In adults analogous processes are relatively more frequent and develop usually after the middle periods of life. Hyde brings forward strong statistical evidence showing that in the colored races pigmentation of the skin appears to provide a relative immunity to cutaneous cancerosis. He furthermore makes the very interesting deduction that colored races seem to suffer less than the whites from cancer of other organs than the skin and suggests that this relative immunity may be the result of the "protection from the actinic rays of light furnished by the pigment of the integument."

The observations and deductions here epitomised emphasize the influence of light on the biologic chemistry of cells, especially the cells in the human skin. They may be cited to illustrate also how abnormal cellular processes, essentially chemical in nature, may lead to the development of carcinoma. They serve, therefore, to direct our attention again to the chemical nature of the problem of the cause of cancer in the recent discussion of which the tendency to disregard the necessity of a parasitic etiologic hypothesis is becoming more and more apparent. This tendency is receiving strong support also from the results of the experimental transplantations of carcinoma to which it is planned to make more extended reference in the future.

PROVISION FOR EPILEPTICS.

Any one who has witnessed the utter disregard for the welfare of epileptics whose disease forces them to become public charges in county alms and poor houses and in institutions for the insane, in which they are an incident and not a factor in the life of the place, must have been forcibly struck with the necessity for a wholly different type of public care for this unhappy class. Students of epilepsy in the United States and abroad place the proportion of epileptics to the population in general at one to five hundred. If this is true, there are not less than 160,000 epileptics in the United States—less than 3,000 of whom are under proper state care at this time, not including those in institutions for the insane. While every state has one or more hospitals or asylums for the enlightened care and treatment of their insane, only five states have made provision for their dependent epileptics—New York, Ohio, Massachusetts, New Jersey and Texas, while we understand that Indiana is about to make such provision. A meeting was held recently in Chicago with the object of stimulating public interest in the establishment of a colony for epileptics in Illinois. It is to be hoped that the movement

2. Ibid., 1905, vol. II, p. 602.
3. Jour. Med Research, 1905, vol. xiv, p. 89.
1. American Journal of Medical Sciences, January, 1906; abstracted in THE JOURNAL, Feb. 17, 1906, p. 541.

may broaden out until the efforts result in the establishment of such an institution not only in Illinois, but in every large state in the Union. It has been satisfactorily demonstrated that the best way to care for epileptics is on a large tract of land and in comparatively small and wholly detached cottages. Adequate classification plays a leading rôle in the institutional treatment of these people, which makes it essential that any successful institution for them must be on the colony, village or community plan.

THE VITALITY OF THE TYPHOID BACILLUS IN FLOWING WATERS.

The contention made in the Chicago drainage canal suit that typhoid germs are short lived in natural flowing waters seems to be supported by some recent experiments made at the hygienic laboratory of the University of Wisconsin. According to the accounts received, the attempt was made to test the question under as nearly the natural conditions as possible, and the results seem to show that in ordinary flowing water the germs live only from eight to ten days, while in sewage polluted water they live scarcely half that time, being apparently killed off by other organisms. In fact, it is only the more resistant minority of the germs that reach the ten days' limit, and the experiments are said to have been remarkably uniform in this respect. While there may be exceptional cases of longevity of the typhoid bacillus, particularly in culture experiments, the evidence is accumulating that it is a short-lived organism in water under natural conditions.

HOTEL ACCOMMODATIONS—IMPORTANT.

The members of the subcommittee on hotels for the Boston session are anxious that every one shall be provided with good accommodations, either in a hotel or in a first-class boarding house. To arrange for such accommodations, however, the committee must attend to the matter before the arrival of those to be accommodated. In behalf of the committee and at its request, we urge those who expect to attend the Boston session to write to the secretary of the hotel committee, Dr. D. D. Scannell, 366 Commonwealth avenue, Boston, stating what is required. Prompt action in this matter on the part of each individual will receive prompt action on the part of the committee. Although none need fear that accommodations will not be found, even after one arrives, it is not worth while to take chances by such delay.

Medical News

CALIFORNIA.

Personal.—Dr. Perry F. Ballington, Oroville, has been elected president of the Board of Health of Butte County.——Dr. J. Dé Barth Shorb and wife, Los Angeles, left for Europe May 2.

Distribution of Medicine Samples.—The city trustees of Chico have passed an ordinance prohibiting the distribution of samples of medicine, either by hand or by throwing into yards, where children might find and eat them.

Vital Statistics for March.—During March, 1,950 births, 2,523 deaths and 1,471 marriages were reported. The mortality of the month is equivalent to an annual death rate of 16.1 per 1,000. Tuberculosis, the principal cause of death, caused 474 deaths; diseases of the circulatory system, 330, and diseases of the respiratory system, 307, of which 231 were due to pneumonia. Of the epidemic diseases, meningitis caused 37 deaths; measles and influenza, 32; typhoid fever, 19; diphtheria, 17; and smallpox, 7.

DISTRICT OF COLUMBIA.

Personal.—Dr. May D. Baker, Washington, is paying a visit to Los Angeles, Cal.——Dr. G. Brown Miller, Washington, has been elected secretary of the Central Dispensary in the Emergency Hospital.

Examiners' Terms Expire.—The health officer of the district has called the attention of the examiners to the fact that the term of office of Dr. Joseph F. Wall, a member of the Board of Medical Examiners, and a police surgeon, will expire on June 15 and that steps would be taken to appoint his successor. The term of a member of a Board of Homeopathic Examiners and Board of Eclectic Examiners expires on June 30.

Opposes Osteopathy Bill.—The Medical Society of the District of Columbia has made an emphatic protest against the enactment of Senate Bill 251 introduced by Senator Foraker of Ohio, which seeks to regulate the practice of osteopathy, to license osteopathic physicians, etc., in the District of Columbia. The arguments that the society advances are as follows: First, the bill, if enacted, will lower all existing medical school standards and thus defeat the very object for which medical practice laws were provided, namely, to guard the people against the effects of imposition and ignorance; second, the bill seeks to legalize and regulate the practice of osteopathy without defining what constitutes the practice of osteopathy, and until this is done Congress can not undertake to legislate intelligently; third, why should a special board be created, composed of five physicians in good standing, adherents to the osteopathy system of practice? fourth, it is conceded that Congress has a right to recognize other schools or sects of medicine than the so-called regular, homeopathic or eclectic systems of practice; and, fifth, refusal on the part of the advocates of the proposed legislation to accept the suggested amendment, indicates preference for low standards and corresponding danger to the public.

ILLINOIS.

Bid for Consumptive Hospital.—The lowest bid for the construction of the consumptive hospital at the Cook County Institutions, Dunning, was $21,430.

Smallpox.—Three cases of smallpox have been reported from Zion City.——A new outbreak of smallpox has been reported at Rushville.——Smallpox has broken out in a children's home near Sterling. The institution has been placed under strict quarantine.

Physicians' Defense Company Not an Insurance Company.—The Appellate Court of Illinois in an opinion handed down May 8, holds that the Physicians' Defense Company of Fort Wayne, Ind., is not an insurance company under the laws of Illinois, as the company does not undertake to indemnify the holder of its agreement against judgment, but to pay such judgment or any part of it, not even the costs of suit, although in making defense it may have to be outgrown the sum it receives. It does not insure the holder against suits for malpractice. It merely makes a defense against them when they are brought and provides legal services for its patrons.

Chicago.

Bequest to Hospital.—By the terms of the will of the late Charles W. Brega, $5,000 is bequeathed to St. Luke's Hospital.

Smallpox.—A case of smallpox was discovered by the health department, May 11, in Lake View. The source of the infection has not yet been located.

Midwife Released.—Mrs. Maggie Motzna, a midwife charged with the murder of Mrs. Ida Brocknow by an illegal operation, was declared not guilty by a jury in Judge Honore's court, May 10.

Fined for Liquor Selling.—George Campbell, a Pullman druggist, charged with selling liquor without a license, was fined $100 and costs on one charge, and costs on the three other charges brought against him.

Personal.—Dr. and Mrs. Daniel R. Brower have returned from Lisbon.——Dr. Hugh T. Patrick has left Lisbon for Paris, and will spend the summer abroad.——Dr. Henry Gradle has returned from the International Medical Congress, Lisbon.——Dr. Camillo Volino has been seriously ill from septicemia, due to a scratch received during an operation.

Physicians on Ambulances.—It is announced that the ambulances of the police department will soon be turned over to the city health department in accordance with the plans of the health commissioner and the chief of police. The eight ambulances which will be transferred will each be under charge of a physician.

Deaths of the Week.—During the week ended May 12 there were 583 deaths, 10 less than for the previous week and 133 more than for the corresponding week of 1905. This is equivalent to an annual death rate per 1,000 of 14.84. Pneumonia still leads the death causes with 109; consumption caused 55 deaths, or 20 less than the previous week; nephritis, 48; violence, including suicide, 39; heart diseases, 37; nervous diseases, 27; acute intestinal diseases, 26; cancer, 24; scarlet fever caused 11 deaths; typhoid fever, 9 deaths; diphtheria, 8; measles, 7; whoopingcough, 5, and influenza, 4.

Cheaper Antitoxin.—Last week we published an item based on matter appearing in the *Health Bulletin* of Chicago, to the effect that a private institution was "supplying the city with antitoxin at $1.50 per 3,000 units as against $5.25 for 3,000 units, the sum charged by the alleged antitoxin trust." Such a statement as this should not have appeared, as it does not represent facts. The institution referred to is supplying antitoxin at $1.50 to the Department of Health, which, in turn, retails it at $2.25 per 3,000 units. Several commercial firms have offered the city the same number of units for practically the same amount. We make this retraction in justice to all concerned.

MARYLAND.

Baltimore.

Memorial Room.—A memorial room has been founded at the Baltimore Eye, Ear and Throat Charity Hospital of the late Dr. Russell Murdoch, who was a founder and a member of the hospital staff.

University to Move.—The Baltimore University proposes to remove from East Baltimore to the northern section, where it has purchased a new site. A building of three stories, embracing hospital, college and dispensary to cost about $45,000, will be erected.

Typhoid in Suburb.—There have been 56 cases of typhoid fever reported at Hampden, a northern suburb of the city. It is supposed to have arisen from contaminated milk and is said to be now on the decline. Only 21 cases were reported for the entire city during the week.

Milk Exhibition.—The Maryland Milk Exhibition, the forerunner, it is believed, of many similar ones to be held throughout the country, opened at McCoy Hall, Johns Hopkins University, May 7, and continued through the week. On the opening evening Dr. Charles Harrington, Boston, secretary of the State Board of Health of Massachusetts, lectured on "The Necessity of Reform in the Production and Methods of the Distribution of Milk." A model kitchen showed the many uses to which milk may be put in cooking and prepared appetizing dishes for visitors. Numerous addresses were delivered.

Personal.—Dr. William H. Howell, dean of the Johns Hopkins Medical School, will spend the summer on Casco Bay, Maine.——Dr. Robert B. Slocum, one of the house officers at the Johns Hopkins Hospital, has resigned to take charge of the Walker Hospital, Wilmington, N. C., and has been succeeded by Dr. P. K. Gilman.——Dr. L. McLane Tiffany is spending May at his country seat in Accomac County, Va.——Dr. Harry T. Marshall, instructor in pediatrics, Johns Hopkins University, has accepted a position as pathologist in the United States Bureau of Science at Manila, and will sail from New York May 19. His place on the Board of Supervisors of City Charities has been filled by the appointment of Dr. J. Whitridge Williams.——Dr. Joseph A. Chatard sails for England May 31, and will spend some time at Oxford.

MASSACHUSETTS.

Hospital Opened.—The formal opening of the two new buildings of the Newton Hospital, Ellerson Hall and Harriet Gould Payne Domestic Building, took place May 1.

Dinner to Medical Examiners.—A complimentary dinner to the medical examiners of the Massachusetts Catholic Order of Foresters was given at the Brunswick Hotel, April 24. Dr. Francis J. McQuerrny presided, and Dr. Frederick C. Shattuck spoke on "Present Day Aspects of American Living."

Birth Insurance a Failure.—At the request of Attorney-General Malone a receiver has been appointed for the American Birth Insurance Company. This was a novel assessment insurance scheme, backed by many prominent Boston women, which has failed because the birth rate exceeded that anticipated. There is said to be some $50,000 or $60,000 insurance outstanding.

Bowditch Resigns.—Dr. Henry Pickering Bowditch, for 35 years a teacher in Harvard University Medical School, has resigned his position as professor of physiology and will retire at the end of this year. He is a recognized authority both in this country and in Europe. He has received honorary degrees in Leipzig, Cambridge, Edinburgh and Toronto. He is a member of the leading physiological societies of the world.

Society Election.—The Norfolk District Medical Society elected, May 8, in addition to its quota of 29 councilors of the Massachusetts Medical Society, the following officers for 1906-1907: President, Dr. Samuel Crowell, Dorchester; vice-president, Dr. Arthur P. Perry, Jamaica Plain; secretary and librarian, Dr. James C. D. Pigeon, Roxbury; treasurer, Dr. Edward G. Morse, Roxbury, and commissioner of trials, Dr. William Noyes, Dorchester.

Personal.—At the annual meeting of the Worcester North District Medical Society, Dr. Edward A. Sawyer, Gardner, was re-elected councilor, and Dr. Atherton P. Mason, Fitchburg, elected president.——Dr. John Dixwell has been re-elected president of the New England Home for Deaf Mutes.——Dr. George P. Howe, Lawrence, has been put in charge of the medical department of the Anglo-American Polar expedition which sails from Victoria, B. C., some time this month.——Dr. John A. Houston, Northampton, was struck by a street car in Washington, April 28, and suffered a concussion of the brain and a fracture at the base of the skull.

NEW JERSEY.

Society Officers.—At the annual meeting of the Salem County Medical Society, May 10, the following officers were elected: President, Dr. Frank B. Husted; vice-president, Dr. Nathaniel S. Hires; secretary and treasurer, Dr. Henry Chavanne, of Salem.

Entertains Medical Club.—Dr. Emory Marvel, Atlantic City, entertained the board of directors of the Medical Club of Philadelphia at a dinner, May 5. After the dinner a reception was held at which many of the leading physicians of Atlantic City were present. Among those present were Drs. Wharton Sinkler, Edward E. Montgomery, L. Webster Fox, T. Chalmers Fulton, Edward L. Duer, James Van Buskirk, J. Gurney Taylor, Gwilym G. Davis, Wilmer Krusen and Louis H. Adler, of Philadelphia, and Dr. Harry Whitcomb of Norristown.

Personal.—Dr. Francis De L. Gray, president of the Jersey City board of health, has resigned.——Dr. Walter A. Taylor, Trenton, has been elected a member of the medical staff of Mercer Hospital. At a meeting of the staff held recently Dr. William Elmer was elected medical director and president; Dr. William A. Clark, vice-president; Dr. Charles F. Adams, secretary, and Dr. George H. Parker, registrar.——Dr. John H. Finnerty has been appointed a member of the Jersey City board of health for a term of three years, vice Dr. Joseph M. Rector.

NEW YORK.

Matteawan Hospital.—There are now 683 inmates in this institution which cares for insane criminals.

Smallpox at Wallkill.—There are at present 6 patients with smallpox being cared for at the isolation hospital in Wallkill.

Personal.—Dr. Albert Vanderveer of Albany, who was elected a member of the State Board of Regents by the last legislature, took the oath of office on May 10.——Dr. Chester Waterman, Ogdensburg, has been appointed to the house staff of the Manhattan State Hospital.

For New Hospital.—Columbus O'Donnell Iselin has offered $40,000 for a hospital in New Rochelle, providing the citizens of that city will raise $60,000 so that a modern fireproof structure can be erected. The local hospital management has already subscribed $20,000 of the required amount.

Result of New York Referendum.—Section 7 of the agreement underlying the consolidation of the Medical Society of the State of New York with the New York State Medical Association, reads as follows:

"It is further covenanted and agreed by the parties hereto, that as soon as practicable after the entry of an order for the consolidation of the corporations, the following proposition shall be submitted by referendum to the vote of the members of the society, namely:

"'The principles of medical ethics of the American Medical Association, being suggestive and advisory, shall be the guide of members in their relations to each other and to the public.'"

Under date of May 11 Dr. Wisner R. Townsend writes:

"Referendum votes were sent to 6,352 members on April 27. The vote was canvassed May 10, at 8 p. m., with the following result: Votes cast in accordance with the provisions of the referendum, 3,525, of which 3,307 voted 'yes,' 197 'no,' 17 defective, 1 duplicate, 3 letters returned by the postoffice owing to imperfect address. Eighty votes were received since the expiration of the referendum. These envelopes were not opened."

New York City.

Gift for Columbia.—Edward S. Harkness has given $2,700 to the morphologic museum at the medical school.

Proposed West Side Hospital Disapproved.—The bill providing for a hospital similar to Bellevue on the west side of town, between Twenty-third and Thirty-fourth streets, has been vetoed for the third time by the mayor. The measure is mandatory and for that reason was rejected.

Honor Professor Duehrssen.—A special meeting of the German Medical Society was held at the New York Academy of Medicine, May 15, in honor of Professor Dührssen, of Berlin, who comes to America as the guest of the American Medical Association, who delivered an address on the subject of "Modern Problems in Diseases of Women." Professor Dührssen operated at the Lebanon Hospital on May 10.

Personal.—Dr. Jokichi Takamine has been decorated by the Mikado with the Fifth order of the Rising Sun in consideration of his researches and discoveries in applied chemistry.——Dr. A. M. Fernandez de Ybarra delivered a lecture on "The First Written Document About the Flora, the Fauna, the Ethnology and the Anthropology of America" before the biologic section of the New York Academy of Sciences, March 5.

New Orthopedic Hospital.—The Jewish Hospital for Deformities and Joint Diseases which is to provide treatment for patients in the district lying north of Central Park, has been completed and will be ready for the treatment of patients before the end of June. The need of this institution is shown by a recent census of the public schools, when more than 6,000 children were found suffering from deformities. A large number of these are curable. The medical head of the hospital is Dr. Henry W. Frauenthal.

Dispute Over New Bellevue.—A controversy between the State Charities Board and the trustees of Bellevue and the Allied Hospitals concerning the plans for the new hospital will tie up the work for some time. The plans provide for a building which will have about 2,400 beds, while the board holds that hospitals of such a size are unwieldy and that two hospitals of lesser capacity would be preferable. Attorney-General Mayer has rendered an opinion sustaining the authority of the state commissioners, but the trustees of Bellevue still refuse to submit the plans to the state body. The city has not yet acquired the additional land which is wanted for enlarging the building.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended May 5, 1,348 cases of measles, with 39 deaths; 375 cases of tuberculosis, with 193 deaths; 339 cases of diphtheria, with 49 deaths; 231 cases of scarlet fever, with 21 deaths; 35 cases of whooping cough, with 9 deaths; 33 cases of cerebrospinal meningitis, with 32 deaths; 19 cases of typhoid fever, with 7 deaths; 103 cases of varicella, and 6 cases of smallpox—a total of 2,489 cases, with 350 deaths. The hospitals for contagious diseases are overcrowded. In the week ended May 8 there were 73 cases of contagious and infectious diseases taken from Ellis Island. This record is lower than that of several preceding weeks. The phenomenal number of immigrants accounts for the larger number of contagious diseases taken from Ellis Island.

Rockefeller Institute Opened.—This institution, which was founded in 1901 by John D. Rockefeller, having for its purpose "the advance by investigation of the science of medicine," was formally opened on May 11. Addresses were made by President Charles William Eliot of Harvard University, President Nicholas Murray Butler of Columbia University, and the president and secretary of the institute, Dr. William Henry Welch and Dr. Luther Emmett Holt. Dr. Holt outlined the history of the institute, which when completely equipped could accommodate 50 workers. The laboratories are for investigation in experimental pathology, bacteriology, physiology, physiologic and pathologic chemistry. At present there are 12 experimenters at work under the supervision of Dr. Simon Flexner, director of laboratories. All the air drawn into the various suites of laboratories and living quarters of animals used in experiments is filtered. There is only one other institute of the kind in the work that is as fully equipped as this and that is in Germany and is said to be no better. The institute not only carries on experiments in its laboratories, but awards money grants to those engaged in work elsewhere. Grants are awarded on application to the board of directors. Applicants for aid in medical research are required to tell why they need assistance, the nature of the problems on which they are working and their qualifications. The results of experimental work are published in the *Journal of Experimental Medicine*, which is issued bi-monthly by the institute.

OHIO.

Typhoid Fever on the Increase.—Typhoid fever has markedly increased in Cincinnati, 24 cases having been reported last week.

Personal.—Dr. John Uri Lloyd, Cincinnati, who was a delegate to the International Chemical Society, has been quarantined at Aden, Arabia, having been exposed to bubonic plague.——Dr. William C. Harris will be in charge of the emergency hospital at the Cincinnati Fall Festival.

Site for State Hospital Secured.—The ground for the new State Hospital for the Criminal Insane has at last been purchased. It consists of a farm of 618 acres situated north of Lima, Ohio. The purchase price was $62,500. No provision was made by the General Assembly to do more than to secure the land, and the trustees of the proposed institution have not as yet been named.

PENNSYLVANIA.

Philadelphia.

Notice.—The section on general medicine of the College of Physicians announces that on account of the proximity of the meetings of several national medical associations, the next meeting of the section will be held in October.

Charity Report.—The annual report of the Union Benevolent Association shows there were 5,000 applications for aid, of which 265 were refused and 257 referred to other societies. Officers of the society made 6,197 visits during the year to investigate the conditions of persons in need of aid, and 151 sick individuals were given attention.

Personal.—Dr. Alfred Gordon was appointed associate in nervous and mental diseases in Jefferson Medical College, May 8.——Dr. Ross Skillern and wife sailed for Europe, May 8.——Dr. William A. Hughes, of the University of Pennsylvania; Dr. Charles A. Service, of the Jefferson Medical College, and Dr. C. Lincoln Furbush, of the Medico-Chirurgical College, conducted the examinations of 120 applicants for internships in the Philadelphia Hospital, May 12.——Dr. O. L. Wingate was acquitted of the charge of assault by the Court of Quarter Sessions, May 9.

Federation of Jewish Charities Report.—At the fifth annual meeting of the Federation of Jewish Charities, May 10, the reports presented show that from 2,065 members the subscriptions amounted to $145,000. This is an increase of $24,000 over the previous year and an increase of $50,000 over the maximum annual subscription before the federation. The sum of $135,550 had been distributed among the following constituent charities for the year ended April 30: Jewish Hospital Association, $34,000; Jewish Foster Home and Orphan Asylum, $22,000; United Hebrew Charities, $33,000; Hebrew Education Society, $6,600; Jewish Maternity, $9,000; Jewish Immigration Society, $800; Young Women's Union, $12,500; Hebrew Sabbath School Society, $3,250; National Farm, $6,400; National Jewish Hospital for Consumptives, Denver, $3,000, and the Alliance Israelite Universelle, $500.

Health Report.—The total number of deaths reported for the week reached 492. This is a decrease of 10 from the number reported for last week, and an increase of 37 over the number for the corresponding week of last year. The principal causes of death were: Typhoid fever, 26; measles, 9; pertussis, 13; diphtheria, 9; consumption, 63; cancer, 21; apoplexy, 21; heart disease, 54; acute respiratory disease, 74; enteritis, 27; hepatic cirrhosis, 5; Bright's disease, 41; appendicitis, 7; suicide, 6, and accidents, 16. There were 415 cases of contagious disease reported, with 36 deaths, as compared with 364 cases and 26 deaths in the preceding week. Typhoid fever is still slightly on the increase, 303 cases being reported, with 26 deaths, as compared with 243 cases and 14 deaths reported in the previous seven days. There was one new case of smallpox reported.

TENNESSEE.

"Patent-Medicine" Motion Tabled.—At a recent meeting of the Memphis and Shelby County Society, a resolution which called for punishment by suspension from the society of any member

holding stock in any so-called "patent-medicine" concern and any member engaging in contract practice except as government official, surgeon of and examiner for a life-insurance company, was tabled after little debate.

Personal.—Dr. Frank A. Jones has been elected professor of physical diagnosis and clinical medicine in the Memphis Hospital Medical College, succeeding Dr. Dudley D. Saunders, retired. Dr. James B. McElroy succeeds Dr. Jones as chief of clinic at East End Dispensary and as demonstrator of physical diagnosis in the college.——Dr. W. S. Nash, Knoxville, has been very ill for several days.——Dr. G. B. Gillespie, Covington, was thrown from his buggy May 2 and sustained severe bruises of the face and breast and a fracture of the nose.

Commencements.—Chattanooga Medical College, the Medical Department of Grant University, held its seventeenth annual commencement exercises April 30. Dr. John R. Rathmell, dean, made the introductory remarks, Rev. Howard L. Jones delivered the address and Rev. John H. Race, D.D., conferred degrees on a class of 33.—The annual commencement exercises of Memphis Hospital Medical College were held April 27, when the Hon. William H. Carroll, president of the board of directors, conferred degrees on a class of 80. Hon. T. U. Sisson delivered the address to the graduates.——The Medical Department of Vanderbilt University, Nashville, held its annual commencement exercises May 1, when a class of 38 received diplomas. Dr. William H. Witt delivered the faculty address and Dr. Richard Douglas the doctorate address. Chancellor Kirkland conferred the degrees on the graduating class.—— The Medical Department of the University of Tennessee, Nashville, held its annual graduating exercises May 1. Dr. Paul F. Eve acted as master of ceremonies. Dr. Perry Bromberg delivered the charge to the graduates, and Prof. Brown Ayers conferred degrees on a graduating class of 25.

TEXAS.

Fined for Illegal Practice.—"Dr." Oscar Ferguson, Marshall, was convicted April 2, in the County Court of Harrison County, of illegal practice of medicine, and was fined $50 and costs.

New College Contemplated.—It is reported that Fort Worth is to have a new medical college to be known as the Fort Worth College of Physicians and Surgeons, and that Dr. Frank D. Boyd has been selected as dean of the institution.

College Election.—At the annual meeting of the faculty and stockholders of the Medical Department of Fort Worth University, May 5, the following officers were elected: President, Dr. Julian T. Field; vice-president, Dr. James Anderson, secretary, Dr. Ira C. Chase; dean, Dr. Frank Gray, and directors, Drs. Frank D. Thompson, James Anderson, Bacon Saunders, William R. Thompson and Frank Gray. During the year 194 students were enrolled and a class of 23 was graduated.

Commencements.—The third annual commencement of the College of Physicians and Surgeons, Dallas, was held April 5, when diplomas were presented to a graduating class of 21.—— The twelfth annual commencement of the Medical Department of Fort Worth University was held May 10. Dr. William R. Thompson delivered the faculty address; Dr. Gause W. Covington delivered the valedictory address and Rev. Dr. Fiedler, president of the university, awarded the diplomas to a class of 23.——The sixth annual commencement of Baylor University College of Medicine, Dallas, was held May 1. President Dr. S. P. Brooks awarded diplomas to a class of 8. Rev. George W. Truitt, in his address, announced that the erection of a new medical school for the university was assured.—— The commencement exercises of Southwestern University Medical College, Dallas, were held May 4, when a class of 4 received diplomas.

Personal.—Drs. Thomas J. Wagley, James H. Happell and William S. Ball have resigned as surgeons of the Gulf, Colorado and Santa Fe Railroad at Cleburne. Dr. Mills Dennis, Temple, has been appointed to succeed Dr. Wagley, and Dr. D. Strickland, Cleburne, has been appointed local surgeon of the road.——Dr. Francis M. Hicks, San Antonio, who was operated on recently at Johns Hopkins Hospital, has returned home.——Dr. George W. Larendon, Houston, has been appointed state health officer of Texas, vice Dr. William M. Brumby, resigned.——Dr. Jesse E. Baldwin, Dallas, has been appointed health officer of Dallas County, vice Dr. Thomas B. Fisher, resigned, to take up the duty of health officer of Dallas.——Dr. Nelson A. Olive has been elected president of the Waco Board of Health.——Dr. Robert W. Noble, Temple, fell from a porch April 26, fracturing his arm.——Dr. John M. Colley, Palestine, was thrown from his buggy April 25 and received a severe scalp wound and fractured a rib.

PRESENT CONDITIONS IN SAN FRANCISCO.

The Work of the Profession in Averting an Epidemic.

Dr. Joseph B. Greene writes:

The daily press has attempted to describe the calamity, but no one at a distance can fully appreciate the horror of the scene. Fortunately, the number of deaths was exaggerated, but it will be some time before the death list is complete on account of the fire following so soon in the track of the earthquake. At the present time the remains of some of the victims lie buried in the ruins, awaiting the removal of débris, before they can be properly buried. San Francisco had a considerable floating population, who suffered largely from the destruction of hotels and boarding houses in the down-town district. The loss of life is variously estimated from 500 to 1,400. Had the earthquake occurred during the busy hours of the day the loss of life would have been appalling.

It was fortunate that the Army was on the scene ready to step in and to preserve order. Not only did they do this, but they dispensed food and clothing to all in need. Tents and blankets were at once supplied, so there was comparatively little real suffering. The large Army General Hospital was thrown open for the reception of patients who were sick or injured. At present everything is moving along smoothly, and the needy are being cared for with a minimum amount of leakage and waste.

No class of men suffered more proportionately than the physicians of San Francisco. With an unselfishness common to the profession, they were found caring for the wounded when their offices were going up in smoke. Not only have they suffered the loss of their offices and homes, but their practices have been scattered to the four winds. It will be some time before affairs have been adjusted and the physicians are again in a position to recover their practices. Grateful appreciation has been felt and expressed at the kind offers of assistance to the medical profession from the large medical centers. The County Medical Society met on the evening of May 3, with Dr. W. I. Terry, president, in the chair. It was decided that relief was to be distributed to all licensed physicians, regardless of school. Of course, all quacks are to be excluded. A general committee was appointed, with Dr. Terry *ex officio* chairman.

From this general committee will be selected committees on (1) finance, (2) supplies, (3) distribution. Arrangements have been made for the committees' headquarters to be at the Cooper Medical College.

From a sanitary and epidemic standpoint, San Francisco is most fortunate. Typhoid fever is naturally the disease most to be dreaded, but fortunately the number of cases occurring in the city prior to the earthquake and fire was not great. In camp, however, the number will be greatly increased, in spite of orders to boil all drinking water. It is always easier to issue such orders than to see that such instructions are carried out. The profession is familiar with the great loss of life from typhoid fever in the Army during the Spanish-American War. This occurred, too, among soldiers who were supposed to be under strict military discipline. The science of sanitation has advanced somewhat since that time, for we now know what an important part the flies play in the transmission of typhoid fever. Every precaution will be taken with the feces and urine to prevent contamination through the means of flies. The time is now at hand for an increase in the number of typhoid cases. It is to be hoped that our fears are groundless, and that the dread of an epidemic will never be realized.

Plague has given the health authorities some concern, though it would seem that the danger can be averted. Chinatown, which nurtured cases of plague so long, has been burned, and it is likely the germs of this disease were consumed. It is probable that very few rats made their escape. The state health authorities have warned the people against infection from ground squirrels. Plague has occurred among these rodents for some time, and the last case was in a huntsman who had killed a squirrel and carried it in his pocket. It is not likely that Chinatown will be rebuilt in the heart of the city again, to be a menace to the public health as it was some

years ago when plague was present. The disease is so insidious, and our relations so direct with the Orient, where plague prevails almost constantly, that it would be a great mistake to allow the Chinese to resume their insanitary life in the heart of San Francisco.

The American White Cross First Aid Association sent from Chicago twenty-five physicians and seventy-five nurses, who arrived on the morning of April 26. This party, in command of Major. P. J. H. Farrell, reported at once to Colonel Torney of the Army on duty at the general hospital. The party was assigned to tents and placed under strict military discipline. The doctors and nurses were assigned to various duties as directed by the Army surgeons. Most of the physicians were assigned to sanitary work, though some did medical and surgical work. The nurses made themselves useful at various stations in and near the city. Six nurses were at once assigned to cases in the smallpox hospital.

An Appeal From San Francisco Physicians.

A committee appointed by a mass meeting of physicians held in San Francisco, May 3, issues the following appeal:

"The members of the medical profession in San Francisco, with the true spirit of their noble calling, have voluntarily rendered great service to the sick and suffering of this stricken community. A large portion of these physicians, more than 1,000, have lost either their homes, offices, books and instruments or all of these. This committee has been appointed to receive contributions of medical supplies, books, instruments, clothes and moneys in order to help the needy start life anew and equip them to earn their livelihood in the exercise of their profession.

"We appeal to the generous-hearted throughout the land to come to our assistance and help the members of a profession who at all times, when called on, have given their aid freely and willingly to suffering humanity.

Direct all communications and donations to the relief committee of the physicians of San Francisco, Lane Hospital, San Francisco. W. I. Terry, Pres. S. F. Co. Med. Soc., Chairman *ex officio*; T. W. Huntington, Emmet Rixford, H. C. Moffitt, H. J. Kreutzmann, Philip King Brown, J. W. Ward, L. M. F. Wanzer, Julius Rosenstirn, F. W. Lux, Secretary.

The above committee has issued the following to the physicians of San Francisco:

"Those of you who are in need of immediate assistance, please report at once to the medical relief committee at Lane Hospital, corner Webster and Clay Streets. The committee rooms will be open from 9 a. m. to 4 p. m. daily, Sundays excepted. In case your name is not in the last state register, be good enough to state from what college you are a graduate and when your license was issued. Address communications to the secretary, Dr. F. W. Lux."

The following subcommittees have been appointed:

Press Committee: J. Rosenstirn, Philip King Brown.

Finance Committee: T. W. Huntington, H. C. Moffitt, H. J. Kreutzmann.

Committee on Instruments, Books and Supplies: Philip King Brown, J. W. Ward, F. W. Lux.

Distribution Committee: Emmet Rixford, L. M. F. Wanzer, J. Rosenstirn.

Sanitary Conditions.

Passed Assistant Surgeon Rupert Blue, U. S. P. H. and M. H. Service, reported on the sanitary condition in Oakland and San Francisco on April 30. Immediately after the earthquake sanitary headquarters were established in Golden Gate Park, where conferences between the Medical Department of the Army, the Public Health and Marine Hospital Service and the state and city health authorities were held. A health commission had already been organized, consisting of Dr. James W. Ward, president; Dr. Simon Harvey Ragan and Dr. Hassler, of the San Francisco Board of Health; Surgeon Sawtelle and Passed Assistant Surgeon Dr. James H. Oakley, U. S. P. H. and M.-H. Service, and Drs. M. Ragensberger and M. K. Foster, representing the State Board of Health. Dr. Blue, having been elected a member of this commission, made an inspection of the refugee camps in Oakland, which at that time consisted mostly of wooden shacks with shallow latrines and open kitchens. These camps, however, are now being concentrated in healthy suburban sites, large tents are being used and latrines and sinks will have sewer connections. Since April 18 twenty cases of smallpox have been detected and isolated in Oakland. The number of refugees in Oakland is estimated at 30,000, and probably 4,000 of the Chinese of San Francisco have here found refuge. On April 29 Dr. Blue was placed in charge of the second sanitary district of San Francisco, which is bounded by the bay on the southeast and east, and by Market, Valencia and Mission streets on the north and west. It is the part of the city which suffered most from the earthquake and fire. In this district there were more than 30,000 people living in shacks, tents and other temporary abodes. Cooking was done in the streets, as all chimneys and water and sewer connections were destroyed. The water supply is inadequate and is not likely to be greatly improved in the immediate future. The proper disposal of sewage, garbage and refuse is also a serious problem. The shallow latrines are not protected from flies or animals and have no sewer or water connections. The public kitchens are open to flies and are in close proximity to heaps of refuse and uncovered latrines. To combat these conditions Dr. Blue recommends removal to healthy suburban sites with ample water and sewer connections and the use of tents instead of wooden shacks for housing; the immediate construction of large sanitary latrines, to be connected with the sewers, and, pending the change, the abundant use of chlorid of lime and crude carbolic acid in the holes formerly used, and the removal or burning of garbage.

The State Journal.

The May issue of the *California State Journal of Medicine* consists of only four pages and begins with a sad greeting, but states that the spirit of the physicians of California is in no wise daunted and that as there will be a newer and better and more beautiful San Francisco, so there will arise, Phœnix-like, a better and more useful *California State Journal of Medicine*. The *Journal* devotes nearly one-fourth of its space to a mention of the semi-centennial meeting of the Medical Society of California, which was untimely adjourned. The editor, Dr. Philip Mills Jones, 1230 Telegraph Avenue, Oakland, deserves much credit for his enterprise. He announces that both its foreign and domestic exchange list is lost and asks us to request by this notice that all exchanges should notify Dr. Jones as soon as possible.

System and Organization.

In an editorial, May 2, the San Francisco *Examiner* gives due credit to the Medical Department of the Army for its work in San Francisco. It says: "The value of system and organization was never better illustrated than in the work of the army doctors and surgeons in handling the emergency. . . . These military doctors did not hesitate to assume responsibility, and if San Francisco escapes an epidemic the major part of the credit will be due to the organization and system of the army's medical department and to the quick action of the medical men in charge of the Presidio. . . . When the injured were hastily transferred from the Mechanics Pavilion the Presidio General Hospital was forced to receive 100 patients in one hour, but there was not the slightest confusion. . . . Captain Kennedy, surgeon in charge, immediately closed the doors against all visitors. This was hard on anxious relatives and friends, but preserved quiet and discipline within the hospital at a time when quiet and discipline were absolutely essential. The 100 patients were operated on and cared for before the burning hospitals of the city began to throw their patients into the Presidio, and, when everything was confusion elsewhere, the 500 or more patients in the Presidio Hospital were treated as if earthquake and fire were problems of a far land. Military precision also proceeded in the important work of caring for the medical and surgical needs of the homeless and the sanitation of the refugee camps. Captain Truby was placed in charge of the refugees in Golden Gate Park, Captain Murtagh of those in Fort Mason and Captain Rutherford of the camp at the Presidio, and in each of these camps a staff of doctors and inspectors was organized, so that every patient had a physician at call and every cot was watched with care. The reports were sent through official channels to Colonel Torney, and as a result of this system the reports of death and disease in San Francisco show slight variations from the normal conditions. . . . Those who are going to have on hand the herculean task of upbuilding a ruined city may well take a lesson in what can be accomplished under system and organization. They have been given their lesson by the men of the army medical department, who took hold of an emergency as if they had been handling earthquakes and fire all their lives."

Physicians Come to the Rescue.

The physicians of Portland, Ore., have contributed $3,000 in cash and Lewis and Clarke Fair stock; the Essex North District (Mass.) Medical Society, $200; the Norfolk District Medical Society, $307, replacing the annual banquet; the Brooklyn Medical Club, $100; the Douglas County (Wis.) Medical So-

ciety, $40; the physicians' committee of Salt Lake City, $500 and abundant supplies; Montgomery County (Ohio) Medical Society, $100; Fresno County (Cal.) Medical Society, $200; Huntington County (Ind.) Medical Society, $10; Washington County (Pa.) Medical Society, $25; Mill Creek Valley (Ohio) Medical Society, $15; New Jersey State Homeopathic Medical Society, $25; Lehigh County (Pa.) Medical Society, $25, and Lewis County (N. Y.) Medical Society, $10.

No Danger of Plague.

The secretary of the State Board of Health announces that he does not think there is any danger of bubonic plague unless it be among people who, driven from the city, have gone into camp in the country. There will be no danger there, he says, if the people avoid contact with rats, squirrels, mice and similar animals.

Afflicted and Can Not Help.

The appeal for aid to physicians of San Francisco has received a reply from Russellsville, Ark. In this city a fire occurred January 15 which swept away the greater part of the city, and by reason of which the physicians of the community suffered to some extent and the loss of many was considerable. For this reason the physicians state that their hands are full in repairing their own losses without calling on aid from the outside.

No More Burials in County.

The Public Health Commission decided on May 5 that after June 1 no more interments should be permitted within the boundaries of the city and county of San Francisco and that the bodies temporarily interred are to be removed later to the cemeteries at San Mateo.

Sanitary Instructions.

The Health Commission has directed that the following instructions be posted in the following various districts:

FOOD AND WATER CONSUMPTION.

1. All water should be boiled, whether for drinking, bathing or cleansing purposes.
Use no unboiled water in the preparation of food for cooking or baking.
Use unboiled water only for flushing purposes.
This order applies to all water, whether Spring Valley, lake or well water.
2. All milk should be boiled, whether used by infants or adults.
3. Food in cans should not be allowed to stand uncovered, lest it become tainted or infected.
4. Do not eat uncooked vegetables.
5. All butcher shops and bakeries should be screened.

SANITATION.

1. Remove all garbage, animal and vegetable refuse from your premises and put into garbage barrels at the curb line of street, and cover the same with chlorid of lime daily.
2. Seal all toilets and other plumbing fixtures in houses where side sewers are broken or disconnected.
3. Screen all windows, doors and other openings, to prevent the entrance of flies, as they are carriers of filth.
4. District sanitary inspectors will report location of latrines to the captain of the district daily, so that the same may be inspected and properly disinfected.

COMMUNICABLE DISEASES.

1. Any person whatsoever having knowledge of the presence of these diseases should report the same to a physician in his neighborhood, as every physician in the city is now a sanitary inspector. And such physician on receipt of this notice should inspect the case, and if verified by him, report the same to the headquarters at the Park Emergency Hospital, Stanyan and Waller streets, or at the temporary headquarters of the board of health, Grove and Laguna streets.
2. A strict observance of these instructions will positively prevent the spread of any of these diseases.
3. For the safety of all, most careful reports of all contagious or infectious diseases should be given to the district inspectors.

Hospital Work.

St. Mary's Hospital, Hays and Stanyan Streets, has been reopened by eight Sisters of Mercy and thirty assistants, who went from Oakland to re-establish the institution. Work has commenced on the Central Eastern Hospital at Golden Gate Avenue and Gough Street. The new hospital will be in the shape of a quadrangle and space will be provided for wards to contain thirty beds each. Quarters for nurses, physicians and stewards will also be provided.

THE CALIFORNIA FUND.

The following committee has been appointed to represent the California State Medical Society and the San Francisco County Medical Society in the distribution of funds, etc. As we understand it, the committee consists of those forming the San Francisco Society referred to above, in addition to which others have been added to represent the state society: Thomas W. Huntington, Emmet Rixford (treasurer), Frederick W. Lux, Henry J. Krentzmann, Lucy M. F. Wanzer, Philip King Brown, Julius Rosenstirn, Herbert C. Moffitt, James W. Ward, Charles E. Jones, Malcolm O. Austin, George H. Evans, George G. Gere, John Galiwey and Frank K. Ainsworth.

All contributions, whether from individual contributors or local or county societies, will be acknowledged in this column. Nearly 500 physicians in San Francisco are in urgent need. Make checks payable to the American Medical Association, marking the check "California Fund." Send to the American Medical Association, 103 Dearborn Avenue, Chicago. Mark envelope in lower left-hand corner, "California Fund."

The following contributions, not acknowledged last week, have been received up to 9 o'clock, Wednesday morning, May 16:

INDIVIDUAL CONTRIBUTIONS.

Bailey, O. L., Ocean Springs, Miss.	$1.50
Bliss, Webster, Deerfield, Mich.	1.00
Cattermole, George H., Boulder, Colo.	5.00
Christie, J. R., Quincy, Ill.	1.00
Clonse, A. W., Geneva, Pa	1.00
Cowen, H. K., Midway, Kans.	1.00
Eccles, R. M., Blissfield, Mich.	10.00
Evers, J. W., Rollin, Mich.	1.00
Gamble, Jr., C. B., Baltimore	10.00
Garrison, Harriet E., Dixon, Ill.	5.00
Gibbs, M.D., Van Houten, N. M.	2.50
Gilbert, O. M., Boulder, Colo.	5.00
Griffin, John M., Warrensburg, N. Y.	3.00
Hanahan, R. B., Winnsboro, S. C.	2.00

Total	$1,081.15
Previously acknowledged	$5,735.65
Duplicates, etc., to subtract*	125.00
Net total previously acknowledged	5,610.25
Grand total	$6,691.20

* One subscription of $100 was a misunderstanding, the subscriber intending only $50. One subscription of $50 and one of $25 were acknowledged twice, once as promises and once when the money arrived. Total, $125.00.

GENERAL.

Pension Surgeons to Meet.—The annual convention of the National Association of United States Pension Examining Surgeons will be held at the New American Hotel, Boston, Monday and Tuesday, June 4 and 5, beginning at 10 o'clock Monday morning.

American Gastroenterological Association.—The ninth annual meeting of this body will be held at Boston, June 4 and 5, 1906.

American Society for the Study of Alcohol and Narcotics.—The thirty-sixth annual meeting of this society will be held in the parlors of the Vendome Hotel, Boston, June 5-7, 1906. A single session will be held from 9 to 10:30 a. m. each day. Scientific papers will be read by eminent persons. The medical public is cordially invited. Programs can be had by applications to the secretary, Dr. T. D. Crothers, Hartford, Conn.

The American Proctologic Society.—This organization holds its eighth annual meeting at the Hotel Vendome, Boston, June 5 and 6, 1906. The president's address will be delivered by L. H. Adler. Papers will be presented on "Cancer of the Rectum," by W. M. Beach, G. B. Evans and J. C. Brick; on "X-Ray Diagnosis of Sigmoid Stricture," by H. A. Kelly; on "Constipation," by J. R. Pennington and L. J. Hirschman, and on "Pruritus," by T. C. Hill and T. C. Martin.

Havana Institutes Quarantine Against Southern States.—It is reported that the superior sanitary board on May 7 formally recommended a quarantine against ports of Louisiana, Mississippi, Alabama and Texas. The reason given is that the government of the United States will not intervene in sanitary matters in those states, that last year Havana was not informed of the existence of yellow fever in New Orleans until six weeks after the first case occurred, and that during the present season there will be great danger of infection. No quarantine is suggested against Florida because the health officer of that state is also an officer of the United States Public Health and Marine-Hospital Service.

Less Cholera in the Philippines.—Chief Quarantine Officer Heiser reports the great improvement in the cholera situation has continued, except for an outbreak in the town of Siniloan, Laguna Province, where 140 cases occurred within a period of ten days. Owing to the remoteness of the town, this information did not reach Manila until the outbreak was well established. Prompt measures were at once taken to stamp out the disease, and within three days after the sanitary measures were begun no more cases occurred. The experience in this town, Dr. Heiser states, affords another example of what may be accomplished in the eradication of cholera whenever it is possible to apply modern sanitary principles. In view of the continued improvement it was deemed advisable still further to modify the outgoing interisland quarantine regulations.

CANADA.

College Examinations.—The examinations of the last class which registered at Trinity Medical College before amalgamation is being proceeded with. They number about 40, and, according to the terms of amalgamation, they were to be examined by the examiners appointed by Trinity University.

Practice of Medicine in Ontario.—The attorney-general of Ontario has cited a stated case before the court of appeal with a view to settling and determining the precise meaning of the Ontario medical act, and to fix definitely whether persons who practice medicine without the use of drugs can do so without being properly registered.

Typhoid.—Dr. F. C. Douglas, Montreal, has returned home after having had charge of the epidemic of typhoid fever at Fort William, Ontario. Dr. Douglas had charge of the epidemic from March 8, when the death rate was one person to every 9.1. When he left on April 8 only two or three cases were reported. During February the average daily number reported was 25.

Toronto General Hospital News.—A special committee of the staff of the Toronto General Hospital, which has been busily engaged all winter on the proper conduct of a large general hospital, have formulated plans which, to say the least, are quite radical. In the first place, every one on the present staff is called on to resign his position in the interests of the hospital and of medical education, so that the staff may be reorganized on ideal lines, and every practitioner in Toronto is asked to apply for positions on the new staff. A medical board is recommended consisting of the chiefs and assistants of all departments to be appointed to advise the board of trustees. Each medical service is to consist of 50 patients under the control of a physician in-chief, who shall be directly responsible to the board. These physicians are to give their entire time to teaching, hospital and consultation work. Assistants are to be appointed who, on account of being required to do much work, are recommended to receive $1,000 per annum. In the out-door department three are to be appointed, to attend two days a week each. Members of the staff will not be allowed to serve on other general hospitals in the city. An age limit of 40 years will be set, when physicians will be placed on the consulting staff. The house staff will probably be appointed on competitive examinations. At least $10,000, the committee states, should be appropriated annually for the scientific departments of the hospital. The emergency branch of the Toronto General Hospital will shortly be closed.

Personal.—Dr. A. A. McArthur, Winnipeg, has returned home after spending three weeks in Ottawa, Montreal and Toronto. ——Dr. S. Douglas, Park River, N. D., having received a license from the University of Manitoba, will hereafter practice in Winnipeg, Man.——Dr. O. Margolese of Montreal has removed to Winnipeg, where he will practice in future.——Dr. Adam H. Wright, editor of the *Canadian Practitioner*, has sailed for Naples. He will be absent about three months in Europe.—— Dr. Bruce L. Riordan, Grand Trunk surgeon at Toronto, is spending two months traveling through Ireland, England and Scotland.——Dr. J. A. Amyot has been elected president of the Toronto Pathological Society; Dr. W. H. Pepler, vice-president; Dr. E. S. Ryerson, corresponding secretary, and Dr. H. S. Hutchison, recording secretary.——Dr. H. B. Anderson has been elected president of the Toronto Clinical Society; Dr. Herbert A. Bruce, vice-president; Dr. G. Boyd, treasurer; Dr. W. J. McCollum, corresponding secretary, and Dr. George Elliott, recording secretary.——Drs. Beal, Black and Davis, London, Ont., have been appointed house surgeons at Victoria Hospital of that city for one year.

Annual Meeting of the British Medical Association.—Considerable progress has been made with the arrangements for the meeting of the British Medical Association in Toronto, August 21-25. A large attendance is expected not only from this continent, but from the British Isles. Among the noted European physicians who are expected to be present are: Dr. Delezenne, director of the physiologic laboratories of the Pasteur Institute, Paris; Dr. L. Lapicque, Paris; Dr. M. Nicloux, Paris; Prof. Justus Gaule, University of Zurich, and Prof. Max v. Frey, University of Würzburg. There will be thirteen sections, which will meet daily from 9:30 till 1 o'clock. The afternoons and evenings will be devoted to general meetings, public addresses, and various entertainments. Sir James Barr will deliver the address in medicine, his topic being "The Circulation, Viewed from the Peripheral Standpoint." Dr. W. S. A. Griffith will deliver the address in obstetrics, Sir Victor Horsley the address in surgery, and it is possible that a public address will be delivered by Dr. Marie of Paris. It is intended that clinics shall be held each morning at 8:30, when interesting cases will be reviewed by some of the prominent physicians and surgeons in attendance.

Hospital News.—The Toronto General Hospital bill has passed the Ontario legislature, and as soon as the new board of trustees provided for by this measure is appointed it will take under consideration the question of a reorganization of the medical staff. The present board will not deal with that question.——The Epileptic Hospital at Woodstock, Ont., which was only formally opened a few months ago, has been found inadequate for the needs of those seeking admission into its wards. Two additional cottages will be erected at once for the accommodation of 80 more patients. The cost is estimated at $48,600. The institution will then consist of the administration building with the superintendent's residence and four cottages.——The dispensary for women opened in Montreal three or four months ago, and attended by women physicians alone, has treated 590 cases of a medical and gynecologic character during the first three months of its existence.——Carlyle, Sask., will erect a small general hospital.——An association has been formed at Hamilton, Ont., the first to be formed in that province under the new Ontario municipal sanitaria act. A site of 98 acres has been donated as grounds for a consumption sanitarium by a Hamilton citizen and the $50,000 in hand for the purpose of a sanitarium will be expended in building cottages. An outdoor department will probably be established in connection therewith.——The total number of patients treated in the Winnipeg General Hospital during the week ending May 5 was 335—183 men, 109 women and 43 children. Eighty-two patients were treated in the outdoor departments.——A year and a half ago the Toronto ratepayers voted $50,000 for the purposes of a municipal sanitarium. Lately Dr. John Noble, the chairman of the local board of health, has revived the prospect of a municipal hospital for consumptives, but the idea met with such strong opposition that the question was taken to the legislature, but the private bills committee of that body was so overwhelmingly against the proposition that it is likely the money will in the near future be handed over to the National Sanitarium Association, for its free hospital ten miles out of Toronto.

FOREIGN.

The Disturbances Near Vesuvius.—The home for incurables at Torre del Greco was adjudged dangerous on account of the

volcanic disturbances, and the 35 inmates have been transported to the public hospital at Naples. The physicians there are discussing the possible pathologic results of the constant inhalation of the volcanic dust in the air.

Biologic Station in Greenland.—The *Presse Méd.* announces that the Danish government has received a bequest of about $10,000 for the erection of the biologic station in Greenland, mentioned in these columns March 11, 1905, page 809. The government will furnish $800 a year toward its maintenance.

Injury of Physician by Insane Patient.—Dr. Thivet, while making his rounds at the asylum at Clermont, France, was struck by one of the patients who had managed to conceal a piece of a bottle. The assistants who interfered were also seriously wounded. The insane patient had also secreted some pepper which he threw in the faces of the medical officers.

Two Physicians at Lisbon Taken from the Congress to the Hospital.—Two members of the International Medical Congress were stricken during the sessions. Dr. Thierry, from Chili, developed symptoms of typhoid fever and was removed to a private room in the hospital of San José, where his wife was also given a room. Another member, Professor Mascaro, an ophthalmologist, residing in Lisbon, while delivering an address on the education of the blind, was stricken with cerebral hemorrhage and was carried to the same hospital in a serious condition. The section adjourned at once after this distressing incident.

Remedy for Seasickness.—The cable states that Professor Hoffa made a thorough trial of the method of treating seasickness described recently in these columns on page 1299. His experience was eminently favorable. He applied hot linen cloths to his brow, bandaging them on tight, and changing about every minute and a half. After half an hour of this treatment he lay down for an hour, and when he arose he was entirely free from seasicknesss then and thereafter. His experiment was made on a recent trip to the Canary Islands. The technic is that proposed by Eugene Wolf, the explorer, who states in an article in the *Deutsche med. Wochft.* No. 3, 1906, that he has never known it to fail even under the most unfavorable circumstances.

A Paris Medical Journal in English.—A monthly review of French medicine has been founded at Paris "to represent English and American interests in France and French interests in English-speaking countries." The first number has been received and is a newsy journal of some 32 reading pages, with original articles and reviews of the work of the French medical societies, clinical lectures, etc. They have all appeared elsewhere (in French) and have already been reviewed in these columns. Some historical sketches of the great hospitals of Paris are given and lists of the private medical and surgical nursing homes, spas, etc. A quotation from Byrom Bramwell of Edinburgh expatiates on the profound impression made during a recent visit to Paris "by the wealth of material, the extraordinary number of rare and interesting cases of nervous disease, the exhaustive manner in which those cases are investigated, the success with which many obstinate diseases are being treated and cured, and with the lucidity with which these great masters of neurology (Déjérine and P. Marie), discussed and explained the intricate and difficult problems which many of these cases presented." He refers to Déjérine's "milk-isolation treatment" as having proved the most successful method of treating functional nervous affections which he has ever tried. An article by Déjérine on this subject is summarized on page 1482. The new *Paris Medical Journal* is published by Drs. A. A. Warden and Edmund L. Gros, 338 rue St. Honoré, Paris, $3.

Egypt and the Soudan.—In his report to parliament for 1905, Lord Cromer, the governor-general of the Soudan, makes many references to medical and sanitary matters. He states that during the early years of the British occupation the financial embarrassments of the government made it impossible to carry out many much-needed sanitary reforms. More recently, however, the water supply of towns has been taken vigorously in hand, and many are supplied with artesian wells. Alexandria is supplied with filtered water, and it is expected that the water-works at Damietta will be completed during the current year. The campaign against malaria which proved so successful at Ishmailia was extended to Suez with excellent results. The number of malarial patients in the hospitals decreased considerably and inquiries in the town indicated that the disease was much less prevalent than usual. The traveling camps for the treatment of ophthalmia, provided for by the Cassel Fund, have proved so successful that it has been decided to augment their work from the government funds. Alcohol, Lord Cromer, states, does not appear to play much part in Egypt. In the seaports there is a certain amount of drinking among the natives who are constantly in touch with Europeans, but the laboring classes scarcely drink at all. On the other hand, hashish smoking is very prevalent and is credited with being a common cause of insanity. The hashish is said to be smuggled into the country from Greece. Lord Cromer quotes from the report of Dr. Christopherson, of the civil medical department, to show that the Soudan is not a fever-stricken, smallpox-ravaged country, into which the Egyptian diseases—ophthalmia, bilharzia and ankylostoma—are being introduced. Smallpox shows itself occasionally, but if the country can be vaccinated properly there is, he says, little danger of an epidemic.

Burlesque Number of the "Muenchener med. Wochenschrift."—Once a year the mail brings us two copies of our scientific and dignified contemporary in a single wrapper. They are apparently identical in makeup and appearance, but the thinner one is pure burlesque from cover to cover. The satire this year is directed mainly against Bier's artificial hyperemia, serum treatment, new drugs, the mania for congresses of all kinds, and the various phases of contract practice. One advertisement purports to be from a sickness insurance company which states that as three of its six contract physicians have just died of starvation and the others have resigned, it is now advertising for 100 new medical officers. Preference will be given to applicants with a congenital faculty for breaking strikes and those who do not yet know anything about the *Leipziger Verband.* The advertisement of a newly founded medical journal follows. Its specialty is to be the discussion of new drugs after they have been tried on 6 animals (2 dogs 1 mouse, 1 guinea-pig and 2 sick-benefit policy holders). A new "Atlas of Mishaps at Operations" is advertised to appear in 80 parts. Part 1 is to be devoted to asphyxia and vomiting under the anesthetic; part 2 to the upsetting of the instrument table; part 3 to sudden detaching of the rubber tube from the full irrigator; 4, to the sudden going out of the lights. The atlas will be completed by the year 1986. One of the sketches is entitled "A New Hypnoticum" and describes the writer's failure to relieve the insomnia of a wealthy patient who was suffering from the results of overexertion in doing nothing (millionaritis hypertrophica). He ordered each of the familiar hypnotics in turn without result, but finally put his patient to sleep by reading aloud a play he had composed. The repeated success of this play as a hypnotic has encouraged him to have it published, and under the name "Dramatol, a New Hypnotic," it is for sale in all the book and drug stores. Among the triumphs of Bier's suction hyperemia reported is the removal of a tapeworm by this means, treatment of impotence, etc. One correspondent puts in a plea for priority, as he commenced years ago to apply the technic of suction hyperemia on his own person for therapeutic purposes, putting his finger in his mouth and sucking it whenever he hurt it. Wassermann reports in the *Grenzgebiete der Utopie und Ironie* the successful cultivation at last of spirochetes in pure cultures. This he accomplished by implanting a Petri dish in the back of a female monkey; he then implanted on the dish a papule on a pedunculated flap from another monkey, immobilizing both animals in a plaster cast. One article advocates removal of hemorrhoids by the abdominal route. Letters from Berlin, Paris and India state among other news that most of the trees in Java are now smeared with mercury, which answers the purpose of inunctions as the inoculated monkeys climb about them. It is stated that the "vaginologist, Prof. Duerr sen.", exhibited an iron woman at the meeting of his local medical society, remarking that the possibilities for rapid and complete sterilization must be regarded as a tendency which might serve as a model. The report of the International Medical Congress at Lisbon contains the alleged opening address of Senor Don Miguel Bombardos Garcia de los Rosinantos y Cravalhyaderos. It opens with the statement: "Of all the countries in the world called to do homage to science and to be celebrated by science none surpasses our radiant Portugal. We were the first to colonize South America and India; it was from our possessions in Brazil that quinin first came to save millions of lives. We invite the world to our colonies to study yellow fever and blackwater fever. We are the land of discoverers and the land of health." Then followed the main addresses, the principal being by his excellency Pampelunos de la Conceepeion y Paradoxos, who spoke exhaustively in Portuguese on the "Respiratory Quotient of an Asthmatic Dancing Mouse under Radium Stimulation of the Right Vagus Center." Other pages are devoted to society reports, parodies, poems, etc., many of them extremely bright. The comic number was first distributed at the banquet closing the proceedings of the Twenty-third German Congress of Internal Medicine, which was held this year at Munich, April 23 to 26.

Pharmacology

The Debt of the Medical Profession to the Manufacturing Chemist.

It is a natural tendency to attack an evil rather than to commend a virtue. There is so much that demands reform in the matter of proprietary medicines that a discussion of them tends to leave the impression that the medical profession is hostile to makers of medicinal preparations. This hostility is certainly justified, in so far as it applies to manufacturers who vaunt the claims of adulterated, dangerous, or worthless foods and drugs, or as it applies to those who would make physicians distributing agents for secret or semi-secret mixtures, or for ordinary drugs and chemicals, sold at an exorbitant price under a fanciful name, and on extravagant therapeutic claims.

There may be a few, possibly, who would dispense with all medicinal preparations not contained in the pharmacopeia, and to a certain extent they are justified, for we must admit that the pharmacopeia represents in an official and formal way the consensus of opinion of the medical profession. And any preparation which has not received this sanction should be used only after it has been carefully looked into by those competent to do so. The pharmacopeia, however, must always follow the vanguard of medical progress, and one of the most potent forces in this vanguard is the manufacturing pharmacist or chemist, especially in the past, when the medical profession was not so well organized and when facilities for experimentation were not so well provided as at present. The practical value of what is known as elegance in the preparation of drugs can not be doubted. Elixirs, pills, tablets, capsules, certain ointments, suppositories, bougies, etc., in which the even distribution of active drugs is of great importance, can not always be so well prepared in small quantities, at retail pharmacies, as in large quantities by manufacturers who can command special apparatus and skilled workmen. Even in regard to official drugs whose collection, recognition and preparation is theoretically within the ability of any one well-trained in pharmacognosy and practical pharmacy, we are greatly indebted to manufacturing pharmacists. Especially is this true concerning drugs not native to our own locality. The assaying of galenicals and the extraction of active principles have reached a basis of practical application only through the enterprise of such firms.

There exists much charlatanry in regard to some of the synthetic chemical compounds, and many of these have proved useless or even harmful, still there are not a few of great value, and for these we are indebted to commercial enterprise.

Instances are by no means unknown in which honorable manufacturers have employed skilled assistants, provided costly apparatus, and have gone to great expense in developing and testing new therapeutic agents and then have failed to place them on the market or have withdrawn them after a brief trial, because they did not prove of value. In so doing, they have, of course, had an eye to the ultimate benefit of their reputation and of the value of demonstrated excellence, still such far-sightedness is rare enough in the business world to merit our gratitude.

Therefore, it is unfortunate that there should have developed any antagonism between the medical and the pharmaceutical professions, yet an antagonism has developed, although not to the extent some seem to think. This antagonism is not toward the legitimate manufacturing pharmaceutical firms that are honestly catering to the needs of the physician by furnishing him with non-secret combinations in a convenient and satisfactory form, but against those who are supplying him with preparations about which there is more or less mystery, and for which extravagant, and often false claims, are made. For the practitioner in the country, the wholesale pharmacist has provided means of convenient, elegant, and efficient medication, whose value is inestimable, and the fact that too slavish reliance on such means has occasionally occurred, by no means detracts from the merits of the case.

Opium Habit in Infant from Kopp's Baby's Friend.

We have to record another case of poisoning from the use of Kopp's Baby's Friend. How many such cases occur annually it is, of course, impossible to state, but undoubtedly there are many children who are ruined for life, morally and physically, by the continued use of "patent medicines" containing opiates.

This patient is the infant daughter of Mr. and Mrs. Edwin Jordan, 1204 West Monroe Street, Chicago. Ten months ago, when the child's mother was visiting her old home in Rebersburg, Pa., the child suffered from colic and the mother was advised by her former pastor, the Rev. Mr. Bixler, a Lutheran minister of that place, to try Kopp's Baby's Friend which, he stated, was perfectly harmless and had been used in his family. Dr. J. J. Deshler, Glidden, Iowa, a relative of the family, recently visited Mr. and Mrs. Jordan and at once noticed that the child was in an abnormal condition. He reports the case as follows:

"The medicine was used continuously, according to the instructions on the label, since the child was about 4 months old, once or twice daily, the last dosage being one teaspoonful. The child was under the influence of the opiate the whole twenty-four hours. Dentition is almost completely absent and a general condition of lassitude and listlessness is present.

Appetite has been fair, so that the child is in a well-nourished condition. Its age now is 14 months. The child has an extremely waxy pallor and appears sleepy. While taking the preparation the child 'did not seem to be able to open its eyes wide' (see illustration). It can now do this. It was formerly constipated, then lately a severe diarrhea set in, but that ceased when the drug was discontinued.

"I prescribed two minims each of tincture of asafetida and tincture of hyoscyamus in a little sweetened water.

"When necessary an occasional dose of a carminative tablet containing a minute dose of codein sulphate was given. The parents were instructed to give plenty of nourishment and Pasteurized milk was prescribed.

"Since the child has been taking this the mother states that it is much better and brighter, and takes more interest in its surroundings, though, naturally, it is cross and irritable."

We sent a physician to see the child and to learn present conditions. They are as reported by Dr. Deshler. Mrs. Jordan expressed her willingness to have the report published in the hope that it may be the means of saving other babies from a similar fate. She declared that had she known the preparation contained morphin she would never have used it, and she was very emphatic in stating that: "the government should prohibit the sale of such dangerous preparations."

Canned Editorials.

Under the above apt title, May 12, *Collier's Weekly* says: Canned editorials, to employ the *Druggist's Circular's* apt phrase, are being sent broadcast to the newspaper offices by the Proprietary Association of America. The medical profession is accused of being a huge trust, warring on "patent medicines" in its own interests. Since doctors give enslaving and dangerous poisons, argues the Proprietary Press Bureau, nostrum makers should be allowed to. Verily, a remarkable plea for immunity, this! "It's true that I'm in a murderous business, but so is Dr. Blank across the street." Another stock argument is that doctors' prescriptions are secret, therefore "patent medicines" should be; further, that all prescriptions should be written in English instead of Latin, if "patent medicine" formulas are to be open. But physicians' prescriptions are not secret. If they were the druggist could not fill them. Moreover, they are always kept on file for reference in case of error or damage. As for the substitution of English for Latin, the Fraud Association advocates this because it knows it to be impossible. Latin is the language of science; prescriptions are scientific compounds. Many Pharmacopeia drugs have no English names: infinite confusion and danger would be the result of substituting an unscientific for an exact terminology. As well require all botanic or entomologic classifications to be couched in the language of the country. *Collier's* is charged with being an ally of the "doctor's trust," and its charges are discredited on the ground that they are the work of "hired scribblers." To the honor of daily journalism, be it said that the prepared editorial arguments of the Proprietary Association have either been totally disregarded by the more important newspapers or received with derision.

Subordination of Medical Journals to Proprietary Interests.

One of the articles on fraud in "patent medicines" in *Collier's Weekly* was on "The Patent Medicine Conspiracy Against the Freedom of the Press." What is needed now is an article on "The Proprietary Medicine Conspiracy Against the Freedom of Medical Journals." There is certainly plenty of material at hand to prove that a majority of medical journals are as much under the domination of the proprietary medicine manufacturers as are most of the newspapers under the control of the "patent-medicine" men.

The *National Druggist* of St. Louis is recognized as a supporter of the "patent-medicine" men's association, and it has tried to live up to its full functions as such. It has defended "patent medicines" in particular and nostrums in general. It has attacked everything and everybody that favored legislation looking to the regulation of the traffic and to the protection of the public. A little while ago it published an article entitled "The Legislative Schemes of the American Medical Association," which, as might be imagined by the title, was an attack on the American Medical Association. In the main it was made up of falsehoods, extravagant statements and garbled extracts. It claimed that the attack on "patent medicines" was instigated by the American Medical Association, and that the American Medical Association was the cause of the introduction of bills in the various legislatures for the regulation of "patent medicines." It attempted to show that the doctors, for selfish reasons of course, were back of the movement against "patents" and that the American Medical Association was a trust of the vilest sort, without a redeeming feature.

Immediately after its appearance in the drug journal the article was reproduced in pamphlet form and evidently no money was spared to make it attractive, for as gotten out it was certainly a credit to the printer's art. It was sent to the newspapers of the country and was evidently well circulated among the druggists. Attached to the pamphlet sent to the newspapers was a slip calling the editors' attention to the contents and indirectly suggesting that they make use of them in their columns. While many newspapers recognized that the pamphlet emanated from their patrons, the Proprietary Association of America, and printed extracts from it with their approval, it must be said to their credit that the majority saw the animus bebind it and ignored it, and still others showed the absurdity of the statements the pamphlet contained and defended the medical profession. So taking it all in all, the "patent-medicine" men did not see the results they expected to see in their appeal to the newspapers, and the American Medical Association has not been injured as they hoped it would be.

Bearing in mind the fact that this article was in reality a defense of "patent medicines" and an attack on the medical profession, it is pitiful to know that an editor of a medical journal—medical in name, at least—swallowed the bait, hook and tackle, to use a slang expression—and reproduced the entire article, something which no newspaper had done, so far as we know. Just why a medical journal would copy this tirade against those it was supposed to represent might at first seem difficult to imagine. Those charitably disposed might think it was because the editor did not know any better. And yet the reason is evident. The journal to which we refer—the *St. Louis Medical and Surgical Journal*—is a representative of the class of papers that, while published ostensibly for physicians, are kept alive by and conducted in the interests of the advertisers, and whenever it becomes necessary to take sides the advertisers' interests rather than those of the reader are protected. The advertisers in this case are nostrum vendors—at least a large majority of them are—and because the American Medical Association is trying to get rid of the nostrum evil, and because the Association's success will mean for the St. Louis publication the loss of that on which it depends for existence, it naturally wants to see the American Medical Association checked. The *St. Louis Medical and Surgical Journal* did not publish this tirade against the American Medical Association and the physicians of the country because it is in favor of "patents," but because it is under obligations to the nostrum manufacturers whose interests are being affected by the American Medical Association, and because it is one of the organs of the nostrum men, at least this might be expected from the character of its reading matter. An examination of its pages for the last year—the first three months of this year averaging about the same—reveals the following: Aside from the articles it copied from the *Proceedings of the Philadelphia County Medical Society*, none of which could be called original, as they had appeared at least in the publication of the society if not in other journals, the *St. Louis Medical and Surgical Journal* published seventeen original papers during 1905, and of these seventeen, thirteen were "write-ups" of proprietary medicines.

The total of the strictly original articles not devoted to proprietary remedies, exclusive of illustrations, occupied less than six pages.

But besides these "write ups" in the "original" department, there were reading notices, most of them attractively presented to catch the innocent and gullible reader, varying in length from three or four lines to three pages.

The proprietaries written up in this manner and the number of times mentioned are: Acetozone, 2; adrenalin, 1; aletris cordial, 3; antikamnia, 2; antiphlogistine, 8; bovinine, 5; bromeotone, 1; bromidia, 1; Burnham's soluble iodin, 1; cactina pillets, 1; campho phenique, 5; celerina, 3; chionia, 1; dermapurine, 8; echthol, 2; ergoapiol, 4; gelineau dragees, 1; Hagee's cordial of cod-liver oil compound, 4; hydrozone, 2; iodalia, 1; listerine, 3; mandragorine tablets, 1; neurilla, 1; Pantauberge's solution, 2; papine, 1; pasavena, 1; passiflora, 3; Peacock's bromids, 1; pinus canadensis, 5; respiton, 1; sanmetto, 15; seng, 2; tongaline, 7; vin Mariani, 13.

An apology is due our readers for devoting space to so unimportant a subject, but while the circulation of the periodical in question may be small and its influence insignificant, it is typical of a class of journals which, combined, has considerable weight with practitioners who are not sufficiently interested in scientific medicine to subscribe for journals edited and published solely in the interests of the medical profession. Although our rule is to ignore attacks made on the American Medical Association and its journal, yet we think it wise, occasionally, to call attention to facts which may enable our readers to discriminate between the true and the false in a matter which is of supreme interest to the profession as a whole.

Society Takes Action.

At a recent meeting of the Ottawa County (Mich.) Medical Society the following resolutions were adopted:

WHEREAS, The American Medical Association, through its Council on Pharmacy and Chemistry, is engaged in the work of bringing to the attention of the medical profession the composition of the various nostrums and proprietary medicines which are on the market and advertised extravagantly and fraudulently to the profession; and

WHEREAS, The interests concerned in the manufacture and sale of these nostrums are spreading literature throughout the country, and are doing everything in their power to defeat the work of the Council on Pharmacy and Chemistry; and

WHEREAS, The American Medical Association, through the editors of the "Councilor's Bulletin" has asked for an expression of the attitude of the different county societies, the component parts of the American Medical Association; therefore, be it

Resolved, That the Ottawa County Medical Society of the State of Michigan hereby expresses its approval of the work that has already been done in this regard and agrees to help in every local way possible this educational campaign; and further,

Resolved, That the members of this society shall refrain from prescribing any of the nostrums which have been analyzed and rejected by the Council and that they shall seek to profit by the articles published in THE JOURNAL of the American Medical Association under the head of "The Pharmacopeia and the Physician"; and further

Resolved, That the society extends its thanks and earnest commendations to *Collier's Weekly* and the *Ladies' Home Journal* in their campaign against "The Great American Fraud" and promises its support in their further work in this direction; and further

Resolved, That copies of these resolutions be sent to THE JOURNAL of the American Medical Association, the *Journal of the Michigan State Medical Society*, *Collier's Weekly* and the *Ladies' Home Journal*.

B. B. GODFREY, M.D., and E. D. KREMERS, M.D., Committee.

Insurance Examination Fees

Cheap Fees and Cheap Services.

PORT RICHMOND, S. I., May 7, 1906.

To the Editor:—I was very much interested in Dr. McCormack's article, and I believe it and similar articles will have a tendency to strengthen the fraternal feeling among "doctors."

The argument that the majority of physicians are willing to make examination for $3 is a weak one, for, if insurance companies should reduce the fees to $2 or $1.30, there would still be a good many men who would work for them, for reasons which are obvious to struggling physicians. Not only was there a cut in wages, but there was also an increased amount of work required. One large industrial company now requires urinary analysis of all applicants, when, as formerly, the age limit was 45 years.

It also has an intermediate form whereby an agent can write several thousand dollars' worth of insurance and yet the physician receives only $1 for examination and often is asked to review his work or answer inquiries without extra compensation.

In the industrial department the instruction book is so worded that they can use the "big stick" on any examiner at a moment's notice and the examiner has no redress.

If any one doubts this I refer them to the instruction book, where it states: "An examiner must make a personal, physical examination and all questions must be answered before applicant signs." The fee for this is 25 cents. How many examiners are there that are not technically guilty and liable to have their reputations smirched whenever the "big stick" falls? Who are the users of the "big stick?" They are members of our own profession, members of our society, state and interstate, and often graduates from the same alma mater.

One of the things that the medical profession needs is more men who are independent and unselfish and who will fight for principle and right regardless of any temporary pecuniary loss.

N. D. CHAPMAN, M.D.

Society Takes Action on Fees.

BUFFALO CENTER, IOWA, May 11, 1906.

To the Editor:—I was instructed by the Winnebago County (Iowa) Medical Society to send to you for publication a memorandum of action at a meeting held at Lake Mills, Iowa, May 10, 1906: It was moved and seconded that a resolution be adopted not to accept the 40 per cent. reduction in life-insurance examinations asked for by certain old-line insurance companies, and that the society sanction any action taken by the state and other county societies in regard to the regulation of fees in fraternal insurance examinations, and that our delegate to the state society be instructed to use all honorable means to co-operate in any movement tending to put the fees for such fraternal examinations at two or more dollars. Carried. H. F. THOMPSON, Secretary.

Medical Organization and Insurance Fees.

GALESBURG, ILL., May 12, 1906.

To the Editor:—The letter from Dr. McCormack in reference to life-insurance fees in THE JOURNAL, May 5, together with your editorial on the subject in the same issue, although perhaps a little late in the day, must come as a welcome help to the many practitioners who are in doubt not only as to their duty, but as to their rights in this important matter.

It does not seem that it was eleven years ago, as stated by Dr. McCormack, that the New York Life Insurance Company notified me that after a certain date the fee for examining applicants for their company would be reduced to $3. However, they were promptly notified to remove my name from their list of examiners. My idea was that I could not consistently examine for the Mutual Life, the Equitable and the Northwestern, including many others who had not reduced their examination fee, and continue with the New York Life at $3. For the same reason I refused to examine for the so-called assessment companies whose examination blanks usually required more work for a dollar than any one of the old line companies which were paying $5.

Is it not reasonable to suppose that one of the explanations of the failure of the many assessment companies to survive any long period is the size of the medical examination fee? A dollar never has bought as much as five dollars and it never will. To illustrate: I knew, professionally, a diabetic who got insurance in every assessment company to which he applied. He furnished his own urine to every one of the examiners, but none of them had time to examine it in addition to all the work necessary to fill out the required blank. This man, although he tried, did not succeed in getting into any old-line company. Many of the examinations for the assessment companies are made in bunches: often nothing but filling out the blanks in a perfunctory manner in the physician's office is attempted, no measurements or physical examination. The head physician of one of these orders recently complained to me that a certain examiner of theirs never turned in an examination blank with the pulse other than 72, respirations 17 and temperature normal. Twenty years ago, when I was a first-year medical student, I remember assisting my preceptor one evening in examining an office full of men. My part of the duties was to make the physical examination, while he sat behind the desk and did the clerical work necessary. Comment is needless, except that the doctor in question was being paid a small fee for each examination, and he was too busy to take the time from work that paid him better.

The point in your editorial relative to the low fees of these companies is well taken, and if they can not be made to modify their examination blank to within reasonable limits for a minimum fee of from two to three dollars, then they should be refused the service. This can easily be done with the present organization of the county societies. The trouble with the assessment companies is that many of them are started by a lot of grafters who do not want an honest medical examination or a permanent institution. This must be true, else the promoters of these concerns would not attempt to sell insurance for the price they ask. They can not be honest, I repeat, else they would not expect to get for a mere pittance an examination which would make them safe in accepting a given risk. Of course, in the final analysis, the doctor is to blame for conditions as they exist, and back of him is the great fact that he has had no organization by which he could systematize and dignify his claims to square treatment.

Some weeks ago I received a letter, with a postal card inclosed, notifying me that the fees had been reduced by the Mutual Life Insurance Company of New York from $5 to $3, and requesting that I use the postal to notify the company of my acceptance of their proposition. As I remember it, this postal was an interesting document: it was printed in

such a way as to assume that only one reply would be received from the recipient. I crossed out the ready-made answer, or its equivalent, and merely stated that they could remove my name from their list of examiners. The reply which I received was identical with that received by Dr. Parsons of Brookings, S. Dak., published in THE JOURNAL, May 12, 1906.

To this I replied in part as follows:

Brandreth Symonds, M.D.,
Medical Director Mutual Life Insurance Company,
New York, N. Y.

Dear Doctor:—Relative to yours of the 9th inst., in reference to my retaining the position as one of the examiners of the Mutual Life at this place, permit me respectfully to decline the position at anything but the old terms.

A life insurance company that has to economize in its medical department is in an unenviable position. The corner-stone of life insurance must be the honesty of its medical examiners, to say nothing of their technical knowledge. To let down in your fee to the amount proposed will, in a large number of instances, make these men, to that proportionate degree, careless in their examination. You will simply get a three-dollar examination in spite of the fact that many of the examiners will try to give you a five-dollar service. On these grounds, I refused to examine for the New York Life a few years ago, and I would not be consistent if I did not do the same with your company now. In passing, and while on this point, it may be well to mention that the New York Life got a very good practitioner to take my place. This man was also examiner for your company at the time he accepted the three-dollar position from the New York Life. In other words, he was willing to take three dollars from the latter company for supposedly the same kind of an examination for which he was charging your company five dollars. But for some unknown reason your Chicago office, some months ago, dismissed him from his position; on what grounds, I do not know. It will not be surprising if a riper experience on the part of your company will show that the twelve thousand who consider your "new fee schedule as adequate" will show in the future characteristics which will make it desirable to dismiss them also. At any rate, I consider myself fortunate in being able to be numbered with the "nine hundred."

An interesting reference in your letter is the one as to the necessity for rigid economy because of recent events in the life insurance business. The "other companies" (I presume you refer to the New York Life) which have had this reduced "fee schedule in force for years" do not seem to have benefited their policy-holders any by reducing their examination fee to three dollars. The New York Life, with its three-dollar economy examination fee, was proved to be even more rotten at the three dollar fee than the Mutual Life, which, up to now, has maintained the five-dollar fee for an examination.

It is an interesting question as to how far the big insurance companies can afford to go in this kind of treatment of their most necessary allies, the physicians of this country. The future alone will decide; but I do not care to be made a part of the experiment.

With the greetings of a colleague, believe me,

Very sincerely yours,
J. F. PERCY.

I believe that the position taken in the above letter is correct, and believe it now more firmly than ever since reading your editorial and the letter of Dr. McCormack above referred to. My only regret is that more of the "twelve thousand" did not take the same view of the question. Some time ago I received notice of my appointment as examiner in one of the old-line eastern companies. The letter containing my appointment, among other things, had this to say:

"We can not refrain from calling your attention to the very responsible character of your duties as medical examiner to this company. It is not too much to say that the safety of an insurance company rests largely in the hands of its medical examiners. If unhealthy risks are taken, it will prove of little avail that the other departments of the company are conducted in an efficient and careful manner."

Another important phase of this subject is the one of the physician as a policy holder in the companies under consideration, because an appointment is usually predicated on the fact of the physician who is willing to become an examiner first taking out a policy. We have heard for years that life insurance offered the best form of investment for the professional man. With thousands of other unfortunates, who are not physicians, we now know that the investment feature was a delusion and a snare, concocted by wileful agents with the connivance of the home officers of these great companies. What is to be the attitude of the "twelve thousand" in the future as these same agents lead into their offices for examination, as sheep to the slaughter, seekers after life insurance whom they (the examiners as well as the agents) will know from now on are being buncoed when the examination is for anything but straight life insurance? Will the medical examiner become a party, with the average agent, to the fraud when the applicant has not been told the whole truth as to what he is buying in the way of life insurance? This most cruel form of deception was the rule with all but a very few of the life-insurance agents who required our services in the past. But now we physicians know, or ought to know, something of the relative value of the various forms of insurance. Will it become part of the duties of those medical examiners who are to make medical examinations for $3 to tell the applicant what he may not have been told by the agent? For the honor of the profession, I trust that the physicians who may continue to hold these positions at the reduced price will not now continue knowingly to aid any agent in deceiving those who apply for life insurance.

J. F. PERCY.

Correspondence

Automania the New Disease.

COLUMBUS, OHIO, April 25, 1906.

To the Editor:—The number of diseases produced by occupation is being augmented by the complexity of modern life. Medical men are acquainted with the ordinary forms of occupation diseases, such as the necrosis of match-makers, the cataract of blacksmiths, the colic of painters and the like.

I wish to call attention to a disease of this class of recent origin. The new disease is so prevalent as to have attracted the attention of many physicians, and I learned from THE JOURNAL, April 21, that not a few physicians have had a personal experience. The new disease is a functional neurosis and spreads through a community, like chorea, by imitation.

The disease is known as motor fever, chauffeur mania and automobiliousness. The spread of the disease is limited only by the confines of civilization and the quarantine enforced by poverty. The disease has followed the train of the horseless carriage into every country able to pay the excise and repair duties.

In the etiology of chauffeur mania, the automobile is the direct cause, and the sporty disposition, plus a large bank account, constitute the predisposing causes. The disease affects a large class of people. It is, indeed, pandemic. The extremes of life are exempt. The male sex furnishes the vast majority of the subjects. Physicians are peculiarly susceptible. The poor are immune. The rich are especially predisposed. The negro is rarely affected, except through reflex relation to employer.

There is little known of the pathology of the disease, as it never proves fatal. Neurologists regard the disease as a neurosis. On the other hand, chemists who have reported delusional insanity, as terminal forms of motor fever, do not regard the disease as a simple neurosis. Although they declare that the pathognomonic symptom, in support of the doctrine of insanity, in all terminal cases of this disease, as observed in hospital practice, is found in the fact that on entering the ward not a patient is visible—all are hidden under the beds working with the springs!

Almost all cases of motor fever are chronic. They seldom last less than one year, and often from two to five years. The most promising cases are those with equine reserves. One pegasus in the end will outrival three "honk, honk wagons."

Coming closer to the clinical history, one of the first symptoms to develop is amnesia. The failure of memory refers especially to routine duty. This neglect of duty often extends to domestic and personal wants. Irregularity of habits follows. The mental attitude is shown in eccentricity of costume. The peculiarities of facial expression are known as "the stony visage" or "the sphinx-face."

The features of the automobile face are drawn, rigid and ruddy, as in paralysis agitans. The eyes wear a steady gaze, and a far-distant focus, attended with a cold glitter. The stony visage often appears in a sort of trance, as though the patient were the subject of autosuggestion rather than automobiliousness. The stony, ruddy visage, with its far-off fixed gaze, prematurely old, dust-laden, garnished with goggles and a "you-be-damned" expression is pathognomonic. This *tout ensemble* once observed is never forgotten.

In cases of long standing, mental excitement is a constant symptom. Sleep is dominated by dreams of speed, cylinders, cooling devices and expenses. The patient becomes arrogant and impervious, impatient and petulant. He is intolerant of everything and everybody, especially police officers.

The diagnosis is not difficult, but the disease has been mistaken for delirium tremens. In chauffeur mania, the patient sees the animals and is positive he sees them.

In *mania a potu*, the patient is uncertain as to the real existence of obtruding animals and his ability to destroy them. Not so the chauffeur maniac, as he is swift and certain of both aim and game.

Chauffeur mania has been confused with football psychosis. In the latter disease the subjects are perfectly harmless concerning the public or domestic animals, but attack and destroy each other. The automaniacs never attack each other, but have predilection for small animals, as chickens, dogs, cats, toads and sometimes babies.

In advanced cases, a kind of strabismus or obliquity of vision has been noted, in which the driver of the machine loses control and the line of transit is direct to a telegraph pole or the goal may be a road-house.

Treatment is unsatisfactory; the most effectual is prophylactic. Army and Navy service should result in prevention. Permanent residence in the mountains is recommended.

Goat lymph was tried as a curative agent in a series of cases. The treatment was discontinued for the reason that patients were butting into lakes, plate-glass store fronts and police stations. J. W. CLEMMER.

Invitation to Mexican Congress.

THE INTERNATIONAL MEDICAL ASSOCIATION OF MEXICO.

TORREON, COAH., MEX., May 11, 1906.

To the Secretary of the American Medical Association: On behalf of the members we have the honor to invite the members of the American Medical Association to be present at the second annual meeting of the International Medical Association of Mexico, which will take place in Mexico City in November next. Due notice of the exact date will be given.

Hoping to have the pleasure of the company of many, if not all, members of the A. M. A., we have the honor to be, yours very truly. W. R. JAMIESON, Sec'y and Treas.

R. D. ROBINSON, President.

Shock as a Curative Agent.

CHICAGO, May 12, 1906.

To the Editor: The editorial on "Shock as a Curative Agent" in THE JOURNAL, May 12, p. 1444, recalls to me a rather interesting and, I believe, unusual experience. Some years ago I was a passenger on a transatlantic liner which met with a mishap, so serious in character, that for nearly two days we expected to go down at any moment. On the evening preceding the accident only 12 of the 250 cabin passengers were down to dinner, one being detained by a recent attack of apoplexy, 237 by seasickness, more or less severe. On the following morning 249 of us assembled in the dining room and ate our breakfast with as much relish as our mental state permitted. The only absentee was the paralytic. The reverse side of the picture was represented by four cases of acute insanity and an acute exacerbation terminating in suicide in a chronic case of mental derangement. SYDNEY KUH, M.D.

Association News

SCIENTIFIC EXHIBIT.

Committee.—FRANK B. WYNN, Indianapolis, Director; W. M. LATE CORLIN, Philadelphia; W. T. COUNCILMAN, Boston; FREDERIC S. DENNIS, New York; JAMES CARROLL, Washington, D. C.

MEETING PLACE: NEW HARVARD MEDICAL SCHOOL BUILDINGS, LONGWOOD AVENUE.

The Scientific Exhibit at Boston will consist of specimens, models, diagrams, apparatus, etc. A laboratory in operation will show newer laboratory methods as applied to diagnosis and to investigation. Demonstrations will be given on special subjects in small rooms; others of more general interest will be conducted in a large amphitheater where a lantern and projection microscope are available. The program of demonstrations follows:

A. ILLUSTRATED LECTURES AND LANTERN SLIDE DEMONSTRATIONS IN THE AMPHITHEATER OF THE ANATOMICAL BUILDING.

WEDNESDAY, JUNE 6—10 to 12 A. M.

HEKTOEN and RUEDIGER: Demonstration of (a) phagocytosis experiments and (b) cultural peculiarities of pneumococci and streptococci.

HODGE: "Locomotion of Amebæ."

CARROLL: Demonstration of *Amœba coli* and life history of Amebæ.

TYRODE: Demonstration in pharmacology.

WEDNESDAY, JUNE 6—2 to 5 P. M.

FITZGERALD: "Biologic Studies Connected with Water Work Construction."

WOLBACH: "Blastomycotic and Allied Skin Affections."

PARK and WILLIAMS: "Rabies."

WRIGHT: "Actinomycosis and Madura Foot."

FROTHINGHAM: "Rabies; Glanders."

THURSDAY, JUNE 7—10 to 12 A. M.

GAGE: Demonstration of (a) projection microscope and its application in teaching; (b) projection of frog's circulation.

PORTER: Demonstration of (a) physiologic apparatus; (b) nutrition of heart by vessels of Thebesius; (c) circulation in a tortoise heart.

CANNON: Kinetoscope demonstration of (a) movements of intestine and stomach; (b) demonstration of action of valves in ox's heart by electric light.

BOWDITCH: Demonstration of optical illusions.

HENDERSON: Demonstration of heart model showing action of valves in production of heart sounds.

LONGCOPE: Demonstration of muscular bundle of His, with cases illustrating heart block.

HATCHER: Demonstration of kidney perfusion.

THURSDAY, JUNE 7—2 to 5 P. M.

(Joint meeting with the Section of Pathology and Physiology.)

FITZGERALD: "The Metropolitan Water Supply of Boston."

BENEDICT: Illustrated lecture, "Metabolism," with demonstration of respiration calorimeter of Atwater.

NOVY: Demonstration of Trypanosome diseases.

KREMERS and REMINGTON: Demonstration of exhibit showing the development of pharmacopeias.

MARCY: Demonstration of historial exhibit, illustrating the life and work of HENRY I. BOWDITCH.

FRIDAY, JUNE 8—10 to 12 A. M.

MEYER: Illustrated lecture, "Psychiatry and Methods."

SOUTHARD: Demonstration of cerebral tuberculosis and of the Bullard collection.

TAYLOR: Demonstration of the systemic diseases of the spinal cord.

NICHOLS: Demonstration of diseases of joints, tuberculosis and chronic arthritis.

WHITE: Demonstration of advanced tuberculosis in childhood and adult life.

B. MICROSCOPIC AND OTHER SPECIAL DEMONSTRATIONS—THESE WILL BE CONDUCTED IN THE SMALLER ROOMS OF THE NEW HARVARD MEDICAL SCHOOL BUILDINGS AT THE HOURS AND BY THE INDIVIDUALS SCHEDULED BELOW.

TUESDAY, JUNE 6.

9 a. m. to 12 m.—FRAZIER: "Surgical Pathology."

2 p. m. to 3 p. m.—BEIM: Demonstration of agglutinins, etc. Room A.

CALKINS: Demonstration of paramecia, etc. Room B.

3 p. m. to 4 p. m.—GAGE: Various glycogen reactions.

HODGE: Demonstration of motile amebæ of nerve cells in fatigue. Room B.

MILLER: "Lymphatics of Lung."

WEDNESDAY, JUNE 7.

9 a. m. to 11 a. m.—SCHULTZ: *Spirochæta pallida*. Room A.

KNOWER: "Lymph Hearts and Lymphatic System of Frog Larvæ." Room B.

11 a. m. to 1 p. m.—MANDELBAUM: Various pathologic specimens. Room A.

COPLIN: Various pathologic specimens showing lesions of mucous membranes.

PARK and WILLIAMS: Rabies, etc. Room B.

MALLORY: Intercellular fibrillæ. Room A.

SOUTHARD: Demonstration of Gliomata.

THURSDAY, JUNE 8.

9 a. m. to 11 a. m.—SCHULTZ: *Spirochæta pallida*. Room A.

ROSENAU: "Cestode Parasites." Room B.

11 a. m. to 1 p. m.—TYZZER: Demonstration of mouse tumors, varicella; dermatitis from Brown tails, etc. Room A.

VERHOEFF: "Eye Lesions, Tumors," etc.

WRIGHT: Blood Plates, etc. Room B.

Clinical Exhibits.

Dr. Richard C. Cabot, chairman of the Committee on Clinical Exhibits at the Boston session, announces an elaborate series of demonstrations at all the hospitals. The list is too long to reproduce here, but we quote the general announcement. The full schedule will be given in the Official Program, a copy of which will be given each member on registration. Dr. Cabot says:

To provide a brief postgraduate course in each and all the branches of medicine, a course free to the members of the Association and conducted by the best teachers of the Harvard and Tufts medical schools is the object of this exhibit. If a physician wishes to inform himself on the current methods of examining blood, urine, sputa, feces or gastric contents he can find specimens and demonstrators in Mechanics Hall. If he wishes to watch the detail of operative technic in general surgery or in any special branch, such as orthopedics and gynecology, he can do so at one or more of the hospitals. If he wishes to compare notes with our best authorities on infant-feeding or on the outdoor treatment of tuberculosis he can avail himself of some of the many demonstrations at the Children's Hospital, the Samaritan Hospital or the Infants' Hospital.

If he wishes to examine and diagnose cases of surgical interest, cases of the contagious exanthema, of gastric, cardiac or pulmonary disease, or neurologic or dermatologic cases, he is welcome to use the clinical material offered for his study in the Boston City Hospital, the Massachusetts General, the Boston Dispensary or the Mechanics Hall exhibit.

Apparatus, instruments, records, models, charts, photographs, lantern slides and *x*-ray plates will be used to supplement the clinical material. Autopsies with the clinical history of each case will be demonstrated, moving pictures of epileptic fits, spasms and gaits of various types will be shown and explained, cases of the various types of mental disease, accompanied by attendants and history, will be ready for study.

