TABLE OF TEN THOUSAND
RANDOMLY DISTRIBUTED
FOUR-LETTER COMBINATIONS

July 1957

TABLE OF TEN THOUSAND RANDOMLY DISTRIBUTED FOUR-LETTER COMBINATIONS

By William L. Porter

Eastern Regional Research Laboratory

Eastern Utilization Research and Development Division

Philadelphia 18, Pa.

In order to establish and install a bibliographical sorting system using IBM* equipment, this Laboratory required a randomly distributed list of 10,000 four-letter combinations to be used as code words. Since each column of an IBM card contains twelve punching positions, an alphabet of twenty-four letters extended over two adjacent columns (A-L and M-X inclusive) was thought best. No list of letter combinations having these requirements could be found. Several attempts to use mechanical systems for the generation of such a list were made. All failed for various reasons, the principal one being that each began to repeat after certain intervals. The method finally adopted was as follows:

1. The even-numbered pages of Rand's "TABLE OF A MILLION RANDOM DIGITS,"** from page 2 to page 48 inclusive, were photostated and enlarged to twice the original size. Rand's numbers are arranged as columns of five-digit groups.

2. A metal mask was made to isolate four adjacent pairs of numbers from two adjacent columns. For example:

6	1	3	0	8	7	7	2	4	1
8	7	2	0	5	4	1	2	3	6
9	3	1	6	3	3	2	1	9	4

The pairs of numbers 61, 30, 87, and 72 were read off.

3. The mask was moved down the pair of columns, reading the four pairs of numbers isolated from each combination giving a 50 four-number combinations.

*Mention of commercial products or equipment does not imply that they are endorsed or recommended by the Department of Agriculture over others of similar nature not mentioned.

**Rand Corporation, "Million Random Digits with 100,000 Normal Deviates," 1955, Free Press, Chicago, Ill.

4. The mask was then returned to the top of these same columns and moved over one digit to the right. For example:

The pairs of numbers 13, 08, 77, and 24 were read off.

5. Moving down the pair of columns in this new position provided another 50 four-number combinations. In this way 100 sets of four pairs of digits each were obtained from each pair of columns, or 500 from each page of Rand's table.

6. To translate these random number combinations into the needed random letter combinations, the numbers 01-24, 25-48, 49-72, and 73-96 were assigned to the keys of a standard typewriter, starting with Q=1, as shown in the diagram.

Q	W	E	R	T	Y	U	I	O	P	A	S	D	F	G	H	J	K	L	Z	X	C	V	B	N	M
01	02	03	04	05	-	06	07	08	09	10	11	12	13	14	15	16	17	18	-	19	20	21	22	23	24
25	26	27	28	29	-	30	31	32	33	34	35	36	37	38	39	40	41	42	-	43	44	45	46	47	48
49	50	51	52	53	-	54	55	56	57	58	59	60	61	62	63	64	65	66	-	67	68	69	70	71	72
73	74	75	76	77	-	78	79	80	81	82	83	84	85	86	87	88	89	90	-	91	92	93	94	95	96

7. As the pairs of numbers were read off from Rand's table as explained above, the corresponding key of the typewriter was depressed. Each combination of eight digits thus produced one four-letter combination. For example, the combinations shown in steps 2 and 4 above were typed as FUHM and FOTM, respectively. Since only the numbers 01-96 were assigned, any group of numbers including the numbers 00, 97, 98, or 99 were not used.

8. In addition to those numbers that could not be used because they were not assigned to any typewriter keys, there were other numbers that had to be eliminated because, when translated into letter combinations, they duplicated combinations already used. From each page of 500 random numbers approximately 420 four-letter combinations were obtained after eliminating the combinations containing these numbers and any duplications.

9. Duplications were detected and eliminated by use of two methods:

(a) Each word, as generated, was written in a notebook arranged alphabetically from AA to XX, and as each was written, all combinations previously recorded were checked visually. About six duplications per page were found by this method.

(b) The four-letter combinations were punched into IBM cards using the IBM alphabet. In addition, a consecutive number was punched into each card. These cards were arranged alphabetically by use of a sorting machine and checked by hand for duplications. By this means nineteen more duplicates were found and discarded.

10. The cards were then rearranged numerically by machine in order to regain the original random distribution. The tables printed in this paper were printed from the cards using an IBM Number 407 Accounting Machine. The order of printing was across each page rather than from top to bottom of each column. The number of possibilities for four-letter combinations from a 24-letter alphabet is $(24)^4$ or 331,776. Additional combinations, above the 10,000 listed in this table, can be obtained by starting with page 50 of Rand's table and converting the numbers to letters as described previously. The only feasible method for checking for duplications is by obtaining a file of cards from the IBM Company punched with the list given in this paper and arranged alphabetically. Duplications can then be detected by comparing with the combinations in the file.
