of negative numbers in the table, we increase the characteristic by 10 , making 9.730217 , and this is the number found on page 376 for the logarithmic sine of $32^{\circ} 30^{\prime}$. The radius of the table of logarithmic sines is therefore sometimes regarded as $10,000,000,000$, whose logarithm is 10 .

The accompanying table contains the logarithmic sines and taingents for every degree and minute of the quadrant.
38. To find the logarithmic sine, cosine, etc., of a given arc or angle. If the angle be less than $45^{\circ}$, find the degrees at the top of the page, and the minutes in the left vertical column, marked M. ; then, in the column marked sine at the top, and opposite to the minutes, will be found the logarithmic sine of the given are; in the column marked cosine, and opposite to the minutes, will be found the cosine of the given arc, etc.

Thus, on page 371 , we find

| the log. sine | of $27^{\circ} 38^{\prime}$ is $9.666342 ;$ |  |
| :---: | :---: | ---: |
| cosine | " | $9.947401 ;$ |
| tangent | " | $9.718940 ;$ |
| cotangent | " | 10.281060 . |

If the angle be greater than $45^{\circ}$, find the degrees at the bottom of the page, and the minutes in the vertical column on the right; then, in the column marked sine at the bottom, and opposite to the minutes, will be found the logarithmic sine of the given arc, etc.

It will be seen that the angle found by taking the degrees at the top of the page, and the minutes from the first vertical column on the left, is the complement of the angle found by taking the corresponding minutes upon the same horizontal line from the vertical column on the right, and the degrees at the bottom of
the page. Thus, on page 371 , having found $27^{\circ} 38^{\prime}$, follow the horizontal line containing the minutes to the right vertical column, and we find $22^{\prime}$ with $62^{\circ}$ at the bottom of the page; and we see that $62^{\circ} 22^{\prime}$ is the complement of $27^{\circ} 38^{\prime}$. Now the sine of $27^{\circ}$ $38^{\prime}$ is the cosine of $62^{\circ} 22^{\prime}$; and the cosine of $27^{\circ} 38^{\prime}$ is the sine of $62^{\circ} 22^{\prime}$. This fact is indicated in the table, where the column marked sine at the top is marked cosine at the bottom; and the column marked tangent at the top is marked cotangent at the bottom.

On page $3 ヶ 9$ we find

| g. sine | $43^{\prime}$ is 9.911853 ; |
| :---: | :---: |
| cosine | 9.761642 ; |
| tangent | 10.150210; |
| cotangent | 9.849790. |

39. If a sine is required for an are consisting of degrees, minutes, and seconds, we must make an allowance for the seconds in the same manner as was directed in the case of logarithms, Art. 26 ; for within certain limits the differences of the logarithmic sines are proportional to the differences of the corresponding arcs. Thus the log . sine of $24^{\circ} 15^{\prime}$ is 9.613545 ;

$$
\text { " } \quad 25 \quad 16 \text { is } 9.613825 .
$$

The difference of the log. sines corresponding to one minute of are, or $60^{\prime \prime}$, is .000280 ; or 280 if we regard the sixth decimal place as units. The proportional part for $1^{\prime \prime}$ is found by dividing the tabular difference by 60 , which in this case gives 4.67 ; that is, the allowance for $100^{\prime \prime}$ would be 467 ; and this is the number given on page 368 , in the column with the title $\mathrm{D} .100^{\prime \prime}$, upon the horizontal line between 15 ' and $16^{\prime}$. The correction for any number of seconds will be found by multiplying the proportional part for $1^{\prime \prime}$ by the number of seconds; or multiplying the corresponding number in the column marked $D$. by the number of seconds, and rejecting the last two figures of the product.

Required the log. sine of $32^{\circ} 45^{\prime} 37^{\prime \prime}$.
On page 376 the corresponding number in the column marked D. is 327 . Multiplying this by 37 , and rejecting the last two figures of the product, we obtain 121, which is the correction for $37^{\prime \prime}$. Adding this to the sine of $32^{\circ} 45^{\prime}$, we find

$$
\text { the log. sine of } 32^{\circ} 45^{\prime} 37^{\prime \prime} \text { is } 9.733298 .
$$

In a similar manner we find the tangent of an are consisting of degrees, minutes, and seconds; and so also for cosines and cotangents, except that the correction for the seconds is to be sub-
tracted instead of added, because the cosines decrease while the arcs increase.

The column marked $D$. between the tangents and cotangents answers for each of these columns, because by Eq. 5, Art. 14, tang. $A \times \cot . A=R^{2}$; that is, log. tang. $A+\log$. cot. $A=20$; and it will be observed that the sum of any two numbers on the same horizontal line in these two columns is equal to 20 . Hence the difference for $1^{\prime \prime}$ is the same in both columns.

Examples. The log. sine of $3 ケ^{\circ} 24^{\prime} 13^{\prime \prime}$ is 9.783493 ;

$$
\text { log. cosine of } 48 \quad 32 \quad 29 \text { is } 9.820910
$$

the log. tangent of $62^{\circ} 45^{\prime} 31^{\prime \prime}$ is 10.288325 ;
log. cotangent of $81 \quad 1758$ is 9.184781 .
40. For ares not exceeding half a degree, the sine and tangent may be found more conveniently, and in general more accurately, as in the following examples: for in so small an are the sine and tangent do not differ from the are by so much as a unit in the sixth decimal place, and hence the sine of a small are may be assumed as equal to the sine of $1^{\prime \prime}$ multiplied by the number of seconds in the arc.

Ex. 1. Required the log. sine of $23^{\prime \prime} .87$.
The log. sine of $1^{\prime \prime}$ is 4.685575
$\log$. of 23.87 is $\quad 1.377852$
The log. sine of $23 .{ }^{\prime \prime} 87$ is $\overline{6.063427}$
Ex. 2. Required the log. tangent of $5^{\prime} 37 .{ }^{\prime \prime} 5$.
The log. tangent of $1^{\prime \prime}$ is
4.685575
log. of 337.5 is
The log. tangent of $5^{\prime} 37^{\prime \prime} .5$ is
2.528274
7.213849 .

For arcs not exceeding $7^{\prime}$ this method will give the log. sine or tangent correct to six decimal places; and for ares not exceeding one degree, the error is quite small.
41. It is not necessary to extend the tables beyond $90^{\circ}$, because the sine of an angle is equal to that of its supplement, Art. 13. Thus the log. sine of $126^{\circ} 17^{\prime} 24^{\prime \prime}$ is 9.906352 ;

$$
\begin{array}{lll}
\text { log. cosine of } 132 & 2953 \text { is } 9.829667 ; \\
\text { log. tangent of } 158 & 4212 & \text { is } 9.590860 ; \\
\text { log. cotangent of } 147 & 51.38 \text { is } 10.201862 .
\end{array}
$$

42. The secants and cosecants are omitted in this table, since they are easily derived from the sines and cosines. We have found, Art. 14, Eq. 2, secant $=\frac{R^{2}}{\operatorname{cosine}}$; or, taking the logarithms, we have $\quad \log . \sec a n t=2 . \log \cdot R-\log$. cosine;

$$
\begin{gathered}
\text { log. secant }=20-\text { log. } \text { cosine. } \\
\text { cosecant }=\frac{R^{2}}{\sin e} ;
\end{gathered}
$$

Also,
or $\log$. cosecant $=20-\log$. sine; that is,
The logarithmic secant is found by subtracting the logarithmic cosine from 20 ; and the logarithmic cosecant is found by subtracting the logarithmic sine from 20.
Thus we have found the logarithmic sine of $37^{\circ} 24^{\prime} 13^{\prime \prime}$ to be 9.783493 .

Hence the logarithmic cosecant of $37^{\circ} 24^{\prime} 13^{\prime \prime}$ is 10.216507 .
The logarithmic cosine of $\quad 48^{\circ} 32^{\prime} 29^{\prime \prime}$ is 9.820910 .
Hence the logarithmic secant of $\quad 48^{\circ} 32^{\prime} 29^{\prime \prime}$ is 10.179090 .
43. To find the arc corresponding to a given logarithmic sine or tangent.
If the given number is found exactly in the table, then, when the appropriate title is found at the top of the column, the degrees will be found at the top of the page, and the minutes in the vertical column on the left; but if the title is found at the bottom of the column, the degrees will be found at the bottom of the page, and the minutes in the vertical column on the right.
But when the given number is not found exactly in the table, look for the sine or tangent which is next less than the one proposed, and take out the corresponding degrees and minutes. Find also the difference between this tabular number and the number proposed; annex two ciphers, and divide the result by the corresponding number in the column $D$. The quotient will be the required number of seconds, to be added to the degrees and minutes before found.

Example. Find the are whose log. sine is 9.750000 .
The next less sine in the table is 9.749987 .
The arc corresponding to which is $34^{\circ} 13^{\prime}$.
The difference between its sine and the one proposed is 13 . Annexing two ciphers, and dividing by 309 (the corresponding number in column D.), we obtain 4 nearly. Hence the required arc is $34^{\circ} 13^{\prime} 4^{\prime \prime}$.
In the same manner we find the are corresponding to log. tangent 10.250000 to be $60^{\circ} 38^{\prime} 57^{\prime \prime}$.

If a cosine or cotangent is required, we must look for the number in the table which is next greater than the one proposed, and then proceed as for a sine or tangent. Thus
the are whose cosine is 9.602000 is $66^{\circ} 25^{\prime} 31^{\prime \prime}$;
" cotangent is 10.300000 is $26 \quad 3710$.
44. For arcs not exceeding half a degree, it will be most convenient to reverse the method of Art. 40. For this purpose subtract the $\log$. sine of $1^{\prime \prime}$ from the given $\log$. sine, and the remainder will be the logarithm of the number of seconds in the arc.

| Required the are whose log. sine is | 7.000000 |
| :--- | :--- |
| Subtracting the $\log$. sine of $1^{\prime \prime}$ | 4.685575 |
| we have | 2.314425, |

which is the log. of 206.26 .
Hence the required arc is $3^{\prime} 26^{\prime \prime} .26$.
Required the arc whose log. tangent is 7.500000
Subtracting the log. tangent of $1^{\prime \prime}$
4.685575
we have
2.814425, which is the log. of 652.27 .

Hence the required are is $10^{\prime} 52^{\prime \prime} .27$.

## SOLUTION OF RIGHT-ANGLED TRIANGGLES.

## THEOREM 1.

45. In any right-angled triangle, radius is to the hypothenuse as the sine of either acute angle is to the opposite side, or the cosine of either acute angle to the adjacent side.

Let the triangle CAB be right-angled at A; then will
$R: C B:: \sin . C: B A:: \cos . C: C A$.
From the point $C$ as a centre, with a radius equal to the radius of the tables, describe the arc DE , and on AC let fall the
 perpendicular EF. Then EF will be the sine, and CF the cosine of the angle C.

Because the triangles $\mathrm{CAB}, \mathrm{CFE}$ are similar, we have CE:CB::EF:BA, $\mathrm{R}: \mathrm{CB}:: \sin . \mathrm{C}: \mathrm{BA}$.
Also, or $\mathrm{CE}: \mathrm{CB}:: \mathrm{CF}: \mathrm{CA}$,
$\mathrm{R}: \mathrm{CB}:: \cos . \mathrm{C}: \mathrm{CA}$.
Cor. If radius be taken as unity, we shall have

$$
A B=C B \sin . C, \text { and } A C=C B \cos . C .
$$

Hence, in any right-angled triangle, either of the sides which contain the right angle is equal to the product of the hypothenuse by the sine of the angle opposite to that side, or by the cosine of the acute angle adjacent to that side.

## THEOREM II.

46. In any right-angled triangle, radius is to either side as the tangent of the adjacent acute angle is to the opposite side, or the secant of the same angle to the hypothenuse.

Let the triangle CAB be right-angled at A; then will

$$
\mathrm{R}: \mathrm{CA}:: \text { tang. } \mathrm{C}: \mathrm{AB}:: \text { sec. } \mathrm{C}: \mathrm{CB} .
$$

From the point C as a centre, with a radius equal to the radius of the tables, describe the arc DE, and from the point D draw DF perpendicular to CA. Then DF will be the tangent, and CF the secant of the angle C.

Because the triangles $\mathrm{CAB}, \mathrm{CDF}$ are similar, we have

$$
\mathrm{CD}: \mathrm{CA}:: \mathrm{DF}: \mathrm{AB}
$$

or R:CA:: tang. C:AB.
Also,
CD : CA :: CF : CB,
or
R:CA:: sec. C:CB.
Cor. If radius be taken as unity, we shall have

$$
\mathrm{AB}=\mathrm{AC} \text { tang. } \mathrm{C} \text {, and } \mathrm{BC}=\mathrm{AC} \text { sec. } \mathrm{C} .
$$

IIence, inn any right-angled triangle, either of the sides which contain the right angle is equal to the product of the other side by the tangent of the angle which is opposite to the first side; and the hypothenuse is equal to the product of either side by the secant of the acute angle adjacent to that side.
47. In every plane triangle there are six parts: three sides and three angles. Of these, any three being given, provided one of them is a side, the others may be determined. In a right-angled triangle, one of the six parts, viz., the right angle, is always given; and if one of the acute angles is given, the other is, of course, known. Hence the number of parts to be considered in a right-angled triangle is reduced to four, any two of which being given, the others may be found.

It is desirable to have appropriate names by which to designate each of the parts of a triangle. One of the sides adjacent to the right angle being called the base, the other side adjacent to the right angle may be called the perpendicular. The three sides will then be called the hypothenuse, base, and perpendicular. The base and perpendicular are sometimes called the legs of the triangle. Of the two acute angles, that which is adjacent to the base may be called the angle at the base, and the other the angle at the perpendicular.

We may, therefore, have four cases, according as there are given,

1. The hypothenuse and the angles;
2. The hypothenuse and a leg;
3. One leg and the angles; or,
4. The two legs.

All these cases may be solved by the two preceding theorems.

## CASE I.

48. Given the hypothenuse and the angles, to find the base and perpendicular.

This case is solved by Theorem I.
Radius: hypothenuse:: sine of the angle at the base:perpendicular ;

Radius : hypothenuse:: cosine of the angle at the base: base.
Ex. 1. Given the hypothenuse 275 , and the angle at the base $57^{\circ} 20^{\prime}$, to find the base and perpendicular.

The natural sine of $57^{\circ} 20^{\prime}$ is .8418 .
" cosine " . 5398.
Hence $\quad 1: 275:: .8418: 231.5=\mathrm{AB}$. $1: 275:: .5398: 148.4=$ AC.
The computation is here made by natural numbers. If we work the proportion by logarithms,
 we shall have
radius, is to the hypothenuse 275 , as the sine of $\mathrm{C} 57^{\circ} 20^{\prime}$, to the perpendicular 231.50 ,

Also, radius, is to the hypothenuse 275 , as the cosine of $\mathbf{C} 57^{\circ} 20^{\prime}$, to the base 148.43,

$$
\begin{array}{r}
10.000000 \\
2.439333 \\
9.925222 \\
\hline 2.364555
\end{array}
$$

10.000000
2.439333
9.732193
2.171526.

Ex. 2. Given the hypothenuse 67.43 , and the angle at the perpendicular $38^{\circ} 43^{\prime}$, to find the base and perpendicular.
$A n s$. The base is 42.175 , and perpendicular 52.612 .
The student should work the examples both by natural numbers and by logarithms until he has made himself perfectly familiar with both methods. He may then employ either method, as may appear to him most expeditious.

## CASE II.

49. Given the hypothenuse and one leg, to find the angles and the other leg.

This case is solved by Theorem I.
Hypothenuse: radius :: base: cosine of the angle at the base.
Radius: hypothenuse:: sine of the angle at the base:perpendicular.

When the perpendicular is given, perpendicular must be substituted for base in this proportion.

Ex. 1. Given the hypothenuse 54.32, and the base 32.11, to find the angles and the perpendicular.