All the hospitals will be open for inspection and study throughout the session, and any one who wishes to devote special attention during the session (or after it) to any one of the medical or surgical subjects exhibited will find no difficulty in arranging to do so. To prevent overcrowding at any one clinic or demonstration, a number of tickets proportional to the seating capacity of each amphitheater will be distributed each day from a central booth at Mechanics Hall. First come, first served.

GENERAL ENTERTAINMENTS.

FOR MEMBERS AND GUESTS.

(The official member's badge, or one of those provided for ladies and guests, will be required for admission.)

TUESDAY, JUNE 5.

4-6 p. m.—Afternoon tea at the New Harvard Medical School buildings, on Longwood avenue, by the invitation of the medical profession of New England and the courtesy of the president and fellows of Harvard College. There will be music in the central court, the grounds will be decorated for the occasion and tea and light refres' ments will be served by the young ladies of Boston.

8 p. m.—Gen. William H. Devine, surgeon-general of Massachusetts, extends a cordial invitation to the members and guests of the American Medical Association to visit the South Armory, Irvington street, at 8 o'clock on Tuesday evening, June 5, to witness a regular drill of the ambulance company of the Massachusetts Volunteer Militia.

8:30 p. m.—Chickering Hall, Huntington avenue. Mr. Charles Truax, of Chicago, will deliver a lecture on the Yellowstone National Park, superbly illustrated by lantern slides.

9-11 p. m.—Boston Public Library reception. The trustees of the Boston Public Library extend a cordial invitation to the members of the Association to a reception at the library from 9 to 11 p. m. on Tuesday, June 5, to meet his honor, the mayor of Boston.

9-11 p. m.—Boston Museum of Fine Arts. The trustees of the Museum of Fine Arts invite the members of the Association to a reception at the museum at 9 o'clock on Tuesday evening, June 5.

WEDNESDAY, JUNE 6.

4-6 p. m.—Afternoon tea at the New Harvard Medical School buildings.

8:30-12 p. m.—A reception and promenade concert will be given by the medical profession of New England to the president, officers, members and guests of the American Medical Association at Mechanics' Hall. There will be dancing and refreshments. The hall will be decorated and music will be furnished by the Medical Glee Club and by an orchestra of thirty-five pieces.

THURSDAY, JUNE 7.

2:30-3:30 p. m.—Organ recital. The rector of the Mission Church, 1545 Tremont street, has extended an invitation to the members of the Association to visit the church and to inspect the school, club, gymnasium and other institutions which are there conducted by the Redemptorist Fathers. An organ recital will be given from 2:30 to 3:30 p. m.

4-6 p. m.—Afternoon tea at the New Harvard Medical School buildings.

8 p. m.—"Theater night." Arrangements have been made for the reservation and sale to members of the Association and their guests, at a booth in Mechanics Hall, of tickets to all of the theaters and to the "pop" concert at Symphony Hall. Special performances will be arranged and the "pop" concert will be reserved entirely for the members of the Association. Special invitations to the members of the American Medical Association have been extended by the officers of the following institutions, and arrangements for their reception and entertainment will be provided: Boston Medical Library, Boston Museum of Fine Arts, Boston Public Library, Boston Young Men's Christian Association, Cambridge School of Nursing, Children's Hospital, Faulkner Hospital, Harvard College, Massachusetts General Hospital, Massachusetts Society of Mayflower Descendents, Waltham Training School for Nurses.

EXCURSIONS.

The excursions planned for the members of the Association and the ladies and guests who may accompany them are too numerous to be enumerated here. A special pamphlet giving details of the various excursions will be issued to each member of the Association at the time of registration, together with the Guide Book, which has been prepared expressly for this occasion.

The Association Insignia.

Since the publication in recent issues of letters by Drs. E. Fletcher Ingals, T. S. Dabney and E. S. McKee relating to the official insignia of the American Medical Association, we have received numerous inquiries concerning the button and how it may be obtained. Many of our readers do not seem to be aware that for years we have made an announcement in our advertising pages for the purpose of giving this information. This week's advertisement appears on page 33 in our advertising department. To all inquirers we desire to say that the American Medical Association insignia can be procured at the office of the Association, 103 Dearborn Avenue, Chicago. The price of the button is $1.00, or a member may receive one as a premium for securing a new member of the Association, or a new subscriber to THE JOURNAL, but not for the transfer of a present subscriber to membership. Women who prefer a pin may secure the badge in the form of a cloak pin on the

same terms. The general use of the official insignia can not fail to promote a fraternal feeling among physicians.

Hotels.

The Committee on Hotels announces that all available accommodations in the first-class hotels are filled, but that applications are coming in only slowly for lodging-houses. The committee has a list of lodging-houses of good quality and of accessible location, with ready facilities for dining out.

Attention is again called to the possibility of securing accommodations near the ocean. As announced in THE JOURNAL May 5, if a sufficient number write immediately making the request, it will be possible to have accommodations provided at Winthrop Beach at the time of the session, although ordinarily the hotels there would not be opened until later in the season. Those who would like to take advantage of this privilege should write immediately to Dr. D. D. Scannell, Secretary of the Committee on Hotels, 8 The Fenway, Boston

New Western Railroad Rates.

Dr. John C. Munro, Chairman of the Committee on Transportation, sends the following additional information:

The Western Passenger Association has granted a rate of one fare, plus $1.00, for the round trip from points on the Missouri River, and east thereof; and a rate of one fare, plus $2.00, for the round trip from points west of the Missouri River. Tickets will be sold June 1-4, and also on May 31 from Missouri River points.

The Southeastern Passenger Association has granted the same rates as announced for other territory, one fare, plus $1.00, for the round trip; tickets to be sold beginning May 31. Stop over at New York will be allowed on return ticket as on other lines.

Date of Entering New England Modified.

A slight modification of the going regulations is the following: The Trunk Line Association will issue tickets good on going passage from New York City on the 11 o'clock and midnight trains, June 1, and on Long Island Sound steamers on the evening of June 1. By previous announcement tickets were not to be good to enter New England until June 2.

Marriages

MAURICE B. WOLFF, M.D., Chicago, to Miss May Steiner of St. Louis, May 15.

C. P. BROKAW, M.D., to Miss Mattie E. Wiggins, both of Dalhart, Texas, May 10.

W. OTWA LEE, M.D., Danville, Va., to Miss Ethel Wood, at Pelham, Va., May 9.

PAUL J. BURRELL, M.D., Winslow, Ill., to Miss Leda Smith of Cadiz, Miss., recently.

TONY EDWARD HUNTER, M.D., to Miss Eva May Stewart, both of Versailles, Ind., May 1.

LEWIS A. MOORE, M.D., Tower, Minn., to Miss Catherine Walter of Monroe, Wis., May 1.

THOMAS ST. CLAIR, M.D., Latrobe, Pa., to Miss Emma Howard of Hagerstown, Md., May 2.

HENRY COWLES RUCKER, M.D., Stonega, Va., to Miss Lillian Rucker of Richmond, Va., April 28.

GEORGE EDWARDS TOOLEY, M.D., Washington, Kan., to Miss Ida Erb of Kansas City, Mo., May 9.

EDGAR L. BOONE, M.D., New Martinsville, W. Va., to Miss Marie Ball of Elizabeth, W. Va., May 4.

GEORGE BYRON THOMPSON, M.D., Kansas City, Mo., to Miss Olive Bright of Los Angeles, Cal., May 15.

SAMUEL J. WYLIE, M.D., Columbus, Ga., to Miss Bessie Dudley of Girard, Ala., in Columbus, Ga., May 3.

JOHN B. STEELE, M.D., Chattanooga, Tenn., to Miss Elizabeth N. McAnally, of Huntsville, Ala., May 2.

GEORGE E. THOMPSON, M.D., Green Bay, Wis., to Miss Flora M. Dart of De Pere, Wis., in Menominee, Wis., May 2.

MAXIMILLIAN MONTROSE COOK, M.D., Columbia, Tenn., to Miss Minnie Mai Wadley of Franklin, Tenn., May 3.

WILLIAM EDWARD REED, M.D., Nashua, N. H., to Miss Elizabeth May Hankin of Clinton, Mass., at Saxonville, Mass., May 2.

Deaths

Bleecker Lansing Howey, M.D. Geneva (N. Y.) Medical College, 1843; surgeon of the One Hundred and Thirty-sixth New York Volunteer Infantry; later surgeon U. S. V., brigade surgeon and division surgeon of the Eleventh Army Corps; medical purveyor and hospital inspector of the Army of the Cumberland and medical director of the Twentieth Army Corps during the Civil War; a member of the American Medical Association; formerly vice-president and president of the New York State Medical Association; formerly president of the Monroe County (N. Y.) Medical Society and honorary member of the Rochester Pathological Society; censor of the Buffalo Medical College for 30 years, and formerly censor of the Syracuse University Medical Department; one of the oldest and most prominent physicians of Rochester, N. Y., died at his home in that city, May 5, after an illness of several months, aged 89.

James Winchell Coleman Ely, M.D. Harvard University Medical School, Boston, 1846, of Providence, R. I., who was tendered a banquet, April 27, in honor of the sixtieth anniversary of his entrance into practice; a member of the staff of Dexter Asylum for 16 years; a member of the Rhode Island Medical Society for 58 years, and its treasurer, secretary and president, and censor at various times; one of the original members, first secretary and once president of the Providence Medical Association; city physician of Providence for 16 years; consulting physician of the Butler Hospital for the Insane; attending and consulting physician of the Rhode Island Hospital for 36 years; a member, secretary and president of the Rhode Island Historical Society, and a member of the American Academy of Medicine, died at his home in Providence, May 6, from pneumonia, after an illness of five days, aged 85.

William H. Crane, M.D. Medical College of Ohio, Cincinnati, 1893; professor of medical chemistry in his alma mater; city chemist and bacteriologist of Cincinnati, and one of the best known of the younger physicians of that city, died suddenly from cerebral hemorrhage, May 7, while speaking before the Cincinnati Academy of Medicine, aged 37. Resolutions setting forth the loss sustained at the death of Dr. Crane were adopted May 8 at a special meeting of the faculty of the university medical department.

William Clarence Egan, M.D. Rush Medical College, Chicago, 1875; a veteran of the Civil War; a member of the Iowa State Medical Society, and some-time physician of Atlantic and of Cass County, died at his home in Atlantic, May 1, from valvular heart disease after a prolonged illness, aged 59. At a meeting of the physicians of Atlantic, May 2, resolutions of respect to the memory of Dr. Egan were unanimously adopted.

Esther H. Hawkes, M.D. New England Female Medical College, Boston, 1857; a nurse and surgeon during the Civil War, and for many years in charge of the work of the Freedman's bureau at Charleston, S. C.; a member of the Gynecological Society of Boston, the New England Hospital Medical Society and the Lynn Medical Fraternity, died at her home in Lynn, Mass., May 6, after a long illness, aged 72.

George W. Porter, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1851; formerly of Harrisburg, Pa.; postmaster of the city in 1867; for 13 years trustee of the State Hospital for the Insane, Harrisburg, and for several years prison inspector and secretary of the board, died May 7, at the home of his daughter in Spring Lake, N. J., aged 81.

John Dudley Meng, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1877; for four years health officer of Chico, Cal., died at the Florence Nightingale Sanatorium, Chico, April 25, from cerebral hemorrhage, after an illness of only a few hours, aged 53. At a special meeting of the physicians of Chico, April 26, resolutions of respect and sympathy were adopted.

Arthur Manley Burns, M.D. Bellevue Hospital Medical College, New York City, 1871; formerly of Brooklyn, N. Y., where he was a member of the board of health and health officer for the Greenpoint district and for six years physician of Kings County; later a resident of Alaska, died at his home in San Diego, Cal., April 26, after an illness of twelve weeks, aged 64.

Onan B. Gross, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1878; a member of the Camden City and Camden County (N. J.) Medical Society, and of the Medical Society of the State of New Jersey; one of the visiting surgeons at the Cooper Hospital, died at his home in Camden, May 9, from cirrhosis of the liver, aged 55.

James P. Hughart, M.D. New York University, New York City, 1878; a member of the American Medical Association; a Confederate veteran; president of the board of health of Hin

ton, W. Va., died at his home in that place, from malignant disease of the mouth, for which operation was performed which checked the malady for a time only, April 28, aged 65.

J. M. Boyd, M.D., founder of Baker City, Ore.; sheriff of Baker County for two terms, and for several years United States marshal for the eastern district of Oregon; for many years health officer of Walla Walla, Wash., and from 1886 to 1877 mayor of that city, died at his home, March 20, from paralysis, after a long illness, aged 68.

Philander Collard, M.D. College of Physicians and Surgeons in the City of New York, 1883; a member of the Medical Society of the State of New York and the Westchester County Medical Society, and once its president; a member of the staff of the Ossining Hospital, died at his home in Ossining, N. Y., from diabetes, May 7, aged 60.

Julius A. Johnson, M.D. University of Maryland School of Medicine, Baltimore, 1871; a member of the American Medical Association, Medical and Chirurgical Faculty of Maryland, and president of the Talbot County Medical Society; county jail physician and pension examining surgeon, died at his home near Easton, Md., May 9, aged 56.

Edwin I. Shores, M.D. Bellevue Hospital Medical College, New York City, 1880; for 12 years surgeon at the Soldiers' Home, Hampton, Va.; surgeon during the Spanish-American War; a member of the Schenectady County (N. Y.) Medical Society, died at his home in Schenectady, May 5, after an illness of three months, aged 51.

John Barry, M.D. Medical College of Virginia, Richmond, 1864; assistant surgeon of the Forty-second Mississippi Infantry, C. S. A., during the Civil War; a member of the Orange County (N. C.) Medical Society, died at his home in Chapel Hill, N. C., March 6, from angina pectoris, after a brief illness, aged 68.

Lawson Allen Long, M.D. Berkshire Medical College, Pittsfield, Mass., 1847, who is said to have warned President Lincoln of the plot for his assassination in 1861, died at his home in Holyoke, Mass., May 6, aged 78. He is said to have been one of the first to note that cholera and yellow fever were filth diseases.

Biddle Arthurs, M.D. Jefferson Medical College, Philadelphia, formerly one of the prominent surgeons of Pittsburg, and a member of the Allegheny County Medical Society, died at his home in Philadelphia, April 19, from cerebral hemorrhage, after an illness of three days, aged 78.

Carrie M. Hayward, M.D. Northwestern University, Women's Medical School, 1897, of Chicago, for eight years a member of the staff of the Mary Thompson Hospital for Women and Children, died in Malden, Mass., May 11, from cancer, after a long illness, aged 35.

Ralph R. Thompson, M.D. Medical College of Indiana, Indianapolis, 1900, of Mooresville, Ind., examining surgeon for the relief department of the Pennsylvania Railroad in Chicago, died at the Gault House in that city, May 4, from acute nephritis, aged 31.

Timothy G. Herrick, M.D. Harvard University Medical School, Boston, 1900, an interne in the Boston City Hospital for three years after his graduation, died at his home in Newport, N. H., from tuberculosis, after an illness of three years, aged 31.

James Ostermann, M.D. Baltimore Medical College, 1904, assistant physician of Salt Lake County, died at the Latter Day Saints' Hospital, Salt Lake City, Utah, May 2, from Bright's disease, after a long illness, aged 32.

John R. Keating, M.D. New York University, New York City, 1857, a Confederate veteran, for many years alderman and mayor of Cleburne, Texas, died at his home in that city, May 1, after an illness of two days, aged 71.

George Cyrus Brown, M.D. Jefferson Medical College, Philadelphia, 1874, for several years health officer of Long Beach, Cal., and a member of the Long Beach Medical Society, died at his home in that city, April 28, aged 57.

R. F. Hall, M.D. Jefferson Medical College, Philadelphia, 1855, a practitioner of Meriwether County, Ga., for more than 50 years, died at his home in Greenville, Ga., April 28, after an illness of eight weeks, aged 76.

Arthur Lee Post, M.D. Johns Hopkins University Medical Department, Baltimore, assistant professor of bacteriology in the West Virginia University, Morgantown, died suddenly in Easton, Md., May 9, aged 56.

Clarence E. Hauver, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1888, of Greenville, Ohio, died in the Memorial Hospital, Piqua, Ohio, May 5, from locomotor ataxia, after an illness of 11 years, aged 48.

A. W. Burten, M.D. Louisville (Ky.) Medical College, of Birmingham, Ala., after killing his wife and fatally wounding A. G. Thaxton, a dentist of Pratt City, Ala., cut his throat and died immediately, April 15.

Naomi A. Pierce Collins, M.D. Women's Medical College, Chicago, 1885, for many years a practitioner of Decatur, Ill., died at her home in Mahomet, Ill., May 3, after an illness of several weeks, aged 44.

David L. De Myers, M.D. Memphis Hospital Medical College, Memphis, Tenn., 1891, died from smallpox, April 29, after an illness of 12 days, near his home at Pearce Station, Tenn., aged about 50.

Edgar L. Draper, M.D. Harvard University Medical School, 1867, surgeon in the Navy during the Civil War, died at his home in Holyoke, Mass., May 6, after an invalidism of a year, aged 64.

William J. Keaney, M.D. Homeopathic Medical College of Missouri, St. Louis, 1888, died at his home in De Soto, Mo., May 3, from ptomain poisoning, after an illness of five days, aged 36.

Delos H. Mann., M.D. Albany (N. Y.) Medical College, 1848; prominent as a physician and as a total abstinence advocate, died at his home in Brooklyn, N. Y., May 2, from pneumonia, aged 70.

Alexander Allan Henderson, M.D. McGill University, Medical Department, Montreal, 1870, died at his home in Ottawa, Ont., May 3, from heart disease, after an illness of six months, aged 60.

Charles H. Holden, M.D. University of Edinburgh, Scotland, 1869, died at his home in St. John, N. B., May 2, from pneumonia, following influenza, after a brief illness, aged 61.

O. D. Fitzgerald, M.D. St. Louis Medical College, 1872, of Los Angeles, Cal., died at the Good Samaritan Hospital in that city, April 28, after an illness of several months, aged 66.

Lewis T. Gandy, M.D. Jefferson Medical College, Philadelphia, 1869, of Chili Center, N. Y., died at the City Hospital, Rochester, N. Y., three days after an operation, aged 58.

Robert Baxter Calvin, M.D. Western Pennsylvania Medical College, Pittsburg, was found dead in bed in his office at Jamestown, Pa., February 19, aged 30.

Edwin H. Chilcote, M.D. Cincinnati College of Medicine and Surgery, 1871, died suddenly from heart disease, at his home in Bloomdale, Ohio, May 4, aged 57.

Richard A. Martin, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, died at his home in Philadelphia, April 22, aged 71.

Jonathan G. Helton, M.D. Geneva (N. Y.) Medical College, 1846, of Minneapolis, Minn., died suddenly on a street car in that city, April 28, aged 81.

S. D. McCauley, M.D. Medical Department of Willamette University, Salem, Ore., 1868, died at his home in Ellensburg, Wash., January 21, aged 85.

Marshall K. Sturdivant, M.D. Tulane University of Lousiana, Medical Department, New Orleans, 1873, died at his home in Avinger, Texas, April 26.

Basil B. Crawford, M.D. University of Maryland School of Medicine, Baltimore, 1851, died at his home near Laytonsville, Md., May 4, aged 73.

John W. Winley, M.D. College of Physicians and Surgeons, Baltimore, 1892, died at his home in Benton, Pa., May 9, after a lingering illness.

Samuel Ritter Ickes, M.D. Cleveland Medical College, 1875, formerly of Harrisburg, Pa., and Brantford, Ont., died in Seattle, Wash., April 27.

Thomas H. Rucker, M.D. (County License, Indiana), 1897, died at his home in Arlington, Ind., April 21, after a long illness, aged 66.

Frank Nelson, M.D. (County License, Indiana), 1897, died at his home in Hazelton, Ind., from cerebral hemorrhage, April 29, aged 75.

Charles W. Weaver, M.D. Hahnemann Medical College, Philadelphia, 1884, died May 9 at his home in Taneytown, Md., aged 46.

Oscar H. Bradley, M.D. Castleton (Vt.) Medical College, 1851, died at his home in East Jaffrey, N. H., March 29, aged 80.

Levi Tharp, M.D. (County License, Indiana), 1897, died at his home in Boyleston, Ind., from cerebral hemorrhage, May 8, aged 47.

Charles S. Beck, M.D. Pennsylvania Medical College, Philadelphia, 1853, died in Wilkesbarre, Pa., from uremia, Dec. 25, 1905.

Louise F. Parker, M.D. New England Female Medical College, Boston, 1861, one of the first women practitioners of New England, died at her home in South Weymouth, Mass., May 9, aged 93.

A. R. Clark, M.D. (Examination, Missouri), died recently from cancer of the stomach at Pittsburg, Kan.

Deaths Abroad.

V. Vleminckx, M.D., president of the National Academy of Medicine of Belgium, aged 80.

A. Haslund, M. D., professor of dermatology at Copenhagen, aged 62.

L. Kleinwachter, M.D., professor of gynecology at Prague and Innsbruck until 1881, when he was obliged to give up teaching on account of his alleged atheism, died April 17, aged 67. His name is familiar to readers of journals devoted to obstetrics and gynecology. He resided and practiced at Czernowitz, in Austria.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

STATES RECIPROCATING WITH MINNESOTA.

CHICAGO, May 3, 1906.

To the Editor:—What states reciprocate with the state of Minnesota, based on an examination taken before the State Board of Medical Examiners of the state of Minnesota? C. C.

ANSWER.—Illinois Iowa, Kansas, Michigan, Maine, Maryland, Missouri, Nevada, New Jersey, Nebraska, Ohio, South Carolina, South Dakota, Wisconsin and Wyoming.

REGISTRATION REQUIREMENTS.

GRAND RAPIDS, WIS., May 5, 1906.

To the Editor:—What are the requirements for registration in medicine in California and in Washington? W. M. R.

ANSWER.—Both states require the passing of an examination, besides presentation of a diploma from a recognized medical college.

PADUCAH, KY., May 5, 1906.

To the Editor:—In what states can a physician register without examination? C. E. W.

ANSWER.—If he is a graduate of a recognized medical college, in Nevada and New Mexico, and with other restrictions, in Colorado.

CARDIO-RESPIRATORY MURMUR.

PHILADELPHIA, May 1, 1906.

To the Editor:—Will you kindly inform me in "Notes and Queries" of the significance of the so-called cardio-respiratory murmur, that is, a cardiac murmur heard only during inspiration?

Some authorities deny that it is pathologic, while others say that it is probably due to phthisis. In cases in which I discovered it there was no evidence of any abnormality in lungs on close examination. NAGLOC.

ANSWER.—The so-called cardio-respiratory murmur is not an uncommon phenomenon in perfectly healthy individuals. It is presumably produced by some distortion or narrowing of the blood supply at the base of the heart when the thorax is expanded. Consequently, vessels of v It may also occur in a variety of mediastinal lesions, in Arditis, etc. Its exact causation is not understood nor pleuro-peric Mo finite known in regard to its clinical significance. is anything de. C. L.

CAUSES OF IRREGULAR HEART ACTION.

BINGHAMTON, N. Y., April, 1906.

To the Editor:—Refe curring to my letter published in THE JOURNAL, April 7, p. 1048, I desire to state that none of the causes mentioned in your reply exist in this case. You may be interested to learn, as I am to report, that for the past two or three weeks the heart has resumed its normal action and that there are no more intermissions of the pulse (which has been marked and continuous for more than two years). I wish I could have an explanation of the cause. M.

THE MOSQUITO IN REFERENCE TO MALARIA.

MOUNT PISGAH, ARK., May 3, 1906.

To the Editor:—Please tell me the best work on the mosquito with reference to malaria. Can malaria be transmitted in any other way than by the mosquito? I have the works of Boston, Osler and Anders, and simply want a more detailed work.

S. T. TAPSCOTT.

ANSWER.—So far as now known, he only way in which malaria is naturally transmitted is by the mosquito. There are a number of short books dealing with malaria and mosquitoes, all of which we shall not attempt to enumerate. Mention may be made, however, of L. O. Howard's book on "Mosquitos," in which their relation to malaria is discussed fully; of Celli's monograph on malaria, which is translated from the Italian, and in which not only the rôle of the mosquito is considered, but also the economic side of malaria, especially so far as Italy is concerned; and of Ross' discourse before the Royal Institution of Great Britain (March 2, 1900), in which the story of the discovery by Ross himself of the actual rôle of the mosquito to malaria is told in a most interesting manner. This discourse is reprinted in the form of a little booklet (George R. Philip & Son, 32 Fleet Street, London, and Philip, Son & Nephew, 75 South Castle Street, Liverpool). In Manson's Lectures on Tropical Diseases, recently reviewed in THE JOURNAL, is also an excellent account of the malaria parasites as they occur in man and mosquitoes. There are numerous other monographs than those here mentioned, a full list of which any medical book-seller can furnish, but we believe that Ross' discourse merits special emphasis as the nucleus for further reading on malaria and mosquitoes.

THE PHYSICIAN AND THE AUTOMOBILE.

DR. R. L. HOYT, Oriole, Md., writes: "I am contemplating the purchase of an automobile and awaited the appearance of your automobile number, April 21, with interest. After reading it carefully I am in just about the same position as before, namely, I can not decide which machine will do the service I desire. If you will help me out I will be under lasting obligation to you. I wish you would refer this letter to some members of the profession who have experience with conditions such as I describe below, with the request that they write me. I am doing a country practice requiring the services of three good horses in the summer and four in the winter months, with an average daily drive of about fifty to sixty miles. My work is entirely in the country, as the village in which I reside is of about 600 population, but the road conditions are the same as the surrounding territory. From April 1 to November 1 our roads are in good condition, the soil being clay and the roads hard. From November 1 to April 1 they are awful, being simply a clay muck, full of holes and ruts. In winter it is about all two good horses can do to pull a light buggy at a trot. Thank you in advance for any assistance you can render me in this matter."

DR. WILLIAM STANTON, Webster, N. J., says: "I was very much interested in the automobile articles. It seems strange to me that the manufacturers all seem to strive to make an automobile resemble a trolley or steam car in size, weight and seating capacity. In horse-frightening qualities, noise and dust-raising they have the trolley outdone, and are a close second to it in cost, speed and in requiring a hard smooth track. Now, if some manufacturer would turn his skill and attention to produce an automobile resembling a stanhope or carriage in size, weight, appearance and comfort he could doubtless give it wheels adapted to the highway, a motor simple enough to be understood by a man of ordinary mechanical ability, and strong enough to propel it over all ordinary country roads with reasonable speed, safety and certainty. Probably he could sell it for the cost of two good horses, the necessary carriages, harnesses, etc., and make a good profit. I believe there is need of such an automobile and that the man who brings out a practical auto-carriage for country roads will confer a lasting favor on the medical profession and will find himself deluged with orders."

DR. T. M. BRIDGES, Idaho Falls, Idaho, writes: "I have read with interest the interesting articles in THE JOURNAL, April 21, and I wish to ask about solid rubber tires. I have used a runabout for two years with the utmost satisfaction and practically no tire troubles until recently. I have long contemplated putting on solid tires, and will appreciate your advice as to a reliable maker. I do an immense amount of work and have never been towed in or had an accident delaying me more than half an hour. Our roads, however, are perfect almost throughout the year."

DR. S. S. DAVIS, Boonsboro, Md., writes: "Your editorial in THE JOURNAL, April 21, in regard to automobiles for physicians was very opportune and pertinent. I keep three horses and numerous vehicles, and though this liver(y) of mine is kept rather active, I am fast becoming automo-billous. I have no doubt there are thousands of physicians like myself, waiting for that machine to turn up—the right kind at the right price."

DR. J. A. KINIGAN, New York, writes: "For the past three years I have been making a study of the automobile as applied to the use of the doctor. The symposium on this subject published in THE JOURNAL is the most interesting and instructive dissertation on the automobile that I have come across."

DR. J. G. HUIZINGA, Grand Rapids, Mich., says: "Up to date the machine is not sufficiently reliable. One never knows when a breakdown is going to occur, and it often takes place at most inopportune times. The machines are being made more perfect every year, but perfection is still a future consideration."

DR. DE FOREST LAMBERT, Salem, Mass., writes: "In regard to my ideal car (described in THE JOURNAL, April 21), I have interested a machinist in my specifications, and he already has plans under way for such a car. There are a number of physicians about here who desire such a car, believing that it will to a large extent solve the problem of a doctor's car. If those interested in this type of machine to the extent of desiring one, would write me, some idea of the demand for it could be had and its production hastened. The price would be, probably, in the vicinity of $800, depending on number built. I am informed that the company has plenty of money, but will not place the machine on the market unless a sufficient number will express a demand for it."

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending May 12, 1906:

Lippitt, Wm. F., surgeon, resignation of his commission as an officers of the Army has been accepted by the President, to take effect, May 26, 1906.

The following named assistant surgeons will proceed at once to San Francisco, Cal., and report in person to the commanding general, Pacific Division, for temporary duty: Captains Edward F. Geddings, Leigh A. Fuller, Frederick M. Hartsock, Walter D. Webb, David Baker; First Lieutenants George H. Scott, Roger Brooke, Jr., Wm. H. Moncrelf, Nelson Gapen, Compton Wilson.

Hallock, H. M., surgeon, sick leave of absence further extended one month.

Bushnell, Geo. E., surgeon, detailed to represent the Medical Department of the Army at the meeting of the National Association for the Study and Prevention of Tuberculosis, at Washington, D. C., May 16 to 18, 1906.

Wertenbaker, Clark L., contract surgeon, left Madison Barracks, N. Y., on leave of absence.

McCord, Donald P., contract surgeon, returned to Fort Rodman, Mass., from leave of absence.

Hereford, John R., contract surgeon, left Fort Moultrie, S. C., and arrived at Fort Caswell, N. C., for temporary duty.

Kelly, John P., contract surgeon, left Presidio of Monterey, Cal., and arrived at San Francisco, Cal., on duty with the 20th Infantry.

Koyle, Fred T., contract surgeon, left Fort McDowell, Cal., and arrived at Fort Mason, Cal., on duty with the 22d Infantry.

Hayes, Melville A., contract surgeon, left Vancouver Barracks, Washington, and arrived at Fort Casey, Washington, for temporary duty.

Gardner, Fletcher, contract surgeon, left Fort Michie, N. Y., and arrived at Fort H. G. Wright, N. Y., for temporary duty.

Griswold, W. Church, contract surgeon, returned to Fort Dupont, Del., from leave of absence.

Rietz, Hugo C., dental surgeon, left Fort Thomas, Ky., and arrived at Fort Wayne, Mich., for duty.

Porter, Elias H., contract surgeon, ordered to duty with troops in Yosemite National Park, Cal.

Kean, Jefferson, Woodruff, Charles E., and Lynch, Charles, surgeons, detailed to represent the Medical Department of the Army at the 57th annual meeting of the American Medical Association.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending May 12, 1906:

Old, E. H. H., asst.-surgeon, detached from the Naval Training Station, San Francisco, and ordered to the Naval Hospital, Canacao, P. I., sailing from San Francisco, May 25.

Steele, J. M., Medical Inspector, detached from the *Brooklyn* and ordered home to wait orders.

Brown, E. M., P. A. surgeon, ordered to the Naval Hospital, New York, N. Y.

Dorsey, B. H., asst.-surgeon, ordered to the *Lancaster*.

Belknap, J. L., asst.-surgeon, detached from the *Brooklyn* and ordered to the *Kentucky*.

Randall, J. A., asst.-surgeon, detached from the *Kentucky* and ordered home to wait orders.

Bogan, F. M., P. A. surgeon, ordered to the *Marietta*, when that vessel is placed in commission.

Grieve, C. C., asst.-surgeon, detached from the *Wilmington* and ordered home.

Rennie, W. H., asst.-surgeon, detached from the *Elcano* and ordered home.

Verner, W. W., asst.-surgeon, detached from the *Wisconsin* and ordered home.

Wikes, G. L., asst. surgeon, detached from the *Ohio* and ordered to the *Wilmington*.

Sellers, F. E., asst.-surgeon, ordered to the *Ohio*.

Olsen, G. M., asst.-surgeon, ordered to the *Wisconsin*.

Eytinge, E. C. J., asst.-surgeon, ordered to the *Elcano*.

Blackwood, N. J., surgeon, detached from the Naval Torpedo Station, Newport, R. I., and ordered to the *New Jersey*, when that vessel is placed in commission.

Morris, L., surgeon, ordered to the Naval Torpedo Station, Newport, R. I., and to additional duty in attendance on Navy and Marine officers, not otherwise provided at that station with medical aid.

Hathaway, G. S., asst.-surgeon, detached from the *Constellation* and ordered to the *New Jersey* when the latter vessel is placed in commission.

Cole, H. W., Jr., asst.-surgeon, detached from the *Maine* and ordered to the *Alabama*.

McLean, A. D., asst.-surgeon, detached from the *Alabama* and ordered home to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending May 9, 1906:

Bailhache, P. H., surgeon, detailed to represent the service at the meeting of the American Medical Association, to be held in Boston, Mass., June 5-8, 1906.

Meade, F. W., surgeon, directed to report in Washington, D. C., for special temporary duty.

Carmichael, D. A., surgeon, granted leave of absence for seventeen days, from May 17, 1906.

Brooks, S. D., surgeon, relieved from "waiting orders" and directed to proceed to San Diego, Cal., and assume command of service at that port.

Woodward, R. M., surgeon, detailed to represent the service at the meeting of the American Medical Association, to be held in Boston, Mass., June 5-8, 1906.

Mathewson, H. S., P. A. surgeon, granted leave of absence for two months, from June 1, 1906.

Earle, B. H., P. A. surgeon, directed to report in Washington, D. C., for special temporary duty.

Frost, W. H., asst.-surgeon, relieved from duty at Ellis Island, N. Y., and directed to report to the medical officer in command, Baltimore, Md., for duty and assignment to quarters.

Addis, W. E., acting asst.-surgeon, granted leave of absence for four days, from May 3, 1906, under Paragraph 210 of the Regulations.

Hallet, E. B., acting assistant surgeon, granted two days' leave of absence from May 6, 1906.

Safford, M. V., acting assistant surgeon, granted leave of absence for three days from April 30, 1906, under paragraph 210 of the regulations.

McKay, M., Pharmacist, granted leave of absence for one day, May 5, 1906.

BOARDS CONVENED.

Board convened to meet in Washington, D. C., May 9, 1906, for the purpose of making sanitary inspection of certain public buildings. Detail for the Board: Surgeon F. W. Meade, chairman; P. A. Surgeon B. H. Earle, recorder.

Board convened to meet at Baltimore, Md., May 10, 1906, for the purpose of conducting physical examinations of cadets of the Revenue Cutter Service. Detail for the Board: Surgeon L. L. Williams, chairman; Asst.-Surgeon W. H. Frost, recorder.

Board convened to meet in Washington, D. C., May 10, 1906, for the purpose of conducting physical examinations of candidates for appointment as cadets in the Revenue Cutter Service. Detail for the Board: Asst. Surgeon-General W. J. Pettus, chairman; Asst. Surgeon-General J. M. Eager, recorder.

Board convened to meet in Washingtoo, D. C., May 7, 1906, for the purpose of conducting physical examinations of an officer of the Revenue Cutter Service. Detail for the Board: Asst.-Surgeon-General J. W. Kerr, chairman; Asst.-Surgeon J. W. Trask, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 11, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, April 21-28, 4 cases.
District of Columbia: Washington, April 21-May 5, 4 cases.
Georgia: Augusta, April 29, 5 cases; April 23-May 7, 4 cases.
Indiana: Indianapolis, April 1-8, 3 cases; April 29-May 6, 2 cases.
Louisiana: New Orleans, April 21-May 5, 26 cases.
Massachusetts: Boston, April 28-May 5, 1 case.
Mississippi: Natchez, April 29-May 6, 3 cases.
Missouri: St. Louis, April 28-May 5, 1 case.
Nebraska: Omaha, April 28-May 5, 2 cases.
North Carolina: General, March 1-31, 10 cases.
North Dakota: General, March 1-31, 3 cases.
Ohio: Cincinnati, April 27-May 4, 10 cases, 1 death.
Oklahoma Territory: Oklahoma City, April 21-May 5, 31 cases.
South Carolina: Greenville, April 21-28, 1 case.
Tennessee: Knoxville, April 28-May 5, 1 case.
Utah: Ogden, April 1-30, 4 cases.
Virginia: Petersburg, March 26-April 26, 6 cases; Roanoke, April 1-30, 16 cases.
Wisconsin: Appleton, April 28-May 5, 1 case; Green Bay, 1 case; La Crosse, 1 case; Marinette, April 21-28, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 10-17, 2 cases, 2 deaths.

SMALLPOX—FOREIGN.

Africa: Monrovia, March 1-31, 3 cases.
Austria: Trieste, March 31-April 7, 1 case.
Canada: Toronto, April 21-28, 1 case.
China: Hongkong, March 17-24, 19 cases, 5 deaths; Shanghai, March 24-31, present.
Germany: Bremen, March 31-April 21, 2 cases, 1 death.
Gibraltar: April 15-22, 3 cases.
Great Britain: Bristol, April 14-21, 2 cases; Newcastle-on-Tyne, 3 cases.
Greece: Athens, April 14-21, 3 deaths; Patras, March 20-27, 2 cases, 2 deaths.
India: Bombay, April 3-10, 23 deaths; Calcutta, March 24-31, 224 deaths; Karachi, April 1-8, 34 cases, 17 deaths; Madras, March 31-April 6, 46 deaths; Rangoon, March 24-31, 62 deaths.
Italy: General, March 22-April 19, 176 cases.
Mexico: Vera Cruz, April 21-28, 2 cases.
The Netherlands: Rotterdam, April 14-21, 1 case.
Spain: Barcelona, April 10-20, 7 deaths; Seville, March 1-31, 15 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, March 18-April 15, 11 cases, 7 deaths.
Honduras: Chaloma, April 21, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Provinces, March 10-17, 116 cases, 101 deaths.
India: Bombay, April 3-10, 35 deaths; Calcutta, March 24-31, 31 deaths; Madras, March 31-April 6, 1 death; Rangoon, March 24-31, 3 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, March 10-17, 1 case, 1 death.

PLAGUE—FOREIGN.

Australia: Freemantle, March 3-24, 3 cases, 1 death; Geraldton, 2 cases, 1 death; Sydney, March 10-17, 7 cases.
Brazil: Rio de Janeiro, April 1-15, 3 cases, 1 death.
India: Bombay, April 3-10, 782 deaths; Calcutta, March 24-31, 232 deaths; Karachi, April 1-8, 150 cases, 126 deaths; Rangoon, March 24-31, 86 deaths.

COUNCIL ON MEDICAL EDUCATION OF THE AMERICAN MEDICAL ASSOCIATION.

Second Annual Conference, held in Chicago, May 12, 1906.

There were present delegates from state examining boards, state medical societies, government medical services, colleges of liberal arts and other organizations, as follows:

State Delegates: Colorado, S. D. Van Meter, Denver; Illinois, Harrison W. Hipp, Chicago; Indiana, J. C. Webster, Lafayette, W. A. Spurgeon, Muncie; Minnesota, W. S. Fullerton, St. Paul; Mississippi, E. J. Johnson, Yazoo City; Missouri, Frank J. Lutz, St. Louis; Nebraska, S. K. Spalding, Omaha; New York, W. W. Potter, Buffalo and Charles F. Wheelock, Albany; North Dakota, H. M. Wheeler, Grand Forks; Ohio, A. Ravogli, Cincinnati and H. E. Beebe, Sidney; South Dakota, Stephen Olney, Sioux Falls; Tennessee, L. E. Burch, Nashville; Washington, P. B. Swearingen, Tacoma; West Virginia, M. H. Proudfoot, Rowlesburg; Wisconsin, W. T. Sarles, Sparta, A. P. Andrus, Ashland, and J. V. Stevens, Jefferson.

State Medical Societies: Indiana, J. B. Berteling, South Bend, and L. F. Page, Indianapolis; Kentucky, W. H. Wathen, Louisville; Missouri, R. M. Funkhouser, St. Louis; Minnesota, F. F. Wesbrook, Minneapolis; Illinois, J. W. Pettit, Ottawa, and D. B. Phemister, LaGrange.

American Medical Association, Geo. H. Simmons, Chicago; Committee on Reciprocity, American Medical Association, William L. Rodman, Philadelphia; Association of American Medical Colleges, F. C. Zapffe, Chicago; National Confederation of Eclectic Medical Colleges, E. J. Farnum, Chicago, and E. G. Trowbridge, Chicago; American Medical Editors' Association, W. C. Abbott, Chicago. William F. Waugh, Chicago; Public Health and Marine-Hospital Service, Passed Asst. Surg. G. B. Young, Chicago.

Others present were:

Dr. B. D. Myers, Indiana University, Bloomington; Professor J. H. T. Main, President of Iowa College, Grinnell; Dr. S. W. Lambert, Columbia University, New York City; Dr. Frederic S. Dennis, Cornell University, New York City; Dr. Chas. R. Bardeen, University of Wisconsin, Madison; Dr. John M. Dodson, Rush Medical College, Chicago; Dr. F. C. Waite, Western Reserve University, Cleveland; Professor I. B. Burgess, Morgan Park Academy, Morgan Park, Illinois.

Full reports of proceedings will appear in the next issue of THE JOURNAL

FIFTEENTH INTERNATIONAL MEDICAL CONGRESS.

Held in Lisbon, Portugal, April 19-26, 1906.

[Special Correspondence from Dr. Nicholas Senn.]

ALGIERS, AFRICA, April 27, 1906.

The Lisbon International Medical Congress has passed into history. Its successes and shortcomings have become matters of record. It was safe to predict that the attendance would be unusually small and that the scientific work would fall short of the average of these triennial great gatherings of physicians from all parts of the globe. The entire number of delegates registered did not exceed 1,600. It could readily be foreseen that two Latin congresses in succession could not fail to reduce the actual attendance to a minimum. A very large majority of the members present were Spaniards, Portuguese and delegates from countries in which the Latin languages are spoken. The United States contributed about 50. Germany was especially well represented in the military section. Few of those from abroad who participated in the Madrid Congress repeated their attendance this year. Most of them had learned from sad experience to dread the miserable railway service and the Babylonic confusion of languages in the general sessions, section work and social functions. The two magnets which attracted not a few to this congress were the beautiful city of Lisbon and the charming Queen Amelia, whose beauty, charity and profound learning have been made known to the outside world through magazine articles and the columns of the public press.

The City of Lisbon.

The average reader accords to Naples the first place among the world's most beautiful cities. The smiling blue bay, the towering, smoking Vesuvius provide a worthy fore- and background for this proud mistress of Italy, but can not serve as a counterpart to the vastly greater picturesqueness of the city of Lisbon as compared to that of Naples. The Tagus, which here is expanded into a broad lake-like basin or quai, constitutes an immense land-locked harbor which is visited annually by 4,000 vessels from all parts of the world—compares well with the Bay of Naples in size and the beauty of its surroundings. The city itself in a dress of immaculate white rises in terraces from the border of the river and crowns the summits of the group of high hills, the highest of them capped by the ancient fortress of St. George, now garrisoned by 400 soldiers. The narrow, crooked, but clean streets communicate with a number of broad, park-like boulevards. Lisbon, although a very old city, has been rejuvenated and has kept pace with the progressive spirit of modern times. It is lighted by electricity and has an excellent water supply and system of sewerage. The numerous electric tramways find their way from the broad avenues through the narrow, irregular, serpentine streets to all parts of the city and suburbs. Many substantial modern business and government buildings impart dignity and an aspect of durability to the principal business streets.

The hotel facilities are ample and there was no undue congestion caused by the presence of the congressites which caused so many complaints during the Madrid congress. Begging and indications of abject poverty were seldom seen on the streets even in the poorest quarters of the city. Two large, clean markets are the busiest places during the early morning hours where the laboring people can supply themselves with food for the day by the outlay of a few cents, the freshest and best that the soil and sea produce. The present population is about 350,000. The people are well dressed and well behaved

Queen Amelia.

Queen Amelia is a remarkable woman physically and mentally. She is above average size and weight, and every look and movement denote a noble bearing. A scion of the noblest and most aristocratic family of France, she was trained from earliest childhood for her present exalted position. The large black eyes, firm well-formed lips, high forehead and luxuriant jet black hair, sharp, perfectly modeled nose, heavy eyebrows and long lashes, pearl-white perfect teeth, round chin, fair complexion and perfect form of face make up a picture of classic beauty. She is one of the most intellectual women of the present age. She speaks several languages, among them excellent English; is a member of the medical profession, in which she takes the keenest interest, and is a trained nurse as well. A picture in which she delights and which is very popular among her subjects is the Queen dressed in the garb of a nun rendering first aid to the wounded. The hospital and clinic for patients suffering from tuberculosis is her own creation built and maintained out of her own private means. She is the mother of two sons, the Crown Prince, now 18 years old and his brother, two years younger. She is a devoted mother giving her own attention to the education and training of her

nildren. She is very wealthy in her own right and makes free se of her wealth in relieving the sick and poor. She was the enter of attraction during the opening exercises and at the inner given by the King to the official delegates of the con-ress.

Opening Exercises.

The opening exercises took place in the great hall of the eographical Society at 2 o'clock, Thursday, April 19. The reather was perfect. Long before the hour fixed for the exer-ses the immense hall and two galleries were densely packed ith surging masses of humanity, all in gala attire. High ourt officials, ambassadors, military officers, university men in arlet gowns, lent a special attraction to the brilliant audi-nce. Shortly after 2 o'clock the strains of a military band tationed in the rear of the hall playing the national air an-ounced the arrival of the King. King and Queen, followed y the queen dowager and court officials, walked up slowly hrough the central aisle and took their places on the plat-orm. To the right of the King sat the Queen; to the left his nother, the Queen Dowager. The King is about 40 years of ge, a blonde with blue eyes, curled mustache, of average eight but very corpulent. He presided with a dignity worthy f his high position. He wore a full dress military uniform ith few decorations. The Queen wore a rich but plain gown, er only ornament being a necklace of large pearls which raced her handsome neck. The King read his address of wel-ome in French from the chair. He spoke slowly and dis-nctly, and with great earnestness. During the delivery of he speech the silence in the hall was profound, and every word oming from his lips was eagerly caught by those near enough o hear him. I was fortunate enough to be given a place on he platform within ten feet of the speaker, and hence enjoyed o the fullest extent the excellent address so magnificently elivered. I can give here only an abstract.

King's Address of Welcome.

"Madam, Ladies and Gentlemen:—In uniting in this Con-ress, so eminently scientific and humanitarian, you are per-orming a beautiful and worthy deed. First of all, let me ongratulate you most sincerely, and in the name of the ountry which now receives you and of which I am the su-reme magistrate, I extend to you all a cordial welcome. As part of the heritage which the century which we have seen orn has bequeathed to our children are these magnificent sci-ntific international gatherings. They attest the solidity and he intellectual fraternity of nations and their representatives ome to them bringing the best offerings of their work and heir activities. In truth, I repeat, in taking part in this con-ress you accomplish a good and beautiful work, because othing is more laudable than a conquest on the vast field of cience, nothing is better than the alleviation of pain and istress. Your learned assembly is about to add, I am sure, rom all I know of your past, a new and brilliant page to the ook of universal science; and the science of medicine is bout to pass in review here the thousands of soldiers whom he has temporarily detached from her powerful army in order o camp, to-day in the shadow of the flag of Portugal. ach of you comes to tell both of the severity of the strug-les and of the glory of these victories, struggles against vil, the most noble of all combats engaged in, from the eld of battle among the cannons which vomit suffering and eath, amid fire and tumult, to the serenity, the repose of the aboratory, among the enemies infinitely small, which coldly, si-ently, without noise or eclat each day strew the earth with ore dead than the most destructive implements of war.

"In the six days of the congress, the six mystic days of work, e will see, as in an immense kaleidoscope, rise up facts, ob-ervations, analyses, investigations. All these will clash gainst each other, will be grouped together and displayed in he most varied combinations, bewildering our eyes with un-xpected forms of images and thereby giving us an impression f the actual state of medical science and to your confrères he point of departure for new conceptions, for still greater onquests. From this assembly where are united so many sa-ants of such wide renown will descend as from a torch on the ighest pinnacle a flood of new light pure and white like that rom glaciers, slow in its progress but irresistible in its ac-tion, a force to drive back before its power pain and death. Your brains are the source of the stream, brilliant and pure, of the sublime torrent. By their powerful action you blaze the way, open up the bosom of Nature to reveal her secrets which will en-able you to render human life stronger and more tranquil.

"You are in a country which knows and appreciates your work, and I can assure you it would be impossible for any country to be more in sympathy with all your actions. Portugal is with you in the accomplishment of that which she knows to be her earthly duty. She never forgets that peoples are citizens of the world, and that just as the citizens of each country have a duty toward their native land, so have nations their duty toward humanity. Portugal has been one of the pioneers in the civilization of the world. She will not renounce her ancient traditions, and with them she receives you on a civilizing mission for the good of humanity. As for me personally, I am entirely in accord with you. Having been an ardent lover of the natural sciences, I admire, comprehend and respect you; and I am happy to be able to assure you that you may rely on me to do everything in my power to aid you. As for her Majesty, the Queen, my beloved consort, in the work she has done with others in the combat against tuberculosis, she has indeed given you proof of how sincerely she is in sympathy with your work. In closing, I wish to thank the committee of organization of the congress for requesting me to preside at this inaugural session. I am very grateful for this honor, and I am proud to find myself here to-day, your president, and to be able again to join my most sincere wishes to those of my country, which is proud to receive and welcome you to-day in its capital city, that the results of this congress may serve the cause of humanity. The congress is now open."

The exit of the royal party was made in the order and manner as its entrance, the audience standing and the band playing. Much of the balance of the afternoon was occupied by additional speeches of welcome and the responses to them by delegates from each country represented, the call for those being made in alphabetical order. That no country was overlooked became evident when a physician from Monaco was called on to respond and although he represented the smallest government in the world, he occupied vastly more time than Captain Richard of the Army, who responded in a few well-chosen words for the United States.

Place of Meeting.

All of the work of the congress took place in the new medical college, including registration and all executive business. The arrangements here were perfect and all officials courteous and obliging. The building is a modern one, and proved admirably adapted for the needs of the congress. Business was conducted much more promptly and systematically than at Madrid. Exhibitions were conspicuous for their absence, and physicians who came here for the purpose of collecting a supply of proprietary medicines were sadly disappointed. The well-equipped laboratories were at the disposal of the delegates, who made free use of them in making their demonstrations. As all the sections met in the same building, it was easy to go from one to the other, either for the purpose of change of subject under discussion or to meet friends. It is true if the congress had been large the space for the general meetings and section work would not have sufficed. As the attendance was small, ample room was given to each section with the exception, perhaps, of the military, which afforded scant space for sixty persons, and being the one which on an average had the largest attendance, it was sometimes badly crowded.

Scientific Work.

The subjects of the general addresses were modern and opportune. They comprised: "Relations of Acute Infectious Diseases with Tuberculosis," by Dr. Aaser of Christiania; "The Prophylaxis of Yellow Fever as the Result of the 1905 Epidemic in Central America and New Orleans," by Professor Boyce of Liverpool; "Infantilism," by Dr. Brissaud of Paris; "The Mechanism of Reflexes and of Muscular Tonus," by Professor Crocq of Brussels; "The Significance of Domestication for Diseases of Animals and Man," by Professor von Hansemann of Berlin; "The Anatomic Causes of Syphilitic Relapses and

Methods to Follow to Combat Them," by Professor Neumann of Vienna; "Local Anesthetics," by Professor Reclus of Paris; "Radium in Biology and Medicine, or Organo therapy of Our Days," by Prince Jean de Tarchanoff of St. Petersburg. I had the honor to deliver the oration for the United States and selected for my subject: "A Plea for the International Study of Carcinoma," at the close of which I suggested the appointment of an international committee to study this subject from non-parasitic standpoints and to report the results of their work to the next congress. [This article appeared in THE JOURNAL, April 28, 1906.]

The programs of all the sections, as usual, contained more material than could properly be disposed of even in six days. Many of the titles lacked the paper as well as the author. This vicious practice of sending in titles and names without any intention on the part of the prospective authors to attend the congress should be suppressed. This practice is by no means uncommon and is a cheap and cowardly way to get names into print, and is always a source of embarrassment to the officers of the sections. Another practice equally detestable is to gorge the programs of the sections with the titles of papers read perhaps years ago before some medical society, large or small, as the case may be, without the authors having made any material alterations or additions. This dishing up of stale food on such important occasions can not be

Fig. 1.—The King and Queen of Portugal.

done away with too soon. The section work of the congress is in need of revision to the effect of reducing the number of papers and the exclusion of material that has done previous service. There is too much reading in the sections and too little discussion and demonstration. Many a time have I seen more than half of the members napping during the reading of a long paper in a monotonous, even tenor of voice. Interesting demonstrations, on the other hand, no matter whether or not the language of the speaker is understood, always rivet the attention of the audience.

Language of the Congress.

The three official languages of the congress are supposed to be French, German and English, but during the Madrid and Lisbon congresses Spanish, Italian and Portuguese were not infrequently made use of. French was the prevailing language and next came German. I admired the Germans for remaining faithful to their mother tongue, although it found few receptive ears. The English language was seldom heard, and when spoken fell on barren ground. When I presented my paper on "First Aid on the Battlefield," in the Military Section, there were about 60 members present, and of this number I am sure that not more than four or five understood a word of what I said. I was prepared for this kind of an audience, and only occupied a few minutes in presenting the salient points of the paper and in making some demonstrations, and in doing so held the attention of the audience. As Americans, it is our imperative duty to give countenance to the language of our country and to popularize the same on all occasions. The English language to-day is the commercial language of the world, the German and French remain the polite languages. It is safe to predict that if at any time a single language is to be the official language of the congress it will be the English, in spite of the opposition made to it up to the present time.

Social Entertainments.

This, like all the previous congresses, has been surcharged with social entertainments of all kinds, including excursions to suburbs on the River Tagus, bull fights, receptions, dinners, garden party, etc. For the American delegates the most notable entertainments were a dinner given by Colonel Bryan, our minister plenipotentiary at the court of Lisbon, to the American delegates, and the dinner given by the King to about 150 official delegates representing all nations. Colonel Bryan

Fig. 2.—Dr. Costa Alemao, President of the Congress.

occupies the Avenida Palace, a former house of royalty, on the most beautiful boulevard of the city. It is a real palace, not only in name, but in its outward and inward appearances, and is maintained as such by its present occupant, who is, besides an able representative of our government, a liberal and charming entertainer. His greatest pleasure is to meet, aid and assist his countrymen. The dinner he gave to the American contingent of the congress was attended by about 50 guests and was in every respect a great success. In this function the host was assisted by his sister, Miss Bryan, and his cousin, Mrs. Page, of Washington, D. C. The table decorations were superb and a splendid band furnished the music. The courses were many, and every one of them testified to the skill of the chef of the kitchen. The mental feast included toasts to President Roosevelt, the King and Queen of Portugal and our honored host. It was after midnight when the well-entertained guests returned to their respective hotels. This occasion was a very pleasant one, and

will live forever in the memory of all those who were present. We have reason to feel proud of our minister at this legation, as he is very popular with the royal family, the natives, and it is his greatest pleasure to be of service to his countrymen.

The King's Dinner.

The dinner of the King was given Saturday evening, at 8 o'clock, April 21, at the palace, and was attended by about 150 of the official delegates, which, with the court officials and ambassadors, brought the whole number of guests up to 200. The American delegation received its full share in this ovation—eight places. The dinner was a very brilliant affair, being attended by the King, Queen, Queen Dowager, diplomats and military officers, all in full-dress uniform. The King wore the same uniform as at the opening exercises, but the Queen appeared in court dress and wore a tiara of diamonds and a broad necklace of precious stones, which dazzled the eyes of the uninitiated. The three flights of stairs we had to

Fig. 3. Professor Miguel Bombarda, Secretary General of the Congress.

ascend were lined on both sides with halberdiers in ancient costume, so it was impossible to lose the way to the reception room. When the hour for dinner arrived, the royal party walked directly through the passageway made by the separation of the assembled guests and took their seats in the center of the two long tables placed parallel to each other, the King on the left and the Queen on the right side, and the guests followed each of them, supplied with a card which accompanied the formal invitation and which indicated the place and number of their seat. The service was perfect, the menu such as can only be done justice to in a royal kitchen, and all of the wines exquisite. I was fortunate to find Professor Curschmann of Leipsic as my left-hand neighbor, and we enjoyed together, besides the superb dinner, a rich mental feast. The King and Queen were served each by a waiter of their own. After dinner the hosts and guests returned to the reception room, where the presentations took place.

Colonel Bryan performed this function for the American delegates. We were first introduced individually to the King, then to the Queen Dowager and lastly to the charming Queen. Almost without exception the delegates kissed the bare hand of the ladies. This as a citizen of two republics I refused to do on this as well as on several former similar occasions. I look on this custom as a relic of the chivalric age, as effeminate, as improper for any citizen of the Great Republic of the United States to comply with. It is my conviction that it is eminently proper to carry our republican customs with us and practice them abroad as well as at home. It was half-past 12 o'clock when we left the palace. The Portuguese, like the Spaniards, are extremely hospitable people and exert themselves to make the social entertainments pleasant and agreeable for all present. On the whole, the social features of every congress have consumed too much time and have been the means of detracting too much from the scientific work of the meetings. A curtailing of these functions is one of the urgent needs of the International Medical Congress.

Abused Privileges—Delegates and Members.

The present system of delegation of the congress is wrong in more than one way. In the first place, any one can become a member of the congress by paying the stipulated fee. This privilege, extended to laymen and physicians, increases the attendance without adding to the working force of the congress. Many take advantage of this provision in order to secure reduced rates and to take part in the social entertainments of the congress. Such attendance is a heavy ballast on the efficiency of the scientific work of the congress and a source

Fig. 4.—The new Lisbon Medical School.

of discomfort to the legitimate members of the congress—the delegates—as they crowd the railway trains and hotels and tax the financial resources of the committee of organization without giving an equivalent of any kind. Lay membership should be abolished. If this were done the doors to the congress would likewise be closed to physicians who have no standing in the profession. In the second place, delegates from disreputable institutions find their way into the congress, although they are not eligible to membership in the smallest and remotest county medical society. Restriction in the matter of appointment and acceptance of delegates should be strictly carried out at the next and all future meetings of the International Medical Congress.

Additional Report of Congress.

From the reports of other representatives and from the accounts in our British, French and Portuguese exchanges THE JOURNAL adds the following details:

The list of presidents of honor appointed for the congress included Nicholas Senn, J. N. Van der Veer and H. E. Bell of this country; Waldeyer, Freudenberg, von Hansemann, Kraepelin and O. Lassar of Germany; Obersteiner and Dollinger of Austria and Hungary; Cornil, Laveran, Bouchard, Landouzy, Poirier, Magnan, Blanchard and Brissaud of Paris, with Pavy Sir Dyce Duckworth, Barlow, D. Ferrier, Mayo Robson and Fergusson of England. The addresses in the 20 different sections and subsections were numerous and many of them were important contributions showing the present status of various medical questions. The views of most of the speakers are

known to our readers, as they have been published or summarized in these columns more or less recently.

International prophylaxis of tuberculosis was urged by S. Bernheim, with the appointment of an international commission to draw up an international code of regulations against the disease. J. Cabral of Lagos presented an exhaustive essay on the subject of epidemic cerebrospinal meningitis based on 178 cases. He found the most effectual treatment to be lumbar puncture either alone or followed by injection of a 1 per cent. solution of lysol or of cyanid of mercury, possibly supplemented by leeches to the mastoid apophyses and wet cupping along the spine, with administration of calomel, opium and bromid. He used also intestinal injection of two quarts of water, alone or with some mild purgative. Weichselbaum attributed the focus of infection and contagion to the nasopharynx. As the micrococcus has little resisting power, it rapidly succumbs outside of the human body. França of Lisbon found lumbar puncture extremely beneficial in his experience with 271 cases, repeated daily or several times a day, withdrawing about 45 c.c. of the fluid, following with injection of some antiseptic. He regards lumbar puncture as curative for the non-bacterial forms of meningitis and palliative at least in the tuberculous form.

DANGER OF MUCH MERCURY IN GENERAL PARALYSIS.

An article on this subject, read by Raymond of Paris elicited corroboratory testimony, although several speakers reported benefit from mild mercurial treatment in the early stages, especially by the Leredde technic.

SURGICAL TREATMENT OF SPASTIC AND PARALYTIC AFFECTIONS.

Vulpius remarked in his address on this topic that although the ultimate results of tendon transplantation in the treatment of contractions and paralyses of nervous origin had not entirely fulfilled the early anticipations, yet they can be regarded as very encouraging. A complete cure can not be expected unless the paralysis is very limited, but satisfactory functional improvement can be counted on for appropriate cases with suitable after-treatment. Examination of patients years after the operation has confirmed the permanancy of the results attained. Redard remarked that periosteal transplantation is preferable to tendon-tendon or muscle-tendon anastomosis and is proving of great benefit in treatment of nervous deformities. S. de Sousa of Lisbon usually prefers arthrodesis to transplantation of tendons for all paralytic affections except those involving the hands. Barbarin called attention to the fact that tendon transplantation or transference can be effectual only when the tendon can be transplanted without tension which reduces its contracting power.

Codivilla of Bologna reported that he has done 415 of these transplanting operations. His experience has demonstrated that good results are never obtained when the muscles are already weakened by some morbid process. They must be capable of an excess of work. He also found that the older the muscles, the less their ability to adapt themselves to new conditions.

ABDOMINAL TUBERCULOSIS.

Broca of Paris commented on the present reaction from the general endorsement of surgical treatment for tuberculous peritonitis. Only about 30 per cent. of the cases treated surgically have remained well for more than two years afterward, according to the latest statistics. The form with acute onset and rapid collection of ascites usually subsides spontaneously. If not, the abdomen should be opened, but not drained. Local abscess formation and complications should be supervised and operated on at need.

UTERINE FIBROMAS.

Pfannenstiel of Giessen argued that as fibromas develop on a basis of chronic endometritis, the rest of the uterus is not sound, and the organ should be removed unless conservative measures are indicated in the exceptional case. Retention of the diseased mucosa may entail menorrhagia later or placenta prævia. One of his patients succumbed to hemorrhage from placenta prævia a year or so after a conservative myotomy. If the uterus is infected the vaginal route is indicated. C. do Pinho of Porto gave as an explanation of the autointoxications of pregnancy that all the poisons generated in the body from various sources are augmented in the pregnant woman, and if they are not eliminated in increased measure trouble is sure to result. The physician should supervise the eliminating functions and strive to keep them equal to their increased task. The total number of official addresses on the program was over 250, on 140 different topics.

OTHER PAPERS READ.

Among the other communications was one by Cajal reporting researches which have confirmed the independent evolution of the axis-cylinders, and thus sustain the [illegible] of his in regard to their monogenesis and also Monroe's assumptions. An animated discussion followed Hasebroek's endorsement of Swedish gymnastics in treatment of angina pectoris (an article by him on this subject is summarized on page 1570). J. Cabral described some cases of what he calls "family cerebral diplegia." Jonnesco of Bucharest reported his experiences with 159 operations on the sympathetic, bilateral in nearly every case, thus bringing his total to 314 sympathectomies. His results in 25 cases of exophthalmic goiter have been especially fine. He regards extensive resection of the cervical sympathetic as the only successful means of treating this affection. He has found it also the best means of curing glaucoma, and reported 91 cures by this means. The results are less favorable in epilepsy, his record being only about 12 cured in 100 cases. Loeffler reported the successful immunization of cattle against foot-and-mouth disease. In a demonstration of Sauerbruch's air cabinet, dogs were anesthetized and extensive operations performed on the [illegible]. R. Turck of Chicago spoke on his experimental production of gastric ulcer in dogs. R. Bensaude of Paris presented two patients in good health six and eight years after extensive resection of the stomach on account of cancer with cachexia. Several other physicians reported similar experiences with long survivals after resection of the stomach for malignant disease. Unna described a new method of staining for the bacillus of leprosy, and emphasized the necessity of continuing treatment of the disease, both general and local, without intermissions. The lepromas must be destroyed to the last traces. A brief course of treatment, although it may apparently have cured the patient, is of no permanent benefit. Chaulmoogra oil is his main reliance. G. Fisac of Madrid presented testimony to confirm the assumption that workers in lime kilns are immune to tuberculosis. The inhalation of lime dust seems to render them refractory to tuberculosis. He has been treating tuberculous patients with lime dust and reported encouraging results. G. W. McCaskey of Fort Wayne presented arguments to prove that absorption of toxins from the intestines was responsible for the development of arterial hypertension under certain circumstances. D. R. Brower of Chicago outlined the proper methods of caring for the acute insane in general hospitals. Two communications that are said to be epoch-making were presented by ophthalmologists: "Serotherapy in Ophthalmology," by T. Axenfeld of Freiburg, and "The Shape of the Crystalline Lens during Repose and Accommodation in the Eye of the Monkey," by von Pflugk of Dresden. Schaudinn was greeted as "the man of the hour."

NEXT MEETING PLACE HUNGARY

On behalf of the American Medical Association and other scientific bodies, Guiteras invited the next congress to meet at New York. Guisy invited the congress to Athens, and Oishi to Japan, but the delegates from Hungary were able to state that the formal invitation they presented was backed by the government, which had already appropriated $50,000 for the purpose. The invitation of the Hungarians was accepted and the next congress appointed for 1909 at Budapest.

The prize of $1,000, endowed by the city of Moscow, was presented to A. Laveran of Paris, the discoverer of the hematozoön of malaria. The prize of $500, founded by the surplus left from the Paris International Medical Congress in 1900, was awarded to Ehrlich of Frankfort [illegible] for his work on serumtherapy, immunization and the side-chain theory. He visited America in 1904, our readers will remember, to receive an honorary degree conferred on him by the University of Chicago.

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND.

The 168th Annual Meeting, held at Baltimore, April 24 26, 1906.

(*Continued from page 1470.*)

Importance of Early Recognition and Operative Treatment of Malignant Tumors.

DR. J. C. BLOODGOOD said that the experience at the Johns Hopkins Hospital showed that of malignant tumors of the breast about 47 per cent. were cured for three years. Recoveries are found up to nine years, and the Germans have observed them up to fifteen years. Mediastinal growths are found in these cases. About 10 per cent. developed late recurrences. Involvement of the supraclavicular glands is considered by the Germans to render the case hopeless; but one case of this has been noted at the Hopkins. There should be no delay in removing any tumor of the breast in a woman over 26. The character of the operation depends on the nature of the tumor. The more readily the diagnosis of cancer can be made, the worse is the prognosis, and vice versa. In a considerable number of instances the diagnosis can not be made; on these the prognosis is highly favorable. Eight other cases of malignant tumor of the thyroid have been noted. Small tumors in patients over 30, which are mostly cystic, should be removed at once. Malignant bone tumors are unnecessarily fatal. It is not creditable to the profession to treat these cases as rheumatism and to deprive patients of their only hope for life. A wrench of the shoulder may develop a sarcoma. The *x*-ray is helpful in the diagnosis.

Analytical Study of Acute Lobar Pneumonia.

DR. J. A. CHATARD gathered statistics from the records of the Johns Hopkins Hospital for the past sixteen years, during which time there were 658 patients treated for pneumonia, excluding ether pneumonias. Of this number 200 died, a percentage of 30.39, though if terminal pneumonias are excluded the number of deaths is 165, or 25.07 per cent. The greatest number of cases occurred in young adults from 20 to 40 years old—55 per cent. In early adolescence the mortality is low —4 per cent.; during the period of greatest frequency, 20 to 30 years, it is 44 per cent., and after that period it rises to about 80 per cent. deaths. The male patients numbered 533, with 154 deaths (28 per cent.), compared with 125 females, with 46 deaths (36 per cent.). White, 238 cases, with a mortality of 30 per cent.; foreign, 170 cases, with a mortality of 29.4 per cent.; black, 250 cases, with a mortality of 31.2 per cent. From January to March there is a rise in the number of cases, while during the summer months there is a great diminution in the number of cases, although the mortality is increased. Outdoor occupations, 347 cases, with 34 per cent. mortality; patients with indoor occupations, 274 cases, with 26.6 per cent. mortality. Alcohol was used by 426 patients, with 30.9 per cent. mortality. One previous attack of pneumonia was stated by 88 patients, two previous attacks by eight, three previous attacks by three patients, and one patient claimed to have had four previous attacks. One hundred and twenty-one of the patients were exposed to bad weather, eight to extremes of temperature; there were eight cases in nurses and orderlies, and three cases among doctors. There was a history of tuberculosis in the family in 11.3 per cent. of the patients. All tuberculous pneumonias were excluded from these statistics.

The most frequent symptoms were pain in the side, chill and cough. Abdominal pain was present in 51 of the cases, or 7.7 per cent. The pulse was considered slow when it registered below 90 and of the patients exhibiting this pulse rate 13.6 per cent. died. Patients with a pulse rate below 125 showed a death rate of 14.9 per cent., this medium pulse rate occurring in 50.7 per cent. of the cases. Patients with a pulse over 125 per minute showed a death rate of 49.4 per cent. Temperature was subnormal, below 98.5 in five cases, with two deaths; between 100 and 102 in 39 cases, with 13 deaths; between 102 and 104 in 49 cases, with six deaths, and between 104 and 106 in 384 patients, with about 27.7 per cent. mortality. The temperature was above 106 in 49 patients, with 55 per cent. of deaths. The admission temperature was generally between 102 and 104, though in one-sixth of the patients it was below 100. The respiratory rate was rapid in the majority of cases, these patients exhibiting labored respiration and cyanosis having a high mortality, about 43.2 per cent. The sputum in the majority of the cases was mucopurulent, tenacious and rusty. In 93 cases the pneumococci were found in the sputum.

In 354 cases the right side was involved, with a mortality of 26.5 per cent.; the right lower 139 times. The left side was involved alone 168 times, with a mortality of 20.2 per cent. In double pneumonia the mortality was about 54 per cent. Pneumococci were isolated from the blood in 25.2 per cent. of the cases, and of these 69.1 per cent. died. The joints were aspirated in three cases and the cocci were obtained in one case. There were 338 cases of pleurisy, with a mortality of 51.2 per cent. Empyema occurred in 27 cases. Pericarditis was present in 35 cases, mortality, 82.8 per cent.; endocarditis 13 times, mortality, 76.9 per cent.; and jaundice in 76 cases, with 21 deaths. This latter complication, jaundice, varied in frequency with the years. In 1901 there were 28 cases, 13 in 1902, and only six in 1900, though there were the greatest number of cases during the latter year. There were 13 cases of meningitis, all fatal. The greatest number of cases showed a leucocyte count of between 25,000 and 30,000, with the lowest mortality—19 per cent. The highest mortality occurred among the cases with the lowest leucocyte counts (below 10,000), also when extremely high. Albumin was present in the urine of 541 cases, casts in 107 cases, and the diazo reaction in 16.8 per cent. Bile was present in 34.3 per cent. Peritonitis, tonsillitis and arthritis occurred each three times. There were eight cases of septicemia, 149 cases of delirium, with about 47 per cent. mortality, 12 cases being admitted with delirium. Herpes was noted in 180 cases and not noted in 265. Where a note was made herpes occurred on the lips in 87 patients, on the nose in 43, on the ears in 3. Among the special features delayed resolution was noted in 35 cases and relapses occurred in 5 patients. The average blood pressure was between 125 and 155 mm. of mercury. Terminal pneumonia occurred 35 times. Defervescence was considered as a true crisis when occurring in twelve hours or less; protracted when occurring in from twelve to twenty-four hours. True crises occurred in 21.6 per cent., and it was protracted in 15.5 per cent.; there were 17 cases of pseudo-crisis. The crisis was usually associated with a fall in the number of leucocytes. The crisis most commonly occurred from the seventh to the ninth day, though there was one case occurring on the third day and one on the fifteenth.

Stimulants were used in 536 cases and symptomatic treatment was employed in 460 cases. Measures employed were the ice bag, poultices, sponges, oxygen and in a few cases the antipneumococcus serum. The serum gave little, if any, good results. Typhoid fever occurred in 21 cases as an associated condition, nephritis 18 times, and heart lesions occurred next in order of frequency.

Among the other papers read were: "Cervical Adenitis (Glandular Fever)." Dr. H. T. Marshall; "Tumors of the Breast." Dr. A. McGlannon; "Hydrotherapy in Private Practice," Dr. J. E. Gichner; "Thrombosis of the Bulb of the Internal Jugular Vein of Otitic Origin." Dr. J. J. Carroll. There were lantern demonstrations on "Insects that Transmit Disease," by Dr. William T. Watson, and "Milk Supply in Foreign Countries," by Dr. J. S. Fulton. A portrait of the late Prof. Richard McSherry was presented to the society by his sons, the speech being made by Dr. S. K. Merrick.

Officers Elected.

The following officers were elected for 1906-07: President, Dr. Hiram Woods, Baltimore; vice-presidents, Drs. William T. Watson, Baltimore, Philip Briscoe, Island Creek, and William F. Hines, Chestertown; secretary, Dr. John Ruhrah, Baltimore; treasurer, Dr. William S. Gardner, Baltimore; trustee, Dr. James M. H. Rowland, Baltimore; council, Drs. Robert W. Johnson, Baltimore; Samuel T. Earle, Jr., Baltimore, Clotworthy Birnie, Taneytown, Paul Jones, Snow Hill, and Guy Steele, Cambridge; committee on scientific work and arrangements, Drs. Arthur P. Herring and G. Milton Linthicum; committee on legislation, Drs. William H. Welch, John D. Blake and John W. Chambers, Baltimore; committee on library, Drs. J. Whitridge Williams, Henry B. Jacobs, J. Frank

Crouch and Harvey W. Cushing, Baltimore, and Dr. William R. Dunton, Jr., Towson; delegate to American Medical Association, Dr. G. Lane Taneyhill, Baltimore, with Dr. Brice W. Goldsborough, Cambridge, alternate. Drs. J. McPherson Scott, Hagerstown, and Edwin J. Dirickson, Berlin, were re-elected on the State Medical Examining Board.

FLORIDA MEDICAL ASSOCIATION.

Thirty-third Annual Meeting, held at Gainesville, April 18-20, 1906.

The President, DR. JAMES M. JACKSON, JR., Miami, in the Chair.

Addresses of welcome were delivered on behalf of the city by Hon. W. R. Thomas, mayor; on behalf of the board of trade by Hon. W. W. Hampton, and on behalf of the Alachua County Medical Association by Dr. J. Harrison Hodges. The president, Dr. James M. Jackson, Jr., Miami, responded to the addresses of welcome.

Quarantine and Yellow Fever.

The papers of especial interest at this meeting were those relative to yellow fever and quarantine. Dr. Eduardo Andrade, Jacksonville, read a paper on "What Services Can the Laboratory Render in the Diagnosis of Yellow Fever"? Dr. Warren E. Anderson, Pensacola, presented some thoughts on the recent epidemic of yellow fever, and Dr. Hiram Byrd, Jacksonville, delivered an address on national quarantine. The matter of national quarantine seemed to meet with favor, although it was manifest that the method proposed would result in opposition from some of the states affected.

One of the most interesting essays was that by Dr. J. Harris Pierpont, Pensacola, on "Medical Materialism."

Election of Officers.

The following officers were elected: President, Dr. John MacDiarmid, De Land; vice-presidents, Drs. William P. Lawrence, Tampa; S. R. Mallory Kennedy, Pensacola, and James M. Dell, Gainesville; secretary and treasurer, Dr. J. D. Fernandez, Jacksonville (re-elected); librarian, Dr. James D. Love, Jacksonville; delegate to the American Medical Association, Dr. Joseph Y. Porter, Key West; state health officer and alternates, Drs. J. Harrison Hodges, Jacksonville, and J. Harris Pierpont, Pensacola. It was decided to hold the next meeting at Tampa.

ARIZONA MEDICAL ASSOCIATION.

Fifteenth Annual Meeting, held at Phoenix, April 24 and 25, 1906

The President, DR. J. W. COLEMAN, Jerome, in the Chair.

The address of welcome to the delegates was delivered by Dr. D. A. Fowler, Phoenix, and was responded to by Dr. John S. Barrett, Prescott.

Approval of Council on Pharmacy—Disapproval of Insurance Fee Cutting.

The following resolutions were unanimously adopted:

Resolved, That the Council on Pharmacy and Chemistry, as organized by the American Medical Association, be commended for its valuable work in disseminating knowledge to the profession regarding proprietary and other drugs and medicines, and that this association heartily endorses this work.

Resolved, That this association recommends to the regular physicians of this territory that five dollars ($5.00) should be the minimum fee for all old-line life insurance examinations.

The annual essay was presented by Captain Henry D. Thomason, assistant surgeon United States Army, Whipple Barracks, and with three exceptions the program as printed was carried out.

Election of Officers.

The following officers were elected: President, Dr. Otto E. Plath, Phoenix; vice-presidents, Drs. William V. Whitmore, Tucson; R. A. Hitteman, Bisbee; R. L. Lowry, Prescott; secretary, Dr. John W. Foss, Phoenix (re-elected); treasurer, Dr. Ralph S. Arons, Roosevelt (re-elected); censor, Dr. John W. Flinn, Prescott; delegate to the American Medical Association, Dr. Clarence E. Yount, Prescott, and alternate, Dr. John W. Foss, Prescott.

Book Notices

NEUROTIC DISORDERS OF CHILDHOOD, Including a Study of Auto and Intestinal Intoxications, Chronic Anemia, Etc. By B. K. Rachford, M.D. Cloth. Pp. 440. Price, $2.75. New York: E. B. Treat & Co., 1905.

This is an interesting work, having as a nucleus several papers written by this author during the last few years. The general theme is that of the normal instability of the nervous system in early life due to the immaturity of nerve cells, especially of the inhibitory centers, plus the effect of various pathologic conditions on these unstable cells. As a result of this combination, immature nerve cells and a varied pathologic state, we see nervous disturbances more easily precipitated in the child than in the more self-controlled adult.

The book is divided into two sections, part I taking up general principles, part II dealing with the application of these general principles to specific neuroses. There is first described the normal function of nerve cells: the generation, discharge and control of energy. A discussion of the heat-generating apparatus next follows, the sudden accumulation and equally sudden dissipation of heat being described. The suddenly high temperatures of early life are attributed to the instability of the thermic centers and the weakness of the thermo-inhibitory centers, while the sudden drops are attributed to the rapid action of the heat-dissipating mechanism, this rapid action being due chiefly to the proportionately greater surface of radiation in the child. The net result of these two processes is the wide oscillations in temperature so familiar in early life.

The subject of intestinal and autointoxications receives careful attention, the author attributing much importance to the action of the xanthin and purin bodies on the unstable nerve cells. Incompetency of the liver, either from hereditary or other causes, is regarded as an important factor in the working of these bases, as a competent liver "stands guard" and prevents their absorption from the intestinal tract. Laboratory experiments are adduced in support of his theory as to the injurious effects of these bodies. These effects assume varied shapes, giving rise to widely differing clinical pictures according to the age of the individual. Thus, in the young, lithemia is attributed to the action of the xanthin and purin bodies, while in later life their presence gives rise to albuminuria, and by their irritating presence in the circulation, to arteriosclerosis with resulting cerebral hemorrhage. On this basis he sees a kinship between these various processes.

The relation of neurotic disorders to anemia is discussed. Anemia plays an important part in these disorders by causing a malnutrition of the nerve centers, thus rendering them more unstable than ever. It is stated that anemia itself, however, is only a symptom, a secondary affair arising from a more deep-seated trouble, the most common causes being chronic intestinal troubles, tuberculosis, syphilis, malaria, rheumatism and rachitis; and to the accompanying anemia rather than to any specific toxin the author attributes the nervous disorders seen in these affections. Thus he sees an intimate relationship between tuberculosis and certain neuroses, insanity, chorea and incontinence. These are all manifestations of great nervous instability on the part of nerve centers insufficiently fed with anemic blood.

A chapter on reflex irritation shows the important part played by reflex causes in producing nervous disturbances. These causes constantly irritate nerve centers, stimulating them to great activity. It has been shown that as a result of activity on the part of nerve cells these cells become fatigued, consequently more unstable than normal and, therefore, more easily upset. Obviously any cause acting as do reflex causes over long periods of time will tend to produce prolonged nervous fatigue and thus lead to nervous disturbances. Furthermore, it has been shown that the process of resting on the part of the nerve cell takes a longer time than does the process of becoming tired out, hence the long time required for the correction of a chronic neurosis, for example, incontinence of urine after removal of its reflex cause, e. g., a tight prepuce.

The first section closes with an excellent plea for more rational and less strenuous methods in the education of our

children, which the author most truthfully maintains lead to much nervous exhaustion. He advocates more parks and playgrounds in our large cities. An especially valuable suggestion is, that promotion from grade to grade shall depend more on the child's physical condition and less on his mental showing. The child's capacity for school work is more dependent on his physical status than on his age and mental advancement.

Part II is a specific application of the general principles laid down in part I, the author using as illustrations, eclampsia, incontinence, laryngismus stridulus, migraine, epilepsy, recurrent vomiting and chorea. He reiterates his belief in the kinship of migraine and epilepsy, citing cases in which the one has merged into the other. His classification of the different clinical forms of epilepsy, however, seems forced. He divides them into three groups: developmental (idiopathic), organic, toxic. The essential factor in the first group he regards as a lack of development of the higher inhibitory centers which control the lower convulsive centers, an hereditary predisposition. This is perhaps as good a conception of true or idiopathic epilepsy as any, considering our ignorance of its real cause and nature. His second group is not genuine epilepsy at all. The attacks in this class are "epileptiform" seizures and are due to some gross cerebral lesion, e. g., an old hemorrhage cyst, and should be given the name of this gross lesion. In the third group the essential factor is an autotoxin, which acting on an individual already predisposed produces epilepsy, but on one not so predisposed causes some other neurosis, e. g., migraine. Thus here as in group 1 the important factor is an hereditary predisposition without which the author believes the individual would not have epilepsy; hence it would seem better to class these so-called toxic cases under the first group, thus giving us (a) idiopathic, and (b) organic.

The author seeks to prove by citation of cases the principles already discussed, yet in these very cases we see illustrated the weakness of his work. Throughout the book, up to this point, he has laid great stress on the important rôle played by the xanthin and purin bodies in the causation of these neuroses, citing the frequent occurrence of these bases in the urine as proof of his theories; but in the 15 cases cited we find a report on the urine in only two! In these two cases the urine contained acetone and diacetic acid. This omission shows in a nutshell the weakness of the whole book. The work lacks sound foundation in facts. There is too much theory. "I believe" and "it is my belief" occur far too frequently; "it has been proved" far too infrequently. The author is dealing with conditions concerning which our actual knowledge is extremely limited and in which there is excellent opportunity for theorizing; of this opportunity he has availed himself to the full. This is, perhaps, proper to a certain extent, but we must not be carried away by the plausibility of the author and accept as fact what at present is unknown and purely theoretical. Nevertheless the book is valuable and well worthy of careful study both by the pediatrician and the general practitioner. Its chief value lies in the emphasis placed on the important rôle played in the nervous affairs of early life by anemia and malnutrition from whatever cause, and by intestinal poisoning and the vital importance of correcting these basic conditions. This writer, at least, is not blinded by the symptom which happens to loom largest at the moment, but he strives diligently to go to the root of things. And perhaps, after all, he is not far from the mark in emphasizing nerve instability (that is as good a term as any at present) and intestinal toxemia as the roots to be aimed at. Certainly his results are better than his theories, for his patients do well under the treatment he practices, even though the exact way in which these results are attained is somewhat obscure.

We regret exceedingly to see mentioned in a work by a man of such reputation such proprietary medicines as "Kutnow's powder," "eolchi-sal," etc., even though it be done unwittingly, as it undoubtedly is in the present instance.

A TEXT-BOOK OF PSYCHIATRY, for Physicians and Students. By L. Bianchi, M.D. Authorized Translation from the Italian by J. H. MacDonald, M.B., Ch.B. 106 Illustrations. Cloth. Pp. 904. Price, $6.00 net. New York: William Wood & Co.

The translator of this work expresses the opinion that it will prove a valuable addition to English psychiatric literature, which is a very moderate recommendation, considering that the work is one of the leading Italian treatises on mental disorders and the only one that has thus far been put in English for the benefit of the English-speaking public. Professor Bianchi's position among the active workers in this department is alone such as would insure his work a welcome. The size of the book may appear at first sight a little formidable, but it is fully justified by the author's handling of his subject. It is divided into three parts. Of these the first, comprising 175 pages, is devoted to an exposition of the physiology of the brain according to the later data. Bianchi does not appear to be an adherent of the neuron theory, but holds rather that the researches of Apathy and Bethe, confirmed by others, have reinstated the old nervous reticulum of Golgi though in a somewhat modified form.

Part second, comprising over 200 pages, is devoted to an examination of the pathologic modifications of the various psychic functions and is largely psychologic. The subjects of perception, attention, memory, ideation and feeling and volition are each interestingly discussed in their relation with abnormal mental phenomena and the author's wide acquaintance with psychologic theories and literature is very much in evidence.

Part three commences with a chapter on the methods and fields of clinical inquiry, followed by a chapter on classification, a subject which he treats respectfully though pointing out its difficulties and its theoretical futility. His classification is his own. He divides the mental affections into three great groups. The first comprises the affections due to original psychocerebral defect; the second includes the infective autotoxic and toxic psychoses occurring in individuals normally evolved; the third includes all the disorders due to a substratum of organic disease. The inclusion of epileptic insanity in the first class, when it is so largely non-evolutionary in its origin, may seem a little out of place, but that it often falls under this head can hardly be denied. Similarly, delinquency as a mental disorder may not be entirely acceptable to everyone, but in treating it here Bianchi is in accord with a large class of thinkers, especially of the Italian school. Hysteria, developmental paranoia, developmental neurasthenia and sexual psychopathies naturally fall under this head, with the phrenasthenias at the other extreme of the scale.

In the second group it is noteworthy that this text-book, while recognizing the work of the Germans, does not accept Kräpelin's conceptions of mania and melancholia or dementia præcox, but follows rather in the old lines based on the clinical experience of the majority of practitioners in the past. Pure mania and melancholia are recognized as independent of each other and dementia præcox Bianchi considers as only one clinical variety out of many of sensory or hallucinatory insanity. Mental confusion comes under the same class in the author's opinion, though he does not deny the possibility of a primary form. It is worth noting here also that Professor Bianchi does not altogether support the very commonly repeated opinion that the Italians, using only pure wine and very little other intoxicants, do not suffer from the abuse of alcohol. On the other hand, he attributes a very considerable portion of the mental disease and criminality in Italy to the abuse of alcohol.

In his third group paresis naturally calls for most attention, and Bianchi considers syphilis as only one out of a number of its possible causes, and gives considerable importance to heredity in its causation. A valuable feature of the work is the clearness of statement as to the author's views on the various controverted points, together with a fair statement of the opposite views. The descriptions are clear and the translation has apparently preserved the style and readableness of the original. The translator has done a favor to English-speaking readers in thus putting in their hands one of the very best of the foreign text-books of the day.

THE DYNAMICS OF LIVING MATTER. By J. Loeb, Professor of Physiology in the University of California. Cloth. Pp. 233. Price, $3.00. New York: The MacMillan Company, 1906.

Since 1894 Columbia University has been issuing from time to time books on the biologic sciences, based on the lectures given by distinguished biologists, both of its own faculty and from outside. The latest addition to the series, and of the

greatest interest to medical men, is this book by Professor Loeb. The author represents perhaps the foremost of the great school of physiologists who are endeavoring to solve the intricate problems of the vital phenomena by going to the bottom of the scale of evolution, and studying the effects of the simplest possible substances and forces on the simplest possible forms of living matter. There can be little room for question that this is the proper way in which to seek for a correct understanding of the so-called "vital processes," for if we can not interpret the phenomena that are observed in the multiplication of a single cell, such as the egg of an invertebrate or the processes of repair of the simple hydroids, what likelihood is there of our understanding the infinitely more complicated processes of the mammalian organism? Being based on a series of open lectures, these fundamental problems and the results so far obtained in their investigation are discussed by Professor Loeb in a broad and general manner, covering the essential principles of life phenomena as now understood by the biologist. Living organisms are considered "as chemical machines, consisting essentially of colloid material, which possess the peculiarities of automatically developing, preserving and reproducing themselves," and in every consideration of the phenomena exhibited by living organisms the attempt is made to bring them into a field of the simplest of chemical and physical processes possible. The physician who desires to acquaint himself with the recent advances in fundamental physiology, as well as to get a glimpse into the life processes of the simpler living forms, will find unending interest and stimulation in this book.

State Boards of Registration

COMING EXAMINATIONS.

INDIANA Board of Medical Registration and Examination, Indianapolis, May 22-24. Secretary, W. T. Gott, Indianapolis.

NEW YORK State Boards of Medical Examiners, Albany, May 22-25. Secretary, Charles F. Wheelock, Albany.

ILLINOIS State Board of Health, Collseum Annex, Chicago, May 23-25. Secretary, J. A. Egan, Springfield.

NEBRASKA State Board of Health, State House, Lincoln, May 29-30. Secretary, George H. Brash, Beatrice.

MINNESOTA State Board of Medical Examiners, Old State Capitol Building, St. Paul, June 5-7. Secretary, O. E. Linjer, Minneapolis.

WYOMING Board of Medical Examiners, State Capitol, Cheyenne, June 6. Secretary, S. B. Miller, Laramie.

MICHIGAN State Board of Registration in Medicine, Ann Arbor, June 12. Secretary, B. D. Harison, Sault Ste Marie.

TEXAS State Board of Medical Examiners, Dallas, June 12. Secretary, T. T. Jackson, San Antonio.

OHIO State Board of Medical Registration and Examination, Cincinnati, Cleveland and Columbus, June 12-14. Secretary, George H. Matson, Columbus.

BOARD representing the Medical Society of Delaware and Board representing the Homeopathic Medical Society of Delaware State and Peninsula, former held at Dover and latter at Wilmington, June 19. Secretary, P. W. Tomlinson, Wilmington.

NEW JERSEY State Board of Medical Examiners, Trenton, June 19-20. Secretary, E. L. B. Godfrey, Camden.

NEW YORK Boards of Medical Examiners, Albany, June 19-22. Secretary, Charles F. Wheelock, Albany.

PENNSYLVANIA State Board of Medical Examiners, Annex Hotel, Pittsburg, and North Building, Philadelphia, June 19-22. Secretary, Joseph E. Willetts, Pittsburg.

VIRGINIA State Board of Medical Examiners, Richmond, June 19-22. Secretary, R. S. Martin, Stuart.

MARYLAND Board of Medical Examiners, Baltimore, June 20-23. Secretary, J. McP. Scott, Hagerstown.

SOUTH CAROLINA State Board of Medical Examiners, Columbia, June 26. Secretary, W. M. Lester, Columbia.

Arizona April Report.—Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, April 2-3, 1906. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of applicants examined was 12, of whom 11 passed and 1 failed. The following colleges were represented:

PASSED.	Year Grad.	Per Cent.
College.		
Medical College of Ohio	(1901)	75
National Med. Coll., Mexico City	(1885)	75
Drake University	(1905)	89
Missouri Med. Coll.	(1899)	83.3
College of P. and S., San Francisco	(1904)	76.3
Kansas Med. Coll.	(1895)	75
McGill University, Montreal	(1900)	86
Rush Med. Coll.	(1899)	86
Barnes Med. Coll.	(1904)	75, 77.4
Harvard Medical School	(1894)	81

FAILED.		
Hospital Coll. of Med., Louisville	(1900)	49.5

Idaho April Report.—Dr. J. L. Conant, secretary of the Idaho State Board of Medical Examiners, reports the written examination held at Pocatello, April 3-4, 1906. The number of subjects examined in was 13; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 19, of whom 13 passed and 6 failed. The following colleges were represented:

PASSED.	Year Grad.	Per Cent.
College.		
College of P. and S., Chicago	(1904)	78.4, 85
Trinity Med. Coll., Toronto	(1883) 75.1; (1895)	85.8
University of Minnesota	(1902)	83.6
Rush Med. Coll.,	(1906) 75; (1906)	88.1
University of Michigan	(1901)	77.5
Baltimore Med. Coll.	(1893)	81.1
Northwestern University	(1901)	87.3
Columbian University	(1902)	85.5
University of Vermont	(1891)	77
Milwaukee Med. Coll.	(1905)	77

FAILED.		
Chicago Homeo. Med. Coll.	(1879) 70.5; (1880)	66.6
University of Iowa	(1895)	72.2
Barnes Med. Coll.	(1898)	51
Rush Med. Coll.	(1889)	73
Jefferson Med. Coll.	(1895)	67.8

The following questions were asked:

MATERIA MEDICA AND THERAPEUTICS.

1. State the average dose of the following: (1) fluid extractum aconiti, (2) allonum, (3) chloralum hydratum, (4) fluid extractum buchu, (5) hydrargyri chloridum corrosivum, (6) tinctura lobeliæ as an expectorant, (7) syrupus senegæ, (8) spiritus glyceryllis nitratis, (9) oleum picis liquidæ, (10) liquor potassii arsenitis. Dosage should be given according to the U. S. P. 1900. 2. Name ten anthelmintics. 3. Name five official preparations of ipecacuanha, and state the average dose of each. 4. What is cocain? Give the physiologic effect of cocain on (*a*) the conjunctiva, (*b*) the pupil of the eye, (*c*) respiration, (*d*) temperature. 5. Define: (1) Hemostatic, (2) styptic, (3) cebolic, (4) sialagogue, (5) myotic, (6) antihydrotic, (7) antizymotic, (8) cholagogue, (9) vesicant, (10) galactagogue. Give an example of each. 6. Name ten alkaloids and the drugs from which they are obtained. 7. Give the therapeutic uses of phenylis salicylas. 8. Mention five purposes for which diaphoresis is produced. 9. Give the dose and therapeutic uses of sparteinæ sulphas. 10. Give the therapeutic uses of guaiacol.

GYNECOLOGY.

1. Define: (*a*) Endometritis; (*b*) endocervicitis; (*c*) perimetritis; (*d*) salpingitis; (*e*) peritonitis. 2. How would you treat prolapsus uteri? 3. What is nymphomania, and how would you treat it? 4. Give symptoms, diagnosis and treatment of urethral caruncle. 5. Differentiate between suppression and retention of the urine. 6. What is the difference between menstruation and ovulation? 7. What is a vesico-vaginal fistula, and how would you treat it? 8. Mention two ways in which fistula is liable to result from ignorance or carelessness on the part of the obstetrician. 9. Give etiology, symptoms and treatment of vaginal cysts. 10. Name and describe four varieties of myoflbromata of the uterus.