By natural numbers we have
Also

$$
54.32: 1:: 32.11: \cos . \mathrm{C} .
$$

By logarithms,

| 54.32, | 1.734960 |
| :--- | ---: |
| is to radius, | 10.000000 |
| as 32.11, | 1.506640 |
| is to cos. $53^{\circ} 45^{\prime} 47^{\prime \prime}$, | 9.771680. |

That is, the angle $\mathrm{C}=53^{\circ} 45^{\prime} 47^{\prime \prime}$, and therefore the angle $\mathrm{B}=36^{\circ}$ $14^{\prime} 13^{\prime \prime}$.
Also radius, 10.000000
is to $54.32, \quad 1.734960$
as sine $53^{\circ} 45^{\prime} 47^{\prime \prime}$, $\quad 9.906647$
is to 43.813 , the perpendicular $\overline{1.641607}$.
Ex.2. Given the hypothenuse 332.49, and the perpendicular 98.399 , to find the angles and the base.

Ans. The angles are $17^{\circ} 12^{\prime} 51^{\prime \prime}$ and $72^{\circ} 47^{\prime} 9^{\prime \prime}$; the base, 317.6.

## CASE III.

50. Given one leg and the angles, to find the other. leg and hypothenuse.

This case may be solved by Theorem II. Radius: base:: tangent of the angle at the base: the perpendicular. :: secant of the angle at the base: hypothenuse.
When the perpendicular is given, perpendicular must be substituted for base in this proportion.

This case may also be solved by Theorem I.

$$
\begin{aligned}
\sin . \mathrm{B}: \text { base }: & : \text { sin. C: perpendicular } ; \\
& :: \text { radius }: \text { hypothenuse } .
\end{aligned}
$$

Ex. 1. Given the base 222, and the angle at the base $25^{\circ} 15^{\prime}$, to find the perpendicular and hypothenuse.

By natural numbers we have

$$
1: 222:: \text { tang. } 25^{\circ} 15^{\prime}: \text { perpendicular. }
$$

Also $\sin .64^{\circ} 45^{\prime}$ : 222 :: radius : hypothenuse.
By logarithims,

$$
\text { radius, } \quad 10.000000
$$

is to 222 , 2.346353
as tang. $25^{\circ} 15^{\prime}$, 9.673602
is to 104.70 , the perpendicular, 2.019955 .
Also
$\sin .64^{\circ} 45^{\prime}$, $\quad 9.956387$
is to 222 , $\quad 2.346353$
as radius, $\quad 10.000000$.
is to 245.45 , the hypothenuse, 2.389966 .
Ex. 2. Given the perpendicular 125, and the angle at the perpendicular $61^{\circ} 19^{\prime}$, to find the hypothenuse and base. Ans. Hypothenuse, 199.99 ; base, 156.12. $260: 433$
CASE IV.
51. Given the two legs, to find the angles and hypothenuse.

This case is solved by Theorem II.
Base: radius : :perpendicular: tangent of the angle at the base.
Radius: base:: secant of the angle at the base: hypothenuse.
When the angles have been found, the hypothenuse may be found by Theorem I.

$$
\sin . C: A B:: \text { r̀adius }: B C .
$$

Ex. 1. Given the base 123, and perpendicular 765, to find the angles and hypothenuse.
By natural numbers we have

$$
\begin{aligned}
& 123: 1:: 765 \text { : tang. C } \\
& \text { sin. } C: 765:: 1 \text { : hypothenuse. }
\end{aligned}
$$

| By logarithms, |  |  |
| :---: | :---: | :---: |
|  | is to radius, | 10.000000 |
|  | as 765, | 2.883661 |
|  | is to tang. $80^{\circ} 51^{\prime} 57^{\prime \prime}$, | 0.793756 . |
| Also | sin. $80^{\circ} 51^{\prime} 57^{\prime \prime}$, | 9.994458 |
|  | is to 765 , | 2.883661 |
|  | as radius, | 10.000000 |
|  | is to 774.82 , hypothenuse, | 2.889203. |

Ex. 2. Given the base 53, and perpendicular 67, to find the angles and hypothenuse.

Ans. The angles are $51^{\circ} 39^{\prime} 16^{\prime \prime}$, and $38^{\circ} 20^{\prime} 44^{\prime \prime}$; hypothenuse, 85.428.

## Examples for Practice.

1. Given the base 777 , and perpendicular 345 , to find the hypothenuse and angles.

This example, it will be seen, falls under Case IV.
2. Given the hypothenuse 324 , and the angle at the base $48^{\circ} 17^{\prime}$, to find the base and perpendicular. $7248.848 .182 / 5.6$
3. Given the perpendicular 543, and the angle at the base $72^{\circ} 45^{\prime}$, to find the hypothenuse and base. $B / 6 \% .66^{\circ} \quad$ h 568,5
4. Given the hypothenuse 666, and base 432 , to find the angles and perpendicular.
5. Given the base 634, and the angle at the base $53^{\circ} 27^{\prime}$, to find the hypothenuse and perpendicular.
6. Given the hypothenuse 1234, and perpendicular 555, to find the base and angles.
7. Suppose the radius of the earth to be 3963 miles, and that it subtends an angle of $57^{\prime} 2^{\prime \prime} .3$ at the moon, what is the distance of the moon from the earth?
8. Suppose that when the moon's distance from the earth is 238,885 miles, its apparent semi-diameter is $15^{\prime} 33^{\prime \prime} .5$, what is its diameter in miles?
9. Suppose the radius of the earth to be 3963 miles, and that it subtends an angle of $8^{\prime \prime} .9$ at the sun, what is the distance of the sun from the earth?
10. Suppose that the sun's distance from the earth is $92,000,000$ miles, and that its apparent semi-diameter is $16^{\prime} 1^{\prime \prime} .8$, what is its diameter in miles?
52. When two sides of a right-angled triangle are given, the third may be found by means of the property that the square of the hypothenuse is equal to the sum of the squares of the other two sides.

Hence, representing the hypothenuse, base, and perpendicular by the initial letters of these words, we have

$$
h=\sqrt{b^{2}+p^{2}} ; b=\sqrt{h^{2}-p^{2}} ; p=\sqrt{h^{2}-b^{2}} .
$$

Ex. 1. If the base is 2720 , and the perpendicular 3104 , what is the hypothenuse?

Ans. 4127.1.

Ex. 2. If the hypothenuse is 514 , and the perpendicular 432 , what is the base?

## SOLUTION OF OBLIQUE-ANGLED TRIANGLES.

## theorem I .

53. In any plane triangle, the sines of the angles are proportional to the opposite sides.

Let ABC be any triangle, and from one of its angles, as A , let AD be drawn perpendicular to the opposite side BC. There may be two cases.

Fïrst. If the perpendicular falls within the trian-
 gle, because the triangle ABD is right-angled at D , we have
$R: \sin . B:: A B: A D$; whence $R \times A D=\sin . B \times A B$.
For a similar reason,
$R: \sin . C: A C: A D$; whence $R \times A D=\sin . C \times A C$.
Therefore or, $\sin . B \times A B=\sin . C \times A C ;$
$\sin . B: \sin . C:: A C: A B$.
Second. If the perpendicular falls without the triangle, we have in the triangle $A B D$, as before,

$$
R: \sin . A B D:: A B: A D .
$$

Also, in the triangle ACD ,

$$
\begin{aligned}
& \text { R : } \sin . C:: A C: A D ; \\
& \quad \sin . A B D: \sin . C:: A C: A B .
\end{aligned}
$$

whence
But, since $A B D$ is the supplement of $A B C$, their sines are equal, Art. 13.
Therefore $\quad \sin . \mathrm{ABC}: \sin . \mathrm{C}:: \mathrm{AC}: \mathrm{AB}$.

## TIIEOREM II.

54. In any plane triangle, the sum of any two sides is to their difference as the tangent of half the sum of the opposite angles is to the tangent of half their difference.

Let ABC be any triangle; then will

$$
\mathrm{CB}+\mathrm{CA}: \mathrm{CB}-\mathrm{CA}:: \operatorname{tang} \cdot \frac{A+B}{2}: \operatorname{tang} \cdot \frac{A-B}{2} .
$$

Produce AC to D , making CD equal to CB , and join DB . Take CE equal to CA; draw AE, and produce it to F . Then AD is the sum of CB and CA , and BE is their difference.

The sum of the two angles CAE, CEA is equal to the sum of CAB, CBA, each being the supplement of ACB (Geom., B. I., Pr. 27). But, since CA is equal to CE, the angle CAE is equal to the angle CEA; therefore CAE is the half sum of the angles CAB ,

CBA. Also, if from the greater of the two angles $\mathbf{C A B}, \mathrm{CBA}$ there be taken their half sum, the remainder, FAB , will be their half difference (Algebra, p. 89).

Since CD is equal to CB, the angle ADF is equal to the angle EBF ; also, the angle CAE is equal to AEC , which is equal to the vertical angle BEF. Therefore the two triangles DAF, BEF are mutually equiangular; hence the two angles at $F$ are equal, and $A F$ is perpendicular to $D B$.

If, then, AF be made radius, DF will be the tangent of DAF, and BF will be the tangent of BAF. But, by similar triangles, we have
$\mathrm{AD}: \mathrm{BE}:: \mathrm{DF}: \mathrm{BF}$; that is,
$C B+C A: C B-C A:: \operatorname{tang} \cdot \frac{A+B}{2}: \operatorname{tang} \cdot \frac{A-B}{2}$.

## THEOREM III.

55. If from any angle of a triangle a perpendicular be drazon to the opposite side or base, the sum of the segments of the base is to the sum of the two other sides as the difference of those sides is to the difference of the segments of the base.

For demonstration, see Geometry, B. IV., Pr. 34, Cor.
56. In every plane triangle three parts must be given to enable us to determine the others, and of the given parts one at least must be a side. For, if the angles only are given, these might belong to an infinite number of different triangles. In solving oblique-angled triangles four different cases may therefore be presented. There may be given,

1. Two angles and a side;
2. Two sides and an angle opposite one of them;
3. Two sides and the included angle ; or,
4. The three sides.

We shall represent the three angles of the proposed triangle by $\mathrm{A}, \mathrm{B}, \mathrm{C}$, and the sides opposite them respectively by $a, b, c$.

## CASE I.

57. Given two angles and a side, to find the third angle and the other two sides.

To find the third angle, add the given angles together, and subtract their sum from $180^{\circ}$.

The required sides may be found by Theorem I. The proportion will be,

The sine of the angle opposite the given side: the given side
:: the sine of the angle opposite the required side
: the required side.
Ex.1. In the triangle ABC , there are given the angle $\mathbf{A}, 57^{\circ} 15^{\prime}$, the angle $\mathrm{B}, 35^{\circ} 30^{\prime}$, and the side $c, 364$, to find the other parts.

The sum of the given angles, subtracted from $180^{\circ}$, leaves $87^{\circ} 15^{\prime}$ for the angle C.
 Then, to find the side $a$, we say,

$$
\sin . \mathrm{C}: c:: \sin . \mathrm{A}: a .
$$

By natural numbers,

$$
.9988: 364:: .8410: 306.49=\alpha
$$

This proportion is most easily worked by logarithms, thus:
As the sine of the angle C, $87^{\circ} 15^{\prime}$, comp. 0.000500
$\begin{array}{lll}\text { Is to the side } c, & 364, & 2.561101 \\ \text { So is the sine of the angle A }, 57^{\circ} 15^{\prime}, & 9.924816 \\ \text { To the side } a, & 306.49, & 2.486417 .\end{array}$
To find the side $b$, we have, $\sin$. C: $c:: \sin$. B: $b$.
By natural numbers,

$$
9988: 364:: .5807: 211.62=b .
$$

The work by logarithms is as follows:

| $\sin . \mathrm{C}, \quad 87^{\circ} 15^{\prime}$, | comp. 0.000500 |
| :--- | ---: |
| $: c$, | 2.561101 |
| $:: \sin . \mathrm{B}, 35^{\circ} 30^{\prime}$, | $\underline{9.763954}$ |
| $: b, \quad 211.62$, | 2.325555. |

Ex. 2. In the triangle ABC , there are given the angle $\mathrm{A}, 49^{\circ}$ $25^{\prime}$, the angle C, $63^{\circ} 48^{\prime}$, and the side $c, 275$, to find the other parts.

Ans. $\mathrm{B}=66^{\circ} 47^{\prime} ; ~ a=232.766 ; b=281.67$.

## CASE II.

58. Given two sides and an angle opposite one of them, to find the third side and the remaining angles.

One of the required angles is found by Theorem I. The proportion is,

The side opposite the given angle: the sine of that angle
:: the other given side: the sine of the opposite angle.
The third angle is found by subtracting the sum of the other two from $180^{\circ}$; and the third side is found as in Case I.

If the side $B C$, opposite the given angle A, is shorter than the other given side AC, the solution will be ambiguous ; that is, two different triangles $\mathrm{ABC}, \mathrm{AB}^{\prime} \mathrm{C}$ may be formed, each of which will satisfy the conditions of the problem.
The numerical result is also ambiguous, for the fourth term of the first proportion is a sine of an angle. But this may be the sine either of the acute angle $A B^{\prime} C$, or of its supplement, the obtuse angle ABC (Art. 13). In practice, however, there will generally be some circumstance to determine whether the required angle is acute or obtuse. If the side opposite the given angle is longer than the other given side, there can be no ambiguity, for $B$ will fall on $B^{\prime} A$ produced, and the triangle $A B C$ will no longer be one solution of the problem. This is always the case when the given angle is obtuse.

Ex. 1. In a triangle ABC , there are given $\mathrm{AC}, 458, \mathrm{BC}, 307$, and the angle $\mathrm{A}, 28^{\circ} 45^{\prime}$, to find the other parts.

To find the angle B ;

$$
\mathrm{BC}: \sin . \mathrm{A}:: \mathrm{AC}: \sin . \mathrm{B} .
$$

By natural numbers,
$307: .4810:: 458: .7176$, sin. $B$, the arc corresponding to which is $45^{\circ} 51^{\prime}$, or $134^{\circ} 9^{\prime}$.

This proportion is most easily worked by logarithms, thus:

| BC, | 307, |
| :--- | ---: |
| $: \sin . \mathrm{A}, 28^{\circ} 45^{\prime}$, | comp. 7.512862 |
| $:: \mathrm{AC}, 458$, | 9.682135 |
| $: \sin . \mathrm{B}, 45^{\circ} 51^{\prime} 14^{\prime \prime}$, or $134^{\circ} 8^{\prime} 46^{\prime \prime}$, | $\underline{2.660865}$ |
| 9.855862 |  |

The angle ABC is $134^{\circ} 8^{\prime} 46,^{\prime \prime}$ and the angle $\mathrm{AB}^{\prime} \mathrm{C}, 45^{\circ} 51^{\prime} 14^{\prime \prime}$. Hence the angle ACB is $17^{\circ} 6^{\prime} 14^{\prime \prime}$, and the angle $\mathrm{ACB}^{\prime}, 105^{\circ} 23^{\prime}$ $46^{\prime \prime}$.

To find the side AB ;

$$
\sin . \mathrm{A}: \mathrm{CB}:: \sin . \mathrm{ACB}: \mathrm{AB} .
$$

By logarithms,

| $\sin . \mathrm{A}$, | $28^{\circ} 45^{\prime}$, |
| :--- | ---: |
| $: \mathrm{CB}$, | comp. 0.317865 |
| $:: \sin . \mathrm{ACB}, 17^{\circ} 6^{\prime} 14^{\prime \prime}$, | 2.487138 |
| $: \mathrm{AB}$, | 187.72, |

To find the side $\mathrm{AB}^{\prime}$;

$$
\sin . \mathrm{A}: \mathrm{CB}^{\prime}:: \sin . A C B^{\prime}: \mathrm{AB}^{\prime} .
$$

By logarithms,

| $\sin . \mathrm{A}$, | $28^{\circ} 45^{\prime}$, | comp. 0.317865 |
| :--- | :---: | ---: |
| $: \mathrm{CB}^{\prime}$, | 207, | 2.487138 |
| $:: \sin ^{\prime} \mathrm{ACB}^{\prime}, 105^{\circ} 23^{\prime} 46^{\prime \prime}$, | $\underline{9.984128}$ |  |
| $: \mathrm{AB}^{\prime}$, | 615.36, | 2.789131 |

Ex. 2. In a triangle ABC , there are given $\mathrm{AB}, 532, \mathrm{BC}, 358$, and the angle $\mathrm{C}, 107^{\circ} 40^{\prime}$, to find the other parts.

$$
\text { Ans. } \mathrm{A}=39^{\circ} 52^{\prime} 52^{\prime \prime} ; \mathrm{B}=32^{\circ} 27^{\prime} \mathrm{S}^{\prime \prime} ; \mathrm{AC}=299.6
$$

In this example there is no ambiguity, because the given angle is obtuse.