THEORY AND PRACTICE.

1. Give etiology, symptoms, diagnosis, prognosis and treatment of pyelitis. 2. Give etiology, symptoms diagnosis and treatment of endocarditis. 3. Give etiology, symptoms, prognosis and treatment of acute intestinal atrophy. 4. Name the complications and sequelæ of scarlet fever and give preventative and curative treatment for each. 5. Give etiology, symptoms, varieties and treatment of stomatitis in children. 6. Cerebrospinal meningitis: Give etiology, symptoms, diagnosis, prognosis and treatment. 7. Give treatment for (*a*) acute ptomaine poisoning, (*b*) bronchial asthma, (*c*) acute catarrhal gastritis, (*d*) icterus neonatorum. 8. Give pathology, symptoms, diagnosis, prognosis and treatment of eczema. malnelia. 9. Give symptoms, varieties and treatment of eczema. 10. Give treatment for pneumonia and complications.

OBSTETRICS.

1. Define: Fetus; funis; placenta prævia; souffle; ballottement. 2. What evils may result to (*a*) child and (*b*) mother from prolonged second stage of labor? 3. How would you accomplish delivery where child's arm is displaced back of neck? 4. Give treatment of hemorrhage of third degree at close of labor. 5. Give symptoms, etiology and treatment of phlegmasia alba dolens. 6. What is the mechanism of labor in L. O. A. and L. O. P. position? 7. Give complete directions for, and five precautions to be observed in, applying the forceps. 8. How would you treat ophthalmia neonatorum immediately? 9. Describe the process of podalic version. 10. Give two distinct indications for podalic version.

DIAGNOSIS.

1. Give differential diagnosis between simple catarrhal laryngitis, spasmodic laryngitis, laryngismus stridulus and membranous croup. 2. Give diagnosis of mucous colitis. 3. Give differential diagnosis between glaucoma and iritis. 4. Give microscopic findings in examination of sputa in acute tuberculo-pneumonic phthisis and croupous pneumonia with full directions for staining and examining. 5. Differentiate bronchial asthma, cardiac asthma, hysterical dyspnea and uræmic asthma. 6. Differentiate nephritis, cholelithiasis and calculous cystitis. 7. What may we learn by a careful examination of the blood? 8. What may be learned by a careful examination of the tongue? 9. Explain the reflexes and name the principal ones. 10. Name four instances of referred pain and five location and character of the lesion producing it.

CHEMISTRY AND TOXICOLOGY.

1. Give formula for ammonia gas, ammonium hydroxid, water, dium chlorid, corrosive sublimate, potassium chlorate, carbon oxid, silver nitrate, hydrochloric acid, and nitric acid. 2. Carbon oxid: Give properties, occurrence, preparation, test, effects on ant and animal life. 3. Water: Mention properties, boiling point, eezing point, distillation, mention nature of substances removed by distillation. 4. What is aqua regia? valence? ozone? ombustion? element? 5. Give comparative composition of cow's nd breast milk. 6. Describe a reliable test for albumin. 7. What re some common drugs used in suicide? In accidental poisoning? 8. ive treatment for poisoning by each drug named above. 9. What s paris green? Mention its toxic symptoms. Give treatment of aris green poisoning. 10. Mention the dangerous drug in each f three patent or proprietary medicines. (You may use hive yrup, catarrh cure, cough medicines.)

PHYSIOLOGY.

1. What are carbohydrates? hydrocarbons? protelds? Meution a pecimen of each. 2. Describe the digestion of each. 3. Describe he process of absorptiou in the alimentary canal, stating the subtance absorbed in each division. 4. What is glycogen, chyle, hyme, myosin, epiphysis? 5. Describe human blood. 6. Describe he general circulation; the portal circulation. 7. What changes ire produced in the air by respiration? 8. Explain how the temperature of the body is maintained and regulated. 9. What are the functions of the white and gray matter of the brain? 10. What would be the effect of a transverse section of the anterior root of a spinal nerve? the posterior root? an efferent nerve? an afferent nerve? How is a divided nerve restored?

HYGIENE.

1. Give some directions for the care of a pregnant woman. 2. State how air becomes vitiated. How is vitiated air purified? 3. Name some diseases that are hereditary. How may they be prevented? 4. State the hygienic care and treatment for a person afflicted with tuberculosis. 5. What relation has food to good health? 6. What sanitary care should a state provide for its citizens? 7. What restrictions should the state impose on the marriage relation? 8. Give some directions for the hygienic care of public schools and school children? 9. Name some of the bad effects of feeding impure milk to children. Give direction for securing a supply of pure milk. 10. Name some contagious diseases. How can they be to a large extent prevented?

ANATOMY.

1. Give the origin, insertion, function, innervation and blood supply of the (*a*) biceps, (*b*) gastrocnemius, (*c*) quadriceps extensor. (*d*) occipito-frontalis, (*e*) sternocleidomastoid. 2. Define the terms: (1) Lien, (2) epiphysis, (3) cubitus, (4) collum. (5) volar, (6) syndesmology, (7) foramen, (8) hiatus, (9) teres, (10) antrum. 3. Describe the ulna and name the muscles attached to it. 4. Name the viscera wholly covered by peritoneum. 5. Number and name the laryngeal cartilages.

HISTOLOGY.

1. Name the elementary tissues and describe one of them. 2. Describe non-striated muscle and mention five places in which it may be found. 3. Describe a typical medullated nerve fiber. 4. Describe the histologic appearance of a cross section of the small intestine. 5. Define the terms: (1) Cell, (2) nucleus, (3) protoplasm, (4) sarcolemma, (5) axon, (6) reticulum, (7) cortex, (8) medulla, (9) neuroglia, (10) erythrocyte.

SURGERY.

1. Iridectomy: (*a*) Describe the operatiou for artificial pupil; (*b*) for closed pupil from iritis; (*c*) for glaucoma. 2. (*a*) In antrum operations for mastoiditis, what variations in anatomic relations should be kept in mind? (*b*) What two particular tissues should not be wounded? 3. Describe the amputation of the foot, when neither injury nor disease of the os calcis is present. 4. Nasal neoplasms: (*a*) Name three most common benign; (*b*) describe each separately; (*c*) name the most common malignant one. 5. (*a*) Name the varieties of bone fracture; (*b*) what are the especial features of gunshot fractures? 6. Complete backward dislocation of proximal phalanx of thumb. (*a*) What is the main obstacle to reduction? (*b*) what tissues are injured? (*c*) how would you reduce it by manipulation? (*d*) when by arthrotomy describe the procedure. 7. Femoral hernia: (*a*) Most common in males or females. Why? (*b*) Differentiate femoral from inguinal hernia; (*c*) when strangulated, where is the seat of constriction? (*d*) describe modern radical operation closing the entire canal. 8. End-to-end anastomosis of jejunum: Give technic, describing sutures used and how applied, instruments and other apparatus required. 9. Fibroid tumors of the uterus: (*a*) Is a fibroid a benign or malignant growth? (*b*) does it ever undergo transformation into another kind of neoplasm, if it does what is it? (*c*) from what locality of the uterus does fibroid usually start? (*d*) how are they classified with relation to normal uterine structures? (*e*) at what period of life are they most commonly observed? (*f*) are they more commonly found in multiparous or nulliparous women? (*g*) what are the symptoms of fibroids? (*h*) differentiate fibroids from pregnancy, ovarian cysts; (*i*) give treatment for fibroids. 10. What is your treatment for asphyxia? (*a*) during chloroform ether anesthesia, (*b*) in resuscitation of the apparently drowned?

PATHOLOGY.

1. (*a*) After death, how many hours supervene before rigor mortis is established? (*b*) In what order do the muscles become fixed, and in what order does rigor mortis disappear? (*c*) how long after rigor mortis is established before it disappears? 2. (*a*) What are the methods employed for preserving pathologic specimens, and preparing them for study? (*b*) give formulas for different processes of preparation. 3. (*a*) What is hemorrhage by rhexis, diapedesis? (*b*) what is understood by the term transudation, what is a hematoma? 4. Give the general methods and principles of artificial immunization of an animal susceptible of communicable diseases. 5. Paris green poisoning, suicidal intent, male, age 24, weight 165 pounds, apparently healthy, poison injested one hour after hearty meal, lived 18 hours, what were the macroscopic findings at postmortem, 6 hours after death. 6. Pathologic polynuclear leucocytosis occurs in how many of the following diseases: Typhus fever, pneumonia, diphtheria, malaria, scarlet fever, measles, tuberculosis, erysipelas, rheumatism, name them; under what conditions is physiologic polynuclear leucocytosis observed? 7. (*a*) In myocarditis what particular tissues are primarily involved? (*b*) describe the arterial anastomosis in the deep heart muscle; (*c*) from what source does the heart receive its nutrient supply, other than the corouary arteries? 8. (*a*) Is a so-called lymph gland, in the true sense of the word a gland? If not what is it? (*b*) what is its function? 9. Acute diffuse nephritis: (*a*) What structures are involved? (*b*) under what circumstances is the medullary portion of the kidney usually the first to be involved? (*c*) what do you understand by the word "diffuse," used to describe this form of nephritis? 10. (*a*) Describe one method of staining the bacillus tuberculosis, gouococcus; (*b*) define hypertrophy, hyperplasia, morphology, neuroglia; (*c*) how do wounded veins heal?

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Exophthalmic Goiter.

In the treatment of exophthalmic goiter MacKenzie, in the *British Medical Journal*, states that when there are signs of serious conditions, the patient must be given as nearly complete rest as possible of both mind and body, and that so long as the patient is losing in weight, rest must be absolute in order to maintain the strength at the best possible standard. All disquieting influences must be interdicted. These patients must be given words of cheer with the prospects of recovery; at the same time friends and relatives must be given to understand that recovery may be extremely slow. Good food and an abundant supply of fresh air are two important elements in the treatment of this disorder. The patients will do best when kept in the open air, and this open-air treatment is more easily carried out in this disease than in almost any other, as the patients are much more tolerant of cold and feel a great deal better in cool weather than in hot weather. They must be carefully fed and given an abundance of wholesome and nutritious diet. The weight must be observed frequently and, if necessary, the ordinary diet may be supplemented with milk in amounts ranging from two to four pints a day. An adequate amount of fat is also necessary in a great many of these cases. When vomiting is present this author recommends potassium citrate or some bismuth preparation to check it. In other cases it is necessary to suspend feeding for the time and to keep up the best nourishment possible by means of the bowels. In combating the diarrhea, which is frequently one of the most difficult complications to deal with in this disease, great care must be observed in the selection of the food. In excessive cases large doses of bismuth or preparations of tannin are necessary. [The latter preparation may be given in the form of an emulsion by high rectal injections.] Massage is of great benefit in patients who are confined to bed, but must be given very judiciously. Careful attention must be paid to the skin, remembering the great tendency to excessive sweating in these cases. Warm seawater baths or brine baths are sometimes of benefit. When patients are able to travel, a change of climate is of great value, but there can be no regularity as to the exact climate to be prescribed in these cases, as one patient will do better at the seaside, while another will do better inland, or at a higher or lower elevation. The chief object, however, is to place a patient where complete rest and quiet can be obtained, with freedom from noise and friends, where good, wholesome food can be procured, with pure air and pleasant surroundings.

In the medicinal treatment MacKenzie recommends potassium bromid, especially in cases in which the nervous symptoms predominate, and in which there is great restlessness, excitability and emotion. He advises giving the drug in doses of from 20 to 40 grains (1.30-2.65) at bedtime. Preparations of iodin are useful in cases in which the goiter is large or in which it is increasing in size. For this purpose he prescribes the syrup of hydriodic acid, as this is better borne than potassium iodid, and seems practically as effective. This syrup can

be given in doses of one dram each (4.00) three times a day, after meals. The tincture of iodin may be applied externally over the goiter, having the disadvantage, however, of producing a dermatitis.

As regards surgical treatment, he states that the operation is a dangerous one, and that the risks happen to be the greatest in that class of cases which respond least to medical treatment. In cases in which there has been little or no exophthalmos, MacKenzie has had good results from thyroidectomy. Thyroidectomy, however, often fails to cure the disease. Ligature of the thyroid arteries is another operation which has been frequently performed, and while it is less dangerous than thyroidectomy, it is less likely to effect a cure. In summing up, he considers the risk of thyroidectomy to be too great to justify the performance of the operation, except in unusual circumstances, and for the present medical treatment should be the line depended on. This should be carried out with extreme care and perseverance, and if this be done the chances of final recovery, he states, are very good.

Sprained Ankle.

H. G. Johnson, in the *New York Medical Journal*, in speaking of the treatment of sprained ankle, states that if the patient is seen soon after the injury, hot water should be applied to the injured part by pouring it from a pitcher, or bathing the foot in hot water for from five to ten minutes. The ankle should then be wrapped with a bandage, which should be kept moist for from twelve to eighteen hours, during which time the patient should be at complete rest. After the removal of this bandage a gentle massage should be applied to the injured ankle, followed by a strapping of surgical plaster, the technic of which is as follows: A number of strips one inch in width and thirteen or fourteen inches long, should be cut. Beginning at the instep, the middle of each strip of plaster is placed at the bottom of the foot; the ends are carried across the front of the foot to lap over. The second strip covers half the first strip, and so on, up the foot, to within two inches above the ankle. The ankle is then reinforced by two or three additional strips. In two or three days a fresh strapping is applied over the first dressing, and the whole allowed to remain a week or ten days, or until the tenderness and pain are relieved.

Littlejohn, in the same periodical, states that the limb should be thoroughly shaved from the knee downward, and cleansed with soap and water. Ether should then be applied, as this insures better adhesion of the plaster. The foot should be restored to its normal position as far as possible, put in the position of acute flexion, and held by an assistant while the dressing is applied. The correct relation to the foot and ankle are extremely important. A strip of plaster twenty inches long and two inches wide should be fastened about four inches below the knee on the inner side of the leg. This should extend down parallel to the long axis of the limb and along the posterior edge of the tendo Achilles, directed under the heel and up the corresponding outer side of the leg. A second strip of the same size is applied just in front of this and overlapping it about a quarter of an inch. In this way the foot is held in a rude stirrup. These strips limit the lateral mobility of the joint. Another strip an inch wide is started on the dorsum of the foot just behind the insertion of the middle toe, and should be carried back along the inner edge of the foot, around the heel, and back the outer side of the foot to the starting point. A similar strip should be applied higher up and overlapping this strip by a quarter of an inch. Beginning just above the internal malleolus, a strip one inch wide follows the first long strip applied down under the heel and up the outer side of the ankle, to just above the external malleolus. Other strips should be applied in order, until the whole foot and ankle are covered, except the small space at the heel. A light gauze bandage then may be applied, beginning at the toes and extending up the leg. An icebag should then be fastened over the injury, and kept in place for three out of four hours. These applications may be dispensed with at the end of the first day. The limb should be elevated and absolute rest enjoined. After forty-eight hours the patient should be urged to take a few steps, and gradually to increase this exercise until he is able to leave the house. After the second day massage and passive motion are practiced, lasting for about fifteen minutes each time. Patients are instructed to wear the adhesive strips for two or three weeks.

The advantages gained by treating a sprained ankle with adhesive strips, cold applications and rest are summed up by Littlejohn as follows: 1. Swelling and hyperemia are largely controlled by the firm pressure of the adhesive plaster and cold applications. 2. The pain is not nearly so acute nor of so long duration. 3. With less pain the patient is more willing to make early efforts in the use of the joint. 4. The confinement to one room is of short duration. 5. This method of treatment greatly lessens the tendency to painful stiffness and adhesion of the joint, while immobilization methods at times undoubtedly lengthen the convalescence into months of partial disability.

Erysipelas.

In the treatment of erysipelas Dr. I. S. Maximoff, in an abstract in the *Journal of American Medical Sciences*, recommends the following local and constitutional treatment. The local treatment consists of dressing the seat of the disease from two to four times daily with the following combination:

℞. Guaiacol
Tincturæ iodi
Spiritus etheris, āā.....3iss 6
Essentiæ menthæ piperitæ, q. s.....
M. Ft. lotio. Sig.: Apply locally.

Internally he recommends camphor, administered in the powdered form, and giving grs. ii (.12) every two hours during the day, or it may be given in solution in the following combination:

℞. Pulverized camphoræ.....gr. iss 09
Aquæ laurocerasi.....3ss 2
Syrupi simplicis 3iss 6
M. One such dose every two hours, followed by a draught of hot tea.

The administration of the camphor is continued until moderate diaphoresis is established, as this symptom marks the crisis, after which the disease usually subsides.

Castor Oil Made Palatable.

Dr. A. E. Midgely, Oshkosh, Wis., writes concerning his method of disguising the taste of castor oil. He combines it as follows:

℞. Alcoholis 3iii 12
Benzosulphinidi (saccharin).....gr. viii 5
Olei anisi.....m. xvi 1
Olei cinnamomi.....m. xii 8
Olei ricini q. s. ad.....3viii 240
M. Dissolve the saccharine in the alcohol, warming if necessary, then add the oils and shake well. Sig.: Dose the same as of the plain oil.

This mixture, he states, may turn cloudy if cooled, but does not suffer thereby, and again becomes clear on warming to room temperature. Other flavors may be used in place of those given, as, for instance, oil of peppermint, but that has the objectionable feature of causing disagreeable eructations in some individuals. The volatile oils serve the additional purpose of preventing, in a measure, the griping tendency of the plain oil. If the use of the oil is to be continued for any length of time the plain oil is better, as the saccharin in the mixture may cause some digestive disturbance. [The amount of saccharin present in Dr. Midgley's prescription would be likely to cause digestive disturbances and it would probably be better to decrease the amount to one-fourth of the quantity given (gr. ii-0.13). Ed.]

The following combination is said to be an almost tasteless emulsion of castor oil:

℞. Olei ricini . . . 3iv 15
Pulv. acaciæ . . 3i 4
Syr. aurantii . . . 3i 0
Aquæ cinnamomi q. s. ad. 3i 30
M. Sig.: To be taken at one draught.

In diarrheas brought on by undigested food irritating the

intestinal canal the following combination is recommended to cleanse the intestine and to check the diarrhea:

R. Olei ricini	5iv	15
Spiritus vini gallici	5ii	8
Tinct. opii	m. x	65
Aquæ cinnamomi q. s. ad	5i	30

M. Sig.: To be taken at one dose.

Medicolegal

Physician Not a Fellow Servant with Trainmen.

The Second Appellate Division of the Supreme Court of New York holds, in the case of Tingley vs. Long Island Railroad Co., an action brought to recover for the death of a physician struck by a train while attempting to cross in front of or board same, that it was error to allow the defendant railroad company to prove a contract by which the physician had agreed to attend surgically the employés and passengers of the company when called on to do so by its officers and agents. It says that clearly such employment did not make him a fellow servant, and besides at the time of the accident he was going to attend one of his own patients.

Proper Things for a Medical Expert.

The Superme Court of Indiana says, in the case of Swygart vs. Willard, that it is eminently proper that a witness dealing with scientific or technical terms, should, if possible, make his meaning more clear by reference to terms in common nse. It was not improper for the same reasons to permit a physician to explain in this case the meaning of "Monomania" as used by him. He was rightly permitted also to explain the distinctive peculiarities of a mind suffering from insane delusions; the symptoms of dementia, and, on a hypothetical statement of facts showing some form of mental unsonndness, to testify nnder what class of unsonndness of mind the testator should be placed. A medical expert may also explain the effect resulting to the brain, nervous system and body of a man from the excessive use of alcohol.

May Testify as to Statements and Observations.

The Appellate Court of Indiana, Division No. 2, holds, in Indianapolis & Martinsville Rapid Transit Co. vs. Reeder, that the statements of an injured party, made to a physician, expressive of his then present existing physical condition, may be given by the physician as a part of his examination. Again, a physician was asked: "To what extent has this woman suffered pain since this injury was inflicted on her, as you have observed it?" The answer was: "As I have observed it, she has suffered qnite a good deal." The objection was made that the question called for a conclusion. If so, the court says, it was one competent for an expert witness to give; but, while the fact might be more keenly appreciated by the person snffering than by an onlooker, it was nevertheless a fact relative to which the onlooker, and especially where he was a physician, might testify.

Damages for Hernia.

The Supreme Conrt of Washington says that in the personal injury case of Leeson vs. Cawmill Phoenix a jury brought in a verdict of $5,500 damages for an inguinal hernia on the right side caused by a blow in the abdomen from the handle of a chisel thrown back by an alleged defective machine. The plaintiff, who was abont 47 years of age, was said by all physicians who testified in the case to be in a healthy normal condition, with the exception of the hernia. There was also testimony that he could probably be cured by an operation which would cost in the neighborhood of $200 or $300. The Supreme Conrt holds the award under these circumstances excessive, and that $3,500 would be ample compensation. An excessive verdict in a case like this, it says, is not only an injustice to the defendants, but it is a menace to the welfare of the state, and shonld not be upheld.

Attitude of Court Toward Prescription of Whisky.

The Appellate Court of Indiana says, in De Tarr vs. State, that it is recognized in the medical profession that the use of whisky for medicinal purposes is in many instances salutary and useful. It is often prescribed and recommended by physicians. When there is a substantial compliance with the statute permitting its prescription, and parties act in good faith, this court would be derelict in judicial discretion if it applied the strict letter of the statute, instead of its spirit, and thus protect those who have done no legal wrong. But as against the pernicious habit which had grown up in the state of the indiscriminate sale by druggists of intoxicating liquors, to be nsed as beverages, under the false guise that such sales were for medicinal purposes, against which the statute was directed, the court nnalterably declares in favor of a strict enforcement of the statute.

Tea and Coffee Not "Provisions."

The Supreme Judicial Court of Massachusetts says that the first qnestion in the case of Commonwealth vs. Caldwell was whether tea and coffee are "provisions," within the meaning of a statute permitting the sale of provisions, by peddlers, without a license. The court thinks that they are not. The word "provisions" as used in the statute, it says, has been held to mean "food, victuals, fare and provender." Tea and coffee are not used as food, in the form in which they are sold by shopkeepers. They are used to make decoctions, to be taken as a beverage for their agreeable taste or their stimulating effect. In this respect they are not very different from wine and beer, which in many countries are in common use at meals. Therefore the court is of the opinion that they are not included in the term "provisions," in its ordinary sense, or in the meaning of this statute.

Liability for Medical Attendance on Wife.

The Second Appellate Division of the Supreme Court of New York says, in re Stadtmuller, that a husband died three weeks after his wife did, but a short time before his death he paid the physician who attended his wife during her last illness. Both husband and wife left estates. The will of the wife directed that all her jnst debts and funeral expenses be paid. Could his administratrix recover from his wife's estate the amount of the physician's bill so paid? No. So long as the wife lived with her husband, he, and he alone, was liable to the physician as for necessaries supplied to the wife, in the absence of agreement between the wife and the physician that credit should be extended to her. No such agreement was shown to exist. Under such circumstances neither the wife nor her estate would have been liable, in the absence of special direction in her will that such payment be made. It was different with regard to her funeral expenses.

Health Officer Entitled to Full Salary of Office.

The Second Appellate Division of the Supreme Court of New York says that the proceeding in People on the relation of Leitner vs. Sipple and others as town board of audit was to review and correct the action of the board in reducing the compensation of the relator as health officer of the town to $25 for the year 1904, from $100, as fixed by the board of health of the town in pursnance of the provisions of the statnte. It did not seem to be questioned that he held the office of health officer of the town, although there was some claim that he had not discharged the duties of his office. But, the court says that, as it views the case, this did not concern the board of audit. If he held the office, so long as he was not removed, he was entitled to the salary which had been affixed to the office by competent authority. The facts as they appeared from the return, in connection with the petition, showed that he was entitled to an audit of the remainder of his claim. The determination of the town board of audit should therefore be annulled and such claim remitted to the board, with instructions to audit the same at the rate of $100 a year for the period during which he acted as health officer.

What Constitutes the Loss of a Hand?

The Supreme Conrt of Nebraska had presented to it by the case of Beber vs. Brotherhood of Railroad Trainmen the question of whether a total loss of three fingers and an injury to the remaining finger and thumb, which materially interferes with their use, and a cutting away of a part of the palm

to the hand constitute a total loss of the hand within the meaning of a by-law of a mutual benefit association, which provides indemnity for any member in good standing suffering "by means of physical separation, the loss of a hand at or above the wrist joint." The District Court decided that it does not; that under such a by-law recovery of indemnity can be had only on proving that the entire hand was severed at or above the wrist joint. But the Supreme Court holds that the lower court erred in taking that position, and directing a verdict for the defendant. It holds that the question was one to be submitted to the jury for its determination, and there leaves it.

8 *Foreign Body in the Orbit. T. A. Boot, Holland, Mich.

1. See abstract in THE JOURNAL, April 28, 1906, p. 1310.

3. **Syringomyelia with Partial Macrosomia.**—Schlapp's patient, a man aged 38, had been well up to two years ago. At this time he had an attack of indefinite illness followed by a swelling of the left shoulder, arm and hand to about twice their normal size. They have since been somewhat larger than the right arm and hand. There is complete loss of the pain and thermal senses over the whole of the left arm and hand, and on the surface of the back and chest, neck and back of head. There were attacks of total blindness in the left eye lasting about five minutes. The bones were involved as well as the soft tissues. They show greater opacity than do the normal bones. In this case there is a paralytic dilatation of the blood vessels with edema caused by a lesion lying remote from the hypertrophied tissue and in no way directly affecting it. Schlapp thinks it probable that the tissue hypertrophy is the result of the bioplastic as well as the kakabiotic process.

4. **Exercise.**—Wainwright states that every physician ought to understand something of the methods of "mechanico-therapeutics," and should avoid vague expressions such as "out-of-door life," "muscular exercise," and so on, when consulted as to the propriety of exercise in an individual case. For practical purposes the moderate use of dumb-bells, Indian clubs, developing machines, bicycling, horseback riding, walking and similar methods of exercise, will accomplish much in promoting the physiologic functions of organs, and thus assist in great part to ward off the ravages of disease.

5. **Rheumatic Manifestations in Children.**—Sicard gives the following résumé: Rheumatism in nursing infants is very rare; in childhood the disease is atypical, the joint signs being but little marked; the so-called complications are in children rather types of the disease, for they may occur without joint symptoms, either alone or associated with each other. The whole attack, while seemingly mild and subacute, is capable of causing severe damage to other structures, notably the endocardium, pericardium and the nervous system. Relapses occur and patients are often left invalids for life.

6. **Cul-de-Sac for Artificial Eye.**—Valk's patient, a woman, was injured by a rocket stick which fell, burnt end downward, passing through the brim of her hat. It lacerated the eyeball, tore out the lower part of the conjunctiva and the free border of the lower lid and passed down through the cheek and out below. The eyeball seems to have been torn out and probably also part of the muscular cone. The outer part of the orbital plate of the superior maxillary bone near the articulation of the malar seems to have been fractured, but the infraorbital nerve was not injured. The superior lid and cul-de-sac were intact and normal. Valk operated for the purpose of forming a lower cul-de-sac so that an artificial eye could be worn, following out the method of Weeks. He does not know what the complete final result in this case will be, but at present he considers the operation a success.

8. **Foreign Body in Orbit.**—Boot reports the case of a patient from whose eye he removed a fragment of clay pipestem one and five-eighth inches long, one-quarter of an inch in its widest diameter, and weighing 50 grains. It had been lodged in the orbit forty-nine days.

10. See abstract in THE JOURNAL, Jan. 6, 1906, p. 65.

11. **Rubber Gloves in Medical Wards.**—Clarke advocates the use of rubber gloves in medical wards for the purpose of protecting the patient from the physician, the physician from the patient, and one patient from another. He has made use of rubber gloves in performing infusions, venesections, intravenous injections, paracenteses and lumbar puncture. He considers the use of rubber gloves during vaginal and rectal examination a great safeguard against syphilitic infection. The nurse, too, is protected against infection by the use of the gloves to be worn while handling specific cases, giving inunctions, douches, enemata, etc. Their use also prevents the spread of infectious diseases and suppurative conditions in general from one patient to another. The technic of caring for the gloves consists of washing them immediately after use, boiling for a few minutes, drying thoroughly and powdering inside and out with talcum powder.

22 *A Consideration of the Treatment of Autointoxication or Auto Infection When They Are the Cause of Mental Disturbance (Concluded). L. V. Briggs, Boston.

18. **Treatment of Joint Disease by Passive Congestion.**—Hartwell reports the results obtained in the treatment of ten cases of joint disease by passive congestion. He says that the treatment must be considered an adjuvant to mutilating operations rather than a substitute. Its success depends on the quality of the blood which the individual presents to combat the disease. In acute or subacute inflammations the best results are obtained in gonorrheal joints, especially in those which tend to anchylosis or in which the inflammation leads to bad stiffness. The duration of the congestion in acute or subacute joints other than tuberculous depends on the effect it produces. If the patient states that after one or two hours' congestion the pain is relieved and motion is increased, this length of time is sufficient, but if the pain soon returns a longer period of congestion must be maintained.

Most of the cases treated by Hartwell represented well-advanced types of the disease so that they presented a most discouraging outlook when treatment was commenced. In each case, however, the passive congestion shortened the course of treatment of these diseased joints and by its means excellent results were obtained where in some the only outlook seemed to be in operative interference.

19. Some Etiologic Suggestions.—Wellman discusses the significance of an embryo intestinal worm found in the blood stream and the possible connection between chiggers and ainhum. He is of the opinion that *S. penctrans* plays a part in the production of ainhum.

21. Influence of Damp Soil and Climate on Respiratory Diseases.—Barnes believes that the conclusions to be drawn from the evidence at hand is that all diseases of respiration are common enough regardless of dry or damp soils, in hot or cold, moist or dry, climates to at least raise a doubt if these conditions have any influence whatsoever as a cause of the diseases of respiration. An excessively dry air, he states, which Nature nowhere provides, but which we create in winter by raising the temperature of air holding a very small volume of watery vapor, and thus lower the relative humidity to an extent sufficient to impair the resisting powers of the mucous membrane lining the respiratory tract, may be a factor in the increased prevalence of respiratory diseases in cold weather.

22. Treatment of Autointoxication or Autoinfection.—The treatment employed by Briggs in an average case of mental disease in which the cause is autointoxication or autoinfection includes a tonic before meals, antiseptic with meals and two hours after meals, daily colonic flushings with normal salt solution, and baths of salt water lasting from twenty minutes to an hour at night. The diet is regulated and consists entirely of milk at first. If there be much decomposition in the stomach, lavage is resorted to. The antiseptics and tonics are varied in quantity and kind according to the individual or the results obtained of antiseptics. In cases in which there has been actual damage to the brain, the treatment has shown that the progress of the disease can be stopped, though damaged areas can not be replaced. Almost every case of mental disease begins with insomnia, and while this is not the cause of the disease, it retards repair, and until normal sleep is established, permanent results can not be obtained. With the elimination of the toxins by antiseptics, sleep usually comes without sedatives. Briggs believes that the treatment of selected cases of mental disturbance with antiseptics and correcting the habits of the various organs, proves that toxins do exist and are the most potent factors in many disorders of the brain.

25. Resection of Bladder in Rebellious Cystitis.—For the management of intractable cases Kelly lays down the following rules: First, to determine the infecting organism or organisms, note how numerous are the colonies which grow out within a given time from say three platinum loops distributed on agar. Second, note exactly the extent of the disease in the urinary tract as a whole, in kidneys, ureters and bladder. Third, it is important to determine and to make carefully written notes describing the exact condition of the bladder. Fourth, in beginning a course of treatment, clear up the disease as far as possible, according to the milder measures, thus rendering the active surgical intervention when undertaken far less aggressive. Fifth, having cleared up the disease to a particular area which is rebellious to further treatment, it should then be excised in toto by a resection of the bladder walls. Kelly urges that many cases of advanced vesical inflammation, even of a tuberculous character, which heretofore have been counted hopeless, are amenable to surgical treatment, which may go so far as to excise half or two-thirds of the bladder.

When the kidney is involved, this organ must be attended to first if the disease is extensive, after the bladder if the infection is mild. He thinks the best method of suturing is to use a row of catgut sutures, including the entire thickness of the bladder walls, for the first row, and to reinforce this with a second row of fine silk sutures. He has experienced no trouble from tying catgut sutures in the bladder, and dropping them when it was easier to pass and to tie the sutures in this way at the base.

26. Exophthalmic Goiter.—Thompson reports the results of a study of 42 cases. He emphasizes the fact that in addition to possessing the four cardinal symptoms of tachycardia, tremor, enlarged thyroid gland and exophthalmos, this disease is subject to exacerbations which are of a distinctly toxemic character, with active fever, acute cardiac dilatation with murmurs, and a variety of symptoms constituting a definite clinical syndrome. In some instances the most serious toxemic attacks have been completely checked by the cytotoxic serum of Dr. Rogers, prepared from the diseased human glands through animal inoculation. In a large proportion of cases the agency which appears to initiate the acute toxemic seizure, is some intercurrent mild infection, such as an attack of tonsillitis, pharyngitis, bronchitis, influenza or similar acute ailment.

27. Treatment of Ocular Injuries.—Hubbell claims that the experience of most ophthalmologists shows that practitioners who are first consulted in these injuries approach them with more or less unconcern, and fail to give the attention and relief demanded. On account of the complexity of the organ of vision, the difficulties of diagnosis, the importance of the results and the technicality of treatment in so many of these cases, Hubbell advises that they should be referred to a specialist as early as possible, and especially when there are penetrating wounds of the eyeball. Injuries of the eyelids and other ocular appendages seldom affect vision, infection rarely follows, wounds heal rapidly, and they are to be treated simply in accordance with the ordinary rules of surgery. This treatment may be carried out by any intelligent practitioner. Superficial injuries of the cornea are more important. Infection frequently takes place, and then there is danger of a suppurative process, which may extend throughout the cornea or even involve the whole eyeball. The early treatment consists in removing foreign bodies and using applications to prevent infection.

Penetrating wounds of the eyeball should always be approached with more or less concern. If not already infected at the time of the injury, they easily become infected afterward. Moreover, a foreign body may have been driven into the eye, which not only carries infection with it, but which in itself becomes, with rare exceptions, a certain cause of destructive inflammation. In every punctured wound of the eyeball inflicted by a small, unseen object, there should always be a suspicion of the introduction of a foreign body. The diagnosis is often most difficult, and requires special appliances and experience. The removal of a foreign body from the interior of the eye is almost imperative to its salvation. Here, too, special equipment and special skill are demanded. Infection, by whatever means it may be introduced, is the agent which destroys the injured eye, both by suppurative processes and by non-suppurative uveitis. In non-suppurative traumatic uveitis, the infection seems to be of a specific kind and is transmissible to the uninjured eye, producing there a sympathetic uveitis, which is also destructive in its course. Sympathetic inflammation does not develop until at least two weeks after the injury of the first eye.

In the absence of a foreign body, or after its removal, the

immediate treatment of a perforating wound consists in sterilizing the eye and its surroundings, freeing the wound of all incarcerated tissues and closing it as perfectly as possible, or touching the opening with carbolic acid. Subsequently sterilization should be kept up as effectually as the circumstances will permit. Infection should be combated by intraocular disinfectants and rendered dormant by the persistent and methodical application of cold over the eye. An eye that is hopelessly lost at the time of the injury should at once be excised, an operation which may be performed by any well-informed practitioner. When an eye is affected with active traumatic uveitis, it should be enucleated within two weeks from the time of the injury, unless the eye has useful vision or many may be given useful vision by some operative measures. In wounds of the eyeball of all varieties delays are dangerous, and if there is the slightest possibility of a foreign body being lodged within the eye, or if infective processes begin, the dangers to sight are so great that the services of a specialist should always be secured, if possible.

38 *Proprietary Medicines and State Medical Society Journals. R. C. Newton, Montclair, N. J.

34. **Effect of Muscular Exercise on the Heart.**—Meylan claims that muscular exercise judiciously prescribed and practiced is a valuable agent in the cure of many forms of cardiac inefficiency. Athletic sports when practiced without medical supervision produce more or less permanent cardiac injuries in weak and untrained individuals. The difference in pulse between the horizontal and the vertical position is a useful sign in the physical diagnosis of cardiac conditions. The adaptability of the heart to suddenly increased work, as measured by the change in pulse rate after muscular exercise, is a valuable indication of cardiac efficiency.

38. **Proprietary Medicines and State Journals.**—Newton says that only the journals really owned and controlled by the state societies are independent enough, honest enough and brave enough to attack this evil of the advertisement of nostrums in the medical press and to keep up the fight. When the medical press has cleared its own skirts it can and will force the lay press and the religious press to follow suit. The average of intelligence both in and out of the profession is gradually rising. It has at last risen to the point where this question is understood in its true bearings. The fact that the majority of the privately owned medical journals are controlled by the nostrum interests, he states, is apparent to everyone, and although the fight may be a long and a hard one, honesty and decency in the medical press will assuredly be exacted at last by the profession. Newton claims that the credit for the inauguration and prosecution of this beneficent work belongs to the state medical journals.

47 Diagnostic Value of Albumin and Casts in Urine as Related to Life Insurance. C. N. McCloud, St. Paul.

39. **Dilatation of Stomach.**—An examination of 37 cases has convinced Head that no one etiologic factor lies at the bottom of all cases of dilated stomach, and the cases seem naturally to divide themselves into groups depending on the factor which played the most prominent part in producing the dilatation. In 5 of the cases, ulcer either of the stomach or duodenum, with resulting stenosis at the pyloric end of the stomach, was the cause of the dilatation. Three of these cases were in men and two in women. All were in individuals over 30 years of age. All had complained of stomach trouble for many years; one patient 20 years, another 10 years, a third 25 years and a fourth 6 years. All complained of vomiting after meals and of pain after eating. In 2 the stomach was much enlarged, the lower border reaching in one case to 10 cm. below the umbilicus; in another to 12 cm. below the umbilicus. In the other two the lower border reached to the umbilicus. In 4 cases of the 37 the cause of the dilatation was a carcinoma of the stomach. Three were in men and one in a woman. In another group of cases, five in number, the etiologic factor was a lesion in or around the gall bladder.

In two of the cases the enlargement was caused by an obstruction at the pylorus due to adhesions between the gall bladder and the duodenum or pyloric end of the stomach. In one case of this group the dilated stomach was caused by a distended gall bladder filled with gallstones which, lying over the duodenum, acted as an obstruction to the outflow of chyme. In all the cases of this group the lower border of the dilated stomach reached below the umbilicus. In all the abdominal pain was referred to the upper abdomen in the pyloric region of the stomach. In all there was epigastric tenderness of mild degree and not well localized. In two of the cases the abdominal distress complained of came at regular intervals after eating. In the other three the pain came irrespective of the taking of food. None complained of vomiting. In four there were large amounts of free HCl in the gastric contents after a test meal. A stomach analysis in the fifth case was not made. In two there was marked hyperacidity after a test meal.

In a fourth group of cases, three in number, the dilatation of the stomach was associated with tuberculosis of the lungs. One case was in a man 41 years, the other two in women, 28 and 55 years of age, respectively. In a fifth group of cases, 14 in number, the enlarged stomach was associated with pronounced nervous symptoms and assumed a position low in the abdomen. In most of them the abdominal wall was loose and flabby, one or both kidneys were out of position and could be palpated, as could also, in some cases, the edge of the liver and spleen. The abdominal aorta pulsated forcibly. The remaining cases, four in number, are classed together as the mucus colitis group. These were cases of dilated stomach associated with the passage of masses of mucus in the stools, the passages usually being accompanied by attacks of colicky pains in the abdomen. Two of these cases were in women and two in men. All were young individuals under 25 years and all had moderately dilated stomachs.

40. **Relation of Dislocated Kidney to the Appendix.**—O'Brien believes that one of the great reasons why many cases of nephrorrhaphy are not attended with relief of the symptoms is because an accompanying appendicitis is overlooked. He insists on the necessity of the removal of the appendix in all cases in which a right nephrorrhaphy is undertaken for the relief of abdominal symptoms.

43. **Significance of Albumin and Casts in Urine.**—Stumm points out that there are instances in which the presence of albumin and casts in the urine have no grave diagnostic significance. He urges, however, that if they are found present the patient should be observed closely and the diagnosis of physiologic albuminuria made with great caution, for once it is impressed on the mind of the patient that the presence of albumin in his urine is of no grave significance he may lead a life that will be of the greatest detriment to him if the physician has erred in his diagnosis.

45. **Albumin and Casts in Urine of Infants.**—Ramsay has found that when systematic examination of the urine of infants is made, albumin and casts are found frequently, especially when the infant is suffering from disturbances of the intestinal tract.

46. **Albumin and Casts in Pregnancy.**—Hall points out that albumin and casts occur in a large percentage of pregnant women and that in most cases it signifies the presence of the

so-called kidney of pregnancy. Most of these cases return to an apparently normal condition after labor, but the presence of pregnancy indicates a danger of eclampsia. About 2 per cent. of these women develop eclampsia, and eclampsia never develops except in these cases.

50 Treatment of Acute and Chronic Maxillary Sinusitis. C. F. Theisen, Albany.

48. **Uterine Myomata Simulating Pregnancy.**—Sampson calls attention to some of the more common conditions causing difficulties in the differential diagnosis, and also emphasizes the important part played by uterine myomata in the simulation of pregnancy, and, therefore, the importance of carefully studying these cases. Uterine myomata through the alterations in the form of the uterus caused by the tumor, the increased vascularity in that organ and surrounding parts necessary to nourish the uterus and tumor, and the stimulus due to a submucous myoma, thus giving rise to uterine contractions, may cause symptoms which may simulate any or all of those caused by pregnancy, except the actual heart-beat of the living child. These simulations, however, nearly always lack the stamp of genuineness, and, if they alone are carefully studied, should teach that they are, in the particular case under study, much more characteristic of a myomatous uterus than a pregnancy; the above, together with a history of the case, should make the diagnosis clear in nearly every instance. Sampson concludes that when mistakes are made it is nearly always the physician's fault; the signs were all there, only he would not see or heed them, or would insist in incorrectly interpreting them.

52. **Observations in the Philippines.**—The remarks on surgery in the Philippines made by Banister are founded on his experiences in the surgical department of the First Reserve Hospital, Manila, during a period of twenty-three and one-half months. Of 775 operations noted by Banister, 181 involved the peritoneal cavity, and 240, counting four cataract extractions, may be easily accounted major operations. Following this amount of operative work there occurred 16 deaths, a mortality rate of 2.06 per cent. Most of these 16 fatalities occurred in patients who were moribund when brought to the hospital, and who were subjected to immediate operation in the forlorn hope of saving life, and the remainder were in hopeless conditions when placed on the operating table, with one exception, and in the latter case death from tetanus was due to infection from dust blown into the operating room during the operation. In this mortality list there is not a death, Banister says, which would not have occurred under the best auspices in any climate, except the fatality from tetanus. The soil of the Philippines is rich in tetanus spores.

For the radical cure of inguinal hernia by the Bassini method 96 operations were performed, there having been first union in every case, and not a single instance of recurrence. Fifty-five operations for appendicitis were performed, with one death. These operations were undertaken for every variety of disease and there was no selection of favorable cases for operation. Eight operations for liver abscess were performed on seven patients, one patient having been aspirated prior to a subsequent operation by abdominal section. These cases of hepatic involvement occurred in patients who had been affected with amebiasis, and were directly due to amebic invasion of the liver. Three deaths occurred; two of these patients had multilocular abscesses and one a large single abscess. Banister says that bone surgery is followed by excellent results in the Philippines, and no one need hesitate to operate on joints, or the osseous tissues generally, on account of any supposed detrimental climatic influence. For the radical cure of ventral hernia five operations were performed. Of these, four patients were radically cured, the wounds healing by first union, and one fatality resulted from tetanus, as before described.

A perfect result followed every operation for varicocele and hydrocele, of which there were 69 for the former and 16 for the latter condition. The suprapubic incision was invariably used in the operation for varicocele, and the excision of the tunica vaginalis, with drainage, was employed in the radical treatment of hydrocele. Seven perineal sections were performed, four with and three without a guide. All were successful. In the case of a patient with extensive adhesions of the cecum and omentum to the parietal peritoneum, which condition had existed for two years as the result of an old suppurative appendicitis which had been subjected to operation with drainage, the patient being an invalid in consequence, a perfect cure was secured by laparotomy with separation of the adhesions, a portion of the omentum being removed.

53. **Hernia in the Services.**—Austin believes that all adults under 55 years of age whose vocation necessitates severe physical exertion, as that of the sailor or the soldier, suffering from inguinal hernia are best treated by an operation for the radical cure, such as the Bassini or Halsted, and that it should be recommended in all such cases, unless there is some special contraindication that would prevent the patient undergoing any surgical operation requiring an anesthetic. Each case of irreducible hernia is a law unto itself, but if the hernia is not very large, and if the patient is in fair health, not over 60 years old, and especially if the bowel comes down at times, Austin recommends an operation. The liability to strangulation in these cases is greater than in any other except in enterocele, in which the opening in the ring is very small. Immediate operation in all strangulated hernia without temporizing is the safest procedure, and the operation should be for radical cure when possible.

1. **Treatment of Enuresis.**—Atropin, used in the form of an extract, or the tincture, or as liquor atropinæ, is the only drug from which Thursfield has derived any good results in the treatment of enuresis. He usually gives 10 minims of the tincture three times a day as the initial dose, and raises the dose week by week up to a dram three times a day. He says it is essential that the dose should be sufficient to produce evidence of its action, and that it be used over a long period. The dose should be diminished slowly until the drug can be dispensed with safety. A period of from three to six months will usually be required to obtain permanent relief. Thursfield employs the belladonna in conjunction with potassium citrate in the majority of cases, and in a few instances, in which he believed that hyperacidity of the urine was the chief cause, he found potassium citrate alone to be efficacious. Another drug which he has found useful, especially in cases of bacteriuria is urotropin (hexamethylenamin, U. S. P.). He says it must be given well diluted. He has used it in a series of thirty consecutive cases with good results in nine instances.

3. **Antityphoid Serum.**—MacFadyen gives an account of the results obtained by the immunization of the goat with the cell juices of the *Bacillus typhosus*. Virulent typhoid bacilli isolated directly from the peritoneal cavity of the guinea-pig were cultivated on nutrient agar in Roux bottles for eighteen hours at blood heat. The growth was brushed off and washed with distilled water in a centrifuge for half an hour. The living bacilli were then triturated at the temperature of liquid air in the author's grinding pot. The time allowed was thirty minutes per gram of bacilli. The resultant mass was taken up in 1 in 1,000 solution of caustic potash and spun for two hours. The fluid obtained represented a 10 per cent. extract of the typhoid cell plasma, along with such bacilli as had not been removed by the two hours' centrifugalization. This was treated with chloroform vapor for half an hour. The cell juices obtained under these conditions were sterile and toxic on intravenous injection into the test animals employed: goats and rabbits.

A goat after receiving doses of 0.05 and 0.1 c.c. died, whilst another after the injection of 0.05, 0.1, 0.5 and 1 c.c., died within four hours after the last dose. The subsequent animals consequently received small sublethal doses which were raised very gradually at duly spaced intervals. One injection weekly proved to be the safest procedure, and the same dose was repeated until it failed to produce any toxic action on the animal. A slightly higher dose was then given and repeated in the same manner. This method proved ultimately successful, as only in this way was tolerance established to otherwise fatal doses of the typhoid endotoxin.

6 **Exophthalmic Goiter.** Dutton suggests that the hypertrophy and overactivity of the thyroid, the exophthalmos, the persistent thymus, the enlarged lymph glands, the increased connective tissue in the neck, the tachycardia, palpitation and tremor, besides the other subjective symptoms of the disease

are symptoms of a lesion of some of the chain of sympathetic ganglia. He sees no reason why ordinary simple goiter and the exophthalmic form should not be varieties of the same disease.

16 Case of Ascites Tapped Sixty-nine Times. F. H. Maberly.
17 *New Method of Operating in Pannus. W. Primrose.

11. The Arterial Pulse.—According to Curl the arterial pulse represents in the main the sudden increase of pressure occurring in the arteries as a result of the ejection into them of the contents of the left ventricle, and it travels from the heart to the peripheral parts in the form of a wave, diminishing in size as it passes along. The pulse curve represents the changes occurring within the artery at the part under examination. Its form varies according to the force of the contraction of the ventricle, to the blood pressure, to the condition of the vessel wall, and to the distance of the vessel from the heart. This sudden increase of pressure in the arteries having reached its maximum is followed by a fall, the fall, however, being interrupted by a slight increase of pressure as the dicrotic wave appears; it then returns to the normal.

Of pathologic pulses he found few, if any, characteristic of the diseases producing them; in the large majority of cases no specific alterations are produced. Alterations in the tension occur in arteries which are either naturally small or are so abnormally retracted that one is apt to overlook high tension, and he thinks that in such cases as these the sphygmograph is especially useful, since it may demonstrate high tension hardly appreciable to the finger.

13. Vaccine Treatment in Surgery.—Gray has employed the vaccine treatment, according to the method advocated by A. E. Wright, with excellent results in the treatment of tuberculous glands, tuberculous joint affections, tuberculous peritonitis, psoas abscess, genitourinary tuberculosis, tuberculous disease of the upper air passages, and tuberculous tenosynovitis.

14. Antistreptococcic Serum in Malignant Endocarditis.—From a prolonged use of polyvalent antistreptococcic serum per rectum, Raw is satisfied of its greater efficacy and personal comfort than by injecting it under the skin. He reports three cases of malignant endocarditis in which this treatment was of immense benefit when other methods had failed. During the past eight years Raw has used this serum in more than 200 cases of septic infection of various kinds, such as puerperal septicemia, pyemia, erysipelas, and septicemia complicating typhoid, pneumonia and endocarditis, and he has come to the conclusion that in purely streptococcal infections the serum is of great value, especially when administered by rectum.

The method adopted is as follows: The bowels are freely cleared by aperients and the rectum is gently washed out with a little warm saline solution. The formula for injection is as follows: antistreptococcic serum, 20 c.c.; normal saline solution, 100 F., 40 c.c.; to be gently injected into the rectum morning and evening, or as required. It is found that there is no pain nor discomfort; the serum is rapidly absorbed and seems to exert the same bactericidal influence as when given under the skin; skin rashes are rarely seen and the thirst and dry tongue are relieved. When given in such a small amount there is no difficulty on the part of the patient retaining it and it is rapidly absorbed.

17. New Operation for Pannus.—The operation described by Primrose consists in causing an extravasation of blood into the subconjunctival tissue around the cornea. This by its mechanical pressure and by acting as an irritant foreign body setting up a localized inflammation, causes the obliteration of the vessels which vascularize the cornea. The only instrument required is a small sharp-pointed knife—a Beer's cataract knife does very well for the purpose. The point of the knife is passed through the conjunctiva at a distance of 2 to 3 mm. from the cornea and made to puncture one of the larger blood vessels. The knife is then withdrawn. The conjunctival wound should be as small as possible and made obliquely by holding the knife at an acute angle with that part of the surface of the eyeball which is being operated on. In this way there is no external hemorrhage; but bleeding takes place into the subconjunctival tissues and is arrested automatically by the pressure of the extravasated blood on the blood vessel walls. In like manner, many of the smaller vessels in the vicinity are mechanically closed. The mechanical action is increased by the formation of a coagulum, the fibrinous part of which shrinks and makes the whole mass smaller. By the time the blood clot has disappeared, the blood vessels in the cornea affected by the operation have shriveled up and the cornea has regained much of its transparency. The whole pannus may be treated in this way at one time, or the operation may be repeated from time to time, only a part of the pannus being treated each time. The latter is always advisable when the pannus is marked, as the inflammatory reaction is sometimes very severe and accompanied by a good deal of pain. Although the structures in the anterior part of the eyeball are all more or less affected by the inflammation this is easily controlled and subsides in a few days with the application of suitable remedies.

19 *Suggestions for the Maintenance of Health by Women in the Mission Field. M. A. D. Scharlieb.
20 Some Striking Facts About Bangkok. R. H. Bremridge.

19. Maintenance of Health by Women in Mission Field.—Scharlieb discusses this subject under the following heads: 1, Preparation for work in the mission field; 2, selection of candidates; 3, allocation of candidates for special work; 4, care of health on active duty, and 5, care of health when on furlough. She advises that in the case of young women proposing to go out as the wives of missionaries there should be a special investigation as to their fitness for maternity. The external measurements of the pelvis should be carefully taken with calipers, and, if any obvious deformity exists, a further examination under anesthesia may sometimes be proposed: loss of valuable lives and much hindrance to work being saved if it is clearly understood that in any given case the wife of a missionary is likely to need specially skilled assistance, and must, therefore, go for confinement to some center where such assistance can be secured. The paper contains many excellent suggestions, but space does not permit of a full abstract.

25. Morbidity in French Colonies.—Kermorgant's official report states that sleeping sickness was noted in all the French colonies in western Africa during 1904, and has depopulated entire villages in the Congo region. Plague was observed only in the Indian possessions, but malaria prevails in nearly all the colonies; it is most serious in Madagascar and Tonquin. It averages about 56 per cent. of the total mortality among the Europeans there. In the Soudan it is endemic throughout the year. All the children, the report states, have enlarged spleens, and the malarial parasite is found in the blood of nine out of every ten children.

26. Yellow Glasses for Sensitive Eyes.—Motais has been prescribing for fifteen years, in cases of ultra-sensitiveness to light, glasses of a yellowish tint, slightly orange, with a

brownish tint on reflection. They increase the perception of light while soothing the eyes. The yellow tint evidently prevents the passage of the chemical rays to some extent. These yellow glasses, he states, will be found far superior to smoked or blue glasses, while they do not impair the vision. When they are taken off even the most brilliant sunlight seems dead and lifeless in comparison.

28. **Inversion of Uterus Reduced with Champetier de Ribes Balloon.**—Mantel has had the unusual experience of 6 cases of complete inversion of the uterus which he was able to reduce with the aid of the inflated bag. In his latest case the inversion occurred during delivery and was easily reduced. Four days later it recurred and reduction then did not seem practicable. After thorough cleansing of vagina and uterus with hydrogen dioxid he introduced the Champetier de Ribes balloon into the vagina and inflated it with air, leaving it in place for twenty-four hours, when conditions were found restored to normal. The balloon was left as a precautionary measure for a week, and no further disturbances occurred.

29. **Decapsulation of Kidneys Plus Nephrotomy in Eclampsia.**—In a case of severe eclampsia, with anuria for forty-eight hours, the kidneys were decapsulated according to Edebohl's technic. Macroscopic and microscopic evidences of acute parenchymatous nephritis were found, and the decapsulation was supplemented by nephrotomy of the right kidney. The nephritic process was manifestly arrested by these measures, and the secretory functions were restored at once. The patient was a primipara of 21. In commenting on this and on Edebohl's cases, Pinard says that many women who die after having presented eclamptic attacks never exhibit anuria, and their kidneys show few if any signs of anything pathologic. In certain cases of eclampsia, however, the symptoms point to a condition which might be called "glaucoma of the kidney." Surgical intervention on the kidneys should be restricted to such cases.

32. **Pathogenesis of Tabes.**—Marineseo was unable to find the treponema in any of the numerous cases of tabes examined, the findings in the cerebrospinal fluid and in the sections of the spinal cord and posterior roots being invariably negative. In this profusely illustrated article he describes the results of his study of these parts in tabetics with the Cajal staining technic. He found that the nerve elements showed evidences of injury and also of attempts at regeneration. The tabetic lesions are twofold, a degenerative atrophy proceeding from the spinal cord toward the spinal ganglia, and a process of regeneration working in the opposite direction. The latter resembles the regeneration which occurs after section of a nerve. The absence of the treponema in the tabetic lesions and the occasional coexistence of syphilids on the skin or of other manifestations of syphilis with the tabes sustains the hypothesis that tabes is not due directly to the agent of syphilis, but is the result of toxins generated by it.

33. **Simple Test for Impending Mercurial Intoxication.**—Severino has found that existing or impending mercurial saturation can be revealed by touching one or more of the teeth with fresh tincture of iodin. As the patient then wets the teeth with saliva, they turn pink in case of intolerance or saturation, while this does not occur when the mercurial treatment is being well tolerated. The mercury eliminated in the saliva combines with the iodin to form the red bi-iodid if the proportion in the saliva is excessive. The proportion eliminated in the saliva is minimal when the kidneys and other emunctories are working properly, and the test gives negative findings, but when the mercury is accumulating unduly in the system this is revealed by the pink stain of the teeth after they have been touched with iodin.

37. **Removal of Thymus to Relieve Asthma.**—Ehrhardt removed the enlarged thymus in a girl of 2 whose trachea was flattened by the thymus. The organ was easily removed, freeing the child at once from her suffocation. He felt justified in removing the thymus, as experimental research has shown that dogs tolerate its removal without disturbances. The child has not apparently suffered any inconveniences from the operation and has been entirely well since; the blood findings are entirely normal. The operation was performed last September. He left the incision open to see whether or not the flattened trachea would resume its normal shape, as it soon did spontaneously. The diagnosis of compression of the trachea was rendered certain by the findings when intubation was attempted.

39. **Possibility of Supplying New Collateral Circulation for the Kidney.**—Martini's numerous experiments on dogs treated by decapsulation of the kidney demonstrate anew that the circulation through the kidney becomes much more extensive after collateral circulation has developed in consequence of the decapsulation. He found that it was possible for dogs to survive after nephrectomy and ligation of the vein of the remaining kidney when the collateral circulation had developed after its decapsulation. This condition was always fatal for dogs with normal, that is, undecapsulated kidneys. The development of new anastomotic routes after decapsulation was unmistakably shown by the passage of gelatin into the kidney through the circulation after all the normal vessels of the kidney hilus had been tied off.

47 Suture of Palate.—Gaumennaht. J. Dollinger (Budapest).
48 (No. 14.) *Zur Technik der Rückenmarks-Anälgesie (spinal analgesia). Hackenbruch (Wiesbaden).

42. **Passive Congestion as Postoperative Measure.**—Kaefer states that he gave Bier's artificial hyperemia a thorough trial soon after it was first announced, and was early convinced of its great value. He has used it now in more than 150 cases and always with increasing satisfaction. He makes a practice of applying the passive congestion after operations when the slightest indications develop suggesting the possibility that healing may not be by primary intention. The prompt application of the constricting band or of the suction cup is invariably followed by the subsidence of symptoms of irritation when the wounds are in tissues that had not suppurated before the operation. In the frequent operations for crushed fingers of factory operatives, the wounds are much soiled, but they heal by primary intention when passive congestion is energetically applied.

44. **Operating Table.**—De Quervain expresses surprise that in all the countless operating tables of which he knows no

provision has ever been made to take advantage of the peculiarly favorable conditions for abdominal surgery which are offered when the spine is bent over backward, the lumbar vertebræ in lordosis, and the hip joints in hyperextension. He gives illustrations of an operating table constructed to bring out these points. He has found it a great help in operating.

45. **Passive Congestion for Fractures.**—Deutschlaender is much pleased with the results of the application of Bier's artificial hyperemia in the treatment of fractures. It is, he states, simple and easy and materially shortens the entire process of the healing of the fracture. The callus forms much more rapidly, and, as the painfulness is very much diminished by the passive congestion, functional use of the parts can be commenced much earlier and be much more extensive than under ordinary conditions; this also prevents atrophy after a fracture. The ordinary methods of treating fracture did not aim to promote directly the healing process, until massage was introduced into the treatment. Massage is merely a mild method of inducing hyperemia; the same purpose is accomplished much more easily and effectually by the artificially induced hyperemia according to the method of Bier.

46. **Dressings for Wounds.**—Oettingen had charge of a Red Cross relief corps during the war in Manchuria and made extensive use of a kind of varnish for dressing wounds. He thinks that the chief aims of a dressing should be to carry off the bacteria in the wound by sucking them into an absorbent material and to prevent other bacteria from getting into the wound. He never washed, shaved nor disinfected the surroundings of the wound, but applied this varnish with a brush all around it. A pad of cotton was then laid over this, and it stuck at once immovably to the varnish. The bacteria in the skin around the wound were arrested by the varnish and could not get into the wound. The simplicity, cheapness and rapidity of this technic commend it, he believes, for general adoption. The results surpassed his anticipations. The varnish is applied with a brush suspended from the stopper of the varnish can, and the pads of cotton are provided in separate parchment wrappers so arranged that they are handled only on the outside. The fingers do not come in contact with the wound in any way. The formula for his varnish is: Mastic 20 parts, with chloroform 50 parts, and 20 drops of linseed oil. A more convenient formula is a heaping tablespoonful of mastic with 3 tablespoonfuls of chloroform and 20 drops of any oil. This varnish will be found excellent whenever it is desired to make dressings, flannel and bandages adhere to the skin.

48. **Technic of Spinal Analgesia.**—Hackenbruch advocates making a small incision before attempting to insert the needle for lumbar puncture and analgesia. This renders the procedure very much easier, while the minute hemorrhage from the incision, 0.5 cm. long, washes out any germs that might be introduced by the needle and also the last traces of the antiseptic used in disinfecting the field.

53. **The Magnet as a Diagnostic and Therapeutic Measure in Gynecology.**—Sellheim comments on the diagnostic value of the information derived from the movements of the uterus. He has been studying the movements of the uterus under the influence of a powerful magnet applied outside, with a large soft iron catheter introduced inside the uterus. The iron inside the uterus follows the movements of the magnet outside, and the organ thus changes its position at the will of the examiner. The procedure is not more difficult or serious than the introduction of any ordinary sound into the uterus. The rod has a projecting rim which prevents its slipping in too far; it is a little more than two inches long by nearly half an inch in diameter. The large electromagnet is mounted vertically on a standard with a horizontal rod and weight to balance it, so that it can be adjusted and moved around readily. The physician palpates with his right hand through the abdominal walls while with his left he explores simultaneously the rectum and vagina. The tip of the intranterine rod is kept pointed toward the center of the magnet, thus utilizing the maximum of attraction. The force is sufficient to straighten the retroflexed uterus with no danger of by-effects. It is particularly useful as a means of familiarizing the novice with the uterus, giving the organ into his hands, as it were, for him to study. It is also useful as a means of mobilizing the uterus and preventing the development of adhesions after inflammatory processes and displacements. The alternate lifting and dropping of the uterus can also be utilized as a kind of massage. The moral effect on the patients is also an important factor, as they can feel the displaced organ return to its normal place under the mysterious influence of the magnet. The details of the technic are illustrated.

58. **Passive Congestion in Treatment of Chronic Endometritis.**—Turan gives an illustration of an instrument which he has devised for the purpose of applying suction to the lining of the uterus, according to Bier's technic. It is like a large uterine catheter with four wide slits, 3 cm. long, near the tip. A tube is applied to the outer end, connected with a suction pump. He has applied this method of treatment in 4 cases of chronic endometritis in sterile women. Their affection had lasted for from four to twelve years, and various other methods of treatment had given no permanent relief. He applied the suction on alternate days, for from five to twenty minutes at a time, repeating about twenty-one times. The discharge became less after the first sittings, and grew constantly less until it became minimal. The subjective disturbances subsided also, and the improvement obtained has persisted to date. He practices at Franzenbad and the patients were taking at the same time the regular course of bath treatment there.

60. **Dangers of Application of Superheated Air and of Steam to the Interior of the Uterus.**—Pincus states that an exact diagnosis, exact indications and exact technic are necessary to avoid dangers from atmocausis and zestocausis. Properly done, under proper conditions, the procedure is harmless, painless and effectual, but it should never be attempted unless malignant disease can be absolutely excluded. He preaches that total extirpation of the uterus on account of uncomplicated bleeding is unjustifiable unless atmocausis has been given a thorough trial. He advises it as an adjuvant to curettement, allowing an interval of about seven days to elapse between. The cavity of the uterus must be entirely free from relics of tumor, ovum, placenta, etc., and also of clots, mucus and fluids, with the mucosa anemic. The interior can be prepared for atmocausis with hydrogen dioxid and suprarenal extract. Stenosis or atresia or unintentional obliteration do not belong to correct atmocausis or zestocausis any more than a perforation is a part of correct curettement.

61. **Aid in Delivery with Breech Presentation.**—Wienskowitz uses a rubber tube to slip over the thigh of the child to aid in its extraction. It is easily pushed in and works its way around the thigh and out again without injury to the child or mother. Gentle traction is spread over a large surface and has an

astonishing effect in facilitating delivery. The rubber tubing he uses is strengthened with some linen fibers woven in it.

63. Postoperative Tetanus.—Martin reports a case of fatal tetanus developing after an operation in the Greifswald gynecologic clinic. It had been undertaken on account of perimetritis, endometritis, rupture of cervix and prolapse of the vagina. The first symptoms of the tetanus were observed five days afterward, proving rapidly fatal. Tetanus germs were cultivated from the secretions of the vagina and uterus. Secretions from vagina and uterus of a large number of other patients were tested at the time for tetanus germs, but none was found.

65. Typical Affection of Medulla Oblongata.—Müller's patient was a man of 46 who used alcohol and tobacco freely and worked constantly under intellectual strain; he had suffered for ten years with paroxysmal headaches and brief attacks of vertigo. After a severe headache of several days' duration, ataxia of the right arm and right leg developed, with crossed sensory disturbances, and right paralysis of the vocal cords. The mind was not affected. The patient succumbed not long after to aspiration pneumonia. The autopsy revealed considerable arteriosclerosis and thrombosis of the right vertebral artery from the first cervical segment to its junction with the basilar artery. The consequence was a focus of softening running through the right half of the medulla oblongata. Crossed hemianalgesia can thus be produced by a narrowly circumscribed lesion in the medulla oblongata, and always indicates a bulbar affection. The parts affected are those which remain intact in case of glosso-labial paralysis.

66. Lactic Acid Formation in Gastric Cancer.—Sick has been investigating 31 cases of cancer of the stomach in which the diagnosis was dubious. He summarizes the conclusions of his findings in the statement that the long lactic-acid bacilli do not flourish in the stomach unless there is a more or less complete lack of free hydrochloric acid in the gastric juice. Disturbances in the motor function also favor their proliferation, but the most important factor for their growth and for lactic acid fermentation is the product of the autodigestion (autolysis) of a cancer, that is, the soluble albuminoids produced by the cancer. The long bacilli are found in patients with lacking or insufficient acidity, and even in the mouths of healthy persons, but they never flourish so luxuriantly as in case of an ulcerating cancer. If there is very little albumin in the stomach, or if it has been coagulated by boiling, very little lactic acid is formed; the volatile fat acids predominate. Addition of albuminoids in the form of extracts of carcinoma or of the thymus or other organ particularly rich in cells, is followed by a rapid increase in the production of acids, with the ether-soluble acids predominating, especially lactic acid. This action of the tissue extracts on the metabolism of the bacteria is probably a fermentative action. The determination of the volatile fat acids is, therefore, not so decisive as the evidence of lactic acid.

68. Study of Tuberculin Reaction.—Bahrdt writes from Marburg to describe some of the points learned in regard to the experimental tuberculin reaction in the course of von Behring's researches. The most important, perhaps, is the fact that a progressive tuberculosis of moderate virulence in a guinea-pig is paralleled by a progressively increasing susceptibility to the action of tuberculin.

75. Circumscribed Inflammation of Large Intestine and Its Peritoneum.—Bittorf called attention some time ago to acute inflammation of the sigmoid flexure, and later experience has confirmed his statements. He has now had occasion to observe 20 such cases, including 3 or 4 with exudation. In 23 cases of pericolitis, 19 were accompanied by exudation, which is much more common when the colon is involved. He gives here a number of histories to show the varying syndromes in case of circumscribed inflammation of the large intestine and its peritoneum. Stomach symptoms may predominate and be the only subjective ones. In one case, a scrofulous boy of 7 exhibited a typical epileptic seizure, his first and last. Extremely painful resistance was found in the region of the sigmoid flexure. Bittorf regards the case as one of true epilepsy. The transient intoxication from the inflammatory intestinal process induced a condition of the brain similar to that which is assumed to be the foundation for epilepsy. In another case there were icterus, cramps in the calves, and enlargement of the spleen, with the characteristic tumefaction and sensitiveness of the region of the sigmoid flexure. The enlargement of the spleen persists in the cases with a chronic tendency.

78. Treatment of Angina Pectoris with Swedish Gymnastics and Massage.—Hasebrock has been treating angina pectoris for years at his Zander Institute in Hamburg. The results have been very gratifying in a number of cases, the frequency and severity of the attacks being evidently much modified. In others the results were negative. Even when the heart and its arteries are not intact the exercises were liable to improve the condition, restoring the pulse to normal and the patient feeling generally very much better. He remarks that the mechanical treatment of the circulatory system is still in the empiric phase, both in practice and in theory. The gathering of material is the main point now. The advantages of mechanical gymnastics are being appreciated more and more; especially in angina pectoris they have proved most valuable adjuvants. His experience has demonstrated that the cases amenable to this treatment are those in which the trouble is probably a sensory reflex neurosis. This can be determined by the discovery of a pronounced sensitiveness to pressure on palpating the left thorax, most intense in the region of the apex beat, extending in the interspace from here to the axilla, or else the finding of tender points at some of the emerging points of the intercostal nerves to the left, close to the sternum, between the second and fourth ribs. In the obese, especially in women, there may be a striking sensitiveness to pressure in the left mamma or its base while the right side is free from this tenderness. The presence of these tender points renders plausible the assumption that the attack of angina pectoris is due to a sensory reflex neurosis. If the sensitiveness of these points can be reduced the angina pectoris will be favorably influenced and possibly the attacks may be banished altogether. The peripheral vasomotor system is acted on, and the blood is drawn to the periphery by suction, not by central propulsion. The effect of the gymnastics is not on the heart directly; it acts on the periphery, outside of the heart. He gives the details of 8 cases showing marked improvement. The patients were men from 43 to 55 years of age, and one woman of 49. He describes also other cases in which remarkable relief was obtained and the general health much improved by the exercises, although when the patients finally succumbed, months afterward, the autopsy disclosed pronounced arteriosclerosis and atheromatosis. He gives the details of these cases to show that there is no immediate danger from the exer-

cises even in these serious conditions. He always noticed that the success of the treatment was marked, both subjectively and objectively, as soon as the pulse was restored to normal and the arterial tension reduced. The exercises do not interfere in any way with simultaneous internal treatment.

80. **Addison's Disease on Traumatic Basis.**—Börrmann reports a case which he had opportunity to observe for four years with the postmortem findings. There was not a trace of anything to suggest either tuberculosis or syphilis. The patient, a man, had fallen on the edge of an open trunk, hitting the region of the right suprarenal. He never quite recovered from the accident, and in the course of a year developed symptoms of Addison's disease, to which he succumbed three years later. Both suprarenals were found transformed into large, hard tumors with necrosis in the center, and no trace of suprarenal substance could be discovered. The solar plexus was mostly included in the tough, fibrous mass forming the tumors. It is the first case on record, he says, of true Addison's disease of unmistakable traumatic origin. The article is illustrated with two colored plates.

81. **The Treponema Pallidum and Congenital Syphilis.**—Gierke remarks that the question of the etiologic importance of the treponema has entered a new phase since the positive findings in sections of tissues. The best results were attained with the Cajal stain for axis cylinders: Saturation with a 1.5 per cent. solution of silver nitrate for three days in the incubator at 38 C.; then rinsing several times briefly with water and placing for forty-eight hours in a mixture of 4 parts pyrogallic acid, 5 parts formol and distilled water to 100 parts in a brown vial; after brief rinsing, then dehydration in alcohol, then xylol and celloidin or paraffin imbedding. Gierke reports his various positive findings in 11 cases of congenital syphilis. He obtained positive findings in tissues that had been preserved for years, especially those kept in formol. His findings also prove that the treponema long resists the effects of maceration.

82. **Neurologic Study of Spinal Anesthesia.**—Finkelnburg regards the present technic of lumbar analgesia as a great improvement over the first methods. Cocain spares the tracts which serve for reflex action, while these are affected first and most prominently by stovain. With stovain the tendon reflexes first feel the effects of the drug and are the last to recover, while the effect on the sensory and motor tracts is felt last and is the first to pass away. This different action of cocain and of stovain on the tendon reflexes demonstrates anew that these differ from other nerve tracts. They are evidently more sensitive to mechanical and toxic influences. Individual variations seem to play a subordinate rôle, although the period of extinction of the reflexes may vary in length, probably from differences in the circulation of the cerebrospinal fluid, as it takes a longer or shorter time to wash away the drug from the nerve elements.

83. **Appendicitis During Pregnancy.**—Füth states that out of 42 cases on record 22 of the women died, a mortality of 52.3 per cent. He ascribes the gravity of appendicitis during pregnancy to the displacement of the cecum by the enlarging uterus, bringing the appendix close to the liver or uterus. In the cases on record, 10 of the patients were in the second or third month of the pregnancy and 3 died; of the 32 cases in which the pregnancy was in the fourth to the ninth month, 19 of the patients died. Out of the total 42 cases, an operation was undertaken in 37, and in 4 it was done within forty-eight hours of the first symptoms. In only one instance in this last group the pregnancy proceeded undisturbed and the patient recovered. Abortion and death ensued in all the others. The abortion possibly may have rendered conditions more serious. If the tendency to abortion in these cases can be controlled with opium or other measures, it may be possible to save more of the patients with appendicitis occurring during pregnancy.

85. **The Desault Operation for Maxillary Sinusitis.**—Koellroetter expatiates on the superior simplicity and convenience of the Desault technic. It is the only one, he states, that allows adequate after-treatment and absolute restitution of the relations between the sinus and the nose and mouth. The main point is careful after treatment.

94. **Prophylaxis of Malarial Fevers.**—The professor of hygiene and bacteriology at Athens, C. Savas, has written a book of instructions in regard to the protection of individuals and communities against malaria. The Grecian government has adopted the work officially and had thousands of copies distributed gratuitously to physicians and others. The work quotes freely from similar pamphlets issued by the Italian and other governments, with maps showing the location of the marshes which are so prevalent in Greece. Malarial fevers cause fully one-third of all the internal pathology in the country, estimated at an annual average of about 9,000 cases with 68 deaths to each 100,000 inhabitants. Malaria is more frequent and more destructive in Greece than in Italy. Among 153,158 patients treated in 43 hospitals in Greece during the five years 1893-1899, 61,125 suffered from malaria, and of this number 56,127 cases were of the intermittent and 127 were of the pernicious type, the latter including 113 comatose cases. An absolute immunity has never been observed in Greece, but a brief relative immunity has occasionally been noted. When residing in a hotbed of malaria, Cardamatis never encountered an individual who had entirely escaped malaria infection. In regard to the mosquito host, the *Anopheles superpictus* and the elaviger are incriminated. While amply sustaining the mosquito transmission of malaria, Cardamatis asks whether some other factor may not be responsible for the epidemics of malaria which follow extensive turning up of the soil in public works of various kinds. He has frequently had occasion to observe epidemics of this kind at Athens and elsewhere in Greece. Savas preaches the necessity for complete isolation of the malarial patient, asserting further that the complete cure of a single individual who has relapses during the winter is more effectual for prophylaxis than the cure of a hundred persons having their first attacks during the mosquito season. He advises administration of quinin all the time in the severer cases and at the time of the sweat and a little after in the mild cases. He announces that common lime, which is very abundant and cheap in Greece, is an effectual means of killing the larvæ in standing water. Unslaked lime thrown into the water will destroy the larvæ in the water and more promptly still at from 1 to 5 per cent. The lime must be of good quality, thoroughly baked, and the powdered form is better than lumps.

95. **Hydrotherapy for Spermatorrhea.**—Stimulating hydrotherapy should be avoided, but tepid douches along the spine, according to the experience of this writer, will be found useful. They are preceded and followed by a cold douche applied to the front and limbs, carefully avoiding application of cold to the spine. He has cured a number of cases of spermatorrhea by this form of treatment.

97. **Malarial Fevers Without Plasmodia.**—Triantaphyllides has had occasion to observe at Batoum a number of patients who presented apparently the malarial syndrome, but without the malarial parasites in the blood. In a case of this kind the individual had had malaria eighteen years previously. His symptoms were chills, intermittent fever and enlargement of the spleen. No plasmodia, however, could be detected in the blood with the most searching examination. He suggests the existence of a "malarial diathesis" as an explanation for such cases. The organism of an individual having suffered once from chronic malaria, responds in a special manner to disturbing causes, autointoxication, etc. This explanation can not apply to the acute cases; they must have some other origin than in paludism, some other infection, possibly telluric also, but of other nature than the plasmodian infection. These fevers occur at any season, usually in the fall or winter. The chill is not very decided, and the fever is not so high as in true malaria. The paroxysms recur generally every day, but without the invariable regularity in recurrence, duration and intensity of true malaria. There may even be two attacks in one day, which is never observed in case of the plasmodian fever. The complexion is not so clay-colored as in true malaria. The attacks may recur for several months and are not influenced by quinin. Dampness seems to be one of the causes of this group of pseudo-malarial fevers. Damp, badly ventilated dwellings or the proximity of a garden or wood with too dense foliage were noted as possible factors in some cases, and change from these surroundings was always followed by a cure. The populace have a tradition that dampness causes malarial fever, but this fever is not always malarial. He cites 9 cases in which the fever assumed a subcontinuous or remittent type. The abrupt invasion, the general phenomena accompanying the marked enlargement of the spleen, the cyclic course of the fever, the absence of any localization and of typhoid symptoms and the termination with a crisis on the seventh or eighth day differentiate it from the diseases with which it might be confounded. He has no suggestion to make as to what the infection can be, only that it is not malaria. Children are most frequently affected. Malarial antecedents were noted in only about half the cases. Besides these two groups he has also had opportunity to study other forms of what was apparently malaria, but without plasmodia. The fever in some cases was simple remittent, in others remittent followed by intermittent, and in others remittent accompanied by congestion of the lungs. Quinin does little good in these cases. He is convinced that a great many affections are now being erroneously classed with malaria which have nothing in common with it.

98. **Treatment of Scarlet Fever.**—Macrides affirms that the essence of scarlet fever is the more or less complete suppression of the functions of the sweat glands, thus causing serious autointoxication by the lack of the sweat secretion and of normal elimination of waste matters by this route. In measles the prognosis is better the more marked the rash, but in scarlet fever, the reverse applies; the more extensive the eruption the severer the case. The skin feels dry and parched; the skin in measles is always more or less moist, even in the patches of rash. The scarlet-fever rash is more like a burn and feels as if varnished. The redder the skin, the graver the infection, the higher the temperature, the more serious the prognosis. The kidneys seem to be unable to act vicariously, and the amount of urine is rather below than above the normal limit. Treatment should aim to promote diuresis and attenuate the toxic-infection. The disease is self-limited and drugs are useless, if not absolutely harmful, as they are liable to hamper the kidney functioning. Instead of striving to promote the eruption, treatment should be with simple tepid baths progressively cooled, and injections of artificial serum. Antidiphtheritic serum is not indicated and may do harm, as it has a tendency to interfere with kidney functioning. Caffein citrate might possibly be used as a tonic for the heart and to promote diuresis, but all other measures except tepid baths and artificial serum should be avoided.

99. **Malaria and Heart Affections.**—Triantaphyllides has observed 68 patients who exhibited symptoms of some heart affection during or immediately after malarial infection or later. The patients were between the ages of 7 and 40; he excludes from this list all cases of heart affections noted with concomitant malarial nephritis or cirrhosis, as also all patients who were addicted to alcohol and all in whom the heart affection subsided with the malarial infection. These 68 patients were encountered among 12,000 malarial subjects in his practice at Batoum. They form about a third of all his cases of heart affections in general. In 24 the cardiopathy was evidently the relics of a long preceding malarial infection; in others it developed during or immediately after the paludism and pursued an independent course. The heart affection in both of these groups did not present any specific symptoms, but it was evidently the work of the malarial infection, although the plasmodia had vanished from the blood and antimalarial treatment was useless. The assumption that, besides the action of its toxins, the malarial infection may have a direct, specific effect on the heart is corroborated by the other cases observed in which the cardiopathy developed during the attack of malaria and without any other appreciable predisposing or determining cause. In these cases the heart affection ran a course parallel to that of the malaria and yielded with it to quinin after resisting all the usual heart measures. In the majority of such cases the cardiopathy became installed during a recurrence of the malarial infection. The left myocardium and endocardium were most frequently affected. He gives the details of a number of his cases.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers

CARBOHYDRATE METABOLISM (A Course of Advanced Lectures in Physiology delivered at the University of London, May, 1905), with an Appendix on the Assimilation of Carbohydrate into Proteid and Fat. Followed by the Fundamental Principles, and the Treatment of Diabetes Dialectically Discussed by F. W. Pavy, LL.D., F.R.S., Honorary Physician to King Edward VII. Hospital; Consulting Physician to Guy's Hospital. Cloth. Pp. 131. Price, $2.40. Philadelphia: P. Blakiston's Son & Co., 1906.

LEPROSY AND FISH-EATING. A Statement of Facts and Explanations. By J. Hutchinson, F.R.S., and F.R.C.S., LL.D., Glasgow, Edinburgh, Cambridge and Oxford, Etc., Formerly President of the Royal College of Surgeons. Cloth. Pp. 420. Price, $3.25 net. London: Archibald Constable & Co., Ld.; Chicago: W. T. Keener & Co., 1906.

PATHOLOGY, GENERAL AND SPECIAL, for Students of Medicine. By R. T. Hewlett, M.D., M.R.C.P., D. P. H., Professor of General Pathology and Bacteriology in King's College, London; Lecturer on Bacteriology, London School of Tropical Medicine, Etc. Cloth. Pp. 540. Price, $3.25. Philadelphia: P. Blakiston's Son & Co., 1906.

PERJURY FOR PAY. An Exposé of the Methods and Criminal Cunning of the Modern Malingerer. By W. P. King, M.D., Ex-Assistant Chief Surgeon of the Missouri Pacific Railway System. Author of "Stories of a Country Doctor." Cloth. Pp. 312. Price, $2.00 Kansas City, Mo.: The Burton Company, 1906.

BULLETIN OF THE UNIVERSITY OF WISCONSIN, No. 115. Science Series, Vol. III, No. 4. Anatomy in America. By C. R. Bardeen, Professor of Anatomy in the University of Wisconsin. Paper. Pp. 205. Price, 50c. Madison, Wisconsin: September, 1905.

EDUCATIONAL PAMPHLET No. 1. The Young Man's Problem. By a Member of the American Society of Sanitary and Moral Prophylaxis. Indorsed and Recommended for Publication by the Executive Committee. Paper. Pp. 24. Price, 10c a copy. Dr. E. I. Keyes, Jr., Secretary, 109, E. 34th St., New York.

AN ESSAY ON THE GENERAL PRINCIPLES OF THE TREATMENT OF SPINAL CURVATURES. By H. Bigg, F.R.C.S., Ed. Illustrated by the Author's Photographs and Sketches. Cloth. Pp. 240. Price, $2.00 Philadelphia: P. Blakiston's Son & Co., 1905.

X-RAYS IN GENERAL PRACTICE. By A. E. Walter, Captain I. M. S., Superintendent of the X Ray Institute of India. Cloth. Pp. 174. New York: John Lane Company, 1906.

SOME PHENOMENA OF TUBERCULOSIS INFECTION.*

WILLIAM PORTER, A.M., M.D.

Director National Association for the Study and Prevention of Tuberculosis.

ST. LOUIS.

The study of tuberculosis is a many-sided proposition. It is not my purpose now to attempt a full résumé of the subject or to discuss at length any of its more important features, but rather to make certain suggestions which have been the outgrowth of daily contact with victims of this most interesting and universal disease. I omit statistics—encouraging as they are—or detailed description of the methods of limitation and plans of organizations which have already been so effective. My thought is to discuss some of the phenomena of tuberculous infection and possibly to make a few therapeutic suggestions as legitimate deductions.

THE BACILLUS.

Naturally, the bacillus is the central point in most of the experiments and investigations concerning tuberculosis. To some it might seem that almost two decades of study had sufficed to learn all that is to be known of this organism, yet, I believe that we are only in the beginning of our lesson and that so far as specific antagonism is concerned we await the dawn. That the dawn is near at hand there is every promise, even without the final victory. In Germany in 1890, the death rate per 10,000 of population was 28.11 and in 1902 it was 19.04. In Great Britain the death rate has been reduced to 50 per cent. and in some of our Eastern cities almost as much. A recent report shows that in less than two decades there has been a decline of 50 per cent mortality.[1]

It is with new courage then that we study some of the characteristics of tuberculosis and, though the presentations may seem disconnected, there is in them as presented an interdependency that may not be ignored. In regard to the bacillus itself, we need not do more than mention the different ways of conveyance, as in dust, in globules of expectorated mucus, by food or by flies, as shown by Lord[2] a year ago. The vitality of the bacillus has been the subject of many experiments. Twitchell[3] found that dried tuberculous sputum in a handkerchief, woolen blanket or on wood when innoculated, would produce a tuberculous lesion after 70 days. Koch[4] dried sputum at laboratory temperature for from four to eight weeks and found that it would produce tuberculosis in animals. Sawinsky, as quoted by Twitchell, found that sputum subjected to the ordinary conditions of the floor of a dwelling house preserved its virulence for over 2 months. Flock[5] says "Consumption may well be termed a house disease. The house is the place where the tubercle bacillus lies dormant in wait for its new host; it is the place where the new host gets his implanation." While it is true that sunlight and air currents and heat extremes limit the life of the bacillus, yet it may be well to remember that under conditions not infrequent such longevity is possible.

A second observation is that the number of bacilli is not indicative of the stage of progress. At Mount St. Rose, we divide our cases into three classes, according to the evidence from physical examination. The three clinical stages are those usually given in the books. The divisions from the microscopic showing are these: one bacillus in a field, or only one found in several fields, is written down in first class; several in a field, as second class; an average of six places, the case in the third class; from six to ten, in the fourth; and a larger number or "clump" of bacilli, places it in class five or five plus. Now it often happens that patients in the first or early stage clinically, are in class five or even in five plus from the bacteriologic tests. Conversely, though this is more rare, advanced cases may show few bacilli An interesting case is that of a soldier at Jefferson Barracks.[6] Although in the most advanced condition by every test, except that of the microscope, there has never been a bacillus found after repeated examinations, by Major Banister, in charge of the post, or by his assistants. It frequently happens that a great variation in the number of bacilli is found in the same patient at different times, without any physical evidence of change. Hence, I am of the present opinion, that while as a diagnostic evidence the bacillus of tuberculosis is valuable, it does not aid in determining the stage or location of infection, or the prognosis as to time and result. In a recent report[7] by Drs. Ravenel and Irwin, three sterile cases were found among thirty, in which the contents of lung cavities were examined. The absence of bacilli in the early or closed stage will be referred to in speaking of early signs.

ROUTES OF INVASION.

The routes of invasion are worthy of continued investigation. At present the respiratory tract is by many considered the main channel, but with a larger opportunity for investigation than formerly, I am convinced that many more pulmonary cases are directly infected through the lymphatic and blood channels than are recognized by the average physician. The phenomena of invasion by the bronchial route have been studied not

only clinically but in their pathologic sequence and to such an extent has this study served that it has, until recently, overshadowed the other scarcely less important questions of infection along the lymph channels, or around the arterioles and capillaries by the blood current.

Without dwelling on the bronchogenic development along the respiratory tract, which, to some extent, we have all followed, I would emphasize the value of infection through the lymph channels as a factor in the etiology of tuberculosis. Here again we find three methods by which the bacilli find their way into the lymphatics. First, it is asserted by Behring,[8] who quotes Roemer, that albuminous bodies may pass through the walls of the alimentary canal and into the blood and lymph unchanged in new-born animals but not in adults. Behring fed anthrax bacilli to adult guinea-pigs and these passed through the alimentary tract without doing harm, while eight-day old guinea-pigs similarly treated died quickly. Attenuated bacilli fed to young pigs were found in the blood. Ribbert[9] believes that most cases of pulmonary tuberculosis are hematogenous, and that the bacilli pass through the pulmonary tissue into the lymph channels and to the bronchial lymph glands. From this point they are carried by the blood stream to the lungs, usually to an apex, because of comparative local anemia and a retarded lymph flow which is due to hindered movement from ossification of the first rib.

A most important recent contribution to the study of lymphatic infection is a paper[10] presented to the Section on Laryngology at the fifty-fifth annual session of the American Medical Association by George B. Wood. After recording the results of his most interesting experiments made in the laboratory of the Pennsylvania Live Stock Sanitary Board and citing many authorities, he concludes: "The tonsillar tissue of the throat, because of its peculiar anatomic construction and of its topographic relations, is more liable to become infected by tuberculosis than any other part of the upper respiratory tract. In nearly all cases of advanced pulmonary phthisis the faucial tonsils become inoculated. In about 5 per cent. of hypertrophied pharyngeal tonsils some form of primary tuberculosis will be found. Primary infection of the faucial tonsil is a rarer condition."

Tuberculous adenitis in the cervical lymphatics develops in the majority of cases from infection originating sometimes in the faucial tonsils, but more frequently in the pharyngeal tonsil. The tubercle bacillus is probably unable to pass through the tonsil without having first overcome the vital resistance of the tonsillar tissue.

The danger of systemic or pulmonic infection resulting from a tuberculous lesion in the tonsillar tissues of the throat is about equal to that of tuberculosis of the cervical lymphatics. The lesion to be expected as a resultant infection from the broken-down glands of the neck is a miliary tuberculosis of the lungs. Further than this possibility, tuberculosis of the lymph glands of the neck is more dangerous than a localized tuberculous lesion in any other portion of the body.

As illustrating this proposition, I may briefly cite a case in the observation ward at Mount Rose:

Patient.—A woman, aged 40, had for many months prior to admission, tuberculous infiltration of the cervical glands of the right side. Bacilli were found in the broken-down structures, but consultation with several surgeons determined non-interference because of the extent and the tissues involved. At first there was neither physical nor microscopic evidence of tuberculosis involving the lung, though we made repeated and frequent examinations. Recently, well-marked signs have appeared in the apex, but the infected lung is evidently as yet in the "closed stage." No bacilli were found in the sputum, though I have little doubt but that they will be found.

The tonsils are more resistant to the action of bacterial toxins than ordinary lymphoid tissue. This latter proposition is also well set forth by Dr. Jonathan Wright,[11] and its soundness will be more readily admitted after reading Dr. Theobald Smith's[12] essay, "Some Problems in the Life History of Pathogenic Organisms."

Autoinfection.—This topic deserves more extended notice. I believe it to be one of the most important chapters in the study of the symptoms and care of tuberculosis. Let me briefly call to mind the fact that constipation (with intermittent diarrhea) is found in most cases of pulmonary tuberculosis. It has been shown that bacilli in the sputum may safely pass the impaired gastric secretions, travel the course of the small intestine, and be found in the fecal accumulation in the colon and rectum; or that they may pass into the deeper structures or lymph or blood channels through an uninjured mucosa. It is not a far cry to the conclusion that reabsorption of bacilli with the products of metabolism and decay from the intestinal tract is a potent addition to the primary infection, especially in children, as before quoted from Behrens and I am inclined to believe that the statement holds good with those of more mature age. That this is more than a hypothesis, can, I believe, be demonstrated. There is here a therapeutic suggestion which we try to make practical. In appropriate cases a high enema containing a small quantity of glycerin is given daily for a week. By that time the lower bowel is probably emptied of all scybalous masses. After that, the normal salt solution is used in quantities which can be retained. The exact form of treatment may vary, but the principle is kept in mind. The reduction of temperatures, and in many cases the improvement in assimilation following this part of the treatment certainly suggests cause and effect. The premises may be wrong but the conclusion is encouraging. The fact that other bacteria are factors in temperature increase in tuberculosis does not alter the deduction as to the value of the method.

Large Doses of Creosote are not Indicated.—Following the adoption of the suggestion last mentioned we have been willing to lessen greatly the amount of creosote and its substitutes. In fact, except with the idea of improvement of digestion and nutrition (and I confess my want of faith in this) the use of this class of remedies is almost forgotten in our treatment at Mount St. Rose, where we have had over 800 cases of tuberculosis in 3 1/3 years. Certainly, large doses of creosote, guaiacol, and their carbonates are not given. Here, again, I may be at variance with many of our best observers, but I predict that in another decade, very little, if any of this class of remedies will be used internally in the treatment of tuberculous cases.

EARLY SIGNS OF INFECTION.

One of the most valuable reports of the past twelve months is "The Report of the Committee on Early Diagnosis of Tuberculosis to the National Association for the Study and Preventation of Tuberculosis." This is a topic in itself, but lack of space permits me to mention only a few points. The committee lays great stress

9. Deut. med. Wochft., April 21, 1902.
10. The Journal A. M. A., May 6, 1905, p. 1125.
11. Med. News, March 4, 1905.
12. Science, Dec. 16, 1904.

on symptoms and signs, indicating a tuberculous infection during the closed stage: i. e., before caseation and breaking down of a tubercle and the appearance of bacilli in the sputum. The symptoms are early, typical, repeated, though possibly slight hemorrhage, increased afternoon temperature and a hacking cough are suggestive but not positive proof.

More important are the early physical signs. Among these are a retardation in the movements over the affected lung portion and a diminution of the excursions of the diaphragm of the infected side shown by Litten's shadow. The use of the blue pencil to mark border line of dullness and points of asymmetry is strongly urged with the stethoscope. The very earliest auscultatory sound is a rough and slightly diminished respiratory murmur, not to be confounded with the sharp puerile murmur of increased function. The respiratory sound loses its smooth quality and (Sahli) becomes impure and roughened. This change is produced by slight inflammatory changes in the bronchioles, the air passing over an uneven surface and through a slightly narrowed tube. It precedes the crepitant râle and all other physical signs.

Of tuberculin, the *x*-ray, and the use of iodin salts to increase catarrhal symptoms, the committee says their value has not been demonstrated and a case will rarely be found in which they would add considerably to the information gained through other sources.

POSTERIOR LESIONS ARE MOST AGGRESSIVE.

Diminution of the percussion note, with harsh breathing and crepitation heard in the upper interscapular region, is suggestive of lymphatic infection and infiltration of the bronchial glands. The cases we have noted of this class run a much more rapid course than those in which the infection has been through the respiratory tract. It is true that the premise is hard to prove, but the fact remains that the cases most difficult to control have been those in which the physical evidence was most marked in the upper dorsal region. I would again urge that no chest examination is complete without most careful investigation of this region.