## CASE III.

59. Given two sides and the included angle, to find the third side and the remaining angles.

The sum of the required angles is found by subtracting the given angle from $180^{\circ}$. The difference of the required angles is then found by Theorem II. Half the difference added to half the sum gives the greater angle, and, subtracted, gives the less angle. The third side is then found by Theorem I.

Ex. l. In the triangle ABC , the angle A is given $53^{\circ} 8^{\prime}$; the side $c, 420$, and the side $b, 535$, to find the remaining parts.

The sum of the angles $\mathrm{B}+\mathrm{C}=180^{\circ}-53^{\circ} 8^{\prime}=126^{\circ} 52^{\prime}$. Half their sum is $63^{\circ} 26^{\prime}$.

Then, by Theorem II.,

$$
535+420: 535-420:: \text { tang. } 63^{\circ} 26^{\prime}: \text { tang. } 13^{\circ} 32^{\prime} 25^{\prime \prime}
$$

which is half the difference of the two required angles.
Hence the angle B is $76^{\circ} 58^{\prime} 25^{\prime \prime}$, and the angle C, $49^{\circ} 53^{\prime} 35^{\prime \prime}$.
To find the side $a$;

$$
\sin . \mathrm{C}: c:: \sin . \mathrm{A}: a=439.32
$$

Ex. 2. Given the side $c, 176, a, 133$, and the included angle $B$, $73^{\circ}$, to find the remaining parts.

Ans. $b=187.022$, the angle C, $64^{\circ} 9^{\prime} 3^{\prime \prime}$, and A, $42^{\circ} 50^{\prime} 57^{\prime \prime}$.

## CASE IV.

60. Given the three sidles, to find the angles.

Let fall a perpendicular upon the longest side from the opposite angle, dividing the given triangle into two right-angled triangles. The two segments of the base may be found by Theorem III. There will then be given the hypothenuse and one side of a right-angled triangle to find the angles.

$$
\text { N } 2
$$

Ex. 1. In the triangle ABC , the side $a$ is 261 , the side $b, 345$, and $c, 395$. What are the angles?

Let fall the perpendicular CD upon AB .
Then, by Theorem III.,

$$
\begin{gathered}
\mathrm{AB}: \mathrm{AC}+\mathrm{CB}:: \mathrm{AC}-\mathrm{CB}: \mathrm{AD}-\mathrm{DB} ; \\
395: 606:: 84: 128.87 .
\end{gathered}
$$

Half the difference of the segments added to half their sum gives the greater segment, and subtracted gives the less seg-
 ment.
Therefore AD is 261.935 , and BD, 133.065 . Then, in each of the right-angled triangles $\mathrm{ACD}, \mathrm{BCD}$ we have given the hypothenuse and base, to find the angles by Case II. of B right-angled triangles. Hence
$\mathrm{AC}: \mathrm{R}:: \mathrm{AD}: \cos . \mathrm{A}=40^{\circ} 36^{\prime} 13^{\prime \prime}$;
$\mathrm{BC}: \mathrm{R}:: \mathrm{BD}: \cos . \mathrm{B}=59^{\circ} 20^{\prime} 52^{\prime \prime}$.
Therefore the angle $\mathrm{C}=80^{\circ} 2^{\prime} 55^{\prime \prime}$.
Ex. 2. If the three sides of a triangle are 150,140 , and 130 , what are the angles?

Ans. $67^{\circ} 22^{\prime} 48^{\prime \prime}, 59^{\circ} 29^{\prime} 23^{\prime \prime}$, and $53^{\circ} 7^{\prime} 49^{\prime \prime}$.

## Examples for Practice.

1. Given two sides of a triangle, 478 and 567 , and the included angle, $47^{\circ} 30^{\prime}$, to find the remaining parts.
2. Given the angle $\mathrm{A}, 56^{\circ} 34^{\prime}$, the opposite side, $a, 735$, and the side $b, 576$, to find the remaining parts.
3. Given the angle $\mathrm{A}, 65^{\circ} 40^{\prime}$, the angle $\mathrm{B}, 74^{\circ} 20^{\prime}$, and the side $a, 275$, to find the remaining parts.
4. Given the three sides, 742,657 , and 379 , to find the angles.
5. Given the angle A, $116^{\circ} 32^{\prime}$, the opposite side, $a, 492$, and the side $c, 295$, to find the remaining parts.
6. Given the angle C, $56^{\circ} 18^{\prime}$, the opposite side, $c, 184$, and the side $b, 219$, to find the remaining parts.
This problem admits of two answers.
7. Given the angle B, $68^{\circ} 35^{\prime} 27^{\prime \prime}$, the angle $\mathbf{C}, 44^{\circ} 48^{\prime} 47^{\prime \prime}$, and the side $c, 479$, to find A, $a$, and $b$.
8. Given the angle. A, $67^{\circ} 23^{\prime} 56^{\prime \prime}$, the side $a, 1486.73$, and the side $b, 2073.22$, to find $\mathrm{B}, \mathrm{C}$, and $c$.
9. Given the angle C, $66^{\circ} 3^{\prime} 27^{\prime \prime}$, the side $a, 897$, and the side $b, 571$, to find $\mathrm{A}, \mathrm{B}$, and $c$.
10. Given $a=2251, b=738$, and $c=830$, to find $\mathrm{A}, \mathrm{B}$, and C .

## INSTRUMENTS USED IN DRAWING.

61. The following are some of the most important instruments used in drawing.
I. The dividers consist of two legs, revolving upon a pivot at one extremity. The joints should be composed of two different metals, of unequal hardness : one part, for example, of steel, and the other of brass or silver, in order that they may move upon each other with greater freedom.
 The points should be of tempered steel, and, when the dividers are closed, they should meet with great exactness. The dividers are often furnished with various appendages, which are exceedingly convenient in drawing. Sometimes one of the legs is furnished with an adjusting screw, by which a slow motion may be given to one of the points, in which case they are called hair compasses. It is also useful to have a movable leg, which may be removed at pleasure, and other parts fitted to its place; as, for example, a long beam for drawing large circles, a pencil-point for drawing circles with a pencil, an ink-point for drawing black circles, etc.
62. II. The parallel rule consists of two flat rules, made of wood or ivory, and connected together by two cross-bars of equal length, and parallel to each other. This instrument is useful for drawing a line parallel to a given line, through a given point.

For this purpose, place the edge of one of the flat rules against the given line, and move the other rule until its edge coincides with the given point. A line drawn along its edge will be parallel to the given line.
63. III. The protractor is used to lay down or to measure angles. It consists of a semicircle, usually of brass, and is divided into degrees, and sometimes smaller portions, the centre of the circle being indicated by a small notch.

To lay down an angle with the protractor, draw a base line,

and apply to it the edge of the protractor, so that its centre shall fall at the angular point. Count the degrees contained in the proposed angle on the limb of the circle, and mark the extremity of the arc with a fine dot. Remove the instrument, and through the dot draw a line to the angular point; it will give the angle required. In a similar manner, the inclination of any two lines may be measured with the protractor.
64. IV. The plane scale is a ruler, frequently two feet in length, containing a line of equal parts, chords, sines, tangents, etc. For a scale of equal parts, a line is divided into inches and tenths of an inch, or half inches and twentieths. When smaller fractions are required, they are obtained by means of the diagonal scale, which is constructed in the following manner. Describe a square inch, ABCD , and divide each of its sides into ten equal parts

Draw diagonal lines from the first point of division on the upper line to the second on the lower; from the second on the upper line to the third on the lower, and so on. Draw, also, other lines parallel to AB , through the points of division of BC . Then, in the triangle ADE, the base, DE , is one tenth of an inch; and, since the line AD is divided into ten equal parts, and through the points of division lines are drawn parallel to the base, forming nine smaller triangles, the base of the least is one tenth of DE , that is, .01 of an inch; the base of the second is .02 of an inch; the third, .03 , and so on. Thus the diagonal scale furnishes us hundredths of an inch.

To take off from the scale a line of given length, as, for example, 4.45 inches, place one foot of the dividers at $F$, on the sixth horizontal line, and extend the other foot to $G$, the fifth diagonal line.

A half inch or less is frequently subdivided in the same manner
65. A line of chords, commonly marked сно., is found on most plane scales, and is useful in setting off angles. To form this line, describe a circle with any convenient radius, and divide the circumference into degrees. Let the length of the chords for every degree of the quadrant be determined and laid off on a scale: this is called a line of chords.
Since the chord of $60^{\circ}$ is equal to radius, in order to lay down

| Chords | 10 | 20 | 30 | 40 | 50 | 60 | 70 | 80 | 90 |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Sines | 10 | 20 | 30 | 40 | 50 | 60 | 70 | 90 | 30 | 40 |
| Tang. | 10 | 20 | 30 |  | 40 | 50 | Secnents | 6n |  |  |

an angle, we take from the scale the chord of $60^{\circ}$, and with this radius describe an arc of a circle. Then take from the scale the chord of the given angle, and set it off upon the former arc. Through these two points of division draw lines to the centre of the circle, and they will contain the required angle.

The line of sines, commonly marked sin., exhibits the lengths of the sines to every degree of the quadrant, to the same radius as the line of chords. The line of tangents and the line of secants are constructed in the same manner. Since the sine of $90^{\circ}$ is equal to radius, and the secant of $0^{\circ}$ is the same, the graduation on the line of secants begins where the line of sines ends.

On the back side of the plane scale are often found lines representing the logarithms of numbers, sines, tangents, etc. This is called Gunter's Scale.
66. V. The Sector is a very convenient instrument in drawing. It is generally made of ivory or brass, and consists of two equal arms, movable about a pivot as a centre, having several scales drawn on the faces, some single, others double. The
 single scales are like those upon a common Gunter's Scale. The double scales are those which proceed from the centre, each being laid twice on the same face of the instrument, viz., once on each leg. The double scales are a scale of lines marked Lin., or L.; the scale of chords, sines, etc. On each arm of the sector there is a diagonal line, which diverges from the central point like the radius of a circle, and these diagonal lines are divided into equal parts.

The advantage of the sector is to enable us to draw a line upon paper to any scale; as, for example, a scale of 6 feet to the inch. For this purpose, take an inch with the dividers from the scale of inches; then, placing one foot of the dividers at 6 on one arm of the sector, open the sector until the other foot reaches to the same number on the other arm. Now, regarding the lines on the sector as the sides of a triangle, of which the line measured from 6 on one arm to 6 on the other arm is the base, it is plain that if any other line be measured across the angle of the sector, the bases of the triangles thus formed will be proportional to their sides. Therefore a line of 7 feet will be represented by the distance from 7 to 7 , and similarly for other lines.

The sector also contains a line of chords, arranged like the line of equal parts already mentioned. Two lines of chords are drawn, one on each arm of the sector, diverging from the central point. This double line of chords is more convenient than the single one upon the plane scale, because it furnishes chords to any radius. If it be required to lay down any angle, as, for example, an angle of $25^{\circ}$, describe a circle with any convenient radius. Open the sector so that the distance from 60 to 60 , on the line of chords, shall be equal to this radius. Then, preserving the same opening of the sector, place one foot of the dividers upon the division 25 on one scale, and extend the other foot to the same number upon the other scale: this distance will be the chord of 25 degrees, which must be set off upon the circle first described.

The lines of sines, tangents, etc., are arranged in the same manner.
67. By means of the instruments now enumerated, all the cases in Plane Trigonometry may be solved mechanically, without the use of tables, and without any arithmetical process. The sides and angles which are given are laid down according to the preceding directions, and the required parts are then measured from the same scale. The student will do well to exercise himself upon the following problems:
I. Given the angles and one side of a triangle, to find, by construction, the other two sides.

Draw an indefinite straight line, and from the scale of equal parts lay off a portion, AB, equal to the given side. From each extremity lay off an angle equal to one of the adjacent angles by means of a protractor or a scale of chords. Extend the two lines till they intersect, and measure their lengths upon the same scale of equal parts which was used in laying off the base.

Ex. 1. Given the angle $\mathrm{A}, 45^{\circ} 30^{\prime}$, the angle $\mathrm{B}, 35^{\circ} 20^{\prime}$, and the side $\mathrm{AB}, 432$ rods, to construct the triangle, and find the lengths
 of the sides $A C$ and $B C$.
The triangle ABC may be constructed of any dimensions whatever; all which is essential is that its angles be made equal to the given angles. We may construct the triangle upon a scale of 100 rods to an inch, in which case the side AB will be represented by 4.32 inches; or we may construct it upon a scale of 200 rods to an inch; that is, 100 rods to a half inch, which is very conveniently done from a scale on which a half inch is divided like that described in Art. 64; or we may use any other scale at pleasure. It should, however, be remembered, that the required sides must be measured upon the same scale as the given sides.

Ex. 2. Given the angle $\mathbf{A}, 48^{\circ}$, the angle $\mathbf{C}, 113^{\circ}$, and the side $\mathrm{AC}, 795$, to construct the triangle.
II. Given two sides of a triangle and an angle opposite one of them, to find the other two parts.
Draw the side which is adjacent to the given angle. From one end of it lay off the given angle, and extend a line indefinitely for the required side. From the other extremity of the first side, with the remaining given side for radius, describe an are cutting the indefinite line. The point of intersection will determine the third angle of the triangle. The side and angles required may then be measured.

Ex. 1. Given the angle A, $74^{\circ} 45^{\prime}$, the side AC, 432 , and the side $\mathrm{BC}, 475$, to construct the triangle, and find the other parts.
Ex. 2. Given the angle A, $105^{\circ}$, the side BC, 498 , and the side $\mathrm{AC}, 375$, to construct the triangle.
III. Given two sides of a triangle and the included angle, to find the other parts.
Draw one of the given sides. From one end of it lay off the given angle, and draw the other given side, making the required
angle with the first side. Then connect the extremities of the two sides, and there will be formed the triangle required. The side and angles required may then be measured.

Ex. 1. Given the angle $A, 37^{\circ} 25^{\prime}$, the side $\mathrm{AC}, 675$, and the side $\mathrm{AB}, 417$, to construct the triangle, and find the other parts.

Ex. 2. Given the angle $\mathrm{A}, 75^{\circ}$, the side $\mathrm{AC}, 543$, and the side $\mathrm{AB}, 721$, to construct the triangle.
IV. Given the three sides of a triangle, to find the angles.

Draw one of the sides as a basc; and from one extremity of the base, with a radius equal to the second side, describe an are of a circle. From the other end of the base, with a radius equal to the third side, describe a second are intersecting the former; the point of intersection will be the third angle of the triangle.

Ex. 1. Given $\mathrm{AB}, 678, \mathrm{AC}, 598$, and $\mathrm{BC}, 435$, to find the angles.
Ex. 2. Given the three sides 476,287 , and 354 , to find the angles.

## Sines, Tangents, etc., of Arcs of any Magnitucle.

68. In a plane triangle each angle is less than $180^{\circ}$, and the sines, tangents, etc., of the angles of such a triangle are the sines, etc., of angles less than $180^{\circ}$, or of arcs less than a semi-circumference. Frequently, however, especially in Astronomy, we have occasion to consider ares greater than a semi-circumference, or even than an entire circumference. Thus the moon, in its motion about the earth, describes an entire revolution in less than 30 days, and in the course of a year completes more than twelve revolutions; that is, its apparent angular motion through the heavens exceeds 4000 degrees.

Suppose the line CF, starting from the position CA, to revolve about the point $C$, in the direction of the are $A F D$; when it arrives at $C D$ it will have described an angular magnitude of $90^{\circ}$; when it arrives at CB it will have described an angular magnitude of $180^{\circ}$; at CE, $270^{\circ}$; and at CA again, $360^{\circ}$. If it continue its revolution, when it arrives again at CD, it will have described an angular magnitude of $450^{\circ}$; and thus we may have an angular magnitude of any number of degrees, and we may have arcs equal to or greater than one, two, or more circumferences.
69. For convenience, we draw two diameters, $\mathrm{AB}, \mathrm{DE}$, at right angles to each other, and suppose one of them to occupy a horizontal position, and the other a vertical position. Then ACD is called the first quadrant, DCB the second quadrant, BCE the third quadrant, and ECA the fourth quadrant; that is, the first quadrant is above the horizontal diameter and on the right of the vertical diameter; the second quadrant is above the horizontal diameter and on the left of the vertical ; and so on. We propose now to consider the values of the sines, tangents, etc., for ares of any magnitude.
70. Sines, etc., of $0^{\circ}$ and $90^{\circ}$. When the line CF coincides with CA, that is, when the are $A F$ is zero, the sine is zero, and the cosine is equal to the radius of the circle. As the point $F$ advances toward $D$, the sine increases and the cosine decreases; when $F$ arrives at $D$, the sine is equal to the radius, and the cosine becomes zero.