Extent of local lesion is not always a criterion of the general condition in pulmonary tuberculosis. This may be truthfully said of many diseases, but it is emphatically true, I believe, in pulmonary tuberculosis. We find it so in lobar pneumonia, which is also a specific disease. It is true, likewise, in many conditions of pus poisoning and local infection. It is no new proposition, therefore, but one that has not been given its full value in formulating our diagnosis and prognosis in this disease. An advanced pathologic stage is not incompatible with fairly good general conditions. Such cases, in spite of extensive tissue disintegration, may become chronic, the advance be checked, and the patient live out his expectancy.

In regard to the relation of pleurisy to tubercular pulmonary infection, where so many of recognized authority are at variance, no one man has a right to speak dogmatically. Nothnagel says: "Tuberculosis of the pleura is almost exceptionally secondary and is most frequently associated with tuberculosis of the lungs or bronchial glands." Von Ruck[13] deducts from forty writers and his own experience as follows:

1. The pleural cavities are readily accessible to bacterial invasion.

2. The great majority of pleurisies with effusion which occur in otherwise healthy individuals are due to infection by the tubercle bacillus. This is proved by autopsy findings, by methods of exact diagnosis, and by the subsequent clinical histories of the majority of persons who have been the subjects of such attacks.

3. There is ample evidence to indicate that the so-called idiopathic, dry pleurisies, are likewise usually tuberculous.

4. The subjective symptoms of inflammation of the pleural apices often simulate those of myalgia or rheumatism.

5. In every case of pleurisy, or of persistent pain in the chest or shoulder, which can not be satisfactorily ascribed to other causes, tuberculosis should be suspected and a careful physical examination should be instituted to determine, if possible, the existence of a tuberculous process in the lungs or elsewhere.

6. Even if physical examination in such cases proves negative, the patient should be regarded as tuberculous until the contrary is proved, and should at least be kept under prolonged observation and re-examined from time to time.

7. The application of these principles will often lead to an earlier recognition of tuberculous disease of the lungs, especially, and to the institution of treatment at a period which, in many cases, will secure to the patient most important advantages in his prospects for recovery.

In the face of such evidence it would be foolishness to raise a feeble negative. I know that I have seen cases of pleurisy with effusions that were not tuberculous and that never became tuberculous, but these may have been exceptions. With our present knowledge I should hesitate to say that the majority of cases of pleurisy become tuberculous and Bowditch, Hanford, Barr, Fiedler and others place the proportion as no greater than one-third. If, however, to this one-third we add the number of cases complicating old tuberculous lesions, it will make a high percentage, indeed, for the majority of tuberculosis cases have pleuritic extension and infection.

WAYS TO COMBAT EVIL.*

HON. CHAMPE S. ANDREWS.

NEW YORK CITY.

1. An authentic source of supply for facts concerning the evils complained of, is an absolute necessity.—No amount of mere abuse will end the "patent-medicine" swindle. The catalogue of crimes and abuses with which the "patent-medicine" man stands charged must be backed up before the public and before legislative committees by cold, hard facts. An abusive statement left unverified reacts against the cause of the enthusiast who makes it; neither will the collection of facts once made remain accurate. The "patent-medicine" man, smoked out of one swindle, plans and executes another, shifting his methods to suit the dangers of every situation. "And even in pennance planning sins anew." When the continuance of one swindler is made impossible by exposure, he falls by the wayside, but others rise to take his place. The ingenuity of crime has been commented on since the dawn of civilization. If "patent-medicine" swindles are to be permanently stopped, there must be an opposition gathering evidence as rapidly as it is made. Eternal vigilance is an essential element in the character of any effective opposition to the "patent-medicine" trust. Those who enlist in the fight should have some central source at which to apply for unvarnished facts, and there should be some central bureau to which every man finding proof of fraud could send the information

* Read before the Philadelphia Society of Medical Jurisprudence, March 19, 1906.

for the general welfare. What is true of "patent-medicine" men is true of quacks generally.

2. The facts once collected should be given widespread dissemination.—When the people are once informed of the true facts of the vile business, its source of revenue will be best attacked. No person will knowingly walk into the lion's mouth. The "patent-medicine" business exists only to make money. Stop the revenue and the fraud dries up of its own accord.

There are many ways in which can be conducted the work of educating the public through the dissemination of specific facts concerning the various "patent-medicine" crimes.

The most effective way is to secure the co-operation of societies already well organized, and particularly of those societies that are professional, philanthropic and religious. A few may be indicated as follows:

PROFESSIONAL SOCIETIES.

The medical profession, in order to add to its supply of knowledge, is given to organization for the purpose of disseminating scientific information. The national body, known as the American Medical Association, the Medical Society of the State (and County) of New York and the other organizations of medical men, even those in the smaller towns in the country, will beyond a doubt lend their aid to any well-organized movement to bring home to the American public a realization of its present degradation brought about by the "patent-medicine" evil and habit.

The influence of the medicolegal societies, such as the excellent Medicolegal Society of New York, must not be forgotten. They have already done some excellent work in exposing quackery, and will certainly lend their aid to further systematic work along broader lines.

Dr. Prince A. Morrow, president of the new society, entitled The Society for Sanitary and Moral Prophylaxis, says that in combating the social evil and the venereal peril this new organization will give every encouragement possible to the exposure of quacks and quack medicines that have done so much to break down the health of many young boys of America.

PHILANTHROPIC AND RELIGIOUS SOCIETIES.

One hardly knows where to begin in mentioning the list of public-spirited organizations of a philanthropic nature that would co-operate in this work of education. In every community there are great numbers of societies, composed of God-fearing men and women who would rejoice at the opportunity to uplift their fellowman and protect him against the avariciousness of the quack and "patent-medicine" charlatan. As typical of these organizations, mention may be made of the Women's Christian Temperance Union and the Young Men's Christian Association.

The W. C. T. U. has already done some substantial work along the educational lines suggested. They have valiantly fought to expose those so-called medicines that are nothing more or less than cheap whisky in disguise. The reason they have not done more lies in the fact that they have not the facilities of the specialist in unearthing the frauds, or in bringing the offenders to justice. The Y. M. C. A., with its well-equipped reading rooms and the excellent system of lectures to young men, could do a great deal toward spreading accurate knowledge of the dangers to young men who rely on the alluringly false advertisements of those medical frauds who make young men their especial prey.

Various Protestant denominations have their young people organized into societies of various kinds. These in turn affiliate with the young people of kindred denominations, and the influence of these combined societies is one of the great moral forces of the day. Could they do a better work than in assisting to uplift the "patent-medicine" drunkards, or in bringing home to themselves and to their friends the dangers lurking in the vile drugs so freely advertised in their daily papers? In this work, the influence of the Roman Catholic clergy, if properly enlisted, would be tremendous. More than once have I seen earnest priests at the meetings of professional societies, where some of the evils we have been enumerating were discussed, and if even a few of the dangers could be accurately stated and proved to them, I feel no hesitancy in saying that they would be the first to co-operate. The Jewish hospital societies, and the various Jewish charitable societies working among the Jews of the "East Side" in New York, only wait an organized movement to lend their aid to a work the importance of which to the tenement dweller can not be overestimated.

3. A counter attack should be made by subscribers on newspapers that accept advertisements of "patent-medicine" swindles.—Just as the "patent-medicine" man quits business when its revenue ceases, so will the newspaper cease to be the "patent-medicine" man's ally when people refuse to pollute their homes by bringing into them papers and magazines containing foul advertisements exploiting quacks and vicious remedies. A society of 100,000 members, stretching from coast to coast, each member of which refused to read newspapers and magazines containing improper medical advertisements, would mark the beginning of the end of the "criminal alliance between quacks and newspapers."

4. The text-books on physiology and hygiene in our schools should have some space devoted to the dangers of "patent medicines" and indiscriminate dosing.—It is difficult to overestimate the influence exerted against "King Alcohol" by the schools employing text-books on hygiene and physiology telling of the dangers of indulgence in alcohol. Let the work be carried to its legitimate end! Let these books give the analysis of scores of "patent medicines" containing dangerous amounts of alcohol and opiates. Let the untruths contained in false advertisements of such medicines be mercilessly exposed.

5. Evidence should be systematically laid before the postal authorities, showing that "patent-medicine" men and quacks generally are using the mails for fraudulent purposes.—If newspaper advertising, and false literature generally, is the life-blood of the "patent-medicine" business, the United States mail is the heart that sends the blood through veins and arteries. Let the society of 100,000 members demand a rigid enforcement of the laws against fraudulent use of the mails, and let the society, if necessary, supply the technical information in a few cases, and the government, which is your government and mine, will not always turn a deaf ear.

6. Penal laws in any way bearing on the evil should be enforced as systematically and thoroughly as possible.—The quack and "patent-medicine" man is not afraid of mere talk. He insolently refers to it as "hot air." But when the majesty of the law says his business is fraudulent and he a criminal, the mighty fabric of this billionaire business must eventually totter and fall. A society of 100,000 people helping to enforce these laws would not be long in putting them in motion.

7. Evidence of the far-reaching dangers of "patent-medicine" swindles should be systematically laid before our various state legislatures and persistent demands

made for such legislation as is necessary to abate the evil.—Already we have some valuable laws applying directly to these evils. But more are needed, and the need would long ago have been supplied if the "patent-medicine" man and the "patent-medicine" lobby had not blocked the way. These obstructions must be cleared by a society of 100,000 members, each one helping to do so.

PROPOSED SOCIETY FOR THE PRESERVATION OF THE PUBLIC HEALTH.

I happen to know that the many recent articles exposing the evils of "patent medicines" have been read with absorbing interest by "patent-medicine" conspirators. Naturally enough, they hope these exposures will end without any permanent remedy for the future.

As they have read the several recommendations for the abatement of the evil above set forth, it is not difficult to imagine these wealthy gentlemen saying to themselves: "If these forces could be practically put in motion our ill-gotten millions might be in danger. However, so long as the influences which might destroy us are not organized in their effort, and have no guiding hand, our wonderful 'patent-medicine' trust, backed by money and brains, can beat the public at every turn. The effect of a few exposures will soon be forgotten by the public with its proverbially short memory."

The truth of that comment no one is prepared to admit sooner than I. It is a comment, however, applicable in every fight against organized crime and entrenched evil. Abuses of every sort thrive for the most part because no one person or no one organization make it a duty to suppress them. For an elaboration of this theory see the writer's article in the October, 1904, *Forum*, entitled "Private Societies and the Enforcement of the Criminal Law." If an evil really exists, there are always forces for good powerful enough to destroy that abuse, provided those powers are unremittingly and diligently and honestly directed.

The "patent-medicine" evil has existed in this country more than in any other country, practically unmolested, save for the desultory attacks here and there by public-spirited people. Some few physicians in a small way have exposed the evil. Attention has here and there been called to it, and flagrant instances of the evil have come to the surface. Unlike most abuses in our national life, however, the "patent-medicine" criminal has the newspaper for an ally. Other abuses that must fall before organized public opinion, to a large extent aroused through the public press, are easier to overthrow than the "patent-medicine" evil. This evil thrives with the connivance of a large part of the press. If the "patent-medicine" man can not advertise, his business dries up and is blown away. Many newspapers in accepting his advertisements agree to suppress information detrimental to the vile business. The "patent-medicine" man bribes a large part of the press through money paid for advertising.

This element in the problem alone makes the suppression of the "patent-medicine" evil one of the most difficult questions now confronting the American people, but the evil can be suppressed, provided some organization with courage and ability, and money enough behind it, will make a business of suppressing it. The "patent-medicine" men are organized as well as an army, and to beat them their opponents must in turn have an organization complete and perfect and well equipped. After a great many years of thought devoted to the subject and a practical experience of over six years in enforcing the laws against quackery in the county of New York, I am of the opinion that the evil will never be suppressed until a society is formed charged with the duty of fighting quackery all along the line. This society could be the directing brain that could concentrate all the powers for good that can be used in the suppression of the "patent-medicine" man and quackery generally.

OUTLINED SCHEME OF ORGANIZATION.

Such a society could be formed along the following lines:

A charter should be applied for, either under the general corporation laws of the State of New York or by special act of the legislature. New York is suggested as the most advisable state because the fight against quackery has been conducted here more systematically than in any other state in the Union, and because the opponents of quackery can be better organized from New York than from any other point in the United States. A charter from Congress would possess some advantages not obtained by incorporation in a single state.

This society should have the necessary number of officers, and care should be taken to place in offices requiring active work only those men who will go on the firing line. The honorary offices should be distributed to public-spirited men, whose names alone will strike terror to the opposition. Rich spies of the "patent-medicine" trust must be detected and denied a place in the councils of the new society.

Certain standing committees must be provided for in the organization of the proposed society. One committee, for instance, should be charged with the duty of advocating and encouraging all legislation directed against frauds in "patent medicines." This committee should meet the well-organized lobby of the "patent-medicine" trust in every legislature of the United States, and with the facts at its disposal expose the evils of "patent medicines" in our legislatures, and at the same time bring public sentiment to bear in every state where the battle for reform is waged.

Another committee should have charge of the distribution of literature and the dissemination of information placed at its disposal by another committee whose duty it will be to collect it. The services of an expert analytical chemist must at all times be at the disposal of this committee.

Another committee, composed entirely of medical experts, will supply the necessary expert testimony, either at public hearings or in the prosecution of criminals, in the courts of law or in the form of written articles and lectures.

Another committee will have charge of the enforcement of the criminal laws now on the statute books, and so on, until each one of the forces for good mentioned above is being supervised and guided by an intelligent committee charged with the power and interested in the work.

Such a society will naturally become the proper source of authoritative information on the abuses of "patent medicine" and quackery, and the agents and investigators of such a society will be always at work gathering information, systematizing it, indexing it and making it generally available for the committees charged with the use and dissemination of this information.

MEMBERSHIP OF THE PROPOSED SOCIETY.

A mistaken idea prevails in many quarters in regard to the duty of the medical profession in suppressing "patent medicines" and quackery. Many think that physicians band themselves together to fight this evil for selfish reasons, failing to realize that the physician

profits much more than he loses by the indiscriminate practice of men with no knowledge of medicine. Sooner or later the victims of the quack and of the "patent-medicine" man must fall into the hands of the skilled physician, whereas, if they were treated by him in the first instance, their health might have been preserved with but little effort.

The physician has led the way in this work because of his public-spirited interest in it. The physician, more than anyone else in the community, realizes the dangers of quackery, and he has tried to suppress it because as a physician he feels it his duty to relieve suffering wherever he could. But the physician can not fight the evil single handed. The physician has been fighting our battle, the battle of the public, for an hundred years and more, and it is time for the public to rally to the support of the common cause.

Medical men would no doubt take a leading part in the activities of the proposed society for the preservation of the public health, but they should not be expected to do it all. At least 50 per cent. of the membership in the proposed society should be laymen of influence and standing in the community.

FINANCIAL SUPPORT.

One more vital point in connection with the proposed society remains to be discussed. The "patent-medicine" man makes his money by millions, and he is a liberal spender when it comes to protecting his interests and extending the fields of his activities. These men employ skilled counsel, they have shrewd agents working in their behalf, they have immense financial resources, and they have a well-organized lobby. To be sure, they have not right and the public interest on their side, but they have everything else for the accomplishment of their purpose.

The society to oppose them must have financial backing strong enough to make its work effective. The proposed society might have several classes of members. The ordinary annual member to become such by contributing $5. A life member to become such by contributing $100, and an honorary life member by contributing $500.

It has become too much the fashion nowadays for people to expect donations and endowments from the public-spirited millionaires of America. Many people seem to think that all one has to do to get money from these men is to request it for any cause that seems to them to be good. They forget that most of these public-spirited men of wealth carefully investigate applications to their bounty, and are careful to aid only the most deserving causes. It is my belief that those gentlemen who, by their benefactions in the past, have shown an interest in the spread of medical science, in the spread of education and in the upbuilding and uplifting of human life and the purity of the American home, if they understand the plan and scope of the society for the preservation of the public health and are convinced that it is in responsible hands, will rally to its support to whatever extent it becomes necessary.

But something more than money is needed by the new society. If its influence is to be felt throughout the United States, it must have a large membership. The moral force that comes from an organization of thousands of public-spirited men and women engaged in a good cause, must be one of the chief assets of the new society.

To that end, people in every state and nation, who are interested in the work, would become charter members of the new society.

When the work of the Society for the Preservation of the Public Health becomes a reality, and it enters into the discharge of its herculean task, every member of it can feel that he or she is taking an active part in the suppression of an evil which, if permitted to spread much further, would strike at the vitals of our national character. And the proposed society must come sooner or later. It is a necessity. The only question is who will launch it, and when? Will the American Medical Association seize the present psychological moment and begin the formation of this life-saving society?

No claim of originality is made for the following indictment of crimes laid at the door of the "patent-medicine" men and quacks. No attempt is made to set forth the facts from which the generalizations have been deducted. For the most part, the indictment consists of mere condensed statements of the fact hitherto set forth in minute detail in lay periodicals and elsewhere. But in order that we may have clearly in mind the dangerous nature of these many crimes, a brief review of them will tend to emphasize the evils of the situation.

THE INDICTMENT AGAINST "PATENT-MEDICINE" MANUFACTURERS, QUACK DOCTORS, AND NEWSPAPERS IN LEAGUE WITH BOTH.

First.—Many drunkards and drug fiends date their downfall from the first dose of "patent-medicine." The most "popular" "patent medicines" contain dangerous drugs, alcohol, and narcotics, to such an extent that their continued use has made drunkards and opium fiends of hundreds of victims. Chemical analysis by the best chemists in the world have exposed over and over again the vicious nature of these leading "patent medicines." Often innocent children are made drunkards, or else killed outright, by cough mixtures and emulsions containing large amounts of alcohol and opiates.

Second.—The "patent-medicine" man preys on womankind. One of the leading "patent-medicine" manufacturers has expressed this well-known principle of the "patent-medicine" business in language better than any outsider could do it. His words were:

"It's the women we are after. We have buncoed them now for a good many years, and so long as they remain as 'easy' as they have been and we can make them believe they are sick we're all right. Give us the women every time."

Third.—Women's letters, instead of being kept "sacredly confidential" by the "patent-medicine" shark, are publicly exploited. The "patent-medicine" shark advertises to treat letters received from women as "sacredly confidential," and to permit no one save an honorable physician, generally mentioned by name, to read them. As a matter of fact, letters from women, laying bare their most confidential and sacred secrets, sometimes telling of the disgrace of a daughter, are opened by prying clerks and passed for reading from hand to hand through the receiving office, and if particularly racy, are shown others outside the business. "Then to cap the climax of iniquity, with some of these houses, these names and addresses, and even the letters themselves, are sold at two, three or five cents a name to firms in other lines of business for the purpose of sending circulars."

Fourth.—Quacks exploit, as a rule, poor people. The largest source of revenue for the "patent-medicine" man is from the pockets of the poor. Many people, after reading the alluring advertisements of the "patent-medicine" man, come to the conclusion that by taking the advertised remedy they can cure themselves and save the bill of a physician. They argue that if they can be cured by using one or two bottles, it will be cheaper than going to a doctor. This science of economy on the part of the poor is responsible for some of the ease with which the "patent-medicine" man amasses his fortune.

Fifth.—Most "patent medicine" testimonials are secured by fraud. "Patent medicine" men generally advertise so-called "testimonials" in the form of letters from alleged patients who paint the curative powers of the remedy in false and alluring colors. A great majority of these testimonials are miserable frauds. In some instances men and women are deliberately paid to make false statements. Other testimonials are

manufactured in the laboratory like the medicines themselves, by the wholesale, and still others are exacted in advance of treatment from poor patients, who gives these false testimonials in exchange for a few bottles of worthless medicines. Before giving newspapers contracts for advertising, some concerns require the newspapers to secure testimonials in advance.

Sixth.—"Patent-medicine" men try to "make business" by causing disease. Instead of trying to heal the sick "patent-medicine" men endeavor to "make business" by so framing their advertisements as to induce the reader to believe that he has one or more well-defined symptoms of a dangerous disease. The men employed to write these advertisements are known in the "patent-medicine" business as "hypo creators," because, by running the whole gamut of simple symptoms from "headache" to "chills down the spine," they are supposed to create hypochondriacs who will buy the drug which the advertisement guarantees will cure the disease the reader thinks he has. This is also a favorite method of deception practiced by the advertising quack doctor, especially one who advertises to cure diseases of men only.

Seventh.—No knowledge of medicine necessary in "patent-medicine" business. The chief "patent-medicine" industries of the country are enormous business institutions, the details of which in every department are conducted by laymen absolutely ignorant of the science of medicine. The scientific knowledge of the healing art is in no sense considered a requisite to the successful carrying on of the "patent-medicine" business. A good sense for advertising and a conscience that does not stick at personal enrichment filched from hoards of ignorant, suffering victims, are the qualities that bring success in that business.

Eighth.—The "patent-medicine" shark hides behind a "secret preparation." People who taken "patent medicines" are taking concoctions the ingredients of which the manufacturers fear to make known. By refusing to make public his so-called "invaluable" remedy, we are forced to conclude his drug is either worthless or dangerous, and that therefore he fears to have his dupes and victims know the true ingredients thereof. If the remedy be valuable, then he violates the honor of the medical profession, whose first rule is that all discoveries in the healing art are for the benefit of humanity, without individual profit or control, by governmental patent or secret methods. Every effort to compel the printing of "patent-medicine" formulas on labels has met with the determined opposition of the "patent-medicine" trust. The reason is obvious.

Ninth.—The "patent-medicine" man substitutes impure and adulterated drugs for pure drugs. In order to reduce the cost of his vile stuff to a minimum the fraudulent substitution of drugs is practiced by the "patent-medicine" man, e. g., wood alcohol is substituted for pure alcohol, and poisonous acids for cherry bark. There is no government inspection of any kind in this nefarious business.

Tenth.—The "patent-medicine" man disregards dangerous conditions and always recommends his particular remedy, knowing that it may be worthless or dangerous. The "patent-medicine" man willingly undertakes to cure the most dangerous diseases without any opportunity for a personal examination and diagnosis of the patient. The patient may be in a dangerous condition, but that is no business of the "patent-medicine" man. His object is to sell his remedy. He will, therefore, prescribe his "cure-all" to every applicant without discrimination, in spite of the fact that such methods bring about the deaths of thousands of victims and are universally condemned by scientists everywhere.

Eleventh.—Patients, by false analyses, are frightened into believing they are dangerously ill. The "patent-medicine" man urges his victim when he first catches him, to send in samples of urine, blood, and some other secretion of the body for inspection and analysis, on the pretense that the disease may be more accurately diagnosed. As a matter of fact, thousands of these samples may be received in a day. They are either thrown away as fast as received, or perfectly natural chemical changes and reactions are misinterpreted so as to cause the victim to believe he has a disease demanding the "infallible" remedy made by the "patent-medicine" exploiter.

Twelfth.—The "patent-medicine" man deliberately makes false claims to the curative powers and to the universal applicability of his drug. If the "patent medicine" be of value in the treatment of disease, its scope, as the scope of any one medicinal remedy, must necessarily be very limited in its efficiency and restricted to comparatively few ailments. Yet the unscrupulous owners and exploiters of "patent medicines" rarely hesitate to assure the public that their remedies are of extraordinary efficacy and will cure the most stubborn cases without fail. Material representations in the sale of a horse or a mine or a watch are often punished as "larceny by a false pretense." Why should the taking of health and money from ignorant or susceptible people by the false pretenses advanced by the "patent-medicine" swindler be called by terms less harsh, or punished by sentences less severe?

Thirteenth.—The "patent-medicine" man exploits the personal skill of a physician who is generally an imaginary person. Many of the most widely-known "patent medicines" are supposed to be controlled, either by some benevolent woman (like Lydia Pinkham, dead these twenty years), or by some celebrated physician (like Dr. Wallace Hadley of the Force of Life Chemical Company). The "benevolent" woman or the "skillful" doctor, as a matter of fact, is generally either a myth or some insignificant individual whose fame is confined to the statements made in false advertisements. These words of praise of the great "physician" may be compared to bird lime skilfully spread to catch unsuspecting birds.

Fourteenth.—The "patent-medicine" men have a strong organization to protect themselves against hostile legislation of every sort. The manufacturers of "patent medicine" have an organization representing thirty-five states in the union. This organization looks after their interests generally, but its chief function is in regard to legislation. The legislative committee consists of thirty-seven members, being several times larger than any other committee of the organization. The object of that committee is to watch national and state legislation which may affect the business interest of members, and to take such action with reference thereto as occasion may require.

The report of this committee from year to year recalls the progress of legislation in every state hostile to "patent-medicine" men and the success of this organization in combating it. The public will have to fight this organization every step of the way in its effort to free the country from the "patent medicine" evil.

Fifteenth.—Quacks make a false diagnosis of loathsome diseases. Quacks, especially those in large cities, who advertise to cure diseases of men only, have a favorite method of diagnosing a simple trouble as a vile and loathsome disease, thus frightening the patient into paying them exorbitant sums for a cure. L. R. Williams and William H. Hale and Henry H. Kane, recently run out of business by the Medical Society of the County of New York, are fair samples of this miserable type of man.

Sixteenth.—The "patent-medicine" evil could not thrive without the active support of a large part of the public press. The responsibility of the newspaper was recently expressed by a resolution passed by the Medical Society of the County of New York, reciting, among other things, as follows:

> In the courts of honor, conscience and morals, if not in the courts of law, the newspaper that profits by the publication of the alluringly false advertisements of notorious quacks and charlatans, whose filthy advertisements can be found in prominent places in the advertising columns of certain New York papers, are in no wise less guilty than these charlatans themselves.

DISCUSSION.

DR. SAMUEL G. DIXON.—When I was invited here this evening to hear Mr. Andrews on "Forensic Medicine," I had no idea of opening the discussion, and I feel much embarrassed, for while I believe that "quackery" kills a large proportion of those who meet with a premature death, I have never given any thought to the remedy to overcome this great evil. However, since I learned that I would open the discussion, and knowing that I would hear such an able and comprehensive treatment of the subject, I have recalled some thoughts that have occurred to me from time to time. Once, when glancing through "Pepys' Diary," I saw a remedy for burns which ran somewhat like this: "There came three angels out of the East. The one brought fire, the other brought frost. Out fire; in frost, in the name of the Father, Son and Holy Ghost. Amen." At the

time I passed it by as an example of a superstition of the past. Last summer, however, when there was an explosion of typhoid fever at Nanticoke which promised to be more killing than that at Plymouth, and every possible means was being pushed to eradicate the original infection, and a systematic effort was being made to teach the people to boil all water that for any purpose would be taken internally, circulars in different languages were sent to each house, placards were posted on the telegraph posts, and corps of nurses visited from house to house to teach that boiled water would, in all probability, prevent infection in new centers. These nurses were met with the declaration from many, "No, we will take no care of the fever, as it is a visitation from the Almighty God on t' people of the earth for permitting the sinking of the Russian war vessels." Such ignorance and superstition being the foundation stones of quackery made me realize the necessity of instructing the people before we can expect to overcome charlatanism. This in a measure can be done through the newspapers which are read before almost every fireside in this great commonwealth. For instance, the free distribution of antitoxin has brought very wide results, and from inquiry from the overseers on the farms I find that the sale of antitoxin, outside of that distributed by the state, has increased between 25 and 30 per cent. The work that has been pushed during the last six months in every township in Pennsylvania to prevent and to overcome smallpox has revealed much ignorance. One physician in Johnstown persisted in circulating vile literature against vaccination, and at the same time guaranteed to prevent smallpox with a remedy of his own to be taken internally. I ran this down and found that he was a graduate of one of the regular medical schools of this state, and that he held a license from the commonwealth to practice medicine. If a lawyer trifled with the affairs of his clients as that physician was trifling with the lives of the people, he would be debarred from practicing law. Yet, the present laws of Pennsylvania permit such quacks to go on practicing medicine under the official license bearing the seal of the state. He may have been convicted of malpractice, and yet go about flaunting a state license in our faces while he continues with his malicious pursuit. It is time, therefore, that we band together and prepare a bill to be presented to the next legislature empowering the State Medical Examining Board to revoke medical licenses when it is proved that they have fallen into the hands of charlatans and quacks. Entrusted as we are with the health and lives of the people, let us take as much pride in having a high standard of honesty, honor and intelligence in our profession as do the lawyers who safeguard the honor and property of the community. So much should we do in the way of our profession. Some years ago I stopped in a restaurant when a colored lad I had known since he was a child came up to wait on me looking thin and weak. I asked what had affected his former good health. His answer was: "Oh, Doctor, I guess it is all up wid Henry. I can't eat nothen, an' I am getten thin and weak and has a bad cough in the mornings. I guess Henry done and got consumptions." On inquiring I learned that he had his usual good health until a few weeks previous when he had contracted a cough and at once purchased a bottle of "cough expectorant," the label of which professed to teach him how to diagnose his own case and how to regulate the dosage. He had been religiously following the instructions, with the result I have mentioned. It goes without saying that a discontinuance of the quack remedy permitted Nature to reassert herself and permitted the poor fellow to take a new lease on life. Relating this simple experience to some of our lawmakers brought out from them several incidents of the same character and the declaration that the law should forbid the sale of such quack medicine accompanied by instructions for diagnosing. The time is right here when we should pass a law forbidding the sale of any quack medicine, when such stuff is sold as a cure for human ills, and this law should provide that such medicines should bear a printed label setting forth the full detailed formula of its composition, and a violation of the law requiring such labeling should be treated as a penal offense. I have spoken of this a good deal during the past year; I have talked with a number of senators and representatives, and with the governor. The governor and a number of the senators are in sympathy with such a measure and have already expressed themselves as being willing to help us pass this law, or rather to pass a law which will enable us to revoke medical licenses in the hands of unworthy holders. A majority are ready to pass a law forbidding the sale of "patent medicines" unless the detailed formula is affixed to the package. I say this tonight because I have been waiting for an opportunity when I could see my medical brethren and tell them what good things are in store for them at the state capitol. The men there are now ready to work with us and we have only to organize and prepare to push forward next year, when I think without doubt we can accomplish these two objects. In reading the card announcing the able address which has just been delivered, I notice the names of those whom I know have given this subject much profound thought; therefore, I cannot conscientiously take up more time from those who must have clear-cut ideas regarding the best methods to overcome one of the greatest and most rapidly growing evils of the day.

DR. ROBERTS.—I have very little to say on the direct subject of this address, but have jotted down a few notes which seem to me to be pertinent to it. I do not believe the "patent-medicine" evil and the quackery evil are entirely diseases of the community, but they are, to a certain extent, affections of the medical profession. The ease with which the public is duped by those whom intelligent men in general call "quacks," is partly due to quackish men in our own professional ranks. The essence of quackery is a boastful assertion of skill and infallibility, coupled with a strong desire to make money out of men's ill-health. The essence of medicine is a humble devotion to science and a burning wish to alleviate human suffering. Not all physicians are impelled by the motives which medicine demands of her followers. The sick often seek the advertising doctor and believe the false assertions of the "patent-medicine" label because they have found the medical practitioners with whom they have come in contact so incapable, so inefficient, or so exhorbitant in fees that help seemed impossible at their hands. The family which can obtain—near its home—efficient medical aid for a moderate fee, does not often drift into the hands of the recognized quacks. The college which graduates an ignoramus, the state examining boards that give a license to an unfit applicant, and the physician who places an unjust value on his services, or who deceives his confiding patient, are potent forces in encouraging quackery. Some years ago the alumni of various medical schools were obliged to compel their almæ maters to stop the output of half-trained graduates, and the profession has at times had need to be on the alert that medical examining boards did not permit improper men to obtain licenses to practice. These sources of supply of quasi-physicians have now been pretty effectually and satisfactorily checked. There remain, however, the secret-remedy prescribers, the commission-paying consultants, and the big-fee doctors to be disciplined by the medical profession itself. When these quackish colleagues have been ostracized a great deal will have been accomplished in the crusade to suppress quackery.

DR. BEATES.—I will make a few brief statements of some of the difficulties against which our profession contends, and as I have had opportunity of viewing them. First, it may be well to elaborate more fully a point raised by the last speaker wherein he refers to certain classes or types of practitioners who, because of their methods, form one of the most potent factors in establishing conditions favorable to the thriving of quackery. Reference is made to the professorial element of the commercial medical college, which is operative for the following reasons: A professor is regarded by the public as a paragon of medical knowledge and skill, and his fiat in matters of public questions, as well as of professional skill, is obeyed with a blind trust and confidence truly surprising. Now, quacks, if apprehended in this commonwealth, and convicted of illegal practice, are simply subjected, because of the Act of Assembly, a relatively weak law, to a mere fine. As we have seen from the speaker tonight, the "gullibility" of the public is such that these quacks receive fabulously large remuneration for their evil practices; therefore, these fines are paid, and within twenty-four hours the quacks are at their nefarious work again, presuming, and ofttimes well founded in so doing, that the annoyance and delay and expense attaching to prosecution will render them secure from repeated arrest. If, therefore, the Act of Assembly could be so amended as to impose

imprisonment in addition to fine, one or both, to be meted out by the courts, quackery could, in a large measure, be controlled. In the efforts in this state to amend the practice act, it was attempted, in addition to standardizing preliminary education on a higher plane, as well as determining the conference of the degree on a full four years' medical college course, to incorporate a punitive clause which would add imprisonment to the above mentioned fines. Unfortunately, the successful opposition of the class of practitioner above referred to —the professor of the commercial and low-standard medical school—swept away this measure with the higher standard provisos, and, therefore, quacks, in this state, have nothing to fear for the present but a small fine. Quackery, unfortunately, prevails among the unprincipled practitioners of medicine who are licentiates. They lack in principle and character, and advertise all sorts of methods for curing this and that disease, and because of possessing a diploma or license, or both, are the better able to make dupes of the community. It would be well, therefore, for every Act of Assembly throughout the country to have amendments providing for revocation of licenses for this and other forms of evil. In this state, a few years ago, when amendments had been framed which would have enabled the Act of Assembly to be so administered as to correct the indicated evils, the commercial medical schools actually contributed money to a political campaign fund, and the unprincipled political party leaders were induced to promise the defeat of the bill, because these colleges laid claim to the fact that, if the standards were raised, as the measure provided for, they would lose students and money and suffer financial disaster. The correction of this sort of thing lies in the hands of the rank and file of the medical profession, who, if they would stand shoulder to shoulder in forming a substantial organization, could, as should be done, sweep out of existence the boards of trustees and faculties of such concerns as are guilty of this truly horrible crime. Dr. Roberts says that colleges that send out illiterate and unfit practitioners are potent forces in the favoring of quackery. Certain it is that illiterate and incompetent practitioners are equaled in the results of their treatment of disease by any class of like ignoramus who claims this or that quack method as a means of curing disease, and it is self evident that, as these illiterate graduates are so numerous, many people obtain about as good results from the quacks as they do from those they believe to be qualified physicians; the only difference is that the quack obtains thousands of dollars for his evil practices where the physician receives but a few pennies. He also speaks of the improved condition of medical education, which is gradually diminishing this factor in the evil, and, while there has, undoubtedly, been truly marvelous advances in higher medical education, the profession should know that there are colleges even in Pennsylvania today that are graduating men concerning whom the following gives you a correct idea: From a college that was very active in defeating medical legislation, having for its end the establishment of proper medical education, as late as June, 1905, graduated, among many others, a man of this type. At the session of the examining board this question was asked: "Explain how intracranial venous pressure and auricular filling of the heart are affected by respiration." The answer given was this: "Because the respiration are not deep enough, or which does not allow enough air to get to the blood, of course we only want the heart to fill with blood when needed, if fill to rapid will cause enlargement of all portion which we did not need, because dead will overtake us, so therefore respiration regular, the amount, quantity and quality of blood to be forced through the ventricles, if that was not true the intracranial venous pressure, etc., would be affected and cause congestion, convulsion & headache therefore we will know the respiration is the fault." I desire to say seriously that I am not exaggerating when I say that 20 per cent. of the graduates of 1905 were of this type of illiteracy, and necessarily proportionately incompetent. The necessary correction for this is self-evident.

The next point, and one which has been well emphasized by Mr. Andrews is that it is useless for one or two individuals alone to try to prosecute quackery. A conviction here and there is absolutely strictly local and does not effect the root of the evil. The medical profession must undergo organization, and one of the things that we have to do to-day, as members of this commonwealth, is to use our influence as individuals to effect on a well elaborated basis a complete organization.

Another matter which is a great obstacle in the successful prosecution of illegal practitioners or quacks is the want of a legal definition of what constitutes the practice of medicine. Courts have decided that the treatment of disease by any means without the use of medicine is not the practice of medicine. A more senseless and absurd fact, not a matter of law, but a fact could not well be imagined. The treatment of disease, deformity or injury, no matter by what means, is the practice of medicine.

In the *Public Ledger* of Philadelphia, on Feb. 7, 1906, a paper which I believe should be credited with having done much to educate the public to a realizing sense of the importance of the medical profession from an economic point of view, appeared an editorial entitled, "The Practice of Medicine," and also the following definition, which is judical, and should, therefore, be a precedent guiding all judges in charging juries when actions of this type are under consideration,—

"The practice of medicine is the exercise or performance of any act, by or through the use of any thing or matter, or by things done, given or applied, whether with or without the use of drugs or medicine, and whether with or without fee therefor, by a person holding himself or herself out as able to cure disease, with a view to relieve, heal or cure, and having for its object the prevention, healing, remedying, cure or alleviation of disease."

The speaker of the evening suggests the advisability, and it is a most excellent suggestion, of a move being instituted to form a national society for the suppression of quackery and the prosecution of those who practice illegally. It is to be hoped that, in Philadelphia, which has the honor of being one of the earliest, if not the earliest center of medical learning, the great Philadelphia Medical Society with a membership of twelve hundred physicians, will appreciate its duty of higher citizenship and originate the effort not only of ridding this community of quacks, but of forming a national organization, whose object it will be to protect fellowmen from the fearful consequences of ignorance and quackery, as well as to save them from such extortion, extortion which passes all comprehension. Thus we could and should have the honor of being the first to identify ourselves with a movement, which disinterestedly interests itself in the highest needs and the welfare of our fellowmen.

Let us, from our membership, get together men strong in character, integrity and energy, full of purpose and force, who are willing from a conscientious point of view to pursue this arduous task and public duty with that spirit which knows nothing but success. A movement in this medical center, launched forth under such conditions must of necessity grow and develop until it has permeated the entire country.

THOMAS N. BARLOW.—I wish to express my appreciation and admiration for the very illuminating and scholarly address to which we have listened this evening. I particularly appreciate it because of the emphasis it gives to the necessity for the establishment of amendments to the police power, exercised by lawful authority, for the benefit of the people. As Mr. Andrews has said, the ordinary police channels are totally insufficient to meet the evils complained of in the paper read this evening. Special laws and special means are required, and the matter of repression and prosecution placed in the hands of people especially fitted for the work. The deterrent influence of such an organization is a thousand times greater than punitive; its very existence is a menace to evil doers. If such a society or committee is organized in Philadelphia, it will require greater expedition in the method of indictment and trial than we now have.

I may say in conclusion that I wish to congratulate my brother from New York on his presentation of one of the most concise, one of the clearest and most orderly addresses that I have ever listened to.

DR. COHEN.—I have listened with pleasure and instruction to the admirable address of Mr. Andrews. Following a thought of the last speaker, it may be recalled that some fifteen or more years ago, the Philadelphia County Medical Society undertook to prosecute offenders against the Medical Practice Act. We did not receive any assistance at the hands of the authorities, not that they were especially unwilling to assist us, but the law or practice in Pennsylvania did not favor it. We secured with much difficulty and expense a few convictions

and then the attempt was dropped. The other day my attention was attracted to a large sign board erected on the top of a house and bearing the name of one of the first offenders convicted by the County Medical Society. It stated that he treated "special diseases."

This bears out what our friend from New York has told us—that the offenders return to work the minute the vigilance is relaxed.

The community is greatly indebted to *Collier's Weekly* and the *Ladies' Home Journal* in particular, for their fight on "patent medicines." One of the greatest difficulties in the way has been pointed out by Mr. Andrews. I merely call attention to it, the Proprietary Association of America, with its unlimited capital and unremitting endeavors in defense of the nefarious occupation of its members. In ordinary fraudulent businesses, if the person responsible is found, the fraud can be broken up and the perpetrator put in jail. The men engaged in the "patent-medicine" trade are looked up to as representative citizens of the towns in which they live; they may be pillars of the church—often they are—liberal patrons of colleges and various other public institutions. It is pretty difficult to stop the disreputable work of respectable men, especially when they have taken the Lord into partnership. Moreover, these men have great political influence, perhaps sufficient in certain parts of the country to make and to unmake governors, senators, congressmen, legislators and the like.

They have been particularly generous sometimes to the villages which they left as poor boys, and thus the church, the school, the press, political interests and often public sentiment are against those who attack "patent medicines." Whatever the source and secret of their influence is, it has been so great as to cause an amendment of the Pure Food Law now before the United States Congress striking out the provision requiring the formulas of "patent medicines" to be printed on the package.

Dr. Roberts has called attention to a phase of the subject that must interest all medical men; the relations of the medical fraternity to the "patent medicine" industry. We can not say as a body that our hands and our spirits are clean, whatever care we may have taken individually, and the skirts of the medical press in particular are not free from contamination with the "patent-medicine" evil. The work of mine to which you have been good enough to refer, and which was done with the help of the Philadelphia County Medical Society and the Medical Society of the State of Pennsylvania, was directed to one end, namely, the purification of THE JOURNAL of the American Medical Association from "patent-medicine" advertisements. I might again relate the manner in which I was led into the work. I happened to have under my care the proprietor of an influential newspaper, and I called his attention to some advertisements of "patent medicines," especially so-called "consumption cures," in his paper. He had excluded the advertisements of abortionists, "specialists in diseases of men," and so forth, and these were what were technically called "clean" medical advertisements. He expressed surprise at my criticism and said: "Don't you know that your own medical journals publish the same kind of advertisements?" It was my turn to express surprise. "Well," he said, "take the trouble to look." I took the trouble and found it so. I had indeed "taken trouble" on myself. I then spoke to the proprietor of an influential medical journal, with whom I occupied a similar relation, and he said: "When you get those advertisements out of the journal, of which you are part proprietor, then come to me and talk about them." The journal of which you and I and many of our friends here are part proprietor, is THE JOURNAL of the American Medical Association. That journal, at that time, contained the worst advertisements of any in the world, so far as my observation has gone. As soon as the matter was brought to the attention of the American Medical Society, a resolution was passed for the exclusion of the advertisements, but that resolution, until within very recent years, remained to a large extent a dead letter, because the authorities of the American Medical Association were not willing to insist on it being carried out, because the pressure of "business interests" was too great to overcome.

We owe a debt of gratitude to Dr. Simmons, the present editor of THE JOURNAL, who has done more to organize the American Medical Association of America into a force for good than any of his contemporaries. He has begun in earnest the work of cleansing THE JOURNAL from nostrum advertisements and has begun to share with some of us Philadelphians the verbal compliments of the quacks and imposters and their journalistic mouth-pieces. Until the medical men succeed in cleaning the medical press, I doubt whether we have any right to say anything to the proprietors of the daily press.

I am very glad that our friends who are not of the profession are willing to bring pressure to bear on the daily newspapers, and to show them what harm they are doing, but I feel with Dr. Roberts, that until we have removed the beam from our own eye, we are not in a position to say anything out loud about the mote in the eye of others.

The American Medical Association has been suggested as the society to take up this work in general. I doubt whether that is possible. The American Medical Association has enough to do with its scientific work, with its work in public health promotion, properly so-called, and in keeping itself clean, to occupy all of its attention. But I believe that the American Medical Association might well co-operate with a national society, such as has been suggested.

In concluding, I have only to say that I have been personally indebted to Mr. Andrews for presenting to us his very clear view of the situation, and for pointing out to us the necessary steps that we must take in Philadelphia to get rid of fraudulent practitioners. There is no doubt that the police law should be changed, and that when it is changed, we should have somebody charged with the execution of this law so that it will not fall into innocuous desuetude. That body might be the State Board of Medical Examiners, or the Philadelphia County Medical Society, or some other society, but it should be some one definite body.

It has been suggested that if a physician abuse his license it should be revoked. I am heartily in accord with that proposition, but I think it would be dangerous to place such power in the hands of any other body than a court of law, which will hear both sides publicly. A lawyer can be disbarred only by order of court, and a physician should not have his license revoked except by order of court, but the State Board of Medical Examiners might call the attention of court to the facts and ask for revocation of license, as is done in the legal profession, I believe by the Bar Association.

PROFESSOR FRAZER—I am surprised that you call on me to say anything on this subject, who am neither lawyer nor physician, but I have listened with great interest to the paper this evening. I had thought the physicians who with altruistic spirit, claim everything for their profession, would also include quackery. I do not wish to introduce a discordant note, or one foreign to the subject which would distract the attention from Mr. Andrews' very able discussion, which concerns the medical profession; any yet not alone, for we have in geology and in chemistry as many quacks as you have, but our quacks are not quite so well off, nor are they so generally known. They are to be found, however, in Washington, Harrisburg, and some institutions of learning. Dr. Dixon, who is both a lawyer and a medical man; eminent in both professions and president of various institutions, could tell us how many professions he has seen invaded by quacks; he has seen many kinds in one hall.

I would simply add what tribute I can to the very excellent paper by Mr. Andrews, and say that I have derived a great deal of pleasure from it, and if I have an opportunity to further the movement he suggests in any way whatever, I will be only too glad to do so.

DR. DIXON.—Mr. Barlow refers to the police laws of Philadelphia, and it may be of interest to us to know that the Department of State had 1700 men in the fall, and will soon have 2800 men, any one of whom can arrest without warning, and the commissioner has power to employ counsel to prosecute the cases. Therefore, it seems to me, that the state has a law sufficiently broad to cover the questions before us to-night, but that is only applicable to the townships, outside of boroughs and cities, and does not apply to local practice.

HAWAII AS A FIELD FOR SCIENTIFIC WORK IN TROPICAL MEDICINE.*

E. S. GOODHUE, M.D.
HOLUALOA, HAWAII.

In an address before the New York Pathological Society, Dr. Flexner, president of the Rockefeller Institute, speaking of dysentery, said:

> The attempt to establish a common etiologic factor for all cases of dysentery has thus far failed. . . . Given a disease that is never entirely absent from tropical regions, that appears with epidemic severity, that permits easy access to the *materies morbi*, one would certainly have been tempted to predict that the success achieved in so many apparently less difficult fields would probably be repeated. . . . Our imperfect knowledge of dysentery should be ascribed neither to lack of opportunity for the study of the disease nor to lack of energy in the pursuit.

After close acquaintance with the disease in the Philippines, Dr. Richard T. Strong recognizes two different forms on which he bases a careful report, from which I quote:

> Owing to the great frequency of dysentery in the Philippines our present inability to cope with the disease, and the fact that one attack appears to afford no protection whatever, makes it necessary that very thorough and careful studies should be made in order to discover, if possible, some method of preventing infection and possibly some serum that will affect a cure.

This applies very well to Hawaii.[1] By means of recruits from Hawaii and the Philippines, Dr. Craig of San Francisco has been able to study the pathology of chronic dysentery of tropical origin, and Professor Kieffer of Philadelphia to trace the relation between abscess of the liver and the *Ameba dysenteriæ*.

ANKYLOSTOMA DUODENALE.

Stimulated by the spirit of research in tropical phenomena, Dr. Stiles of Washington, D. C., discovered a new species of hookworm (*Uncinaria americana*), also giving rise to disease in man. This is the parasite that has caused the Porto Rican anemia we see in Hawaii and the heavy losses among sheep in Texas.

Egypt was the original habitat of the species, but, owing to our modern methods of travel, this undesirable foreigner is making himself hated away from home.

Another observer attributes ground-itch, a disease common in Assam, India, West Indies and the tropics generally, to the same parasite. He says:

> With this . . . to stimulate observation, no doubt others will be found in this country, and it is possible that the prevention of the spread of the disease will become an important matter of sanitation.

Dr. Claude A. Smith, demonstrator of pathology in the medical school of Atlanta, has made an exhaustive study of the disease in the South, a subtropical country, where it is extremely common and where it gives rise to anemias and cachexias that were formerly attributed to malaria. Since the arrival of the Porto Ricans in Hawaii, Dr. Sandow of Waimea, Kauai, has contributed a valuable paper on the subject,[2] but the disease still offers a free field for investigation.

A form, at least, of ankylostomiasis has been here for many years, and in 1895 I described a case in a Portuguese who had never been out of Hawaii. The symptomatology was classical, though little was known as to the etiology of the case.

BILHARZIA HEMATOBIA.

From far Egypt, where it is supposed to have originated, this disease came to the notice of Drs. Booth of Sparta, Ill., and Walker of Indiana. The latter says, "Practically no attention has been paid to the disease in this country."

Since the discovery of the trematode worm by Bilharz in 1851, the disease has been described by Drs. Allen, Henderson, Atherstone, Cobbold and Griesenger from cases seen in Cairo, the Cape, Natal, the Transvaal and islands neighboring to Africa. Hematuria attributed to cystitis, vesical calculus, nephritis and, particularly, malaria may be found in most cases to be caused, even here, by a specific hematobic organism.

In a case of persistent and rather extensive hematuria which came under my care at the Malulani Government Hospital in 1897, the patient[3] suffered considerable pain and at each micturition passed variable quantities of pure blood. Occasionally there were clots. By placing a specimen in a transparent vessel and holding it before a strong light, wavy threads might be seen. These contained numerous typical ova. Small quantities of blood containing ova were occasionally passed per rectum, and some dysenteric symptoms supervened as a result of the presence of the parasite.

BUBONIC PLAGUE.

Although so much has been written there is much more to know concerning this very ancient disease which, despite the liking its germ has for coolness, persists in staying with us. Perhaps it is an indirect compliment to our climate.

The Institute of Infectious Diseases of Berlin established a separate department for the study of plague, but its facilities are meager compared with what our own might be, especially as regards the etiology and symptomatology of the disease.

We have abundant clinical material and shall continue to have; and our autopsies have already furnished rich pathologic data.[4] What better field in which to differentiate scientifically plague from certain phases of cerebrospinal meningitis *en transport* between here and other ports. We have meningitis here on occasion, and we had a few cases in Hawaii at the time it was sporadically prevalent through the United States. Why was it prevalent? Why did it persist with untraceable foci? Have we had any cases of non-specific plague or climatic bubo? Should we know them if we did?

In 1902 Dr. Coty made an interesting report of twelve cases of non-specific plague. They were European males who had lived in the tropics from three and a half months to twenty-seven years. He says:

> We have in this condition an adenitis occurring in debilitated persons in the tropics, and the exciting cause is the entrance of the ordinary microbes of suppuration into the lymphatic system, most often through trifling lesions of the skin.

Manson speaks of abortive plague, another name for the mild or ambulatory form which Cantlie specifies as a type. The latter also classifies "climatic bubo" (really a non-specific adenitis) as pestis minor, stating that the disease "remains at present undetermined." He says:

> Climatic buboes as generally described give signs and symptoms wholly analogous to the descriptions of pestis minor we are familiar with. There exists a febrile state, an enlarged

inguinal gland which may or may not go on to suppuration, and the course of which can not be assigned to any local site of infection.

Dr. Sinclair of Honolulu has made a reasonable suggestion in recommending the use of pestis simulans instead of pestis minor. He says:

I would suggest the abolishing the term pestis minor (inherently it means a form of plague) and suggest pestis simulans as being non-committal for cases that run a mild course of true plague in districts where plague is more or less epidemic, and where it is impossible to demonstrate the presence of plague bacillus; pestis ambulans may be retained for cases of true plague as shown by bacteriologic examination, the case being ambulatory in its nature.

In 1903 a case of supposed plague was brought to the Mariam Emerson Hospital, Eleele, by the patient's physician and placed under my care.

CASE 1.—A Japanese woman, aged 20, married, with a good history, had been somewhat indisposed for a few days previous to the swelling of the glands in her right groin. When she presented herself she was suffering from headache, pain in the swollen, reddened femoral region, with a pulse rate of 115, and a temperature of 104 F. This continued for three days, the gland in the right groin reaching the size of a goose egg. The vertical string of glands in the opposite side and the axillary glands were also enlarged somewhat.

The right gland suppurated and broke down on the twelfth day, discharging a large amount of pus, which contained no plague bacilli, but many streptococci and diplococci. Much loss of tissue resulted, but the patient recovered and was discharged after three weeks.

Nearly every symptom of ordinary plague was present, though the case occurred about a year after the Eleele epidemic, near the site of which the patient had lived.

Manson's query as to whether pus germs might not neutralize the toxins of plague is worth considering.

Certainly the cases that go on to suppuration are the milder ones.

FILARIASIS.

Filariasis is little known here clinically, although it is widely distributed in Porto Rico, and several cases have been traced from that source to districts in the United States.

Dr. Sassure of Charleston, S. C., reports 22 cases, and Dr. Manson, in his work on tropical diseases, says that the *Filaria nocturna* has been found as an indigenous parasite in most tropical and subtropical districts. He says:

In many places quite 10 per cent, and in other places half, of the population harbor it. One-third at least of one district in India carry blood filaria. I find that in some of the islands of the South Seas, Samoa, for instance, fully one-half of the people are affected.

It would be interesting to know why Hawaii is blessed above her sisters.

CHOLERA.

This disease[5] came to us in 1895. It may not offer the field for research that some others do, but an enthusiastic laboratory student would have enough to do even with only eighty-seven cases. The question of diagnosis would have been settled quickly by expert opinion, and some new knowledge perhaps furnished regarding effective quarantine and infection through fish.

BERIBERI.

Theoretically as well as clinically this is another disease of great interest. The causation is largely unknown and offers a wide field for speculation, Rost and Ashmead holding that the disease is caused by the eating of fermented rice.

In 1903 the Institute for Medical Research, Federated Malay States, made a report of great value, basing their summary on 500 beriberi cases at the Kwala jail. Dr. Ross' reference to the similarity between beriberi and chronic arsenical poisoning is suggestive, and the theory may account for some epidemics which occurred outside of the beriberi habitat. Hawaii has had and still has much valuable material relating to the disease.[6] Dr. Donald Currie of Washington, D. C., describes some cases (1903) of "beriberi, or a disease closely resembling it, met in San Francisco in Chinese fishermen returning to San Francisco from Alaska." While the paper is interesting, its value is not so great as it would have been had the writer verified his diagnosis.

SYPHILIS.

While not particularly tropical, a compilation and careful record of syphilitic cases, the prevalence of the disease and its effect on the Hawaiian race, would be valuable data. There is much to be learned, too, from an examination of old Hawaiian skeletons which show, particularly in the vertebral portion, the destructive effects of syphilis in the days when that disease was new to the race.

Some work in the line of Dr. E. F. Robinson's investigations regarding the Philippines would be not only interesting but profitable.

OTHER DISEASES.

"I can assign no reason for the high percentage of tetanus in Florida," writes a practitioner to his editor, "unless it be that tetanus is far more prevalent in warm and moist climates than in cool and dry ones. This I read when I was a student about 40 years ago, and my residence here for 35 years confirms it."

It would be interesting carefully to tabulate the cases of *tetanus neonatorum* among Japanese in Hawaii and make an illustrative comparison between that disease and rheumatic tetanus.

Why is there absolute absence of scarlet fever in the tropics? Can it be transmitted here, or is Dr. Manson's theory correct? Why are acute rheumatic fever, erysipelas, rachitis and sunstroke rare in warm countries? What modifications, if any, do pertussis, measles, chicken pox, smallpox and German measles undergo when transferred to warm countries? Will diphtheria ever be a common disease in the tropics? With all our climatic tendencies, is pneumonia any milder here than it is abroad? What about that delightful disease of our childhood—mumps?

Dr. Malcolm Morris, always versatile and instructive, says of ringworm: "For years wisdom had been crying in the streets and no man regarded it, and about all we know of the disease is that it is caused by fungi and that those fungi are of more than one kind." I am now battling with a case of tropical ringworm, due, I believe, to the *Audouini*, differing from other forms, persistent, recurrent, having no regard whatever for the reputation of the attending therapeutist.

Would you know epidemic, gangrenous rectitis, said to be confined to hot, damp regions in the north of South America and in the islands of the South Pacific; sprue found in all tropical and subtropical countries; yaws distributed among the natives of all parts of the tropics, related perhaps to syphilis, and lately described by Dr. Musgrave of Manila, and the various lesions caused by the *Filaria medinensis*—would you recognize them, I ask, if you came across them?

Lecturer in Gynecology, Albany Medical College; Gynecologist to Albany Hospital,
ALBANY, N. Y.

The so-called false or acquired diverticula of the small intestine have been of very little interest to clinicians because of their supposed rare occurrence and also because it was thought that they rarely or never give rise to any clinical symptoms.

The following case with multiple mesenteric diverticula of the small intestine shows that, apparently, even in these heretofore considered benign diverticula inflammatory changes may occur which may give rise to clinical symptoms and even endanger the life of the individual. In this case, apparently, one of the diverticula became inflamed and a diverticulitis occurred, causing a partial obliteration of the diverticulum. As the diverticulum extended between the folds of the mesentery, the later became inflamed, thickened and puckered, thus causing an angular bending of the intestine and obstructing its lumen. The local peritonitis arising as the result of this gave rise to the formation of adhesions between the mesentery of the small intestine and the transverse colon and its mesentery, and thus kinked the transverse colon.

Patient.—Mrs. ——, aged 45, was first seen by Dr. Gordinier Oct. 13, 1905.

Complaint.—Abdominal tenderness, with constipation following a supposed attack of appendicitis about three weeks previous.

Past History.—The patient was married, but never had any children; menstrual history was negative. Ten years ago she had an apparently definite attack of appendicitis; she was very ill, being in bed three weeks and was incapacitated for several weeks afterward. Since then she has enjoyed good health. She has always been troubled with constipation, and occasionally has some indigestion after eating, but the latter troubles her very little and has not been worse recently.

Present Illness.—While in Bennington, Vt., on Sept. 27, 1905, her previous health having been good, she was suddenly seized with severe abdominal pain starting near the umbilicus and extending in all directions, and followed by nausea and vomiting. Dr. A. S. M. Chisholm, Bennington, was called. Morphin had to be given to control the pain, and the bowels were moved with enemata and cathartics. After the bowels had been moved, this taking place on the second or third day, the patient felt much better, but remained in bed about a week altogether. From a communication received from Dr. Chisholm we learned that the patient's temperature was never over 1.5 degrees above normal, and that only on his first visit, and that her pulse never reached a hundred. There was great abdominal distension and, on this account, palpation was very unsatisfactory. The attack seemed like one of appendicitis to Dr. Chisholm, but he states that it was so atypical that it was impossible for him to make a positive diagnosis.

The patient returned to Troy, N. Y., on October 12 and was seen the following day by Dr. Gordinier of that city. He found that she felt weak and looked somewhat "run down" as the result of her recent illness. Her bowels had been moved each day by means of cathartics, but the movements were watery and had not appeared normal since her illness. She still complained of abdominal tenderness, and on palpation a sausage-shaped superficial mass could be felt just to the left of the umbilicus, and on deeper palpation a smaller mass was felt just about at the umbilicus (Fig. 1). Under catharsis, enemata and restricted diet the superficial mass gradually disappeared, but the deeper one persisted. Dr. Gordinier made a diagnosis of partial intestinal obstruction and inferred that the superficial mass was formed by a loop of the intestines distended with fecal material.

Consultation.—Dr. Sampson was called in consultation October 23. The patient had gained in strength and felt much better. She was still on restricted diet and the constipation persisted, the movements being watery. The deep-seated mass could still be palpated. It seemed to descend with inspiration, was tender, and it was difficult to estimate its size, as the abdominal walls were very thick, the patient weighing about 185 pounds. We considered many things which might account for the mass we felt and which could also cause obstruction of the intestine in that situation, such as a malignant growth, a Meckel's diverticulum, inflammatory mesenteric lymph glands, a mesenteric cyst, fecal concretions, etc.

Examination.—On vaginal examination the pelvic organs were found to be normal, and rectal examination, except for the presence of hemorrhoids, was negative. The stomach was distended by giving the patient tartaric acid and sodium bicarbonate, and it apparently did not bear any relation to the mass near the umbilicus.

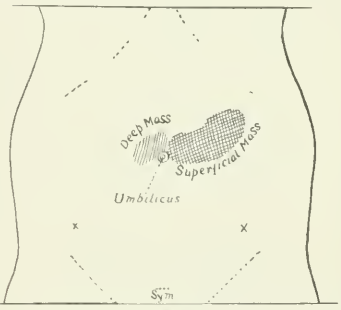

Fig. 1.—Tracing of the abdomen, showing the situation of the superficial and deep masses. The superficial, sausage-shaped mass was undoubtedly caused by the loop of small intestine, containing the diverticula and distended with fecal matter. The deep mass was probably formed by the adhesions between the kinked small intestine, caused by the inflamed diverticula and the mesocolon. See Figure 2.

Course of Disease.—As the patient's general health had greatly improved since her acute illness in September, it was thought best to wait. During the following four weeks she continued to improve, but the same indefinite mass could be felt at the umbilical region, at some times more distinctly than at others; and the constipation persisted, it being necessary to employ cathartics or enemata. The stools still continued to be watery, as they had been since her acute illness.

Preoperative Treatment.—As a deep-seated mass could still be palpated and had persisted, in spite of vigorous catharsis and the use of enemata, for over six weeks, it was thought best to make an exploratory incision in order to ascertain the cause of the trouble. With this in view the patient was admitted to the Samaritan Hospital of Troy, N. Y., on Nov. 23, 1905. After admission to the hospital she was put to bed and, for two days, she was given a course of treatment in order to empty the intestines thoroughly. Liquid food only was given, and that in small quantities. A vigorous course of saline catharsis was given. In addition the colon was irrigated with large quantities of water three times a day by means of a rectal tube connected with a fountain syringe, the patient lying in the Sims' position with hips elevated. On the second day she passed two large enteroliths, and after these a large quantity of soft fecal matter, the first approach to anything like a normal fecal movement since her illness in September.

On examining her, after this, the abdomen was much softer

* Read before the Medical Association of Troy and Vicinity, Jan. 2, 1906.

and the tumor had apparently disappeared. There was still some tenderness present about the navel and it was thought that this might have been due to a local inflammatory condition about the place where the enteroliths had been lodged. At this time it was thought that the entire condition might have been caused by the enteroliths. The patient wished to have a minor operation done, but was persuaded to wait a week until we felt sure about the other condition. The treatment by colonic irrigations was continued and also the catharsis, but the latter less vigorously. At the end of the week, during which time the patient had been having normal fluid bowel movements for the first time in two months, she was again examined and the same tender area was found near the umbilicus, and it seemed as if one's fingers rolled over an indefinite tender mass.

Operation.—On December 2 Dr. Sampson performed an exploratory laparotomy; a loop of small intestine adherent to the transverse colon and its mesentery was freed, the distal portion of an occluded diverticulum was removed and the angular kink in the small intestine, caused by the mesenteritis, resulting from the inflamed diverticulum, was released.

An incision about 10 cm. long was made through the left rectus muscle, at about the level of the umbilicus. The omentum was freed and lifted out of the way, and the transverse colon with adherent loop of the small intestine was delivered into the wound. Thirteen diverticula varying from 0.5 cm. to 1.5 cm. in diameter were found in about 40 cm. of the small intestine, which was distended to about half again its natural size. These diverticula were all in the mesenteric border and extended between the folds of the latter, in ten instances being more prominent on its upper surface. They bore a very definite relation to the large blood vessels, penetrating the intestines at the mesenteric border; as in every instance a large vessel extended over the surface of the diverticulum. Apparently they all consisted of serosa, submucosa and mucosa, the musculature being absent, i. e., they were hernial protrusions of the mucosa and submucosa through a weakened spot in the wall of the gut and beneath the serosa of the mesentery. They could all be invaginated into the lumen of the bowel, and the base of each diverticulum seemed to be nearly as large as its distal portion (Fig. 2). On freeing the loop of the small intestine, which was adherent to the colon and its mesentery, a small infected cyst, about 1.5 cm. in its long diameter, was ruptured (Fig. 3). This cyst was situated in the inflamed mesentery of the small intestine at its attachment to the latter. Apparently a diverticulum had become inflamed and its base occluded. It, therefore, no longer communicated with the lumen of the intestine, and its patent distal portion became converted into an infected cyst. The origin of mesenteric cysts from mesenteric diverticula has been recently suggested by Ayer[1]. Unfortunately the non-dilated portion of the intestine, beyond the kinked portion, was not very carefully examined and diverticula were not observed in this portion.

It could be argued that a small mesenteric cyst, situated at the intestinal border, had become infected, causing a mesenteritis and kinking of the bowel, and that these diverticula had arisen as a result of the distension from the partial obstruction of the intestine. There is no doubt but that the obstruction made the diverticula larger and more conspicuous, but if they owed their origin to intestinal distension alone we would expect to find them in every case of intestinal obstruction, whether acute or chronic, and especially the latter. On the other hand small diverticula could be present which would easily escape observation unless the intestine was examined very carefully (unfortunately not done in this case). Should one of these diverticula become infected a mesenteritis would result; the base of the diverticulum might become compressed and then occluded by inflammation. Its distal patent portion would become distended and a condition such as the above would occur. As a result of the kinking of the intestines obstruction would take place and previously insignificant and small diverticula would become greatly enlarged, and therefore more conspicuous.

The distal cystic portion of the partially obliterated diverticulum was removed and its base reinforced with sutures of fine catgut, taking care to avoid injuring the mesenteric vessels. The puckered mesentery was straightened out, thus relieving the angular kink in the small intestine. The question arose as to what should be done with the remaining diverticula. One hesitates to resect over forty centimeters of the small intestine unless it is absolutely indicated, especially when the distension would cease and the diverticula would become much smaller after the obstruction had been relieved. The invagination of each diverticulum and the closure of its hernial opening in the intestine was considered, but this did not seem advisable on account of the intimate relation between the diverticula and the larger blood vessels. The procedure would certainly occlude some of the larger blood vessels of the intestine and might cause necrosis of the portion of intestine nourished by the blood vessel.

Still further it seemed best not to disturb the remaining diverticula because:

1. They had probably been present for a long time and only one had given rise to any clinical symptoms.

2. Their situation in the upper portion of the circumference of the intestine and between the folds of the mesentery insures better drainage of their contents and also greater protection from secondary pathologic changes than in diverticula arising from the free border of the intestines.

3. The fluid contents of the small intestine, and the broad bases, with patent orifices of the diverticula, both make it very unlikely that any trouble will ever arise from the accumulation of fecal material in the diverticula, as occurs in similar diverticula of the large intestine. In addition, all the other diverticula were examined and found empty, and in none could any secondary pathologic changes be detected.

A small gauze drain covered with rubber protective was placed down to the raw and infected area and the abdominal incision was closed. The drain was removed at the end of forty-eight hours. Convalescence was uneventful; the patient left the hospital three weeks after the operation.

Remarks.—The exact portion of the small intestine involved was not ascertained, but judging from the length of the intestines exposed proximal to the involved portion of the intestines, the diverticula were situated in the upper portion of the ileum or in the lower portion of the jejunum.

An interesting question arises as to the situation of the enteroliths. There were two, about the size of hen's eggs, and we do not believe that they could have been situated in the small intestine. If they formed the mass which was palpated just before the very vigorous catharsis and colonic irrigations, they must have been situated in the transverse colon, which had been kinked by the adherent mesentery of the small intestine, otherwise the enteroliths were never palpated and the mass which disappeared was fecal material which had accumulated back of the stricture. It is impossible to settle this point.

INTESTINAL DIVERTICULA.

Diverticula of the intestines may be classified as congenital and acquired. Histologically they may be classified as true and false, the former containing all the coats of the intestine and the latter being but hernial protrusion of the inner coats through the muscularis. All congenital diverticula are true ones and the acquired ones are nearly always false, but true acquired diverticula have been reported.

The vermiform appendix is a true congenital diverticulum containing all the coats of the cecum. The pathologic changes which may occur in this diverticulum and their clinical manifestations will not be considered here.

Meckel's diverticulum is another example of a congenital true diverticulum. According to Kelly and Hurdon[2] it occurs in 0.5 to 2 per cent. of all bodies coming to autopsy and usually arises from the ileum from 80 to

2. Kelly and Hurdon: "The Vermiform Appendix and Its Diseases," Saunders & Co., Philadelphia, Pa., 1905, p. 594

290 cm. from the cecum, but may arise from the duodenum or jejunum. This diverticulum is of great surgical importance, causing, according to Halstead,[3] 6 per cent. of all cases of intestinal obstruction, aside from giving rise to other forms of acute abdominal conditions demanding surgical interference. A full consideration of the subject, with a complete review of the literature, has recently been made by Dreifeus,[4] and Porter[5] has recently analyzed 184 cases and has described the pathologic conditions caused by this diverticulum.

The acquired diverticula occur much more frequently than autopsy records show and are apparently less likely to give rise to symptoms than Meckel's diverticulum, which may account for their supposed infrequency. They may be classified according to the portion of the intestines from which they arise, i. e., whether the small or large intestine. Judging from autopsy and clinical reports, they occur more frequently in the large intestine and especially in the sigmoid.

FREQUENCY OF ACQUIRED DIVERTICULA OF THE INTESTINES.

These diverticula, especially as they are frequently mesenteric, could be easily overlooked at autopsy unless the intestines were examined very carefully. Heretofore they have been of very little general pathologic and clinical interest, and for these reasons all pathologists have not borne them in mind while making their autopsies and studying the intestines afterward. These points are well shown in Table 1.

TABLE 1.

Source.	Number of autopsies.	Meckel's diverticulum.	Acquired diverticula. Small intestine.	Large intestine.
1	8,133	8	1	6
2	2,600	15	14	19
3	2,382	11	1	1
4	953	5	0	2
Total	14,068	39	16	28

Table 1.—Compiled from: 1, Records of the City Hospital of Dresden, Freidrich Stadt (Georgi's[6] article); 2, the Johns Hopkins Hospital (communicated by Dr. C. H. Bunting); 3, the Boston City Hospital (communicated by Dr. F. B. Mallory), and 4, the Bender Hygienic Laboratory (communicated by Dr. R. M. Pearce).

This table does not show the actual occurrence of these diverticula, but rather that they are much more frequent than the records indicate when one institution has recorded 32 instances (one case presenting diverticula in both the large and the small intestine) of acquired diverticula of the intestines, as compared with only 11 similar cases in over four times the number of autopsies from three other sources. Two other interesting features of the records of the above-mentioned hospital show that in 2,600 autopsies these acquired diverticula occurred over twice as often as Meckel's, and, furthermore, that they were nearly as frequent in the small as in the large intestine. It is evident that these diverticula occur more frequently than the autopsy records indicate, and, as shall be shown, they are of much greater clinical importance than has been accorded them.

ETIOLOGY OF ACQUIRED INTESTINAL DIVERTICULA.

Of the predisposing causes, constipation, old age, cachexia, obesity and chronic passive congestion seem to have been important etiologic factors in many of the reported cases. Traction undoubtedly causes, occasionally, an intestinal diverticulum, as shown by a few cases reported, in which a tumor, which was adherent to a portion of the intestines, has pulled it out, forming a diverticulum. Their prevalence at the mesenteric border and their relation to the blood vessels penetrating the intestines at this place was explained by Klebs[7] on the theory of traction. More probably they arise from pressure within forcing the inner coats of the intestine through a weakened place in the intestinal wall, and this better explains their frequent intimate relation to the blood vessels penetrating the intestines at the mesenteric border, as has been emphasized by several of the later investigators.[8]

Many experiments have been made to ascertain the origin of these diverticula by injecting intestines removed at autopsy and also by injecting the living intestines of dogs. The results of these experiments have been fully described by Beer.[9] While these experiments may be interesting, they have very little value in explaining the etiology of these diverticula, for if they were caused by intraintestinal pressure alone they would be found in every instance of acute, and especially of chronic, intestinal obstruction from any cause. These diverticula are hernias, and, as in other hernias, there must be a local weakness of the wall through which the hernial sac may be forced. In many instances—and this is especially true of the small intestine—the penetration of the intestinal walls by the large vessels at the mesenteric border causes this weak place. In other cases in which they occur on the free border of the intestines, as they may in the large intestines or even in the epiploical appendages, we must assume that here, too, there was present a weakened place in the musculature of the intestinal wall.

CLINICAL SIGNIFICANCE OF ACQUIRED DIVERTICULA OF THE SMALL INTESTINE.

We have been unable to find a single case reported in the literature in which clinical symptoms have arisen from diverticula of the small intestine. In our case the patient did not suffer from any marked attacks of indigestion, nor were there any local disturbances until the sudden onset of diverticulitis, causing mesenteritis and intestinal obstruction two months before her operation. We therefore conclude that the diverticula which must have been present for some time did not give rise to any marked symptoms until the present attack.

On the other hand, the presence of inflammatory changes found in the diverticula described by Fischer, together with our case, shows that not only is it possible for these diverticula to have minor secondary pathologic changes and hence possibly give rise to minor clinical disturbances, but it is also possible that serious changes may occur, thus endangering the life of the individual. One may have all the inflammatory changes (but less frequently, for reasons already given) that may occur in any diverticulum, with the secondary local or general peritonitis. In addition its usual situation between the folds of the mesentery causes a mesenteritis as a complication of the diverticulitis. In such cases the mesentery may become thickened, puckered and folded, giving rise to the angular bending of the intestine found in our case

and causing intestinal obstruction. It is also possible that a diverticulum may become so thin that a sudden increase in intra-abdominal pressure may cause its rupture, as has occurred in cases of diverticula of the large intestine.

As shown in the consideration of the frequency of false diverticula of the small intestine, these occur more often than the autopsy records show. As they have not been duly recognized, they undoubtedly have given rise to minor or serious secondary pathologic changes, which either have been overlooked or the cause of the trouble has not been correctly interpreted, the condition being incorrectly attributed to pathologic changes caused by the appendix or by Meckel's diverticulum or some other condition.

Our present knowledge suggests that the acquired diverticula of the small intestine, when present, are less of a menace to the life of the individual than similar diverticula of the large intestine or Meckel's diverticulum, and possibly even less than the vermiform appendix. On the other hand, we do not as yet know what rôle it plays in the causation of minor complaints, as indigestion and indefinite abdominal pain and discomfort.

TREATMENT OF ACQUIRED DIVERTICULA OF THE SMALL INTESTINE.

For the following reasons it would seem that these diverticula do not need surgical interference unless causing definite symptoms, and the treatment in these cases should vary with the demands of each individual case:

1. The fact that this condition has frequently been overlooked at autopsy and that we have been unable to find any cases reported in which secondary pathologic changes have caused clinical symptoms, suggests that these rarely occur. The reason for this can readily be understood from the situation of the diverticula and the fluid contents of the small intestine, as has previously been explained.

2. The usual situation of the diverticula between the folds of the mesentery and their intimate relation with the larger blood vessels make any operative measures on individual diverticula attended with danger of injuring the blood vessels crossing the diverticulum, and thus possibly causing local intestinal necrosis.

3. The diverticula are usually multiple and a long area of the intestine may be involved, sometimes the greater portion of the small intestine, thus excluding, in most cases, the advisability of resecting the area of the intestine involved.

THE CLINICAL SIGNIFICANCE OF ACQUIRED DIVERTICULA OF THE LARGE INTESTINE.

Judging from autopsy reports, acquired diverticula of the large intestine are more frequent than those of the small intestine. In 2,600 autopsies at the Johns Hopkins Hospital there were thirteen diverticula of the small intestine, as compared with eighteen of the large and one of both. Secondary pathologic changes occur in these more frequently than in those of the small intestine, and this may account for their having been observed more frequently. They are also usually multiple and may arise from any portion of the circumference of the intestine, the mesenteric border or free surface, and they may also extend into the epiploical appendages. They have been observed most frequently in the sigmoid flexure, but may occur in the other parts, including the appendix. In some instances it has been possible to demonstrate their relation to the larger blood vessels, i. e., in cases in which they develop in the mesentery, as in those of the small intestine. In other cases in which they have arisen from the free border this relation has not been so evident.

The contents of the large intestine being harder than that of the small, and thus the liability of these diverticula becoming filled with hardened fecal matter renders them more prone to secondary inflammatory changes, which is especially true for the diverticula arising from the free surface of the intestine.

In 1904 Beer[9] collected from the literature 18 instances of inflammatory processes arising in these diverticula and leading to grave, often fatal, results. The same year Heine[10] collected 8 instances of intestinovesical fistula, including one case of his own, where such a fistula had resulted from a false diverticulum of the large intestine becoming adherent to and ulcerating into the bladder. He states that these fistulæ occur more frequently than has been supposed, and he gives abstracts of 9 other reported cases of vesico-intestinal fistulæ, which from their description should probably be included in this group, but in which the author had not considered this condition. It is evident that these diverticula are of considerable clinical importance, especially as they cause trouble much more frequently than the literature shows, because they either have not been recognized or the true condition has been attributed to something else. Cases representing all forms of acute inflammatory conditions and the results of these conditions have been reported, and Hochenegg[11] has reported one instance of cancer arising in one of these diverticula.

Stricture of the intestine or a localized abscess formation which may result from inflammatory changes in these diverticula form a most important group of cases, as they have usually been diagnosed as cancer, thus suggesting that other cases diagnosed as cancer may have been these. This would well account for some of the good results following colostomy in clinically diagnosed inoperable cancer of the sigmoid.

The following case may have been one of this class:

Patients.—Mrs. C. F., aged 63, was admitted to the Johns Hopkins Hospital May 7, 1904.

History.—She complained of pain in the lower abdomen and pressure on the rectum caused a great desire to go to stool, but she was not relieved by movements of her bowels. For two years there had been slight pain in the left ovarian region, and her present illness was of one week's duration, with the onset of severe cramps and with rectal symptoms necessitating her staying in bed.

Examination.—On pelvic examination a mass about the size of one's fist was felt adherent to the left side of the pelvis in the region of the right ovary. A probable diagnosis of malignant growth of the ovary, causing pressure on the rectum, was made.

Operation.—An exploratory laparotomy was made by Dr Sampson (then resident gynecologist of that hospital), and the tumor, which was densely adherent, was found to have arisen from the sigmoid. A diagnosis of carcinoma of the sigmoid was made and attempts were made to remove it, but after partially freeing it this was abandoned. During the manipulations necrotic tissue was encountered, suggesting the presence of an abscess which could well have arisen from a necrotic cancerous involvement of the sigmoid. A loop of the sigmoid

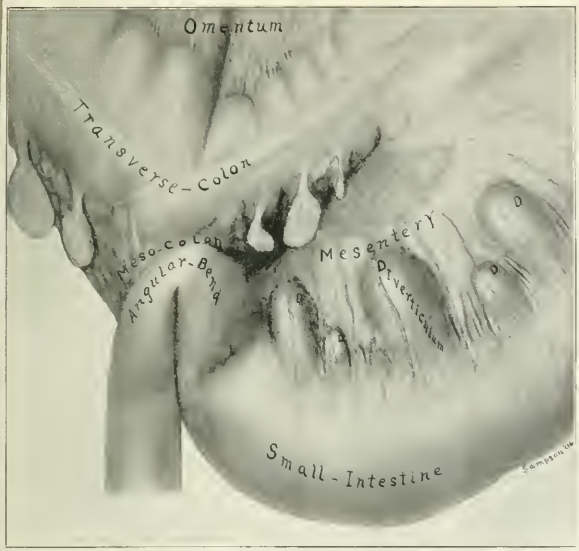

Fig. 2.—Distended loop of small intestine, showing five mesenteric diverticula and a kinking of the intestine due to adhesions resulting from an inflamed diverticulum (natural size). The omentum has been lifted up, showing the under surface of the transverse colon, with its mesocolon and a partially obstructed loop of the small intestine adherent to the latter. Notice that the diverticula of the distended portion of the small intestine extend between the folds of the mesentery and are crossed by large blood vessels supplying the intestine.

above the tumor was brought out through a gridiron inguinal incision and sutured there so that a colostomy could be made whenever the occasion demanded. The field of operation was drained and the abdominal incision closed.

The patient left the hospital in a month's time feeling greatly relieved, and with the understanding that a colostomy would be established whenever necessary. From a reply dated Dec. 16, 1905, to a communication addressed to her physician, Dr. E. B. Fenby of Baltimore, we learn that it has not yet been necessary to open the sigmoid, and also that the patient is in the best of health, teaching school, and on examination it was found that the lump, previously felt in the pelvis, has disappeared.

The effect of mesenteritis arising from diverticulitis is well shown in the first case here reported, where the puckering, thickening and folding of the mesentery had given rise to an angular bending of the intestine, and one can well see how such a condition could be the axis about which a volvulus might be formed. Our case, then, supports the views of Brehm[12] as to the possible relation between diverticulitis, mesenteritis and volvulus.

THE TREATMENT OF ACQUIRED DIVERTICULA OF THE LARGE INTESTINE.

It is evident that these diverticula are much more likely to undergo secondary pathologic changes and hence to give rise to clinical symptoms than similar ones of the small intestine, and for this reason they more often demand surgical interference. On the other hand it is apparently the exception rather than the rule for these diverticula to cause serious trouble. We do not know how important a rôle they play in the cause of minor ailments. A very interesting clinical feature is the mistake made in their diagnosis and especially their being taken for cancer of the large intestine. In cases demanding operative interference the treatment should vary with the condition found.

On the other hand, when found accidentally these diverticula should be removed, unless too numerous, and if this can be done without interfering with the nourishment of the intestines. This is especially true of those arising from the free surface of the intestines, as they are more easily removed and also more likely to cause trouble than those developing into the mesentery.

CONCLUSIONS.

Acquired diverticula of the small intestine occur much more frequently than the autopsy records show, and undoubtedly have often caused minor symptoms and even occasionally endangered life, and the true cause of the trouble has not been recognized. These diverticula are usually multiple and long areas of the intestine may be involved, even the entire length of the small intestine. They consist of hernial protrusions of the mucosa and submucosa through a weakened place in the intestinal wall, and they usually escape alongside of the blood vessels penetrating the intestinal wall at the mesenteric border, and thus push between the two folds of the mesentery. Their usual situation, between the folds of the mesentery, renders them less likely to undergo pathologic changes than diverticula hanging free in the peritoneal cavity or attached to the abdominal wall. Also the fluid contents of the small intestine render

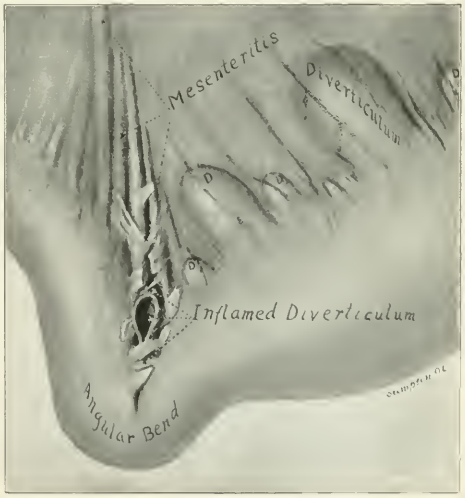

Fig. 3.—Diverticulitis causing local peritonitis and mesenteritis with a resulting angular bend in the intestine causing obstruction (natural size.) The loop of the small intestine, adherent to the mesocolon, has been freed, and in doing so the distal portion of the inflamed diverticulum has been ruptured. The base of the inflamed diverticulum has been occluded, so that the distal portion appears like a small infected mesenteric cyst situated near the border of the intestine.

12. Brehm: "Ueber die Meseuterialschrumpfung in ihre Beziehung z. Volvulus der Flexura sigmoidea," Archiv. f. klin. Chir., 1903, vol. lxx, pp. 267 to 301.

them less of a menace to the individual than similar diverticula of the large intestine. Should inflammatory changes arise, a mesenteritis is likely to occur with a resulting puckering of the mesentery and possible kinking of the bowel, as occurred in the case here reported. As these diverticula are usually multiple, thus involving a long area of the intestinal tract, and as they are usually intimately associated with the larger blood vessels of the intestines, they are ill adapted to safe operative procedures and apparently these have seldom been indicated. When secondary pathologic changes occur, thus endangering the welfare of the individual, operative treatment may be indicated, and this must vary with the demands of each case.

The acquired diverticula of the large intestine may arise from any portion of its circumference and have been most frequently found in the sigmoid flexure. They have been more frequently observed than similar ones of the small intestine, and several cases have been reported in which they have given rise to serious trouble. They are usually multiple and consist of hernial protrusions of the mucosa and submucosa through a weakened spot in the intestinal wall. As the contents of the large intestine are harder than those of the small, and as these diverticula occur more frequently on the free border of the intestine than do those of the small, they are more apt to undergo secondary pathologic changes and to endanger the welfare of the individual. Of great clinical interest is the difficulty in diagnosing the structures and inflammatory tumors which may result, from cancer, and also that intestinal diverticula are a frequent source of vesicointestinal fistula.

We again emphasize the fact that acquired diverticula of both the small and large intestine undoubtedly occur more frequently and also more frequently give rise to clinical symptoms than the reported cases and autopsy records indicate, and for this reason we would especially urge that this condition be borne in mind, both by pathologists and clinicians, in order that the medical profession may learn the frequency of their occurrence and also the part played by them as a cause of both minor and more serious abdominal disturbances.[13]

SOME ANATOMIC AND PHYSIOLOGIC CONSIDERATIONS OF THE FAUCIAL TONSIL.*

J. GORDON WILSON, M.A., M.B. (Edin.)
Hull Anatomic Laboratory, University of Chicago.
CHICAGO.

INTRODUCTION.

In the true pharynx—that is, posterior to the tongue—there exists a more or less continuous ring of lymph follicles with their accompanying lymphatic vessels, differing in macroscopic but similar in microscopic appearance, generally called Waldeyer's ring. Beginning in the posterior pharyngeal wall as the pharyngeal tonsil, this ring passes to the follicular tissue in the pharyngeal recess, Rosenmüller's fossa, thence around the pharyngeal orifice of the Eustachian tube to the soft palate, and along the posterior pillar of the fauces to the palatine tonsil, which is connected with its fellow by the mass of follicular tissue at the base of the tongue, the so-called lingual tonsil. From this ring, lymphatic prolongations of varying extent pass off into the nasal fossæ, to the epiglottis and to the larynx.

This ring exists as:

1. More or less irregular masses—as in the soft palate.

2. Continuous layers at the base of tongue and round the tube comparable to Peyer's patches.

3. Circumscribed masses possessing a fibrous connective tissue boundary and forming a more or less distinct unit. These form on the pharyngeal wall the pharyngeal tonsil, and between the pillars of the fauces, the palatine or faucial tonsil. They are analogous in many respects to the lymphatic glands, but differ in having crypts or furrows which communicate with the buccal cavity.

It is to the last of these, the palatine tonsils, that attention is here directed; and it is to the palatine tonsils I refer when speaking generally of the tonsils.

In this section of the paper I limit myself to a brief discussion of some points bearing on the surgical anatomy of the tonsil.

THE NORMAL SIZE AND DEVELOPMENT OF THE TONSILS.

The normal size of the palatine tonsil is hard to determine, since few have escaped some irritation and inflammation. The following measurements appear to me to be as nearly accurate as any: Length, 20 mm. (Luschka); breadth, 12 to 15 mm. (Sappey); thickness, 13 mm. (Luschka).

Of the follicular masses forming Waldeyer's ring, the pharyngeal tonsil is the first to develop; it is well marked at birth and reaches maturity at the end of the first or second year. It retains this mature state till the twelfth year, when it begins to retrograde.[1] The activity of the palatine tonsil has been demonstrated at the end of fetal life not only

by the multiplication of lymphocytes in the follicles, but by the infiltration of leucocytes into the overlying epithelium.[2] It is well developed at the end of the first year, but apparently does not reach maturity till the fifth year. The lingual and tubal lymph follicles are slower in reaching maturity and can only be said to be definitely developed about the twelfth year. All these dates, however, are very variable, depending on individual peculiarities.

The Capsule of the Tonsil.—The tonsil is enclosed in a capsule of connective tissue which, according to Zuckerkand, is normally 1 mm. thick.[3] From the capsule bands go off between the lymph follicles in which lie the blood vessels and lymphatics. The capsule is covered externally by the superior constrictor muscle and by the attachments of the anterior and posterior pillars of the fauces containing the M. glosso-palatinus and M. pharyngo-palatinus.

What is the effect of hypertrophy of the tonsil on the capsule? In hypertrophy either or both of the pillars may become more closely related to the capsule and the follicular tissue in the pillars may blend with the corresponding tissue of the tonsil. Labbé[4] showed that in children and young adults there is in hypertrophy no real thickening of the connective tissue and that the proportion of connective tissue is relatively not greater than normal. This has received ample corroboration. In the enlarged tonsils I have examined, this appears to be the case. It is especially to be noted in tonsils which are removed along with their capsule immediately after the sudden death of a healthy adult. In such cases one can note how the crypts and follicular tissue encroach on the connective tissue capsule (Fig. 1).

The Blood Supply.—The blood supply to the tonsils is given differently in English anatomic texts. Thus Gray[5] gives "the dorsalis linguæ from the lingual artery, ascending palatine and tonsillar from the facial, the ascending pharyngeal from the external carotid, and the descending palatine from the internal maxillary, and a twig from the small meningeal." While this description may apply to such animals as the dog, in which certainly the main supply comes from the lingual, it does not accord with what we usually find in man. My observations lead me to believe that the main blood supply in man comes from the facial, either through a distinct tonsillar artery or more commonly from the tonsillar branch of the ascending palatine branch of the facial. The dorsalis linguæ gives one or two branches which pass into the lingual side of the sinus tonsillaris, but its distribution is chiefly to the pillars of the fauces and to the plica triangularis and any follicular tissue which may be there. A branch of the descending palatine lies in the soft palate in the region of the supra tonsillar fossa. I have observed a few cases in which

it was relatively large and lay on the floor of the fossa, being distributed to the follicular tissue which at times appears in considerable amount.

The branch from the facial comes off near the origin of this artery from the external carotid. It passes under the mandible and internal pterygoid muscle and over or under the styloglossus into the loose fatty tissue of the pterygo-pharyngeal space. At or near the middle of the tonsil the arterial supply, usually a single branch, passes to the buccopharyngeal fascia, which covers the superior constrictor externally and there divides into two branches, a superior and an inferior.[6] These two trunks pass through the superior constrictor muscle and divide on the capsule of the tonsil into numerous branches which pass into the gland along the interfollicular connective tissue septa (Fig. 2).

The pterygo-pharyngeal space appears to me to play an extremely important part in the surgical anatomy of the tonsil. It is of irregular conical form—more or less triangular in cross section. It contains a varying amount of loose fatty areolar tissue in which lie the ascending palatine and tonsillar arteries. It is bounded externally by the internal pterygoid muscle, internally by the pharyngeal wall, posteriorly it communicates with the fatty tissue of the pharyngeal maxillary space adjacent to the postero-lateral angle of the pharynx, in which lie the internal carotid artery, the external carotid artery, the internal jugular vein, with its branches, numerous nerves, and the styloid muscles (Fig. 3). The tonsil rests in the medial side and is, therefore, separated by the fascia and fat in this space from the pterygoid muscle and mandible against which it may be pressed.

It is by no means an uncommon opinion that in operations on the tonsil it is relatively easy to injure the internal carotid artery. This artery at the level of the tonsil lies some distance lateral to the inner angle of the pharynx, about 1.5 cm. from the tonsil, and separated from it by the superior constrictor muscle, by the stylo-pharyngeus muscle and to some extent by the styloglossus muscle. With a space of 1.5 cm. filled with semi-fluid fat and loose connective tissue, it will be apparent that in tonsillectomy the chance of injury to this vessel is very small. Moreover, the ease with which the tonsil can be pulled forward on account of the presence of this loose areolar tissue, leaving the internal carotid *in statu quo*, reduces the danger of injury to a minimum.

The external carotid is usually 2 cm. to the side and posterior to the tonsil. In this position, shielded by the styloid muscles, it is little liable to injury. Occasionally it curves medially, approaching to or entering the pterygo-pharyngeal space, and there giving off the tonsillar artery; but this variation is extremely rare.

There is no disease of the tonsil so common and none which gives the ordinary practitioner so much concern in regard to treatment as the so-called tonsillar abscess. The anatomic relations of the area in which this usually occurs are very definite. From the upper part of the sinus tonsillaris, a supratonsillar fossa (*Recessus palatinus* of Killian) passes into the soft palate, curving superiorly and anteriorly. The upper part of this fossa often appears as a narrow recess whose extremity may lie from 8 to 10 mm., in rare cases from 12 to 15 mm., from the edge of the fossa. The apex of this recess, when of medium size, may be indicated by a point in the soft palate above and slightly anterior to the anterior pillar (Fig. 4). Postmortem examination shows the floor of the recess to be occasionally irregular with bands and constrictions.

In probably 90 per cent. of the cases of tonsillar abscess it is in this locality that the pus forms—in short, it is a supratonsillar or peritonsillar abscess. It is apparent from Figure 4 that it is by no means difficult, even though the tissues are swollen, to locate the usual site of pus formation. The deeper relations of the supratonsillar fossa are seen in Figure 5. From this it is obvious that injury to the internal or external carotid artery by judicious use of a knife in opening this form of abscess is impossible.

This brief account will explain why at times an easy way to evacuate the abscess is by means of a curved probe passed into the supratonsillar fossa.

To what is due the hemorrhage which occurs at times in tonsil operations? Considering the anatomic side of this question, a common cause is injury to the ascending palatine artery. The artery may be of very considerable size and often is in close relation to the bucco-pharyngeal fascia in the tonsillar region of the pterygo-pharyngeal space. Treves[7] quotes a fatal accidental perforation of the ascending pharyngeal artery. Such accidents in tonsillectomy could not result unless the superior constrictor had been cut through. The danger of such an accident is diminished by pulling the tonsil inward.

In operations involving, as they so often do, the anterior and posterior pillars and the plica triangularis, the branches of the lingual artery distributed there may give considerable hemorrhage.

A hemorrhage may occur from injury to a branch of the superior palatine artery. This artery, however, is not likely to be cut in opening a supratonsillar abscess because of its relation to the deeper wall of the abscess cavity.

Another though very rare source of hemorrhage is an abnormal relation of external carotid to the pterygo-pharyngeal space.

Hemorrhage from the tonsillar artery is, of course, the most common cause. In ordinary tonsillectomy the risk of severe hemorrhage is slight, since, as a rule, the vessels contract satisfactorily. In enucleation, however, especially with injury to the superior constrictor muscle, the main tonsillar artery or one of its two primary branches, might easily be cut and give troublesome hemorrhage. A severe hemorrhage from this source is not likely to occur in the most common form of tonsillar abscess.

Hodenpyl[8] has offered this explanation of tonsillar hemorrhages. As the branches of the tonsillar artery penetrate the tonsil they are surrounded by a fibrous sheath from the capsule; this sheath, when the tonsil is cut, contracts and hinders the artery collapsing. Anatomically, this explanation does not appear to me convincing, and I doubt if surgical experience permits us to consider it adequate.

ARE THE TONSILS A PHYLOGENETIC RESIDUE?

Before beginning consideration of the physiology of this organ, one may well consider whether we have here an organ of primary importance or one which may have had some definite purpose in the past history of the race, but which now exists as a phylogenetic residue.

Reasoning from residual organs generally, one may

6. It is interesting to note how the blood supply corresponds to the development of the tonsil in two parts.

7. Treves: "Surgical Anatomy," 1881, p. 117.

8. Hodenpyl: "Faucial Tonsils." Amer. Jour. Med. Sciences, 1891, p. 265.

affirm that were the tonsil a residual organ, we should find some of the lower animals in which it is better developed and more differentiated than in man, with a function not to be gainsaid. We should expect to find an ontogenetic history with early appearance in fetal life, rapid maturity and retrogression. What we do find is that in mammals of all the lymph nodes of the throat the tonsils are the most constant and most differentiated. According to Packard,[9] they appear in the crocodile as pharyngeal folds. It is generally agreed, however, that it is in mammals that one can definitely recognize them as distinct and particular organs.

The tonsil develops in a depression, the sinus tonsillaris, formed in the second branchial cleft. The mode of development varies in different species. Hammar,[10] to whom we are indebted for the most recent and most careful account, distinguishes two varieties:

1. A primary form, seen in such rodents as the rabbit, and in such carnivora as the dog and cat, where a tubercle appears at the oral side of the sinus and both in the sinus and round this tubercle the follicular tissue develops.

2. A secondary form, seen in pig, sheep, cow and in man, in which epithelial processes grow down into the sinus tonsillaris, round which lymph follicles form. The tubercle appears, but atrophies very early, and takes no part in the subsequent development. In its simplest form this is seen in the pig. What must be regarded as a more complex development is apparent in man, the cow and sheep, marked by an intratonsillar fold of tissue which divides the sinus into two recesses.

In man, the tonsillar anlage appears during the third month of fetal life. The remains of the tubercle persist as the plica triangularis. From the two recesses into which the sinus tonsillaris is divided by the intratonsillar fold there grow down epithelial buds which open out and form crypts. In the mesenchyme around the buds adenoid tissue develops and lymphocytes accumulate to form the tonsillar follicles. In short, the human tonsil develops in two parts, which afterward coalesce, and are usually indistinguishable as separate parts.

So far these researches show that there are certain groups of mammals in which the tonsils have reached an advanced stage of development—perhaps in no group as high as in man. From this it would appear that there is in the phylogenetic history not the least support for the hypothesis that in the tonsil we have a vestigeal organ. It is true that they reach maturity early, but in this respect they agree with lymph glands generally, which are more active physiologically in early life.

One might well hope that a comparative study would throw some light on their function. It would appear that in rodents, carnivora and insectivora the tonsils show the simplest type. In this connection it is interesting to note that in some rodents, e. g., rat, mouse and guinea-pig, there is no tonsil, and that no trace of an embryonic anlage has been noted. In ruminants and in man the tonsils are more complex. But from the meager supply of facts on their comparative anatomy it is impossible to divine their function.

THE SECRETION OF THE TONSIL.

In studying the secretion from the tonsil, the first fact that presents itself is that we have here a definite organ actively engaged in the production of lymphocytes. The germ centers of the follicles contain many cells undergoing mitotic division. From these follicles the lymphocytes may pass in one of two ways: 1. Directly into the lymphatic system. 2. Though the mucous membrane into the mouth, either directly or indirectly through the crypts, from which they are expressed during the act of swallowing.

In regard to the first of these, we need only say that, so far as our present knowledge goes, they do not appear to differ in any way from those secreted by other follicular glands; further, that the large and numerous efferent lymphatics point to the large outflow of lymph.

In regard to the secretion into the mouth, a great amount of discussion has taken place. The large majority of cells which pass normally out are lymphocytes, and these form the so-called salivary corpuscles. Commingling with these there are a varying number of polymorphonuclear leucocytes from the blood.

When one examines a little mucus from the surface of the tonsil of any one in good health and with no apparent inflammatory condition of the fauces, there are always found, in addition to the surface epithelium and innumerable micro-organisms, numerous lymphocytes and many polymorphonuclear leucocytes—some of which latter contain bacteria.

It has been asked whether this secretion is a physiologic or a pathologic process. It appears to me that we must regard it as physiologic, though one recognizes that here the line between a physiologic and a pathologic function is hard to define. One is led to this conclusion from its occurrences at all ages; even in embryonic life Stöhr[2] found lymphocytes in tonsillar epithelium. Further, this emigration is a phenomenon common to follicular tissue in all parts of the body.

This fact brings us no nearer to the reason for its occurrence. Hagenschmidt, however, showed that saliva, which contains bacterial products and enzymes, is capable of exciting in leucocytes a positive chemiotactic activity. Metchnikoff[11] believes that this afflux of leucocytes must be regarded as important for the protection of the buccal cavity, and suggests that it is probably due to this attraction of leucocytes and their phagocytic property that lesions of the mouth heal so quickly. He also recognizes the important rôle played by the epithelium of the buccal cavity and the effect of the growth of non-pathogenic organisms on the development of pathogenic. It must be acknowledged that this account of the phagocytic action of the excretion is not altogether satisfactory, because we find a relatively small number of leucocytes containing bacteria. Not only may the living leucocytes play an important part, but the leucocytes, after they have undergone dissolution, may set free a varying amount of cytases which they contain, and communicate bactericidal properties to the saliva.[11]

While one acknowledges the probability that the leucocytes from the tonsil—living or dead—may exert bactericidal properties, at the same time one can not but remember that in the mouth so many processes are still unknown[12] that it may well be the additional function of these lymphocytes to assist in one or other of these processes. Further, there is the possibility that the lymphocytes have already in the tonsil fulfilled partly their physiologic function and that their extravasation may be more of the nature of an excretion than a se-

12. For example, the purpose of sulphocyanid in parotid secretion.

cretion—an hypothesis quite in keeping with the anatomic appearance of their passage through the tonsillar epithelium.

Under all these considerations, however, the general belief seems to be that in the tonsil we have a definite organ, part of a ring of follicular tissue which surrounds the upper part of the alimentary canal at a point which, from its location and structure, is very open to disturbance and infection, whose physiologic function is connected with active processes at the beginning of the alimentary tract. One function may be to act as a defensive barrier against micro-organisms and, it may be, against other injurious bodies; and in these processes the lymphocytes and leucocytes may exert no unimportant part.

A question which appears to me to have received too little consideration is this: What effect have diseases which demand increased leucocytosis within the body on tonsillar exudation into the mouth and what is the relation of this to the disturbances of buccal and gastric activity which occur in these diseases?

It is well for us at all times to consider the physiologic aspect of problems which present themselves to us, even though we can not give a complete and satisfactory explanation. We are too apt so to magnify the pathologic importance as to diminish the physiologic consideration. It is well to give the tonsil some thought, not as a frequent seat of inflammatory trouble, and therefore a constant source of danger and a menace to the individual, but as part of a group of active glands placed in an area susceptible to disease. Such a view does not preclude the possible necessity for the removal of a tonsil should it be diseased. If this gland become the center of recurring inflammatory attacks, if its mucous covering is obviously a nidus for micro-organisms, if its size is hurtful to the development of the individual, if, in short, it is obviously no longer physiologic but pathologic, as a pathologic structure it requires appropriate treatment.

A CONSIDERATION OF PRURIGO, PRURITUS, AND SOME COMMON ITCHING DERMATOSES.*

OLIVER S. ORMSBY, M.D.
CHICAGO.

The object of this paper is to consider the points of interest in some of the commoner diseases of the skin, which are accompanied by the sensation of itching, with special reference to their differential diagnosis.

Prurigo is a rare disease, and the only reason for including it here is properly to place it and practically eliminate it. A disease productive of itching of varying intensity is one which sooner or later compels its host to seek for relief. Patients may carry for years without complaint cutaneous eruptions of different kinds that are not productive of physical discomfort, especially when these manifestations are hidden beneath the clothing; but when the peace of mind is disturbed by constant or intermittent suffering incident to the subjective symptom, itching, the physician is sought in the hope of relief.

* Read before the Aux Plaines Branch of the Chicago Medical Society, March 23, 1906.

* In the preparation of this article the following text-books have been consulted, in addition to special articles, for which due credit is given in the text: Hebra, Kaposi, Hyde and Montgomery, Stelwagon, Crocker, Osler; Morrow's "System of Dermatology"; Allbutt's "System of Medicine."

TERMS DEFINED.

The terms prurigo, pruritus and itching have been used so often interchangeably that they would seem synonymous.

Prurigo is now restricted to designate a disease first described by the master dermatologist, Hebra; pruritus, pruritus essentialis (Bronson), or pruritus cutaneus, to designate a disease which is a sensory neurosis. Itching is a prominent feature of the former disease and the only essential symptom of the latter. It occurs as a prominent symptom also in many cutaneous affections, but in all of these is secondary to cutaneous lesions. Among other such diseases are scabies, pediculosis, eczema, urticaria, etc. It is not to the lesional itching diseases, such as eczema, urticaria, etc., that reference is to be made, for usually these are easily recognized. Scabies, however, will be considered, for evident reasons, later.

PRURIGO.

Prurigo is a chronic and usually incurable disease. It is rare in America, but is common in Austria, and in varying degree in Germany and England. It begins, as a rule, in infancy, but at times has been noted to begin from the fifteenth to the thirty-fifth year of life. Though, as a rule, it remains throughout life, some patients have recovered, and the disease may be modified by treatment. It is always accompanied by intense itching. The earliest lesions are urticarial, after which the classical lesion appears, which is a colorless or slightly reddened papule. In time the skin becomes harsh, dry, thickened, excoriated, crust-covered and pigmented. Pustules and superficial ulcerations occur. At a glance one sees that the major part of these lesions are due to the scratching. The sites of predilection are the extensor surfaces of the limbs, and to a less degree the abdomen, buttocks, chest, and occasionally the face. Inguinal and axillary adenopathy occurs. The former glands often become very large. The prurigo mitis of Willan presents the same, but a less intense, picture.

The essential cause is unknown, but it is commonly classed as a neurosis. Poverty and insanitary conditions predispose, and the male sex is more often attacked. Although examples of this disease are occasionally seen here, it is so rare that a more detailed description is not necessary, this much being given merely for its identification.

PRURITUS.

In cutaneous medicine to-day, pruritus signifies a disease, not a symptom. It is a sensory neurosis, in which itching is the sole essential symptom. Other symptoms are usually present, however, and are evidenced locally by the torn and injured skin, and systemically by varying degrees of malnutrition and lowering of the vitality of the patient through loss of rest. It is usual to classify pruritus into two varieties, general and local, and with propriety a seasonal variety, pruritus hiemalis, could be added.

General Pruritus Essentialis.—General pruritus occurs usually in adults, a common example being the so-called senile pruritus. Although all parts of the cutaneous surface are liable to be attacked, it rarely attacks the whole area simultaneously, but moves about from place to place. The itching may be intense; is worse at night, but occurs more or less throughout the day, the morning hours being the least uncomfortable. The intensity of discomfort is sometimes relieved only by producing sufficient trauma to bring blood, and thus change the sensation to one of burning and smarting. The paroxysms are of varying duration, and, while early in

the disorder no objective symptoms are present, all those belonging to traumatic dermatitis may be added later. Many of these patients restrain themselves and avoid scratching while awake, but during sleep inflict serious damage on their skins.

Local Pruritus Essentialis.—In local pruritus the areas attacked are the anal, vulvar and scrotal regions, and occasionally the palms, face and scalp. Pruritus vulvæ may affect the labia, vagina and clitoris. The whole area or any part of it may be involved. The disorder may extend over the perineum and surround the anal region. In men the scrotal or anal region, alone or in combination with the perineum, may be attacked. The skin about the anus presents a whitish, sodden appearance, with increase in depth of the folds, in which there collects a foul-smelling secretion. The scrotum also becomes thickened and soggy, and may even become vitiliginous. Frequently the intensity of the itching in these cases can not be described. Naturally, after a time, local inflammatory symptoms develop, due to the scratching and rubbing, which for a time might render the diagnosis difficult as to whether the case was originally a pruritus or an eczema. The methods of obtaining relief employed by some of these victims of the intense suffering testify strongly to its severity. In women the intense itching is irresistible, and the effect produced by the rubbing is detrimental not only physically, but morally. Not once or twice, but several times patients have come under observation whose suffering for years with such a pruritus have driven them to contemplate self-destruction to end the torture.

The palmar cases of local pruritus are rare, and when present, for anatomic reasons, are not accompanied by marked secondary lesions. The scalp and face cases are not common, but are seen occasionally. Recently two cases occurred in the practice of Drs. Hyde and Montgomery in which a local pruritus, limited to the nose, cheeks and chin, had existed for several years. In each case moderate traumatic dermatitis accompanied the disorder. At times one small area may be noted over the course of a special nerve. Crocker reported one such case, limited to the course of the sciatic nerve. With one of the members of this society, I saw such a case, in which the pruritus occurred in a narrow band, which extended from the vulva along the entire length of the leg, terminating at the heel.

Etiology.—In every case of pruritus a probable cause must be diligently sought. While pruritus cutaneous is dignified by a name and described as a disease *per se*, it is essentially merely a symptom of some disturbance, local or more or less general, of the nervous system; and this disturbance is further secondary to many and varied internal and local organic and functional diseases, and even to increased or decreased physiologic activity, exhibited in pregnancy and the menopause, and finally to abnormal mental states. Bronson[1] states that hyperesthesia is the chief predisposing cause in all cases. This hyperesthesia may be acquired by long-continued irritation of the cutaneous nerves in various itching dermatoses, such as eczema, lichen planus, scabies, etc., or it may be inherited.

In casting about for light on the cause of a general or local pruritus, one must make an extensive examination of the patient. Functional or organic disease of the stomach, intestines (including the rectum), liver, kidneys, bladder, urethra, uterus, ovaries, etc., may be causative. The intense itching accompanying jaundice is well known to all practitioners of medicine. This often appears only when the icterus is subsiding. An unaccountable pruritus may be the earliest symptom of an internal carcinoma. Gastric carcinoma has been known to produce intense general pruritus. Pregnancy is often accompanied by local or more or less generalized pruritus. At the menopause in women, when the organs of reproduction are undergoing organic changes, pruritus occurs; and may be due to reflex local irritation or to the changes incident to the general effect these changes produce on the nervous system as a whole. Among the more common general diseases concerned in the production of pruritus are tuberculosis, malaria, various forms of nephritis, diabetes, mellitis, gout, etc.

Common among local causes of pruritus is constipation. The hard fecal matter lying in the rectum sets up a reflex irritation, as do also varicose veins and ascarides in this locality. Fistulæ, fissures and local hyperidrosis are causative. In the genito-urinary tract, vesical calculi, polypi and stricture may be effective.

Reflexly, general pruritus may be caused by a local pruritus. For example, severe generalized cases have occurred in people the subjects of an anal pruritus, the whole disorder clearing up by treating simply the local disease.

At times, psychic disturbances produce pruritus. This may be seen when a class of medical students or nurses are suddenly attacked by real pruritus when viewing a patient covered with pediculi. Another example of this form occurs in patients who believe themselves to be infected with certain parasites. These patients will declare that they not only feel the parasites, but see them emerging from the skin, and are able to catch quantities of them. The pruritus in these cases is often severe.

The degenerative changes occurring in the skin of the aged are a cause of senile pruritus, but other factors are also active here, such as deficient excretion, and various changes in the internal organs incident to age. Neurotic cases of pruritus occur in such diseases as hysteria and hypochondriasis.

Pruritus Hiemalis (Duhring).—This form of cutaneous pruritus might be classed as a seasonal variety, as it occurs only during the cold weather. It is properly classed with the neuroses. Special stress is laid on it here, because in this climate it is a fairly common affection and is not generally credited with the importance its frequent occurrence demands, and because of its likelihood to be mistaken for other itching diseases, especially scabies and other equally distinct diseases with demonstrable etiologic factors. It was first described by Duhring[2] in 1874, and has since been studied and carefully reported by many competent observers, such as Hutchinson,[3] Hyde,[4] Corlett,[5] and others. The disorder occurs in the autumn and winter, but clears up with the approach of warm weather. The chief symptom is itching, which is worse usually on retiring to bed. The skin in these cases is usually harsh and dry, and after a time presents lesions, induced by the rubbing and scratching to which it is subjected; namely, excoriations, broken stumps of hair, blood crusts, and enlarged follicles. It is due to changes incident to the cold weather, and is often aggravated by the coarse

5. Corlett: Jour. of Cut. Dis., 1891, p. 41.

woolens worn at this season, though it occurs also in those whose personal habits as to clothing and cleanliness leave nothing to be desired. At times, several members of a family are attacked simultaneously or successively, which fact has led often to the erroneous belief that it is contagious. The lesions are commonly situated on the antero-internal aspect of the thighs, around the joints and to a lesser degree on the forearms and other parts of the body, such as the waist and other parts where pressure is exerted by the clothing.

Etiology: From a study of his cases with a review of others, Corlett[5] concludes that (1) the state of the general health plays no appreciable part in the production of the disease; that (2) though irritation of rough clothing aggravates the disease, it is not, *per se,* capable of producing it; (3) that meteorologic conditions are most important, the most potent combination being low temperature, low humidity, and a northwest wind, increased velocity meaning increased symptoms. This combination inducing evaporation and the low temperature reducing glandular activity to a minimum, the result is a harsh skin and irritation of the peripheral nerves, inducing the disease; (4) that it may be associated with other cutaneous neuroses.

Bath pruritus, described by Stelwagon, occurs in some people immediately following a bath. The sensations are itching or burning of varying intensity. It is usually located on the lower part of the body, from the hips down, but occasionally involves the arms also. It lasts from a few moments to an hour or so, then gradually subsides. It attacks adult males more frequently, and those who habitually have an irritable, dry skin. The temperature of the water appears to have little to do with the cases, as any temperature produces the same results.

SCABIES.

Owing to the markedly increased prevalence of scabies in this region during the past two years, it seems justifiable to lay some stress on this disorder as now seen.

In March, 1905, Dr. Hyde[6] published the observations of himself and associates on this subject, in which he demonstrated this increase. He attributes it to two main factors: first, that during the preceding year the immigration to this country from countries abundantly supplied with scabies exceeded that of past years: and, secondly, to the massing together of large numbers of people in the west, due to the exposition at St. Louis. The increase is noticeable in private as well as public practice. It is not at all common for whole families to appear at the public clinics affected with the disorder. In the public clinic of the Chicago Clinical School, scabies represented 10 per cent. of the total cases treated in 1903, 11 per cent. in 1904, and 16 per cent. in 1905; a fact which demonstrated the marked increase here. In private practice, the ratio of increase is as great or greater.

In December, 1904, Dr. E. Wood Ruggles[7] called attention to this fact in a paper in which he calls the increase an epidemic of scabies in the United States. The classical cases that one sees in clinics and hospitals abroad are not evident here; and it is important to recognize the fact that the disease attacks people in the best stations of life, where anything bordering to filth is not to be thought of.

As Dr. Hyde pointed out, the lesions may be few, and very careful search must be made to identify the disorder positively. In place of an enormous number of typical lesions, vesicles, vesico-pustules, papules, furrows, crusts, excoriations, etc., in the usual places—on the hands, between the fingers, around the wrists, about the axillæ and breasts of women, the nates of children, and the penis and scrotum of men—only a few lesions can be found, half a dozen furrows, not well marked, a few vesicles and papules, and some staining, but still accompanied by the usual intense itching, especially on retiring. The fact must be recognized, however, that very many more moderately severe cases of scabies are now appearing than formerly.

Two or three important points, which have a bearing on diagnosis and treatment, have been impressed in this connection: First, a number of cases are seen in which marked irritability of the skin has been induced by over-treatment, which makes it appear that the disease, instead of yielding, is increasing in severity, a dermatitis of varying intensity being present, accompanied by itching and many lesions, all of which subside on the withdrawal of the energetic treatment and the institution of a mild one in its place. Secondly, in some cases a form of dermatitis of moderate degree, accompanied by vesicle formation and other lesions simulating scabies, will remain for some time after the original disease has been eradicated, this, too, usually in private cases; and if the patient is aware of the original diagnosis, he is tormented by the thought that he is still the host of the dreaded *Acarus scabiei.* This cutaneous irritability is due either to the long-continued irritation of the nerve endings by the original disease, or to the treatment pursued for its relief, or to both, and is productive of itching, often of severe grades. When the skin in these cases is scratched or rubbed, vesicles and other lesions are induced, which resemble scabies but are not identical, as no furrows can be found, nor can the essential cause, the *Acarus scabiei,* be demonstrated. The vesicles, too, differ, in that they are not located at one end of the furrow, as in scabies. These cases have yielded best to complete protective dressings in the weakened areas.

DIFFERENTIAL DIAGNOSIS.

Under this heading, it is not necessary to consider at all the itching diseases whose symptomatology aside from itching is characteristic. Eczema, lichen planus, urticaria, dermatitis herpetiformis, and the like, are all sufficiently characteristic and rarely cause any confusion with the groups considered in this paper; so also are the local varieties, such as pruritus vulvæ, etc. They are described here and treatment outlined on account of their more or less common occurrence and obstinate character, as well as to complete the description of the term pruritus.

For the past twenty years, including the present winter, perhaps the commonest question presented to the dermatologist for solution by the general practitioner has been one concerning the diagnosis of some seemingly epidemic itching disease, which did not correspond apparently to the usual descriptions given for diseases with which they are familiar. In 1885-86, Dr. Hyde published two articles on winter pruritus, in which many letters from practitioners of medicine were quoted showing the confusion and perplexity existing on this subject. Under the titles "prairie itch," "Texas mange," "Ohio scratches," "swamp itch," "lumberman's itch," etc., these disorders have been described, and one sees

6. Hyde: The Amer. Jour. of the Medical Sciences, March, 1905.
7. Ruggles, E. Wood: Buffalo Med. Jour., December, 1904.

that geographical distribution had to do with the naming. It is generally conceded by the men doing most work with these diseases that the bulk of the cases variously named, belong in one of three categories—pruritus essentialis, pruritus hiemalis, or scabies. So it is with these that we are concerned in differential diagnosis.

Itching is the prominent symptom of all, and in all the itching is worse at night, either during disrobing or shortly after retiring.

Scabies and pruritus hiemalis appear among comparatively large numbers of people at about the same time; and as several members of one family may be attacked, both diseases at first glance appear contagious. But on closer examination it may be demonstrated that in scabies a variable length of time elapses between exposure to the disease and its subsequent development. A child brings the disease from school; shortly afterward, the person with whom this child sleeps will develop the disease, and so on, until perhaps the whole family, including the parents, are successively attacked. When very close association exists in families, an almost simultaneous development may occur; but still the time factor is of value. On the other hand, pruritus hiemalis is apt to develop more nearly simultaneously, as its etiologic factor affects all at the same time. Differences in susceptibility must here be considered, but it is true that the ones susceptible are apt to be attacked at the same time.

Lesional Points.—If sufficiently careful search be made in scabies, the following points may be found and are of value in the order named: first, the *Acarus scabiei;* secondly, the coniculus or gallery; thirdly, the vesicle at one end of the furrow; all of which are absent in the majority of cases of the other two disorders; and after these all the lesions due to scratching, such as papules, pustules, crusts, excoriations, etc. In pruritus hiemalis, a harsh, dry skin, with reddened follicular papules and broken stumps of hair, is important. In pruritus essentials (general or local) only the lesions due to trauma are present.

Regional Points.—If the lesions are located on the hands, between the fingers, and on the penis, scabies is the only solution. Pruritus essentialis and pruritus hiemalis do not attack these regions. Scabies selects by choice, in addition the area about the wrists, the axillæ and breasts of women, and the buttocks in children. Pruritus hiemalis selects chiefly and most markedly the antero-internal surface of the thighs, the anterior surface of the legs, and, to a lesser degree, the arms, etc. Pruritus essentialis is variable as to regions, as it attacks first one and then another, moving about from area to area.

Scabies and pruritus essentialis may occur at any season; pruritus hiemalis only during cold weather. An epidemic in July could only be scabies; one in November might be either. In isolated or single cases, all elements must be considered—season, lesions, and regions of the body involved. The fact that pediculi, fleas, human bugs or bedbugs may induce severe itching should be borne in mind. The long linear excoriations about the shoulders and back and other points of pressure on the trunk, with the small puncta where the *Pediculus vestementorum* obtained his meal from his temporary host, are characteristic of pediculosis corporis. The itching about the pubic region, with the easily demonstrable *Pediculus pubis* and its ova on the hair, are sufficient for this variety; while the enlarged suboccipital glands, the pus-infected lesions in the occipital region of the scalp, and the *Pediculus capitis* and its ova here are sufficient to settle the question.

The human bug attacks the extremities earliest about the ankles, as these areas are nearest his abode, and later other parts of the body. The lesion produced in procuring his meal is apt to be hemorrhagic. The flea, in susceptible people, induces urticarial lesions, in the center of which a punctum is evident. These wheals may occur in lines, being produced as he passes and feeds along. All of these local causes of pruritus are not difficult of recognition, but should be borne in mind, especially in isolated or doubtful cases.

TREATMENT.

Under this heading I shall consider only the treatment positively proved of value in pruritus, deeming it unnecessary to consider that of prurigo and only mentioning that of scabies.

Scabies.—Sulphur stands at the head of the list of remedial agents in the treatment of scabies, but on account of its disagreeable odor when used in an ointment, and its liability to produce dermatitis its otherwise universal use is somewhat restricted. It may be employed in the following formula:

℞ Sulphuris sublimat. ..... ʒii-ʒi 8-30
Adipis benzoinat
Unguenti petrolat., āā ..... ʒiss 45

M. Ft. unguentum. To overcome the odor balsam of Peru may be added in the same quantity as the sulphur.

Karosi recommends the following, which is reliable and has no odor and is not so likely to irritate:

℞ Naphthol ..... ʒiv 15
Cretæ preparatæ ..... ʒiiss 10
Saponis mollis ..... ʒiss 45
Adipis ..... ʒiii 90

M. Ft. unguentum.

In any case the patient should begin the treatment with a warm bath of about thirty minutes' duration, during which the surface is thoroughly shampooed with either green, or castile soap. In this way the furrows are opened and allow the medicament to come in closer contact with the active cause. The ointment should be used daily for three or six days, which is usually sufficient to eradicate all activity of the disorder. Should a few areas escape they may be treated later with the ointment. It is necessary to sterilize the under garments and bed clothing by boiling and the outer clothing by baking to prevent reinfection of the patient. Sherwell[8] recommends using dry powdered sulphur, rubbed lightly over the surface after bathing, once in two or three days changing the under garments and bed linen each time, also having the sulphur sprinkled between the sheets. This method is of distinct value in many cases, is clean and requires one or two weeks to eradicate the disease. One or the other of these three simple formulæ will accomplish the result in all cases. The dermatitis arising from the sulphur in ointment form will soon clear up on suspension of the drug, and using in its place a simple dusting powder, such as the compound stearate of zinc.

Pruritus Essentialis.—The treatment of any case of pruritus is simple if the etiology is clear. In many cases this can not be absolutely determined, and then recourse to some of the general rules laid down must be resorted to. There are some general principles of treatment, both as to internal and local management, which are of great value, both in mitigating and completely relieving the disease. As a rule constitutional

8. Sherwell: Jour. Cutan. Dis., 1899, p. 494

treatment is unsatisfactory unless especially directed to some discoverable etiologic factor, such as diabetes, rheumatism, or the various other hepatic and renal diseases concerned in its production. Among other constitutional remedies should be mentioned cannabis Indica, gelsemium, pilocarpin, belladonna, quinin, the salicylates, (acetyl-salicylic acid) phenacetin, antipyrin, chloral, sulphonal, arsenic, and chlorid of calcium, as recommended by Savill.[9] Local remedial agents are very important, and if properly selected and applied are of great value. The best of these are carbolic acid in oil or lotion; thymol, or menthol, 1 to 4 per cent. in an ointment; resorcin, ½ to 2 per cent. in lotion; camphor in an ointment or dusting powder; chloral in an ointment or lotion and the tars; also hot water, electricity and radiotherapy. These local remedies may be used in the following combinations:

R.	Acidi carbol	3i-iii	3-12
	Aquæ calcis		
	Olei olivæ, āā	℥viii	240
Or:			
R.	Acidi carbol	℥ss-iss	2-6
	Pulv. amyl	℥ii	8
	Pulv. zinc. oxid	℥iii	12
	Aquæ calcis	℥iv	120
	Aquæ rosæ q. s. ad	℥xvi	480
Or:			
R.	Thymol vel menthol	gr. v-xxi	0.33-1.33
	Adipis lanæ		
	Unguenti petrolati, āā	℥ss	15
Or:			
R.	Resorcin	gr. xv-3i	1-5
	Glycerini	3iss	6
	Spts. vin. rect. q. s. ad	℥viii	240
Or:			
R.	Camphor or chlorali	℥ss-i	2-4
	Unguenti petrolat	℥i	30
Or, Anderson's dusting powder:			
R.	Pulv. camphor	℥iss	6
	Pulv. amyl	℥viii	32
	Pulv. zinc. oxid	℥iv	16
Or, Wilkinson's salve:			
R.	Olei rusci (birch tar)	℥ii	8
	Sulphuris sublimat	℥ii	8
	Cretæ preparatæ	gr. liii	3.5
	Saponis viridi		
	Adipis, āā	℥ss	15

In all cases, free elimination should be encouraged by salines and other laxatives, with abundant water drinking and perhaps other diuretics. Cotton, linen, or silk should be worn next to the skin. The diet should be simple and non-irritating, and, as a rule, tobacco and alcohol should be interdicted.

In the generalized variety known as senile pruritus, a large number of the measures may have to be resorted to, for the reason that these cases are often intractable and may be absolutely incurable. In a private communication Dr. F. H. Montgomery recommends in these cases general massage once or twice weekly with a bland oil or lanolin to promote general nutrition, the rubbing being done in the direction of the return venous flow. Other cases of generalized pruritus are amenable to treatment by making sufficient search for and removal of the cause, combined with the measures outlined above. The following case illustrates the necessity of careful search in these cases for an exciting cause:

The patient, a man aged 48 years, had been the subject of general pruritus for several months, and recently was so tormented with the intolerable itching that his general health was impaired and his nervous system was becoming wrecked. An examination of his urine, together with the several internal organs, revealed nothing abnormal. He had used various measures without relief. In his sleep, or when partially asleep, he would tear his skin until the blood would flow freely.

Radiotherapy was recommended, and during the treatment it was found that the patient had suffered with anal pruritus for several years. This was immediately given thorough attention, with the result that in two weeks this condition was relieved, and with it all the generalized pruritus without special treatment, the case evidently being a reflex sympathetic general pruritus caused by the local condition.

The importance of having means at our disposal to combat the local varieties of pruritus, especially anal and vulvar, can be attested by any one who has had charge of a severe case. They are often chronic, and have had almost every known antipruritic used, with only temporary relief; and the point here of greatest importance is the skill with which we use the means at our command. Many cases can be relieved completely by using thoroughly the same remedial agents that were used before and failed. Some of the very best of these agents become discredited because the patient either used them improperly or insufficiently. It is not sufficient to examine the patient and write a prescription for an ointment, and say: "Get it compounded and apply it twice daily." With such directions, the chances are that the ointment will be in apposition with the affected parts a few moments only, instead of hours, as intended.

An outline for the treatment of a case of anal pruritus, for example, might be as follows: The case is severe, with no discoverable general etiologic factor. Locally, there will be evidence of traumatic dermatitis. Before retiring at night the patient is instructed to bathe the part with hot oatmeal water, as hot as can be borne, for from fifteen to thirty minutes. The part is then dried thoroughly and the dressings are thoroughly saturated with a lotion containing equal parts of oleum olivæ and liquor calcis, to which 1 per cent. of carbolic acid has been added. These dressings are placed with care so as to cover the whole area, and are held in place over night with a T bandage. In the morning the parts are cleansed with more of the same oil, and then for the day a strip of surgeon's absorbent cotton, thoroughly covered with dusting powder, such as stearate of zinc, is inserted between the nates. This may be applied fresh, if for any reason it becomes displaced. This procedure is intended to keep the skin surfaces apart. After a few days of this treatment, an ointment containing a small amount of tar may be substituted for the oil at night, continuing the powder during the daytime. A convenient and safe procedure is to give the patient two ointments—one, such as Wilkinson's salve, containing tar, the other a comparatively neutral one—instructing him to mix one part of the tarry, one with ten parts of the other the first night and apply it on a linen cloth, being sure to have the ointment cover the affected area thoroughly, and keeping it in place with the T bandage as before. Each evening more of the tar may be added until the desired result is accomplished. The patient is cautioned that, should irritation from the ointment arise, he is to reduce the amount of tar or suspend it entirely for a time. After a time, all evidence of the disease having disappeared, active treatment may be suspended; but strict cleanliness, with use of the powder, should be kept up for a long period. The remedial agents of especial value in anal pruritus are carbolic acid, menthol, hot water, the tars, and at times cocain, the latter with caution. Fissures about the

9. Savill, Thos. D.: "Pathology of Itching, and Its Treatment by Large Doses of Calcium Chloride, with Illustrative Cases," London Lancet, August, 1896.

anus may be penciled with silver nitrate or treated with bichlorid, or by means of the actual cautery.

Some surgeons believe most cases are due to fissure, and that these fissures may be well within the rectum, and hence require search for their location. It is true that they play a part in the production of this disorder, and should always either be excluded or eradicated. Fistulæ, hemorrhoids, etc., should be given their appropriate treatment, as should also the tags often seen in these cases, especially after various operations for hemorrhoids, etc. If after these various methods have been carefully used recurrences continue, radiotherapy will be of greatest value. During the past five years it has given me most happy results in cases that apparently resisted all other means of treatment.

In vulvar pruritus, the plan of treatment is similar to that outlined above. Here hot water, carbolic acid in ½ to 2 per cent. solutions, dilute hydrocyanic acid in 1 to 2 per cent. lotions, are of great value. The dressing must extend up a short distance into the vagina and be kept thoroughly in place by means of the T bandage. The cause of any leucorrhea must be sought and removed, as well as other etiologic factors. Bichlorid of mercury in solution is often of value also; and, finally, radiotherapy may be resorted to if necessary. Whichever method is employed, minute detailed instructions should be given and carried out. In severe cases, rest in bed for two weeks, with restricted diet and with the treatment detailed above, accomplishes more than can be done in a very much longer time with the patient up and about. Scrotal and perineal pruritus may be managed similarly to the above.

Treatment of Pruritus Hiemalis:—As these cases are due entirely to lowered temperature, it is essential to overcome the change, so far as possible, by appropriate clothing. Cotton should be worn next to the skin, but extra clothing can be worn over this. Corlett advises resorcin as a local application, and believes internal treatment is of no value. Menthol and carbolic acid are the two chief local antipruritics employed. Bronson advises bandaging the limbs and smearing them with a 5 per cent. salol superfatted soap. Warm weather is always curative.

THE TREATMENT OF LOBAR PNEUMONIA.

E. RUSSELL ZEMP, B.S., M.D.

Professor of Materia Medica and Therapeutics, Diseases of Children, and Clinical Medicine, Tennessee Medical College.

KNOXVILLE, TENN.

Pneumonia is a self-limited disease and runs its course uninfluenced in any way by medicine. It can neither be aborted nor cut short by any known means at our command. Even under the most unfavorable circumstances it will terminate abruptly and naturally without a dose of medicine having been administered. So also under the favoring circumstances of good nursing and careful diet the experience of many physicians in different lands has shown that pneumonia runs its course in a definite time, aborting sometimes spontaneously on the third or fifth day, or continuing until the tenth or twelfth. We have then no specific treatment for pneumonia. The practitioner may bear in mind that the patient is more often damaged than helped by the promiscuous drugging which is still only too prevalent. In cases of moderate severity a purely expectant plan may be followed—keeping the bowels open, regulating the diet and, if necessary, giving a Dover powder at night to procure sleep. In severer cases a symptomatic plan of treatment should be pursued, meeting the indications as they arise (Osler).

In spite of the above clear-cut statement by one of the greatest physicians of modern times many physicians continue to drug their patients in this disease to their detriment and this can be proven by glancing over the medical journals for the last few years. In them will be found almost every combination of drugs recommended as a specific for this trouble. This fact alone proves that we know of no drug that is curative of pneumonia.

While no drug is curative, strictly speaking, we possess the means of saving many patients who would certainly die if left alone to Nature. As Dr. Hare says: "In this disease the doctor should be a watchman all the time and only a therapeutist when necessity arises." Pneumonia is a condition which demands that the physician have a thorough knowledge of the possibilities of medication, but at the same time he must keep clearly in mind the pathology of the condition and the physiological actions of his remedies. A drug which apparently may be indicated on account of one of its actions, may produce a death blow by another effect. Here ignorance is criminal, for while cooling the fevered patient's brow it stabs him in the heart, or vasomotor system. The number of patients who die annually from too much drugging can never be estimated.

GENERAL MANAGEMENT.

A patient suffering from pneumonia should be put to bed and kept strictly in the recumbent posture until several days after the crisis. He should be clothed in a light flannel gown and the bed-pan should be used. Food should be administered in such a way that the patient will not have to sit up to take his nourishment. The sick room should be bright and airy, with plenty of sunshine and fresh air. It should be well ventilated. There will be no danger of the patient taking "cold," as the high temperature prevents this. The patient should be isolated, both to prevent infection of others and because he needs mental, as well as physical, rest. Baruch says: "Plenty of oxygen, in the way of fresh air, early in the disease will do away with the necessity of administering oxygen later." He also suggests administering about four ounces of cold water frequently. This has an excellent effect on the heart, kidneys, skin and nervous system.

As a routine procedure it is well to administer from 5 to 10 gr. calomel, to be followed by a saline if a good, large action of the bowels is not produced by the mercurial.

The diet should consist principally of milk, broths and egg-water, liquid-beef preparations being added to suit the case. As this disease is a depressing one, the diet should be of the most nutritious sort and easily digested. Over-feeding should be avoided as much as under-feeding, for a distended stomach, or bowel, may easily interfere with an already over-taxed heart. Good feeding, absolute rest during the waking hours, a proper amount of sleep, and keeping the bowels open, are generally the points on which success or failure depends. To summarize: Put the patient to bed in a well-lighted and well-ventilated room. Keep him at rest, both mentally and physically. Give plenty of cold water at brief stated intervals. Feed him light, but nutritious diet, and keep his bowels open. This is all the treatment that a large number of patients really need. Its simplicity should appeal to all who realize that pneumonia is a self-limited disease. Those who are in the habit of drugging their patients should try it. I am sure they will find that they have been attributing a power to certain drugs that these do not possess.

SYMPTOMATIC TREATMENT.

Probably the first symptom that attracts our therapeutic attention is pain. This is often sharp and severe. It is best relieved by a hypodermatic injection of morphin ⅛ gr. Frequently a brisk counterirritation applied over the seat of pain gives relief. Strapping the chest with adhesive plaster not only relieves pain but puts the part at rest. I have found that the local application of a mixture containing methyl, salicylate, iodin and camphor liniments, acts well and perhaps, has some good influence over the disease.[1] The prescription I use is as follows:

R. Iodini (crystals)	gr. viii	50
Methyl salicylatis	ʒss	15 00
Liniminti camphoræ, q. s.	ʒii	60 00

M. Sig.: Apply over chest three times daily. Cover with oiled silk.

I do not countenance the use of poultices. They can not possibly do any good except in relieving pain, and may do a great deal of harm.

Fever.—Unless the temperature rises above 104 F. it should be left severely alone. This rise is not only without danger, but is actually beneficial; it is Nature's effort to control the disease. There is nothing more pernicious than the constant attacking of a pneumonic temperature with coal-tar derivatives or arterial sedatives. Dr. Douglas Powell has demonstrated that pneumococci grow to perfection at the normal temperature of the body, but not at all at a temperature of 104. Besides, fever produces leucocytosis and, as is well known, cases without an increase in leucocytes are almost always fatal. So that the patient's general condition and not the temperature alone must be the guide in the use of antipyretic measures.

Some patients bear a much lower temperature than 104 very badly. In these cases antipyretic drugs should be used, if at all, for their effect on the nervous system alone. The application of cold is the best means of reducing temperature. Large ice-bags may be applied to the chest and head, or ice-cold compresses may be applied to the chest, as advocated by Baruch. In some cases, the sponge bath acts well, and some writers boldly declare that the temperature of pneumonia when excessive, should be treated by the cold tub bath. While this latter procedure may be satisfactory in hospital practice, it can not be generally recommended for various and obvious reasons. The occasional use of coal tar remedies in small doses, carefully guarded, is not objectionable. The fever of pneumonia, it must be emphasized, is not a symptom that demands treatment, unless it goes over 104 F., or unless the patient is showing a marked intolerance to a febrile rise. Under no circumstances, should an attempt be made to reduce the temperature to normal. Generally reduction of a degree or two is all that is necessary, and a host of practitioners are having forced on them the fact that hydrotherapy is the best and the safest way to reduce the fever of pneumonia when it demands attention.

Cardiac Failure.—The use of stimulants in pneumonia requires very careful attention. There are many patients who require no stimulation at all. The practice of giving every patient suffering from pneumonia whiskey, digitalis or strychnin, is a therapeutic outrage. There are times when these patients need stimulants, but the drug to be used and the time to use it should be selected with care. "If the pulse goes over 120, if the first sound becomes weak, if the pulmonary second sound loses its accentuation, or if marked nervous symptoms appear, then a stimulant is indicated." (Anders).

Alcohol is not only a stimulant but a food, as well. It increases the force of the heart by directly stimulating it (Wood), removes, to a certain extent, the peripheral resistance and hastens the movement of the blood current. In other words, it restores a disturbed equilibrium and overcomes passive congestions. There is evidence that seems to prove that alcohol increases the bacteriolytic power of the blood, so that, although a great deal of experimental evidence has arisen within the past few years proving that alcohol is not a stimulant to the circulation inasmuch as it does not raise arterial pressure, we use it in pneumonia because clinically it has been proved to be of great value when it is given at the proper time and in a proper manner. Dr. Wood says that when the odor of alcohol can be detected on the breath of the patient, too much is being given. In the general improvement of symptoms we have, however, a faithful index as to how much to give. On the other hand, if the patient becomes more nervous, the circulation more "irritable," the tongue and skin dry and parched and the entire picture becomes manifestly worse, it is certain that too much alcohol is being given. The human body is capable of consuming only a very limited amount of alcohol. In febrile conditions this amount is considerably increased. In amounts easily assimilated alcohol is a food and imparts force. If more than can be assimilated be given the food becomes a poison.

Ramberg and Santvoored have proved that the pneumococci paralyze the vasomotor centers, besides weakening the heart. Hence, much of the circulatory disturbance must be attributed to paralysis of the vasomotor system as well as to a weakened heart. All measures, therefore, which increase the work of the heart, or in any way interfere with its function should be carefully avoided. According to Dr. Powell, the heart dangers are three in number; impaired nerve power, impaired nutrition and mechanical dilatation. To overcome these, nothing is so satisfactory as digitalis. This drug stimulates the pneumogastric, slows the heart's action, strengthens its beat and tightens up the vasomotor system. Under its influence the heart empties itself more completely; is supplied with better blood and does its work in a quiet, steady manner. Digitalis should not be given until it is clearly indicated. A weak, fast, empty pulse calls for its administration, especially if irregularity in the heart's rhythm is present. It is best given in the form of a standardized fluid extract, two minims of which may be given hypodermically at intervals of from four to eight hours. It must be remembered that this drug manifests its effect slowly but that the effect lasts for a long time, hence the doses should not be given too close together or one may get an overlapping of them. It is well to bear in mind that high temperatures prevent the action of this drug, and to remember that it takes several hours to manifest its full effect; it can not be relied on in emergencies, such as heart failure following the crisis.

Perhaps the most universally used drug in pneumonia is strychnin. Here we have another illustration of the physician using a drug without a clear and perfect understanding of what he is trying to accomplish. Dr. Hare says: "Strychnin is a drug that goads the system to increased endeavor and does not aid it simultaneously. It is the crack of the whip that keeps the team from being mired. Would any sensible driver whip his horses all day and then whip them all the more when they are stalled?"

1. When the druggist mixes this, a little iodin will be left in the mortar, but this amount is prescribed to insure a saturated solution.

Strychnin is a drug to be used at the crucial moment when it is necessary for the system to make one grand effort to pull itself out of a desperate situation. It is not a drug to be used continuously, although its use may extend over several days. The constant use of this drug keeps the nervous system on a "wire edge" and will undoubtedly result in more harm than good. Strychnin should be reserved for the crowded hour, when a sharp, quick attack upon the impending depression, by administration of a twentieth, or a fifteenth of a grain hypodermically, will call forth the patient's best effort to recover, and in many cases he will succeed. Another drug of great value for its effect on the vasomotor system is belladonna. This drug also should only be used when symptoms of arterial depression appear. It is of immense value just following the crisis when the patient's skin is cold, pale and clammy. Its use is indicated especially in the later stages of the disease, and also whenever the blood paths show signs of relaxation. This condition sometimes appears quite early. In no other way can belladonna be of service in pneumonia. The mistake should be avoided of giving this drug early in the disease with the idea of relaxing the blood vessels and thus aiding the inflamed lung. Belladonna never lowers arterial pressure, unless it is given in toxic doses. Then it paralyzes the vasomotor centers. Caffein and camphor are reliable heart stimulants and are sometimes useful. The former may be given in the form of one of its salts or as strong black coffee. The latter is best administered hypodermically in the form of camphorated oil. Adrenalin chlorid is a powerful vasomotor stimulant and acts directly on the heart as well. It may be given in from 15 to 30 minim doses hypodermically.

The use of diffusible stimulants as recommended by Elsner, is a very valuable procedure but I believe that Elsner's doses are too frequent. It is not necessary to give these stimulants every fifteen minutes day and night, as advised by him. With the disturbed circulation, and the condition of the patient's mucous membranes, it is hardly possible that any dose of medicine of sufficient size to be felt, will have spent itself in fifteen minutes. Every one or two hours is often enough, if necessary, the dose may be increased. There are few patients who would not be markedly disturbed by having to take a dose of medicine every fifteen minutes, and when we are vainly trying to get a patient to sleep it would seem but folly immediately to wake him up again as soon as we accomplished our purpose.

Diffusible stimulants are best given in the form of a mixture composed of equal parts of Hoffman's anodyn, aromatic spirits of ammonia, spirits of lavender and brandy. A teaspoonful of this may be given as above stated well diluted with ice water. This can be kept up as long as indicated.

An injection of decinormal salt solution under the skin is of great benefit in all cases of pneumonia. Not only does it strengthen the heart and tone up the vasomotor system but it also dilutes the toxins, starts up all the secretions and prevents heart clot. Its effect on the skin and kidneys is especially marked. With ordinary precautions it can produce no harm. It is not necessary to have an elaborate apparatus. A large syringe, such as an otologist uses for washing out the ears, will answer all purposes. A large needle can be attached to this syringe by means of a small rubber tube and the injection made just as if giving a hypodermic. From 8 to 16 ounces may be given at once and the injection repeated from time to time.

I shall speak of the use of nitroglycerin only to condemn it. It produces all harm and no good. It can not be regarded in any sense as a heart stimulant, but it does most certainly paralyze the pneumogastric and the respiratory and vasomotor systems. It also destroys the oxygen carrying properties of the blood. No one who clearly understands the physiologic action of this drug can be excused for killing a patient with pneumonia by its use. I am fully aware of the fact that some writers advocate its use late in the disease when the right heart is vainly struggling to empty itself. This drug will empty the heart certainly, but unfortunately it will liberate the soul at the same time. It is said to be indicated in cases associated with arterial sclerosis but it is in such cases that it is most likely to kill and least likely to produce the desired result. I notice that most writers advocate giving this drug at intervals of from three to six hours, and as the effect of nitroglycerin probably does not last over thirty minutes, I am constrained to attribute their success from its use, in a measure at least, to the goodness of God.

If the right heart must be relieved it is best done by bleeding, but Osler says out of twelve patients treated in this way eleven died. The collapse following the crisis, when severe, is best met by a hypodermic of strychnin 1-15 gr., atropin, 1-120 gr., and standardized fluid of digitalis 2 minims, repeated pro re nata. The patient's body temperature should be kept up with blankets and hot water bottles.

Cyanosis.—Beginning cyanosis calls for respiratory stimulants, the best of which is strychnin. Atropin is not so good a respiratory stimulant as was once believed, and as poisoning is easily produced it must not be used carelessly. Caffein as a respiratory stimulant has been highly overrated. Its power lies more in its awakening effect than in any stimulation of the respiratory centers. The inhalation of oxygen is a doubtful procedure, so far as producing any effect on the disease goes. It gives temporary relief sometimes, but as Manges says: "The fact that the dyspnea is markedly relieved immediately after the crisis, while the lung is just as much consolidated as it was before the crisis proves that cyanosis and dyspnea are not altogether due to mechanical causes, but are largely due to the pneumococci infection." In tiding the patient over sudden attacks of cyanosis and dyspnea oxygen is most useful.

Nervous Symptoms.—These consist chiefly of headache, restlessness, delirium, insomnia and hiccough. Generally they can be successfully combated by hydrotherapy. When necessary a small dose of morphin, hypodermically, will help to quiet delirium and to produce sleep. Hyoscin hydrobromate is also a useful drug at times. Hiccough when prolonged may cause exhaustion. It can usually be checked by a small dose of morphin and atropin. It is best in all these conditions to give small doses of the medicines recommended and to repeat the dose until the desired effect is produced. Marked nervous symptoms call for alcoholic stimulation.

Cough.—The cough in pneumonia is not generally distressing enough to require any treatment, but when it does call for attention a small dose of morphin hypodermically, or heroin in 1/24 gr. doses by the mouth will relieve.

Vomiting.—This is sometimes distressing. Feeding by the rectum for a day will nearly always stop it. When an initial dose of calomel has been given, vomiting is rarely severe. Cracked ice sometimes acts well when everything else fails. Continued and severe vomiting calls for stomach washing. It is very important to remember that with some patients opium in any form

causes nausea and vomiting. It is useless to try to remedy this condition in these patients while continuing to give this drug. Counter irritation over the stomach is a simple but useful procedure.

This covers the symptomatic treatment of lobar pneumonia. In the treatment of this disease, I have not mentioned venesection and arterial sedatives because their field of application is so limited as to make it a rare chance for the physician to use either to the betterment of his patient. Certainly the average patient when seen by the physician has passed the time for venesection, or arterial sedation. I will admit that there is a pre-pneumonic stage in which these measures will prevent the patient from contracting pneumonia. This is in no sense of the word an abortion, for how can any condition be aborted when it does not exist? The cases that are suited to these measures are found in strong robust persons. If the pulmonary congestion is not relieved in twelve hours, and the symptoms of pneumonia supervene, all depressing measures should be discontinued and an expectant, stimulating plan adopted.

SPECIFIC TREATMENT.

Various drugs have been advocated as specifics in pneumonia, but all of them have had an early death. Chief among these are digitalis, as advocated by Petresco, who recommends the giving of 180 grains a day and claims a mortality of a little over 2 per cent. This treatment has not met with favor. Salicylic acid has been highly lauded, but has failed to establish the claims made for it. This is not surprising when we remember that this drug depresses the heart and irritates the kidneys and digestive tract. Of late creosote carbonate has been claimed as a curative agent in this disease. It certainly benefits the accompanying bronchitis and seems to modify the infection, but after a careful trial in the Pennsylvania Hospital by Drs. Scott and Montgomery, the most that they can say for it is that experiments with it should continue with increased dosage. Iodid of potassium has very lately appeared on the field. It is said to be a specific in doses ranging from 1,500 to 3,000 grains daily. Any one who can believe this should try it. The internal administration of antiseptics has been tried with poor success. Sepine has obtained good results by injecting very dilute solutions of mercuric chlorid directly into the inflamed lung. Antipneumococci serum has disappointed the profession at large, as Dr. Welsh has shown that the antitoxin is not only absent from the blood at the time of and after the crisis, but that the toxin is actually stronger then than at any other time. So we are forced to believe Dr. Osler when he says that we have no specific for pneumonia.

Perhaps the nearest approach to a specific treatment of pneumonia is the hypodermic injection of quinin. This treatment receives the endorsement of no less an authority than Nothnagel. Muriate quinin 7½ grs. are dissolved in ½ ounce of sterile water. This is injected once daily into the lateral parts of the abdomen, where the cellular tissue is loose. Generally two or three injections suffice. The effect on the temperature is less than that on the general condition. It gives one the impression that the subcutaneous administration of quinin lessens the effect of the products of the bacteria which have found their way into the blood current. This treatment is worthy of a very careful trial.

Pneumonia is an infectious disease, and as such every precaution should be taken to prevent its spread. Not long ago a small house epidemic of this disease was reported from the Episcopal Hospital of Philadelphia. The sputum should be cared for, all bed clothing sterilized, and the patient isolated. After the patient is discharged the room should be disinfected. There is no reason why pneumonia should not be included in the diseases that are to be reported to the board of health.

DYSPEPSIA IN ELDERLY INDIVIDUALS.*

JAMES S. McLESTER, A.B., M.D.
Visiting Physician to the Hillman Hospital.
BIRMINGHAM, ALA.

A large number—I had almost said the largest number—of our errors are those of omission. It is of a very common error of omission that I wish to speak.

Optimism is ordinarily a virtue, but when carried too far it becomes failing. It is characteristic of most of us in the consideration of the various possibilities surrounding the complaining individual who consults us that we give first thought to the minor ailments which he may have and in a falsely optimistic manner leave from our consideration all thought of the graver diseases. Reflection will, I am sure, convince any one of the fallacy of this mental attitude; for where there are conditions making possible any of several disorders certainly we should endeavor, first of all, to exclude by all the means of our power the most serious of these, and then take into consideration the least serious.

In passing, I might suggest that were pulmonary tuberculosis the first instead of the last possibility considered in the case of every youthful individual with a cough and a record of lost weight, the mortality from this disease would be lessened. We can best serve the patient in such doubtful cases not by holding tuberculosis a dreadful thought to be put behind us and not to be mentioned, but, on the other hand, by tactfully but plainly making such provisional diagnosis as will give him opportunity to take those steps which would in its incipiency lead to the healing of a tuberculous process.

Somewhat similar, and this is the error alluded to above, is our mental attitude toward the elderly patient who for the first time suffers from indigestion, or who late in life begins to have acute exacerbations of an old but previously mild dyspepsia. Such a patient may have cirrhosis of the liver—he may have chronic interstitial nephritis—but he may also have, and to this possibility I ask your especial attention, cancer of the stomach.

Exactly why cancer of the stomach is a probability in these cases it is difficult to say; but experience teaches us that such is the case. Ordinary indigestion is almost always due to some faulty habit of diet, the quality or quantity of the food or else the manner of taking it is wrong. Such habits are acquired in youth or early adult life, and the resulting dyspepsia quickly follows. The person who has passed through the toils and stress of early adult life and has by hygienic living preserved his digestion will not late in life change these good habits. Advancing age carries with it many notable diseases and disorders of function, but disorders of digestion *per se* are not among them; so that the individual who has reached advanced or middle age without experiencing the discomforts of dyspepsia is not likely to do so unless some remote disease to which his age renders him liable becomes responsible.

These cases of dyspepsia in elderly individuals are naturally first seen by the family physician and on him

* Read before the Medical Association of the State of Alabama, April 18, 1906.

lies the burden of omitting nothing in his consideration of the various possibilities. In hospital and consultation practice we do not usually see them until the condition has lasted some time and considerable progress of the disease has rendered cancer of the stomach a probability even to the casual observer. Then little can be done for the sufferer, although much might have been done a few months earlier.

As has been very aptly suggested, we have been educated up to the point of thinking immediately of cancer of the uterus when a woman who has passed a menopause bleeds from that organ; so why not give to the stomach the same consideration when, previously healthy, it begins in old age to show signs of disease.

Examples are common and I mention the following merely by way of illustration:

CASE 1 (Hosp. No. 7463).—M. H., laborer, age 43. Symptoms of dyspepsia, bad taste in the mouth, discomfort after eating, anorexia and belching first appeared seven months before admission to the hospital. He had been during this time treated by his family physician for dyspepsia. Diagnosis of cancer of the stomach was made soon after admission and he was operated on. On opening the abdomen it was seen that, in addition to the primary growth at the pylorus, metastatic carcinomata were present in the liver and the pancreas. Death occurred a short time later.

CASE 2 (Hosp. No. 8978).—A. B., boiler fireman, age 44. Patient was admitted complaining of "much trouble with the stomach." He had suffered with dyspepsia for past ten months, for which he had been treated. Physical examination revealed a tumor in the left hypochondrium and gastric analysis showed it to be a carcinoma. Operation revealed carcinoma of the pylorus. The patient left the hospital a little more comfortable than on admission, and nothing more was heard from him, but I think it safe to assume that the course of the disease was not interrupted at the late stage in which this operation was undertaken.

CASE 3.—Another case, in a man of 50 years, which made a profound impression on me, but of which, unfortunately, I have no clinical record, came under my care as an ordinary case of dyspepsia. He complained of discomfort after eating, anorexia, belching and occasional vomiting of a year's standing, for which he had been under constant treatment. I remember this man's statement, in answer to my question, that no physical examination of him had ever been made nor any attempt at determining the functionating capacity of his stomach. His clothing being removed, a tumor in the left hypochondrium was very evident, and closer examination convinced me that it was of the pylorus. Gastric analysis confirmed the diagnosis of cancer. The patient would not consider an operation, and feeling it to be hopeless, I could not urge it.

I selected these three cases for reporting because each was hopeless when it came under my care and because much could have been done for each of them had cancer of the stomach been suspected and looked for when the group of symptoms called dyspepsia first appeared.

It is not the function of this communication to discuss the means of diagnosticating cancer of the stomach, which may, with the exception of a few suggestions in the recent literature, be found in any of the text-books on that subject. While there is no truly pathognomonic sign, there are conditions to be observed from an examination of the stomach contents and otherwise which, taken together, at least approach certainty in their significance. And where there is a reasonable doubt, I believe, in view of the skill attained to-day by our colleagues in surgery, that an exploratory incision is a perfectly legitimate means of diagnosis.

It seems hardly necessary to dwell on the advantages of an early diagnosis in cancer of the stomach. Many surgeons, like Czerny and Rindfleich, state that when a recognizable tumor has appeared or marked cachexia is present, operative measures can not accomplish anything. Yet we are agreed, and I speak as an internist, that in the earlier stages of this disease surgery can do much for the patient by increasing his comfort and prolonging life. Therefore, you can understand why I make the plea, and make it before this association of practitioners, that every middle-aged or elderly individual who for the first time has dyspepsia be studied most carefully to determine whether cancer of the stomach be present.

FIVE CASES OF MECKEL'S DIVERTICULUM.*

O. M. GILBERT, M.D.
Associate in Clinical Medicine in the Medical Department of the University of Colorado.
BOULDER, COLO.

In order that we may call to mind the nature of a Meckel's diverticulum, it will be necessary to recall briefly the method of development of the alimentary canal.

When the three blastodermic layers have formed a longitudinal axis and the mesoderm has partially segmented to form the celom or the body cavity, the infolding process begins from all directions, but as the embryo is by this time much elongated, approximation takes place laterly much sooner than from above and below, i. e., from headward and tailward.

Also the splanchnopleuric or inner layer approximates much more rapidly than the somatopleuric or outer layer. As a consequence of the almost complete approximation of the inner layer, the incomplete alimentary canal is formed and a narrowly constricted communication remains between it and the general vitellin cavity from which the embryo draws its nourishment until the allantois is formed. Then the vitellin cavity begins to diminish relatively very rapidly and as the outer layers close in, forming the body wall, it is again constricted at the umbilicus and divided into an extra-abdominal portion or vitellin sac proper and an intra-abdominal portion or vitellin stalk or duct, extending from the intestine to the umbilicus.

After the complete formation of the allantois, all that remains of the sac is an almost unrecognizable vestige which afterward forms a part of the umbilical cord. The duct, the intra-embryonic portion, also begins to atrophy and soon after the formation of the placenta should entirely disappear.

This disappearance, however, does not always take place and the duct may persist throughout life as a more or less patulous tube, known as Meckel's diverticulum. This is generally attached at the greatest convexity of the umbilical loop of the embryonic intestine which represents a point in the adult about three or four feet above the ileocecal junction, but may be attached anywhere from the duodenum to the cecum, or even to the rectum.

It is generally from one to four inches in length and often ends in a more or less pouched extremity, though not uncommonly it terminates in a fibrous cord several inches in length.

It is generally attached nearly opposite the mesentery and may have a mesentery of its own.

In size, it may be a mere fibrous cord throughout or as large as the intestine from which it springs, and it contains all the intestinal coats.

It is said to occur in from 1 to 2 per cent. of all individuals.

* Read before the Boulder County Medical Society, 1900

This small series of five cases has been met with in ess than one hundred autopsies. In two cases it was the ause of death, but in the other three it gave no symp- om whatever of trouble.

They were all discovered at autopsy and were wholly nsuspected during life except in one case as a possi- ility.

Halstead estimates that it is the cause of 6 per cent. f all cases of intestinal obstruction and Fitz classes it s more dangerous to its possessor than a veriform ap- endix.

Its most common method of causing difficulty is by and; i. e., the fibrous cord which often extends from its ip, becomes attached by some inflammatory process, or otherwise to some point on the abdominal wall, the in- estine or mesentery, creating a band behind which a loop of the intestine become incarcerated. Fitz has proved by his demonstration of the presence of the remains of the omphalomesenteric vessels that this is not ordi- narily an inflammatory or accidental attachment, but s a remnant of the original connection with the um- bilical opening.

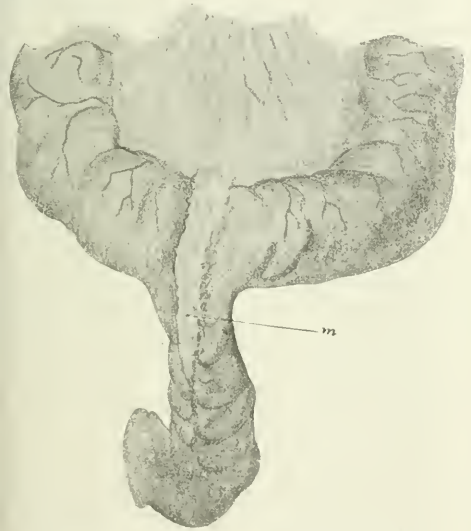

Illustration of mesentery of the diverticulum in Case 4.

Other methods of causing trouble, probably in order named, are: volvulus, intussusception, diverticulitis, hernia—umbilical, inguinal, or internal—and perfora- tion by various ulcerative processes.

Dr. Miles F. Porter, Ft. Wayne, Ind., to whom I am indebted for much data, has recently collected from the literature 149 cases and reported 35 more from other sources, from which he gives a very admirable sum- mary of the conditions in all its phases.

He concludes that the enormously high death rate is due to non-operative interference or late operations and urges early operations in all cases of intestinal ob- struction.

My cases were as follows:

Case 1. Mrs. H., aged 40, two or three children, general health good, except for a number of attacks of intestinal colic of great severity, but of short duration.

History.—She was seen first on April 1, 1901, in an attack which had lasted about twelve hours. Pulse was 156 and weak; the abdomen was somewhat distended and imprint of coils of intestine could plainly be seen through the walls; there was some vomiting of fecal matter, with practically all symptoms of intestinal obstruction. The patient grew rapidly worse and died next day—thirty-six hours from beginning of attack—without operation.

Autopsy.—On opening the peritoneal cavity, a mass of shiny, ebony-black, distended intestine protruded itself. This mass proved to be a loop of the ileum about 3 feet in length and sprang from near its middle. It was found to be firmly constricted at its base by a Meckel's diverticulum which arose from the ileum 3 or 4 feet from the ileocecal junction. It had a mesentery which had tended to draw it upward and to the right where it had fallen into a hole in the mesentery of the ileum, else had made one for its passage.

This increased the tension on its mesentery and it continued the curling process until it entirely encircled the loop of intestine mentioned and again passed through the hole in the mesentery, thereby making one and one-half circuits. It was dislodged with difficulty, and only after enlarging the opening in the mesentery, and was found to be about four and one-half inches in length. The extremity was slightly expanded and there was no fibrous continuation.

Judging from the suddenness of the grave symptoms, the amount of the shock and the appearance of the strangulated bowel, the strangulation must have been sudden, giving insufficient time for much peritonitis to be established in the constricted portion of the bowel, yet there must previously have been some interference with the intestine, from traction or otherwise, causing the colicky symptoms. I can find no other case in the literature like this unless it be Taylor's case, reported by Porter, in which he says: "The diverticulum wound round the gut through a hole in the mesentery."

Case 2. Male, aged about 50. In course of routine autopsy, Meckel's diverticulum about 2 inches long and about two-thirds the diameter of the ileum from which it sprang and with a free and somewhat pointed extremity was found. There was no attachment of its free extremity and no evidence of there ever having been any trouble from it.

Case 3. Male, aged 40. This case was the same as Case 2, except that the diverticulum was about 3 inches in length and was slightly clubbed at its extremity. There was no mesentery in either of these cases.

Case 4. R. M., male, aged 22, single, laborer, was brought down from a mining town with a history of intestinal obstruction of forty-eight hours' duration with abrupt onset. There was then general peritonitis, and the patient died in three hours, without operation. There was history of previous attacks of appendicitis.

Autopsy.—This revealed adhesions from old appendicitis, and behind one of the bands thus formed was a loop of intestine about 6 or 8 inches in length, and hanging from the most dependent portion of it was a Meckel's diverticlum about three and one-half inches in length and ranging from an inch in diameter near its attachment to one and one-fourth inches near its extremity, which was inclined to be bifid. It was entirely filled with a hard fecal mass and it, as well as the incarcerated portion of the ileum, was gangrenous and seemed on the verge of perforation near its extremity.

Case 5. This instance was found in course of routine autopsy on a woman 73 years old and had given no symptoms. It was situated about 3 or 4 feet above the ileocecal junction, seven-eighth of an inch in diameter and was slightly expanded at its extremity. It also had a small diverticulum growing from near its extremity, probably one-half inch in length and half as thick.

SUMMARY.

I found five cases in a little less than one hundred autopsies—being over 5 per cent., whereas they are ordinarily found in from 1 to 2 per cent.—this, of course is merely incidental to the small series. In two of my cases this condition caused death, although in one of them the peritoneal adhesion from the former attacks of appendicitis was also a factor. In both cases which

caused the trouble there was a mesentery of the diverticulum. All the diverticula were between two and one-half and four feet from the ileocecal junction. The manner of causing strangulation in Case 1 was unique.

I believe from this short series of cases, as well as the reports of some of our most careful observers, that diverticulum troubles are more common than are generally supposed and should be borne in mind as one of the not uncommon causes of intestinal obstruction.

A PORTABLE RATION FOR SOLDIERS IN BATTLE AND ON THE MARCH.*

LOUIS L. SEAMAN, M.D., LL.B.
Surgeon and Major U. S. V.
NEW YORK CITY.

So many and so complex are the considerations involved in this question that it can be readily seen no uniform standard can be made applicable to all armies or to all countries. Climate, season, custom, fixed tastes of different nationalities inherited through generations, distance from base of supplies, cost of preparation, are all factors that materially influence the selection of a portable ration and also indicate the impossibility of uniformity. It is, therefore, not my purpose to advocate any single standard ration, but rather to point out the advantages of certain articles of food that may be added to or replace others in already existing standards, as gathered by an experience with different armies in various lands.

An efficient dietary requires that its constituents shall furnish the proximate principles in amounts necessary for the economy, that they shall be easily digested as well as palatable, and that they shall fulfill their requirements with the minimum waste.

Briefly, the nutritive substances in food are the proteids, the carbohydrates and the hydrocarbons or fats. To these are added the mineral salts, water and accessories. The function of the proteids consists principally in the repair of waste, and they also supplement the carbohydrates and hydrocarbons in the generation of heat and energy.

The inorganic salts and water, although not foods, since they neither repair waste nor produce energy, are absolutely necessary to the chemical and metabolic changes which take place in living organisms.

Muscular energy requires for its generation a far more complicated process than mechanical force, just as the human machine is much more complex than the mechanical. In the steam engine the transformation of force from fuel to heat, and heat to power, is rapid and can be measured with mathematical exactness. In the animal machine this is not the case. A complicated process of digestion and assimilation are necessary, and these are often influenced by surrounding conditions which affect the nervous state of the individual and impair the production of energy and the repair of tissue. Nature provides for this by conserving the animal forces and storing them, so they may be available when needed. No more striking example of this conservation of energy in muscle can be found than in the hunting dog, who works from morning till night on his stored muscular power, often covering a hundred miles without a morsel of food until his day's work is done, when he is given a full meal before his rest. During the night his food becomes thoroughly digested, absorbed and stored, so that he is ready next morning to repeat his labor. Feeding during the day impairs his keenness of scent and produces heaviness and desire to rest.

All animals naturally rest after eating. It is by following these dictates of Nature that the most beneficial results are obtained.

A portable military ration for soldiers on the march or in battle requires special elements which are not demanded in the dietary of those in other walks of life. Such a ration must be small in bulk, compact so as to be easily carried by the soldier in sufficient amounts for several days' use; it must be previously prepared or capable of being prepared with facility by the individual soldier, often under the most adverse conditions, and it must be non-irritating and of such character that it will keep under varying conditions of climate and weather.

That these requirements are not easily fulfilled is apparent by the varied rations in use in different armies, and the frequent changes made in them.

For many years the data deduced by Voit as to the amounts of the proximate principles of food necessary to maintain health and to produce heat and energy have been accepted as a standard. He estimated that a man of 154 to 156 pounds, working at moderately hard labor for nine or ten hours per day, required 118 grams proteids, 105 of which shall be absorbable, 56 grams fat and 500 grams carbohydrates, the food values of these principles being equivalent to 3,054 calories.

Chittenden, in an elaborate series of careful investigations, carried on for many months with students, soldiers and athletes, has demonstrated that Voit's estimates were excessive, that less than half the amount of proteids is ample under ordinary conditions and that with this diminution in proteids no increase in carbohydrates is necessary. He also proved that 3,000 calories is in excess of the real needs of the economy; in other words, that the average individual consumes double the amount necessary for the maintenance of health, and that the excess of food frequently acts detrimentally in producing imperfect digestion, fermentation, the creation of toxins and thereby necessitating additional work of elimination, for excess will as surely produce disease as insufficient or improper food.

While these conclusions hold good in the case of the subjects of Chittenden's experiments, a soldier in campaign or in battle undergoes an entirely different process of nervous tension and physical fatigue, wear and tear. Admitting his results, however, the proportions of one part proteids, two-thirds of a part of fat and three and one-sixth parts of carbohydrates, with one-fourth of a part of mineral matter, hitherto taken as a standard, may be changed to advantage. In the hitherto accepted scale of proportions the relation of nitrogen to carbon is as 1 to 15.

The results achieved by the Japanese in the prevention of disease in their army in the recent war with Russia, wherein the death rate from disease was far below that of any other army in history during active warfare, was due to several factors, of which the ration only concerns us at present.

This ration up to February, 1905, was as follows:

Rice	6 go	= 1,020	grams.
Or hard bread	270 momme	= 480	grams.
Fresh meat without bone	40 momme	= 68	grams.
Or fresh meat with bone	50 momme	= 85	grams.
Or dried salt meat	30 momme	= 51	grams.
Pickled plums	15 momme	= 25.5	grams.
Powdered misc.	20 momme	= 34	grams.
Salt	3 momme	= 5.1	grams.
Sugar	3 momme	= 5.1	grams.
Tea	1 momme	= 1.7	grams.
10 go = 100 momme = 170 grams; 1 momme = 1.70 grams.			

* Presented before the Military Section of the International Medical Congress, Lisbon, April 23, 1906.

The nutritive value of this ration is approximately as follows:

Articles.	Protein. gms.	Fats. gms.	Carbohydrates.	Nitrogen. gms.	Carbon. gms.	Fuel Value. Calories.
Rice, 36 oz., 1,020 gms.	81.60	6.12	805.80	13.05	302.97	3604

Nitrogen to carbon, 1 to 19.

According to Voit's tables it is markedly deficient in fats, though the fuel value is high. The proteids are likewise below his standard. The carbon in the ration is almost entirely derived from the carbohydrate elements, which can not entirely replace the fat element without detriment to the nutritive process. Yet with this ration the Japanese troops endured all the hardships of a most vigorous campaign. The Russian troops likewise, according to Colonel Havard, U. S. Army, maintained a state of health superior to that of troops at home in the Russian garrisons on a ration which American or English soldiers would reject with scorn. The same observer gives the Russian field ration as follows: Fourteen ounces (396 grams) of fresh meat; two pounds (907 grams) of black rye bread; three or four ounces (85-113 grams) cereals or fruits, and vegetables, tea and sugar when procurable. In emergencies these quantities, especially the meats, were often reduced. This ration has a nutritive value of about 150 grams of proteids and 450 grams of carbohydrates, while its value in calories is 4,180.

Among the Japanese troops there was a noticeable absence of gastrointestinal diseases, and I am firmly convinced that their easily digested, non-irritating and readily assimilated ration was an important factor in eliminating disease of this class. On the other hand they suffered greatly from the scourge of Oriental races, beriberi. Almost one-half of the sickness in the army during the war with Russia was from that disease. The estimate of the number of cases—24.3 per cent. of the entire sick and wounded—shows the enormous total of 84,545. The disease had been practically eliminated from their navy in 1885, and no case occurred among the naval forces during the Russo-Japanese war. This result was accomplished by Baron Takaki, medical director of the navy, through a change in the naval ration, principally by the addition of barley, whereby its nutritive value was increased from 109 grams of proteids, 15.8 grams of fat and 622 grams of carbohydrates to 196 grams of proteids, 43 grams of fat and 775 grams of carbohydrates.

Bread and meat are the essential constituents of all dietaries, and military men generally recognize the importance of making provision for their supply whenever possible. Portable field ovens for baking bread and the furnishing of fresh beef by herds accompanying the army or the preservation of meat by refrigeration and its transportation in the frozen state are now commonly employed in the military service for this end. Vegetables will always be supplied when practicable, as their use is of the greatest importance in the maintenance of the health of troops.

I wish, then, to be distinctly understood that in proposing a portable ration for soldiers on the march or in battle I advocate it only as a field ration, when fresh meat and bread and vegetables can not be supplied; that in no manner is it proposed to replace the ration issued under ordinary military conditions; neither do I wish to be understood as advocating it as a substitute for the numerous varieties of the emergency ration, which is only to be taken under occasions of great stress.

As the proteid constituent of such a ration I desire to call attention to smoked beef. In the process of its preparation the meat is exposed to the slow action of wood smoke. After a preliminary salting and drying the meat is suspended in a closed chamber and saturated with the smoke on alternating days for at least a month. Green hickory and beechwood are the best varieties for this purpose, as they generate more creosote than other woods. As a result of the action of the smoke, the meat becomes impregnated with pyroligneous and acetic acids and creosote. Meat preserved in this manner will keep indefinitely, is easily digested and palatable, and it may be eaten raw or cooked. It does not soon become distasteful, like canned roast beef or corn beef; it is small in bulk, hence there is no transportation of unnutritious material; it is not irritating and is not likely to cause gastrointestinal disturbances. Its nutritive value is high as it contains 26.4 per cent. protein and 6.9 per cent. fat; and owing to the creosote with which it is impregnated it possesses antiseptic qualities, which I consider of great value in a military diet.

For the carbohydrate constituent of the ration I would suggest a mixture of 7 parts rice to 3 parts barley meal. Rice, while deficient in proteids and fat, possesses the quality of being easily digested, its starch granules ranking first among the carbohydrates in this respect. It is procurable everywhere, cheap and economical, in that there is no loss of any of its constituents in the cooking. Barley meal is slightly richer in proteids and nearly four times as rich in fats, and approaches wheat in its nutritive power.

The mixture of these two grains is a very good substitute for bread, and lends itself particularly to the making of a palatable soup or stew. It should be cooked, dried and ground; so prepared it keeps well, is easily transported, and can be quickly prepared by the individual soldier. It is especially proposed as a substitute for the hard bread which now forms such an important constituent of most military field rations. Hard bread is irritating to the alimentary canal and unless well masticated or soaked in fluids its sharp angular particles will cause diarrhea. While theoretically it appears to be a good substitute for leavened bread, it is well known that it soon becomes distasteful and men do not thrive on it. It also has the objection of readily becoming moldy if exposed to the damp weather. (Prepared breads like French *pain de guerre* and Austrian aerated hard bread, are either too expensive or unsatisfactory in other respects.)

In the proportions suggested, the water-free combination of rice and barley, weight for weight, has a larger percentage of fats and carbohydrate than hard bread, and though its proteid value is somewhat less, there is less loss from non-absorption, because of its greater digestibility.

In this form it was issued to the Japanese troops after February, 1905, with the result of rapidly diminishing beri-beri in their armies.

Napoleon, commenting on the terrible trials of the Moscow campaign, mentions that of all his army the Italian troops withstood the hardships best. They were subsisted on a ration made up almost exclusively of vegetables and cereals. Leonidas and his little Spartan band defended the pass of Thermopylæ on a diet of lentils. The winner of the late Marathon race at the Olympian games trained on the same food, the lentil.

Barley meal and rice with smoked beef are then to constitute the bread and meat components of the ration. In addition to these nutritive elements I would strongly advocate the issue of sugar in greater amounts than is now used in any army. While it is recognized as a necessary adjunct to the military ration, I do not believe its advantages are appreciated to the extent that its qualities merit. When energy is to be liberated rapidly, with the least tax on the digestive system, sugar, an almost pure soluble carbohydrate, would seem to be the ideal food for the purpose. It is essentially a producer of muscular energy; it increases the ability to perform work and lessens or delays fatigue. Harley showed that when 200 grams were added to a small meal the total amount of work done was increased from 6 to 30 per cent., and when added to an ample meal, this total was increased still more. Comparative experiments made by Prantur and Stowasser in 1899, showed that men to whom sugar was administered were able to perform more work with less fatigue than those from whom it had to be withheld. The pulse rate and respiration were less affected when it was given than when it was withheld.

Sugar is readily soluble, easy of digestion, appeases hunger, and lessens thirst. Possessed of such qualities, its value as a part of a military ration is unquestioned. Its combination with chocolate has been frequently recommended, especially as an ingredient of the emergency ration. When so combined it makes an excellent food or drink and is a valuable adjunct to the field ration. Chocolate is easily digested and absorbed. It has slight stimulating properties, due to its active principle, theobromine, though in this respect it has less of the active principle than coffee, but like these it appeases the cravings of hunger. It contains 12.9 per cent. protein, 48.7 per cent. fat and 30.3 per cent. carbohydrates. Its nutritive value is therefore very high. It is palatable and can be eaten uncooked or readily made into a beverage with hot water. It is easily compressed into tablets, making it easily portable, and possesses excellent keeping qualities. It thus meets with all the requirements of a military food. The only objection against it for general use is its cost.

All military men agree as to the necessity of tea or coffee as an article in the soldiers' ration. Both, when properly made, are agreeable, refreshing and stimulating beverages; both diminish bodily fatigue, and allay hunger, and as they are prepared with boiling water, they are certain to be sterile. Both enable men to endure cold and hardships, but the experience of Arctic travelers give tea the preference. When drunk hot they maintain the bodily temperature and permit the use of food for purposes of energy which would otherwise be applied to the maintenance of bodily heat. Tea is in my opinion far preferable to coffee as a component of the military ration under consideration. Coffee when roasted and ground, and in that form only is it feasible in the ration under discussion, rapidly loses its fragrance and aroma. Tea retains these qualities much longer. The equivalent of a ration of tea as compared with a ration of coffee is but one-sixth in weight, while its bulk is correspondingly smaller. Compression into tablets increases its economical value through the breaking up of the vegetable cells by pressure. The readiness with which the infusion can be made by the individual soldier is another great advantage it has over coffee. To this purpose the water bottle or canteen of the Japanese soldier lends itself readily. This is made of aluminum with a flat bottom, with a screw top which serves as a cup; water can be quickly heated in a bottle so shaped, and in a very short time the soldier's tea is prepared. Another advantage of the aluminum water bottle is that tea does not attack the metal and produce a tannate of iron as is the case when an iron vessel is used.

To the above articles should be added salt and pepper. The necessity for them is self-evident and needs no argument. The quantities in which these ingredients of the proposed daily ration should be issued, and their nutrient force values are as follows:

Articles.	Protein. gms.	Fats. gms.	Carbohydrates. gms.	Nitrogen. gms.	Carbon. gms.	Fuel Value. Calories.
Smoked beef, 170 gms.	44.88	11.73	.....	7.18	9.26	283
Rice, 315 gms.	25.20	1.89	248.85	4.00	93.56	1113
Barley meal, 135 gms.	14.18	2.97	125.78	2.36	46.54	586
Sugar, 79 gms.	....	....	66.56	...	24.60	266
Chocolate, 70 gms....	9.03	34.09	21.26	1.42	7.84	424
Tea, 10 gms.	....	....	.....	...	....	...
Salt, 10 gms.	....	....	.....	...	....	...
Pepper, 1 gm.....	....	....	.....	...	....	...
Total	93.29	50.68	462.33	14.96	181.80	2672

Nitrogen to carbon as 1 to 17.8.

This ration is easy of digestion, is palatable, satisfying, and with water it has considerable bulk; it is non-irritating, and to a degree antiseptic, and in my opinion meets with the requirements demanded.

The main objection to be apprehended from the use of a concentrated ration is its lack of bulk. Quantity is as essential as quality in rendering a food digestible. The stomach and intestinal canal require a decided amount of distension to stimulate their normal secretions, while at the same time the bulk serves to increase peristalsis, to flush the kidneys, and carry off waste products, which, if retained, would generate toxins. For this purpose I believe nothing equals hot water in value. It mixes admirably with every constituent of the ration enumerated; it furnishes that most grateful quality—heat to the digestion tract, especially at night when the soldier is exhausted and chilled after a hard day's march or the nervous tension of field service—it relieves fatigue, reinvigorates the system, and rapidly restores it to the best possible condition to resist disease.

An essential adjunct for the successful use of this ration is the portable water and soup kettle, which should form a part of every company's outfit. It should be made of aluminum, with attached fire box, mounted on wheels, and light and easy of transportation. These kettles, or similar ones, were in almost universal use by both armies in the recent oriental conflict, and they proved a most important factor, through the sterilizing of food and water, in reducing mortality from preventable diseases to the minimum point known in the history of war.

247 Fifth Avenue.

Treatment of Typhoid.—At the beginning, says Van Zant in the *Denver Medical Times*, I am accustomed to clear out the bowels with calomel and a saline, but later I rarely give purgatives for this purpose, relying entirely on colon enemata. In accordance with this plan, I have never felt it wise to resort to the Woodbridge treatment, for it is essentially laxative and irritant, increasing peristalsis and, I fear, the tendency to hemorrhage. A moderate experience with the new intestinal antiseptics has not impressed me in their favor. Salol has seemed useful in limiting tympanites, due to fermentation of food, and also as a urinary antiseptic; likewise the sulphocarbolates and creosotal. Turpentine by the mouth and in high colon flushings has a well-merited place in treatment. If the movements are not especially loose or frequent, it is not best to check them by medication, but to limit the degree of tympany as above suggested. Hemorrhage is best met by ice-bags to the abdomen, morphia hypodermically, and hypodermoclysis of normal salt solution; perforation by immediate laparotomy. Of direct specific treatment I believe there is none

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XXII.

Vesicants.

Vesication is the result of greater irritation than that which merely causes rubefaction. The exudate from the blood vessels is not absorbed, but collects beneath the horny layer of the skin, which it can not penetrate, but which it separates from the layers beneath. Such collections of fluid are called vesicles or blisters, and the agents which produce them are termed epispastics, vesicants or "blisters".

If the vesicle is ruptured soon after it has formed, and the horny layer removed, it leaves a tender surface of the skin exposed; this is irritated even by contact with the air, and, being easily permeated, it is liable to infection, hence it is better to puncture the blister with a sterile needle inserted at the periphery; the fluid is allowed to escape while the loose layer of epidermis is left in place for protection until a new hard layer is formed.

While there is some sensory stimulation, vesication may occur from slowly acting agents which do not penetrate readily, with merely an itching.

Those agents which applied to the skin cause vesication also cause an irritation of the mucous membrane, but, as the exudate escapes more readily from such surfaces vesication does not usually occur.

Vesicants, and, in fact, all but the mildest of irritants, such as heat, are contraindicated in the treatment of infants, in diabetics who are prone to gangrene, and for the old and the feeble.

The internal use of irritants which are excreted by the kidneys, and their external use if they are absorbed, as sometimes occurs with cantharides, are to be avoided in nephritis: in such cases stronger ammonia water may be used, but it is very painful.

Mustard occasions so much pain before blistering, owing to the volatility of the oil of mustard, which, therefore, penetrates readily, that it is seldom used to produce an irritation beyond the stage of rubefaction.

Cantharides contains cantharidin, which, though readily volatile at a higher temperature, is not much affected at the body temperature and does not rapidly penetrate the tissues, hence cantharides causes vesication with but little pain and is much the most popular of the vesicating agents.

OFFICIAL PREPARATIONS OF CANTHARIDES.

Cantharis.—U. S.—Cantharides, more popularly known as Spanish flies, is officially described as the thoroughly dried beetle of *Cantharis vesicatoria*. The powder of cantharides, which is the form of the drug that is most frequently found in the shops, is grayish brown in color with shining green particles. It should contain few or no hairs.

Ceratum Cantharides.—U. S.—Cantharides cerate, also known as blistering cerate or blistering plaster, contains 32 parts of powdered cantharides in a mixture of liquid petrolatum, yellow wax, rosin and lard. Cantharides cerate is most frequently used in the form of a plaster, spread on the official adhesive plaster or some other suitable grease-proof material.

Collodium Cantharidatum.—U. S.—Cantharidal collodion represents the chloroform soluble portion of 60 parts of cantharides dissolved in sufficient flexible collodion to make 100 parts.

Tinctura Cantharidis.—U. S.—This preparation represents 10 parts of cantharides extracted with alcohol. It is not usually efficient as a vesicant, but is frequently used externally as an irritant or rubefacient.

The active principle of cantharides is not soluble in water, and as the normal skin is usually covered with a thin film of perspiration or water, the necessary precautions must be taken to have the blistering preparation come in contact with the dry skin.

This is most readily accomplished by washing the part with soap and water and wiping it with a small amount of strong alcohol. In the case of the cerate or plaster the alcohol may be followed by a fatty oil, or, better still, the surface of the plaster may be thinly covered with a coating of oil.

In directing the use of a blister it should be remembered that the resulting vesicle is usually larger than the plaster that has been applied, and the size of the latter, therefore, should be gauged accordingly.

Cantharidal collodion is simply painted on the surface, and is more cleanly than the cerate. In using blistering collodion the same precaution of thoroughly cleansing the skin, with soap and water, and alcohol, should be observed so as to insure vesication.

Vesication usually ensues in about six hours after the application of the vesicant, but a somewhat longer period may elapse even in cases in which all the necessary precautions have been observed, and the physician should allow ample time before he concludes that the preparation is worthless.

Cantharides is prone to deteriorate with age, and one is often inclined to attribute the failure to cause blistering, to the worthlessness of the product, but even a faultless preparation may at times fail to produce vesication.

The now widely used rubber-base plaster containing cantharides, although not official, has many points of advantage over the less cleanly extemporaneous plaster made from the cerate. After preparing the surface of the skin, as indicated above, the plaster is smeared over with a thin film of oil and applied at once. After causing sufficient vesication it can be removed readily, and in this respect offers some advantage over the blistering collodion which continues to act until exhausted.

While cantharides is commonly employed as a vesicant, it is sometimes applied for a shorter time to produce rubefaction, and its irritant action is also made use of in hair tonics, as it is supposed to stimulate the growth of hair.[1]

The expensive Packer's tar soap has no advantage over the very much cheaper tar soap generally used by machinists for washing grease from the hands.

Where an oleaginous preparation, containing cantharides, is desired, the following may be used:

R.	Olei ricini		
	Tincturæ cantharidis, āā	f ʒii	8
	Spiritus myrciæ	f ʒi	30
	Alcoholis q. s. ad	f ʒvi	200

M. Sig.: Apply locally to scalp.

The toxicology of cantharides is of some importance because the laity has an exaggerated idea of its efficiency as an aphrodisiac without a corresponding appreciation of its harmful effects on the kidneys.

Poison oak has been used as an irritant, but it is wholly unsuited for the purpose because of the extraordinary activity of the irritant principle, the uncertainty of its action, and the inability to control it, which render it far inferior to many other available irritants.

It is of much greater toxicologic interest because of the frequency with which accidental poisoning occurs, either from handling it or merely coming into the immediate neighborhood, since even dust particles may carry enough of the extraordinarily active fixed oil, toxicodendrol, on which the action depends, to poison susceptible persons.

Toxicodendrol penetrates the skin very easily and, therefore, is difficult to remove. Even bland oils are to be avoided in the treatment of poisoning by it, since they but serve to dissolve and to spread the poison, the same being true, of course, of ointments, vaselin and cerates.

In treating a case of rhus poisoning as much as possible of the poison should be removed by repeated washing with soap and fresh portions of warm water, after which a paste of soap or a solution of lead acetate is applied. If vesicles form they should be opened with care and the liquid received on absorbent cotton or a powder such as baking soda, since it would but spread the infection if the exuding liquid were allowed to spread over the surface of the skin.

---

1. The following formula fairly represents the form of mixture commonly used as a hair tonic:

R.	Tincturæ cantharidis	f ʒii	8
	Ammonii carbonatis	ʒi	4
	Spiritus myrciæ	f ʒii	60
	Aquæ q. s. ad	f ʒvi	200

M. Sig.: Apply with brush, rubbing into the scalp after washing with tar soap.

The place should then be carefully washed with soap and warm water to remove even traces of the fluid from the vesicles, and the soap paste or the solution of lead acetate applied.

Fluidextract of grindelia robusta, diluted with water, or with a saturated solution of sodium bicarbonate (about 6 per cent.) has had a special reputation as a wash for the treatment of poison oak.

Pustulants.

Pustulants are those irritants which give rise to pustules instead of vesicles. The pustulants appear to be unable to affect the skin through the horny layer as a rule, but can only penetrate the orifices of the glands. They are much less frequently used than the rubefacients and the vesicants.

As tartar emetic is not irritant except in acid solution it has been suggested that it is decomposed by acids in the cutaneous glands, and there produces pustulation.

Croton oil owes its irritant action to crotonoleic acid, which exists mainly in combination as a fat. This fat is not affected by the gastric juice, but is split up in the intestines and the crotonoleic acid is then able to exert its violent irritation resulting in purgation.

Applied to the skin croton oil causes pustulation. It is not now so much used externally or internally as it was formerly.

Official Pustulants.

ANTIMONII ET POTASSII TARTRAS.—U. S.—Antimony and potassium tartrate, more commonly known as tartar emetic, is usually seen as a white granular powder, without odor, and having a sweet, afterward disagreeable metallic taste. It is soluble in about 16 parts of cold water, but is much more readily soluble in hot water.

Antimony and potassium tartrate may be used externally, as a pustulant, either in the form of the powder, in aqueous solution, or in the form of an ointment. The German pharmacopeia contains a formula for the latter preparation that appears to be quite popular on the continent of Europe. This is a simple mixture of 20 parts of antimony and potassium tartrate, with 80 parts of petrolatum.

Because of its irritant action tartar emetic produces nausea or emesis, when taken internally, according to the amount employed. It is much more frequently used as a nauseant than as an emetic, and least often as a pustulant; for the latter purpose it will be found to be preferable to use it in the form of an ointment, similar to the one referred to above, simply rubbed on the skin.

OLEUM TIGLII.—U. S.—Croton oil is described as a fixed oil expressed from *Croton Tiglium*. It occurs as a pale yellow, or brownish yellow viscid, fluorescent liquid, having a mild, oily, afterward acrid and burning taste. In eastern countries croton oil appears to have been known from a very early period. It was known in Europe several centuries ago, but fell into disuse and was reintroduced there with several other drugs from India, about 1813.

Caustics.

Caustics are irritants which either cause violent inflammation, resulting in necrosis, or dissolve the tissue by direct chemic action.

Caustics may be used to produce counterirritation alone, to remove exuberant or diseased tissue, or, in diluted form, to stimulate non-granulating surfaces.

Apart from the use of the thermo-cautery in surgery, that of lunar caustic for exuberant growths and non-granulating tissues, and of arsenic for the destruction of the nerves of teeth, caustics are not very widely used at the present time.

The number of substances possessing a corrosive action is of course very great, but many of them are not suited for therapeutic use, thus the strong alkalies, such as caustic potash and caustic soda, dissolve the tissue and penetrate deeply, hence their action is not easily controlled, besides they are very painful.

Potassium hydroxid, better known, perhaps, as potassa, is sometimes used to soften and to remove the callous of corns and warts.

The action of silver nitrate, and of copper sulphate, in the form of molded sticks, or cones, is so easily controlled that they are very comonly used.

ARGENTI NITRAS.—U. S.—Silver nitrate, as lapis infernalis, appears to have been known to Geber in the eighth century and has been used extensively since that time. It occurs as colorless crystals, which are freely soluble in about one part of water and melt or fuse at 200 C. (392 F.). This latter feature is taken advantage of in making the official forms of fused silver nitrate, and is also of advantage in forming extemporaneous preparations, for local application, by melting or fusing silver nitrate onto suitable metallic instruments such as sounds.

ARGENTI NITRAS FUSUS.—U. S.—Molded silver nitrate contains about 95 per cent. of silver nitrate, with a small amount of silver chlorid, which is added to make the sticks tough and fibrous.

ARGENTI NITRAS MITIGATUS.—U. S.—Mitigated silver nitrate is composed of one part of silver nitrate and two parts of potassium nitrate fused together.