The tangent begins with zero at A , and increases with the arc. As the point F approaches D , the tangent increases very rapidly; and when the difference between the arc and $90^{\circ}$ is less than any assignable quantity, the tangent is greater than any assignable quantity. Hence the tangent of $90^{\circ}$ is said to be infinite.

Since the cotangent of an arc is equal to the tangent of its complement, the cotangent is infinite at $A$, and zero at $D$.

The secant begins with radius at $A$, increases through the first quadrant, and becomes infinite at D . The cosecant is infinite at A, and equal to radius at $D$. Hence we have

$$
\begin{array}{r|r}
\sin .0^{\circ}=\cos 90^{\circ}=0 ; & \cot \cdot 0^{\circ}=\operatorname{tang} \cdot 90^{\circ}=\infty ; \\
\cos 0^{\circ}=\sin 90^{\circ}=1 ; & \sec 0^{\circ}=\operatorname{cosec} 90^{\circ}=1 ; \\
\operatorname{tang} \cdot 0^{\circ}=\cot 90^{\circ}=0 ; & \operatorname{cosec} 0^{\circ}=\sec .90^{\circ}=\infty .
\end{array}
$$

71. Sine, etc., of $180^{\circ}$. As the point F advances from D toward $B$, the sine diminishes and becomes zero at $B$; that is, the sine of $180^{\circ}$ is zero. During the motion through the second quadrant the cosine increases, and becomes equal to radius at $B$.

In the motion through the second quadrant the tangent is at first infinitely great, being drawn from A downward to meet the secant, and it rapidly diminishes till at $B$ it is reduced to zero. The secant also diminishes in the second quadrant, till at B it becomes CA, or radius. Hence we have

$$
\begin{array}{l|l}
\sin .180^{\circ}=\operatorname{tang} \cdot 180^{\circ}=0 ; & \cot .180^{\circ}=\operatorname{cosec} .180^{\circ}=\infty . \\
\cos .180^{\circ}=\sec .180^{\circ}=1 ;
\end{array}
$$

72. Sine, etc., of $270^{\circ}, 360^{\circ}$, etc. During the motion through the third quadrant the sine again increases, and becomes equal to radius at E ; the tangent and secant, which are now AI and CI , also increase, and become infinite at E .

When the line FC, in its motion about C, has revolved through $360^{\circ}$, it comes again into coincidence with AC. Hence the sine, tangent, etc., of $360^{\circ}$ are the same as those of $0^{\circ}$.

The same reasoning shows that the sine, tangent, etc., of $450^{\circ}$ are the same as those of $90^{\circ}$; the sine of $540^{\circ}$ is the same as that of $180^{\circ}$, etc.

If C represent an entire circumference, or $360^{\circ}$, and A any arc whatever, we shall havè

$$
\sin . A=\sin .(C+A)=\sin .(2 C+A)=\sin .(3 C+A) \text {, etc. }
$$

The same is true of the cosine, tangent, etc. ; that is, the sine, tangent, etc., of an arc which exceeds $360^{\circ}$, is the same as those of the excess above $360^{\circ}$, and so also for any multiple of $360^{\circ}$. In fact, since the sine is drawn from one end of an are perpendicular to a diameter through the other end, two ares that have the same extremities must have the same sine; and so of the tangent, etc.

Values of the Sines, Cosines, etc., of certain Arcs or Angles.
73. Sine, etc., of $30^{\circ}$ and $60^{\circ}$. By Art. 8 , the sine of $30^{\circ}$ is equal to half radius; and if we call radius unity, we have

$$
\sin .30^{\circ}=\cos .60^{\circ}=\frac{1}{2} .
$$

Also, since cos. $A=\sqrt{R^{2}-\sin ^{2}{ }^{2}}$, Art. 15, we have

$$
\sin .60^{\circ}=\cos .30^{\circ}=\sqrt{1-\frac{1}{4}}=\sqrt{\frac{3}{4}}=\frac{1}{2} \sqrt{ } 3 .
$$

Since tang. $A=\frac{\sin . A}{\cos . ~ A}$, Art. 15 , we have

$$
\operatorname{tang} .30^{\circ}=\cot .60^{\circ}=\frac{\frac{1}{2}}{\frac{1}{2} \sqrt{3}}=\frac{1}{\sqrt{3}}=\frac{1}{3} \sqrt{3} .
$$

Since cot. $A=\frac{\mathrm{R}^{2}}{\operatorname{tang} \cdot \mathrm{~A}}$, Art. 14 , we have cot. $30^{\circ}=$ tang. $60^{\circ}=\sqrt{ } 3$.
Since sec. $A=\frac{R^{2}}{\cos . ~} A^{\prime}$ we have sec. $30^{\circ}=\operatorname{cosec} .60^{\circ}=\frac{2}{\sqrt{ } 3}=\frac{2}{3} \sqrt{3}$.
Since cosec. $\mathrm{A}=\frac{\mathrm{R}^{2}}{\sin . \mathrm{A}}, \operatorname{Art.14}$, we have $\operatorname{cosec} .30^{\circ}=\sec .60^{\circ}=2$.
74. Sine, etc., of $45^{\circ}$. Since sin. $45^{\circ}=\cos .45^{\circ}$; and $\sin .^{2} \mathrm{~A}+$ $\cos ^{2}{ }^{2}=R^{2}$, Art. 15, we have

$$
\sin .^{2} 45^{\circ}+\sin ^{2} 45^{\circ}=1 . \text { Hence } \sin ^{2} 45^{\circ}=\frac{1}{2},
$$

and

$$
\sin \cdot 45^{\circ}=\cos .45^{\circ}=\sqrt{\frac{1}{2}}=\frac{1}{2} \sqrt{ } 2 .
$$

Also,
and tang. $45^{\circ}=\cot .45^{\circ}=\frac{\sin .45^{\circ}}{\cos .45^{\circ}}=1$, $\sec .45^{\circ}=\operatorname{cosec} .45^{\circ}=\frac{1}{\sin .45^{\circ}}=\sqrt{ } 2$.
75. Algebraic signs of the trigonometrical functions. If we attribute proper algebraic signs to the trigonometrical functions, the formulæ which have been demonstrated for ares less than $180^{\circ}$ will apply also to arcs greater than $180^{\circ}$. For this purpose we adopt the general principle that lines measured in opposite directions from a fixed line must have opposite signs. It is also convenient to assume that in the first quadrant the sines and cosines are both positive.
76. In the first and second quadrants the sines are measured upward from the horizontal diameter $A B$, while in the third and fourth quadrants they are measured downward. Hence, regarding the sines as positive in the first quadrant, they will also be positive in the second quadrant, but negative in the third and fourth.

In the first and fourth quadrants the cosine extends to the right from the vertical diameter DE , but in the second and third quadrants to the left. Hence the cosines are positive in the first and fourth quadrants, but negative in the second and third.
77. The signs of the tangents are derived from those of the sines and cosines. For tang. $=\frac{\text { R. sin. }}{\cos .}$ (Art. 14). Hence, when the sine and cosine have like algebraic signs, the tangent will be positive ; when unlike, negative. That is, the tangent is positive in the first and third quadrants, and negative in the second and fourth.

Also, cotangent $=\frac{R^{2}}{\text { tang. }}$ (Art. 14); hence the tangent and cotangent have always the same sign.

We have seen that sec. $=\frac{\mathrm{R}^{2}}{\cos }$; hence the secant must have the same sign as the cosine.

Also, cosec. $=\frac{\mathrm{R}^{2}}{\sin .}$; hence the cosecant must have the same sign as the sine.

The same results are obtained from the figure; for the tangent is drawn from A upward for an are ending in the first or third quadrant, and downward for one ending in the second or fourth.

The cotangent is drawn from $\mathrm{A}^{\prime}$ to the right for an arc ending in the first or third quadrant, and to the left for the second and fourth.

The secant is positive when drawn from the centre through the
 end of the arc ; that is, for an arc ending in the first or fourth quadrant; and negative when drawn from the centre azoay from the end of the are; that is, for the second or third quadrant. So also for the cosecant.

The accompanying figure may assist the student to retain in memory the algebraic signs of the different trigonometrical lines. 78. The preceding results are exhibited in the following tables, which should be made perfectly familiar:

| Sine and cosecant, |  | First quad. | Second quad. | Third quad. | Fourth quad. |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | + | $+$ | - | - |
| Cosine and secant, |  | $+$ | - | - | $+$ |
| Tangent and cotangent, |  | + | - | $+$ | - |
|  | $0^{\circ}$ | $90^{\circ}$ | $180^{\circ}$ | $270^{\circ}$ | $360^{\circ}$ |
| Sine, | 0 | +R | 0 | -R | 0 |
| Cosine, | $+\mathrm{R}$ | 0 | -R | 0 | +R |
| Tangent, | 0 | $\infty$ | 0 | $\infty$ | 0 |
| Cotangent, | $\infty$ | 0 | $\infty$ | 0 | $\infty$ |
| Secant, | $+\mathrm{R}$ | $\infty$ | $-\mathrm{R}$ | $\infty$ | $+\mathrm{R}$ |
| Cosecant, | $\infty$ | + R | $\infty$ | -R | $\infty$ |

79. Negative arcs. We generally consider those arcs as positive which are estimated from A in the direction ADBE. If, then, an arc were estimated in the direction AEBD, it should be considered as negative; that is, if the arc AF be considered positive, AH must be considered negative.

Now, wherever a plus arc may end, the equal minus are will end upon the opposite side of the horizontal diameter AB , and in the same vertical line. The sines will evidently be equal, but one will be plus, and the other minus. Thus
$\sin , \mathrm{AH}=-\sin . \mathrm{AF}$, and $\sin . \mathrm{AEF}=-\sin . \mathrm{ADH} \cdot$
and universally

$$
\sin .(-\mathrm{A})=-\sin . \mathrm{A} .
$$

In like manner, $\quad \cos .(-A)=\cos . A$.
Hence, also, dividing, tang. ( -A ) $=-$ tang. A, and

$$
\cot \cdot(-A)=-\cot \cdot A
$$

## TRIGONOMETRICAL FORMUL.

80. Expressions for the sine and cosine of the sum and difference of two arcs.

Let AB and BD represent any two given arcs; take $B E$ equal to $B D$ : it is required to find an expression for the sine of AD , the sum, and of AE , the difference of these arcs.

Put $\mathrm{AB}=a$, and $\mathrm{BD}=b$; then $\mathrm{AD}=$ $a+b$, and $\mathrm{AE}=a-b$. Draw the chord DE , and the radius CB , which may be represented by $R$. Since DB is, by construction, equal to $\mathrm{BE}, \mathrm{DF}$ is equal to
 FE , and therefore DE is perpendicular to CB. Let fall the perpendiculars EG, BH, FI, and DK upon AC, and draw EL, FM parallel to AC.

Because the triangles BCH, FCI are similar, we have $\mathrm{CB}: \mathrm{CF}:: \mathrm{BH}: \mathrm{FI}$; or $\mathrm{R}: \cos . b:: \sin . a: \mathrm{FI}$.

Therefore,

$$
\mathrm{FI}=\frac{\sin . a \cos . b}{\mathrm{R}}
$$

Also, $\mathrm{CB}: \mathrm{CF}:: \mathrm{CH}: \mathrm{CI}$; or $\mathrm{R}: \cos . b:: \cos . a: \mathrm{CI}$.
Therefore,

$$
\mathrm{CI}=\frac{\cos . a \cos . b}{\mathrm{R}}
$$

The triangles DFM, CBH, having their sides perpendicular each to each, are similar, and give the proportions

$$
\mathrm{CB}: \mathrm{DF}:: \mathrm{CH}: \mathrm{DM} ; \text { or } \mathrm{R}: \sin . b:: \cos . a: \mathrm{DM} .
$$

Hence

$$
\mathrm{DM}=\frac{\cos \cdot a \sin . b}{\mathrm{R}} .
$$

Also, $\mathrm{CB}: \mathrm{DF}:: \mathrm{BH}: \mathrm{FM}$; or R : $\sin . b:: \sin . a: \mathrm{FM}$.
Hence

$$
\mathrm{FM}=\frac{\sin . a \sin . b}{\mathrm{R}}
$$

But
$\mathrm{FI}+\mathrm{DM}=\mathrm{DK}=\sin .(a+b)$;
and
$\mathrm{CI}-\mathrm{FM}=\mathrm{CK}=\cos .(a+b)$.
Also,
$\mathrm{FI}-\mathrm{FL}=\mathrm{EG}=\sin .(a-b)$;
and
$\mathrm{CI}+\mathrm{EL}=\mathrm{CG}=\cos .(a-b)$.

Hence

$$
\begin{align*}
& \sin .(a+b)=\frac{\sin . a \cos . b+\cos . a \sin . b}{\mathrm{R}} ;  \tag{1}\\
& \cos .(a+b)=\frac{\cos . a \cos . b-\sin . a \sin . b}{\mathrm{R}} ;  \tag{2}\\
& \sin .(a-b)=\frac{\sin . a \cos . b-\cos . a \sin . b}{\mathrm{R}} ;  \tag{3}\\
& \cos .(a-b)=\frac{\cos a \cos . b+\sin . a \sin . b}{\mathrm{R}} . \tag{4}
\end{align*}
$$

These four equations express important geometrical theorems. The last of them may be stated as follows: The product of radius and the cosine of the difference between two arcs is equal to the sum of the product of the sines and the product of the cosines of those arcs.
81. Expressions for the sine and cosine of a clouble arc.

If, in the formulas of the preceding article, we make $b=a$, the first and second will become

$$
\begin{aligned}
& \sin 2 a=\frac{2 \sin . a \cos a}{\mathrm{R}} \\
& \cos 2 a=\frac{\cos ^{2} a-\sin ^{2} a}{\mathrm{R}}
\end{aligned}
$$

Making radius equal to unity, and substituting the values of $\sin . a, \cos . a$, etc., from Art. 14, we obtain

$$
\begin{aligned}
& \sin .2 a=\frac{2 \operatorname{tang} \cdot a}{1+\operatorname{tang} \cdot{ }^{2} a} \\
& \cos \cdot 2 a=\frac{1-\operatorname{tang} \cdot{ }^{2} a}{1+\operatorname{tang}^{2} a}
\end{aligned}
$$

82. Expressions for the sine and cosine of half a given arc.

If we put $\frac{1}{2} u$ for $a$ in the preceding equations, we obtain

$$
\begin{aligned}
& \sin . a=\frac{2 \sin \cdot \frac{1}{2} a \cos \cdot \frac{1}{2} a}{\mathrm{R}}, \\
& \cos . a=\frac{\cos \cdot \frac{1}{2} a-\sin \cdot \frac{21}{2} a}{\mathrm{R}} .
\end{aligned}
$$

We may also find the sine and cosine of $\frac{1}{2} a$ in terms of $a$.
Since the sum of the squares of the sine and cosine is equal to the square of radius, we have

$$
\cos . \frac{1}{2} a+\sin .2 \frac{1}{2} a=\mathrm{R}^{2} .
$$

And, from the preceding equation,

$$
\cos .2 \frac{1}{2} a-\sin \cdot 2 \frac{1}{2} a=\mathrm{R} \cos . a
$$

If we subtract one of these from the other, we have

$$
2 \sin \cdot \frac{1}{2} a=\mathbf{R}^{2}-\mathbf{R} \cos . a .
$$

And, adding the same equations, we have $2 \cos ^{2} \frac{1}{2} \alpha=\mathrm{R}^{2}+\mathrm{R} \cos . \alpha$.
Hence

$$
\begin{aligned}
& \sin . \frac{1}{2} a=\sqrt{\frac{1}{2} \mathrm{R}^{2}-\frac{1}{2} \mathrm{R} \cos . a} ; \\
& \cos \frac{1}{2} a=\sqrt{\frac{1}{2} \mathrm{R}^{2}+\frac{1}{2} \mathrm{R} \cos \cdot a}
\end{aligned}
$$

83. Expressions for the products of sines and cosines.

By adding and subtracting the formulas of Art. 80, we obtain

$$
\begin{aligned}
& \sin .(a+b)+\sin .(a-b)=\frac{2}{\mathrm{R}} \sin . a \cos . b . \\
& \sin .(a+b)-\sin .(a-b)=\frac{2}{\mathrm{R}} \cos . a \sin . b \\
& \cos .(a+b)+\cos .(a-b)=\frac{2}{\mathrm{R}} \cos . a \cos . b \\
& \cos .(a-b)-\cos .(a+b)=\frac{2}{\mathrm{R}} \sin . a \sin . b .
\end{aligned}
$$

If, in these formulas, we make $a+b=\mathrm{A}$, and $a-b=\mathrm{B}$; that is, $a=\frac{1}{2}(\mathrm{~A}+\mathrm{B})$, and $b=\frac{1}{2}(\mathrm{~A}-\mathrm{B})$, we shall have

$$
\begin{equation*}
\sin . A+\sin \cdot B=\frac{2}{R} \sin \cdot \frac{1}{2}(A+B) \cos \cdot \frac{1}{2}(A-B) ; \tag{1}
\end{equation*}
$$

$$
\begin{equation*}
\sin . \mathrm{A}-\sin . \mathrm{B}=\frac{2}{\mathrm{R}} \sin \cdot \frac{1}{2}(\mathrm{~A}-\mathrm{B}) \cos \cdot \frac{1}{2}(\mathrm{~A}+\mathrm{B}) ; \tag{2}
\end{equation*}
$$

$\cos . A+\cos B=\frac{2}{R} \cos \cdot \frac{1}{2}(A+B) \cos \cdot \frac{1}{2}(A-B) ;$

$$
\begin{equation*}
\cos \cdot B-\cos . A=\frac{2}{R} \sin \cdot \frac{1}{2}(A+B) \sin \cdot \frac{1}{2}(A-B) \tag{3}
\end{equation*}
$$

These four equations express important geometrical theorems. The first of them may be stated as follows: The sum of the sines of any two arcs is equal to twice the sine of half the sum of the arcs multiplied by the cosine of half their difference, radius being unity.
84. Theorems relating to the sum and difference of two arcs.

Dividing formula (1) by (2), Art. 83, and considering that $\frac{\text { sin. } a}{\cos . a}=\frac{\text { tang. } a}{\mathrm{R}}$ (Art. 14), we have
$\frac{\sin . A+\sin \cdot B}{\sin \cdot A-\sin \cdot \mathrm{B}}=\frac{\sin \cdot \frac{1}{2}(\mathrm{~A}+\mathrm{B}) \cos \cdot \frac{1}{2}(\mathrm{~A}-\mathrm{B})}{\sin \cdot \frac{1}{2}(\mathrm{~A}-\mathrm{B}) \cos \cdot \frac{1}{2}(\mathrm{~A}+\mathrm{B})}=\frac{\text { tang. } \frac{1}{2}(\mathrm{~A}+\mathrm{B})}{\text { tang. } \frac{1}{2}(\mathrm{~A}-\mathrm{B})} ;$
that is,
The sum of the sines of two arcs or angles is to their clifference as the tangent of half the sum of those arcs is to the tangent of half their difference.

Since the sides of a plane triangle are as the sines of their op-
posite angles (Art. 53), it follows, from the preceding theorem, that the sum of any two sides of a plane triangle is to their difference as the tangent of half the sum of the opposite angles is to the tangent of half their difference.

This is the same as Theorem II., Art. 54, which is here demonstrated by a more general method.

Dividing formula (3) by (4), and considering that $\frac{\cos .}{\sin .}=\frac{\cot .}{\mathrm{K}}$ $=\frac{\mathrm{R}}{\text { tang. }}$ (Art. 14), we have

$$
\frac{\cos \cdot A+\cos \cdot B}{\cos \cdot B-\cos \cdot A}=\frac{\cos \cdot \frac{1}{2}(A+B) \cos \cdot \frac{1}{2}(A-B)}{\sin \cdot \frac{1}{2}(A+B) \sin \cdot \frac{1}{2}(A-B)}=\frac{\cot \cdot \frac{1}{2}(A+B)}{\operatorname{tang} \cdot \frac{1}{2}(A-B)} ;
$$

that is,
The sum of the cosines of two arcs is to their difference as the cotangent of half the sum of those arcs is to the tangent of halt their difference.

From the first formula of Art. 82, by substituting $A+B$ for ", we have

$$
\sin .(A+B)=\frac{2 \sin \cdot \frac{1}{2}(A+B) \times \cos \cdot \frac{1}{2}(A+B)}{R}
$$

Dividing formula (1), Art. 83, by this, we obtain

$$
\frac{\sin \cdot A+\sin \cdot B}{\sin \cdot(A+B)}=\frac{\sin \cdot \frac{1}{2}(A+B) \cos \cdot \frac{1}{2}(A-B)}{\sin \cdot \frac{1}{2}(A+B) \cos \cdot \frac{1}{2}(A+B)}=\frac{\cos \cdot \frac{1}{2}(A-B)}{\cos \cdot \frac{1}{2}(A+B)} ;
$$

that is,
The sum of the sines of two arcs is to the sine of their sum as the cosine of half the difference of those arcs is to the cosine of half their sum.

If we divide equation (1), Art. 80 , by equation (3), we shall have

$$
\frac{\sin \cdot(a+b)}{\sin \cdot(a-b)}=\frac{\sin \cdot a \cos \cdot b+\sin \cdot b \cos \cdot a}{\sin \cdot a \cos b-\sin \cdot b \cos \cdot a}
$$

By dividing both numerator and denominator of the second member by cos. $a \cos . b$, and substituting $\frac{\operatorname{tang} .}{\mathrm{R}}$ for $\frac{\sin .}{\cos \text {. }}$, we obtain

$$
\frac{\sin \cdot(a+b)}{\sin \cdot(a-b)}=\frac{\text { tang. } a+\operatorname{tang} \cdot b}{\operatorname{tang} \cdot a-\operatorname{tang} \cdot b}
$$

that is,
The sine of the sum of two arcs is to the sine of their difference as the sum of the tangents of those arcs is to the difference of the tangents.

From equation (3), Art. 80, by dividing each member by cos. a cos. $b$, we obtain

$$
\frac{\sin .(a-b)}{\cos a \cos . b}=\frac{\sin . a \cos . b-\sin . b \cos . a}{\mathrm{R} \cos . a \cos . b}=\frac{\tan \cdot a-\operatorname{tang} \cdot b}{\mathrm{R}^{2}} ;
$$ that is,

The sine of the difference of two arcs is to the product of their cosines as the difference of their tangents is to the square of radius.
85. Expressions for the tangents of arcs.

If we take the expression tang. $(a+b)=\frac{\mathbf{R} \sin .(a+b)}{\cos .(a+b)}($ Art. 14), and substitute for sin. $(a+b)$ and $\cos .(a+b)$ their values given in Art. 80, we shall find

$$
\operatorname{tang} \cdot(a+b)=\frac{\mathrm{R}(\sin . a \cos . b+\sin . b \cos . a)}{\cos a \cos b-\sin . a \sin . b}
$$

But $\sin . a=\frac{\cos . a \operatorname{tang} . a}{\mathrm{R}}$, and $\sin . b=\frac{\cos . b \text { tang. } b}{\mathrm{R}}$ (Art. 14).
If we substitute these values in the preceding equation, and divide all the terms by cos. $a \cos . b$, we shall have

$$
\text { tang. }(a+b)=\frac{\mathrm{R}^{2}(\operatorname{tang} \cdot a+\operatorname{tang} . b)}{\mathrm{R}^{2}-\operatorname{tang} \cdot a \text { tang. } b}
$$

In like manner we shall find

$$
\operatorname{tang} \cdot(a-b)=\frac{\mathbf{R}^{2}(\text { tang. } a-\text { tang. } b)}{\mathbf{R}^{2}+\text { tang. } a \text { tang. } b}
$$

Suppose $b=a$, then

$$
\text { tang. } 2 a=\frac{2 \mathrm{R}^{2} \operatorname{tang} \cdot a}{\mathrm{R}^{2}-\operatorname{tang} \cdot{ }^{2} a}
$$

Suppose $b=2 a$, then

$$
\text { tang. } 3 a=\frac{\mathrm{R}^{2}(\text { tang. } a+\text { tang. } 2 a)}{\mathrm{R}^{2}-\text { tang. } a \text { tang. } 2 a}
$$

In the same manner we find

$$
\begin{aligned}
& \cot .(a+b)=\frac{\cot . a \cot . b-\mathrm{R}^{2}}{\cot \cdot b+\cot \cdot a}, \\
& \cot .(a-b)=\frac{\cot . a \cot \cdot b+\mathrm{R}^{2}}{\cot \cdot b-\cot \cdot a}
\end{aligned}
$$

86. Formula for an angle of a triangle when the three sides are given.

When the three sides of a triangle are given, the angles may be found by the formula

$$
\sin . \frac{1}{2} \mathrm{~A}=\mathrm{R} \sqrt{\frac{(\mathrm{~S}-b)(\mathrm{S}-c)}{b c}}
$$

where S represents half the sum of the sides $a, b$, and $c$.

## Demonstration.

Let ABC be any triangle; then (Geom., B. IV., Pr. 12)
 $\mathrm{BC}^{2}=\mathrm{AB}^{2}+\mathrm{AC}^{2}-2 \mathrm{AB} \times \mathrm{AD}$.

Hence

$$
A \mathrm{D}=\frac{\mathrm{AB}^{2}+\mathrm{AC}^{2}-\mathrm{BC}^{2}}{2 \mathrm{AB}}
$$

But in the right-angled triangle ACD we have

$$
\begin{gathered}
\mathrm{R}: \mathrm{AC}:: \cos \mathrm{A}: A \mathrm{D} \\
\cos . A=\frac{R \times A D}{A C}
\end{gathered}
$$

or, by substituting the value of $A D$, we have

$$
\cos \mathrm{A}=\mathrm{R} \times \frac{\mathrm{AB}^{2}+\mathrm{AC}^{2}-\mathrm{BC}^{2}}{2 \mathrm{AB} \times \mathrm{AC}}
$$

Let $a, b, c$ represent the sides opposite the angles $A, B, C$; then

$$
\cos \mathrm{A}=\mathrm{R} \times \frac{b^{2}+c^{2}-a^{2}}{2 b c}
$$

This equation expresses the following theorem : In every plane triangle the cosine of either of the angles is equal to the sum of the squares of the adjacent sides, diminished by the square of the opposite side, and divided by twice the product of the adjacent sides, radius being unity.

This formula is not well adapted to computation by logarithms, but may be rendered suitable by the following transformation:

By Art. 82, we have $2 \sin .{ }^{2} \frac{1}{2} \mathrm{~A}=\mathrm{R}^{2}-\mathrm{R} \cos . \mathrm{A}$.
Substituting for cos. $A$ its value given above, we obtain

$$
\begin{aligned}
2 \sin .^{2} \frac{1}{2} \mathrm{~A} & =\mathbf{R}^{2}-\mathbf{R}^{2} \times \frac{b^{2}+c^{2}-a^{2}}{2 b c}=\mathbf{R}^{2} \times \frac{2 b c+a^{2}-b^{2}-c^{2}}{2 b c}, \\
& =\frac{\mathbf{R}^{2} \times(a+b-c)(a+c-b)}{2 b c} .
\end{aligned}
$$

Put $\mathrm{S}=\frac{1}{2}(a+b+c)$, and we obtain, after reduction,

$$
\sin \cdot \frac{1}{2} \mathrm{~A}=\mathrm{R} \sqrt{\frac{(\mathrm{~S}-b)(\mathrm{S}-c)}{b c}}
$$

In the same manner we find

$$
\begin{aligned}
& \sin . \frac{1}{2} \mathrm{~B}=\mathrm{R} \sqrt{\frac{(\mathrm{~S}-a)(\mathrm{S}-c)}{a c}} \\
& \sin . \frac{1}{2} \mathrm{C}=\mathrm{R} \sqrt{\frac{(\mathrm{~S}-a)(\mathrm{S}-b)}{a b}} ;
\end{aligned}
$$

that is, in every plane triangle the square of the cosine of half
cither of the angles is equal to the product of the excess of the semiperimeter over the two adjacent sides dividled by the product of those sicles, radius being unity.

Ex. 1. What are the angles of a plane triangle whose sides are 432,543 , and 654 ?

Here $\mathrm{S}=814.5 ; \mathrm{S}-b=382.5 ; \mathrm{S}-c=271.5$.

| log. 382.5 | 2.582631 |
| :--- | ---: |
| $\log .271 .5$ | 2.433770 |
| $\log . b, 432$ | comp. 7.364516 |
| $\log . c, 543$ | comp. 7.265200 |
|  | $2) \frac{19.646117}{9.823058}$ |
| n. $\frac{1}{2} A, 41042^{\prime} 36 \frac{1}{2}^{\prime \prime}$. |  |

In a similar manner we find the angle $B=41^{\circ} 0^{\prime} 39^{\prime \prime}$, and the angle $\mathrm{C}=55^{\circ} 34^{\prime} 8^{\prime \prime}$.

Ex. 2. What are the angles of a plane triangle whose sides are 245,219 , and 91 ?

Ex. 3. What are the angles of a plane triangle whose sides are 538,475 , and 647 ?
87. On the computation of a table of sines, cosines, etc.

In computing a table of sines and cosines, we begin with finding the sine and cosine of one minute, and thence deduce the sines and cosines of larger arcs. The sine of so small an angle as one minute is nearly equal to the corresponding arc. The radius being taken as unity, the semi-circumference is known to be 3.14159. This, being divided successively by 180 and 60 , gives .0002908882 for the arc of one minute, which may be regarded as the sine of one minute.

The cosine of $1^{\prime}=\sqrt{1-\sin ^{2}}=0.9999999577$.
The sines of very small angles are nearly proportional to the angles themselves. We might then obtain several other sines by direct proportion. This method will give the sines correct to five decimal places, as far as two degrees. By the following method they may be obtained with greater accuracy for the ell tire quadrant.

By Art. 83 we have, by transposition,

$$
\begin{aligned}
& \sin (a+b)=2 \sin a \cos b-\sin (a-b) \\
& \cos (a+b)=2 \cos a \cos b-\cos (a-b)
\end{aligned}
$$

If we make $a=b, 2 b, 3 b$, etc., successively, we shall have

$$
\sin .2 b=2 \sin . b \cos b ;
$$

$\sin .3 b=2 \sin .2 b \cos . b-\sin . b ;$

$$
\begin{gathered}
\sin .4 b=2 \sin .3 b \cos . b-\sin .2 b, \\
\text { etc., } \quad \text { etc. } \\
\cos .2 b=2 \cos . b \cos . b-1 ; \\
\cos .3 b=2 \cos 2 b \cos . b-\cos . b ; \\
\cos .4 b=2 \cos .3 b \cos . b-\cos .2 b, \\
\text { etc., } \quad \text { etc. }
\end{gathered}
$$

Whence, making $b=1$ ', we have

$$
\begin{gathered}
\sin .2^{\prime}=2 \sin .1^{\prime} \cos .1^{\prime}=.000582 ; \\
\sin .3^{\prime}=2 \sin .2^{\prime} \cos .1^{\prime}-\sin .1^{\prime}=.000873 ; \\
\sin .4^{\prime}=2 \sin .3^{\prime} \cos .1^{\prime}-\sin .2^{\prime}=.001164 ; \\
\text { etc., } \quad \text { etc. } \\
\cos .2^{\prime}=2 \cos .1^{\prime} \cos .1^{\prime}-\quad 1=0.999999 ; \\
\cos .3^{\prime}=2 \cos 2^{\prime} \cos .1^{\prime}-\cos .1^{\prime}=0.999999 ; \\
\cos .4^{\prime}=2 \cos .3^{\prime} \cos .1^{\prime}-\cos .2^{\prime}=0.999999, \\
\text { etc., }
\end{gathered}
$$

The table of tangents may be computed from the sines and cosines by the formula tang. $A=\frac{\sin . A}{\cos . A}$. The rule is, divide each sine by the corresponding cosine.

The secants are computed by the formula $\sec . A=\frac{1}{\cos . A}$; or, the rule, divide unity by each cosine.