CUPRI SULPHAS.—U. S.—Copper sulphate or blue vitriol occurs as large, transparent deep blue crystals. For external use these crystals may be rasped or filed into suitable shape, and are then used in very much the same way as are the sticks of silver nitrate.

The various uses of these agents are so well known that they scarcely require extended treatment here.

When the lunar caustic is used on exuberant granulations care should be taken to avoid bringing it into contact with the newly formed skin, which is recognized only as a bluish line, since this occasions pain and is, of course, destructive of the very object it is intended to promote.

ARSENIC AND ZINC CHLORID.

ARSENI TRIOXIDUM.—U. S.—Arsenic trioxid, also known as arsenous acid and as white arsenic, occurs most frequently as an odorless and tasteless white powder, that is but slowly soluble in about 100 parts of water.

ZINCI CHLORIDUM.—U. S.—Zinc chlorid occurs as a white granular powder or a porcelain-like mass. It is freely soluble in water, but the solution decomposes, on long standing or boiling, depositing a basic salt.

Arsenic and zinc chlorid have been used to destroy cancerous growths. Arsenic, particularly, has been widely used as the active constituent of various cancer cures that have been proposed by regular as well as irregular practitioners. Its action is very slow, and therefore it can be readily controlled, but it occasions considerable pain. Arsenic may be employed in the form of powder, as an ointment, either with lard or petrolatum, or as a paste. In the latter case the arsenic is suitably diluted with either starch or powdered althæa, and subsequently mixed with water to which a trace of gum or mucilage has been added. At present arsenic is most frequently used for the destruction of the nerves in carious teeth.

Zinc chlorid is now but seldom used for its local corrosive action. It may be used in aqueous solution or fused on to and over suitable metallic instruments, much as silver nitrate is used.

Mercuric chlorid is the most corrosive of the metallic salts, but it is too toxic to permit of its general employment for its local caustic action.

SOME OTHER OFFICIAL CAUSTICS.

ACIDUM NITRICUM.—U. S.—The official nitric acid contains 68 per cent. by weight, of absolute nitric acid, and occurs as a colorless, fuming liquid that is very caustic and corrosive.

LIQUOR HYDRARGYRI NITRATIS.—U. S.—Solution of mercuric nitrate occurs as a clear, nearly colorless liquid, having a faint odor of nitric acid and a strongly acid reaction. It should contain about 60 per cent. of mercuric nitrate and about 11 per cent. of free nitric acid.

UNGUENTUM HYDRARGYRI NITRATIS.—U. S.—Ointment of mercuric nitrate is made by dissolving 7 parts of mercury in 10.5 parts of nitric acid and adding this solution to 76 parts of lard that has, previously, been partially decomposed by 7 parts of nitric acid, and continuing the heat, if necessary, until the reaction is completed. The resulting ointment should have a bright yellow color, whence its popular name, "citrine ointment."

UNGUENTUM HYDRARGYRI AMMONIATI.—U. S.—The oint

of ammoniated mercury is now directed to be made by mixing 10 parts of ammoniated mercury with 50 parts of white petrolatum and 40 parts of hydrous wool fat.

Nitric acid is a popular domestic remedy for the removal of warts. The surrounding surface should be thickly covered with petrolatum and a single drop at a time of the acid applied to the excrescence.

Emollients.

The word emollient is derived from *emollio*, to soften; demulcent comes from *demulceo*, to smooth. Since the same agent is usually demulcent as well as emollient, the term to be used depends on the tissue to which the agent is to be applied, rather than on the medicinal agent itself. Mucous membranes rarely require softening, but an inflamed skin is frequently hard and rough, we therefore speak of applying demulcents to mucous membranes and emollients to the skin.

Not only bland oily substances and fats, but mucilages and diluted glycerin act as emollients. Glycerin, when diluted with water, and rubbed into the skin, prevents it from becoming dry and harsh, and the tendency to crack. Oils and fats penetrate the skin and render it soft.

SOME OFFICIAL EMOLLIENTS.

Adeps Lanæ Hydrosus.—U. S.—This preparation, formerly official as lanolin, is the purified fat of the wool of sheep (*Oris aries*), mixed with about 30 per cent. of water.

Glycerinum.—U. S.—Glycerin or glycerol is a clear colorless liquid of syrupy consistence, obtained by the decomposition of vegetable or animal fats. Anhydrous glycerin is slightly rubefacient, but when diluted, as noted above, is an efficient emollient.

Mucilago Tragacanthæ.—U. S.—Mucilage of tragacanth contains 6 per cent. of tragacanth and 18 per cent. of glycerin, with water to make 100 parts.

Petrolatum.—U. S.—Under this general heading the present Pharmacopeia includes what was formerly known as hard and soft petrolatum.

Petrolatum, a mixture of hydrocarbons, of the methane series, is obtained from petroleum and should be of about the consistence of an ointment. The official substance may vary in color from yellow to light amber and have a melting point varying from 45 to 48 C. (113 to 118.4 F.). In addition to this, which is popularly known as yellow petrolatum, the Pharmacopeia also includes:

Petrolatum Album.—U. S.—This is a white unctious mass, of about the consistence of ointment, that otherwise has the same chemical and physical characteristics as petrolatum.

Petrolatum Liquidum.—U. S.—Liquid petrolatum is a colorless or only slightly yellowish, oily transparent liquid without odor or taste, but giving off, when heated, a slight odor of petrolatum.

Of the vegetable oils that are useful as demulcents, it will suffice to enumerate:

Oleum Amygdalæ Expressum.—U. S.—Expressed oil of almonds.

Oleum Gossypii Seminis.—U. S.—Cotton seed oil.

Oleum Olivæ.—U. S.—Olive oil; and

Oleum Theobromatis.—U. S.—Oil of theobroma, cacoa butter.

Of the several official preparations by far the most popular is:

Unguentum Aquæ Rosæ.—U. S.—Ointment of rose water, or, as it is usually called, cold cream. This ointment consists of a mixture of spermaceti, white wax, expressed oil of almonds, sodium borate and rose water, and in one form or another has been the most popular of the mild emollients from the time of its originator, Galen.

Emollients are used for the protection of inflamed skin against irritants, the choice depending on individual preference or convenience rather than on the nature of the drug. Thus mucilage of tragacanth, ointment of rose water and petrolatum differ widely in their physical properties, but they are all used for chapped hands, sunburn, and to soften the skin when it is rough and hard.

The bland oils and ointments penetrate the skin more readily than does diluted glycerin, and, therefore, they are to be preferred as emollients when they are also to serve as carriers of medicinal substances intended for absorption.

Diluted glycerin is an excellent agent for softening the skin, but is somewhat irritant, and when the sensitive layers of the skin are exposed, a bland oil or ointment, such as cold cream, is to be preferred.

To prevent chapping of the skin when it is exposed to the wind, to alternate wetting and drying, or to irritants, the mucilage of tragacanth, preferably mixed with equal portions of glycerin, will be found useful. The exposed surface is washed with warm water and soap to soften the skin, and while still moist, but not wet, a little of the mucilage, or the mixture of mucilage and glycerin, is rubbed into the surface until the latter feels smooth. Instead of the tragacanth mixture the following may be preferred by some, but it is somewhat irritant to very delicate skin:

One ounce of glycerin soap is reduced to shavings and dissolved with the aid of gentle heat, in half a pint of equal parts of glycerin and water. This mixture solidifies on cooling, and a piece about twice the size of a pea is to be rubbed into the moist skin as often as may be necessary. Those who work with irritant or corrosive chemicals will find this an excellent agent for keeping the hands soft.

A liquid preparation that has met with considerable favor may be made by mixing ten parts of tincture of benzoin, fifty parts of water, and forty parts of glycerin. To secure a homogeneous mixture the water should be gradually added to the tincture of benzoin and the glycerin added to this mixture. If the resulting mixture should still be irritating the amount of glycerin may be further reduced, with a corresponding increase in the quantity of the water. If rose water be substituted for the water in the above formula the resulting mixture would simulate some of the well known and widely advertised proprietary toilet preparations of glycerin and roses.

Clinical Notes

TUMOR OF THE CECUM AND ASCENDING COLON; REMOVAL AND RECOVERY.*

A. B. KNOWLTON, M.D.
COLUMBIA, S. C.

History.—The patient, a lady aged 56, unmarried, was admitted to my infirmary as the patient of Dr. E. J. Wannamaker of Columbia, S. C. She weighed about 96 pounds, being emaciated from twenty years of gradually increasing intestinal obstruction. No bowel movement could be had except in response to patient, persistent and painful effort, both by enemata and by powerful purgatives. In consequence her suffering had gradually increased, each exacerbation becoming more and more pronounced till her condition was that both of physical suffering and mental anguish, which only slowly increasing intestinal obstruction can induce.

The patient periodically eructated quantities of gas and vomited nearly all liquids and nourishment. Anodynes gave her her only relief, except occasionally when in response to cathartics, and by dint of much suffering, a few drams of fecal matter would pass.

Examination.—The abdomen was enlarged from chronic gaseous distension and fecal retention. Through the thin parietes could be plainly seen the peristaltic waves in their oft repeated attempts at emptying the bowel of its contents. There was a mass in the right iliac region extending upwards in the direction of the right kidneys.

Treatment.—Patient was surely but slowly failing, and operation, which Dr. Wannamaker requested me to perform, was done for the first time Sept. 30, 1904. On account of her condition nothing more was anticipated than the relief of possible constricting bands of adhesion or perhaps the evacuation of any fluid that might be encysted. The tumor proved to be one of the head of the cecum and the entire ascending colon surrounded by a mat of intestinal adhesions throughout

* Read before the Tri-State Medical Society of the Carolinas and Virginia, White Stone, S. C., Feb. 18, 1906.

its extent. The patient being unable to endure a radical operation a right inguinal ileostomy should undoubtedly have been performed, but having promised before operation not to leave her with an artificial anus under any circumstances, we were compelled to content ourselves with snipping a few adhesions and closing the abdomen.

To our great surprise the patient evidenced remarkable recuperative powers, and although the obstruction was not in the least degree removed, she was still alive at the end of two weeks. At this junction patient consented to an artificial anus, provided we promised to do a subsequent operation and remove it. Accordingly, Oct. 15, 1904, the second laparotomy was performed and a right inguinal ileostomy established. The incision was made in the line of the preceding one, and a loop of ileum two inches from its termination in the cecum was brought out and suspended on a glass rod by running the same through the mesentery, after the manner of Grieg Smith, and the redundant incision closed. In twenty-four hours the ileum was opened. The relief from suffering was magical, as would have been expected. Recovery was rapid, appetite returned, and patient was given six weeks in which to go home and recuperate. At the end of this time she returned, much increased in weight, looking well, and according to her statement, feeling better than she had in ten years.

A third abdominal section was performed Dec. 28, 1904. Incision was made in the left inguinal region, and the ileum was resected (intra-abdominally) two inches from its termination in the artificial anus. The distal end was inverted and closed by a silk purse string suture. The free proximal end was implanted by Murphy button into the lower end of the descending colon just above its passage over the pelvic brim—the operation constituting technically a left inguinal ileo-colic implantation. It was with some hesitancy that the Murphy button was used in this procedure as the colon was so narrowed and shrunken from years of comprhrative disuse that it was at first doubtful whether or not the button could ever pass through. It was, however, finally adopted. The bowels moved naturally in forty-eight hours. The patient said this was the first natural and comfortable bowel movement she had had in approximately fifteen years. The button was passed on the twenty-second day. Nothing thenceforth passed through the artificial anus but an occasional drop of mucus, and patient was dismissed for another holiday.

March 31, 1905, she returned in excellent condition, the fourth and last laparotomy was done, the old scar of the first two operations in the right iliac fossa was dissected out, and the abdomen opened. Many old and dense adhesions were broken up and the cecum with the appendix buried in a tumorous mass, the entire ascending colon up to and including a portion of the hepatic flexure and the four inches of ileum leading up to the ileo-cecal juncture constituting the artificial anus all removed in one mass. The distal end of the hepatic flexure was inverted with silk purse-string. The abdomen was closed, and April 28, 1905, the patient was dismissed without obstruction, without tumor, and without artificial anus, and in excellent health and comfort.

Owing to an oversight, the microscopic nature of the tumor was not determined, but from the history of the case, the absence of mesenteric lymphatic involvement, the macroscopic appearance of the growth, together with the subsequent conduct of the case, I believe that there was nothing malignant. I judge it to have been fibrolipoma. Operation, however, was just as essential as if it had been malignant. For a distance of six inches the caliber of the ascending colon through the tumorous mass was reduced to the size of a goose quill.

The case emphasizes the value of intermittent surgery in certain intestinal conditions where there is a neoplasm, stricture, volvulus, or other obstruction to be removed and where the patient's physical condition debars an immediate radical procedure. A quick, clean enterostomy or colostomy in these cases is, indeed, one of the most valuable resources known to surgery. Whether the obstruction be acute or chronic, when the patient's ability to endure a radical operation has long since vanished, a timely opening of the bowel just above the seat of obstruction is a procedure to which every such victim is most honestly entitled. By this means the patient is immediately given a respite from his suffering and an opportunity to gain sufficient strength for whatever radical operation should be attempted at a later date.

Another point which this case illustrates is the "resisting power" so often evidenced by those who have been invalids for years. There is no doubt that old chronics oft times show a most remarkable ability to withstand the exhausting effect of surgical procedure. The intestine, from long-continued overdistension from gas, has acquired a degree of toleration which is truly astonishing, while from chronic fecal retention there results a degree of acquired immunity from intestinal toxemia which undoubtedly contributes largely to the actual recovery of these cases after operations. These facts should not be lost sight of in estimating the probable termination of any prospective operation on such cases. It must ever be remembered, too, that in *acute* obstructions the effects of gaseous and fecal distention are quite the opposite. In a subject who is accustomed to daily normal bowel movements, the obstructive retention can not but result in a deleterious amount of autointoxication, while the sudden, unusual and persistent gaseous distension is sure to induce a degree of intestinal paresis which, even after the relief of the obstruction, may be sufficient to produce death.

Thus it would seem that in chronic cases the intestinal canal is one of the most tolerant of all of the abdominal organs, while in acute conditions, especially acute obstruction, it is one of the most easily damaged.

All intestinal neoplasms should be operated on early, for, whether malignant or benign, the inevitable tendency is toward obstruction. The condition is strictly surgical. Palliative treatment leads only to a lowered vitality and an increasingly difficult operation. In view of the prompt and kindly healing of every portion of the intestinal tract, the operative outlook in regard to this organ is one of the brightest of modern surgery.

A NEW METHOD FOR THE DETERMINATION OF LEAD IN THE URINE.

ARTHUR LEDERER,
Demonstrator of Chemistry, College of Physicians and Surgeons (University of Illinois).

CHICAGO.

In examining two specimens of urine for lead in Prof. Charles S. Williamson's clinic at the College of Physicians and Surgeons, Chicago, I experienced great difficulty in using the different methods, inasmuch as some take too much time, some are not sufficiently sensitive, while others require expensive apparatus. Considering the fact that the amount of lead found in chronic poisoning rarely exceeds 10 mg. per liter, the method must be exceedingly sensitive. The methods heretofore used are that of Fresenius and Babo as described in v. Jaksch "Klinische Diagnostik," and that given by E. E. Putman in Keating's "Cyeopedia of the Diseases of Children." Both of these methods require a great deal of time and considerable chemical training. Two other methods, very simple, but not sufficiently sensitive, are those of v. Jaksch[1] and J. H. Abram.[2]

An electrolytic method was worked out by S. R. Trotman and F. H. Jacob.[3]

1. "Klinische Diagnostik."
2. The Lancet, London, ——, 1897.
3. British Medical Journal, ——, 1903.

This method has several advantages and does not consume a great deal of time, but requires an expensive platinum dish and an electric battery, neither of which is apt to be in the possession of the average practitioner. Other metals, if present in the urine, may lead to an erroneous conclusion.

It was my intention to find a method which would be reliable, free from fallacy, sufficiently sensitive, which could be performed by every physician, required but little chemical training, and for which the material could easily be obtained. As the destruction of organic matter is absolutely necessary I found potassium persulphate in sulphuric acid solution the best means for this purpose. Strong sulphuric acid alone does not work satisfactorily and potassium chlorate and hydrochloric acid work too slowly and give off disagreeable fumes of chlorin gas.

Five hundred cubic centimeters of the urine to be examined are placed in a porcelain dish (lead free) or in a sufficiently capacious beaker, and about 70 c.c. of concentrated sulphuric acid (free from metals) are added and the combined amounts are heated over a Bunsen burner. Potassium persulphate is added in small portions to the amount of 20 or 25 grams. The urine which is colored red by the addition of the sulphuric acid is only slightly yellow when boiling starts; the urine probably cloudy before, almost instantly becomes clear and transparent. It is then evaporated to about half its volume.

Should the solution become cloudy during evaporation a small amount of concentrated sulphuric acid is added and the boiling continued for about ten minutes. A few crystals of potassium persulphate should be added in case the urine darkens again during evaporation, but care should be taken to remove the burner first to prevent the liquid from boiling over. This procedure is only occasionally necessary as the urine generally remains clear, and slightly yellowish. After the urine has evaporated to about 250 c.c. it is allowed to cool and about 250 c.c. alcohol (90 vol. per cent.) is added. It now is allowed to stand about four hours in a cool place; during this time the smallest amount of lead is precipitated as insoluble sulphate. The evaporation of the urine can also be carried on till less than half its volume remains, but an equal volume of the alcohol should always be added.

The solution is then filtered through a quantitative filter, washed with hydrochloric and fluoric acid, and the beaker or dish carefully washed out with alcohol. Washing the filter is only necessary once to remove coloring matter. A clean small beaker, or test tube, is put underneath the funnel, and a small hole is punched through the tip of the filter with a clean glass rod. Everything on the filter is then washed down carefully with distilled water from a wash bottle, care being taken not to get too much fluid. If carefully handled not more than 10 c.c. are required. Care also should be taken to remove all particles left on the small glass rod. If considerably more than 10 c.c. is used the solution can be evaporated again if a quantitative determination is wanted. For qualitative determination it does not matter if a few c.c. more or less of distilled water are present. The solution in the test tube now contains all the lead of the 500 c.c. urine, if such was present, in the form of an insoluble sulphate of lead. The amount is sometimes too small to be observed as a precipitate with the naked eye. It might be only a slight cloudiness, hardly visible. The solution is heated over the Bunsen burner and crystals of sodium acetate are added till the solution appears entirely clear and transparent. After the solution is cleared up it is allowed to cool and hydrogen sulphid gas is passed through it. The slightest yellowish-brown discoloration proves the presence of lead.

The test for lead with hydrogen sulphid gas is one of the most sensitive in analytical chemistry. To prove the limitations of the test I performed several experiments and found that 2 c.c. of a 0.002 per cent. lead acetate solution made up to 10 c.c. with distilled water still gave a very slight yellowish discoloration if the solution is looked at from above. This would correspond to 0.00002 gm. lead. It is preferable to pass the gas also through a test tube containing the same amount of distilled water, inasmuch as a slight discoloration can be easily differentiated by comparing the two solutions after the gas has been passed through. Five minutes is sufficient for the passage of the gas.

A great advantage of this method is that even if bismuth is present in the urine it will not interfere with this test, neither will any other substance likely to be present. By comparison with artificial lead solutions containing 1 mg., 2 mg., 3 mg., etc., of lead per liter, a simple quantitative colorimetric method can be established (One part lead acetate crystal contains 0.54 parts of lead.)

Sensitive as the reaction is, it takes but little training to perform the described determination most accurately. If 500 c.c. are taken originally the amount of lead found must of course be multiplied by two in order to get parts per liter. In the two specimens mentioned in the first part of this article I was able by this method to detect 5 mg. in one case and 3 mg. in the other.

The advantages I claim for this method are accuracy of the determination, rapidity with which the determination can be made, and simplicity of technic.

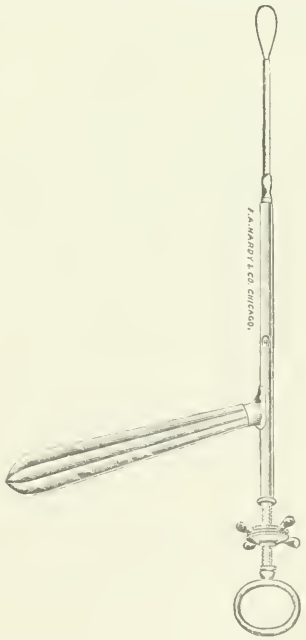
New Instrument

A TONSIL SNARE.

J. A. PRATT, M.D.
AURORA, ILL.

In presenting this tonsil snare to the profession I wish to recommend its simplicity, strength, lightness and cheapness.

The instrument consists of three parts: The shaft, with handle, the stylet and the tip. In place of the straight tip the



different size Vedder tips can be used, all of which are easily taken apart and cleaned.

Wire from Nos. 5 to 8 can be used. The instrument weighs four ounces.

After the tonsil is dissected free from the pillars and the loop is passed over it to the base, by a slight pull on the ring in the end of the stylet the loop is drawn tight and the set-screw is twirled down by the finger setting the loop. The tonsil can now be quickly and easily ecrased.

INSTRUCTION IN OPERATIVE MEDICINE.

In a recent address at New Haven, Dr. Harvey Cushing[1] discusses certain newer developments in the teaching of surgery, or operative therapy, and, inasmuch as the fundamental ideas are of great importance to medical men in general, a brief summary, with comments, may not be without some value. Cushing emphasizes very forcibly the fact, perhaps not so thoroughly understood as it should be, that the essential distinction between surgeons and physicians, between surgery and medicine, as these words are usually employed, lies not in any fundamental differences in general principles or in early training, but wholly in the degree to which manipulative or operative therapy is employed in these two great but largely artificial subdivisions of medicine.

In his daily work the physician employs various essentially surgical methods for diagnosis and treatment, e. g., aspiration of pleural and other cavities, meningeal puncture, etc., methods that require rigid observation of surgical cleanliness, and he early learns to realize when the limits of his operative skill are reached. It is the major forms of operative procedure that, especially in the larger cities, are given over to the surgeon, who, unless he chooses to be a mere handicraftsman, an operator pure and simple, and to occupy no higher plane than the cutter for hernia and stone of a few centuries back, must ever endeavor to maintain familiarity with disease and its diagnosis both at the bedside and in the laboratory, and especially so in these days when anesthesia and surgical cleanliness have made it possible more and more to apply operative therapy to disturbances of visceral functions and structure. Assuming that these general considerations rest on a sound basis, how may the most sympathetic relations be established between "the species surgeon and the species physician" and how may the surgeon best guard himself from losing touch with general medicine so that his chosen branch of it be not made into a mere trade?

Cushing believes that these desirable developments may be favored by certain changes in the manner in which the subject of operative surgery is presented to the student. At first surgery in our medical schools was taught largely by didactic methods, the dissecting room furnishing the only opportunity for acquiring manual dexterity. To Langenbeck is given the credit of having added to the curriculum a practical course in operative surgery on the cadaver, and now our medical schools are supposed to give their students courses of this kind (we fear that in many cases they are given hurriedly and somewhat perfunctorily). But didactic lectures, amphitheater clinics and operations on the cadaver can not impart in the right way to the student the underlying principles of aseptic operative technic on the living subject, and to remedy in some measure this defect, as well to study the diseases that invite operative treatment, there was established in 1901, under Cushing's direction, a course for undergraduate students in operative surgery on living animals, especially dogs, normal and diseased. Largely for this purpose a building, the Hunterian Laboratory of Experimental Medicine, has been specially constructed. We can not enter on a discussion of the details of the course or of the arrangements of the building; both present many points of interest. The point for special emphasis is that actual surgical work and training under favorable conditions have been organized for undergraduate students and put into what seems to be successful, practical operation. The two main purposes one may hope to accomplish in some degree by such a course are "practical finger-end knowledge" of the principles of modern surgical technic and asepsis and to inculcate the fact that "the operation is not the beginning and the end of surgery, but a therapeutic measure alone, and that those employing this manner of treatment must have the same knowledge of disease, the same ability to make examinations, the same instincts to follow pathologic material to the laboratory and to investigate there the causes and symptoms of disease as should characterize any other member of the body medical."

After giving due allowance to the attractiveness of a course like this on account of its very novelty and because of its idealistic program, it is, indeed, difficult to escape the conclusion that its inauguration marks a definite advance in medical teaching. We say medical teaching because the advantages of a course of this kind must be just as great to the future non-operating as to the operating physician. Certainly the principles of asepsis can not be too strongly impressed on the physician, whatever his future work may be. It is plain, too, that a course like this fits the student directly for immediate practical responsibilities which is especially desirable in the unfortunate event that his medical course can not be supplemented by actual service as interne under competent teachers in a good hospital (which, by the way, in time, and let us hope before too long, must be required of all applicants for license to practice). Various side issues also press in for consideration, only one of which can be mentioned, namely, the great influence which work of this kind eventually is bound to exert on veterinary medicine.

1. Johns Hopkins Hospital Bulletin, 1906, vol. xvii, p. 123.

THE CHEMISTRY OF TUMORS.

Chemical investigations of tumors have been relatively few in number, but so far as they have yet been made there has been little found indicating any important deviation of the chemical processes of tumors from those of normal cells of similar origin. Likewise the chemical composition of tumors resembles closely, on the whole, the composition of the parent cells from which the tumor arose, often to the most minute details. Thus Bang found that sarcomas derived from lymph glands contain the particular nucleoproteids that are found normally only in lymph glands; hypernephromas contain, like adrenal tissue, much fat, lecithin and cholesterin; squamous carcinomas develop great amounts of keratin; while carcinomas of mucous membranes often contain great quantities of mucin.

Many investigators have sought in cancer tissues a poison that might account for the cachexia characteristic of new growths. Extracts have been obtained that were destructive to red corpuscles (hemolytic) and that were sometimes slightly toxic to animals, but the results have not been sufficiently striking to account for all the features of cancer cachexia. Because of the abundant areas of anemic necrosis in malignant tumors, autolysis often occurs extensively, and the products of this self-digestion are both hemolytic and toxic to a certain degree, which probably explains the experimental results, but scarcely accounts for the cachexia. As yet no substance has been isolated from or detected in malignant growths that is peculiar to them and not found in normal cells; and much less has any substance been found that will account for the occurrence of tumors or for the results they produce.

Recently a number of interesting positive findings have been made, and, although they have not as yet served to elucidate any of the problems of tumor pathology, yet they possess sufficient interest to repay a brief review. Wolff[1] has studied the proteids contained in the juice expressed from cancer cells, and found that it differs from the juice of normal cells in containing a very much smaller proportion of globulins as compared to the albumins; qualitatively, however, no differences between cancer proteids and normal proteids could be detected. Bang[2] has found that sarcomas derived from lymph glands contain the particular nucleic-acid-histon compound that is characteristic of normal lymphatic tissues, and believes that it is possible to prove chemically the origin of a round-celled sarcoma from lymphatic tissue by a simple chemical test for the histon-nucleinate. Bergell and Döringhaus[3] have studied the structure of the proteids of tumors by isolating the amino-acids by Fischer's ester method, and have found them quite different from ordinary tissue proteids. In the material they examined, which consisted of a mixture of several varieties of carcinoma and a sarcoma, they found relatively high proportions of alanin, glutaminic acid, phenylalanin and asparginic acid, while leucin was relatively small in amount, and glycocoll and tyrosin were also very scanty. These results are important, but need confirmation with pure materials and on a larger scale.

There has been much interest concerning the glycogen of tumors, particularly because of the view advanced by Brault and others that glycogen is a characteristic of fetal tissues in particular, and that, therefore, the proportion of glycogen present in a tumor is an expression of the degree to which it has reverted to the fetal type, and, therefore, an indication of its malignancy. This idea has been found to be entirely erroneous, and the amount of glycogen that a tumor contains seems to depend on two chief factors: (1) The embryonal origin of the tumor, those arising from tissues normally rich in glycogen (e. g., cartilage, squamous epithelium), containing most glycogen. (2) The presence of areas of degeneration from impaired cell nutrition, which leads to glycogenic infiltration alike in tumors and normal tissues (Gierke). Lubarsch[4] reports the results of the examination of 1,554 tumors for glycogen, with positive results in 447, or 29 per cent. It was present in all teratomas, rhabdomyomas, hypernephromas and syncytiomas; in 70 per cent. of the squamous carcinomas, but never in mucoid or colloid cancers; in about 50 per cent. of the sarcomas; but rarely, indeed, in fibromas, lipomas, gliomas, and adenomas. Of other carbohydrates in tumors the pentose group has been especially studied by Neuberg and by Beebe,[5] the former believing that the production of pentose in autolysis is quite characteristic of tumor tissues, the latter finding no characteristic features in the occurrence of this substance. Beebe, however, has advanced the interesting suggestion that a tumor metastasis frequently resembles chemically the organ in which it grows, quite as much as it does the tissue from which it arose, if not more. This observation is quite important, suggesting that the microscopic features of a growth may follow quite different laws from its chemical features, since the former remain true to the tissue giving rise to the tumor, and never irritate the tissue in which the metastasis may have been implanted.

The same author, in a study of the inorganic constituents of tumors, found evidence that potassium is quite prominent in rapidly growing tumors, while in slower growths the potassium sinks and the proportion of calcium increases. Clowes and Frisbie,[6] studying the same question in experimentally produced tumors in mice, with which the age and rate of growth could be well controlled, came to similar results. This agrees with the known importance of potassium for actively growing cells in plant life and in the lower animal forms.

6. Ibid., p. 173.

Martha Tracy[1] found nothing characteristic concerning the location or quantity of iron and phosphorus in tumors.

That tumors should show, on the whole, so little variation in chemical composition from normal tissues is not surprising, if we stop to consider a number of well-known facts concerning their biology. The metabolic products of tumors, as well as their histologic structure, vary little from those of the parent tissue. Thus metastatic growths of thyroid tissue will produce thyroiodin in the most remote parts of the body; metastases from carcinomas of the liver may produce bile when located in the lung or any other organ; tumors from the choroid or from pigmented moles produce melanin that seems to be quite the same as the normal melanin. If tumor cells are able to produce such complicated metabolic products as these, which are quite specific for the tissues from which they are derived, there can be little question that the course of chemical processes in tumors must be almost or quite identical with the chemical processes of normal cells of similar origin.

PSYCHIC RESEARCH.

Such subjects as apparitions, psychism, spiritualism and the like have been so much exploited by charlatans and pseudo-scientists, with interests so obviously personal and selfish, that reasonable men, honestly desirous of ascertaining the truth, have generally abandoned this field. Professor Hyslop, however, is an honest, earnest searcher for the truth, and his latest book, "Enigmas of Psychical Research,"[2] is entitled to scientific consideration, even though this must be quite adverse to his position. He accuses scientific men, especially "physical" or "materialistic" scientists, of purposely and even maliciously ignoring the work of those engaged in psychic research, of a very culpable indifference to supernormal or metaphysical phenomena. "Science," he declares, "having become accustomed to residual facts within its own domain, is loath to admit the existence of facts which limit that domain or demand the acceptance of a larger than the ordinary material world." Let us inquire how just are these accusations:

Charles Darwin some thirty years ago, when spirits were rather rife in England, was invited to inquire into their nature and habits. Though skeptical, he respectfully and attentively considered the subject and got Huxley to help him. The latter visited a seance held in a private house and reported to Darwin that "the performance was as gross an imposture as ever came under my notice." Professor Darwin, who was also present, declared: "Unless I had seen it I could not have believed in the evidence of any one with such perfect good faith as Mr. Y. (the host) being so worthless. It has given me a lesson with respect to the worthlessness of evidence which I shall always remember, and, besides, will make me very diffident in trusting myself." Charles Darwin concluded concerning the medium on this occasion who "had the highest credentials": "To my mind, an enormous weight of evidence would be requisite to make one believe in anything beyond mere trickery"; and again: "The Lord have mercy on us all if we have to believe in such rubbish." Tyndall, who investigated "spirits" exhaustively, has described his many difficulties in conducting a thoroughly scientific investigation in the presence of believers or, shall we say, gullible people. He could not persuade them to employ such ordinary precautions as are essential to investigate these phenomena; and he clearly demonstrated their fraudulent character. Prof. Simon Newcomb, who was perfectly willing to oblige the spiritists and to study the phenomena which interested them, has left in his "Reminiscences" diverting accounts of how he found it impossible to continue on the farcical lines laid down by them. Faraday, at the cost of much time and trouble, convinced all who were open to conviction that fraud and self-deception were at the bottom of most of the spiritist doings with which he came in contact. He was shocked at "the superstitions which in this day of boasted progress are a disgrace to the age and which afford astonishing proofs of the vast flood of ignorance overflowing and desolating the highest places."

If these great names do not suffice Professor Hyslop we would add that Podmore, who was president of the Psychic Research Society, demonstrated in his book, "Studies in Psychic Research," the preposterous and flimsy basis for most of the "established facts" on which spiritism was founded. This book, by the way, is a splendid exposition of the laws of evidence which should obtain in any investigation, and is well worth the perusal of both physicians and lawyers. Jastrow, in his "Fact and Fable in Psychology," submits some very illuminating data. Balfour, the recent British premier, as the result of an exhaustive study of psychic phenomena, has become the most conspicuous modern example of the "philosophic doubter." Among the great men in science who have taken up this subject was Wallace, who has been characterized as a "willing believer"; this should not surprise any one who has noted how "easy" Wallace was in the hands of the anti-vaccinationists.

Professor Hyslop does not help his position by such characterizations as "physical" or "materialistic" scientists. Herbert Spencer, the great formulator of the doctrine of evolution, was justly impatient of those who held that doctrine to be purely materialistic. His "First Principles" begin with an earnest and reverent consideration of the immaterial "unknowable" whence is derived so much of the knowable as finite human wis-

dom can by patience and reason come to understand. Science is knowing; and the real scientist is eager only for the truth, no matter where he may find it or whither it may lead him. Each worker gathers what he can within his own ken, insisting only that his facts shall be true and absolutely incontrovertible; and all which he gathers together he gladly adds to the sum of all science or knowing, which is philosophy, in the hope that his gleaning may redound to the welfare and happiness of his kind.

DISPENSARY TREATMENT FOR TUBERCULOUS WORKING PEOPLE.

The journey of the tuberculosis exhibit through the country has been marked by a distinct awakening of public sentiment on this subject in each city which has received it. The exhibit, covering, as it does, the sociologic aspect of tuberculosis, has stimulated the interest of philanthropists as well as physicians and we hear of new plans for various preventive measures in many of our larger cities. It is generally conceded that what is most needed at present is the development of home treatment and, therefore, of special dispensaries for the tuberculous. Without in the least detracting from the value of sanatorium treatment, it must be admitted that its field is limited, for working people can not, in the great majority of cases, undertake a course of treatment which necessitates giving up their work. Sanatorium treatment, while always the ideal, is, as every one knows, applicable only to the favored few. Moreover, there are certain advantages which home treatment will always have over sanatorium treatment. The patient who is treated in a sanatorium, on his return home, must change his habits of life, his home surroundings, often his working place in accordance with the hygienic rules which he has learned at the sanatorium. The patient treated at home makes these changes as he goes gradually, as a part of his cure. The sanatorium patient must seek a new medical adviser on his return home, the home patient is throughout under the same control. Statistics show that relapses after discharge from sanatoria are deplorably frequent owing to the patient's slipping back into his old habits. Sanatorium treatment usually can be given only for a short period of time—three months is the average in the workingmen's sanatoria in Germany—but the treatment of tuberculosis must often be carried on for years.

Now, if home treatment is to be given, part of it must be given in connection with special dispensaries, for many patients can not pay even a small fee for treatment extending over many months and requiring frequent visits to the physician. According to the directory of institutions and societies dealing with tuberculosis which the Tuberculosis Committee of New York has published, there are at present in the United States nineteen special dispensaries for the treatment of tuberculosis, seven of them being in New York City. Only three, however, are reported as offering treatment to patients at hours which will not interfere with their work. Day dispensaries provide fairly well for patients among the working classes who need but few treatments or are incapacitated temporarily and not working, but for consumptives who are in the early stages and who can not cease work without becoming dependent or plunging their families into poverty, the day dispensaries can do little, and the workingman finds that medical treatment is beyond his reach until such a time as he shall have become unable to work, until, that is, the hopeful period of his disease is passed.

Physicians who have charge of consumptives in private practice know that it is necessary to see these patients far more frequently than the disease really demands, for patients of this class need encouragement, sympathy, the feeling that they are not being neglected and constant urging to persistence and to self-control. Working people can have such constant oversight only in a dispensary and in one which has hours adapted to their needs. Such dispensaries should be open from 6:30 to 8:30 in the morning and for an hour or two in the evening. It is also advisable that they be open for certain hours on Sunday, which hours could be set apart for physical examinations, the weekly weighing, the more detailed instructions. This adjustment of the hours to the needs of the patients is the most important feature of dispensary work among the tuberculous poor.

THE INFLUENCE OF DEFECTIVE NASAL BREATHING ON GROWTH AND DEVELOPMENT.

Among the functions subserved by the nares in the respiratory process are the heating of the inspired air and the addition of watery vapor, as well as the filtration of particles of solid matter. If this mechanism be deranged from any cause, infection is likely to take place, with resultant catarrhal disturbances and impairment of hearing in case of extension to the Eustachian tube. If nasal breathing be obstructed, especially in children, only imperfect expansion of the lungs can take place and deformity of the chest results. A certain amount of adenoid tissue is present normally in the nasopharynx of healthy children, but an excess appears to cause effects apart from the obstruction of breathing to which this gives rise. The mouth-breathing child with adenoids not alone presents a dull, stupid look, but it also seems intellectually below the average, and it is usually stunted in general growth. The improvement in all directions following removal of such excessive adenoid tissue is a most striking and convincing phenomenon. In a discussion of this subject in a recent communication Dr. P. Watson Williams[1] emphasizes the physiologic importance of the nose in influencing respiratory activity and the pernicious effect of the absence of the nasal respiration, not alone on account of the commonly recognized results of unwarmed, unmoistened and unfiltered air reaching the lungs, but also from the persistent abrogation of nasal respiratory

1. Bristol Medico-Chirurgical Journal, March, 1906, p. 17.

stimulation. At the same time he does not underestimate the factors responsible for the defective physiologic activity of the respiratory centers in children suffering from enlarged tonsils and adenoids, especially chronic sapremia, causing tissue inactivity and hence absence of the normal need for more rapid respiratory exchanges. Children who persistently fail to expand their lungs fully, or in whom the respiratory exchanges are subnormal, are underfed, for a due supply of inspired oxygen is essential for the utilization of food in the processes of internal respiration. Accordingly, after the removal of abnormal conditions in the nose and throat, it is wise to recommend activity in the open air, cold baths and particularly physiologic drill, comprising appropriate respiratory exercises, in order that the listless, partially asphyxiated child may grow up in the fulness of life.

Medical News

ILLINOIS.

Chicago.

New Hospital.—A small neighborhood hospital, with a capacity of 10 beds, is being erected at 264 and 266 West North Avenue and will be ready to receive patients August 1. It will be under the charge of Dr. Frank H. Booth.

Smallpox.—During the week three cases of smallpox were discovered and the patients removed to the Isolation Hospital. Of these one was a resident of the city, 21 years of age, who had never been vaccinated. The second was a colored woman from Texas, who was in the eruptive state on her arrival in the city. The third was a colored man from Memphis, who was in the fifth day of the eruption, on his arrival. Neither of these had been vaccinated. There are now 11 smallpox patients at the Isolation Hospital. Last year at this time there were 85.

Cocain Sellers Convicted.—Albert Dahlberg, a clerk in the drug store of Adolph C. Brendecke, was fined $200, May 8, for selling cocain illegally. On a similar charge Vincenzo Colletto, a druggist at Polk and Clark Streets, was fined $200. Both cases were prosecuted by the authorities of Hull House. The defendant, Dahlberg, claims to be a graduate of Rush Medical College. Dr. Nicholas Rey, 438 Dearborn Street, was fined $200 and costs on a charge of selling cocain, May 10. The attorney for the State Board of Pharmacy announces that he has submitted testified evidence in two of these cases to the State Board of Health and has asked that the licenses of the physicians in question be revoked.

Mortality of the Week.—During the week ended May 19, 652 deaths were reported, equivalent to an annual mortality of 16.59 per 1,000. This shows a great increase over the mortality of the previous week, 583, and a still greater increase over that of the corresponding week of 1905, which was 539. The three days of misplaced midsummer heat are probably responsible for this increase in death rate, especially among the very young, as during the week 33 more deaths of individuals under 5 years of age were reported than during the week previous. Pneumonia caused 138 deaths; consumption, 68; violence, including suicide, 58; heart diseases, 41; Bright's disease, 39; acute intestinal diseases, 35, and cancer, 32.

INDIAN TERRITORY.

Health Board Election.—At the meeting of the Muskogee Board of Health, April 18, Dr. O. C. Klass was elected secretary and Dr. Claude A. Thompson, chairman.

Smallpox.—The public schools of Holdenville have been closed on account of an epidemic of smallpox which has broken out in the city. The disease is of mild type and there have been thus far no serious cases.

Territorial Medical Association.—At the meeting of the Indian Territory Medical Association, held at South McAlester, March 20, it was voted that the association merge with the Oklahoma Medical Association and that a joint meeting be held at Oklahoma City, May 8, 9 and 10. This action was taken in confirmation of an agreement made ad referendum to that end by a committee appointed at the last regular meeting. It is provided, however, that the merger should be void in case the statehood bill should fail of passage. Dr. Floyd E. Waterfield, Holdenville, was elected secretary, vice Dr. Rufus J. Crabill, resigned.

District Association Meeting.—The Medical Association of the Northern District of Indian Territory met at Pryor Creek, May 1. The president, Dr. William T. Tilly, Pryor Creek, read an able paper on organization, urging all physicians in the district to avail themselves of the advantages to be derived from affiliation with the association. The following officers were elected: President, Dr. William T. Tilly, Pryor Creek; vice-president, Dr. Franklin M. Duckworth, Claremore; secretary and treasurer, Dr. Robert H. Harper, Afton; censors, Drs. Benjamin F. Fortner, Vinita; Charles M. Ross, Tahlequah and W. J. Whitaker, Pryor Creek; and delegates to the Oklahoma and Indian Territory Medical Association, Drs. Benjamin F. Fortner, Vinita, and Franklin M. Duckworth, Claremore. The next meeting will be held at Afton in August.

INDIANA.

Pays Fine.—Dr. Harry R. Spickermon, Muncie, pleaded guilty to a charge of assault and battery preferred against him by Harry Levy, May 9, and paid a fine of $11.

State Board of Health Laboratory.—Dr. T. Victor Keene, superintendent of the laboratory of the State Board of Health, Indianapolis, reports that during the month of April 171 tests were made for tubercle bacilli.

Fails to Secure Endowments.—The Indiana University has been unable to provide the library and laboratory equipment necessary to secure the endowments for pathologic research recently offered it at a joint value of $20,000.

Case Dropped.—The State Board of Medical Registration and Examination, which a short time ago revoked the license of Dr. Nelson B. Ross, Muncie, on the ground of unprofessional practice, was ordered by Judge Leller, on May 3, to revoke the order cancelling the license.

Personal.—Dr. Albert R. Burton, Princeton, underwent operation at St. Mary's Hospital, Evansville, May 4.——Dr. John Williams, Brazil, celebrated his ninety-fourth birthday anniversary, May 9.——Drs. Moses S. Canfield, Frankfort, and William A. Spurgeon, Muncie, have been appointed by the governor to succeed themselves as members of the State Board of Examination and Registration.

Summer Department of Purdue.—The work of the summer school of Purdue University, Medical Department, Indianapolis, will begin May 28 and continue for eight weeks, embracing both laboratory and clinical subjects. Credit of one semester is granted to students who take this course. The work will be as purely practical as possible. The course will be open to all students and graduates of medicine and no tuition fee will be charged.

Councilor District Meeting.—The Eighth Councilor District Medical Society, comprising Madison, Randolph, Blackford, Jay and Delaware counties, was organized at Muncie, May 5. The following officers were elected: Dr. G. W. H. Kemper, Muncie, president; Dr. Jonathan B. Garber, Dunkirk, vice-president; Dr. Maynard A. Austin, Anderson, secretary and treasurer; and Drs. Etta Charles, Summitville, Madison County; Henry C. Davisson, Hartford City, Blackford County; Reuben E. Brokaw, Portland, Jay County; Granville Reynard, Union City, Randolph County, and Winfield S. Brandon, Daleville, Delaware County, censors.

Graduation Exercises.—The annual commencement exercises of the Indiana Medical College, the School of Medicine of Purdue University, were held in Eliza Fowler Hall, Lafayette May 15, when a class of 124 received diplomas. The doctorate address was delivered by Prof. George E. Vincent of the University of Chicago, and Dr. H. McKain was valedictorian. The faculty, student body and friends of the medical department went to Lafayette in a special train chartered by the faculty of the college.——A reception was given May 8 at the sanitarium of Dr. William B. Fletcher, Indianapolis, in honor of the graduating class of Indiana Medical College.——The faculty of the college gave a banquet to the graduating class at the Claypool, May 9, at which Dr. Theodore Potter was toastmaster. Toasts were responded to by President Winthrop E. Stone of Purdue University, Dean Henry Jameson of the local department of the university; Mr. Stewart, president of the board of trustees; Dr. Albert E. Bulson, Fort Wayne, and Drs. Thomas B. Noble, Frank B. Wynn and John H. Oliver, Indianapolis.

LOUISIANA.

Home for Incurables Opened.—The administration office and children's annex of the Home for Incurables, New Orleans, erected at a cost of more than $10,000, were dedicated April 28.

Board Trusts Local Practitioners.—The Louisiana State Board of Health, at its session in New Orleans, April 13, adopted a resolution that "in the event of any report reaching the president of a case of suspicious fever, the committee shall appoint a committee of reputable physicians to investigate the case and accept their report as final."

Smallpox at Munroe.—As a result of the investigation of the smallpox situation in Munroe, Dr. Robert W. Faulke, a member of the board of health, reports that the minimum number of cases is 44, 40 of whom are negroes; that every known exposed person has been vaccinated and that all patients and suspects are being removed to the pest house.

Tulane Graduation.—The seventy-second annual commencement exercises of Tulane University of Louisiana, Medical Department, New Orleans, were held May 3, when a class of 102 received degrees in medicine. The annual report was given by the dean, Dr. Stanford E. Chaille, and the annual address was delivered by Surgeon Joseph H. White, United States Public Health and Marine-Hospital Service.

Personal.—Dr. Charles L. Ramage, Winsboro, has been elected president and executive officer of the Franklin Parish health board.——Dr. and Mrs. Arthur W. De Roaldes left for New York, April 24, on their way to Europe.——Dr. Robert L. Randolph, Alexandria, has been elected a member of the local board of health.——Dr. C. W. Loomis, Lake Charles, was severely burned while endeavoring to extinguish a fire in his office, May 8.

Hospital Alumni Association Meeting.—The Alumni Association of Charity Hospital, New Orleans, held its annual meeting and banquet May 7, at which the following officers were elected: Dr. Eugene H. Walet, New Orleans, president; Dr. Adrian A. Landry, Paincourtville, vice-president; Dr. Narcisse F. Thiberge, secretary, and Dr. E. Loeckert, treasurer. Dr. J. B. Guthrie acted as toastmaster at the banquet. Hon. H. Terriberry responded to the toast "To the Victims," and Dr. Warren S. Bickham, present as the guest of honor of the association, responded to the toast of "The Prodigal Son."

MARYLAND.

Secure Hospital Building.—The managers of the Union Hospital of Cecil County have purchased a residence in Elkton for the proposed institution.

Personal.—Dr. Edward R. Trippe of Easton has been appointed health officer of Talbot County.——Dr. Joseph R. Owens was elected mayor of Hyattsville.——Dr. Jesse W. Downey, New Market, was stricken with paralysis, April 26.

Faculty Will Not Start Journal.—The Medical and Chirurgical Faculty has practically decided not to publish a journal of its own, but to accept the offer made by the *Maryland Medical Journal* with a few slight modifications. The *Journal* has been the official organ of the faculty for the past year.

County Association Election.—The Baltimore County Medical Association has elected the following officers: President, Dr. James H. Jarrett, Towson; vice-president, Dr. William L. Smith, Sherwood; treasurer, Dr. Benjamin Whiteley, Catonsville; recording secretary, Dr. N. R. D. Cox, Arlington, and corresponding secretary, Dr. Richard C. Massenburg, Towson.

Health Board Appointments.—At the semi-annual meeting of the Montgomery County board of health Dr. William L. Lewis, Kensington, was reappointed health officer. The following were appointed vaccine physicians: Drs. H. G. Spurrier, Unity; Vernon H. Dyson, Laytonsville; Horace B. Haddox, Gaithersburg; Augustus Stabler, Brighton; James E. Deets, Clarksburg; Philemon S. Lansdale, Damascus; I. Newton Simpers, Germantown; James H. Stonestreet, Barnesville; Richard T. Gott, Poolesville; Upton D. Nourse, Dawsonville; W. Frawley Pratt, Potomac; C. H. Nourse, Barnestown; Claiborne H. Mannar, Rockville; John L. Lewis, Bethesda; John R. Batson, Spencerville; William T. Brown, Burnt Mills; William L. Lewis, Kensington; Roger Brooke, Sandy Spring; Charles Farquhar, Olney, and F. Green. The vaccine physicians are required to visit the public schools to see that all children are vaccinated. In order to insure complete records of vital statistics, each physician is paid 10 cents for every birth certificate or burial permit. The board of health consists of the county commissioners.

Baltimore.

Milk Exhibit Closed.—The milk exhibit closed May 14, after a week of lectures and demonstrations. It was attended by thousands, as many from out of the city as from within it.

Alumni Meeting.—At the annual meeting of the Alumni Association of the University of Maryland School of Medicine, to be held June 1, Dr. Randolph Winslow, Baltimore, will deliver the oration on "The University in 1871 and 1906."

Suicides.—There were three suicides last week and, according to the weekly reports, 17 suicides in the previous five weeks. It is interesting to note that foreigners predominate. Nearly 60 per cent. were attributable to love; only one of the 17 was colored.

Commencement.—The twenty-fifth anniversary and commencement of the Baltimore Medical College was held May 22. There was a lecture at noon in the assembly room by Prof. Robert W. Johnson on "The Conservative Treatment of Acute Appendicitis." A class of 17 was graduated.

Personal.—Dr. Daniel Z. Dunnott has been appointed surgeon-in-chief of the Western Maryland Railroad.——Dr. Robert S. Kirk has been re-elected superintendent and Dr. John Roth, assistant, at the Baltimore Eastern Dispensary.——Dr. J. W. Baird, assistant in psychology at the Johns Hopkins University, has been appointed to the chair of experimental psychology in the University of Illinois.

Typhoid.—The milk epidemic of typhoid fever, in the northern section of the city, has been causing the health authorities much concern. There have been about 100 cases. Trained nurses have been sent out and the combined efforts of city and state authorities are endeavoring to clear up and arrest the epidemic. Dr. Marshall L. Price of the State Board of Health has been sent out into the country to investigate conditions there. The authorities are disposed to lay the blame on the bad politics in the county. The report of the city health department for the week ended May 19 shows 47 cases of typhoid fever, with only one death.

MASSACHUSETTS.

Personal.—The board of health of Dedham has organized with Dr. Edward W. Finn as chairman.——The board of health of Chicopee has reorganized with Dr. Charles H. Prindle as chairman.——Dr. Perley P. Comey, Worcester, has been appointed lieutenant and assistant surgeon of the Second Infantry, M. V. M., vice Lieut. Thomas B. Shaw, resigned.

Jefferson Graduates Organized.—Graduates of Jefferson Medical College, residing in New England, held a meeting in Boston, May 10, and organized an association to be known as the New England Association of Jefferson Medical College Graduates. The officers of the association are: Dr. Edward L. Parks, Boston, president; Dr. J. Q. Adams McCollester, Waltham, vice-president, and Dr. E. Winfield Egan, Boston, secretary.

Society Meetings.—At the annual meeting of the Essex South District Medical Society, held in Salem, May 8, the following officers were elected: President, Dr. Harry W. Mitchell, Hathorne; vice-president, Dr. Percy C. Proctor, Gloucester; secretary, Dr. George K. Blair, Salem; treasurer, Dr. George Z. Goodell, Salem, and librarian, Dr. Alice M. Patterson, Peabody.——At the annual meeting of the Hampshire District Medical Society, May 11, the following officers were elected: President, Dr. Herbert B. Perry, Northampton; vice-president, Dr. Justin G. Hayes, Williamsburg; secretary, Dr. Arthur G. Minshall, Northampton; treasurer, Alfred H. Hoadley, Northampton, and librarian, Dr. Edward W. Brown, Northampton.——The annual meeting of the Worcester District Medical Society was held May 9, at which the following officers were elected: Dr. David Harrower, president; Dr. Ernest V. Scribner, vice-president; Dr. George E. Emery, secretary; Dr. George O. Ward, treasurer, all of Worcester, and Dr. Jacob R. Lincoln, Milbury, orator.——At the meeting of the Middlesex East District Medical Society, May 9, Dr. Harrison G. Blake, Woburn, was elected president.

"Patent-Medicine" Bill Passed.—The state legislature has passed a bill compelling its manufacturers to publish on the label of any proprietary or "patent" medicine or food preparation the amount of alcohol (if any) which it contains, as well as the quantities of opium or other narcotic. Section 2 states:

> Every package, bottle or other receptacle holding any proprietary or patent medicine or any proprietary or patent food preparation shall bear a label containing a statement of the quantity of any opium, morphine, heroin or chloral-hydrate contained therein, provided that the package contains more than two grains of opium, or more than one-fourth grain of morphine, or more than one-sixteenth grain of heroin, or more than eight grains of chloral-hydrate in one fluid ounce, or, if a solid preparation, in one avoir-

dupois ounce; and the provisions of section nineteen of chapter seventy-five of the Revised Laws shall apply to the manner and form in which such statements shall be marked or inscribed.

Section 3 states:

It shall be unlawful for any person to sell, or to expose or offer for sale, or to give or exchange, any patent or proprietary medicine or article containing cocaine or any of its salts, or alpha or beta eucaine or any synthetic substitute of the aforesaid.

These provisions do not apply to sales made at wholesale, to retail druggists or dental depots, or to physicians, dentists, or regularly incorporated hospitals. This act is to take effect Sept. 1, 1906.

MISSOURI.

Case Dismissed.—In the case of Dr. J. Clement, Kansas City, charged with practicing medicine without a license, the defendant was discharged on the recommendation of the assistant prosecuting attorney, May 2.

Would Enjoin State Board.—Dr. Caleb E. Mathis, Kansas City, appeared before the circuit court at Independence, April 30, and asked for a temporary order restraining the Missouri State Board of Health from revoking his license as a practicing physician.

Licenses Revoked.—The State Board of Health has revoked the licenses of Drs. Charles Palmer, Kansas City, and Mary E. Murphy, St. Louis, charged with criminal practice, and the license of Dr. Earl J. Dennis, St. Louis, charged with allowing another individual to impersonate him.

Personal.—Dr. H. L. Ebert has been reappointed clerk of the Kansas City board of health.——Dr. Albert Vogel has been appointed assistant dispensary physician of the St. Louis board of health.——Dr. and Mrs. John M. Brown, St. Joseph, have returned from Europe.——Dr. and Mrs. Jefferson D. Griffith, Kansas City, have returned after a three months' tour of Europe and Northern Africa.

Commencement Exercises.—The commencement exercises of the University Medical College, Kansas City, were held April 24. The baccalaureate address was delivered by Rev. C. C. Woods, St. Louis, and Dr. James E. Logan, president of the college, conferred degrees on a class of 49.——At the commencement exercises of the St. Louis College of Physicians and Surgeons, April 23, Dr. John C. Murphy delivered the faculty valedictory, and Dr. Waldo Briggs conferred degrees on a class of 56.

Health Board Appointment Held Up.—The committee on sanitation affairs of the St. Louis city council reported unfavorably on the name of Dr. H. McC. Johnson, recommended by Mayor Wells as a member of the local board of health. The committee explained that it was unacquainted with the physician, that he had been given plenty of time to call on the committee, but up to date he had not put in an appearance at any committee meeting. Final decision was deferred until next meeting, giving Dr. Johnson another opportunity to "come around and introduce himself to the committee." Dr. Johnson afterward received the appointment.

NEBRASKA.

Fined for Obstructing Justice.—Dr. James L. Gandy, Humboldt, was found guilty of obstructing justice and fined $500. He has filed notice of appeal.

Governor Requests Resignations.—Governor Mickey on May 8 called for the resignations of Dr. James M. Alden, superintendent of the State Hospital, Norfolk, and Dr. Frank Nicholson, his assistant, on account of friction which, it is claimed, has made it impossible for the institution to be conducted properly.

X-Ray Damage Suit.—In a damage suit at Center in which $6,000 damages were claimed for injuries alleged to have been received while being exposed to *x*-rays for the purpose of obtaining a skiagraph to locate a stone in the bladder, the jury brought in a verdict for the plaintiff, May 6, assessing the damage at $600 and costs.

Personal.—Dr. G. P. Stokes, an instructor in chemistry at Omaha Medical College, was seriously burned about the face and hands by an explosion of gasoline in the laboratory.——Dr. Simon C. Bedde, David City, has been appointed a member of the board of insanity for Butler County.——Dr. Robert C. MacDonald, Fremont, has been appointed local surgeon for the Great Northern System.——Dr. Voorhees Lucas has been made city physician of North Platte.——Dr. L. R. Craig, Mitchell, has been committed to the state asylum under the provisions of the new dipsomanine law.

Itinerant Practitioner Fugitive from Justice. "Dr." W. F. Munroe, an itinerant medicine vendor, calling himself a "Quaker doctor", was arrested in Humboldt, March 31, and trial was set for April 2. A change of venue was taken and the complaint was quashed on an alleged defect. New complaints were made before the county court and a new warrant issued. Thereupon "Dr." Munroe fled precipitately, but was apprehended in a neighboring town and held until service was obtained. He outwitted the officer in whose charge he was placed and escaped, crossing the river to Missouri. As the offense with which he was charged was not extraditable, he escaped by flight a possible fine of $350 and costs.

Hospital Notes.—The Swedish Alliance Home of Mercy and Bethany Hospital Association are raising $25,000 for a new hospital for Omaha, of which Dr. J. O. Nystrom is to be chief surgeon.——The South Omaha Hospital Association, on April 30, formulated plans for the raising of $40,000 for the construction of a new and modern hospital to accommodate at least 40 patients.——The contract for building the Wise Memorial Hospital, Omaha, has been awarded, the contract price being $67,500. The building will be a two-story and basement structure 150x75 feet.——The cornerstone of the Methodist Episcopal Hospital, Omaha, was laid May 24. Bishop Hamlin of San Francisco made an address and the governor of the state presided.

NEW YORK.

No Night Work for Children.—Governor Higgins has signed an amendment to the labor law providing that minors under 16 years shall not be employed in factories or mercantile establishments after 7 o'clock p. m.

Attempt at Arson.—An attempt was made to fire the laboratory of Dr. Edward F. Brush, Mount Vernon, May 13. When the fire was discovered the whole lower floor of the building was found to be saturated with kerosene.

New York City.

Chloroform and Crime.—The Medicolegal Society at its May meeting discussed the possibility of persons facilitating crime by the use of chloroform, and the various phases of the case against Albert T. Patrick were discussed.

Bay Pollution Bill Signed.—Mayor McClellan has signed a bill providing for a commission to consider means for protecting the waters of New York Bay from pollution. The commission will act in conjunction with a similar body from New Jersey.

Personal.—Dr. and Mrs. W. Whitehead Gilfillan and Dr. and Mrs. John G. Perry sailed for Europe on the *Königin Luise*, May 19.—Dr. Emil Heuel gave a dinner on May 16 at the New York Athletic Club in honor of Dr. E. Delgado, minister of foreign affairs of Salvador.

Ambulance Accident.—An ambulance belonging to the Williamsburg Hospital was struck by a street car at Driggs Avenue and South Third Street. The driver received probably fatal injuries and Drs. Rarick and Dangler were incapacitated for service for a considerable time.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended May 12, 1,068 cases of measles, with 32 deaths; 387 cases of diphtheria, with 34 deaths; 340 cases of tuberculosis, with 153 deaths; 56 cases of whooping cough, with 4 deaths; 32 cases of cerebrospinal meningitis, with 32 deaths; 27 cases of typhoid fever, with 9 deaths, and 90 cases of varicella, altogether 2,228 cases, with 294 deaths.

OHIO.

Dr. Haugh to Be Electrocuted.—Dr. Oliver Crook Haugh, convicted of the murder of his parents and brother, has been sentenced to be electrocuted August 29.

Fined for Illegal Practice.—"Dr." D. D. Brice, self-styled "Hindoo witch doctor," was fined $50 and costs in Columbus, May 2, for illegal practice of medicine.

Memorial Meeting.—The Cincinnati Academy of Medicine devoted its regular session of May 14 to memorials of the late Dr. Edward A. Crane, all of the business being relegated to future meetings.

Hospital Staff Election.—At the meeting of the official staff of Aultman Hospital, Canton, the following officers were elected: Dr. J. Frank Kahler, president; Dr. John P. Dewitt, vice-president; Dr. Frank W. Gavin, secretary, and Dr. Alonzo B. Walker, treasurer.

Guilty of Criminal Malpractice.—Dr. David P. Maxwell Cleveland, has been found guilty of performing a criminal operation, which caused the death of Celia Ritzer, Akron, and sentenced to imprisonment for three years in the penitentiary. Execution of the sentence has been suspended for 30 days in order that an appeal may be made to the circuit court.

Dermatological Society.—Dr. Meyer L. Heidingsfeld, Cincinnati, has been elected as the first president of the Ohio Dermatological Society. It was through the efforts of Dr. Heidingsfeld that the society was organized. Dr. E. Otis Smith, also of Cincinnati, was elected treasurer. The society decided to affiliate with the Ohio State Medical Association.

Personal.—Dr. Curtis Marquart, Osborne, is suffering from septicemia, due to a slight abrasion of the skin.——Dr. and Mrs. Charles G. Foertmeyer, Cincinnati, left for Europe May 7. ——Dr. William H. Humphreys, Yellow Springs, is seriously ill with pneumonia.——Dr. Estell H. Rorick, formerly superintendent of the Athens State Hospital and later superintendent of the Ohio Institution for Feeble-Minded, Columbus, has resigned.——Dr. Otto Huffman has been appointed pathologist of the Miami Valley Hospital, Dayton.——Dr. Nellis C. Satterlee, West Williamsfield, who recently underwent a grave surgical operation at Cleveland, is making a satisfactory recovery.——Dr. Fred A. Cobb has been appointed physician of the Toledo Workhouse, vice Dr. William V. Anderson.——Dr. John B. Kotheimer, Youngstown, has been seriously ill with heart disease.—Dr. Edward A. Montenyohl, Akron, has been elected first vice-president of the Ohio Dermatological Association.——Dr. Millard F. Hussey, Sidney, has been appointed a member of the board of trustees of the Lima State Hospital.

Commencement Exercises.—The fifty-ninth annual commencement exercises of Starling Medical College, Columbus, were held May 3. Attorney-General Wade H. Ellis made the address of the evening, and Dr. O. W. Huntington, president of the board of trustees of the college, presented the diplomas to a class of 30.——Cleveland College of Physicians and Surgeons, Medical Department of Ohio Wesleyan University, held its annual commencement exercises May 2, when addresses to the graduating class were given by Dr. Roland E. Skeel, dean of the college, Rev. Worth M. Tippy and Rev. Herbert Welsh, president of the university. A class of 24 was graduated.—— The fourteenth annual commencement exercises of the Ohio Medical University, Columbus, were held May 1. The principal address was delivered by Rev. J. Knox Montgomery, D.D., president of Muskingum College. Dr. William S. Van Fossen delivered the faculty address, and Prof. W. R. Lazenby, secretary of the board of trustees, conferred degrees on a class of 42. Dr. James U. Barnhill, chancellor of the university, presided.——The annual commencement of the Toledo Medical College was held May 13. President Charles W. Dabney, of the University of Cincinnati, delivered the principal address, on "Municipal Universities," and a class of 9 received diplomas.

PENNSYLVANIA.

Fever-Breeding Parasites Must be Destroyed.—It is the purpose of Health Commissioner Dr. Dixon to destroy the breeding places of mosquitoes in this commonwealth. The task will involve the examination of all places holding or capable of holding water in which the species can breed. Dr. Dixon has employed an expert entomologist to take up the work and map out all the malarial districts in the state. The report of the entomologist will give all conditions supplying the environment necessary to support the lives of the variety of mosquito which carry the poison from one person to another. That this work shall prove most economic, it is proposed that the country surrounding the larger centers of population be investigated and the most dangerous pools and streams be mapped out, starting with the built-up municipalities in the southern part of the state, where malaria is most prevalent. For the purpose of mapping the breeding places it is proposed that the United States geological survey maps be used.

Alienists' Meeting.—The meeting of the Association of Trustees and Physicians of State and Incorporated Hospitals for the Insane of Pennsylvania was held in the Pennsylvania Hospital for the Insane, May 17. Alienists from all parts of the state were present, and both the "county care" and "state care" systems were advocated by the speakers. Dr. John B. Chapin, superintendent of the Pennsylvania Hospital for the Insane, and Thomas C. Zimmerman, trustee of the Wernersville Hospital for the Insane, supported the state institution idea, while Cadwallader Biddle of the board of public charities favored "county care." Dr. Chapin read a paper on "The Care of the Indigent Insane in Pennsylvania." He said without being moved by our sympathies or emotions, it were well if some general agreement could be reached concerning the indigent insane. He would urge that the care of the insane be distinct and separate from that of the county poor who are not insane. He said that it is right to ask that the insane shall be regarded as subject to a condition of disease for which they should be placed under the care of physicians and not so-called wardens or keepers, who are often selected and changed solely according to the dictates of public opinion and not for any special fitness.

The School Vaccination Law.—The State Department of Health is much gratified over the opinion filed by Chief Justice Mitchell in disposing of the famous Waynesboro vaccination case. The people of Waynesboro openly defied the state authorities and, to a certain degree, prevented the enforcement of the vaccination law. The action was followed by litigation which was finally carried up to the supreme court. This tribunal not only sustained the right of the state health board to exercise police powers, but the opinion of Justice Mitchell takes a much wider sweep concerning the value of the statute, which requires that school children must be vaccinated before they shall be admitted to the public schools. The supreme court ruled that the act of 1895 requiring the exclusion from the public schools of children who have not been vaccinated, is a valid exercise of the police power of the state. Chief Justice Mitchell observed that the vast preponderance of opinion among intelligent and educated people is that vaccination is a highly useful ameliorative, if not always a preventive of one of the greatest diseases that has in times past afflicted humanity, and that the regulation of it by statute is not only justifiable, but a wise and beneficent exertion of the police power over the public health. It was emphasized by the Waynesboro contestants that there had been no smallpox in the community for 40 years and that, consequently, the people should not be required to provide by vaccination against possible occurrence of an epidemic. Concerning this Justice Mitchell stated that immunity for 40 years in the past affords no guaranty of immunity for even 40 days in the future, if a chance visitor from an infected locality or a borough resident returning from a visit to such a locality, should bring with him the germs of infection.

Philadelphia.

Bequests.—By the will of the late Laura V. Morrell, the Children's Hospital and the Methodist Hospital each receive $250.

Duehrssen Here.—Prof. Dr. Dührssen, the eminent surgeon, Berlin, Germany, visited this city May 19 and was entertained by Dr. Charles P. Noble.

Hospital Receives New Ambulance.—The Frankford Hospital has received and has put in commission the new ambulance donated by Mrs. Robert H. Foerderer.

Officers Elected.—At the organization meeting of the Northwest Branch of the Philadelphia County Medical Society, May 8, the following officers were elected: Chairman, Dr. Morris J. Karpeles, and clerk, Dr. Howard F. Geisler.

Personal.—Dr. and Mrs. George Fales Baker have returned home from Europe.——Drs. Hiram R. Loux and Robert O. Kevin sailed for Europe, May 19.——Dr. John H. Musser has been selected to deliver the oration on medicine before the Wisconsin State Medical Society, which meets in Milwaukee, June 27.

Examination Notices.—Civil service examinations by the civil service commission men will be conducted on the following dates for the positions named: Superintendent of Philadelphia Hospital, $3,000 a year; chief resident physician of Philadelphia Hospital, $4,000 a year; examination, May 28. Assistant chief resident physician, Municipal Hospital, $800 a year; outdoor physicians, allopathic, for district work, $360 a year; assistant chief resident physician, Philadelphia Hospital, $900 a year; assistant physicians, insane department, Philadelphia Hospital, $1,000 and $800 a year; examination, May 29. Instructor in massage, Philadelphia Hospital, $500 a year; examination, June 1. Milk inspectors, $1,020 a year; examination, June 4.

Health Report.—The total number of deaths reported for the week reached 567. This is an increase of 75 over the number reported last week, and an increase of 111 over the number reported in the corresponding week of last year. Tuberculosis of the lungs alone caused 76 deaths, the largest number in any week in five years. The death rate from typhoid fever was also large, the deaths numbering 31. The principal causes of death were: Measles, 4; scarlet fever, 4; pertussis, 12; diphtheria, 13; meningitis, 3; cancer, 23; apoplexy, 25; heart disease, 55; acute respiratory disease, 73; enteritis, 25; nephritis, 54; premature birth, 14; suicide, 3; accidents, 18, and marasmus, 7. There were 428 cases of contagious disease reported, with 48 deaths, as compared with 414 cases and 36 deaths in the previous week.

SOUTH CAROLINA.

Change of Location.—The office of publication of the *Journal of the South Carolina Medical Association* has been changed from Charleston to Greenville. Dr. J. Wilkinson Jervey is now editor of the *Journal*.

Specialist Acquitted.—In the case against "Dr." I. E. Crimm, Spartanburg, who was charged by the representative of the Spartanburg County Medical Association with violating the state statutes by practicing medicine without having been previously licensed, the magistrate on May 11 decided that the prosecution had failed to make out its case and discharged the defendant.

VIRGINIA.

Meningitis.—It is reported that Franklin, Va., is suffering from an epidemic of meningitis.

Memorial Tablet Unveiled.—A memorial tablet to the late Dr. W. A. Lyne, Jr., was unveiled at the Medical College of Virginia, May 15. An address was made by Dr. G. H. Bowman, representing the adjunct faculty of the college, of which Dr. Lyne was a member.

Semicentennial of Hospital.—St. Vincent's Hospital, Norfolk, celebrated its semicentennial, May 15. Among the distinguished guests were Cardinal Gibbons, Dr. Virgil P. Gibney, New York City; ex-Governor Montague of Virginia, and Dr. J. Allison Hodges, Richmond.

Commencements.—The University College of Medicine, Richmond, conferred degrees on a graduating class of 18, May 17. Dr. Stuart McGuire, president, gave the faculty address and Hon. St. George Tucker was the orator of the evening.——The commencement exercises of the Medical College of Virginia, Richmond, were held May 16; a class of 44 received diplomas.

Personal.—Dr. Otho C. Wright, Jarratt, has been appointed director of the Eastern State Hospital, Williamsburg.——Dr. Henry L. Cabell, Cedarville, is critically ill at a hospital in Winchester.——Dr. Walter A. Plecker, Hampton, has been reappointed health officer of Elizabeth City and County, and Drs. Harry D. Howe, Hampton, and George W. Vanderslice, Phoebus, have been made members of the board.——Dr. James H. Garlick, Petersburg, has been elected a member of the medical staff of the Western State Hospital, Staunton.

WISCONSIN.

Found Insane.—Dr. William H. Rowe, Waukesha, was adjudged insane in the county court, April 26, and committed to the Northern Hospital at Oshkosh.

License Refused. The State Board of Medical Examiners has refused to grant license to practice medicine to Dr. Edward Newton Flint, because the applicant admitted in his application that he advertised.

Autopsy Worth More Than Ten Dollars.—Judge Fruit has handed down a decision setting aside the action of the Monroe County board in cutting down the bills of Drs. J. Simonson and Charles E. Quigg for performing an autopsy from $50 to $10 each.

The Afflicted.—Dr. Morton K. Green, physician at the Mendota State Hospital, is suffering from appendicitis.——Dr. John R. Minahan, Green Bay, was operated on for appendicitis, March 27.——Dr. Matthew S. Hosmer, Ashland, is critically ill with septicemia.

Report Accidents.—The physicians of Milwaukee are complying with the law passed last year, requiring a report to the health department of every accident which results in incapacitating the injured from pursuing his vocation for two weeks or longer. An average of 175 cases a month has been reported thus far this year.

Seize "Patent Medicine." Under instructions from the United States revenue department, two United States marshals visited a store in Odanah, on the Red River Indian Reservation, and confiscated hundreds of bottles of patent tonics and preparations containing alcohol. The seizure was made under the law which prohibits the sale of liquor on Indian reservations.

Commencement.—The thirteenth annual commencement exercises of the Wisconsin College of Physicians and Surgeons, Milwaukee, were held May 16. Rev. James C. Hodgins delivered the baccalaureate address, and Dr. A. Hamilton Levings conferred diplomas on a class of 15. At the annual banquet, which was held at the Republican House, Dr. Gustave A. Kletzsch presided as toastmaster.

Joint Meeting.—At a joint meeting of the Northwestern Wisconsin Medical Association and the Portage County Medical Society, April 17, the following officers were elected: Dr. Karl W. Doege, Marshfield, president; Dr. Daniel R. Freeman, Colby, vice-president; Dr. Carl von Neuport, Jr., Stevens Point, secretary and treasurer, and Drs. Levi H. Pelton, Waupaca, George M. Steele, Oshkosh, and Douglas L. Sauerhering, Wausau, censors.

Get License to Practice.—Dr. R. A. Burg, who was refused a diploma and license to practice by the State Board of Medical Examiners on the ground that he was deficient in preliminary education and asked for a writ of mandamus, directing the Milwaukee Medical College and State Board to issue a diploma and license, has had the case decided in his favor by the supreme court and a diploma and license to practice have been granted. The same decision affects six other graduates of the college.

Personal.—Dr. Chester M. Echols, Appleton, has moved to Milwaukee.——Dr. and Mrs. Alexander C. Fraser, Manitowoc, celebrated the twenty-fifth anniversary of their wedding, May 4.——Dr. J. Nicephore Aubin, mayor of Peshtigo, has resigned. ——Dr. and Mrs. William H. Judd, Janesville, have returned after a trip to Cuba.——Dr. Gerhard A. Bading has been appointed health officer of Milwaukee.——Dr. John F. Farr has been elected health officer of Eau Claire.——Dr. Lawrence H. Prince, for many years physician in charge of the Palmyra Springs Sanitarium, has gone to Madison, where he will engage exclusively in surgical work. Dr. Searle succeeds him at the sanitarium.

Tuberculosis Exhibit.—Extraordinary popular interest has been aroused in Milwaukee by the tuberculosis exhibit, which was open to the public from May 3 to 19 inclusive, under the auspices of the National Association for the Study and Prevention of Tuberculosis and the tuberculosis commission of the Milwaukee County Medical Society. The collection included the extensive traveling exhibit of the former society and the pathologic collection of the state veterinary, Milwaukee health department, Milwaukee County Hospital and Milwaukee Medical Society. Models and plans for the proposed pavilion for the Milwaukee County Hospital and County Insane Hospital, and plans for the proposed sanitarium for tuberculosis, to be erected at Wales, Waukesha County, were also on exhibition. Popular lectures were given every afternoon by local physicians, and altogether 65,000 people visited the exhibition.

CANADA.

Personal.—Dr. Don. Armour, Toronto University, 1894, and for some time senior demonstrator of anatomy at Rush, has been appointed senior assistant surgeon in the National Hospital, London, Eng.——Dr. A. H. Tuerner of Milton, Ont., has been appointed medical superintendent of the Vancouver General Hospital.

Hospital News.—Grace Rescue Hospital, recently erected by the Salvation Army in Winnipeg, was formally opened May 15. ——Increased accommodation has recently been provided at the Toronto Free Consumption Hospital, which treats advanced cases of the disease. Plans are executed for two other cottages soon to be gotten under way.——The quarterly meeting of the governors of the Montreal General Hospital was held April 15. During the first three months of the present year the hospital treated 751 patients. Fifty-two deaths occurred. The outdoor work showed an increase of 672 consultations over the corresponding quarter of last year.——The Toronto Emergency Hospital, which was established eight years ago, has been closed.——Lord Strathcona has donated $25,000 to the Alexandra Hospital for Contagious Diseases, Montreal and $200 to a new hospital at Virden, Man. ——The Montreal Dispensary treated 19,195 patients during the past year. Of these cases 9,077 were general diseases; 2,366 diseases of the eye and ear; 1,333 diseases of women; 671 diseases of the nose and throat; 2,771 diseases of the skin; 2,827 diseases of children, and 210 dentistry cases.——The Alexandra Hospital, Montreal, will be ready for occupation in ten days. The medical superintendent, Dr. J. C. Fyseche, has just returned from Boston. Appointments to the staff have been made as follows: The three representatives from the Montreal General Hospital are Drs. Blackader, Latleur and H. D. Hamilton; from the Royal Victoria Hospital, Drs. C. F. Martin, W. F. Hamilton and Beckett; from the Western Hospital, Drs. McConnell and Grant Stewart.

SAN FRANCISCO.

Devise Means for Relief.

Nearly 500 members of the medical profession attended the meeting held May 10 in the auditorium of Cooper Medical College, San Francisco, to devise means for assisting licensed practitioners who lost their homes, offices, books, records and instruments in the earthquake and fire. A resolution was passed asking the San Francisco County Medical Society to reduce its dues to a nominal sum for the next year and to allow all licensed physicians an opportunity of becoming members. A representative from the Santa Clara County Medical Society thanked the assembly for its offer of aid, and said that he was delegated to offer what services he could on behalf of the organization.

Relief Fund.

The California medical relief fund in St. Louis amounts to $908.——Members of the Pasadena Branch of the Los Angeles County Medical Society have thus far contributed $145 toward the relief of their San Francisco brethren.——Smith County (Texas) Medical Society has collected $8 for the San Francisco physicians.——Columbia County (Pa.) Medical Society, at a recent meeting, decided that as a society it would contribute to the relief of San Francisco physicians.——The Southwestern Kentucky Medical Society, at its meeting, May 8, contributed $100 for the San Francisco sufferers.——The Oklahoma and Indian Territory Medical Association, at its meeting May 9, contributed $100 for the San Francisco physicians.——Lehigh County (Pa.) Medical Society has donated $25 to the San Francisco fund.——The Grand Forks (N. D.) District Medical Association has voted $100 for the relief of the practitioners of San Francisco.——At the meeting of the Ohio Medical Association, May 9, aid was voted to the San Francisco sufferers.——The Medical Club of Brooklyn has voted $100 to be sent to the relief of the practitioners of San Francisco, and individual members of the club have contributed an additional $400.——The McLean County (Ill.) Medical Society on April 25 sent a contribution of $90 to Dr. Devine, representative of the American Red Cross, requesting it to be turned over to the proper officers of the Medical Society of San Francisco.

Hospital News.

St. Mary's Hospital, San Francisco, is to be rebuilt, but on a new site. The patients in this hospital were saved by being transferred to a river steamer, and then provided with accommodations in tents on vacant pieces of land owned by the hospital.——At a meeting held May 9, the Agnews Hospital board of trustees resolved to ask the governor for special aid through legislative enactment for sufficient money to put the hospital in condition necessary to meet the present exigencies.

CALIFORNIA RELIEF FUND.

The committee, the complete list of which we printed last week, representing the medical profession of San Francisco, the county and state societies, Thomas W. Huntington, chairman, and Emmet Rixford, treasurer, will not only attend to the receipt and proper distribution of funds, but will gladly receive books and instruments as well. Considerably more than half the physicians of San Francisco lost their medical libraries and all of their instruments and office equipment. The necessity of providing essential instruments as soon as possible will be apparent, and the secretary of the state society, too, has asked all who may be able to contribute from their stock of instruments, to send what they can spare to the relief committee. Shipments should be made to Dr. Emmet Rixford, Lane Hospital, corner of Webster and Clay Streets, San Francisco. The more generally used reference books will also be very welcome contributions. As soon as possible the library of the county society is to be re-established and the donations of journals and medical books of all sorts will be gladly received.

Pennsylvania.

The following amounts have been contributed by the physicians of Pennsylvania:

Philadelphia County Medical Society	$ 200.00
Contributions by individual members in addition to the above	1,136.00

GENERAL.

National Confederation of State Medical Examining Boards.—This association will hold its annual convention in Boston, June 4. The address of welcome will be delivered by Dr. Walter P. Bowers, Clinton, on behalf of the Massachusetts Board of Registration in Medicine. Members and ex-members of state medical examining boards, and physicians and educators who are interested in the cause of higher education, are invited to attend.

Railway Surgeons' Meeting. The surgeons of the St. Joseph & Grand Island Railroad held their annual meeting in St. Joseph, Mo., May 3. Dr. George C. McKnight, Hiawatha, Kan., was elected president; Dr. Charles H. Suddarth, Smithville, Mo., vice-president, and Dr. Luther V. Todd, St. Joseph, secretary and treasurer. The next meeting will be held at Hiawatha, Kan., in November.

American Therapeutic Society.—At the seventh annual meeting of this society, held in New York City, the following officers were elected: President, Robert Reyburn, Washington, D. C.; vice-presidents, Joseph E. Janvrin, New York, Frederick H. Gerrish, Portland, Maine, Howard van Rensselaer, Albany, N. Y.; secretary, Noble P. Barnes, Washington, D. C.; treasurer, John S. McLain, Washington, D. C. The next meeting of this society will be held in Washington, May 4-7, 1907.

American Climatological Society.—At the twenty-third annual meeting of this Association, held at Atlantic City, May 12-14, the following officers were elected: President, Thomas Darlington, New York; vice-presidents, Frank Fremont Smith, Washington, D. C., and C. L. Minor, Asheville, N. C.; secretary and treasurer, Guy Hinsdale, Hot Springs, Va. Dr. E. L. Trudeau, Saranac Lake, and Dr. Leonard Weber, New York, were elected honorary members. The next meeting will be held in Washington, D. C., in May, 1907.

American Academy of Medicine.—The thirty-first annual meeting of the American Academy of Medicine will be held at the Hotel Brunswick, Boston, June 2 and 4, immediately preceding the session of the American Medical Association. The president, Dr. Donly C. Hawley, Burlington, Vt., will deliver an address on "Heredity and Environment as Causes of Delinquency and Crime." At the Monday session a symposium will be held on the subject, "How May the Medical and Teaching Professions Co-operate to Improve the Moral, Mental and Physical Conditions of the Young?"

Pathologists and Bacteriologists Meet.—The American Association of Pathologists and Bacteriologists met in Baltimore, May 18 and 19. There were about 100 in attendance. The meeting was held at the Johns Hopkins Medical School. The next meeting will be held at Washington. The following officers were elected: President, Dr. William H. Welch, Baltimore; vice-president, Dr. Alfred S. Warthin, Ann Arbor, Mich.; secretary, Dr. Harold C. Ernst, Boston; treasurer, Dr. H. U. Williams, and council, Drs. Richard M. Pearce, Albany, N. Y.; James Ewing, New York City; Frank B. Mallory, Boston; Ludvig Hektoen, Chicago, and William T. Howard, Jr., Cleveland.

Association of Medical Officers of the Army and Navy of the Confederacy.—The ninth annual meeting of this organization was held in New Orleans, April 25-26, the president, Dr. Charles H. Todd, Owensboro, Ky., in the chair. Dr. Ernest S. Lewis, New Orleans, delivered the address of welcome, in which he alluded in eloquent terms to the work of the Confederate surgeons in saving lives on the field of battle and in preserving them for service in the ranks. Dr. Charles W. P. Brock, Richmond, Va., responded on behalf of the guests. The following officers were chosen to serve during the ensuing year: President, Dr. Ernest L. Lewis, New Orleans; vice-presidents, Drs. Robert Y. Rudicil, Tryon Factory, Ga.; William F. Beard, Shelbyville, Ky.; Dr. Thomas E. Pruett, Tennessee, and Dr. James D. Croom, Maxton, N. C.; secretary and treasurer, Dr. Deering J. Roberts, Nashville, Tenn. (re-elected).

Plague-Infected Rats in Manila.—Dr. Heiser, chief quarantine officer, reports that for the first time in over a year plague-infected rats have been found in Manila. The rodents so far found to be infected were obtained from the district of Binondo in the Chinese quarter. The bureau of health is having the infected district thoroughly cleansed and disinfected. Rat catchers have been employed for the purpose of ridding that section of its rats so far as possible, and also for the purpose of ascertaining the extent of the disease among them. No cases of human plague have occurred in that particular district for nearly two years, and that locality has never been classed among those sections of the city most likely to be infected. If the views with regard to rat plague expressed by the leading Japanese medical authorities are correct, Dr. Heiser states that there should be an outbreak of human plague in the district of Binondo in from six weeks to two months.

FOREIGN.

Directorship of Senn Laboratory in Siam.—Dr. Paul G. Woolley, formerly of the Government Laboratories, Manila, P. I., has assumed the directorship of the Siamese Government Senn Laboratory, which is located at Phrapatom.

The Virchow Statue.—The design for the memorial to Rudolf Virchow at Berlin which won the first prize represents a titan struggling with a sphinx. This portrays the struggle between Virchow, the giant of science, and the riddle of the origin of disease. The bronze group stands on a marble pedestal which bears Virchow's portrait in a bronze relief.

International Conference of Red Cross Societies.—The *British Medical Journal* announces that arrangements have been completed for the third international conference of the societies of the Red Cross at London, June 10, 1907. These conferences are held every five years. The first was held at Vienna in 1897, when 184 delegates were present, and the second at St. Petersburg in 1902, with 132 delegates.

Hospital Ships.—It is reported that an English syndicate is being formed in Austria for the purpose of building a fleet of hospital ships to cruise in the Adriatic Sea, as that climate is supposed to be unusually beneficial to invalids. Each ship will have accommodations for 180 patients. The voyages will not follow any prearranged routes, but will be directed only with regard to the most favorable climatic conditions.

Tilanus Medal Awarded to Bolks.—The Amsterdam correspondent of the *Wiener klin. Rundschau* for April 29 states that the gold Tilanus medal was given this year to Professor Bolks for his researches in anatomy. He is one of the younger set, and has been professor of anatomy at Amsterdam for a few years. His most important work has been the supplying of a morphologic basis for Sherrington's theory of physiologic segments. The medal in question was founded by the local medical society in memory of C. B. Tilanus, the eminent surgeon. It is awarded every fifth year for special achievements in surgery or the allied sciences.

Insurance Against Professional Infection with Syphilis.—The Breslau Dermatological Society has taken up this question and is seeking information as to the way in which insurance societies are treating their medical policy-holders who contract syphilis in the practice of their profession. It seems that at present the insurance societies manage to escape paying the indemnity on some technical grounds in many instances, and concerted action is necessary to enable physicians to obtain their rights and more favorable conditions. Those with any experience or knowledge in the matter are requested to confer with the secretary, Dr. M. Chotzen, Breslau XVIII, Landsbergerstrasse 1, Germany.

Medical Men as Electors for the Russian Douma.—A St. Petersburg exchange states that 32 per cent. of the electors chosen to select the members of the Douma belong to the ranks of university medical teachers and 6.2 per cent. to physicians in general. It states further that the national medical society, the Pirogow, has collected data which show that 288 medical men or women have been involved in the more recent repressional acts of the government. This includes 13 physicians killed or wounded, 155 arrested and banished, and 24 dismissed from official service. The veterinarians have also contributed 20 arrested or dismissed and 16 "feldschers" have also been arrested. Five additional physicians are mentioned as still more recently banished from their homes.

International Congress for Medical Electrology and Radiology.—The third international congress of medical electrology and radiology was to have been held at Amsterdam in 1905, but was postponed on account of the Roentgen jubilee congress at Berlin the same year. It has now been decided to hold the international gathering at Milan, Sept. 5 to 9, 1906. Among the subjects on which addresses have been promised are "Laws of Electrical Stimulation of Nerves," "Excitability of Various Muscles and Nerves," "Electricity in Treatment of Cutaneous Affections," "Treatment of Surgical Tuberculosis with High-Frequency Currents," "The Fundamental Principles of Modern Electrotherapy," "Measurement of Faradic Currents," "Stereoscopic Radiography," "Treatment of Carcinoma," "Radium as a Therapeutic Agent" and "Present Status of Phototherapy." An exhibition of electrical appliances, etc., will supplement the congress. The fee for the congress is $5.00 for regular members and $2.50 for associates. Dr. Luraschi of Milan, via S. Andrea 11, is the secretary, and Bozzolo of Turin has been appointed president.

Sixth International Congress for Criminal Anthropology.—The name of Cesare Lombroso is indissolubly connected with the science of criminal anthropology, and it was fitting that this sixth congress should be held in his home city and on the fiftieth anniversary of his entry into his professional career. The congress opened April 28 at Turin, where Lombroso has been professor of legal medicine and psychiatry since the early sixties. He was presented with albums containing autograph greetings from the profession at home and abroad, and the city of Verona gave a gold tablet. Lombroso presided, speaking in French, and Van Hamel and Magnaud were appointed honorary presidents, with Max Nordau, Tamburini, Sommer of Giessen, Sergi, Ottolenghi and others. The second day of the congress was devoted entirely to inspection of the prisons and insane asylums under Lombroso's guidance. His main address was on the relations between sexual psycopathies and criminality. A *Festschrift* has been published by Boccha of Turin, containing articles by 29 of the leading men in the science, discussing the ideas and works of Lombroso and their practical application.

Professional Secrecy in Case of a Crime.—A physician in Holland was recently fined by the authorities because he had failed to notify them in regard to a supposed crime. The circumstances were that he was called to attend to a man, a stranger to him, who had died suddenly. There was a small bullet wound in the skull and an odor of hydrocyanic acid in the room. He made out the death certificate, stating "Cause of death unknown." He was arrested for false testimony, the authorities affirming that it was his duty to have stated the suspicions circumstances attending the death. An Amsterdam letter in the *Wiener klin. Rundschau* for April 29 states that the physician allowed the time limit for appeal to a higher court to lapse, but later presented a plea and argument to the minister of justice, saying that professional secrecy is an institution in the interests of the public and not in the interests of physicians themselves. Every one at any time and without apprehension should be able to appeal for medical help, even when a crime has been committed or attempted. This would be impossible if the decree of the first court should stand, compelling physicians to serve as officers of justice.

Medical Fees in Case of Railway Accidents.—Two years ago a large number of persons were injured in an accident on one of the government-owned railroads of Belgium. Physicians were summoned from the vicinity to treat the wounded, and in many cases they had to continue their care for days or weeks. The government is, of course, pecuniarily responsible for their remuneration, and the charge presented for their services was according to the standard rate for middle-class patients. The government has refused to pay them at this rate, claiming that as the majority of the injured belonged to the working classes, remuneration should be according to the wage-earner's scale. The *Gazette Médicale Belge* comments that in future physicians summoned to the scene of an accident will be liable to be tempted to attend first to the better dressed wounded—if such a graduated scale of remuneration is sanctioned—and leave the wage-earners to the last. Physicians will not do this, the editorial adds; the claims of the most seriously wounded will always take precedence, but the lawsuit brought by the officials of the railroad companies to adjudicate the claims of the physicians does them little honor. The case has not yet been decided.

Twenty-third German Congress for Internal Medicine.—Nearly 600 physicians gathered at Munich, April 23, for this annual meeting of the leading men in internal medicine and their followers. Notwithstanding the clashing of dates with the international congress at Lisbon, a number of prominent foreigners were present, including Knud Faber of Copenhagen, Osler from Oxford, and Talma and Heilbronner of Utrecht. From the reports in our foreign exchanges we should judge that the most interesting and important feature of the congress was the evidence presented in respect to the curability by operative measures of exophthalmic goiter. Kocher of Berne has performed 3,000 operations on the thyroid gland, including 216 cases in which he operated on account of exophthalmic goiter. Of this last group 72 per cent. of the patients have been entirely cured. In the early stages, he asserted, rest, a milk and vegetable diet, the milk of thyroidectomized goats and administration of phosphates are liable to induce material improvement, but radical treatment is by ligation of the vessels and, possibly, resection. In affections due to inadequate functioning of the thyroid, the only radical treatment is by implantation of a sound thyroid gland. He presented the subject in a masterly manner, preaching the curability of exophthalmic goiter by operation and the necessity for early interference. He was invited to present the same address in London this week. The addresses and discussion of the thyroid gland and its problems was a notable symposium by 22 of the leading internists of Germany and Switzerland. Hönicke reporting that he had succeeded in inducing experimental exophthalmic goiter in dogs by feeding them with thyroid gland extracts. Most of the other papers read were on the problems of metabolism, physiologic chemistry, physiology of the heart, anatomy of the auriculo-ventricular bundle, and similar topics, only a few being devoted to treatment. The almost entire absence of communications in regard to immunity, bacteriology and pathologic anatomy is a commentary on the trend of the present moment. The *Muenchener med. Wochft.* invited the members of the congress and ladies to a gala presentation at the Opera-house of Mozart's "Cosi fan tutte", and distributed its annual burlesque number at the banquet at the close of the congress. The correspondent of the *British Medical Journal*, commenting on this congress, remarks: "The transactions of these congresses for the past 22 years reflect as perhaps no other series the remarkable evolution of clinical research. Looking over the volumes one is

impressed by the sense of responsibility shown by the leaders of the profession in Germany—men who have made their mark, and yet, year by year, faithful to their trust, they spend the three or four days in intellectual commerce with their compeers and in social fellowship with the younger workers and with the more important of the general practitioners of the country. It is impossible to overestimate the advantages of such an annual gathering. Alike to young and old, it is an inspiration; to its stimulus may be attributed not a little of the intensity and thoroughness which to-day characterize German medicine."

LONDON LETTER.

Action Against a Physician.