The cotangents and cosecants are computed by the formulas cot. $=\frac{1}{\text { tang. }}$, and cosec. $=\frac{1}{\sin e}$.

The logarithmic tables are formed by taking the logarithms of the numbers in the tables computed as above, and adding 10 to each index.
88. Formulce of verification. In so extended a work as the computation of the sines and cosines of all angles from $0^{\circ}$ to $90^{\circ}$, it is necessary from time to time to verify the accuracy of the results by independent computations. For this purpose we employ special formulæ for the values of the sines and cosines of certain angles. The sines and cosines of $30^{\circ}, 45^{\circ}$, and $60^{\circ}$ have been given in Arts. 73 and 74. The sines and cosines of other angles may be found by means of the preceding formulas. By means of the Equations of Art. 82, from the cosine of any angle we can find the sine and cosine of its half; hence from the cosine of $45^{\circ}$ we can find the sine and cosine of $22^{\circ} 30^{\prime}$; and from these, the sine and cosine of $11^{\circ} 15^{\prime}$. Also, from cos. $30^{\circ}$, we can find the sine and cosine of $15^{\circ}, 7^{\circ} 30^{\prime}$, and $3^{\circ} 45^{\prime}$. If the values of the
sines of these angles agree with the values obtained by the process of Art. 87, the whole work may be presumed to be correct.

## Examples for Practice.

Prob.1. Given the three sides of a triangle, $627,718.9$, and 1140, to find the angles.

$$
\text { Ans. } 29^{\circ} 44^{\prime} 2^{\prime \prime}, 34^{\circ} 39^{\prime} 26^{\prime \prime} \text {, and } 115^{\circ} 36^{\prime} 32^{\prime \prime}
$$

Prob. 2. In the triangle ABC, the angle A is given $89^{\circ} 45^{\prime} 43^{\prime \prime}$, the side AB 654 , and the side AC 460 , to find the remaining parts. Ans. $\mathrm{BC}=798$; the angle $\mathrm{B}=35^{\circ} 12^{\prime} 1^{\prime \prime}$, and the angle

$$
\mathrm{C}=55^{\circ} 2^{\prime} 16^{\prime \prime} .
$$

Prob.3. In the triangle ABC , the angle A is given $56^{\circ} 12^{\prime} 45^{\prime \prime}$, the side BC 2597.84 , and the side AC 3084.33 , to find the remaining parts.

$$
\text { Ans. } \mathrm{B}=80^{\circ} 39^{\prime} 40^{\prime \prime}, \mathrm{C}=43^{\circ} \quad 7^{\prime} 35^{\prime \prime}, c=2136.8 \text {; }
$$

$$
\text { or, } \mathrm{B}=9920 \quad 20, \mathrm{C}=242655, c=1293.8
$$

Prob.4. In the triangle ABC, the angle A is given $44^{\circ} 13^{\prime} 24^{\prime \prime}$, the angle $\mathrm{B} 55^{\circ} 59^{\prime} 58^{\prime \prime}$, and the side AC 368 , to find the remaining parts.

$$
\text { Ans. } \mathrm{C}=79^{\circ} 46^{\prime} 38^{\prime \prime}, \mathrm{AB}=436.844, \text { and } \mathrm{BC}=309.595
$$

Prob. 5. In a right-angled triangle, if the sum of the hypothenuse and base be 3409 feet, and the angle at the base $53^{\circ} 12^{\prime} 14^{\prime \prime}$. what is the perpendicular? Ans. 1707.2 feet.

Prob.6. In a right-angled triangle, if the difference of the hypothenuse and base be 169.9 yards, and the angle at the base $42^{\circ} 36^{\prime} 12^{\prime \prime}$, what is the length of the perpendicular? Ans. 435.732 yards.
Prob.7. In a right-angled triangle, if the sum of the base and perpendicular be 123.7 feet, and the angle at the base $58^{\circ} 19^{\prime} 32^{\prime \prime}$, what is the length of the hypothenuse? Ans. 89.889 feet.

Prob. 8. In a right-angled triangle, if the difference of the base and perpendicular be 12 yards, and the angle at the base $38^{\circ} 1^{\prime} 8^{\prime \prime}$, what is the length of the hypothenuse? Ans. 69.81 yards.

Prob.9. A May-pole 50 feet 11 inches high, at a certain time will cast a shadow 98 feet 6 inches long; what, then, is the breadth of a river which runs within 20 feet 6 inches of the foot of a steeple 300 feet 8 inches high, if the steeple at the same time throws its shadow 30 feet 9 inches beyond the stream?

Ans. 530 feet 5 inches.
Prob. 10. A ladder 40 feet long may be so placed that it shall reach a window 33 feet from the ground on one side of the street, and by turning it over, without moving the foot out of its place,
it will do the same by a window 21 feet high on the other side. Required the breadth of the street.

Ans. 56.649 feet.
Prob. 11. A May-pole, whose top was broken off by a blast of wind, struck the ground at the distance of 15 feet from the foot of the pole; what was the height of the whole May-pole, supposing the length of the broken piece to be 39 feet?

Ans. 75 feet.
Prob. 12. How must three trees, $\mathrm{A}, \mathrm{B}, \mathrm{C}$, be planted, so that the angle at A may be double the angle at $B$, the angle at $B$ double the angle at $\mathbf{C}$, and a line of 400 yards may just go round them?

Sol. Assume $\mathrm{AB}=1$, and compute the corresponding values of AC and BC .

$$
\text { Ans. } \mathrm{AB}=79.225, \mathrm{AC}=142.758 \text {, and } \mathrm{BC}=178.017 \text { yards. }
$$

Prob. 13. The town $\mathbf{B}$ is half way between the towns A and C , and the towns $B, C$, and $D$ are equidistant from each other. What is the ratio of the distance $A B$ to $A D$ ?

$$
\text { Ans. As unity to } \sqrt{ } 3
$$

Prob. 14. There are two columns left standing upright in the ruins of Persepolis; the one is 66 feet above the plain, and the other 48. In a straight line between them stands an ancient statue, the head of which is 100 feet from the summit of the higher, and 84 feet from the top of the lower column, the base of which measures just 74 feet to the centre of the figure's base. Required the distance between the tops of the two columns.

$$
\text { Ans. } 156.68 \text { feet. }
$$

Prob.15. Prove that tang. $\left(45^{\circ}-\mathrm{b}\right)=\frac{1-\operatorname{tang} . b}{1+\operatorname{tang} . b}$.
Prob. 16. One angle of a triangle is $45^{\circ}$, and the perpendicular from this angle upon the opposite base divides the base into two parts, which are in the ratio of 2 to 3 . What are the parts into which the vertical angle is divided by this perpendicular?

Sol. Let $x=$ the larger angle; then

$$
\text { tang. }\left(45^{\circ}-a\right)=\frac{2}{3} \operatorname{tang} \cdot a=\frac{1-\operatorname{tang} \cdot a}{1+\text { tang. } a}
$$

which can be solved as an equation of the second degree.

$$
\text { Ans. } 18^{\circ} 26^{\prime} 6^{\prime \prime} \text {, and } 26^{\circ} 33^{\prime} 54^{\prime \prime} .
$$

Prob. 17. Prove that $\sin .3 b=3 \sin . b-4 \sin .^{3} b$.
Prob. 18. One side of a triangle is 25 , another is 22 , and the angle contained by these two sides is one half of the angle opposite the side 25 . What is the value of the included angle?

Sol. $\frac{\sin .3 x}{\sin .2 x}=.88=\frac{3 \sin . x-4 \sin .{ }^{3} x}{2 \sin . x \cos x}=\frac{3-4 \sin .^{2} x}{2 \cos . x}=\frac{3-4 \sin .{ }^{2} x}{2 \sqrt{1-\sin \cdot .^{2} x}}$, which can be solved as an equation of the second degree. Ans. $39^{\circ} 58^{\prime} 51^{\prime \prime}$.
Prob.19. One side of a triangle is 25 , another is 22 , and the angle contained by these two sides is one half of the angle opposite the side 22. What is the value of the included angle?

Sol. Like the preceding. . Ans. $30^{\circ} 46^{\prime} 38^{\prime \prime}$.
Prob. 20. Two sides of a triangle are in the ratio of 11 to 9 , and the opposite angles have the ratio of 3 to 1 . What are those angles?

Sol. $3 \sin . x-4 \sin ^{5} x: \sin . x:: 11: 9$.
Ans. The sine of the smaller of the two angles is $\frac{2}{3}$, and of the greater $\frac{2}{2} \frac{2}{7}$; the angles are $41^{\circ} 48^{\prime} 37^{\prime \prime}$, and $125^{\circ}$ $25^{\prime} 51^{\prime \prime}$.
Prob. 21. One side of a triangle is 15 , and the difference of the two other sides is 6 ; also, the angle included between the first side and the greater of the two others is $60^{\circ}$. What is the length of the side opposite to this angle? Ans. 57.
Prob. 22. One side of a triangle is 15 , and the difference of the two other sides is 6 ; also, the angle opposite to the greater of the two latter sides is $60^{\circ}$. What is the length of said side?

Ans. 13.
Prob.23. One side of a triangle is 15 , and the opposite angle is $60^{\circ}$; also, the difference of the two other sides is 6 . What are the lengths of those sides? Ans. 11.0712, and 17.0712 .

Prob. 24. The perimeter of a triangle is 100 ; the perpendicular let fall from one of the angles upon the opposite base is 30 , and the angle at one end of this base is $50^{\circ}$. What is the length of the base?

Ans. 30.388.

N.B.-In the following table, commencing with page 322 , the two leading figures in the first column of logarithms are to be prefixed to all the numbers of the same horizontal line in the next nine columns; but when a point (.) occurs, its place is to be supplied by a cipher, and the two leading figures are to be taken from the next lower line.

The logarithms of the first 100 numbers are given with their characteristics; but for all other numbers the decimal part only of the logarithm is given, and the characteristic is to be supplied by the usual rule.

The last column of each page shows the difference between the successive logarithms on the same horizontal line; and on the lower portion of each page are given the Proportional Parts for a fifth figure in the natural number.

LOGARITHMS OF NUMBERS.

## LOGARITHMIC

## SINES AND TANGENTS <br> FOR EVERY DEGREE AND MINUTE OF THE QUADRANT.

N.B.-The minutes in the left-hand column of each page, increasing downward, belong to the degrees at the top; and those in the right-hand column, increasing upward, belong to the degrees below.

## LOOMIS'S

## SERIES OF

# TEXT-BOOKS. 

## PUBLISHED BY

HARPER \& BROTHERS, New York.

The publishers of the series of text-books by Prof. Loomis invite the attention of professors in colleges and teachers generally to an examination of these works. They are the results of a long series of years devoted to collegiate instruction, and it is believed that they possess in an eminent degree the qualities of simplicity, conciseness, and lucid arrangement, and are adapted to the wants of the students generally in our colleges and academies.

Prof. Loomis's text-books in Mathematics are models of neatness, precision, and practical adaptation to the wants of students.-Methodist Quarterly Review.

Prof. Loomis's text-books are distinguished by simplicity, neatness, and accuracy, and are remarkably well adapted for recitation in schools and collegres. I am satisfied no books in use, either in America or England, are so well adapted to the circumstances and wants of American teachers and pu-pils.-W. C. Larrabee, late Prafessor of Mathematics, A sbury University, Ind.

## Loomis's Elements of Arithmetic.

## Designed for Children. <br> 16mo, 166 pages, Half Sheep, 40 cents.

This little volume is designed to introduce young children to a knowledge of Arithmetic. It assumes no previous knowledge of the subject-not even the ability to count ten correctly; and the successive steps are believed to be so gradual as not to be beyond the capacity of ordinary children of eight years of age. Whenever a new principle is introduced it is made plain by the use of examples containing small numbers; and the transition is gradually made from small to larger numbers. Very little explanation is given of the proper method of solving the examples, since the design is to commence each subject with questions so simple as to require no explanation, and to proceed from these to more difficult exercises so gradually that every child will be able to invent his own methods.

Throughout the first nine sections of the book the pupil is not allowed the use of a slate or blackboard, but required to depend entircly upon his memory in the solution of every example. In the tenth, which is the last section, larger numbers are introduced, requiring the use of a slate, and this is designed as preparatory to a
work on Written Arithmetic. It is believed that any one who will go through this little volume understandingly will have acquired a very clear knowledge of most of the fundamental principles of Arithmetic, and will be prepared to enter profitably upon the study of some full treatise upon the subject.
This appears to us to be a practical book, and well fitted to the purpose for which it is designed.-New Englander (Qnarterly Marazine).
This Arithmetic is very simple and very gradnal. It does not push a child off into the mysteries of Mathematics as one weuld plange him into a deep pool of water, but inch by inch the yonng mind is led down into the depths of figures.-Indianapolis Journal.

## Loomis's Treatise on Arithmetic,

Theoretical and Practical. With an Appendix on the Metric System. Eighteenth Edition. 12mo, $35^{2}$ pages, Sheep extra, \$r 25 .
This volnme explains in a simple and philosophical manner the theory of all the ordinary operations of Arithmetic, and illustrates them by examples sufficiently numerous to impress them indelibly upon the mind of the pupil. The most important information required respecting the usual forms of business is given in a clear and concise manner. The book is designed for the use of advanced students in our public schools, and farmishes a complete preparation for the study of Algebra, as well as for the practical duties of the count-ing-louse.

The answers to about one-third of the questions are given in the body of the work; but in order to lead the student to rely upon his own judgment, the answers to the remaining questions are purposely omitted. For the convenience, however, of such teachers as maty desire it, there is published a small edition containing the answers to all the questions.

A pretty full exposition of the metric system of weights and measures is appended to this volume.
As an introduction to the anthor's incomparable series of mathematical works, and displaying as it does like characteristic excellences, jndicions arrangement, simplicity in the statement, and clearness and directness in the elucidation of principles, this work can not fail of a like flattering reception from the public-O. L. Castre, Professor of Rhetoric, and Warien Leverett, A.M., Principal of Prep. Dep't, Shurtleff College, Illinois.
I have adopted Prof. Loomis's Arithmetic (as well as his entire Mathematical Series) as a text-book in this institution. The rnles in this Arithmetic are demonstrated with that musual cleamess and brevity which so preeminently distinguish Prof. Loomis as a mathematical anthor.-J. M. Ferresi, A.M., Professor of Mathenatics, Dickinson Seminary, Pa.
-In general arrangement and adaptation to the wants of onr schools, I have never seen any thing equal to Prof. Loomis's Arithmetic.-Danimi Mobride, Bellefonte (Pa.) Academy.
We have used Loomis's Arithmetic in this Institnte since its publication, and I can truly say that, in arrangement, accuracy, and logical expression, it is the best treatise on the subject with which I an acquainted. It has stood the test of the class-room, and I ann well pleased with the resnlts.-N. B . Wrisstra, President of Virginia Collegiate Institute, Portsmouth, Va.
Prof. Loomis has given us a work on Arithmetic which, for precision in language, comprehensiveness of definitions, and suitable explanation, has no equal before the public.-P. E. Wilder, Greenfield (lll.) Dfale and Femate Seminary.
This work is calculated to make scholars thoroughly acquainted with the science of Arithmetic. It is certainly superior to any other we have ever seen.-Louisville Courier.

We have taken some pains to examine Prof. Loomis's Arithmetic, and find it has chaims which are peculiar and pre-eminent. The principles are developed in their natural order; every rule is plainly though briefly demonstrated, and the pupil is taught to express his ideas clearly and precisely. - Western Literary Messenger.

The clearness and simplicity of Prof. Loomis's Arithmetic are in charming contrast with our own reminiscences of similar compilations in our school days, whereof the main and mistaken object was to baffle a child's compre-hension.-Albion.

## Loomis's Elements of Algebra.

## Designed for the Use of Beginners. Thirty-third Edition. I2mo, 28 I pages, Sheep extra, \$1 25.

This volume is intended for the use of students who have just completed the study of Arithmetic. It explains the method of solving equations of the first degree, with one, two, or more unknown quantities; the principles of involution and of evolution ; the solution of equations of the second degree; the principles of ratio and proportion, with arithmetical and geometrical progression. Every principle is illustrated by a copious collection of examples, and two hundred miscellaneons problems will be found at the close of the book.
I have used Loomis's Elements of Algebra in my school for several years, and have found it fitted in a high degree to give the pupil a clear and comprehensive knowledge of the elements of the science. I bclieve teachers of academies and high-schools will find it all that they can desire as a textbook on this branch of Mathematics.-Prof. Alonzo Gray, late Principal of Brooklyn Heights Seminar'y.
I have carefully examined Loomis's Elements of Algebra, and cheerfully recommend it on account of its superior arrangement and clear and full cx-planations.-Soromon Jennle, Principal of N. Y. Commercial School.
Loomis's Elements of Algebra is worthy of adoption in our academies, and will be found to be an excellent text-book. The definitions and rules are expressed in simple and accurate language, the collection of cxamples subjoined to each rule is sufficiently copions, and as a book for beginners it is admirably adapted to make the learner thoroughly acquainted with the tirst principles of this important branch of science.-D. Macatlay, Principal of the Polytechnic School, New Orleans.
Lonmis's Elements of Algebra is prepared with the care and judgment that characterize all the elementary works published by the same author.Methodist Quarterly Review.

## Loomis's Treatise on Algebr'a.

New and Revised Edition. 12mo, 384 pages, Sheep, \$I $50 ; 8 \mathrm{vo}, 384$ pages, Sheep, \$200.
This work was first published in 1846 , since which time about 70,000 copies have been issued. The stereotype plates having become too much worn for further use, the opportunity was improved to make a thorongh revision of the work. Criticisms were solicited from several college professors who had had long experience in the use of this book, and in reply numerous suggestions were received. The book has been almost entirely re-written, nearly every page of it haring been given to the printer in manuscript. The general plan of the original work has not been materially altered, but the changes of arrangement and of execution are numerous.

This book aims to exhibit in logical order all those principles of Algebra which are most important as a preparation for the subsequent branches of a college course of Mathematics. This edition retains, with but slight alteration, a feature which was made promi-
nent in the former editions-that of stating each problem twice: first as a restricted numerical problem, and then in a more general form, aiming thereby to lead the student to cultivate the faculty of generalization. . The number of examples incorporated with each chapter of the book has been greatly increased, and at the close is given a large collection of examples to which the teacher may resort whenever occasion may require.

Prof. Loomis's work is well calculated to impart a clear and correct knowledge of the principles of Algebra. The rules are concise, yet sufficiently comprehensive, containing in a few words all that is necessary, and nothing more-the absence of which quality mars many a scientific treatise.- The collection of problems is peculiarly rich, adapted to inipress the most important principles upon the youthful mind, and the stadent is led gradually and intelligently into the more interesting and higher departments of the science.-Jomn Brocklesisy, A.M., Professor of Mathematics and Natural Philosophy in I'rinity College.

Prof. Loomis's Algebra is peculiarly well adapted to the wants of students in academies and colleges. The materials are well selected and well arranged; the rules and principles are stated with clearuess and precision, and accompanied with satisfactory proofs, illnstrations, and examples.A. D. Staniey, late Professor of Mathematics in Yale College.

I have carefully exanined the work of Prof. Loomis on Algebra, and am much pleased with it. The arrangement is sufficiently scientific, yet the order of the topics is obviously, and, I think, judicionsly made with reference to the development of the powers of the pupil. I think this work better suited fur the purposes of a text-book than any other I have seen. Augustus W. Smith, LL.D., late President of Wéleyan University.

Prof. Loomis's Algebra possesses those qualities which are chiefly requisite in a college text-book. Its statements are clear and definite, the nore important principles are made so prominent as to arrest the pupil's attention, and it conducts the pupil by a sure and easy path to those habits of generalization which the teacher of Algebra has so much difficulty in imparting to his pu-pils.-Julian M. Sturtevant, LL.D., President of Illinois College.

The fact that this work, after many rears' use as a college text-book, has been carefully revised, with the aid of the suggestions of many experienced professors who have nsed it, will commend it to all who are in search of the best text-book in this branch of Mathematics. It exhibits pre-eninently the characteristics of Prof. Loomis's other works-conciseness, clearness, and logical method. The examples are abundant and well chosen. The assurance that the proof-sheets have all passed under the critical eye of Prof. H. A. Newton is a further guarantee of the high character of the work. -New Englander (Quarterly Magazine), Jan., 1569.

Prof. Loonis has here aimed at exlibiting the first principles of Algebra in a form which, while level with the capacity of ordinary students and the present state of the science, is fitted to elicit that degree of effort which educational purposes require. Throughout the work, whenever it can be done with advantage, the practice is followed of generalizing particular examples, or of extending a question proposed relative to a particular quantity to the class of quantities to which it belongs-a practice of obvions utility, as accustoming the student to pass from the particular to the general, and as fitted to impress a main distinction between the literal and numerical calculus. The general doctrine of Equations is exponnded with clearness and independence. The anthor has developed this subject in an order of his own. We venture to say that there will be but one opinion respecting the general character of the expositiou.-American Journal of Science and Arts.

## Loomis's Elements of Geometry, Conic Sections, and Plane Trigonometry.

New and Revised Edition. I2mo, 388 pages, Sheep extra, \$1 50 .
This work was first published in 1847, since which time over 80,000 copies have been issued. The stereotype plates having be-
come so much worn that it was found necessary to recast them, the opportunity has been improved to give the entire book a thorough revision. As the general plan of the original work has met with very extensive approval, it has not been thought best to modify it matcrially; nevertheless, the minor changes which have been made are numerous and of considerable importance.

The volume commences with a brief sketch of the history of Elementary Geometry ; the definitions throughout have been somewhat amplified, and several notes have been added which it is hoped may be found useful and suggestive. The subject of Ratio has been expanded; a few new propositions have been added to several of the books; and there is given a considerable collection of musolved problems, with some numerical exercises.

In the treatise on the Conic Sections the alterations are numerous, and at the close of each chapter is given a collection of numerical exercises. The treatise on Plane 'Trigonometry, although concise, is pretty complete, and this is followed by a Table of Logarithms and of Sines and 'Tangents for every minute of the quadrant.
Having used Loomis's Elements of Genmetry for several years, carefully examined it, and compared it with Euclid and Legendre, I have found it preferable to either. 'T'eachers will tind the work an excellent text-book, suited to give a clear view of the beautiful science of which it treats.-A monzo GR.1r, A M., late Principal of Brooklyn Heights Seminary.
I consider Loomis's Geometry and Trigonometry the best work I have ever seen on any branch of elementary Mathematics.-Janes B. Dodi, A.M., Professor of Muthematics, Transylvania University.
Every page of this book bears marks of careful preparation. Only those propositions are selected which are most inportant in themselves, or which are indispensable in the demonstration of others. The propositions are all ennnciated with studied precision and brevity. The demonstrations are complete, without being encumbered with verbiage ; and, unlike many works we could mention, the diagrams are good representations of the objects in-tended.-American Review.
Prof. Loomis's Geometry is characterized by the same neatness and elegance which were exhibited in his Algebra. While the logical form of argumentation pecnliar to Playfair's Euclid is preserved, more completeness and symmetry is secured by additions in Solid and Spherical Geometry, and by a different arrangement of the propositions. It will be a favorite with those who admire the chaste forms of argumentation of the old school; and it is a question whether these are not best for the purposes of mental disci-pline.-Northern Christian Advocate.
The enunciations in Prof. Loomis's Geometry are concise and clear, and the processes neither too brief nor too diffuse. The part treating of Solid Geometry is mondobtedly superior in clearness and arrangement to any other elementary treatise.-N. Y. Evangelist.

## Loomis's Trigonometry and Tables.

Thirty-seventh Edition. 8vo, 360 pages, Sheep extra, \$2 00.

## The Trigonometry and Tables, bound separately, \$150 each.

If desired, the first 52 pages of the Trigonometry (embracing the whole of Plane Trigonometry) may be bound with the Geometry and Conic Sections. Price \$1 50.
This work contains an exposition of the nature and properties of logarithms; the principles of plane trigonometry ; the mensuration of surfaces and solids; the principles of land surveying, with a full
description of the instruments employed; the elements of navigation, and of spherical trigonometry. The tables furnish the logarithms of numbers to 10,000 , with the proportional parts for a fifth figure in the natural number; logarithmic sines and tangents for every ten seconds of the quadrant, with the proportional parts to single seconds; natural sines and tangents for every minute of the quadrant ; a traverse table; a table of meridional parts, etc. The last edition of this work contains a collection of one hundred miscellaneous problems at the close of the volume.

Loomis's Trigonometry is well adapted to give the student that distiuct knowledge of the principles of the science so important in the furtler prosecution or the study of Mathematics. The descriptions and representations of the instruments used in surveying, leveling, etc., are sufficient to prepare the student to make a practical application of the principles he hats learned. The Tables are just the thing for collcge students.-Join Tatloon, A.M., 1 rofessor of Mathematics in Williams College.

Prof. Loomis has done up the work admirably. The brevity and clearness which characterize this excellent system of mathematical reasoning are the ne phus ultra for such a work. Ilis Trigonometry will meet with the appproval already accorded to his Algebra aud Geometry.-C. Dewer, late Professor in Rochester University.

Loomis's Tables are vastly better than those in common use. The extension of the sines and tangents to ten seconds is a great improvement. The tables of natmral sines are indispensable to a good understanding of Trigonometry, and the natural tangents are exceedingly convenient in Analytical Geometry--I. Warid Anmbews, A.M., President of Marietta College.

Loomis's Triyonometry is sufficiently extcusive for collegiate purposes, and is every where clear and simple in its statements, without being redundiant. The learner will here find what he really needs without being distracted by what is superfluous or irrelevant.-A. Caswell, D.D., President of Brown University.

Loomis's Trigonometry and Tables are a great acquisition to mathematical schools. Iknow of no work in which the principles of Trigonometry are so well condensed and so admirably adapted to the course of instruction in the mathematical schonls of our country.-Thomas E. Sudler, A.M., Professor of Mathematics in Dickinson College.

In this work the principles of Trigonometry and its applications are discussed with the same clearness that characterizes the previons volnmes. The portion appropriated to Mensuration, Surveying, etc., will especially commend itself to teachers by the jndgment exhibited in the extent to which they are carried, and the practically use ful character of the matter introduced. The Logarithmic Tables will be found unsurpassed in practical convenience by any others of the same extent.-Avgrstus W. Smitir, LL.D., late Professor of Mathematics and Astronomy in the Wesleyan University.

## Lominis's Elements of Analytical Geometry,

And of the Differential and Integral Calculus: Thir-
ty-first Edition. $\quad 8 v o, 286$ pages, Sheep extra, $\$ 200$.
The first part of this rolume treats of the application of algebra to geometry ; the construction of equations ; the properties of a straight line, a circle, parabola, ellipse, and hyperbola; the classification of algebraic curves, and the more important transcendental curves. The second part treats of the differentiation of algebraic functions, of Maclaurin's and Taylor's theorems, of maxima and minima, transcendental functions, theory of curves, and evolutes. The third part exhibits the method of obtaining the integrals of a great variety of differentials, and their application to the rectification and quadrature of curves, and the cubature of solids. All the principles are illustrated by an extensive collection of examples, and $\Omega$ classified collec-
tion of a hundred and fifty problems will be found at the close of the volume.
No similar work is at the same time so concise and yet so comprehensive -so well adapted for a college class, wherein every part can be taught in the time prescribed for this department.-J. Towler, A.M., Professor of Mathematies, Hobart Free College.
Loomis's Analytical Geometry and Calculus is the best work on that subject for a college course and mathematical schools. It contains all the important principles and doctrines of the calculns, simplified and illustrated by well-selected problems.-Thonas E. Sunler, A.M., l'rofessor of Mathematics in Dickinson College.
In no part of a mathenatical study was simplification and clear, palpable illustration more urgently called for than in this, and in no American work has this object been more satisfactorily accomplished.-A AGGUSUS W. Smiti, LL.D., late Professor of Mathematics and Astronomy in the Wesleyan University.

I have examined Loomis's Analytical Geometry and Calculus with great satisfaction, and shall make it an indispensable part of our scientific course. -Jamis B. Donm, A.M., Professor of Mathematics in T'ransylvania University.
Loomis's Calculus is better adapted to the capacities of young men than any book heretofore published on this sulject.-A. P. Hoo:ce, Professor of Mathematics in Bethany College.

Analytical Geometry is treated, amply enough for elementary instruction, in the short compass of 112 pages, so that nothing need be omitted, and the student can master his text-book as a whole. The Calculus is treated in like manner, in 167 pages, and the opening chapter makes the nature of the art as clear as it can possibly be made. We recommend this work, without reserve or limitation, as the best text-book on the subject we have yet seen.Methodist Quarterly Review.

## Loomis's Elements of Natural Philosophy.

Designed for Academies and High-Schools. Fourteenth Edition. I2mo, $35^{2}$ pages, Sheep extra, \$r 50.
This volume exhibits in a concise form the fundamental principles of Natural Philosophy, arranged in their natural order, and explained in a clear and scientific manner, without requiring a knowledge of the mathematics beyond that of the elementary branches. It treats of Mechanics, Hydrostatics, Pneumatics, Acoustics, Heat, Optics, Magnetism, and Electricity. Special pains have been taken to make this work both practical and interesting, by borrowing illustrations from common life, and by explaining phenomena which are familiar to all, but whose philosophy is not generally well understood. The volume is designed particularly for the use of the higher classes in academies and high-schools.
Prof Loomis's Elements of Natural Philosophy combines conciseness with very great clearness of illustration, and is the best text-book of the kind that I have examined.-Wılinam Ferbire, Aautical Almanac office, Cambridge, Mass.
Prof. Loomis's Natural Philosophy is a digest, and not a compilation. It meets a great want in our academies, being a mean between the strictly mathematical treatises of the college course and the merely descriptive works commonly nsed in schools.-E. W. Evans, Professor of Mathematics, Cornell University, N. Y.
Prof. Loomis's Elements of Natural Philosophy is clear, accurate, and methodical.-Danirl Kinkwood, LL.D., Professor in Indiana University.
The claracteristics of Loomis's mathematical works are fully sustained in the Philosophy. I am glad to find a text-book on this subject so logically expressed, so complete, and so accurate.-N. B. Waisstri, A.M., President of Virginia Institute, Portsmouth, Va.
Prof. Loomis's Natural Philosophy possesses much more clearness and conciseness than any other rolume nuon the subject which I have examined.Einward T. Fristor, Professor of Mathematies, Columbian College, D. C.

Dr. Loomis is no compiler from the text-books of other writers. Every thing which he puts on paper has first passed throngh the alembic of his own mind. His scientific writings are singularly free from superfluons technics, and rarely send away a reader who consults them on some difficult point without a satisfactory elncidation. His Natural Philosophy in 110 respect falls short of the high standard of excellence attained by the preceding volumes of the series.- New Monthly Mafazine.
This work claims to be a philosophical Philosoply. For clearness of style, fullness of illustration, and general good looks, we have not met its equal. The uumerous references to the every-day phenomena of life make it exceedingly interesting.-Alabama Lducational Journal.

## Loomis's Elements of Astronomy.

Designed for Academies and High-Schools. I2mo, 254 pages, Sheep extra, \$1 50.

This volume is designed to communicate clear and definite ideas respecting the most important facts and principles of Astronomy to persons who have made but little progress in the mathematics. It describes the instruments employed by astronomers, as well as the mode of making the observations, and shows how from these materials the entire structure of Astronomy is reared. It explains the mode of determining the figure and dimensions of the earth; the construction and use of the terrestrial and celestial globes; the apparent motions of the sun, the moon, the planets, and the comets, together with their physical condition as far as it can be ascertained; the phenomena of eclipses and the tides, and the determination of longitude; and, finally, treats of the fixed stars-the double stars, clusters of stars, and the nebulæ. Every page of the book is divided into short paragraphs, with appropriate headings indicating the subject of the article and serving as a guide both to the pupil in his studies and to the teacher in conducting his recitations. The volume is designed to give a correct idea of the actual state of Astronomy for the year 1869.

I am much pleased with the book, as being a concise, clear, and practical text-book-A. H. Wenzei, Principal of High-School, Marlboro, Mass.
It embodies in a remarkable degree the characteristics of a good text-book. It is comprehensive and methodical, clear and concise. In my opinion it is the best elementary work on Astrinomy yet published.-Prof. Cirinlris C. Burnett, A.M., Principal of English and Classical School, Sprinafield, Mass.
I unhesitatingly recommend it to the use of all who would desire an easy and, at the same time, clear and explicit treatise npon the subject of Astronomy. - Prof. A. Rambo, Principal of Washington Hall Collegiate Institute, Trappe, Pa.