An action against a physician has been brought under peculiar circumstances, which illustrate the uncertainties of the law, against an Irish physician. The object was to recover $1,250 for injuries said to have been sustained by a youth in consequence of negligence. The case had been tried previously at the County Antrim assizes. On the first occasion the jury disagreed. On the second they found a verdict for the defendant. Against this decision the plaintiff appealed and a new trial was granted on the ground that there had been misdirection on the part of the judge. The plaintiff suffered from mumps which was complicated with orchitis. On April 4, 1904 (a Monday), the defendant was asked to see him. He recommended the use of a splint or failing that a cushion. He also prescribed an application consisting of equal parts of belladonna and soap liniments. The instructions were "to be applied as directed." He ordered the friends to keep the lotion sprinkled on lint and to lay it on the part, and promised to see the boy again on Thursday. The cushion was made, the liniment was applied, and on the following morning the flesh was blistered and inflamed. Notwithstanding, the liniment was still applied. On April 6 the boy was so ill that the physician was sent for, but as he was away from home another had to be called in. The latter found the boy suffering from belladonna poisoning. The defendant denied that he ordered the treatment to be continued until Thursday and said that he told the patients at once to seek advice in the locality, as he lived at a distance, if the case did not progress favorably. Medical evidence was given that the directions of the defendant were what was usual in the profession; but two of the witnesses admitted in cross-examination that it would be prudent to caution people to use care in the application of belladonna liniment. The jury brought in a verdict for the plaintiff and awarded him $325 damages. The plaintiff gave notice of appeal on the ground of misdirection.

Baron Takaki at St. Thomas' Hospital.

Baron Takaki, formerly Director General of the Medical Department of the Imperial Japanese Navy, has delivered a series of three lectures on "The Preservation of Health Among the Personnel of the Japanese Navy and Army." Mr. Wainwright, the treasurer of the hospital, who presided, said they were all proud of Baron Takaki, because he came as a student to St. Thomas' Hospital in 1874 and greatly distinguished himself there, winning all the prizes he possibly could, including the Cheselden medal for surgery and the treasurer's gold medal. Baron Takaki's lectures covered similar ground to those which he recently delivered in America. He was accorded a most enthusiastic reception by a large audience, consisting of the staff of physicians and students of the hospital. He deprecated the fact that so many Japanese students went to Germany to complete their education and expressed a preference for the English schools, and promised that he would use his influence in favor of the latter. Incidentlly, he mentioned that he was made director general of the medical department of the navy at the age of 37, while in this country he believed that men were not promoted to responsible positions until they were bald or gray, a statement which was received with much laughter.

The Open-Air League.

Another association, "The Open-Air League," has been added to those which are engaged in the crusade against consumption. It has received the support of several eminent physicians and persons of high social position. Its object is to enlist a vast army, who by house-to-house visitation and by the advocacy of the open window, will reach the poor in a manner never before practiced in England. It is the intention of the league to establish on inexpensive lines sanatoria for the early treatment of consumptive poor, and it is hoped that working men and women will join the league as associate members at a subscription of 60 cents per annum, in return for which members of their families will receive concessions in the cost of sanatorium treatment. The league proposes to educate the public regarding the advantages of the open window in the prevention and cure not only of consumption, but of many other diseases, for which purpose lectures, pamphlets and skilled house-to-house visitation will be employed. Provision will be made for the after-care of cured patients by the establishment of industrial farm-sanatorium colonies. A register will be kept of patients who have successfully undergone the open-air treatment and who are in search of suitable outdoor occupation and also a register of persons willing to engage workers of this class. Open-air methods will also be advocated for schools and public buildings and pupils in training colleges for teachers will be instructed in the advantages of the open window in the school room.

Polluted Water of the East End of London.

FROM AN OCCASIONAL CORRESPONDENT.

American cities have long held an unenviable reputation with regard to the quality of their water supply. Of course, in almost every instance, so far as quality has been concerned, there has been no cause for complaint. Some of the large centers of population in the United States have been actually stigmatized and have become almost a by-word on account of the bad quality of their drinking water. Typhoid fever has been rife and has been traced directly, in the majority of instances, to a polluted water supply. Fortunately, of late a great change has come over the situation in this respect. Public sentiment has been profoundly stirred and municipalities everywhere have been exerting themselves in the effort to procure as pure a water supply as possible. The results of this enlightened policy have already been plainly apparent. In certain cities and localities in which formerly typhoid fever was somewhat of a scourge the disease has wholly disappeared or has only manifested itself in the form of a few sporadic cases, and it is more than likely ere many years have elapsed that, instead of being behindhand in questions relating to water supply, the cities of America will lead the world. Their advantages, as a rule, are obvious, and when all opportunities are seized their water supplies should be second to no cities of the world. For a considerable period Great Britain has been in the van in regard to all sanitary matters. She was first in the field and her municipal authorities were pioneers in this branch of preventive medicine. In fact, public health has been the strongest feature of British municipal government. Of recent years, however, signs have been evident that the cities and towns of the United Kingdom have been losing, to some extent, their exalted position as models of sanitation among the countries of the earth. The German municipalities, in particular, have taken a "leaf from the book" of British sanitarians and now excel their masters.

Especially were British cities renowned for pure water supplies. Frequently the quantity was insufficient, at any rate insufficient as measured by generous American standards, but the quality was considered above reproach. London has often had cause to complain of a scant supply of water, but until recently no serious reflections have been cast on its purity: that is to say, it was believed to contain few, if any, disease-bearing germs. Within the past few months there has been a rude awakening from this contented state of mind. Indeed, water experts have for some time recognized the fact that water consumers in certain districts of London are in a situation of the gravest danger, and with a view of obviating this danger the London water board had brought in a bill to be presented to parliament for the purification of the water supply of the east end of London. For some unknown cause this bill has been suddenly dropped, and in consequence a feeling almost of consternation has been produced among water experts of the British metropolis.

Sir Alexander Binnie, who was formerly chief engineer to the London County Council, stated at a public dinner a short time ago that a time would come, if the present state of things continued, "when there will arise among the teeming millions of London an epidemic which will startle the world." The same authority, in the course of an interview, said: "The condition of things in the east end of London is in the highest degree perilous, and one morning the inhabitants of that section may wake up to find themselves plunged in as serious an epidemic as that which visited Hamburg a few years ago owing to the consumption of the polluted waters of the Scheldt. This part of London, comprising about one-third of the entire population of the metropolis, draws its drinking water from the mains of the old East London water company; the water is drawn from the River Lea."

The River Lea is terribly polluted, about 2,000,000 gallons

of crude sewage per diem being discharged into the river at no great distance whence the water is extracted, the supplies taken amounting to 32,000,000 gallons a day.

There is no doubt that the water supply of the east end of London is at present a menace to the whole community. The remedy suggested is that a supplemental supply should be obtained from the Welsh lakes, a distance of more than 150 miles. The supply of London is notoriously inadequate, and, despite the fact that all water before being used is passed through sand filters, it would seem to have been proved to be dangerous to health as well. It goes without saying that no expenditure should stand in the way of providing London with a pure water supply. In the past America has learned most of her lessons in sanitation and in public health from Great Britain; in the future it is more than probable that the positions will be reversed.

Pharmacology

Subsidized Medical Journals.

"CANNED EDITORIALS."

Three or four weeks ago the Antikamnia Chemical Company sent a letter to some of the medical journals in which the American Medical Association, THE JOURNAL of the American Medical Association, *Collier's Weekly* and the *Ladies' Home Journal* were discussed in very harsh and uncomplimentary terms, as might be expected, considering the source of the letter.

Now there was nothing to indicate that the letter was sent to any other journal than the one receiving it, and consequently some of our editorial friends were led astray. One of these was the editor of the *Southern Practitioner*. In the May number that journal has one editorial; but it is a long one, much longer than the editorials usually found in that journal. It bears the caption, "As to Proprietary Medicines," and is introduced with this sentence:

"The bitter and selfish fight made by THE JOURNAL of the American Medical Association, some of its satellites, and a few lay papers, on pharmaceutical preparations, has degenerated to a point where misrepresentation and positive mendacity have become their chief stock in trade."

As these were the identical words that formed the first sentence of the Antikamnia letter, we compared the two, and lo, the editorial was the letter *in toto*, practically. To be sure, here and there a word or phrase was modified and some comments added at the end, but otherwise the letter and the editorial are the same. For instance, the letter said:

"Knowing that we had little to fear from anything truthfully said of Antikamnia or any of the coal-tar preparations"; but the editorial had it:

"Knowing and believing that right in the end would prevail." This is better, and makes it easy to drop a give-away word.

Farther down the editorial it reads: "Yet *Collier's*, assisted by THE JOURNAL of the American Medical Association", whereas the letter had it: "Yet *Collier's*, assisted by the American Medical Association." Evidently the editor of the *Southern Practitioner* wanted to hit THE JOURNAL a rap, rather than the American Medical Association, which was not kind on his part. "Millions on millions of pounds of the coal-tar preparations" is the way the letter put it, but the editorial was not so reckless in statement, as it said "numbers of pounds."

The concluding paragraph of the letter was not incorporated in the editorial. It is as follows:

"We write you at length to make plain to you just what is being done to injure coal-tar preparations and to show the depths to which seemingly reputable business and professional men will sometimes descend to accomplish a purpose beneficial to themselves.

"If you can see your way clear to assist in counteracting the injustice being done you will greatly oblige."

It will be noticed that the closing sentence is not a command, but a request "to assist" in "counteracting the injustice being done."

The editor adds some original remarks of his own, which he introduces with:

"We have used freely antikamnia in our remarks," whereas the word "antikamnia" appeared only once in the editorial. The writer forgot that, in transposing the letter into the editorial, "antikamnia" had fallen by the wayside once or twice. The last part of the editorial—the really truly original part of it—is devoted to praising Fellows' syrup of hypophosphite, Robinson's hypophosphites, tongaline, bromidia, iodia, papine, echthol, Gray's glycerin tonic, Hayden's viburnum compound, Wayne's elixir, antiphlogistine, listerine, glyco-heroin, glycothymoline, cystogen, etc., and, of course, abusing the editor of THE JOURNAL of the American Medical Association, which nowadays is a very common pastime with some medical editors.

Evidently it is intended that the Antikamnia letter shall be well circulated among the profession of the country. The *Southern Practitioner* for May was no sooner off the press than reprints of its "editorial" were scattered broadcast. The reprint is entitled, "As to Proprietary Medicines, by Deering J. Roberts, M.D., Reprint of leading editorial in the *Southern Practitioner*, Vol. XXXIII, No. 5, May, 1906." "Leading editorial" is good. Detail men of certain nostrum houses are distributing this reprint to physicians, in connection with their samples.

"To what depths will we mortals fall to win our point!"

THE AMERICAN MEDICAL COMPEND ALSO.

But while the *Southern Practitioner* is the worst sinner up to present writing, others to be heard from—in that it published the complete letter minus the closing paragraphs, the *American Medical Compend* of Toledo, Ohio, is not far behind. This journal obeys the injunction "to assist" by transferring the greater portion of the antikamnia letter, word for word, without credit or quotation marks, into its editorial pages as an original editorial. But it does introduce the editorial with three or four actually original sentences:

"Apparently a selfish fight is being made by some," says the editor, "against the use of coal-tar preparations, and they carry it so far as to condemn what we know from personal experience" (the editor is given as W. W. Grube, A.M., M.D., professor of physiology and clinical medicine, Toledo Medical College; it is to be hoped he is not the one who wrote these introductory sentences, or that he is not endorsing antikamnia), "to be good and valuable remedies. There must be no misrepresentation as the profession will not tolerate it." The last sentence should be read twice, keeping in mind that all that follows in the long editorial is—the antikamnia letter. There is no hint that it is not an original editorial of the editor of the *American Medical Compend*.

THIS TIME IT IS AN ANONYMOUS LETTER.

The *Atlanta Journal-Record of Medicine* takes it up differently. The antikamnia letter in this instance is put into the editorial department, double leaded, but under the caption "A Letter." It is, of course, not signed; the readers are kept in blissful ignorance of the author; they might naturally conclude that some disgruntled subscriber had gone back on his fellow-practitioners and had turned to the defense of the "patent-medicine" men. One short paragraph in the body of the letter is omitted, and the concluding paragraph in which the journal is asked "to assist" is kept from the reader.

By the way, this number of the *Atlanta Journal-Record of Medicine* devotes sixteen editorial pages to the defense of nostrums. Besides the antikamnia letter it quotes nearly all of the pamphlet sent to newspapers entitled "Legislative Schemes of the American Medical Association"; also another article

circulated by the Proprietary Association of America, "The Mendacious Campaign Against Domestic and Proprietary Remedies," which is an attack on *Collier's* "Great American Fraud" articles.

IF NEWSPAPERS, WHY NOT MEDICAL JOURNALS?

The "patent-medicine" men's association has a very effective press committee, which prepares and furnishes to such newspapers as are under the control of that association, material to be used to influence public opinion in favor of "patent medicines." As this material is usually attractively presented and readable, it is a great temptation to editors to print it as received rather than to transpose the arguments into their own words. This is the reason that the same editorials defending "patent-medicine" appear in newspapers all over the country. This press committee, therefore, is a great labor-saving device for the weak newspapers that are willing to be used by their supporters.

If newspapers can do this—can use as original the material furnished them—why can not medical journals? They can. They do. But as there is no real central press committee to act for the "ethical" nostrum manufacturer, some of them are doing it for themselves, as the Antikamnia Company, with its letter to the medical journals. As a member of the Proprietary Association of America that company learned how to do it.

And the medical journals are even more willing to aid the "ethical" nostrum men than are the newspapers to aid the "patent-medicine" men. As the former have no press committee, certain medical journals are working up their own material, and then sending it around for others to copy. For instance, we have before us "advance sheets of editorial pages of *Medical Sentinel*, Portland, Ore., for May, 1906, Henry Waldo Coe, M.D., Editor." It contains six editorials for the faithful to copy: "The American Medical Association Gang," "A Medical Bureaucracy," "Directors Who Do Not Direct," "The Self-Effacement of Local Medical Journals," "Is the A. M. A. Ring 'Unbustable'," and "The House of Delegates of the A. M. A."

The faithful will copy.

Physicians and Proprietary Remedies.

It occurs to me it might be worth while to allow a layman, "the wisest Frenchman that ever lived," to express himself in the discussion now going on in your columns and those of other journals regarding "patent" and proprietary medicine, the credulity of many physicians and the gullibility of the public, etc. Montaigne so clearly apprehended the truth concerning so many of these matters we are now discussing that it seems somewhat discouraging that the intelligence and wisdom of the profession and public should have increased so little apparently in the last 325 years.

To illustrate, the excellent paper by Dr. Henry P. Loomis, published in your issue of December 9, entitled "Physicians and Proprietary Medicines," really points to no fallacy, sophistry or abuse to which Montaigne was not alive. The pity of it is that Dr. Loomis' words should be needed to-day; that they are needed we must sadly confess.

Who has ever—physician or layman—shown the unwisdom and folly of the shotgun prescription more clearly than Montaigne does in these words?

"Even the very promises of physic are incredible in themselves; for having to provide against divers and contrary accidents that often afflict us at one and the same time and that have almost a necessary relation, as the heat of the liver, and the coldness of the stomach, and the other will cool the liver; one has its commission to go directly to the kidneys, nay even to the bladder, without scattering its operations by the way, and is to retain its power and virtue through all these turns and meanders, even to the place to the service of which it is designed, by its own occult property; this will dry the brain; that will moisten the lungs. Of all this bundle of things having mixed up a potion, is it not a kind of madness to imagine or to hope that these differing virtues should separate themselves from one another in this mixture and confusion to perform so many various errands? I should very much fear that they would either lose or change their tickets, and disturb one another's quarters. And who can imagine but that in this liquid confusion, these faculties must corrupt, confound and spoil one another? And is not the danger still more, when the making up of this medicine is entrusted to the skill and fidelity of still another, to whose mercy we again abandon our lives?"

And who has ever portrayed the mental state of the sufferer from a chronic or incurable disease and at the same time shown how and why they become such easy victims to quack doctors or the claims of the patent-medicine manufacturers quite so well as does Montaigne in the following paragraph:

"'Tis the fear of death and pain, impatience of disease, and a violent and indiscreet desire of a present cure, that so blind us; 'tis pure cowardice that makes our belief so pliable and easy to be imposed on, and yet most men do not so much believe as they acquiesce and permit; for I hear them find fault and complain as well as we; but they resolve at last, 'What should I do then?' As if impatience were of itself a better remedy than patience. Is there any one of those who have suffered themselves to be persuaded into this miserable subjection, who does not equally surrender himself to all sorts of impostures? who does not give up himself to the mercy of whoever has the impudence to promise him a cure? The Babylonians carried their sick into the public square; the physician was the people; everyone who passed by being in humanity and civility obliged to inquire of their condition, gave some advice according to his own experience. We do little better; there is not so simple a woman whose chattering and drenches we do not make use of; and according to my humor, if I were to take physic, I would sooner choose to take theirs than any other, because at least, if they do no good, they will do no harm. What Homer and Plato said of the Egyptians, that they were all physicians, may be said of all nations; there is hardly a man among any of them who does not boast of some rare recipe, and who will not venture it on his neighbor, if he will let him. I was the other day in company where some of my fraternity told us of a new sort of pills made up of a hundred odd ingredients; it made us very merry, and was a singular consolation, for what rock could withstand so great a battery? And yet I hear from those who have made trial of it, that the least atom of gravel will not stir for it."

It is to be remembered that Montaigne himself sought in vain for relief from a stone in the bladder.

THEODORE DILLER.

A Death from Trional.

Dr. J. Reynolds Brown, Tacoma, Wash., sends us a clipping from the *Daily News* of that city, containing an account of the death of a young man from trional.

The clipping states:

The irresponsible prescribing of medicines by druggists and their clerks was indirectly responsible for the death of Charles F. Athol, according to Coroner Stewart and County Physician W. B. McCreery. The physicians gave this opinion after performing an autopsy on the body of the young man, and Drs. E. M. Brown and C. F. Kinnear, who assisted, concurred.

Athol, who was but 21 years old, was the son of Mr. and Mrs. Frank Athol, of 1331 South D street. Last week the young man was troubled with sleeplessness and in a drug store he asked for some sleeping-powders. The man in charge gave him a remedy known as "trional" and he took about fifteen grains. Athol was an advanced consumptive and the medicine had the effect of raising a slight fever. This alarmed his parents, who went to another drug store, told the clerk the symptoms and got some more "trional," which they administered according to the clerk's directions. Their son became rapidly worse, and, though a physician was called, he died shortly afterward.

The *Daily News*, in an editorial in the same issue, calls attention to what it designates as the "drug store habit." The editorial states that this is a habit to be deplored and has resulted in many evils as it leads to the misuse and excessive use of many dangerous drugs.

The editorial concludes:

It is easy for the man with what seems to be a slight ailment in his family to ask the druggist for a potion, and so cheap compared with the cost of visiting a physician and then the druggist, that we run the wildest of risks. Oftentimes for "two bits," or even less, a man gets from the apothecary what he has been taught by experience would cost him several times that sum if he first saw the physician and then the apothecary, for the price seems to grow in all directions with that bit of prescription paper.

But it is dangerous and probably unlawful. It is the intention of the medical law of the state to confine the practice of medicine to

raduate physicians, which is eminently correct, and the warning of he coroner, with the death of young Athol before us, is given with he emphasis merited by the seriousness of the custom.

[Trional is a proprietary name for what is now official in he U. S. P. as Sulphonethylmethanum.—ED.]

Lay Resolutions Endorsing the Nostrum Campaign.

JACKSON, MICH., May 3, 1906.

To the Editor:—IN THE JOURNAL, April 21, Dr. Blair, of Lebanon, Ohio, submits a copy of a memorial to the general assembly of the Cumberland Presbyterian Church adopted at he Miami presbytery on April 4, 1906, urging action to eliminate objectionable medical advertising from their denominational papers.

For some unaccountable reason the religious press is very low to institute reform in this direction, and to one who is observing the character of the advertising admitted to the columns of the religious papers of all denominations, these Presbyterian resolutions are remarkably vigorous and show a grasp of the situation which is somewhat unexpected. It is truly refreshing to read them. The Miami presbytery is to be congratulated.

The point of priority, however, must be conceded to the Baptists of Michigan. At the seventieth annual meeting of he Baptist convention of the state of Michigan, held at Jackson, Oct. 16-20, 1905, the following resolutions were passed and placed on record:

We are in the midst of startling and lamentable revelations of ethical corruption, revelations which show not alone the moral delinquency of a few men in high places, but which seem to be expressive of dishonesty as present in every rank of our American life.

We would register our conviction: That this is to be corrected only by a clear reaffirmation of the truth that the ultimate standard of human conduct is not personal desire or profit, or even the permissions of human laws, but the eternally righteous laws of the personal God and our Lord Jesus Christ; that every person who bears the name of Jesus Christ is under most solemn obligation to make his conduct in social and business relations correspond to his profession; that the church of Jesus Christ has the privilege and the duty of being faithful to her high mission of bringing the personal God and His righteous requirements close to the lives of men.

As a specific cause of complicity, conscious or unconscious, in business of questionable honor and honesty, we would express our regret that there are found in the pages of our denominational press advertisements of such things as "patent medicines" and get-rich-quick schemes, which border on, if they do not reach, the obscene, and are delusive and misleading to many.

We would further express the hope that our noble denominational papers would lead in the fight against corruption and graft by excluding such advertisements from their pages.

T. S. LANGFORD, M.D.

Insurance Examination Fees

The Recent Reduction in Fees.

ROCHESTER, N. Y., May 17, 1906.

It appears very proper at this time to take up the discussion of medical insurance examinations in view of the recent cut in the examination fee by the Mutual Life and the Equitable Life Insurance companies from $5 to $3, and the contemplation of the same cut by other companies.

Old-line life insurance companies, except the New York Life and a few others, until recently have been paying $5 for examinations, and have appeared to regard it as a just compensation and to appreciate the fact that it would be unjust to expect a competent physician to make a thorough examination of applicants for less than $5, inasmuch as the examination is usually made at the home of the applicant. For various reasons it is often necessary to make two trips to the applicant's home to complete the examination, and two or more urinalyses are often necessary and required, and also the usual necessary writings of explanations and letters to the home office.

The great majority of companies have realized that for all this a fee of $5 is only a proper compensation, and now, when we consider the advances in almost every branch of labor, and with living expenses very high, compared with five or ten years ago, and constantly increasing, it would be only natural to expect that if there were a change in the physician's fee for examining, it would be an increase.

Who are responsible for this unnecessary and unmerited injustice can readily be appreciated by examining Section 97, laws enacted by the New York General Assembly Session, 1906, and recommended by the Armstrong committee. Section 97, in part, is as follows:

97. *Limitation of Expenses.*—No domestic life insurance corporation shall in any year after the year nineteen hundred and six expend or become liable for or permit any person, firm or corporation to expend on its behalf or under any agreement with it (1) for commissions or first year's premiums, (2) for compensation, not paid by commission, for services in obtaining new insurance exclusive of salaries paid in good faith for agency supervision either at the home office or at branch offices, (3) for medical examinations and inspections of proposed risks, and (4) for advances to agents, an amount exceeding in the aggregate the total loadings on the premiums for the first year of insurance received in said calendar year (calculated on the basis of the American experience table of mortality with interest at the rate of three and one-half percentum per annum) and the present values of the assumed mortality gains for the first five years of insurance on the policies on which the first premium, or instalment thereof, has been received during such calendar year, as ascertained by the select and ultimate method of valuation as provided in Section 84 of this chapter.

This means that the agent, the medical examiner and inspection of risk must be paid out of this limited allowance; for instance, an agent wrote an application at age 30, twenty-year endowment, according to the insurance laws recently passed, there would be $18 to be divided between agent and medical examiner, after deducting the fee for inspecting the risk and the proportionate loss on account of rejections, which would leave about $16 to be divided between the agent and the examining physician. If we deducted $5 for the examiner the agent would have $11 for writing the case.

Now the companies say that it would be quite necessary, because of this section 97, to cut the medical examiner's fee that they may be able to obtain new business. If the Armstrong committee, in drafting the insurance laws, had not mentioned medical examinations the companies could, and in all probabilities would, continue to pay their medical examiners the regular fee of $5.

The law, in its restrictions, throws out a protecting arm to the agents and allows them to receive extra compensation from the home office, when it says, in section 97: "Exclusive of salaries paid in good faith for agency supervision, either at the home office or at the branch office", under which the agent can be given $1,000 or more a year extra, but no shelter under the law is given the examining physician; there is no loophole for him; he must take his little 40 per cent. reduction and smile, if he can.

Eleven years ago the New York Life, as Dr. McCormack puts, it, the original and arch sinner against the best interests alike of their policy holders and the profession in this regard, had cut its fees and probably a majority of leading physicians in all sections of the country failed to resent the recognized indignity. Now, what shall the profession do when the New York state legislature makes it very convenient, if not necessary, for the other companies to make this unmerited and discourteous cut? Shall we let the blow pass unheeded, or stand together and demand that we be not unjustly legislated against? JAS. H. FINNESSY.

Societies Take Action.

BUNCOMBE COUNTY (N. C.) MEDICAL SOCIETY.

At a meeting of this society, held May 7, the following committee report was adopted:

Your committee report:

1. That there has been lately a concerted attempt of most of the insurance companies to reduce the standard fee for medical examinations for policies of $3,000 and under to $3.

2. That the success of this movement, which is unfair to the profession in that it would make them bear a part of the burden brought on the companies by the dishonesty of their managers and directors, and with which the doctors had nothing to do and for which they can not be held responsible, is dependent on the willingness of doctors to agree to the new rate, as is shown by the letters the companies are sending to their examiners and their anxiety not to have the county societies pass resolutions opposed to the reduction. If the profession practically as a whole refuses to do the work for such a fee the companies are powerless, as they can not afford to put their examining work in the hands of men who, for various reasons, are not in societies and only a small percentage of whom are of high standing.

3. It seems, then, to the committee that if the members of the society, which includes a very large majority of the medical men of the county, determined as one man to refuse consent and stick to their agreement faithfully and honestly, we are bound to win in what is a perfectly fair and just contest for our rights.

4. Therefore, we would recommend that the Buncombe County Medical Society and all its members binds itself and themselves by a written agreement to make no insurance examinations for less than the usual fee of $5.00, save that when a company is willing to omit the family history and urinalysis, thus very materially lessening the work of such an examination, the members of this society will agree to make $3 the regular charge.

5. That the secretary be directed to obtain within two weeks the signatures of each and every member to this resolution and to send to each one a copy of this report showing that the interest of each will be best served by a united stand of our profession against this movement.

6. Farther, that all physicians in good standing in the county, even when not members of this society, be urged to join with us in this movement.

7. That the secretary be directed to send a copy of these resolutions to the secretary of each county society in this state, and to the state society, with the request that they be read at the next meeting, and that similar resolutions be passed by them; for unless the profession as a whole realizes that only in union is strength and stand together, it is easy to foresee the coming of the time when the companies, seeing their power in our disunion, will further reduce the fee, till as in Germany and France at present, a physician will be obliged to take fees of 50 cents and less for skilled work, which is none too largely paid at present rates.

8. That to further the fight by the profession against this movement, the secretary be directed to send a copy of these resolutions to THE JOURNAL of the American Medical Association, with the request that they be published in its columns.

CHARLES L. MINOR,
M. H. FLETCHER,
C. V. REYNOLDS,
Committee.

OKLAHOMA MEDICAL ASSOCIATION.

At the annual session of this association, held at Oklahoma City, May 7-9, 1906, the following resolution was passed:

WHEREAS, We, the members of the Oklahoma State Medical Association, in convention assembled, ever ready to promote the general welfare of the people, corporations and bodies we serve, and mindful of the duties imposed and services required of us by these people believe that it is not for the best interests of all concerned that our examination fees be reduced, but that it rather tends to lower the dignity and cause us to become more lax in our examinations and thereby render poorer service to our constituents, all of which is subversive of any good, and believing, as we do, that all good people, corporations and bodies demand the best service that we can render and should be willing to pay a just compensation for such service, and further believe that it is the practice of poor economy by any corporation, to lower examination fees and still demand the same service, and that this association should use its influence with all the people, corporations and bodies demanding our services, and endeavor to impress on them the necessity of paying what the services are really worth. Therefore be it,

Resolved, That the Oklahoma State Medical Association recommends that each constituent organization of this body take the proper steps to establish a minimum fee of $5.00 for each and every examination made; that this society condemns contract practice, and hereafter our members be forbidden to accept the same unless paid for at the regularly established rate.

JOHN RANSOM HAMILL, Guthrie, Chairman.
FLOYD E. WARTERFIELD, Holdenville.
W. E. DICKEN, Oklahoma City.

COLUMBIA (S. C.) MEDICAL SOCIETY.

At a recent meeting this society formally adopted the resolutions regarding insurance fees, passed by the South Carolina Medical Association, published in THE JOURNAL May 5, 1906, page 1386.

SACRAMENTO SOCIETY OF MEDICAL IMPROVEMENT.

SACRAMENTO, CAL., April 25, 1906.

At a regular meeting, held April 24, 1906, the following preamble and resolutions were unanimously adopted:

WHEREAS, Several of our members have been notified that the Mutual Life Insurance Company of New York has reduced the fee for the examinatoion of applicants from five ($5) to three ($3) dollars, and,

WHEREAS, These members have referred this action to our society, which, for many years, has had in force a fee bill rate for such examinations for old line companies of five ($5) dollars, and,

WHEREAS, The last-named figure for a full and complete examination, with analysis of urine, filling blanks and necessary correspondence, is but a fair compensation for the time occupied by professional men on whose honesty and capability the success of life insurance companies must mainly rest; it is therefore,

Resolved, That the members of the Sacramento Society for Medical Improvement agree to adhere to their fee bill rate and earnestly protest against the reduction made by the present officers of the Mutual Life Insurance Company of New York, as unjust, unfair, and unworthy, and they recommend all medical men in affiliation with the State Medical Society, and the American Medical Association to refuse to examine at the lowered rate for a corporation the officers of which have taken this course under the pretense of a necessary reduction of expenses, while at the same time they are allowing the president fifty thousand dollars a year for his services.

Resolved, That the dignity, honor, influence and success of the medical profession largely depend on the recognition of a proper compensation by those able to pay for services rendered and that no organization can rightfully require its medical examiners to work for a less amount than that charged private parties."

It was further moved and carried by unanimous vote of the members present:

That members of the Sacramento Society for Medical Improvement who examine in life insurance for a fee less than that of the fee bill, whether paid in individual fees or in salary, be dropped from the roll of the society.

That it is the sense of this society that the rights and privileges of consultation with members of this society be denied those whose names have been dropped from the roll for examining for less than the prescribed fee.

That any special arrangement for increase of fee to $5.00 per examination made between medical examiner and local agent shall not be accepted by this society, and the special arrangemeot must be made between the medical director of the company and the examiner.

E. M. WILDER, M.D., Secretary.

Medical Legislation

Department of Public Health.

At a recent meeting of the Norfolk District Medical Society the enclosed resolutions were unanimously adopted:

Resolved, That the Norfolk District Medical Society of the State of Massachusetts endorses the action taken by the American Medical Association in favor of the establishment of a Department of Public Health with representation in the Cabinet of the President of the United States.

Resolved, That a certified copy of the above resolutions be forwarded by the Secretary to the Chairman of the Committee on Legislation of the American Medical Association.

JAMES C. D. PIGEON, Secretary.

Correspondence

The Philadelphia School for Nurses.

ORANGE, N. J., May 17, 1906.

To the Editor:—In a recent *Bulletin of the Philadelphia School for Nurses* there are given several hundred names of physicians who endorse this school. A paragraph printed at the head of these names reads as follows: "In every instance one or more letters have been received giving specific permission to use the writer's name as reference in connection with this movement."

Under Orange, N. J., the names of eleven physicians are given, my own among that number. As I have never endorsed this school I was interested to know how many of the men named had actually done so. I find two of the men named removed from Orange more than two years ago, and I understand one of them is now dead. Another is a graduate of 48 years' standing and has not engaged in practice for more than 35 years. Of the remaining eight all deny absolutely that they have endorsed the Philadelphia School for Nurses.

It does not seem that such a piece of barefaced assurance should go unchallenged, and I have no doubt that many of the names given are used without authority. LINN EMERSON.

Association News

Hotel Committees in Boston.

Dr. D. D. Scannell, secretary, writes: "The headquarters of the committee on hotels and transportation will be located in a special booth at Mechanics Building. There will be here a sufficient list of suitable accommodations for those who have deferred making arrangements until the last moment. There will be a sufficient clerical force to minimize delay so far as possible. There will also be a reasonable number of messenger boys whose duty it will be to help our visitors in locating their rooms. In addition to all this, there will be at each of the four railroad stations representatives from a subcommittee who will help in the distribution of information, and for those who desire it, help to secure accommodations by telephoning to the Mechanics Building headquarters. While it is desirable, of course, that all who can should go to the Mechanics Building office, still we can help also from these railroad stations: For those coming into Boston on the Boston and Albany railroad, or the Providence division of the New York, New Haven and Hartford, and whose hotel reservations are in the Brunswick, Buckminster, Copley Square, Lenox, Nottingham, Oxford, Somerset, Abbottsford, Vendome, Victoria or Westminster, we

would recommend getting off at the Huntington Avenue or Back Bay stations, respectively. Most of the lodging-houses will be easily reached from these two depots. To those coming in on the same divisions, but being quartered at the Adams House, American House, Bellevue, Cecil, Essex, Lexington, Parker's, Young's, Touraine, Quincy, Crawford House and the Revere House, it would be best to come into the South Terminal. At each point any additional information can be secured. The majority of the lodging-houses are within from ten to fifteen minutes' walk from Mechanics Building. For any overflow that may occur beyond our reasonable expectation, we will have ample accommodations twenty to thirty minutes' from Boston.

Entertainment for Women Physicians.

The medical women of Boston and vicinity extend a cordial invitation to all women physicians attending the session of the American Medical Association to a garden party on the grounds of the New England Hospital for Women and Children, Dimock Street, Roxbury, on Wednesday, June 6, from 4 to 6. A notice as to special conveyance will be posted in the women's rest room.

A Trip to the Thousand Islands.

A small party is being formed to go to Boston by way of Toronto, taking the boat there for the St. Lawrence River trip through the Thousand Islands and the rapids to Montreal, thence to Boston. The party starts Friday, June 1, at 3 p. m., and reaches Boston, Monday, June 4, at 7:30 a. m. Those wishing reservations made for this trip are referred to Dr. Frank E. Brawley, 72 Madison Street, Chicago.

Visit to New Haven.

NEW HAVEN, May 9, 1906.

To the Editor:—At a meeting of the New Haven Medical Association, held May 2, it was resolved that the rooms of the New Haven Medical Association, 962 Chapel Street, be thrown open to members of the American Medical Association who desire to visit New Haven after the Boston session of the Association. W. E. HARTSHORN, Secretary.

Correction in Rates.

By a typographical error, May 12, page 1464, we announced a rate of $20 from Chicago to Baltimore via the Baltimore & Ohio Railway to Baltimore, thence to Boston via the Merchants and Miners' Steamers. This price is $29.

Marriages

SAMUEL NICHOLAS, M.D., to Miss Esther Trallis, in New York City, April 24.

WALDO BRIGGS, M.D., to Miss Anna Blow Shipley, both of St. Louis, Mo., May 14.

JOSEPH J. BANSBACH, M.D., to Miss Bessie Neese, both of St. Joseph, Mo., May 5.

CHARLES REA, M.D., York, Pa., to Miss Bessie W. Bailey of Bloomsburg, Pa., May 9.

L. DOYTE HOLLIDAY, M.D., to Miss Mabel Lucas, both of Fairmount, Ind., May 10.

JOSEPH SAGER, M.D., to Mrs. Gabie Williams, both of Celina, Ohio, in Cincinnati, May 12.

JAMES L. PARKES, M.D., Madden, Miss., to Miss Alice Sanders, at Harperville, Miss., May 13.

EDGAR WINFIELD GARDNER, M.D., Literberry, Ill., to Miss Mary Machin of Keokuk, Iowa, May 9.

LOUIS NEILL TATE, M.D., Carthage, Ill., to Miss Gertrude Almeda Andrews of St. Elmo, Ill., May 16.

JOHN ROBERT LIONBERGER, M.D., Boonville, Mo., to Miss Rebekah Kinnard of Franklin, Tenn., May 16.

LIEUT. JAY RALPH SHOOK, M.D., assistant surgeon, United States Army, to Miss Helen Slade of Des Moines, Iowa, May 23.

ROBERT J. MCNEILL, M.D., Germantown, Philadelphia, to Miss Jane E. Mason of Philadelphia, May 15.

HENRY WIREMAN COOK, M.D., Minneapolis, Minn., to Miss Ellen McCall Davenport of Richmond, Va., May 15.

FRANCIS ASHLEY FAUGHT, M.D., Philadelphia, to Miss Anna Mabel Brown of North Asbury Park, N. J., May 18.

LIEUTENANT COMMANDER LEWIS MORRIS, M.D., surgeon, United States Navy, to Miss Mary Gibbs Murphy, in New York City, May 12.

Deaths

Thomas Sargent Latimer, M.D. University of Maryland, School of Medicine, Baltimore, 1861; a member of the American Medical Association; president of the Medical and Chirurgical Faculty of Maryland in 1884 and 1885; professor of principles and practice of medicine in the College of Physicians and Surgeons, Baltimore; assistant surgeon and later surgeon in the Confederate service, and filling important position in the army of Northern Virginia; for two years resident physician to the University Hospital, Baltimore; one of the founders of the College of Physicians and Surgeons; president of the lunacy commission of Maryland; editor of two medical journals, died at his home in Baltimore, May 16, from nephritis, after an illness of six months, aged 67.

William H. Focht, M.D. College of Physicians and Surgeons, Baltimore, 1883; a member of the American Medical Association, the Ohio State Medical Society, and once president of the Seneca County Medical Society; a member of the Northwestern Ohio Medical Association and American Academy of Medicine; one of the board of regents of Heidelberg University, and at one time president of the alumni association of that institution; some-time a member of the board of education and of the city council of Tiffin, Ohio, died at his home, May 12, from suppurative meningitis, following an abscess of the ear, after an illness of several months, aged 48.

William M. E. Mellen, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1876; delegate of the Tenth International Medical Congress, Berlin, 1890; president of the Hampton District Medical Society, 1905; mayor of Chicopee in 1904; town physician in 1883 and 1884; for several years a member of the board of health, and its chairman in 1899; in 1891 a member of the board of aldermen, and the following year chairman of that board; a delegate to the national democratic convention in Chicago, 1892, died at his home in Chicopee, from cerebral hemorrhage, May 14, after a short illness, aged 57.

Theodore B. Lashells, M.D. National Medical College, Medical Department of Columbian University, Washington, D. C., 1863; of Meadville, Pa.; surgeon of the Twelfth Pennsylvania Cavalry and One Hundred and Seventy-fourth Pennsylvania Infantry during the Civil War; for many years a member of the State Board of Medical Examiners and the State Board of Charities; chief surgeon of the Bessemer Railroad, and for 35 years local surgeon of the Erie Railroad, died in the Spencer Hospital, Meadville, May 9, three months after an accidental fall in which he sustained a fracture of the hip, aged 67.

Lyman Skeen, Jr., M.D. University of Virginia, Medical Department, Charlottesville, 1895; a member of the American Medical Association, who, after graduation became first assistant in the biologic department of the university and for several years served as instructor in that institution, died at his home in Ogden, Utah, May 14, from tubercular meningitis, after an illness of more than a year, aged 34.

John M. D. France, M.D. University of Georgetown (D. C.) Medical Department, 1865; a pioneer practitioner of St. Joseph, Mo.; organizer of the old St. Joseph Medical College, afterward consolidated with Ensworth Medical College; some-time city and county physician of St. Joseph, who had been suffering from anemia for a year, died suddenly at his home, May 9, from cardiac dilatation, aged 64.

George Leolkes, M.D. Hahnemann Medical College, Philadelphia, 1868; of Belleville, Ill.; a member of the St. Clair County Medical Society, and for several terms a member of the Belleville board of education and library board, died from heart disease at Mullanphy Hospital, St. Louis, May 15, aged 60.

D. Franklin Powell, M.D. Louisville Medical College, 1873, of St. Paul, Minn.; for seven years mayor of La Crosse, Wis.; noted as an Indian fighter and plainsman; a veteran of the Spanish-American War, died suddenly from heart disease, May 8, while on a train eastbound from Los Angeles.

Carl V. Vischer, M.D. Hahnemann Medical College, Philadelphia, 1887, of Philadelphia; one of the organizers of St. Luke's Hospital, Philadelphia, and consulting surgeon at McKinley Memorial Hospital, Trenton, N. J., died in Bellefonte, Pa., May 13, from diabetes, after an illness of six months, aged 37.

Newell L. Johnson, M.D. Department of Medicine of the University of Pennsylvania, 1891, of Williamsport, Pa., a member of the American Medical Association, died in the hospital of the University of Pennsylvania, Philadelphia, from cancer of the colon, May 16, aged 44.

James Wardlaw Pelham, M.D. Jefferson Medical College, Philadelphia, 1888; house surgeon of Blockley Hospital for three years; of Asheville, N. C., died in the Biltmore Hospital, Biltmore, N. C., May 11, from nephritis, after an illness of several years, aged 45.

Thomas W. Evans, M.D. Detroit Medical College, 1871; hospital steward in the Civil War; for 45 years a prominent practitioner of Ross County, Ohio, died at his home in Richmonddale, May 11, from disease of the stomach, after a long illness, aged 66.

Valentine Vermilye, M.D. College of Physicians and Surgeons in the City of New York, 1844, one of the oldest citizens of Sandwich, Ill., died at the home of his daughter in that place, May 7, after a prolonged period of invalidism.

Edwin Forrest Rush, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1878, a great-great grandson of Benjamin Rush, died at his home in Chicago, April 21, after a prolonged illness, from chronic nephritis, aged 54.

John B. Evans, M.D. University of Louisville, Medical Department, 1860, a surgeon in the Confederate service during the Civil War, died at his home in Riley, Ky., from heart disease, after a prolonged illness, May 7, aged 69.

Leroy D. McWayne, M.D. Medical Department of the University of Tennessee, Nashville, 1880, a veteran of the Civil War, died at his home in Hoosick Falls, N. Y., May 10, from chronic nephritis, after a long illness, aged 69.

B. E. Bushaw, M.D. (County License, Indiana, 1897), a member of the American Medical Association, and a prominent practitioner of Marengo, Ind., died suddenly from heart disease, at his home in that place, May 1, aged 65.

William Ferguson Cartmill, M.D., a practitioner in Missouri from 1847 to 1849, and in California for several years, died at his home in Tulare, Cal., March 26, from heart disease, after an illness of 15 days, aged 84.

William Alexander McDonald, M.D. Harvard University Medical School, Boston, 1871, of Lynn, Mass., a member of the Massachusetts Medical Society, died in Lynn, May 11, from cerebral hemorrhage, aged 62.

William J. Collins, M.D. Illinois Medical College, Chicago, 1904; of Geneva, Ind.; a member of the Adams County Medical Society, was struck by a train at Geneva and instantly killed Dec. 3, 1905, aged 39.

George Ralph Breckon, M.D., Toronto University Medical Faculty; a member of the American Medical Association and of the Michigan State Medical Society, died recently at his home in Caledonia, Mich.

Eliza L. Pierce Fountain, M.D. New York Medical College and Hospital for Women, New York City, 1867, died at her home in New York City, May 11, after an illness of five months, aged 69.

Marshall D. Murray, M.D. Medical Department of the University of the South, Sewanee, Tenn., 1895, of Pinewood, S. C., died in St. John's Hospital, Baltimore, May 9, after a long illness, aged 38.

Andrew M. Crawford, M.D. Rush Medical College, Chicago, 1877, a retired practitioner of Denver, died from the effects of an overdose of acetanilid, in his apartments in Denver, May 2.

O. N. Heise, M.D. Medical College of Ohio, Cincinnati, 1886, of Cincinnati, a member of the American Medical Association, died at the home of his sister in Indianapolis, May 15.

James E. Gibson, M.D. St. Louis Medical College, 1860, died at his home in Bissell, St. Louis County, Mo., May 12, from appendicitis, after an illness of one week, aged 70.

Thomas P. Hudson, M.D. Eclectic Medical Institute, Cincinnati, 1859, formerly of Streator, Ill., died in Maize, Kan., May 3, after an illness of five years, aged about 60.

Walter A. Garton, M.D. Temple College, Department of Medicine, Philadelphia, 1899, died in that city from a self-inflicted gunshot wound, May 8, aged 29.

James M. Young, M.D. University of Louisville, Medical Department, 1860, a veteran of the Civil War, died recently at his home in Bloomfield, Ky., aged 68.

Solomon C. Warren, M.D. Hahnemann Medical College, Philadelphia, 1855, died at his home in Syracuse, N. Y., May 7, from cerebral hemorrhage, aged 73.

John W. Tuck, M.D. Louisville Medical College, a Confederate veteran, died at his home in Virgiliana, Va., May 7, after a long illness, from heart disease.

John S. Failing, M.D. University of Buffalo, Medical Department, 1868, formerly of Grand Rapids, Mich., died recently at his home in Los Angeles, Cal.

James E. Kelly, M.D. Albany (N. Y.) Medical College, 1901, died at his home in Saratoga Springs, May 14, after an illness of five months, aged 42.

Milburn McCarty, M.D. Medical Department of the University of Cincinnati, 1866, died at his home in Granger, Texas, May 7, aged 78.

Frances Linton Sharpless, M.D. Woman's Medical College of Philadelphia, died at her home in West Chester, Pa., May 15, aged 50.

B. L. Davis, M.D. New York Homeopathic Medical College and Hospital, 1864, died at his home in Bellevue, Pa., May 15, aged 66.

Judah Isaacs, M.D. Eclectic College of Pennsylvania, Philadelphia, 1861, died at his home in Philadelphia, May 19, aged 72.

John W. Suggs, Jr., M.D. Southern Medical College, Atlanta, Ga., died at his home in Prattsburg, Ga., May 9.

Book Notice

INFECTION, IMMUNITY AND SERUM THERAPY. In Relation to the Infectious Diseases which Attack Man; with Considerations of the Allied Subjects of Agglutination, Precipitation, Hemolysis, etc. By H. T. Ricketts, M.D., Instructor in Pathology, University of Chicago. Cloth. Pp. 600. Illustrated. Price, $2.50. Chicago: American Medical Association Press, 1906.

This book is a reprint of a series of the much appreciated articles on immunity which appeared anonymously in THE JOURNAL during 1905, with a number of additions and such revisions as were made necessary. The type is large and the reading made easy by convenient side headings. The book is divided into two parts, the first dealing with the fundamental principles of infection and immunity, natural and acquired, and the second with the main facts of infection and healing in the various infectious diseases. The author is to be congratulated on the thoroughness, the simplicity, and the clearness with which he presents the intricate and difficult subject largely the outgrowth of the active investigations of the past few years in this field. He has avoided, and we think wisely in a work of this character, any evidence of partisanship as regards the different theories, especially the phagocytic and the humoral, which have dominated these investigations, and particularly because, as knowledge increases, it is becoming more and more evident—and this Dr. Ricketts shows very clearly—that no single theory is applicable to all infectious diseases, but that the mechanisms emphasized by the different theories all play a significant part though not to the same degree in every infectious process. In Dr. Ricketts' book there is made available to the general medical reader desirable and important reliable information concerning immunity and infection now contained in special technical journals not usually in the hands of physicians and students, and the book, therefore, has a distinct field. Only comparatively little of this recent knowledge has found its way into text-books in common use, and then usually in such condensed form as to be difficult to understand. Physicians frequently complain of the fact that they are unable to read intelligently discussions on the subject of immunity and serum therapy because of the many new terms used and the new methods of experimentation. Many of these terms, made necessary by the growth of our knowledge of the subjects in question, have not yet crept into our dictionaries and consequently the reader often is quite helpless in dealing with articles in current literature. The index to this book is unusually complete and will be of great aid to the wide-awake and plastic physician and student who desires to keep in touch with so important a subject.

Miscellany

MY ANSWER TO "MEDICAL FORGERIES."

G. L. Hagen Burger.
BOSTON.

To the Editor:—Unfortunately for Dr. Van Meter,[1] he based his prognosis *a priori* on false premises, as will appear when the curtain falls. Ever since civilized man has been able to peruse the pages of history he finds duality in all things. And so here there are two sides to this question.

My aim in life has been to know, to see, to search, to labor. My life's aim has been, and I hope will be, one of service. Replying to the attack as to my titles, it is, therefore, hard for me to see that I had no right to accept them for the work and research I had rendered. Moreover, my name, which is made the subject of comment, was given me without choice. I have had no other, within my period of memory.

THIS WONDERFUL MEDICAL SAVANT'S HISTORY.

My history differs from that alleged. Some day I will furnish data for Dr. Van Meter to rewrite my real record. Had it been inquired into impartially it would appear that I was born in Hetten Leidelheim, Rhein.-Pfalz, Bayern, Dec. 4, 1864. After the usual training I studied natural sciences in Germany and Holland in the early '80s, and did not graduate, as alleged, from a veterinary college in Brooklyn. I never studied law. During 1890-91-92 I studied toxicology, forensic, preventive and comparative medicine, with other subjects, at the American Veterinary College, State University, New York City. There I took the first prize in comparative anatomy when I received my degree for the mounting and dissecting of a human fetus. In 1894 I passed the municipal service examination for the Bureau of Chemistry, City of New York, with the highest rank (9373 1/30) among sixty applicants, and was appointed to the service, as is evidenced by a copy of paper which I have filed with the editor.

In 1897 I went to Montana and presented my application for examination to the secretary, Dr. Chappell, together with the degree I had received from Kiel, Germany, a year before. I passed the examination and was admitted to practice. The percentages attained are filed with this article and were made by affidavit of Secretary W. C. Riddell. They are as follows: Anatomy, 88; physiology, 80; materia medica, 80; therapeutics, 89; histology, 84; diseases of women and children, 67; chemistry, 72; eye and ear, 79; medical jurisprudence and toxicology, 90; surgery, 81; diseases of the nervous system, 78; obstetrics, 86; preventive medicine, 68.

I agree with Dr. Van Meter that the crucial test of a practitioner's qualifications can not be determined by a diploma. The responsibilities are twofold—on the applicant and the examiner. The man who judges the candidate must be of a superior mind. His sense of justice must be unquestionable. Some such men are on the Colorado State Board. I refer to President Dr. W. T. Miles, Dr. C. K. Fleming, Dr. David Strickler and Dr. G. McHugh. Their kindness to me has fallen on fertile soil, and I shall never give them cause for regret.

"CAREER IN MONTANA AS A SELF-STYLED SPECIALIST IN ABDOMINAL SURGERY."

Had I had my choice in the matter, perhaps fate would have thrown me among other men than gynecologists, but I took what was offered me and have done the best I could ever since.

"HIS FIRST CELIOTOMY ON MRS. A. J. SCHUHMACHER." . .

I wish to state that I had several celiotomies the same month in the same hospital, not mentioning others in which I witnessed and assisted some eminent men, not only in this country, but abroad. With the assistance of Drs. Bernheim and Schultz, the latter city physician of Butte for many years, I operated on Mrs. Schuhmacher for an ovarian tumor, which was removed. The patient recovered from the operation, but was taken with pneumonia three weeks later and died the same night. A copy of the full report of this case, as per record of Sisters' Hospital, Butte, with assistants and consultants, is on file with the editor. At some later date I hope to have published the full report of this case.

Dr. Van Meter refers to her husband's bringing my earthly career to an end and states that "with aching bones and bandaged wounds I left the state between suns." Would that show that he would indorse an assault on an operator who loses a case? This, regardless of conscientious care in the preparation and after-treatment of his case. His attack implicates the other gentlemen who assisted in the operation and after-treatment. What is his purpose? To help our profession? As a matter of fact I was in practice in Montana for three years after that operation and the assault made on me by Schuhmacher. For verification I refer to the courts, Sisters' Hospitals, Butte and Helena, Mont., and to the state and city license collector of the city.

In the spring of 1899, six months after the death of Mrs. Schuhmacher, and while our bills were in the hands of attorneys for collection, Schuhmacher, while intoxicated, assaulted me, when my back was turned, with an iron billy, in my own office, for which offense he was later held under $2,000 bail for assault in the first degree. Out of consideration for his family I refused to prosecute him, for which I was censured by the other physicians, whom he had also threatened. He declared then that he would spend $50,000 to make me all the trouble he could. The methods he used for this purpose will appear later.

Dr. Van Meter goes on to say that a few months after the operation I made my début in Colorado. When an individual is as careless in such serious statements and juggles with time as he does, would it not seem that there is an ulterior motive other than to bring to justice a man who, according to Dr. Van Meter, is neither morally nor educationally fit to practice his profession?

Supposing now, as I have a right to suppose, his peers judge Dr. Van Meter's morale, I fear in advance and sympathize with my accuser that the pendulum swings in a direction other than in his favor.

As to my hobby, I refer to the manuscript read before the Æsculapian Society, Canada, as published by the *Queen's University Journal*, February, 1903. If a pseudo-scientific crank, I am willing to be convinced, but much prefer the opinion of others in my profession if given a chance to be heard.

BOARD'S FIRST KNOWLEDGE OF MY PRACTICING IN COLORADO.

As to the board's first knowledge of my practicing medicine, in which my assailant shows a unilateral palsy in not stating the true facts of the case, he says that I was arrested for reporting a case of smallpox as typhoid. First, I was not arrested, but summoned; second, I reported nothing, as I had nothing to report; third, I was not practicing medicine, but only asked to see a case in consultation with the family physician, which, I thought, I had a perfect right to do as a licensed practitioner from a neighboring state. I was discharged in court, the judge saying that he did not see why I was before him. Here is *nuda veritas*. For verification I refer to the health department, municipal court of Denver, and file a copy of the entire report with the editor.

The first information as to my practicing medicine without a license was not, as Dr. Van Meter alleges, by notification of the board, but through a newspaper article, contemporaneous with the smallpox case. I then called on Dr. Van Meter on Jan. 4, 1902, and informed him that I was not practicing, but only in consultation on the smallpox case. He said it was best to pay him the fee of $5 and leave my credentials with him. The following day I handed my check, my Montana license and my New York Postgraduate Medical School and Hospital certificate to Mrs. Van Meter, in the absence of the doctor, together with a note, in effect that I presented myself with credentials for examination.

PRESENTATION OF CREDENTIALS TO DR. VAN METER.

The following day Dr. Van Meter asked if I had an M.D. degree. I told him that I made my Doctor of Medicine in Kiel, but did not have the degree with me, as it was in Montana, but that I could have it in a few days. He handed me a receipt for the check, which he said was equal to a temporary license. He held in his hand a paper and asked me to sign it, which I did. I was also informed that when the board met I would be told whether I could practice without an examination.

1. THE JOURNAL A. M. A., Feb. 3, 1906, p. 324.

Five or six days later my things arrived from Montana. I presented my degree, which Dr. Van Meter examined, returning it with the query as to how long I had studied at Kiel. I replied that I had never studied at Kiel, that I presented my application and consequent dissertation there while studying in Berlin, where I collected my material for my thesis. He said that the law required that one must have studied three or four years in one school, from which an M.D. degree is received; otherwise the candidate must take an examination. I assured him of my willingness to take the examination, although I had come to Denver merely to present my work to the profession to get their opinion as to its feasibility. He asked me how long I had practiced in Montana, to which I replied, "From the fall of 1897 to several weeks ago."

Several days later a letter from a friend to a well-known physician in Montana, against whom I testified as an expert witness several times with the city coroner, when he was tried for murder as the result of illegal practice, was shown me by Dr. Van Meter. This letter declared, among other things, that the signatures on my degree were non-genuine and that there was no record at Kiel of such a degree. The secretary said there was something wrong with it and asked if he could see my degree again: *Mens sibi conscia recti*, I gave it to him again and consented to his retaining it.

I positively deny in this connection that I was ever asked or ever made to any one connected with this board any sworn statement while applying for registration, but had I been asked I would have readily consented at that time.

At this time Schuhmacher, whom it will be remembered was last mentioned in Montana with the threat on his lips to spend $50,000 in making trouble for me, visited Dr. Van Meter. Living across the street from the latter's office, I saw him emerge frequently from the doctor's office. Why he was there I hope to publish some time hence.

LETTERS FROM MONTANA.

Following these interviews, emanating from the secretary of the board in Colorado, articles of my shady career in Montana were published in the Denver papers, which brought forth inquiries as to my professional character and standing. From former professional associates and members of the Associated Charities Association of Helena, of which I was an executive member during the last two years of my residence in that city, the following replies were received, of which a few excerpts are stated. Copies of the letters are on file with the editor:

HELENA, MONT., Jan. 29, 1902.

Replying to your letter of recent date, I would say that I have been county attorney for the past three years, and, as such, have had to do with criminal charges preferred against anyone residing here. I do not know of any charge ever having been preferred against Dr. Ilugen Burger. So far as I am informed, he is straightforward, honorable, upright man in all his dealings. While a practicing physician in this city, I had occasion several times to use him as a witness in criminal proceedings in our courts here, and found him able, capable, bright, intelligent, and a most excellent witness. I am inclined to think there is a personal grievance which prompts the letter you write.

O. W. MCCONNELL,
County Attorney, Lewis and Clark Co.

Another letter stated that:

He was always regarded highly here, and is so still. We never heard the slightest word against his character or professional standing, and can only think that some personal animosity must be back of these accusations.

Another reply stated:

He has commanded our highest esteem always, and has enjoyed, as far as I know, a good reputation.

DEMAND FOR EXAMINATION.

The publication of these newspaper reports prompted me to consult an attorney, the Hon. J. Warner Mills, who accompanied me to the secretary's office, demanding an examination before the full board. I was abruptly informed by Dr. Van Meter that he was the whole board. He later tried to get the board together, but failed to get a quorum. When I renewed my demands for an examination Van Meter rose from his seat, with an epithet, and rushed for me. My lawyer insisted on an examination before that board, which was refused. The assault attempted was prevented by Mr. Mills stepping between us and ordering him to desist. I informed Dr. Van Meter that I had not come to fight, but to meet the board, as was my privilege.

THE TRIAL.

Several days after this scene a warrant was issued for my arrest on the charge of practicing medicine without a license, for perjury and forgery. I was held under $500 bail, which was promptly furnished without any deception on my part, as alleged. On April 8 I received a letter from the secretary (copy of which is on file with the editor), to the effect that my license was refused, owing to conclusive evidence that the Kiel document I presented was a forgery. I repeatedly requested prosecution, since he had conclusive evidence, and waited from April to July, unable to get a trial. On June 9, on motion of my attorneys to quash the proceedings, Judge Palmer, in granting the motion, as per record of June 9, 1902, No. 15,448, said: "This man made no affidavit under oath, and consequently there can be no perjury. That charge is dismissed. The other charges I will take under consideration."

Later the complaint against me for practicing medicine and forgery was *nol. prossed*, as Dr. Van Meter himself stated, in letters and affidavit, 1903-04, to the Senate of Queen's University, of which copies are in my possession. Compare his accusations with his own affidavits and later publications in this journal. I charge that on his own affidavits or in his articles he has deliberately falsified the facts.

EXAMINATION GRANTED.

After much delay I called on the president, Dr. Miles, in July, and presented myself again for examination. I took the examination at his office, lasting one week, in which I failed. His certificate gives the following rating: Surgery, 46; chemistry, 70; diseases of women, 90; anatomy, 11.5; physiology, 70; practice of medicine, 50; pathology, 87.5. Kindly note difference in rating.

After reading my three papers in which I failed to President Miles, he said that he was in favor of my reading my entire papers before the full board. Some members refused to attend the meeting. Dr. Miles then suggested that I read my papers to them at their offices. Some gave me an audience and others refused. I reported the matter to Dr. Miles, July 23, and on August 9 he said (and I quote Dr. Miles' words *verbatim*): "Doctor, you ought to have your license. I am in favor of it and that your papers shall be read before the whole board." Two letters received from members of the board were shown Dr. Miles, who said: "Now, doctor, I believe there are some members of the board prejudiced against you because of the scrap you had with Van Meter."

Finally, after several months, by consent of the board, I had typewritten copies made by their stenographer, every page compared and sworn to and open for the inspection of any member of the profession, as it appears by affidavit, a copy of which is filed with the editor. I mandamused the board to grant me a license. Some of the members suggested that I go somewhere else to practice. I replied: "I have done nothing wrong here. Why should I go away? Your secretary must prosecute me first and make good his threats."

OPINIONS OF OTHER PHYSICIANS.

I submitted my papers to men of high professional standing in Denver and other cities. Some of their replies I append in brief. These copies of letters are on file with the editor. From Dr. George C. Stemen, for fifteen years professor of surgery in the Fort Wayne College of Medicine, now a member of said board in Denver, I received the following:

I unhesitatingly say that the papers submitted to me are among the best I have ever examined, and show beyond question of doubt that the applicant is qualified in every department of medical science, and above the average among medical men.

From Dr. Bates, professor of anatomy, Women's Medical College, Northwestern University, Chicago, from 1883 to 1889, the following was received:

They give ample evidence of his medical knowledge and of his unusual thoroughness and scientific character, and that he is an earnest and constant student, an ethical physician, and possessed of the highest ideals of the duties and privileges of our profession."

Dr. Hart's letter states:

Reading your examination papers, I was a member of that board many years, and never saw papers showing the competency yours did.

The above attestations as to my medical attainments are of themselves answers to Dr. Van Meter's accusations that I lack

revious education and am of the country bumpkin type of udent. Many of this class helped to make history what is.

MY STAY IN NEW YORK.

I have said that the charges preferred by Dr. Van Meter hrough the county attorney at Denver were *nol. prossed.* efore this was granted, after requesting trial many times p to November 1, and failing, at the suggestion of my bonds- an and attorney I determined to get evidence to support the ioral side of my case, in this country first, and, failing, to go > Germany. Accordingly I left Denver Nov. 1, 1902, for ew York, where I presented my case to Dr. J. R.. repre- ntative of the German consul-general in New York City. pecial investigation revealed the fact that there was no ecord of the degree granted me at Kiel and that the signa- ures were denied.

This made me more desirous than ever to go to Kiel and to scertain the identity of the persons responsible for my calam- y. I was taken ill at that time and confined to bed for five eeks. After recovery I had another consultation with the onsul's representative, who again advised me I could do othing effective in Germany, since I was reduced physically nd financially to a minimum. At the same time I received dvice from my bondsman stating that the case would be discon- inued and advising me to go to no further expense. My pro- essional friends in New York concurred in the following ad- ice given me by Dr. Niles in Denver, in July, 1902: "Doctor, ow listen to me; go to any good school which will admit you in he final year, get your degree, come back and nothing further vill be done in the matter."

I acted on the advice given and went to Queen's University nd notified my attorney and bondsman to that effect, offering o come back any time if wanted. I was notified that it was ot necessary, unless I wished to proceed with the mandamus rit.

THE ALLEGED FRAUD PRACTICED ON QUEEN'S UNIVERSITY.

As to my alleged fraud practiced on Queen's University in ny entrance and final examination, there is nothing so sublime s a fact. The records of the university will not show that I resented any degree of any German or other university, as roved in the Senate hearing on Dec. 20, 1905, on which hear- ng I insisted, after a lengthy correspondence, as per letter nd request of June 5, 1905, to the dean of the medical fac- lty. I also offer affidavit of Arthur McCabe, M.D., as fol- ows:

GLOUCESTER, March 3, 1906.

This is to certify that I was with Dr. G. L. Hagen Burger in Kingston when he presented his credentials to the secretary of the Faculty of Queen's University; that he did not present any German degree, that he did not state that he was a graduate of any col- ege or an M.D., but simply a licentiate from the state of Montana; hat I was present when he was told that he could register with the credentials which he presented to the secretary of the faculty. Sworn and subscribed.

As to my final standing in examinations, I quote my per- centages from the blackboard of the university and *British Daily Whig*, April 8, 1903:

Written and oral examination in mental diseases, 95 per cent.; enior practice of medicine, thirty-ninth place; clinical medicine. ixth place; senior obstetrics and gynecology, seventh place; linical pathology, thirty-third place; surgery and surgical anatomy, nknown to me.

As to my fellowship degree of the Royal College of Physi- ians and Surgeons, this was granted me on April 4, 1903, by he censors, Prof. Fowler, dean of Queen's University, and Prof. M. Sullivan, member of parliament and professor of sur- gery, and Prof. E. Ryan, professor of anatomy, on the presen- ation of a thesis on original feeding experiments on chickens y feeding with meat, and the production of gouty arthritis vith pathologic specimens and microscopic findings, as well as n oral examination, lasting four hours, covering scientific ubjects in medicine.

As to my desire for unearned professional titles, I file copy vith the editor of Professor Sullivan's convocation address, April 8, 1903, in which he referred to two gentlemen who were warded this year the fellowship degree by the faculty of Royal College of Physicians and Surgeons, and who were well vorthy of the honor for the scientific research work they had endered, etc.

ALLEGED IMPOSITION PRACTICED ON MASSACHUSETTS STATE BOARD OF MEDICAL EXAMINERS.

As to the imposition practiced on the State Board of Medical Examiners and Censors of the Massachusetts Medical Society, I offer the following, through the kindness of Drs. Harvey and Crandon, secretaries:

Surgery, 77.5; physiology and hygiene, 64; pathology, 81; obstetrics and gynecology, 77; diagnosis and practice of medicine, 84; anatomy, 66; general average, 74.9 (Dr. Harvey).

Dr. Hagen Burger passed with a percentage of 72; 60 per cent. is necessary to pass (Dr. Crandon).

In April, 1903, I was engaged by the College of Physicians and Surgeons of Boston to instruct third and fourth year students in clinical diagnosis and lecture on gynecology, which I did during that semester. In April, 1904, I was appointed, on the recommendation of two of Boston's eminent professors of surgery in one of its universities, as gynecologist to the Mt. Sinai Hospital (as per letter on file with the editor). In this capacity I have served ever since, as shown in the following extract from a letter received from the president of the board of trustees of that hospital:

Jan. 25, 1906.

. . . We have been more than pleased with the manner in which you conduct your clinics, the great interest you have shown in the development of this institution and the care you have taken in treating the patients in your department. All are greatly appreciated by us (Leon Pickert, president).

In the fall of 1904 I applied to the Boston City Hospital for clinical work and was appointed as volunteer assistant. A copy of this letter is also on file with the editor.

MY OLD-TIME EFFRONTERY.

I came to Boston to practice my profession after being licensed, and in an humble and ethical way attended to my clinical work and teaching, and with the moral assistance of my brother physicians, to many of whom I am greatly indebted, I gained a foothold in the Athens of America, notwithstanding the obstacles Van Meter has placed in my way, as evidenced by letters sent to the Massachusetts State Board of Medical Examiners, the Massachusetts Medical Society and Queen's University, copies of which are in my possession. All this time I have worked with a view to enabling me to go to Germany when the proper time comes and to learn how much I have imposed or how much I have been imposed on, also the methods by which others seemingly made me an imposition. Until then, and until the Senate of Queen's University has spoken, it would be premature for me to say anything further about the degree.

MY ASSISTANTSHIP IN CLINICS.

I said that I was in Chauta's, Kehrer's and Leopold's clinics. In regard to other clinics I said, "late at," meaning that I had done clinical work under the direction of the men in charge, as volunteer and hospitant, usually called "hospitieren." I mentioned that I was last in Boston at Cabot's and Hewes' clinic and laboratory, and said nothing about having been an assistant there. Statements otherwise are either a mistake or a misprint by some one. Through the courtesy of Dr. Cabot I utilized my mornings in his clinic waiting for Dr. Hewes to return from his vacation, to take his laboratory course.

MY OVERFLOWING WITH PERSONAL PROCLAMATIONS OF SKILL.

I know nothing of these. I am a good listener to a physician who talks shop, and I will express an opinion when asked, when I have one; if not, I say I do not know and try to learn. Anyone who has ever been associated with me on a case in the past will testify that I leave no stone unturned to help my patient with all available and scientific means known to me, regardless of whether I receive a guerdon or not. When in doubt I seek counsel of older and wiser heads. Often I have been in doubt and never have I been afflicted with the egoism of the "know-it-all" doctor.

MY "UNFAILING NERVE."

This is the courage resulting from the consciousness of having done and of doing no wrong.

DR. VAN METER'S STUDY OF CHARACTER.

Since character makes its own destiny, I fear naught, not even malice. Never does a man portray his own character better than in the manner in which he portrays another's.

MY TOTAL DISREGARD OF THE CONSEQUENCES OF MY WRONGDOINGS.

Let me say this: I feel that I know right from wrong and am aware of the consequences of wrong. Furthermore, I know of no instance in Europe or this country where I have willfully deceived or defrauded anyone. I am willing to feel that "heavy hand of the law" for any crime I have committed, as I have never shirked my duty knowingly anywhere, and fully believe in the maxim, *Salus populi, suprema lex.* I know right from wrong to such a degree that even now I am endeavoring to teach Van Meter a better and a nobler aim in life than the persecution of one whose every energy is bent on the education and uplifting of suffering humanity, and one who is ever arrayed on that side of the profession and society that works toward that achievement.

MY SANITY.

I know full well, as a physician, the responsibility and trust vested in me, but am further willing for the benefit of mankind to have a committee of psychiatrists appointed, excluding Dr. Van Meter, of course, to pass judgment on me, and, if declared *non compos mentis*, or a criminal, as my assailant designates me, to abide by their council and decision. Moreover, I would ask their help, if possible, to overcome the depraved, moral and criminal instincts this close observer of human nature has detected in my character, "inspite of his self-esteem as a reader of human nature." *O vanitas, vanitatum!*

His sophistry and paralogism evidently know no bounds. I am ever ready and willing to improve myself, and no man recognizes more than I the dictum that "individual improvement is the only keynote to progress universal."

I know that I have many faults and often err. Who has not? But such deep chrome yellow epithets as "bunco steerer," "scamp," "scoundrel," "impious wretch," "arch medical impostor," and "criminal of the worst type," I resent. They are false and malicious. I further deny that I offered knowingly any false or forged evidence before any state board, in the West, in Massachusetts, or to any university in Canada.

I challenge Dr. Van Meter to come to Massachusetts and to Canada, and to prove his accusations. I am as willing to be prosecuted here as I was in Denver, where I waited and pleaded eight months for a trial.

CONCLUSION.

In conclusion I would suggest to this now self-styled famous author of "Medical Forgeries," that the asylum of oblivion is full of moral assassins.

"Authors and readers now find, as once Achilles found,
The whole is doubtful, where are so many parts unsound."

Dr. Van Meter's Reply.

A copy of the above was sent to Dr. Van Meter, who writes:

"The foregoing answer to 'Medical Forgeries' is such a garbled misstatement of facts and assertions of that which is untrue that it does not demand from me anything further than a general denial.

"The reproduction of the forged Kiel diploma; the admission on the part of Hagen Burger that 'special investigation revealed the fact that there was no record of the degree granted me at Kiel and that the signatures were denied;' and the following letter from the dean of Queen's University are all-sufficient to convince any doubting Thomas as to the true character of the man."

MEDICAL FACULTY, QUEEN'S UNIVERSITY,
KINGSTON, ONT., Dec. 23, 1904.

D. S. D. Van Meter, Denver, Colo.:

Dear Sir:—In reply to your letter of the 19th, I beg to say that Hagen Burger is without doubt the same man who recently received our degree of M.D.

He came to us in the fall of 1902, and presented a German degree, certificates of license to practice in the states of Colorado and of Maine and a certificate of having been an inspector for the board of health in New York for four years. On the strength of these he was admitted to fourth-year standing. At the spring examinations in 1903 he failed to qualify. In September, 1904, he appeared for supplementary examinations and passed.

At a meeting of the faculty held to-day the matter was referred to me to consult with the solicitors of the university as to revoking his degree. When in Boston the early part of this week I saw his sign in a window on Massachusetts Avenue, near the corner of Huntingdon Avenue. One of my former students told me this was the man who was registered with us two years ago.

I am obliged to you for your information, and your courtesy in writing so fully. I also return his letter. About the date of your affidavit he came here. Did he leave to avoid the criminal action against him? Was the trial completed or does it still stand?

J. C. CONNELL, Dean.

A STUDY IN PERSONAL HYGIENE.

Thomas Scott Lowden has made a study[1] of the care taken by Americans in regard to their health based on the responses to a questionnaire on "Keeping Well" sent out by President Hall of Clark University.

The questions were asked in some detail relating to: 1. The disease feared. 2. Affectation or feigning of illness, and what aroused the desire for health. 3. Habits regarding food. 4. Use of medicines. 5. Toilet appliances. 6. Sleep. 7. Exercise. 8. Dress. 9. Work and study. 10. Precautions against inherited disease. 11. Epidemics. 12. Experience with quacks and "patent medicines." 13. Results of experience of sickness on personal regimen. 14. Views regarding exposure, etc. 15. Sexual hygiene. 16. Mental states and environment. 17. Sketch of an ideal life to maintain oneself at the top of his condition and live as long as possible.

The questions were addressed to intelligent people who were interested in health, morals and education. Personal hygienic experience was sought, not theories. Four hundred and fifty manuscripts were returned by students, teachers, professors, physicians, ministers, and the public generally. The papers exhibited a sane view of the subject with little tendency to awaken morbid interest. Seventy per cent. of those answering the question fear disease, 38 per cent. of these from heredity 13 per cent. from personal experience, and the rest from observation or report. The author quotes several answers showing "what a nightmare weight hereditary fear, whether well founded or imagined, is likely to become." The precautions taken against heredity show some understanding of hygiene and some are doubtless doing all for themselves that can be done. The answers in regard to the affectation of invalidism are peculiarly significant. One hundred and twelve answer affirmatively and about an equal number negatively. The papers indicate that it is the feminine sex that is given to feigning illness for the sake of sympathy, to attract attention, etc. Boys sometimes do so to avoid work.

Of 255, 44 per cent. eat some particular food for the sake of health, and 62 per cent. are obliged to abstain from some kinds of food. Three meals is the rule, and the spirit of the papers is strong against the "no breakfast" idea. Bolting food is objected to. Vegetables and fruit are the leading foods, but nearly all want meat once a day, the average twice so that no tendency to vegetarianism is shown. Water is the preferred drink. Coffee is abstained from by some for fear of headache and taken by others to prevent it. Many can not get a reaction after the cold bath, but those who do, find it highly beneficial. All testify to the benefits of rubbing the body after the bath. Massage is not much practiced. Reports regarding cosmetics are meager. Many are trying to improve the skin and complexion through general hygiene. The evidence shows a lack of care of the bust, hands, feet and teeth. The usual time of sleeping is from 10 p. m. to 6 a. m. Three times as many report nine hours' sleep as seven; most sleep on a medium hard mattress, with light covering, in a thoroughly ventilated room; most completely change the clothes worn during the day. The very few who resort to drugs to induce sleep have found the after-effects evil. The greater number speak against eating before going to bed, but some find it a help. Various methods of inducing sleep are described.

Walking is the most general form of exercise, but other special forms are favored by a few. There is strong opposition to "apparatus exercise"; neither gymnasium nor bedroom apparatus is in high favor, nor the more violent forms of exercise. Most of the women wear corsets.

The author believes that more intelligent people resort t

1 A dissertation submitted to the faculty of Clark University, Worcester, Mass., in partial fulfilment of the requirements for the degree of Doctor of Philosophy and accepted on the recommendation of G. Stanley Hall. Pedagogical Seminary, March, 1906, vol. xiii

uackery than the returns indicate. All who report having ad such experience deplore it. The papers from Poland show nuch faith in quackery. The quack in Poland is usually some ld woman herb doctor and the faith element undoubtedly nters into the real or supposed cure. The answers of the nen in regard to sexual matters show the evils of ignorance n regard to physiologic sexual function. The escape of semen s regarded as abnormal and leads many to resort to quacks r advertised nostrums.

The second chapter deals with the question of medicine and uackery and makes interesting and profitable reading. The ollowing questionnaire was submitted to druggists:

1. *Have "patent medicines" any merit?* The majority of druggists agreed that they have no merit, unless, from the lcohol which they contain. The danger from alcohol in medines, supposed to contain none, and especially the danger from he substitution of wood alcohol, is emphasized. The price it which the "patent medicines", comparatively harmless, are old makes them fraudulent. "All evidence from druggists, chemists, physicians and medical journals amasses itself to prove that 'patent medicines' are costly and dangerous to body, mind, life and morals, and that their producers are deceivers and robbers."

2. *What sells "patent medicines"?* There was but one answer given by all druggists visited. "'Patent medicines' are sold wholly through the susceptibility of the people to advertisements."

3. *Who buy "patent medicines"?* The sales, by no means, are confined to the poor and ignorant. The rich and intelligent buy much. One druggist says, "The ministers of the city are among my best 'patent-medicine' customers." Six druggists report that at least 75 per cent. of all "patent medicine" is taken by women. "Patent medicine" is given to the children and consumed largely by the young, but the real "patent-medicine" period sets in about 28 or 30 and lasts until 55, use being most marked between 40 and 50. The medicine sold depends partly on fashion, but mostly on efficient advertising.

4. *Do physicians make use of "patent medicines"?* One-third of the druggists visited state that the physicians that deal with them make more or less use of "patent medicines". All, however, emphasized the fact that the majority rely almost wholly on the pharmaceutic compounds. Six druggists said physicians buy "patents" of them, change the label, or put the medicine into their own bottles under their labels. "It may be said that the physician generally frowns heavily on 'patents', compounds little himself or has his druggnst to do it, but resorts to the compounds sent out by the pharmaceutical houses." One druggist says: "The physician frequently does not know what he is giving. It is not infrequently hit or miss with him as in diagnosing diseases. Physicians are as gullible as the laity. A live up-to-date agent of a compounding house can sell them most anything, as our full shelves of this sort of stuff show."

5. *What is your estimate of the work of the average physician?* According to the druggists "the average physician is incompetent, knows neither disease nor medicine; neither the science nor the art of his so-called profession; has little interest in his work other than a commercial one; will stoop to any practice for money, and the drug business is being constantly lowered by his demands."

It is impossible to believe that the use of "patent medicines" by physicians is sufficiently common to justify the above statements or that many intelligent druggists entertain the sentiments toward the medical profession attributed to them by the author. In his investigations he must unfortunately have come in communication with pharmacists actuated by jealousy or who had been criticised for counter prescribing. It is believed that the medical profession is weak on the side of mental therapeutics. The physician is often unable to apply the stimulus of a strong personality.

6. *What do you know of the advertising doctor and the quack?* "All evidence goes to show that the advertising doctor is flourishing and is steadily on the increase. Physicians state that comparatively few men having private diseases have gone to them. More resort to the druggist, but the majority seek assistance of the traveling doctor and 'advertiser,' who are successful in playing on the whole gamut of fears and succeed in robbing thousands who have no sex ailments. The newspapers are accomplices in this nefarious work. Recently one of the leading dailies had six full columns on one page, besides scattered notices, devoted to doctors advertising 'lost-manhood cures.'"

7. *What is your opinion of the drug business as it is conducted today?* Of the thirty-five druggists interviewed, not one is satisfied with the business. The older druggists say the business is no longer so clean nor professional as it used to be.

The third chapter deals with the relations of emotion and health, recognizing the injurious effects of worry, anger and depressing emotions. The influence of pessimism is contrasted with the life-joy "that knows no bounds, welling out of the animal surplus, the source of all real health. The remote end of personal hygiene is racial welfare."

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

COLLECTION AGENCY.

WICHITA, KANS., May 15, 1906.

To the Editor:—I understand that there is a collection agency somewhere that makes a business of finding and collecting from railroad men, no matter where they are, so long as they are in the United States and in the employ of a railroad company. Can you give me the address of this concern. C. E. CASWELL, M.D.

THE PHYSICIAN AND THE AUTOMOBILE.

HAVERSTRAW, N. Y., May 6, 1906.

DR. N. B. BAYLEY, Haverstraw, N. Y., writes: "I live in a moderately hilly country, with fair roads, but a ten-horse power machine does not fill the bill satisfactorily, I know that is the trouble with many other men. It is better to wait until one can buy a satisfactory car; it will save work and worry. My conclusions, based on experience and observation, are that to find satisfactory results the following factors must appertain: Either there must be mechanical ability to meet all ordinary difficulties that arise, or financial ability to employ competent assistance always at hand to keep the car in order and to drive. Also, the motor car must have reserve power sufficient to meet the exigencies constantly arising in a physician's practice. To traverse hills or bad, muddy roads with ease requires more power than the majority of runabouts possess, without straining the engines to their full limit, entailing, as a consequence, frequent overhauling. In a locality with hard roads a car with less power may give good service, but oftener a physician's car needs as much power as an ordinary tonneau car, which, with intelligent care and its reserve power will be an agent of pleasure and profit.

WATER PURIFICATION.

KAUFMAN, TEXAS, May 11, 1906.

To the Editor:—Please inform me through THE JOURNAL whether or not water settled with alum (℥iv to 800 gal.) and used for household purposes, has any injurious effects. C. M. GRIGSBY.

ANSWER.—The use of alum and similar coagulants should be adjusted to the alkalinity of the water to be tested. In some waters where the natural alkalinity is deficient, provision should be made for increasing it to the extent necessary for the use of the amount of coagulant required for complete purification. When this is done there is no reason to suppose that the use of these substances in proper proportions is injurious to health. We may add that sulphate of alumina is much more commonly used than alum as a coagulating material. Copperas (ferro-sulphate) together with lime has also been successfully used.

State Boards of Registration

COMING EXAMINATIONS.

NEBRASKA State Board of Health, State House, Lincoln, May 29-30. Secretary, George H. Brash, Beatrice.

MINNESOTA State Board of Medical Examiners, Old State Capitol Building, St. Paul, June 5-7. Secretary, O. E. Linjer, Minneapolis.

WYOMING Board of Medical Examiners, State Capitol, Cheyenne, June 6. Secretary, S. B. Miller, Laramie.

MICHIGAN State Board of Registration in Medicine, Ann Arbor, June 12. Secretary, B. D. Harison, Sault Ste Marie.

TEXAS State Board of Medical Examiners, Dallas, June 12. Secretary, T. T. Jackson, San Antonio.

OHIO State Board of Medical Registration and Examination, Cincinnati, Cleveland and Columbus, June 12-14. Secretary, George H. Matson, Columbus.

BOARD representing the Medical Society of Delaware and Board representing the Homeopathic Medical Society of Delaware State and Peninsula, former held at Dover, and latter at Washington, June 19. Secretary, P. W. Tomlinson, Wilmington.

NEW JERSEY State Board of Medical Examiners, Trenton, June 19-20. Secretary, E. L. B. Godfrey, Camden.

NEW YORK Boards of Medical Examiners, Albany, June 19-22. Secretary, Charles F. Wheelock, Albany.

PENNSYLVANIA State Board of Medical Examiners, Annex Hotel, Pittsburg, and North Building, Philadelphia, June 19-22. Secretary, Joseph E. Willetts, Pittsburg.

VIRGINIA State Board of Medical Examiners, Richmond, June 19-22. Secretary, R. S. Martin, Stuart.

MARYLAND Board of Medical Examiners, Baltimore, June 20-23. Secretary, J. McP. Scott, Hagerstown.

SOUTH CAROLINA State Board of Medical Examiners, Columbia, June 26. Secretary, W. M. Lester, Columbia.

District of Columbia April Report.—Dr. W. C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports the written examination held at Washington, April 12-16, 1906. The number of subjects examined in was 17; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 18, of whom 12 passed and 6 failed. The following colleges were represented:

College.	PASSED. Year Grad.	Per Cent.
Baltimore Med. Coll.	(1905)	79.5
Boston University	(1899)	89.6
Georgetown University	(1905)	75.2
George Washington University	(1905) 79.6	79.9, 88
Hahnemann Med. Coll., Philadelphia	(1900)	88.8
Howard University	(1904)	78.9
Jefferson Med. Coll.	(1902)	82.2
University of Illinois	(1902)	82.8
University of Pennsylvania	(1898)	86.5
Woman's Med. Coll., Philadelphia	(1904)	75.2

	FAILED.	
Georgetown University	(1905)	73.8
George Washington University	(1905) 49.9, 68,	73
Howard University	(1905)	71.3
Missouri Med. Coll.	(1896)	58.2

Florida April Report. Dr. J. D. Fernandez, secretary of the Regular Board of Medical Examiners of Florida, reports the examination held at Gainesville, April 16-17, 1906. Forty-nine applicants were registered, 6 withdrew and 5 failed. Two were granted certificates under the old law, having practiced in the state prior to the passage of the act creating examining boards, and 36 passed the examination. Under the law no member of the board can issue a second temporary license. An average of 75 per cent. is required to pass. The following colleges were represented:

College.	PASSED. Year Grad.	Per Cent.
Jefferson Med. Coll.	(1886) 79; (1887)	81
College of P. and S., Baltimore	(1890) 80; (1905)	88.
Atlanta Med. Coll.	(1895)	76.2
Meharry Med. Coll.	(1902) 88; (1906)	81
Bellevue Med. Coll.	(1898)	88.5
Fort Worth University	(1905)	92.5
University of Maryland	(1897) 87.2; (1904)	90.5
Birmingham Med. Coll.	(1904)	84, 90
Vanderbilt University	(1898)	89
Maryland Med. Coll.	(1904) 83; (1906)	81
University of Georgia	(1906)	81, 89
Atlanta Coll. of P. and S.	(1906)	79, 86
St. Louis Coll. of P. and S.	(1905)	77
Atlanta College of Medicine	(1906)	89
Queen's University, Ontario	(1903)	84
Howard University	(1902)	82.1
University of the South	(1901)	75
Medico-Chirurgical College, Phila.	(1904) 92.4; (1905)	87.4
Medical College of Virginia	(1905)	80
Medical College of Alabama	(1902)	89
Manitoba Med. Coll.	(1905)	91
University of Nashville	(1897)	90.4
University of Virginia	(1905)	89
University of Arkansas	(1905)	85.2
University of Palermo, Italy	(1903)	82.7
Barnes Med. Coll.	(1905)	75
Milwaukee Med. Coll.	(1903)	81

	FAILED	
Meharry Med. Coll.	(1905) 54.7, 58.1; (1906)	47.2
University of Palermo, Italy	(1898)	70.8
Barnes Med. Coll.	(1898)	65

Minnesota April Report.—Dr. W. S. Fullerton of the Minnesota State Board of Medical Examiners reports the written examination held at St. Paul, April 3-5, 1906. The number of subjects examined in was 16; total number of questions asked, 93, percentage required to pass, 75. The total number of candidates examined was 19, of whom 14 passed and failed. The following colleges were represented:

College.	PASSED. Year Grad.	Per Cent.
Northwestern University	(1901) 87.7; (1905)	82
Laval University, Quebec	(1905)	77
University of Christiania, Norway	(1895)	83
Imperial Alexander University, Helsingfors, Finland	(1886)	84
College of P. and S., Chicago	(1904)	80
Hamline University	(1900) 75; (1905)	78
Rush Med. Coll.	(1897) 79.2; (1905)	83
University of Minnesota	(1905)	78
Baltimore Med. Coll.	(1902)	79
Omaha Med. Coll.	(1902)	80
University of Michigan	(1890)	83

	FAILED.	
Queen's University, Ontario	(1905)	72
Hamline University	(1905)	71
University of Minnesota	(1905) 57.8,	72
Milwaukee Med. Coll.	(1904)	71

At the last meeting of the board five reciprocal licenses we granted.

At this examination the following questions were asked:

MEDICINE.

1. What are the early symptoms and physical signs of tube culosis of the lungs? 2. What findings by palpation, auscultati and percussion of the cardiac region would warrant the diagnos of mitral stenosis? 3. What diseases cause enlargement of th liver? 4. Describe purpura hemorrhagica. 5. Give the patholog symptoms and prognosis of infantile paralysis (poliomyelitis a terior acuta). 6. Prescribe a no-milk diet for a child of s months suffering from acute gastrointestinal disorder. 7. Give th chief points of distinction between the epileptic and the hysteric convulsion. 8. Describe and treat a case of scabies. 9. Differe tiate in parallel columns between the chancre and the chancroi 10. Trichina spiralis: its source in man and its life history.

PATHOLOGY AND BACTERIOLOGY.

1. Describe pathologic changes of intestines in case of typho fever. 2. Give pathology of acute lobar pneumonia. 3. Descril pathology of atrophic cirrhosis of liver: What causes the abdomin dropsy in such cases? 4. Describe pathology of atheroma of a lar artery. 5. Give pathologic changes of spinal cord in locomot ataxia. 6. Mention bacteria that are known as the common caus of inflammation and suppuration. 7. On what scientific facts is th serum therapy based? Illustrate case. 8. Describe method microscopic examination for tubercle bacilli. 9. Name portals infection and dissemination of typhoid bacillus. 10. What do yo understand by mixed infection? Illustrate case.

ANATOMY AND HISTOLOGY.

1. Describe the heart briefly and give its nutritive blood supp and its nerve supply. 2. Describe the palmar fascia fully. 3. Nam the leucocytes and describe each one. 4. Diagram a typical mucot membrane and name the structures composing it. 5. Name th branches of the abdominal aorta. 6. Name the varieties of epith lium and diagram each one. 7. Give origin, course and terminatio of long saphenous vein. 8. Describe the rectum and give the bloc and nerve supply. 9. Describe a Peyers' patch and where foun 10. Describe a lobule of the liver, dingram preferred.

PHYSIOLOGY.

1. Locate and describe and give function of glomerulus of kl ney. 2. Locate and describe and give function of spleen. 3. San of pancreas. 4. Describe the general circulation. 5. How is th normal temperature of the body maintained? 6. Describe and e plain the normal heart sounds. 7. Describe the lymphatic syste 8. What are the chief differences of function between the two ner ous systems, cerebrospinal and sympathetic? 9. Describe the po tal circulation. 10. What are proteids and what are the variou steps in their preparation, and, finally, how do they reach the ge eral circulation?

OBSTETRICS.

1. Give recognized causes and preventive treatment of puerper eclampsia. 2. Describe the normal lochia. Give significance of l suppression. Fetid odor. 3. Give your method of delivering th after-coming head in cases of breech presentation. 4. How woul you diagnose death of the fetus in utero at the fourth month pregnancy? 5. Alarming hemorrhage begins immediately after d livery of placenta; uterus fails to contract. Give your active trea ment.

DISEASES OF WOMEN.

1. What are the principal causes of displacement of the uterus 2. Give three common causes of sterility in the female and trea ment for same. 3. Describe fully the ovaries and Fallopian tub and state what are their natural supports. 4. Give symptoms prolapse of the ovary and treatment for same. 5. Give early sym toms of cancer of the uterine cervix. Differentiate from cyst degeneration; simple ulceration.

CHEMISTRY, TOXICOLOGY AND URINALYSIS.

1. Define atomic weight, molecular weight, specific gravity, chem ical reaction, chemical formula. 2. Give the boiling and freezin point of water in the centigrade, Fahrenheit and Reaumur the mometric scales. 3. What is actinism? 4. What is an alloy? Give symptoms and treatment of acute cocain poisoning. 6. Giv symptoms and treatment of plumbism. 7. Give one reliable test fo albumin in urine. 8. Give one reliable test for sugar in urin 9. Give a chemical test for pus in urine. 10. Describe Ehrlich diazo reaction test for urine and the clinical significance of th diazo reaction when present.

MEDICAL JURISPRUDENCE.

1. Give two positive signs of death. 2. What are the duties the coroner's jury? 3. What is the difference between an ordinar

witness and an expert witness? 4. What constitutes a dying declaration? 5. Is a licensed physician exempt from jury duty in the courts of justice in this state?

PREVENTIVE MEDICINE.

1. Give some practical suggestions that would lessen the spread of tuberculosis. 2. What diseases are commonly transmitted through drinking water? 3. What prophylactic measures would you recommend for the prevention of typhoid fever? 4. Give a practical method of obtaining pure drinking water for the home. 5. Give a simple, practical method of ventilating buildings in this climate in the winter season.

HOMEOPATHIC MATERIA MEDICA.

1. Differentiate aconite, arsenic, hel. and gels. in fevers. 2. What three remedies are often indicated in typhoid fever? Give prominent symptoms of each, indicating their use. 3. Give symptoms indicating the use of bry, phos., ferr. phos., veratrum in pneumonia. 4. Name three remedies usually indicated in case of cholera morbus. 5. Give three leading symptoms for lyc. lach. podo. china. 6. Differentiate between sniph. mezereum, graphites and rhus. in skin troubles. 8. What is meant by dilution, potency, polychrest?

SURGERY.

1. What is dacryocystitis? Causes, symptoms, treatment. 2. What are the most usual causes of iritis? Give differential diagnosis and treatment. 3. What is trichiasis, a chalazion; granular ophthalmia, nystagmus? 4. What conditions cause deafness in children? 5. Give etiology, symptoms and treatment of mastoiditis. 6. What is a Potts' fracture? Give treatment. 7. Diagnose fracture of hip. Give treatment. 8. Given a crushing injury of a limb, what symptoms would cause you to advise amputation? Give technic of operation at junction of lower and middle third of leg, naming the tissues ent through. 9. Give the usual dislocation of the elbow. Give diagnosis and treatment of the condition. 10. How do you differentiate concussion from compression of the brain? 11. Give treatment for strangulated hernia. Describe operation for inguinal hernia. 12. Give differential diagnosis between appendicitis, salpingitis, stone in ureter, colic. 13. What conditions would cause you to choose chloroform or ether in a case? Give precautions to be observed in administering each.

MATERIA MEDICA AND THERAPEUTICS.

1. Name two extensively used alkaloidal derivitives of morphia (not salts of morphia), stating what salt of each is commonly used, purposes and dosage. 2. A child 18 months old has been allowed the ordinary table diet of the family; you are called suddenly to see it in convulsions; describe fully how you would treat it. 3. Write a prescription for calomel combined with ipecac and bicarbonate of soda, to be given in divided doses hourly for twelve hours to a child 2 years old. 4. What physiologic action of veratrum renders it particularly safe in the matter of dosage? 5. When is digitalis indicated in organic heart disease and when contraindicated? 6. Name the most generally useful emetic and give the reason for your opinion. 7. Outline briefly and clearly the proper management of a case of acute nephritis. 8. During the course of the above case, (*a*) what threatened emergency would warrant full doses of elaterium or croton oil, and (*b*) what symptoms would signal the approach of such an emergency? 9. State the dose of each of the following that you would give, together with frequency of repetition, under the conditions named: (*a*) Arsenous acid, as an alterative; (*b*) antimonii et potas. tart., as an expectorant; (*c*) tr. veratri, U. S. P., 1900, in the first stage of sthenic croupous pneumonia; (*d*) tr. strophanthi, U. S. P., 1900, in aortic regurgitation with venous stasis; (*e*) sulfonal, as a hypnotic. 10. Criticise the following prescription:

R. Solut. strychniæ sulphat. (gr. i to 3i).....3i
Spts. ammoniæ aromat. q. s. ad.....3ii
Misce et sig. Half a dram in water before each meal.