Loomis's Astronomy is especially adapted for the class-room by the judicious selection of topics and the clearness with which they are presented. For classes sufficiently advanced to use it, I know of no better treatise in the langrage.-Prof. C. C. Rounins, Principal of State Normal School, Farmington, Me.
Loomis's Elements of Astronomy is the best text-book on this sulbject for scliools I have ever seen.-Charies Pininirs, D.D., Professor of Mathematics in Davidson College, N. C.

We have exanined Loomis's Elements of Astronomy with much pleasnre. The snbjects treated of are carefnlly, bnt not ton elaborately explained, and uo more technicalities are employed than seem to be absolutely necessary. There is more than usual clearness in the definitions of terms, and the judicious illnstrations serve to make the anthor's meaning distinctly under stood.-Historical Magazine (N. Y.), July, 1869.

## Loomis's Treatise on Astronomy.

Designed for Colleges and Scientific Schools. With numerous Illustrations. Twelfth Edition. 8vo, $35^{2}$ pages, Sheep, \$200.

The design of this treatise is to furnish a text-book for the instruction of college classes in the first principles of Astronomy. The aim has been to limit the book to such dimensions that it may be read entire, without omissions, and to make such a selection of topics as shall embrace every thing most important to the student. Every truth is expressed in concise and simple language ; and when it was necessary to introduce mathematical discussions, only the elementary principles of the science have been employed. The entire book is divided into short articles, and each article is preceded by a caption which is designed to suggest the subject of the article.

This volume contains a full discussion of various physical phenomena, such as the constitution of the sun, the condition of the moon's surface, the phenomena of total eclipses of the sun, the laws of the tides, and the constitution of comets. It also contains the results of recent researches respecting binary stars and the nebula.

Prof. Loomis's Astronomy is just the book for which I have been looking a long time.-J. M. Vanvleck, Professor of Mathematics, Wesleyan University, Middletown, Conn.

I like Prof. Loomis's Treatise on Astronomy, and shall adopt it.-Joun Brookiesby, Professor of Mathematies, Trinity College, Hartford, Conn.

Loomis's Astronomy is well adapted to the purposes for which it is designed. In general accuracy it surpasses any similar work with which I am acquainted.-Daniei Kirkwood, LL.D., Professor of Mathematies, Indiana University.

I am much pleased with Loomis's Astronomy. It is concise in its language, lucid in its explanations, and comprehensive in its statements.-Joun P. Marshate, Professor of Mathematies, I'ufts College, Mass.

Loomis's Astronomy is an admirable text-book, both in arrangement, clearness, and compactness of matter, and in being brought down to the present time. I never had a text-book that pleased me more.-H. M. Perkins, Professor of Mathematics, Ohio Wesleyan University, Delaware, 0.

Prof. Loomis's Astronomy is just the kind wanted for college classes.James II. Coffin, LL.D., Professor of Mathematics, Lafayette College, Easton, $P a$.

I have not read a book npon any scientific snbject for a long time that has given ine so much real pleasure as Loomis's Astronomy. I must express my warmest commendation of the plan and execution of the work.-Rionaris C. Stanhey, Prineipal of Nashua High-School, N. II.

This Astronomy is characterized by the same care and thoroughness which distinguish all of Prof. Loomis's works. - Menry S. Noyes, Northwestern University, Evanston, Ill.
This work is designed to meet the wants of the college course. Special prominence has been given to several points which have not usually received attention. The work is thins rendered more attractive to the stndent, and it becomes a manual suited to those who wish to become acquainted with some of the recent additions to this noblest of the physical sciences.-New Englander (Quarterly Magazine).

## Loomis's 'Treatise on Meteorology.

With a Collection of Meteorological Tables. 8vo, 308 pages, Sheep extra, $\$ 200$.
This volume is designed to give a general view of the science of Meteorology in its present advanced state. It treats of the constitu-
tion and weight of the atmosphere; of its temperature and moisture; of the movements of the atmosphere; of the precipitation of vapor in the form of dew, hoar frost, fog, clouds, rain, snow, and hail; of the laws of storms, including tormadoes and water-spouts; of various electrical phenomena, including atmospheric electricity, thunderstorms, and the Polar Aurora; of varions optical phenomena, including the rainbow, twilight, mirage, coronæ, and halos; and, finally, of shooting-stars, detonating meteors, and ærolites. The volume is designed not me- ely as a text-book for students, but also as a guide for observer and for this purpose the instruments employed in meteorologicas observations are fully described and carefully represented by figures. The Appendix contains a collection of 'Tables (36 in number), such as are most useful to observers and instructive to students.

Prof. Loomis's Meteorology appears to me both very instructive and very intelligible to a large class of readers. It is full of snbjects in which I take a great deal of interest.-James Ciallels, Plumian Professor of Astronomy, Cambridge Univer'sity, England.
Prof. Loomis's Meteorology is a work of great valne, and one which was needed in this department.-W. Cuauvinet, late Chancellor of Waskingtorb University, St. Louis, Mo.
Loomis's Meteorology meets a long-felt want in this department of science. It is comprehensive, concise, systematic, and thorongh, and admirably snited to the purposes of a text-book as well as to the waints of observers.-C. S. Lrman, Professor of Physics in Yale College.

This is the only treatise in the English language which is comprelensive enongh to meet the wants in this department, and at the same time compact enongh to make it valuable as a text-book or useful as a hand-book.-Jons L. Camprelic, Professor of Astronomy, Wabash College, Ind.

Prof. Loomis's Meteorology embraces a vast amount of valuable information, and it is presented in it perspicnons and satisfactory manner. It supplies a want which has been very nunch felt in our higher institutions.-F. A. P. Barnard, LlL.D., President of Columbia College, N. Y.

In this work Prof. Loomis has admirally systematized the heterogeneous materials which make up the science of Meteorology, and, with his characteristic clearness of statement and skill in condensation, reduced them to the form of a methodical treatise well adapted to be used as a text-book in colleges and schools of science, and at the same time suited to the wants of meteorological observers as well as of all persons desirons of studying the phases of nature which most frequently arrest our atteution.-New Linglander (Quarterly Magazine).

The phenomena of Meteorology are described hy Prof. Loomis with rare perspicuity and precision. His treatise is well fitted to interest the lay reader as well as the professional scientist.- Bibliotheca Sacra (Quarterly), Audover, Mass.
The student of Meteorology has hitherto been unable to find in a single volume its principles developed with reasonable minuteness and at the same time a presentation of the latest investigations. The present volnme supplies this want. The sclection and arrangement of material is judicious and the statements are lucid.-American Journal of Science and Arts.

## Lommis's Introduction to Practical Astronomy.

With a Collection of Astronomical Tables. Tenth Edition. 8vo, 499 pages, Sheep extra, \$200.
This work furnishes a description of the instruments required in the outfit of an observatory, as also the methods of employing them and the computations growing out of their use. It treats particularly of the 'Iransit Instrument and of Graduated Circles; of the methods of determining time, latitude, and longitude, with the computation of eclipses and occultations. The work is designed for the
use of amateur observers, practical surveyors, and engineers, as well as students who are engaged in a course of training in our colleges. The Tables which accompany this volume are such as have been found most useful in astronomical computations, and to them has been added a catalogue of 1500 stars, with the constants required for reducing the mean to the apparent places.

Letters commendatory of this work have been received from G. B. Airy, Astronomer Royal of England; William Wheivele, D.D., Master of Trinity College, Cambridge, England; Prof. J. Challis, Plımian Professor of Astronomy in the University of Cambridge, England; J. C. Adams, late President of the Royal Astronomical Society; Augustus De Morgan, Professor of Mathematics in University College, London; M. J. Johnson, Director of the Radeliffe Observatory, Oxford, England; William Lassell, Astronomer of Liverpool, England; C. Piazzi Smyth, Astronomer Royal for Scotland; the late Earl of losse, Ireland; Edward J. Cooper, of Markree Castle Observatory, Ireland; and from numerous astronomers in every part of the United States.

Prof. Loomis's work on Practical Astronomy is likely to be extensively useful, as containing the most recent information on the subject, and giving the information in such a manner as to make it accessible to a large class of readers. . I am of opinion that Practical Astronomy is a good educational sulject even for those who may never take observations, and that a work like this of Prof. Loomis should be a text-book in every university. The want of such a work has long been felt here, and if my astronomical duties liad permitted, I sliould have made an attempt to supply it. It is remarkable that in England, where Practical Astronomy is so much attended to, 110 book has been written which is at all adapted to making a learner acquainted with the recent improvements and actual state of the science.-Jamis Cilallis, Plumian Professor of Astronomy in the University of Cambridye, England.
Prof. Loomis's volnme on Practical Astronomy is by far the best work of the kind at present existing in the English language.-J. P. Nionot, LL.D., late Professor of Practical Astronomy in the University of Glasgov, Scotland.
The science of the age was most assuredly in want of a work on Practical Astronomy, and I am delighted to find that want now supplied from America, and from the pen of Prof. Loomis. I propose to make this volume a text-* book for my class of Practical Astronomy in the University of Edinburgh. C. Piazzi Smytio, Astronomer Royal for sicotland.

No work since that of Prof. Woodhouse places the reader so directly in communication with the interior of the observatory as the work on Practical Astronomy by Prof. Loomis; and he has supplied a want which young astronomers, actually wishing to observe, must have felt for a long time. It is more than possible that this work may establish itself as a text-book in England.-Augustus Dis Morgan, Professor of Mathematics in University College, London.

## Loomis's Recent Progress of Astronomy,

> Especially in the United States. I2mo, 396 pages, Cloth, \$ 50 .

This volume (published in 1856) is designed to exhibit in a popular form the most important astronomical discoveries of the preceding ten years. It treats particularly of the discovery of the planet Neptune; of the newly discovered Asteroids; of the new satellite and the new ring of Saturn; of several recent comets; of the parallax of the fixed stars; the motion of the stars; revolution of the nebulx, etc.; the history of American Observatories ; determination of
longitude by the electric telegraph; manufacture of telescopes in the United States, etc.

Prof. Loomis's view of the circumstances attending the discovery of Neptune appears to me the truest and most impartial that I have seen.-James Challis, I'lumian Professor of Astronomy in the University of Cambridge, England.

I thank yoll for your interesting little work on the "Recent Progress of Astronomy." You have reason to be proud of the rapid advances which science in general, and especially Astronomy, has lately made in America.J. C. Anams, late President of the Royal A stronomical Society.

Prof. Loomis's volume on the "Recent Progress of Astronomy" contains a great deal of useful and valuable information. What is said about American observatories was in great part new to me. - J. Lamont, Divector of the Astronomical Observatory, Munich, Bavaria.
Loomis's "Recent Progress of Astronomy" has afforded me great interest, for it is admirably done. As a work to be read by a multitude of our intelligent people who are not adepts in Astronomy, it has no competitor. It supplies a desideratum that was strougly felt, and must gratify numbers who are interested in the progress of Astronomy in our ow'n country.-Cinester Dewey, LL.D., late Professor in Rochester University.
In the "Recent Progress of Astronomy" we have the model of a class of works which we deem of great importance to the popular diffiusion of scientific knowledge. Without sacrificing any thing of mathematical exactuess, and employing no trickery of method or style to attract attention, it is strictly a popular treatise, presenting the results of protracted aud extensive research in language of transparent simplicity, and placing the difficult topics which it discusses in a light which makes them comprehensible by the generality of intelligent readers. The author writes from that fulluess of knowledge which enables him to make a compact and lucid statement of the point under consideration. Prof. Loomis is eminently happy in seizing on the most essential points, and unfolding them with a clearness and precision which make his work no less readable than it is instructive.-New York I'ribune.
The design of this work is to exhibit, in a popular form, the most important astronomical discoveries of the last ten years. The author has executed the task with his usual thoroughness and accuracy, and the student is here furnished, in a condensed and reliable form, with a large amount of important information, to collect which from the original sources would cost him much time and labor.-American Journal of Science and Arts.

## HARPER Ev BROTHERS, Publishers,

NO. LONGFR THE MOPERTY OF TIE LKodiy UNIVERSITY OE MAINE

[^0]:    * In geometrical figures or diagrams we are obliged to employ physical lines and points instead of mathematical ones, since the finest line that we can draw has breadth. Our reasoning is not, however, thereby vitiated, because it is conducted on the supposition that the lines have no breadth, and nothing in our reasoning depends upon the breadth of the lines in our diagram.
    $\dagger$ If two points be taken upon the surface of a ball, the straight line which joins them will lie within the ball, and not on its surface. Therefore the surface of a ball is not a plane surface.
    $\ddagger$ A clear idea of the nature of an angle may be obtained by supposing that one of its sides, as AC , at first coincided with the other side AB , and
    that it has revolved about the point A (turning about A as one leg
    of a pair of compasses) until it has reached the position AC . By
    A
    continuing the revolution, an angle of any magnitude may be formed. It is eri-
    dent that the magnitude of the angle does not depend upon the length of its sides.

[^1]:    * When this axiom is applied to geometrical magnitudes, it must be understood to refer simply to equality of areas. It is not designed to assert that when equal triangles are united to equal triangles, the resulting figures will admit of coincidence by superposition.

[^2]:    * The words in which a Proposition is expressed are called its enunciation. If the enunciation refer to a particular diagram, it is called a particular enunciation, otherwise it is a general one.

    A demonstration is a series of arguments which establish the truth of a theorem, The drawing of such lines as may be necessary to a demonstration is called the construction.

    Under each proposition there is usually given, first, the general enunciation; second, the particular enunciation; third, the construction; and, fourth, the demonstration.

[^3]:    * The enunciation of a theorem embraces two parts, an hypothesis and a conclusion. The hypothesis is a supposition made, and the conclusion is a consequence of the supposition. Prop. 3 might be enunciated thus : Hypothesis, if, at a point in a straight line, two other straight lines upon the opposite sides of it make the adjacent angles together equal to two right angles, then, Conclusion, these two straight lines are in one and the same straight line.

    Proposition 3d is the converse of the 2 d ; that is, the conclusion of the 3 d is the hypothesis in the 2 d .

    Proposition 2d may be enunciated thus : Hypothesis, if, at a point in a straight line, two other straight lines upon opposite sides form but one straight line, then, Conclusion, the two adjacent angles are together equal to two right angles.

    Demonstrations are either direct or indirect. The direct demonstration com-

[^4]:    * Throughout this Treatise we shall assume the possibility of constructing our figures, although the methods of constructing them have not yet been explained. It is not essential to a geometrical demonstration that the precise mode of constructing the figures should be previously given. For the purpose of discovering the properties of figures, we are at liberty to suppose any figure to be constructed, or any line to be drawn, whose existence does not involve an impossibility. We shall show hereafter how the figures employed in these demonstrations may be constructed.

[^5]:    * In the references, the Roman numerals denote the Book, and the Arabic numerals indicate the Proposition. Thus, B. I., Pr. 17, means the serenteenth proposition of the first book.

[^6]:    * In all the preceding propositions, it has been supposed, in conformity with Def. 6, that spherical triangles always have each of their sides less than a semicircumference, in which case their angles are always less than two right angles.

    It should, however, be remarked, that there are spherical triangles of which certain sides are greater than a semi-circumference, and certain angles greater than two right angles. For if we produce the side AC so as to form an entire circumference, ACDE , the part which remains, after taking from the surface of the hemisphere the triangle ABC , is a new triangle, which may also be designated by ABC , and the
     sides of which are $\mathrm{AB}, \mathrm{BC}, \mathrm{CDEA}$. Here we see that the side CDEA is greater than the semi-circumference DEA, and, at the same time, the opposite angle ABC exceeds two right angles by the quantity CBD.
    Triangles whose sides and angles are so large have been excluded by the definition, because their solution always reduces itself to that of triangles embraced in the definition. Thus, if we know the sides and angles of the triangle ABC, we shall know immediately the sides and angles of the triangle of the same name, which is the remainder of the surface of the hemisplere.

[^7]:    * The subtangent is so called because it is below the tangent, being limited by the tangent and ordinate to the point of contact. The subnormal is so called beeause it is below the normal, being limited by the normal and ordinate. The subtangent and subnornal may be regarded as the projections of the tangent and normal upon a diameter,