Rhode Island April Report.—In the report of the examination held at Providence, April 5, 1906, published in THE JOURNAL, May 12, 1906, page 1468, one candidate, a graduate of Tuft's College Medical School, 1905, was reported as having failed. We are now informed that this candidate's papers have been reconsidered and that he has passed.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending May 19, 1906:

Perley, H. O., deputy surgeon general, Glennan, James D., surgeon, Straub, Paul F., surgeon, appointed members of a board of medical officers to meet at West Point, N. Y., about June 1, 1906, for the physical examination of the cadets of each class at the U. S. Military Academy, and such candidates for admission as may be ordered to appear before it.

Stephenson, Wm., surgeon, Russell, F. F., asst.-surgeon, Rutherford, H. H., asst.-surgeon, appointed members of examining board to meet at Presidio of San Francisco, Cal., for examination of such candidates for appointment in the Medical Corps of the Army as may be invited to appear before it.

Banister, J. M., deputy surgeon general, relieved from treatment at General Hospital, Washington Barracks, D. C., and will return to his proper station.

Shook, Jay R., asst.-surgeon, granted leave of absence for one month and fifteen days.

Wilson, Wm. H., asst.-surgeon, ordered to report in person, May 22, 1906, to Major William H. Arthur, surgeon, president, examining board, Army Medical Museum Building, Washington, D. C., for examination for promotion.

Little, Wm. L., asst.-surgeon, reported for temporary duty at Fort Sill, O. T. Left Fort Sam Houston, Texas, May 9, 1906.

Roberts, William, asst.-surgeon, granted 10 days' leave.

Kirby-Smith, R. M., asst.-surgeon, relieved from duty in the Philippines Division, to take effect Aug. 1, 1906, and will proceed by the first available transport sailing after that date to San Francisco, Cal., and on arrival report by telegraph to the Military Secretary of the Army for further orders.

Wertenbaker, Clark L., contract surgeon, returned to Madison Barracks, N. Y., from leave of absence.

Watkins, Victor E., contract surgeon, ordered to Fort Mansfield, R. I., for temporary duty.

Reagles, James, contract surgeon, returned from Fort Snelling, Minn., to duty at Fort Keogh, Mont.

Kelly, John D., contract surgeon, returned from temporary duty at San Francisco, Cal., to duty at Presidio of Monterey, Cal.

Springwater, Samuel A., contract surgeon, granted leave of absence for two months.

Slater, Ernest F., contract surgeon, left Fort Hancock, N. J., for temporary duty at Fort Hamilton, N. Y.

Wing, Franklin F., dental surgeon, relieved from duty at Fort Riley, Kans., and ordered to duty at Fort D. A. Russell, Wyo.

McCallum, Francis M., contract surgeon, returned to Fort D. A. Russell, Wyo., from leave of absence.

Richardson, George H., contract surgeon, assigned to duty at the Presidio of San Francisco, Cal.

Hogan, David D., contract surgeon, left San Francisco, Cal., on leave of absence for one month.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending May 19, 1906:

Cordeiro, F. J. B., surgeon, having been examined by a retiring board and found incapacitated for active service on account of disability incident thereto, is retired from active service, May 9, 1906, under the provisions of section 1453, Revised Statutes.

Curl, H. C., surgeon, commissioned surgeon, with rank of lieutenant commander, from Dec. 16, 1905.

Pugh, W. S., Jr., asst.-surgeon, ordered to the *Lancaster*.

Miller, James, Jr., asst.-surgeon, died at Midway Islands, May 13, 1906.

Haynes, J. R., asst.-surgeon, ordered to the Naval Hospital, Washington, D. C.

Brown, H. L., asst.-surgeon, detached from the *Texas* and ordered home to wait orders.

Manchester, J. D., asst.-surgeon, ordered to duty at the Naval Recruiting Station, Cincinnati.

Campbell, R. A., acting asst.-surgeon, detached from the Naval Recruiting Station, Cincinnati, and ordered to the Midway Islands.

Reeves, I. S. K., asst.-surgeon, ordered to the Naval Hospital, Boston.

Allen, A. H., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant (junior grade), from May 2, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and noncommissioned officers of the Public Health and Marine-Hospital Service for the seven days ending May 16, 1906:

Kerr, J. W., asst.-surgeon-general, detailed to represent the Service at the meeting of the National Association for the Study and Prevention of Tuberculosis, in Washington, D. C., May 16-18, 1906.

Smith, A. C., surgeon, granted leave of absence for seven days, from May 14, 1906.

Rosenau, M. J., P. A. surgeon, granted leave of absence for two days, from May 11, 1906, under Paragraph 189 of the Regulations.

Oakley, J. H., P. A. surgeon, relieved from special temporary duty at San Francisco, Cal., and directed to rejoin his station at Port Townsend, Wash.

Grubbs, S. B., P. A. surgeon, temporarily relieved at Chicago, Ill., and directed to proceed to Cleveland, Ohio, May 31, for temporary duty.

Billings, W. C., P. A. surgeon, granted leave of absence for five days, from April 23, 1906.

Billings, W. C., P. A. surgeon, granted leave of absence for one day, May 6, 1906.

Stansfield, H. A., P. A. surgeon, relieved from duty in the Hygienic Laboratory, Washington, D. C., and directed to proceed to Baltimore, Md., reporting to the medical officer in command for duty and assignment to quarters.

Earle, R. N., P. A., surgeon, leave of absence granted for four months, from Feb. 4, 1906, amended so as to be for three months and three days only.

Ebert, H. G., asst.-surgeon, relieved from special temporary duty in San Francisco, and directed to rejoin his station at Seattle, Wash.

Salmon, T. W., asst.-surgeon, granted leave of absence for seven days, from May 10, 1906, under Paragraph 191 of the Regulations.

Guthrie, M. C., asst.-surgeon, relieved from duty at Ellis Island, N. Y., and directed to proceed to Havana, Cuba, reporting to P. A. Surgeon R. H. von Ezdorf for duty.

Delgado, J. M., acting asst.-surgeon, granted leave of absence for twenty-six days, from May 14, 1906.

Ottaway, J. E., acting asst.-surgeon, directed to proceed from Charlotte to Rochester, N. Y., for special temporary duty, on completion of which to return to Charlotte.

Schug, F. J., acting asst.-surgeon, leave of absence granted for fifteen days, from May 3, 1906, amended to be effective from June 8, 1906.

BOARDS CONVENED.

A board of medical officers was convened to meet at the Bureau in Washington, D. C., May 22, 1906, for the purpose of making physical examinations of applicants for the position of cadet in the Revenue Cutter Service. Detail for the Board: Asst.-Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon-General J. M. Eager, recorder.

A board of medical officers was convened to meet at Mobile, Ala., May 17, 1906, for the purpose of conducting a physical examination of an officer of the Revenue Cutter Service. Detail for the Board: P. A. Surgeon Edward Francis, chairman; Acting Asst.-Surgeon A. S. Taylor, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 18, 1906:

SMALLPOX—UNITED STATES.

Florida: General, April 28-May 5, 10 cases.
Illinois: Chicago, May 5-12, 1 case.
Indiana: Terre Haute, May 5-12, 1 case.
Kentucky: Covington, May 5-12, 1 case.
Maryland: Baltimore, May 5-12, 1 case; Crisfield, May 7, 1 case.
Minnesota: General, April 29-May 7, 18 cases.
New Hampshire: Portsmouth, May 10, 1 case.
New York: Buffalo, May 5-12, 1 case; Haverstraw, May 9, 1 case; New York, May 5-12, 3 cases, 2 deaths; Roswell, April 1-30, 2 cases.
Ohio: Toledo, April 28-May 5, 1 case.
Rhode Island: Pawtucket, March 23, 4 cases.
Tennessee: Knoxville, May 5-12, 1 case.

SMALLPOX—INSULAR.

Philippine Islands: Manila, March 17-31, 2 cases, 1 death.

SMALLPOX—FOREIGN.

Africa: Cape Town, March 24-April 17, 14 cases; Frectown, April 18, present.
China: Hongkong, March 24-31, 12 cases, 11 deaths; Shanghai, April 7-14, 1 death.
Ecuador: Guayaquil, April 12-24, 5 deaths.
Gibraltar: April 22-29, 4 cases, 1 death.
Great Britain: Bristol, April 21-28, 4 cases. Glasgow, April 27-May 4, 1 case.
India: Bombay, April 10-17, 14 deaths; Calcutta, March 31-April 7, 137 deaths; Karachi, April 8-15, 21 cases, 17 deaths; Madras, April 7-13, 30 deaths; Rangoon, March 31-April 7, 61 deaths.
Italy: General, April 19-26, 38 cases.
Japan: Formosa, March 1-31, 5 cases; Yokahama, April 7-14, 2 cases.
The Netherlands: Flushing, April 21-May 5, 3 cases; Rotterdam, April 29-May 5, 1 case.
Russia: Moscow, March 31-April 21, 37 cases, 6 deaths; Odessa, April 7-21, 16 cases, 4 deaths.

YELLOW FEVER—FOREIGN.

Ecuador: Guayaquil, April 12-24, 17 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, March 17-24, 1 case, 1 death; Provinces, March 17-23, 27 cases, 23 deaths.

CHOLERA—FOREIGN.

India: Bombay, April 10-17, 26 deaths; Calcutta, March 31-April 7, 43 deaths; Madras, March 31-April 6, 1 death.

PLAGUE—INSULAR.

Hawaii: Honolulu, May 12-16, 5 deaths.

PLAGUE—FOREIGN.

India: Bombay, April 10-17, 875 deaths; Calcutta, March 31-April 7, 301 deaths; Karachi, April 28-15, 194 cases, 162 deaths; Rangoon, March 31-April 7, 72 deaths.
Japan: Kobe, March 24-April 7, 2 cases, 1 death.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5-8.

Med. Soc. of State of North Carolina, Charlotte, May 29-31.
Rhode Island Medical Society, Providence, May 31.
American Dermatological Assn., Cleveland, May 30-June 1
American Pediatric Society, Atlantic City, May 30-June 1.
American Surgical Association, Cleveland, May 30-June 1.
American Laryngological Assn., Niagara Falls, May 31-June 2.
American Assn. of Genito-Urinary Surgeons, New York, June 1-2.
American Academy of Medicine, Boston, June 2-4.
Amer. Assn. of Life Insurance Exam. Surgeon, Boston, June 4.
American Gastro-Enterological Assn., Boston, June 4.
American Urological Assn., Boston, June 4-5.
American Proctologic Society, Boston, June 5-6.
American Medico-Psychological Society, Boston, June 12-15.
Massachusetts Medical Society, Boston, June 12-13.
Maine Medical Association, Portland, June 13-15.
Minnesota State Medical Association, Minneapolis, June 20.
West Virginia State Medical Assn., Webster Springs, June 20-22.
Medical Society of New Jersey, Atlantic City, June 19-21.
State Medical Society of Wisconsin, Milwaukee, June 27-29.
American Ophthalmological Society, New York City, June 28-29.

ARKANSAS MEDICAL SOCIETY.

Annual Meeting, held at Hot Springs, May 8-10, 1906.

This meeting of the Arkansas Medical Society was the best in the history of its organization, the registration being the largest ever recorded.

The special feature of Wednesday was a popular lecture, given by Dr. Joseph M. Mathews, Louisville, Ky., at the auditorium.

Secretary's Report.

The report of the secretary showed the organization of three new county societies and one district society, leaving a total of nine counties and three districts in the state as yet unorganized.

Important Business Transacted.

STATE JOURNAL TO BE ISSUED.

It was decided to change the monthly bulletin into a monthly journal and to discontinue the publication of the annual volume of proceedings. The proceedings will be published in the new journal instead.

INSURANCE FEES.

The matter of regulating insurance examination fees was referred by the house of delegates to the various county societies to act on as they might see proper.

ENDORSEMENT OF COUNCIL ON PHARMACY AND CHEMISTRY.

In accordance with the report of a special committee, a resolution endorsing the Council on Pharmacy and Chemistry of the American Medical Association was unanimously adopted.

COMMITTEES APPOINTED.

A committee was appointed to report at the next annual meeting on the feasibility of forming a liability insurance organization within the state society. A committee was also appointed to report on the propriety and advisability of the society, by joint stock company or otherwise, erecting and maintaining a medical building for the state and county societies.

NEW SECTIONS CREATED.

A resolution was passed creating the following sections: Dermatology and syphilology, pathology, state and public hygiene, diseases of children, and ophthalmology, laryngology and otology.

Papers Read.

The following are some of the principal papers presented: "Uncinariasis," Dr. Morgan Smith, Little Rock. The author recommended especially the administration of menthol. In a paper on "Ophthalmia Neonatorum," R. H. T. Mann, Texarkana, embodied a plea for a law compelling midwives and others to report cases to competent physicians or health authorities. B. G. Wood reported an epidemic of influenza complicated with colitis. Large pieces of mucous membrane were discharged from the bowel, death following in a few hours after the complication manifested itself. H. Moulton, Fort Smith, read a paper on "Mastoid Operation." In the discussion the contention was made that the mastoid operation could be done by the general practitioner as well as by the specialist. It was clearly shown, however, that this operation should not be undertaken by any one not properly qualified. In a paper on ectopic gestation Dr. Preston Hunt, Texarkana, advised operation in the earlier months of pregnancy on account of greater safety. In a paper by J. W. Price on "Injuries to the Eyeball" and the discussion that followed, the advisability of not enucleating if there is vision and hope of saving the eye was urged.

In a paper on "Some Advantages of the Sigmoidoscope Over the Ordinary Proctoscope" Dr. W. V. Laws, Hot Springs, stated that the advantages of the sigmoidoscope are the comparative ease and freedom from danger in making examinations and the exposure of the lumen of the gut for examination.

DR. C. C. STEPHENSON, Little Rock, read a paper on "Anthrax of the Postnasal Space" in which he reported an interesting case, and exhibited exfoliated pieces of the turbinal bodies. The diagnosis in this case was repeatedly confirmed by microscopic examinations.

In a paper on "Surgical Treatment of Gastric Ulcer," Dr. J. P. Runyan, Little Rock, contended that the chances for recovery from this affection are much better when the patient is operated on.

Other papers read were: "Congestion of Brain in Infancy," W. T. Whaley; "Hemoglobinuria," R. N. Smith, Collins; "Malarial Hematuria," J. W. Cook, Mineral Springs; "New Phases in Treatment of Pneumonia," C. M. Lutterloh, Jonesboro; "A Case of Ainhum," O. M. Bourland, Van Buren; "Treatment of Diseased Conditions of Kidneys," R. L. Saxon, Holly Grove; "A Case of Disorganized Wrist Joint Following a

Case of Septic Fever," C. E. Davis, Eureka Springs; "Smallpox and Its Management," O. G. Blackwell, Pine Bluff; "The Race Question from a Medical Standpoint," H. Thibault, Scott; "Tuberculosis," G. E. Penn, Marvell; "Modern Views of Neurasthenia and Its Treatment," John Punton, Kansas City; "Rational Treatment of Vaginismus," J. R. Dale, Chicago; "Presentation of Shoulder," E. H. Winkler, De Witt; "Cases of Version," M. G. Thompson, Hot Springs; "Hemorrhage from the Uterus During Gestation and Its Effect on the Mother," J. T. Clegg, Siloam Springs; "Toxemias of Pregnancy, with Report of Some Acute Cases," H. C. Dunnavant, Osceola; "Placenta Prævia," J. W. Meek, Camden; "Complete Perineal Laceration," J. P. Runyan, Little Rock; "Inflammatory Conditions of the Female Organs of Generation as Met and Treated by a General Practitioner," N. S. Wood, Camden; "Carcinoma Uteri," C. R. Shinault, Little Rock; "The Pathology of Carcinoma of the Uterus," Nettie Klein, Texarkana; "Some Interesting Cases in Minor Surgery," E. K. Williams, Arkadelphia; "Gunshot Wound of Kidney and Liver, with Report of Case," Marion King, Texarkana; "Some Observations on the Use of Formaldehyd in Treating Carcinoma," Leonidas Kirby, Harrison; "Vaginal Hysterectomy," J. R. Dale, Texarkana.

In addition to these papers there were a number of interesting case reports.

Election of Officers.

The following officers were elected for the ensuing year: President, C. Travis Drennen, Hot Springs; vice-presidents, St. Cloud Cooper, Fort Smith; J. J. Morrow, Cotter, and L. J. Gillespie, Hope; secretary, C. C. Stephenson, Little Rock; treasurer, J. W. Scales, Pine Bluff.

The office of secretary was put on a salaried basis of $600 a year.

On invitation of the board of trade of Little Rock, the Society decided to hold its next meeting in that city.

A committee of five was ordered appointed by the newly elected president to confer with similar committees looking to the organization of the Southwestern Medical Association, to be composed of the states of Missouri, Arkansas, Texas, Kansas, and Indian Territory and Oklahoma.

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-first Annual Meeting Held at Washington, D. C., May 15-16, 1906.

President's Address.

DR. FRANK BILLINGS, Chicago, spoke particularly of the program for the meeting. A possible criticism is that it is too long, but it was felt that to refuse any of the papers offered would be exercising undue discrimination. Hence, all were given a place, with the request that each reader present only an oral abstract, instead of reading the entire paper. It is intended that hereafter no paper shall be read in full. Two symposia are included and Dr. Billings hopes to see them continued in future programs. During the past year the Association lost by death two members—Dr. D. D. Stewart and Dr. J. M. Ely. Dr. Billings read a cablegram conveying best wishes from Dr. Osler.

Under the head of general business of the society, Dr. Billings appointed a committee of nine members for the purpose of aiding in the formation of a new library for the physicians of San Francisco.

Mechanism of the Blood Pressure Changes in Mitral Insufficiency.

DR. W. G. MACCALLUM, Baltimore, studied a series of cases of experimental mitral insufficiency for the special purpose of determining the cause of hypertrophy of the right ventricle. He regards the findings as applicable to the spontaneous lesion as found in human beings. Increase of work in this lesion will not entirely explain the right ventricle changes. The essential features in mitral insufficiency are that the left ventricle is rendered practically useless and the blood regurgitates into the pulmonary system. A lessened amount of blood reaches the right ventricle and the lung. There is thus a smaller amount of blood in the circulation and more stagnant in the auricles. A series of charts obtained by his experiments showed that when mitral insufficiency was produced there was in most instances a fall of arterial pressure in the aorta, but the pulmonary pressure was hardly changed. However, there were alterations in the pulmonary circulation consisting mainly of a reflex wave from the left auricle. This affected to a certain extent the pressure in the pulmonary artery through the capillaries in the lung and affected the right ventricle before the closure of the pulmonary valve, as shown by the insertion of extra canulas. This will account for hypertrophy of the ventricle, although the old contention that there is no obstacle to the outflow of blood from the right ventricle, is not true, as that chamber has to pump blood into over-filled lungs.

Experiments of Venous Blood Pressure and Its Relation to Arterial Pressure.

DR. HENRY SEWALL, Denver, detailed experiments in which the venous pressure was determined by a specially devised instrument. The venous system is naturally divided into two departments, the somatic or superficial, and the splanchnic or central. The veins of the first are subject to various external stimuli and may be used for deducing conclusions as to the state of the circulation in all other parts of the body. The splanchnic circulation, from its importance, must be considered in every estimate of arterial pressure. The physiology of the depressor nerve, as applied to clinical conditions, is of the utmost importance. In heart lesions the beneficial action of rest is due to the fact that this permits recovery from the hyperirritability of the nerve. Blood pressure in the superficial veins depends on the ratio of in-put to outflow. The former is increased by muscular exercise and by heat; the latter is decreased by cold and by obstruction of the passage of blood into the heart. In some individuals venous pressure falls, in others it rises during digestion. Respiratory movements are fundamentally active in aiding transfer of blood from arteries to veins. Pressure in the peripheral veins increases during deep inspiration. It can be shown that both cardiac and respiratory variations of arterial blood pressure are frequently transmitted through the capillaries and hence are shown by the veins. The characteristically high venous pressure in gout and in lithæmia is particularly significant. In arteriosclerosis and arterial spasm the venous pressure is low, but rises when the cardiac circulation is impaired.

Rupture of Thoracic Aneurism Into the Superior Vena Cava.

DR. M. HOWARD FUSSELL, Philadelphia, related the clinical history of a man perfectly well until three days before he saw him. There was dyspnea and the upper part of the thorax and the arms were intensely cyanosed and edematous. Dullness over the upper part of the sternum finally developed and over it was a systolic murmur, which later became a to-and-fro murmur. There was no tracheal tug and no difference in the pulses nor in the pupils. The man died from exhaustion 41 days after onset of symptoms. Autopsy showed 5 cm. above the aortic valve a dilatation of the aorta 3 cm. in diameter, the upper part involving the beginning of the innominate. This was free from clot, but between the aorta and the vena cava was an adventitious sac filled by clot. From this sac there was a round opening into the vena cava, permitting the passage of a match stick. In most of the cases which have been reported the aneurism was large, and in at least 50 per cent. of them there was a loud, singing continuous murmur; this sign was absent here.

DISCUSSION.

DR. WILLIAMS for DR. CHARLES CARY, Buffalo, reported a case of varicose aneurism of the aorta and superior cava, in which the symptoms were very much like those in Dr. Fussell's case. The patient, a large man, was suddenly seized with pain while lifting. Cyanosis became striking, the color being a blue-black. The diagnosis was aneurism of the aorta compressing the cava and possibly with rupture into the cava. Death occurred on the fifth day and autopsy showed aneurism of the aorta the size of a fist, beginning one inch above the valve. The vena cava was occluded for a distance of two inches, beginning two inches above the auricle. The opening from the sac into the cava transmitted a No. 10 catheter.

DR. JOHN H. MUSSER, Philadelphia, mentioned a case of

aortic aneurism that pressed on the esophagus and the left bronchus, producing bronchoesophageal fistula. The patient, a woman, presented signs of aneurism and of esophageal pressure. Bronchopneumonia developed and she died suddenly from insufflation of blood.

DR. J. P. CROZER GRIFFITH, Philadelphia, presented the specimen of aortic aneurism ruptured into the vena cava that he reported to the society some years ago. The patient, a Chinaman, had shown all the signs described by Dr. Fussell.

DR. FUSSELL said that the Roentgen rays were used in his case, but were negative, because of the small aneurism immediately beneath the sternum.

Experimental Study of Cardiac Murmurs.

DRS. W. S. THAYER and W. G. MACCALLUM, Baltimore, reported a study of the heart sounds and of murmurs by direct auscultation of the exposed dog's heart. The heart was exposed by removing a portion of the chest wall, auscultation being performed by means of a stethoscope with a very narrow and long bell. The sounds of the normal dog's heart are the same as those of the human organ; from the nearness of the stethoscope a very much better idea could be gained of the superior strength of the aortic second sound. A striking point in the work was the ease with which a systolic murmur in the pulmonary artery could be produced by slight pressure on the conus arteriosus. This suggests that in man a soft systolic murmur may be produced by the resistance to the conus of the chest wall. A number of each of the various murmurs were produced by causing lesions analogous to those causing such sounds in human beings and in general these corresponded very closely. In mitral insufficiency murmurs were heard over the ventricle, the same as in human subjects, but in the dog the murmur and thrill were most intense in the left auricle, which is theoretically correct. In the dog, however, as in human subjects, this is transmitted through the chest wall as a soft murmur. This experiment illustrated the value of this feature to students if it were demonstrated to classes, showing the need of accurate anatomic knowledge.

DISCUSSION.

DR. W. G. MCCALLUM, Baltimore, described the technic of the experiments and showed instruments with which the lesions were produced. The series was a part of the attempt to teach experimental medicine and pathology to the students at Johns Hopkins, this being now made possible by the recent completion of a building for that purpose.

DR. T. W. JANEWAY, New York, said that on forced expiration there was not only a soft systolic pulmonary murmur, but also a harsh murmur and a thrill; the pulmonary valve can also be felt to close. These are apt to be thought indications of organic disease. He has attributed them to pressure by the expiratory effort or by a long auricular appendix overlapping the pulmonary artery and reaching the aorta.

DR. HENRY SEWALL, Denver, said regarding the murmur after infusion of salt solution, that it is generally understood salt infusions cause an increase of venous pressure first. The murmur suggests a relative insufficiency due to increased intra-cardiac blood pressure. He asked if Dr. Thayer paid any attention to the contraction of the papillary muscles. He believes that the first sound of the gallop rhythm is due to the difference in time of this contraction, as compared to the heart wall.

DR. L. F. BARKER, Baltimore, said that the work of Drs. Thayer and MacCallum represents a development in experimental pathologic physiology that is particularly pleasing. This is the kind to which Cohnheim and Bernard were partial. It will help the clinician much more than will pathologic anatomy. He earnestly hopes that more of this kind of work will be done.

DR. S. J. MEITZER, New York, suggested that if the experimenters had listened through the lung when not interfered with by artificial respiration, a better understanding of cardiorespiratory murmurs would have been obtained.

DR. THAYER said that he had not observed the contraction of the papillary muscles. The cardiorespiratory murmurs form an important subject that will have to be taken up especially in other investigations.

Intravenous Injections of Nicotine in Experimental Arteriosclerosis.

DRS. I. ADLER and O. HENSEL, New York, said that Josue's negative results from the use of nicotin were probably due to the fact that he used too small doses. They employed 0.015 gm. of pure nicotin in a 1 to 200 solution for each dose. Each time a rabbit was injected it had a violent convulsion. Tolerance was not produced even after 100 doses. The convulsions did not appear to affect the general health of the animals and were entirely over it in a few minutes. The injections were made every day or with intervals of two days occasionally. Some animals were immune to the action of the nicotin, while others were very susceptible. Most of them after from 18 to 25 doses showed characteristic lesions in the aorta, as after the administration of adrenalin. The very earliest effect is on the muscle cells of the media, the external or longitudinal layers rarely being affected. In some aortas showing no gross lesion, staining showed distinct changes as chromatolysis and karyolysis. Finally lime salts were deposited. One type of the lesion is quite diffuse, large parts being destroyed and leading to aneurismal dilatations. In another form, the degeneration is localized, assuming the appearance of atheroma. Experiments are now under way to determine whether these lesions are toxic, hypertensive or of other nature. Special points are: 1. The primary and essential factor is destruction of the muscle cells. 2. The elastica, contrary to the general belief, plays an entirely passive rôle. It remains normal just so long as the muscle remains normal and the later changes are entirely mechanical, degenerative changes being lacking. 3. It is frequently said of late that these changes in animals are not analogous to human arteriosclerosis, though human sclerosis, it is believed, is primarily a degeneration in the depths of the vessel wall. The reason there is no fatty degeneration in the rabbit is probably that in such animals calcareous are much more common than fatty changes.

Clinical Observations on Arteriosclerosis from Alimentary Toxins.

DR. C. S. BOND, Richmond, Ind., reported the result of twenty years' study of private patients, 150 cases being observed. Cases due to senility, alcohol, or syphilis were excluded. A great deal of work examining the stomach contents and the feces confirmed the clinical diagnosis. The diagnosis was also based largely on the urea output in each 24 hours.

DISCUSSION.

DR. J. L. MILLER, Chicago, said that very interesting work on vascular lesions had been done by an Italian observer who gave tobacco to rabbits by the mouth and obtained lesions similar to those described by Dr. Adler. The evidence produced during the past year is in favor of toxins rather than pressure as the cause of these changes. In his work with barium chlorid the changes were not confined to the media, but changes in the elastica and in the intima apparently were first.

DR. JOSEPH COLLINS, New York, said that the lesions produced by nicotin do not explain the initial step in the pathogenesis of the condition. Dr. Brooks and he are carrying out experiments which bring them a step nearer the solution. They are producing lesions by the inhalation of nicotin, rabbits being kept in chambers where smoking tobacco is being burned. No convulsions are produced in this way, nor is there initial rise in blood pressure. If this produces arteriosclerosis without the necrotic changes induced by increased blood pressure then the first change is nearer approached. The best explanation of the condition now is that it is due to hypertonus, and this may be caused by toxins, increased pressure or in other ways.

DR. H. A. HARE, Philadelphia, said that there is danger in criticising experiments and asked Dr. Adler the following questions: 1. Is there any relation between the frequency of the convulsions and the extent of the changes in the vessels? 2. Were the convulsions controlled by drugs? 3. Did he try antipyrin, which also causes convulsions in animals? Many controls are necessary in such experiments, as there are different changes in the tissues of animals in captivity without the interference of artificial causes.

Dr. Adler, in closing, said that he had some years ago reported a series of experiments in which he fed tobacco to rabbits; it produced no effect on the larger blood vessels. There were some interesting changes in the liver, heart and smaller vessels of the kidney and also of the liver. He had not set out to study the causes of arteriosclerosis in general. All the studies on human arteriosclerosis thus far are purely histologic and made in advanced stages of the disease. This accounts for the small amount of headway made in the study of the affection. The early stages in human beings are absolutely unknown. An interesting point in this connection is that the rabbits, which were immune to the action of nicotin, so far as vascular lesions were concerned, never failed to have a convulsion when given the injection.

Tricuspid Insufficiency in the Course of Pernicious Anemia.

Dr. Robert B. Preble, Chicago, said that in a typical case of pernicious anemia he observed pulsation in the jugular vein, but with none of the ordinary associated phenomena. There was no cyanosis, nor edema, nor passive congestion of the liver. In a second case, in a woman, seen when in coma, there was also a positive pulse in the jugular and in the small veins of the thorax and arms. As in the first case, the other signs named were lacking. Leube has reported finding similar conditions in cases of chlorosis. A third case showed essentially the same features. It seems possible that there may be such a lesion without seriously interfering with the circulation. Jugular pulse is possible under other conditions, as the rupture of an aneurism into the superior vena cava, or with an open foramen ovale with other added disturbance, but each of these could be ruled out of the cases reported. This venous condition in pernicious anemia is probably more common than is noted, or at least described.

Typhoid Spine with Deposits of Bone Along the Vertebrae in Relation to Spondylitis.

Dr. Thomas McCrae, Baltimore, reported a case of typhoid fever with the usual clinical history of typhoid spine. Later relapse occurred and during this attack the spine symptoms improved and the patient was discharged well. Definite bony changes in the second and third lumbar vertebræ were shown by the Roentgen rays. In a second patient the same symptoms and lesions as shown by the Roentgen rays appeared on the thirty-seventh day. This was a case of paratyphoid fever and may have been influenced by a previous gonococcus infection. There were no further explanation of the symptoms in these patients. One point is the explanation of the neurotic features. Spondylitis is seen in other conditions and is also accompanied by similar nervous conditions. The lesion is believed to be due to the local action of the typhoid bacillus. In the spondylitis of arthritis deformans there are all grades of lesions and so in typhoid spine. These cases of typhoid spine are thus of interest in connection with the cause of arthritis deformans, the lesions in the two being the same except in degree. This suggests the theory that arthritis deformans may be due to infection by different micro-organisms.

DISCUSSION.

Dr. James B. Herrick, Chicago, said that he was glad to see Dr. McCrae rescue typhoid spine from the list of functional diseases. He has seen two cases of the condition. In one no organic lesion was made out; in the other pain was localized over a distinct swelling. When the swelling subsided the pain also ceased. The lesion is thus a definite organic and inflammatory process.

Dr. W. S. Thayer, Baltimore, said that one reason inducing physicians to believe typhoid spine a pure neurosis is the curiously indefinite character of the pain in some cases. The symptoms in secondary carcinoma of the spine with similar manifestations are also indefinite. He believes that there is a definite local lesion of the spine in all cases of typhoid spondylitis.

Dr. Joseph Collins, New York, considers that the relations of gonorrheal spondylitis are confirmatory of McCrae's theory. A patient of the type described by Marie had a stiff spine for three years. From opening and draining of the seminal vesicles the patient is now greatly improved and recovery seems assured. It is a mistake to call all cases of typhoid spine organic, because some patients recover. If there be exudate and lesion of the bone they would not recover, though in some cases recovery does occur when there seems no doubt of the presence of periostitis.

Dr. Vickery, Boston, mentioned a case of typhoid spine in which the lesion was so high up that pleurisy or intercostal neuralgia was suspected. Finally a definite lesion of the dorsal spine was demonstrated by the Roentgen rays. Rest was at once instituted and the usual nervous symptoms did not develop.

Dr. James Tyson, Philadelphia, described a case of nuchal spondylitis of two years' duration. There were first the ordinary symptoms of wry neck, followed by a peculiar distortion of the neck, due to the spondylitis. This is the first he has seen in this location; the osseous changes appear due to the wry neck. He believes that all cases of spondylitis should be put in the category of infections.

Dr. J. K. Mitchell, Philadelphia, said that a very small lesion in the neighborhood of the spine may cause marked symptoms. In one case of three years' duration with agonizing pain in one side of the back, thus excluding spondylitis, the patient was operated on. This showed that the lesion was the tearing off of a fragment one-fourth by one-third inch in size from the lateral process of a vertebra in the lower thoracic region. The operation was followed by perfect comfort.

Dr. S. Solis Cohen, Philadelphia, believes that the question of pain is a very important one and that something more than spondylitis causes the intense pain often complained of. In some forms there are lesions of considerable extent and yet no pain whatever.

Dr. McCrae stated that he did not say that all typhoid spines are organic. In arthritis deformans the lesions sometimes clear up and so do they in typhoid spine. The Roentgen rays showed what was taken to be new bone formation in the cases he reported. There appears to be no association between the degree of pain and the extent of the lesion.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Ocular Complications in Measles.

In considering the ocular complications which may arise in the course of measles, Aaron Brav, in the *Medico-Chirurgical Journal*, states that every such patient with conjunctivitis requires treatment in order to avoid corneal complications and resulting damage to the eyesight. Therefore, when the physician is called to see a case of measles, he should instruct the parents regarding the necessity of absolute cleanliness, as the percentage of corneal opacities resulting from inflammatory conditions complicating this apparently mild disease of childhood is considerable. The child's hands should be thoroughly washed three or four times daily with warm soapy water, as he is liable to rub the eyes with the hands and not only increase the irritation, but transmit the infection. The face should also be kept clean. The child should be kept in a large, well-ventilated room, with uniform temperature and light covering. He should remain in bed for at least two weeks, during which time the toxins are eliminated. The room should be kept shaded, and no direct light should be permitted to fall on the eyes. Brav speaks against the practice of completely darkening the room, as light is essential in such illnesses. Full light should be permitted only after the eyes have become normal in appearance and conjunctival inflammation has entirely subsided. In carrying out these instructions, one guards against the irritation of the cornea and lessens the tendency to photophobia. Brav also recommends that an eye wash be prescribed in all cases of measles. The

physician should be specific in his instructions concerning this eye wash rather than prescribing the ordinary borax solution, in order that the necessary instructions will be more accurately carried out by the patient's nurses. An ordinary rag or cloth should not be used; the eye cup in older children is permissible, and in younger children the eye dropper should be used. The eye should be washed three times a day. As an antiseptic and as a soothing lotion, Brav recommends the following combination:

R.	Acidi borici	
	Sodii biboratis, āā.....gr. x	6
	Aquæ menthæ piperitæ 3ss	2
	Aquæ camphoræ .....℥ss	15
	Aquæ destillatæ, q. s. ad.....℥xvi	500

M. Sig.: To be instilled into the eyes three times a day.

The itching of the eyelids should be relieved by the following ointment:

R.	Hydrargyri oxidi flavi .....gr. ¼	015
	Lanolini 3i	4

M. fiat unguentum. Sig.: A small amount to be applied to the conjunctivæ at bedtime, followed by gentle massage over the eyelids.

The foregoing ointment will allay the itching and prevent blepharitis and the glueing of the lids when the patient awakens in the morning.

This author states that irritating drugs, such as silver nitrate, should not be used. When the congestion of the conjunctiva is very marked, one drop of the 1 to 4,000 solution of adrenal extract may be instilled into the eye three times a day. If the lids show the presence of marked edema, warm moist compresses are of great value.

When intense photophobia is present, the instillation of a few drops of a cocain solution will afford relief. If this condition should persist, the physician should always be on the lookout for some corneal involvement, and if present, a 1 per cent. solution of atropin should be instilled.

If general catarrhal symptoms, such as rhinitis, be present, the nose should receive a daily spray of boric-acid solution, as this greatly assists in the prevention of any inflammation and of any obstruction to the lachrymal sac. Children who have recently recovered from attacks of measles should not be allowed to read or to write until the system is entirely rid of toxic substances, and has entirely recovered from the influence of the toxic conditions. Such debility not infrequently affects the ocular muscles, both intrinsic and extrinsic, and produces a great deal of strain. Consequently, during convalescence extreme care should be observed, as it is mainly in this stage of the disease that the majority of the ills and complications arise. The general condition of the child must be improved. If there are any tendencies to strumous diathesis, tuberculous, scrofulous, syphilitic or rachitic, they must be combated, for in such cases the vitality is low and the resistance to corneal complications is lessened. During the cold season, the author recommends cod-liver oil during the stage of convalescence and continued throughout the entire season. When the oil can not be taken, the following combination is recommended as an alterative and as a tonic:

R.	Syrupi ferri iodidi ..... m. v.	30
	Liquoris potassi arsenitis.....m. ii	12
	Syrupi hypophosphiti 3ss	2
	Syrupi simplicis 3i	4

M. Fiat mistura. Sig.: The entire amount to be given at one dose and similar amounts given three or four times daily.

Bathing during the stage of convalescence must not be neglected. A warm bath should be given daily, as it not only facilitates desquamation and prevents the dissemination of the scales, but greatly assists in the elimination of toxins which not infrequently contribute to the development of the anemia and general debility.

Tuberculosis of the Larynx.

The treatment of tuberculous conditions of the larynx and epiglottis, according to the *Medical Bulletin*, should be largely systemic in the milder forms of the disease. It should be borne in mind that the disease does great harm only when it causes pain or prevents the taking of food, and in some cases large ulcers may heal with practically no local treatment. The method of curetting in order to eradicate the local disease is regarded as worse than useless, as it is impossible to know how deeply the bacilli have penetrated the apparently sound tissue in the vicinity of the superficial lesion. Ulcers should be cleansed with the following combination:

R.	Hydrogenii peroxidi	
	*Liquoris sodii boratis comp. (N. F.), āā..3i	30

M. Sig.: To be introduced into the larynx by means of a spray from the atomizer.

After the parts have been thoroughly cleansed, the ulceration should be dusted by means of a powder, as follows:

R.	Bismuthi subnitratis 3ii	8
	Pulv. acaciæ .....gr. xv	1
	Iodoformi 3ss	2
	Morphinæ sulphatis .....gr. xx	1 30
	Acidi tannici.....gr. xxx	2

M. Sig.: To be insufflated directly into the larynx by means of a powder blower.

If for any reason the morphin in the foregoing combination is objectionable, it may be omitted from the powder; and in any case, morphin must be prescribed with caution.

In order to relieve the excessive pain produced by swallowing, the use of cocain applied to the larynx either with an atomizer or a laryngeal applicator is recommended, but it must also be used with caution, in order to avoid the creation of a habit.

Acute Prostatitis.

In cases of acute prostatitis, the Cyclopedia of Med. and Surgery states that the outline of treatment should include absolute rest and a position that will favor emptying the part of blood as completely as possible. Consequently, the patient should be put to bed with the hips elevated. Hot sitz baths or hot applications to the perineum lessen the pain. If vesical irritation is present, the administration of the following combination is recommended:

R.	Acidi borici	
	Sodii bromidi, āā.....3ii	8
	Tinct. belladonnæ 3ss	2
	Potassii citratis 3iiss	10
	Aquæ dest. q. s. ad.....℥viii	240

M. Sig.: One tablespoonful every three hours in water.

If marked temperature is present the following combination may be substituted:

R.	Acidi borici	
	Potassii, bromidi, āā.....3i	4
	Potassii citratis 3ii	8
	Tinct. aconiti .....m. xxv	1 65
	Tinct. belladonnæ 3ss	2
	Spts. etheris nitrosi.....℥ss	15
	Aquæ q. s. ad.....℥vi	180

M. Sig.: One tablespoonful every three hours in water.

When the pain is severe, a suppository may be used as follows:

R.	Ext. belladonnæ .....gr. iii	20
	Ext. opii aqueous ..... gr. vi	40
	Olei theobromæ q. s.	

M. fiat suppos. no. xii. Sig.: One suppository to be introduced into the rectum two or three times a day, according to the severity of the pain.

Medicolegal

Sufficiency of Hypothetical Questions.

The appellate term of the Supreme Court of New York says that where the ground of the defendant's exceptions in the personal injury case of Coles vs. Interurban Street Railway Co. was that the questions put to the expert witnesses did not fairly and fully state all of the facts proved in the case the contention seems unsound in law. It is sufficient if a hypothetical question is within the possible or probable range of the evidence, without being based on all of the evidence given or on a judicial summing up of the fair effect of that evidence.

No Forgery of Invalid Prescription.

The Supreme Court of Vermont says that the defendant in the case of State vs. McManus was charged with committing

* Dobell's Solution.

the crime of forgery by altering a physician's prescription for whisky. The prescription in question, however, contained no statement that the liquor prescribed was necessary for medicinal use. It therein failed to comply with the statute in a very essential particular. The paper was invalid on its face, and could not be relied on as authority for a sale. This has been held in respect to similar provisions in other states. State vs. Tetrick, 34 W. Va. 137; State vs. Nixdorf, 46 Mo. App. 494. And it has been long and uniformly held that a paper that is invalid on its face will not sustain a charge of forgery at common law. The writing must be such that, if genuine, it would be apparently of some legal efficacy. It is not to be presumed that any one could be deceived or defrauded by a document that is void on its face.

Hospital Record as Evidence of Pain and Suffering.

The Superior Court of Delaware says that in the personal injury case of McMahon vs. Bangs the head nurse of the hospital to which the plaintiff had been taken was produced by him as a witness, and after testifying as to his condition when taken to the hospital, was questioned concerning a certain record of the case, which she testified was regularly kept by one of the nurses of said hospital, who had since been dismissed and was not present in court. Said record was thereupon offered in evidence and was objected to by counsel for the defendant on the ground that the only person who could testify to said record, so as to make it proper evidence, would be the person who made it. The object of offering this paper in evidence, the court says, seemed to be to show pain and suffering. For that purpose the nurses themselves might be called, and under proper circumstances this paper could be used to refresh their memories. Beyond that the court thinks it was not admissible.

Physician Entitled to Recover for Services.

The appellate term of the Supreme Court of New York says, in the case of Denenholz vs. Kelly and another, that a boy in the defendants' employ had his hand crushed and severely injured. The defendants employed the plaintiff, a physician, to care for him. No agreement was at first made about compensation, but after a time the defendants wished to limit their probable liability, and agreed to pay the plaintiff $175 for his services in the case, and $20, the fee of a consultant. They paid only $100, and this action was for the balance. The defendants said that after the plaintiff's bill had run up to $100 the question of agreeing on a sum was broached, and that $175 was agreed on after the plaintiff had said that the treatment might still continue "six, seven, or eight weeks—quite indefinite," while they claimed that the treatment did not continue so long as they had been led to believe it would. But the court says that the statement attributed to the plaintiff, of course, was not a representation that the case would take any definite time, but merely the expression of an opinion. In point of fact the treatment did continue for some weeks thereafter. On the case the plaintiff was clearly entitled to the sum sued for.

Distinction Between "Expert" and "Opinion" Evidence.

The Supreme Court of Wisconsin holds, in Schwantes vs. State, that the scope of opinion evidence is not limited by the technical meaning of the term "science, art or skill." It says that the quoted expression, often found in decisions, in a view that might be taken thereof, conveys rather too narrow an idea of the scope of opinion evidence. It may have no appreciable connection whatever with "science, art or skill," in a technical sense, and yet be admissible just as clearly as if it possessed such connection. All opinion evidence is not expert evidence in the technical sense, but all expert evidence is opinion evidence in any view of the matter, and all admissible opinion evidence is expert evidence in the general—the legal—sense of the term. The term "skill," as used in the quoted expression, must be regarded in its broadest signification, not applied, necessarily only to mechanical or professional knowledge. It includes every subject susceptible of special and peculiar knowledge derived from experience. The term "science, art or skill" as a limitation of expert evidence is more of a lexiconic than judicial origin. Webster defines the noun "expert" as, "One who has skill, experience, or peculiar knowledge on certain subjects of inquiry in science, art, trade or the like; a scientific or professional witness." That, strictly construed, is hardly a safe guide. The law writers define the term as "a person having special knowledge and skill in the particular calling to which the inquiry relates." The preliminary questions respecting opinion evidence, that is, that of the competency of the witness and that of whether the subject is within the scope of opinion evidence, are in the field of competency, in which the judgment of the trial court is conclusive, unless shown to be clearly wrong.

Insane Asylum Not Liable for Acts of Inmates.

The Court of Appeals of Kentucky says that the case of Leavell vs. Western Kentucky Asylum for the Insane was brought to recover damages for an injury to the hand of the plaintiff caused while an employé in the defendant's laundry, it was alleged, by a lunatic allowed to work there, wrongfully starting a machine. Thus the question presented was: Can the defendant asylum be held responsible for a tort committed by a lunatic of whom it has custody? In the court's view of the law the question must be answered in the negative. The defendant, the court says, is purely an eleemosynary institution created by the state and maintained at its expense for the beneficent purpose of caring for such of its citizens as may by judgment of a court of competent jurisdiction be declared of unsound mind, and, by reason thereof, disqualified for the duties of citizenship and of caring for themselves. Such institutions are mere instrumentalities of the state government brought into being to aid in the performance of governmental duty, hence the rule of respondeat superior (the superior must answer) does not apply to them. The defendant cannot therefore be made to respond in damages for a personal injury inflicted on another by its servant, or a lunatic in its charge, though such injury results from negligence or malicious act on the part of such servant or lunatic. Nor does the court think the contention sound that because the statute from which the defendant derives its corporate life and powers declares that it may sue and be sued that places it on the footing of all other corporations with respect to torts committed by those in its care or employ. There are, it says, many causes of action for which the defendant may sue, and also grounds on which it may properly be sued. It may, through its officers, make contracts for supplies for its inmates, incur liabilities on that account, and for the proper maintenance of the institution it may sue for debts due it, or to enforce any right allowed by law. It may incur liability in damages for creating and maintaining public nuisances which endanger human life, or destroy or injure the land of another, and be sued to enforce such liability. The court is of the opinion, therefore, that the right given the defendant by statute to sue, and to others to sue it, is to be taken in a qualified sense, and should not be so construed or extended as to make it responsible to persons injured, as was the plaintiff, by reason of the misconduct or negligence of its inmates of employés. Whether the policy of thus exempting eleemosynary institutions from liability in such cases be wise, or unwise, it is undoubtedly sanctioned by a long line of authorities, and the attention of this court has been called to no case in which a contrary rule has been announced.

5 *Concerning the Diagnosis. J. N. Study, Cambridge City, Ind.

2. **Cerebellar Apoplexy.**—Starr declares that the existence of cerebellar apoplexy is not generally recognized. He cites the histories of five cases which present the common symptoms of an extreme degree of vertigo at the onset, which gradually

subsides to some extent, but which recurs on any attempt to walk and which also remains as a permanent symptom; an uncertainty in gait, which is due not to paralysis, but to a lack of balancing power, which results in staggering and uneven steps. There is also an unnatural posture of the head when at rest, and nystagmus. When in combination these symptoms are characteristic of cerebellar disease. The vomiting and headache observed in all the cases are doubtless due to irritation of the vasomotor and pneumogastric centers in the floor of the fourth ventricle, which lies immediately below the cerebellum.

5. **Concerning the Diagnosis.**—Study declares that it is unwise to declare that an individual is suffering from some disease simply because the specific bacillus is found in the body; that the presence of the Widal or diazo tests indicate typhoid fever, or that the tuberculin test indicates tuberculosis. These helpful methods of diagnosis he believes to be somewhat limited in value, and too much dependence should not be placed on them as a class unless they are accompanied by the clinical phenomena which are characteristic of the disease. The microscopic examination of diseased structures, secretions and excretions will often clear up a doubtful diagnosis. The physician who would serve his patient best must use all methods for correctly interpreting disease and other abnormal conditions of the body, not relying on any one procedure to the exclusion of others which have been proved to be meritorious.

6. **Effects of Uric Acid on the Genitourinary Tract.**—Porter summarizes his paper as follows: Uric acid is one of the normal end products of proteid oxidation reduction. It is never present in any food substances and is never found in the blood. The antecedent proteid molecule from which uric acid is made is contained in the blood. Uric acid is made in the renal cells by the oxidation reduction of the desulphurized proteid molecule. The proteid molecule is desulphurized in the epithelial cells of the gastric follicle and in the hepatic cells. In gout, uric acid is formed in protoplasmic structures other than renal cells by a vicarious action by which the proteid molecule is oxidized at an abnormal point. It is absolutely necessary to have uric acid produced in the renal cells. When uric acid is produced faster than it can be converted in the uriniferous tubules into a urate it is overproduced. The urate is produced by the action of the uric acid on the neutral phosphate, thus forming the urate and an acid phosphate. Sulphuric acid is formed in the epithelial cells of the kidneys from the proteid molecule. In the cavity of the stomach the sulphuric acid acts on the sodium chlorid, forming hydrochloric acid and sodium sulphate. The hydrochloric acid in the lumen of the intestine attacks the alkaline sodium phosphate, restoring the sodium chlorid lost in the stomach and forming the neutral salt for the blood. The three etiologic factors causing overproduction of uric acid are defective oxygen supply, overfeeding, disturbances in the nervous mechanism. Uric acid is formed by oxidation reduction and not by synthesis. The intensity of the toxin transformed in the kidneys determines the character of the lesion. The effects of the overproduced uric acid are renal hypertrophy, parenchymatous degeneration of the kidneys and diffuse or interstitial transformation. This overproduction may cause a catarrhal condition of the pelves of the kidneys or a truly inflammatory process may result, or it may act as a general irritant to the whole genitourinary tract. Giving alkalies masks symptoms, but never removes the etiologic factors, while the removal of the latter should be the main object of all therapeutics. Overproduction of uric acid may aid in causing phosphatic as well as uric acid calculi. Uric acid may act as an irritant in solution, in its isolated crystalline form, or massed together in the form of a calculus. The action of uric acid on the genitourinary tract is always mechanical. The effects of the overproduced uric acid are often confounded with disturbances in metabolism that cause the overproduction.

9. **Diagnosis of Renal Functions.**—Cabot urges that functions, not histologic appearances, are what we should strive to recognize in kidney disease. Albumin and casts alone never prove the existence of nephritis. They may or may not accompany it. The physical characteristics of the urine, the visceral evidence of uremia, dropsy and cardiac involvement are, with time, the best help to the functional diagnosis of kidney disease. The dilution test, the concentration test and, if opportunity offers, the quantitative estimation of the capacity of the kidneys to excrete particular substances may render valuable assistance. Cabot particularly recommends a very simple test, which seeks to determine whether and to what extent the kidney is injured to secrete a dilute urine after profuse ingestion of fluid, or a concentrated urine when liquid is withheld. In the early stages of acute renal insufficiency the kidney often loses for the time the power to secrete a dilute urine. On the other hand, in some cases of chronic interstitial nephritis the kidney continues to secrete a concentrated urine, even when water is considerably restricted.

17. **Ununited Fractures of Neck of Femur.**—Cobb claims that fractures entirely intracapsular are very rare. When they do occur and are unimpacted the obtaining of union by any form of fixation apparatus is exceedingly doubtful. The operation of nailing the fracture with or without open incision is to be adopted, he thinks, whenever possible. In the young and middle aged, when no contraindications to operate are present, such as obesity, general debility, marked arteriosclerosis or complicating disease, the method with open incision is more accurate and preferable. In persons of advanced age and those with definite contraindications to surgical interference the direct method without incision, as practiced by Nicolaysen, should be used in all cases if seen sufficiently early. In employing the method of Nicolaysen a general anesthetic should be given.

30 *Open Air Treatment of Tuberculosis. J. W. Pettit, Ottawa, Ill.

30. **Open-air Treatment of Tuberculosis.**—According to Pettit the constant supervision of the patient is the most important point in which the sanatorium treatment must neces-

sarily differ from that adopted by the general practitioner. The patient being under constant supervision, early symptoms of an intercurrent affection are noted and serious complications often anticipated. Medicines are used as indications arise and are usually administered to meet symptoms. Cough, night sweats, loss of appetite and anemia, as a rule, lessen at once and soon disappear under rest and fresh air without the use of drugs. Speaking of the home treatment of tuberculosis, Pettit says that since the agencies are so simple it would seem there would be no difficulty in carrying out the treatment at home. Experience, however, teaches that, as a rule, it can not. First, because so many cases occur in families where it is not possible to make the application. Second, when patients are more favorably situated it is impracticable for the reason that the treatment has not been accepted by the laity with that degree of confidence so essential to its application. A third reason may be given that the methods are not well understood by the average physician, and when they are they consume so much time and energy that it is hardly possible for the busy physician to get the time from his other work to devote to the few patients whom he may have under his care. In other words, it is for practical rather than for theoretical reasons that the treatment can not be applied at home. The education of the public and of the profession must come through sanatoria. These will be training schools which will be centers of influence in propagating the new doctrine and its methods; it will be wise, therefore, for physicians to devote their energies, for the present at least, to the establishment of sanatoria rather than to take the risk of bringing the treatment into disrepute by many failures, which must result through lack of experience on the part of physician, patient and friends.

40 Surgical Conditions of the Puerperium. J. C. Hubbard, Boston.

32. **Clinical Observations on Eclampsia.**—In 37 cases reported by Ryder, 13 patients died, a mortality of 35 per cent. The period of pregnancy seemed to affect the mortality. Of the series, 25 patients were over seven months pregnant and 12 seven months or under. Of the former, 6 died, a mortality of 24 per cent. Of the latter 12 died, a mortality of 58 per cent. In other words, the mortality when the disease occurred on or before the seventh month was more than twice as high as when it occurred after the seventh month. The mortality among primiparæ and multiparæ was nearly even. Of 21 primiparæ, 8 died, 38 per cent., and of 16 multiparæ, 5 died, 31 per cent. Age seemed to affect the mortality very little. Of 19 who were 25 years old or less, 6 died, 31 per cent. Of 10 over 25, 7 died, 38 per cent. The mortality was less in the colored than in the white women. Of the former, 9, 2 died, 22 per cent.; of the latter, 28, 11 died, 39 per cent. The severest and most fatal type of the disease was the hemorrhagic, with vomiting of blood, blood in the stools or petechiæ over the body. In the 37 cases there were 11 patients of this type, and of these 9 died, 82 per cent. mortality. Moreover, of the entire 13 deaths of this series, 9, or 69 per cent., were of the hemorrhagic type. When these signs of hemorrhage in the vomitus, stools or skin are seen the prognosis is always bad.

On the other hand, cases of postpartum eclampsia were nearly all of mild type. There were seven of these, the first convulsion occurring from within a few minutes to several days after delivery. One case occurred as late as the eleventh day. All except one of these patients recovered, a mortality of 14 per cent. Of the 30 cases of antepartum or intrapartum eclampsia, 12, or 40 per cent., were fatal. Postpartum, 7 cases, 1 death, 14.3 per cent.; intrapartum, 6 cases, 2 deaths, 33.3 per cent.; antepartum, 24 cases, 10 deaths, 41.6 per cent. After delivery many of these patients showed marked and immediate improvement, a few seemed to grow worse and the rest were apparently not immediately affected. Eleven, or 37 per cent., showed immediate improvement; 4, or 13 per cent., seemed to grow worse, and the rest, 50 per cent., were not immediately affected. Over one-third then showed immediate improvement after emptying the uterus, and only one-eighth seemed worse.

The time elapsing from the first convulsion to the delivery of the patient was twelve hours or over, and of these 6 died, a mortality of 60 per cent. In 20 the interval was less than twelve hours, and of these 6 died, 30 per cent. mortality; or the fatality was about twice as high where the delay in delivery was over twelve hours. In 19 cases the cervix was dilated less than two fingers when first seen; in 11 two or more fingers. Of the former, 9 patients died, a mortality of 47 per cent. Of the latter, 3 died, 27 per cent. mortality. In method of delivery (nearly all the cases were dilated first with bags) there were four so-called vaginal Cæsarean sections; of these patients 3 died, 75 per cent. mortality. Accouchement forcé was performed in 18 patients; 7 died, a mortality of 39 per cent. Forceps operations were done in 5 patients; 1 died, a mortality of 20 per cent. In 10 normal deliveries (including the postpartum eclampsias) 2 patients died, 20 per cent. mortality. Premonitory symptoms, giving ample warning of approaching danger, were present in 29 out of the 37 cases. Of the infants 50 per cent were saved (one set of twins made the total number of infants 38). Of the 19 that were lost, 12 were stillborn and 7 died, many showing the typical lesions found in the adult cases of eclampsia.

34. **When to Remove Ovary.**—Emmet advises that on thorough inspection of a suspected ovary anything which does not at once proclaim itself innocent and harmless be removed immediately, and that if a growth, however small, suggests active proliferation or malignancy, the ovary be taken away in time.

35. **Time of Ovulation.**—Rowe advances the hypothesis that ovulation occurs normally at the close of the period of quiescence, and initiates and, indeed, directly causes the period of hypertrophy. Menstruation, on the contrary, is the result of the exhaustion and disappearance of the stimulus. If the ovum dies, then all the preparations made for its reception are useless and must be disposed of. Menstruation, therefore, is an almost infallible proof that the last ovum discharged from the ovary is dead. If, on the other hand, the ovum does not die, the stimulus begun with ovulation goes on and the time for menstruation passes without that event. Therefore, if the expected menstruation does not occur, then the ovum last expelled from the ovary was still alive. And if the last expelled ovum is alive at the time of the next expected but suppressed period, then that ovum was fertilized, for otherwise menstruation would have occurred.

37. **Ventrofixation.**—In all cases in which retroversion is the only lesion, and when there are no adhesions, Smith performs a modified Alexander operation. This modification consists in crossing one ligament under the skin, tying the two ligaments with a reef knot opposite the right external inguinal ring, which knot is secured from slipping by a few fine catgut stitches. When doing a ventral fixation Smith scarifies a space an inch in diameter on the anterior surface of the fundus and on the corresponding abdominal peritoneum. The uterus is anchored by two chromicized catgut stitches passing through the peritoneum, muscle and fascia on both sides and deep in the uterine wall. These stitches must last a month. In both the Alexander and ventral fixation operations Smith says that it is important to amputate the cervix if it is too long, so as to leave the uterus only two and one-half inches deep, thus lightening the load to be carried by the shortened ligaments or by the adhesions.

39. **Radium Therapy.**—Abbe claims that radium gives the most satisfactory results in the treatment of birthmarks, lupus and keloids. It is helpful in the late cases of cancer of the uterus to palliate some of the symptoms, and may proba-

be curative in the very early stages. It is the most desirable treatment of inoperable strictures of the rectum and esophagus, where it gives more comfort to the patient than colostomy or gastrostomy.

42. **Medical Treatment of Appendicitis.**—Carveth sums up his paper as follows: 1. Absolute rest in bed until all the symptoms have subsided for some days. 2. The withdrawal of all food by mouth and the severest restriction on liquids swallowed. 3. The avoidance of purgatives, for while they may appear to be good in some cases, they are dangerous. 4. The careful employment of opium to the extent of relieving pain and lessening peristalsis, but not to the extent of materially contracting the pupils nor of arresting the urinary flow. 5. That very large enemata are very dangerous, and that the bowels should be moved, after all the acute symptoms have subsided, by small oil enemata, aided by gentle aperients, such as small doses of calomel or oil.

48. **Treatment of Cancer of Larynx.**—Mackenzie insists on the application of the naked-eye method of diagnosis in the case of malignant tumors of the larynx. He urges that every resource and refinement of clinical diagnosis, including the exclusion of syphilis by the iodids and tuberculosis by tuberculin, should be resorted to before an appeal to the microscope is made. The moment the continuity of the growth is broken, in that moment is opened the pathway for self-poisoning, and an unfavorable influence is exerted on the local process. If ulceration has already taken place, a portion of the growth can be taken, if skilfully removed, for microscopic examination, but in the majority of cases the tumor is buried and an exploratory incision for purposes of microscopic diagnosis means two operations. If the tumor is malignant, this opens the way for general dissemination. The microscope should be the final method of appeal. If microscopic examination is necessary the patient and surgeon should be prepared for immediate operation.

49. **Treatment of Hypertrophic and Intumescent Rhinitis.**—In order to show the value of galvano-cautery Ingals and Friedberg studied 100 cases, 50 of the hypertrophic and 50 of the intumescent form of rhinitis, in which treatment had been carried sufficiently far to serve as a basis for comparison. They conclude that the galvano-cautery, when properly used, offers one of the best, if not the best, methods for the treatment of the intumescent and hypertrophic forms of rhinitis. The dangers of the middle ear infection have been greatly exaggerated, not any case in the series and only one among several thousand cauterizations having come under their observation. The liability to adhesion formation is not great, providing sufficient care be taken not to injure the opposite septal mucous membrane, and providing, in cases in which the subsequent swelling is marked, that a probe be passed between the opposing surfaces in four or five days. A 4 per cent. solution of cocain is sufficient in the vast majority of cases to induce complete local anesthesia, from three to six applications on a cotton-wound flat applicator being sufficient for the purpose.

As the result of experience, especially in cases of marked intumescence, they believe that a spray of adrenalin or suprarenalin, gr. 1/8 to the ounce, materially assists in producing anesthesia. The objection that the galvano-cautery destroys too much of the mucous membrane does not obtain if the cauterization is linear, as here recommended, and if it is done properly, whereby very little mucous membrane is destroyed. Scab and crust formation does not occur any oftener following cauterization than after other nasal operations. In fact, it was noted in but very few instances, and in some of these a change in the spray solution caused a cessation of this trouble. No packing is needed to prevent hemorrhage, and this factor makes the discomfort following the operation very much less than when some other methods are employed. There is very little pain after galvano-cauterization of the turbinated bodies.

62 Incidence of Chronic Bright's Disease. Its Frequency, Diagnosis and Treatment. F. A. Carmichael, Goodland, Kansas.
63 *Treatment of Recent Sprains and Contusions. R. McC. Schauffler, Kansas City.
64 Incurable Skin Disease. W. Frick, Kansas City.

63. **Treatment of Recent Sprains and Contusions.**—Schauffler claims that early massage to diminish the exudate and improve the circulation is strongly indicated. This should be toward the body and from the proximal side of the swelling progressively across it. Unload the blood vessels at a distance up the limb, then rub down the upper edge of the swelling, then advance to the center, etc. Support may be afforded by a flannel bandage or, better, by some form of elastic bandage. This may be replaced, often early and nearly always later, by appropriately applied strips of rubber adhesive plaster. Over the contusion in the soft parts and where applied to prevent swelling, the strap should be at "fascial tension," i. e., about the tightness of the fascia over a large muscle. Only when it is desired to relieve a torn ligament by outside strapping should the plaster be tightly drawn, and in that case it should, of course, never completely encircle the limb. Hot compresses may be used early, or to still greater advantage, dry heat in an appropriate bake oven, if the affected part be a limb. The temperature can be pushed up to 300 F. if proper precautions are taken to absorb all the moisture. The advantage of baking in old joint lesions is well known. When the apparatus is at hand it may be advantageously employed in most recent cases.

Passive motion should be substituted at once by the surgeon. It should be light, but of good range, and persisted in, in spite of moderate pain. Schauffler says that the whole treatment of a sprained ankle by the "army strapping method" fails unless the patient is made to walk from the first; carefully, to be sure, and in short installments, with the foot elevated between times; but walk he must, or the circulation becomes sluggish and the treatment fails. A large joint effusion is the only contraindication to early active motion, except fracture, and some kinds of fracture do well under the ambulatory treatment after a few days of rest. Massage may be continued through the strapping, or an elastic bandage may be used and removed for rubbing, baking, and so on. A belladonna ichthyol ointment may be applied under the bandage. In the latter stages electricity is of distinct value. It is Schauffler's custom to treat all fractures of the forearm between flat padded board splints and to remove these every few days for bathing of the skin and light massage. Passive motion is instituted in ordinary cases within a week and always after two weeks. He has never had the bone slip out of place under such manipulation if it had been properly reduced at first. In fracture of the neck of the femur in old

people he applies no traction or splints. The limb is kept quiet with sand bags for 48 hours, then the patient is made to sit up in a reclining chair and is early allowed to walk with crutches. The weight of the limb is supported by slings of plaster or by a hip splint.

67 *Presence of Indican in the Urine of Those Affected with Dermatitis Herpetiformis. M. F. Engman, St. Louis.

66. **Roentgen Ray in Mycosis Fungoides.**—The patient whose case is reported by White and Burns is believed to have succumbed to the effects of a too rapid relief from his malignant disease. The machines used were six inches and twelve inches in coil. About one-third of the exposures were given on the six-inch coil. The total time of exposures was eight hours and twenty minutes in the space of 54 days. The tumors disappeared rapidly and death evidently was the result of a toxemia caused by the absorption of broken-down tissue.

67. **Indicanuria in Dermatitis Herpetiformis.**—During the past five years Engman has examined the urine of all his patients with dermatitis herpetiformis for indican; the hydrochloric-acid nitric-acid test being the one most frequently employed. The intensity of the resulting color reaction was used as a comparative test of the amount present. He reports on 18 cases, 6 having occurred in his own practice. He reports that 14 of these cases are reliable, the other 2 being of uncertain value. In all of these 14 cases indican was found in marked excess in the urine. In the author's 6 cases eosinophiles were of high percentage in the blood and bullæ contents, and careful observation was made to see if there was coincident eosinophilia and indicanuria. As the indican was found in greatest excess during an exacerbation of the dermal process, and as eosinophile cells occur in the blood of this condition in the highest per cent. during a like period, the two conditions were found to be coincident.

68. **Significance of Urinary Analysis.**—Davis believes that a pathologic diagnosis is impossible in many cases of nephritis, and that in making a diagnosis, the condition of the blood and blood vessels, and nutrition, and the existence of edema and the uremic manifestations, and not changes in the urine, are of the most importance. Albumin and casts are always significant of defective kidneys. The defect may be functional or anatomic, or both. But the converse of these is not true, for nephritis may exist when the urine is normal. Red blood corpuscles in more than very small numbers indicate an actively developing lesion, and therefore either an acute one or an exacerbation in a chronic one. However, again, the converse of this statement is not true, for red blood corpuscles may be wanting in the urine from kidneys which are acutely inflamed. A large amount of sediment made up chiefly of casts indicates an extensive involvement of the renal epithelium in pathologic changes. The same conclusion is justified when the sediment is large in amount and contains a large proportion of renal epithelium.

The best evidence of the competence of kidneys to perform their work is by estimating from the specific gravity of the urine the total solids voided in twenty-four hours. Such new methods of determination as cryoscopy and electrical conductivity afford no better information. The relative amount of ammonia voided as compared to urea or total nitrogenous matter is sometimes of use in roughly gauging the functional activity of the liver, for it is in this organ chiefly that the ammonium compounds in the blood are transformed into urea. Therefore, if ammonia is eliminated in excess and urea in lessened amount, the liver, rather than the kidneys, is inactive. But it must be remembered that if there is an excess of acid in the blood it may form compounds with ammonia which will effect the same result. This relationship of ammonia to urea exists commonly in uremia and often is a warning of its approach. The recognition of the presence of indican or of combined sulphates in large quantities is important, because they indicate much decomposition of proteids in the intestines and the production of substances which are abnormal to the human body and which, when eliminated by liver or kidneys, may injure them, or at least tax their functional powers. They indicate an intestinal indigestion which must be corrected, especially when there is nephritis, because it so often provokes uremia.

72. **Cold Applications in Hay Fever.**—All other attempts to relieve the patient during a very bad attack of hay fever having failed, Wolner applied cold compresses to the man's forehead and face, wringing them out of ice water, and reapplying them as soon as they began to get the least bit warm. In about three-quarters of an hour relief was obtained. The treatment was kept up constantly for about three hours, and off and on for about six hours. The patient did not have another attack that season. A year later the attack came on again. The patient applied cold compresses for about four hours and was entirely relieved in twenty-four hours. The attack did not recur.

74. **Suprapubic Hysterotomy.**—The procedure employed by Russell is described as follows: A uterus which is suspiciously enlarged or which has given rise to intractable, unexplainable hemorrhages, is exposed, either in the course of an abdominal operation for other purposes or in the course of a purely exploratory operation in which the abdomen had been opened for the particular purpose of doing a hysterotomy. After the pelvic organs have been examined the uterus is drawn out of the abdominal opening as far as the cervical portion and is surrounded by gauze on all sides. It is then grasped below on both sides by an assistant, who lifts the body of the organ well up while the operator boldly splits it in the median line on the anterior wall, half-way down toward the neck, as well as through the fundus to the posterior surface. The entire thickness of the uterine wall is divided for a distance of two or more centimeters down into the cavity, the mucosa can then be inspected at every point, the finger can be inserted and the whole cavity felt, and if there are any nodules in the wall they can be palpated. If the mucosa is diseased it can be scraped away with surprising ease and with the certainty of reaching all points efficiently, even in the cornua about the entrance of the tubes, a procedure which is almost impossible by the cervical route. The bleeding is only moderate, and it has not been necessary to put ligatures around a vessel. The wound in the uterus is closed with interrupted catgut sutures passed from the peritoneal surface down to the mucous membrane. These are placed about 0.5 cm. apart, leaving the detail of closer approximation to fine catgut sutures. Catgut sutures, if properly sterilized, may be employed with safety in cases in which there is not history of infection; otherwise fine silk is preferable.

Russell says that suprapubic hysterotomy is of conspicuous service in cases of persistent uterine hemorrhage which is not controlled by any form of treatment and in which bimanual palpation of the pelvic organs has given an absolutely negative diagnosis. Small submucous and pedunculated myoma, which do not affect the size or contour of the uterus, but which may be the source of dangerous hemorrhage, are easily

detected and removed by this method. When the abdomen has been opened for some other purpose, and no explanation has been found for the uterine hemorrhage, he would then also advocate its application. No deaths have occurred among 32 patients operated on, notwithstanding the fact that many of these cases were complicated by other serious abdominal or pelvic disturbances, proving quite conclusively the slight danger attending the operation.

1. **Extroversion of Bladder.**—Special reference is made by London to the extraperitoneal transplantation of the ureters into the rectum and three cases are reported. In the first case, after careful disinfection of the bladder surface, a director was passed in each ureter. A button or rosette of mucous membrane was cut around the ureteral orifice so as to save any valvular or sphincteric action which that opening might possess. A finger was inserted into the rectum and a pair of Lister's forceps was guided along the finger and thrust through the wall of the bowel. Its blades were opened widely enough to seize the end of the ureter, which was then drawn through into the rectum and kept there in position with an ordinary pair of clip forceps. The same was done on the opposite side, the handles of the forceps dangling outside the anus. Unfortunately, an assistant removed the forceps attached to the right ureter, which worked its way out of the rectum. Later this ureter was transplanted into the sigmoid flexure. The result was an excellent one. There was no irritation of the rectum, no frequent urination, and the patient has enjoyed physical comfort for nearly seven years. In the case of the second patient the right kidney had been removed previously so that only one ureter remained to be dealt with. The only modification of the technic of the previous operation consisted in first inserting a rubber catheter, with its point removed, into the ureter, and stitching it to the mucous membrane. This facilitated the drawing of the ureter into the rectum without so much bruising of the orifice. The patient died three months later, and at the autopsy it was found that the ureter had escaped from the rectum, the urine meanwhile having found its way through an ulceration into a loop of small intestine, at a distance of a few inches from the ileocecal valve. The third patient was operated on by this method with complete success about a year ago.

2. **Id.**—Newland also calls attention to the advantages of extraperitoneal implantation of the ureters and reports one successful case.

4. **Rickets and Lactation.**—With a view to determining the relation of the incidence of rickets to the varying conditions

under which the function of lactation is exercised, Fordyce examined 200 children of different families, aged from 6 months to 3 years. Rickets was marked in 61, slight in 55 and absent in 84 patients. He found that the amount of rickets among infants mixed-fed is approximately the same as among those bottle-fed, but differs in this respect that whereas among the former the percentage number of marked cases of rickets among those suffering from the disease was 50 per cent., in the latter it was 65.1 per cent. There appeared to be a steady increase in the amount of rickets with successive breast-fed children in the family. Of first children breast-fed 25 per cent. showed rickets; of second children, 41 per cent.; of third, 58 per cent., and of those later, 65 per cent., this gradual increase being probably in part accounted for by the later children getting a less plentiful supply of maternal milk than the earlier. Of children later than the third in the family the percentage of those with rickets among the breast-fed not only equaled but even exceeded that of corresponding children bottle-fed. Fordyce thinks that it is clear that bottle-feeding *per se* has no greater tendency to produce rickets among later children than among those earlier in the family.

5. **Adrenalin in Pleuritic Effusions.**—Ewart and Murray treated their patient at first by a modification of Barr's method, which combines the evacuation of fluid with its replacement by air. The air was not injected, but was allowed to be drawn in by thoracic suction. The secondary effusion which ensued was treated with preliminary intrapleurosus injections of adrenalin with a view to eventual paracentesis, but the latter was not performed as the fluid underwent complete absorption. Five injections were given of 10 minims each of a 1 to 1,000 solution of adrenalin.

6. **Treatment of Branchial Fistula.**—In the case reported by Chevers the fistula extended from the origin of the sternomastoid into the clavicle, at which point it was discharging, and ended at or about the level of the upper border of the hyoid bone. There was no tumor in connection with the fistula or anywhere in the neck. There was one communication in the pharynx. The fistula had been discharging since the patient (now 22) had been a child. The patient was treated by electricity, the galvanic current being used daily for a few minutes after the fistula had been washed out thoroughly with a 1 in 40 phenol solution. The method employed is described at great length.

10. **Surgery of the Blood Vessels.**—Power discusses the various methods now employed in the treatment of aneurisms of both the arterial and the venous systems.

14. **Volvulus of Cecum.**—When Maunsell opened the abdomen in this case a tensely distended cecum and ascending colon were seen filling the lower abdomen and pelvis. These were deflated and withdrawn, when it was found that the cecum and portion of the ascending colon had made a complete turn from below upward and from right to left. The lower portion of the ileum having been carried in front of the colon was tightly wound around the neck of the strangulated large intestine. The twist having been reduced, it was found that the cecum and colon had a well-formed mesentery, thus rendering volvulus a possible and likely accident. Having closed the incision which had been made for deflation, he determined to fix and to drain the cecum by performing the operation of appendicostomy. In this instance he had to ligate and to divide a portion of the meso-appendix, but took care to leave sufficient blood supply to the portion near the cecum. A stab wound was made at the outer border of the rectus and the appendix was drawn through and fixed by two sutures, its distal end was amputated, and its lumen was dilated with sinus forceps. A gum elastic catheter was then passed through it into the cecum and fixed in position by an encircling ligature. The after-history of the case was uneventful except for some slight suppuration which occurred in the abdominal wound about eight days after operation, evidently due to infection of the incision when the intestine had been opened for deflation.

The after-history of the appendicostomy is of interest. The catheter was left in position for four days, when the bowels were well cleared out by castor oil. From the first a small quantity of fluid feces and a large quantity of intestinal gas escaped through the catheter, thus keeping the intestines free from gaseous distension and rendering the patient's convalescence most satisfactory. As soon as the appendicostomy had completed its mission it became necessary, or at least advisable, to close the little opening. This was done by excising and invaginating the mucous lining of the stump of the appendix. The muscular tube healed promptly.

20 *An Uncommon Dislocation. W. A. James.

16. **Multiple Polypi of Intestine.**—In the case reported by Officer the whole intestinal tract, from the stomach to the rectum, except the ileum, was found to contain tumors, some sessile, some pedunculated, the largest being in the stomach itself near the pylorus. There were 41 tumors altogether.

18. **Spinal Hydatid.**—Connell reports the case of a man, aged 48, who complained of considerable pain in the left groin, worse after work and after going to bed. The veins of the left leg became dilated; the femoral glands were enlarged and tender, and there was diminished tactile sensibility in the region supplied by the upper part of the external cutaneous nerve (second lumbar). All reflexes were normal. There was some wasting of the left buttock and a general loss in weight. For some time the patient was regarded as having some lesion about the brim of the pelvis and groin. He seemed to improve with rest and local applications of aconite, and hot fomentations.

Later there was loss of power in the whole left leg and absence of the reflexes, with the exception of the cremasteric. The condition was then regarded as one of pressure in the spinal canal. The symptoms became gradually worse. A laminectomy was performed. At the base of the under edge of the lamina of the twelfth dorsal, on the left side, was a small erosion through which a cyst escaped. An extradural cyst, of the size of a pigeon's egg, was found beneath the twelfth dorsal and part of the first lumbar arches. On several occasions afterward daughter cysts escaped from the wound. The patient made a complete recovery.

20. **Uncommon Dislocation.**—The case reported by James is one of dislocation of the manubrium sterni from the gladiolus following a severe injury caused by the man being pinned against the wall of a shaft by a mass of earth weighing about half a ton.

21. **Infants Responsible for Endemic Yellow Fever.**—This final part of the official report of the French commission to Brazil fills 45 pages and is accompanied by 19 full-page plates showing the pathologic anatomy of yellow fever in various organs. Marchoux and Simond ascribe the perpetuation of yellow fever in endemic foci to the infant population. In a climate which allows the *Stegomyia fasciata* to flourish all the year around by the favorable conditions of temperature and moisture, when yellow fever is introduced for the first time an extensive epidemic results, as no one is immune, causing

deaths, and leaving the population almost entirely vaccinated and immune to the disease. The few people who escape the epidemic furnish later the isolated, so-called sporadic cases which form the connecting link between one epidemic and another. This contingent would soon be exhausted, however, were it not for the births. A new contingent is being constantly furnished by the newborn infants, and this infant population, constantly renewed, is the principal element which creates and perpetuates endemic yellow fever. On account of the mildness of the disease in children, mentioned in the previous communication, summarized in these columns on page 1243, the disease in the children escapes notice, and this explains why years pass after a violent epidemic without the development of any recognized new cases. The disease is supposed to have died out, when in reality the town is an endemic focus. This is proved by the infection of newly arrived, non-immune aliens, who contract the disease in the severe type which it assumes in the adult. These views are sustained by the experiences with yellow fever at Guadeloupe and elsewhere in the Antilles. A mild disease has long been known there among children which has never been recognized as yellow fever, principally because none of the adults contract it. The adults are all immune to yellow fever and the children are the only ones who take it. As it usually has such an attenuated course in them its true nature has not been recognized. In the endemic foci, therefore, it is the floating foreign population which furnishes the contingent for typical yellow fever. When this floating population is increased by public works, then formidable and deadly epidemics of yellow fever break out, such as was observed at Santos when the new harbor was built. One of the conclusions drawn from the facts presented is that a city in which the adult alien population furnishes the majority of cases of yellow fever is an endemic focus whose permanent inhabitants are all immune. If, on the other hand, a group of aliens escapes the disease when it is epidemic it is safe to conclude that they come originally from some locality where the disease is endemic. This explains the supposed immunity of the blacks. In conclusion Marchoux and Simond protest energetically against the assumption that it is possible for the stegomyia to become infected elsewhere than from man or that the yellow fever virus can affect man without the intermediation of the mosquito. An official or a physician, they say, who is not thoroughly convinced in respect to the exclusive rôle of the mosquito in the transmission of yellow fever is incapable of organizing effectual prophylaxis, and endangers the colonists, the soldiers and other people in his charge. Sanitation of an endemic focus or changes in its population, climate or in other conditions which have rendered it favorable for the stegomyia may exterminate the disease and free the place from being an endemic focus. On the other hand, a place in the mosquito zone where the disease has hitherto appeared only accidentally, as the stegomyia was imported, if conditions favoring the growth of the stegomyia develop, may become an endemic focus at any time. The microscopic pathologic anatomy of yellow fever is that of a generalized fatty degeneration, a diffuse steatosis. The reason why Petropolis is exempt from yellow fever, although only eighty miles from Rio, is its altitude, with the cool nights. The stegomyia may be brought up on the trains, but it is rendered torpid by the coolness and neither lays eggs nor bites. Even infected mosquitoes soon lose their infecting power in the chill of the nights. In Rio Janeiro the present conditions of distribution of the drinking water favor the proliferation of mosquitoes, and a number of remedies are suggested, among them that sea water which does not attract mosquitoes should be used for industrial purposes, fountains, etc.; that the trees in the gardens be freed from the parasites of the bromelia genus, and that the ornamental vases on houses, etc., be filled with cement. As the number of places where the mosquitoes are liable to lay their eggs diminishes, it will be easier to keep watch over those that remain. After a few years of work by the sanitary brigades the entire species of *Stegomyia fasciata* can be eradicated from the city. And this is the only certain means of stamping out yellow fever. The general conclusions of the entire research are recapitulated at the close of this final part of the report. The principal points have already been summarized in these columns. See page 917.

24. **Origin of Antibodies.**—The conclusions of research in Metchnikoff's laboratory by Kraus and Schiffmann are to the effect that the bactericidal antibodies are generated in the spleen, bone marrow and lymphatic ganglia. The precipitins and the agglutinins, on the other hand, are generated in the vascular system.

29. **To Facilitate Catheterization of Ureter.**—Suarez cuts off the end of a No. 18 sound and slips it over the catheter in the ureter, after withdrawal of the cystoscope, until the cut-off tip of the sound enters the bladder. The outer end of the ureter catheter is kept at a higher level than the outer end of the bladder sound. The urine from the bladder flows out through the latter, and the ureter catheter can be withdrawn through it.

30. **Polycystic Tuberculous Affection of Kidney.**—Curtis and Carlier describe a case of this kind. The affection was distinguished by its chronic and protracted character. The anatomic features were the hypertrophy of the kidney and the multiplicity of the cysts, suggesting the congenital polycystic condition.

31. **Diagnostic Cytologic Findings in Tuberculous Urine.** Colombino calls attention to the changes in the leucocytes which he has found exclusively in cases of tuberculous processes in the urinary apparatus. The microscope shows that the leucocytes are longer than usual and grooved, and that the outline is angular instead of round. The protoplasmic outline is very irregular and looks as if the envelope had burst. When such leucocytes are found mixed with red corpuscles the diagnosis of tuberculosis is almost certain. The nuclei may be found almost entirely detached in some of the leucocytes, and vacuoles can be seen in the protoplasm. He gives the details of 20 cases with 13 non-tuberculous cases for comparison.

38. **Fibrinous Tube Casts in Urine.**—Padoa describes casts formed by disintegration of red corpuscles in the tubuli. Their presence indicates preceding extravasation of blood.

39. **Rupture of Child's Urethra.**—Broca reports a case and discusses the indications. Immediate suture is required, but even the most careful technic does not insure against stricture later. He has had cases completely successful and others in which the patients returned with stricture. Speedy and very serious stricture may develop after apparently trivial injury without perineal tumor and with very little dysuria and a few drops of blood.

52 (No. 4.) Les tumeurs fibro-kystiques de l'utérus. G. Piquand. (Commenced in No. 3.)

45. **Massage of the Heart.**—Le Normant's study of the 25 cases of direct massage of the heart which have been reported shows that in 4 cases the heart-beat was definitely restored, but the contractions ceased when the massage was discontinued, either at once or soon after. In the 8 positive cases only 4 of the patients were definitely revived. In the other 4 the heart continued to contract, apparently normally, for from five to twenty-four hours, and then gradually became quiescent again. The 4 cases of definite survival include Cohen's case, published in THE JOURNAL for November 7, 1903, besides Lane's, Keen's and Sencert's cases, 1902 to 1905. The 4 cases of survival for a few hours includes one personally observed by Le Normant and not published before. The final conclusions of his monograph are that massage of the heart is an easy maneuver, simple and free from danger, if done through an incision in the abdomen and through the diaphragm without opening the latter. It is liable to prove successful in all cases of sudden arrest of the heart action, especially in chloroform syncope. Under these conditions it has resulted in temporary survival in 4 instances, with 1 permanent resuscitation, not to mention the dubious cases of Lane, Cohen and Igelsrud, in which the resuscitation might have been due to other factors. As adjuvants he recommends artificial respiration and possibly also centripetal intra-arterial injections of serum to raise the arterial tension. He gives the details of all the 25 cases. In Sencert's favorable case, after eight minutes of artificial respiration, etc., without response, he introduced his hand through the laparotomy wound and applied rhythmic massage to the heart, which could be felt empty and flaccid. After five minutes of massage the heart could be felt growing hard and larger, and a spontaneous contraction was observed two minutes later. The patient was an emaciated man of 51 undergoing a second operation for stone in the common bile duct. He felt no ill effects later from what he had been through, except slight occasional pains in the intercostal region.

46. **Cysts of the Urachus.**—Delore and Cotte publish a case of a very large cyst in the urachus in a young woman. It was operated on under the diagnosis of tuberculous peritonitis with ascites. It had been about a year in developing and contained 8 or 10 liters of fluid. The walls were about 3 or 4 mm. thick and the location of the cyst was mostly intraperitoneal. Eight similar cases are on record. The extirpation of the cyst was not a difficult matter. The discovery of a suprapubic and subperitoneal pedicle was the only means of differentiation in some cases, and then only during the operation. When the cyst was merely punctured the fluid promptly reaccumulated and a persisting fistula frequently followed. In one instance the cyst was tapped three times in nine months, and 18, 17 and 6 liters of fluid were withdrawn, and 50 were found at the autopsy.

48. **Mixed Tumors of the Breast.**—Lecène reports 2 cases in which a tumor removed from the breast of women 25 and 54 years old presented characteristics of sarcoma and also of cartilaginous and bone elements. The tumors were evidently, he thinks, of teratoid origin, due to embryonal inclusion of ectodermic or mesenchymatous elements. In evolution, in the physical signs and prognostic significance they resemble ordinary encapsulated tumors of the breast (adeno-fibroma, cystic adeno-sarcoma). The cases of cholesteatoma of the breast probably come also within this category.

50. **Osteo-periostic Lipomas.**—Schwartz and Chevrier advocate radical extirpation for these lipomas when the growth is rapid, but add that intervention may be postponed when the growth is very slow and gradual. They have collected 63 cases of these tumors at various points, including a number from their own experience. Some were evidently of congenital and others of acquired origin. They may have the most diverse sites, sometimes remote from the centers of complementary ossification and the epiphyseal cartilages. The liponia may be encapsulated or diffuse, and may have contingent connection with organs, muscles, vessels, nerves or the large joints. In only one of the cases reported was exostosis observed in connection with the osteo-periostic growth.

51. **Rational Treatment of Congenital Luxation of Hip Joint.**—Le Damany's extensive monograph fills 76 pages and is accompanied by 44 illustrations. He affirms that anthropologic congenital luxation of the hip joint does not occur before birth, but becomes established during the course of the first year. It may be prevented, and this prophylaxis is the ideal treatment. The cure of the dislocation is simpler and easier the younger the child, and it should be commenced early, although the care for cleanliness requires constant supervision, and fixation of the reduction is a little more difficult and tedious in the very young than after the age of 3. He describes and illustrates his technic in detail. He commences treatment by the fifteenth or the eighteenth month, when radiograms have made the diagnosis certain. In reduction he follows the modified Paci-Lorenz technic under an anesthetic. A plaster cast is then applied, holding the femur in abduction of from 80 to 90 degrees with flexion of the thigh, sometimes at a right angle. This cast is worn for two or three months, when it is substituted by correcting apparatus. This holds the limb in adjustable abduction, which can be gradually diminished from 90 to 60 degrees, or down to zero. The apparatus consists of a plaster corset supported by the iliac crests with a projecting metal arm, parallel to the thigh, fastened to a bracelet worn above the knee, with chains and straps to regulate the position of the femur. The child is able to walk, even when the apparatus is applied to both hip joints at once. In conclusion he describes the technic for various exceptional conditions liable to be encountered. His aim is to correct not only the luxation of the hip joint, but also the causal malformation as well as the secondary deformity. He insists that congenital luxation is always perfectly curable both from the anatomic and the functional points of view. He intends publishing soon his clinical experiences, which have been most gratifying.

53. **Sarcoma in Vagina in Childhood.**—Rollin gives summaries of 12 cases of sarcoma developing in the vagina of girls under 8. In some the tumor was noticed soon after birth. The first symptom was generally bleeding from the vagina, but sometimes there were pains and disturbances in urination and defecation, and occasionally the protrusion of the tumor was the first manifestation of its existence. The course of these tumors in children is essentially rapid. Death is soon entailed by the local extension of the tumor and the resulting cachexia. Metastases at a distance are rare. The duration varies from one to eighteen months. The prognosis is grave, as the diagnosis is generally not made until too late for relief from operative measures. Recurrence is the rule, and with exception of Schuchardt's and Hollaender's successful cases, the children soon succumbed to recurrence. Tumors in the vagina in childhood are almost always sarcomas. Any symptoms calling attention to the genital sphere in children should be regarded with suspicion. Physical examination is the only means of detecting the neoplasm. In children the sarcoma usually develops as a solitary bunch at first, assuming the bunch-of-grapes form later. The structure of the peripheral portions may differ from that of the base of the tumor. It may be mistaken for a harmless growth on this account.

55. **Access to the Common Bile Duct.**—Sencert gives an illustrated description of his method of opening up the common

bile duct. He calls it the retroduodenal route with mobilization of the second part of the duodenum. Its advantages are its great simplicity, the ease with which it can be done in all cases in which the region beneath the liver is not altered by peritoneal neoformations, the possibility of extraperitoneal operating with subperitoneal drainage and "peritonization" similar to that possible in the small pelvis. It is a less serious operation than exploratory duodenotomy followed by transduodenal choledochotomy. The technic has been successfully applied on 6 patients to date.

56. **Volvulus of Cecum.**—A case personally observed is described in detail and 39 others previously published are reviewed. Early reduction of the volvulus was successful in 74 per cent. of these cases. Previous statistics have reported cures in 50, 55 or 67 per cent. after operative intervention and a mortality of 100 per cent. without surgery. The earlier the operation the better the prospects. The majority of cases have been observed in Finland (79), Germany (50) and England (57). Only 4 or 5 cases are known in France, and none in the southern countries. These differences are evidently due to the lighter diet in the South, he thinks. Sargent's patients were mostly from 20 to 40 years old, but one was 9 days old; another 10 months; 3, 5 years, and 8 from 10 to 20 years old. The symptoms are those of recurring colic of the cecum, aggravated by lying on the side. The patients sometimes learn to assume an attitude that will favor spontaneous reduction of the volvulus. The protrusion of the cecum may simulate a floating kidney, but the gurgling sound produced by palpation differentiates it. The volvulus occurs, as a rule, in healthy persons, or there may have been a history of repeated colics. The onset of the pain is sudden, and it is not localized to such an extent as in appendicitis. The first phase is that of cecal colic of unusual severity; the second phase is a remission of the pains after two or three days, and the third phase is that of complete occlusion. The deceptive remission for one or two days frequently makes the surgeon hesitate. Faltin cites one case in which the course was more rapid than the ordinary five to eight days; the cecum became gangrenous and perforated in 55 hours. The principal diagnostic features are the sudden onset, the localized meteorism, toward which the peristaltic waves are directed, the absence of temperature, the arrest of feces and flatus, and the false remission which follows the tempestuous onset. Spontaneous reduction is favored by lying on the side, and by massage of the abdomen. Some patients have felt spontaneous reduction follow a sudden violent effort to turn over in bed. In a few instances relief was obtained from purgatives and injections. If reduction has not been accomplished by the second or third day, surgical intervention is necessary. Resection is preferable, for reasons enumerated, uniting the ileum with the colon with side-to-side anastomosis, and drainage through the lumbar region, the vagina or rectum.

57. **Surgical Treatment of Gastric Ulcer.** The article by von Eiselsberg, which opens the sixteenth volume of the "Communications from the Borderland of Medicine and Surgery," was read as one of the main addresses at the recent International Congress of Surgery. He reviews his extensive experience and advocates immediate laparotomy in case of perforation. In case of severe gastric hemorrhage he tries internal measures first. Among these measures found useful are rinsing with ice water, solutions of iron and 1 per thousand silver nitrate. He gives his patients a 10 per cent. solution of gelatin to drink and injects subcutaneously up to 6 gm. of a 2 per cent. solution of gelatin after repeated sterilization. Cautious evacuation of the stomach is advisable on account of the shock. Surgical interference is necessary in case of recurring severe hemorrhages. He has observed cases of perforation and also of fatal hemorrhage occurring tardily after skillful resection of the stomach. Consequently he now advocates less extensive operations as a rule. He has witnessed subsidence of large areas of induration of the stomach wall and serious hemorrhages arrested as if by magic after gastroenterostomy. In case of duodenal stenosis or ulcer it is the only operation, and the results are generally brilliant in case of stenosis of the pylorus from an ulcer. Jejunostomy can be done on the weakest patient and with local anesthesia is scarcely at all dangerous. He considers it the standard operation in case of hour-glass stomach with a very small cardiac portion, when the stenosis does not permit gastroanastomosis. Also in case of contraction of the stomach as result of multiple ulcerations or of ulcerative gastritis and perigastritis, and plastic linitis. It has also rendered him good service in some cases of severe hemorrhage, in which he refrained from other intervention, even from any examination of the stomach. It is also very useful in case of the action of a caustic on both esophagus and stomach, and it allows the feeding of the patient after suturing a perforation in the stomach. In this latter capacity he regards it as a valuable aid in internal medication, as it leaves the stomach entirely at rest while allowing much more abundant feeding. As such a fistula is generally continent, and as it soon heals spontaneously after withdrawal of the catheter without further operation, the inconvenience from it is trifling. He is convinced that the cases now accepted as spasm of the pylorus will be found to have some ulcerative process at bottom. He mentions that his pupil, Lempp, is now engaged in research which may ultimately lead to the production of a practical gastroscope. Lempp is trying to produce an instrument with which, through a small opening into the stomach, its interior can be safely and thoroughly inspected. Retrocolic posterior gastroenterostomy is the best means of treating obstinate spasm of the pylorus. Plastic operations for this condition give only transient results. In only a single instance has he had peptic ulcer develop after gastroenterostomy.

60. **Cryoscopy and Its Technic.**—Neudörfer states that Kümmell was the first to point out the importance of cryoscopy as a diagnostic test of kidney functioning. His later experience has only confirmed its value more and more. He has never had a mishap in the 160 cases in which he has performed nephrectomy since its introduction, and regards it as a fine test of the total work done by the kidneys. The Beckmann apparatus is used. The glass cylinder and platinum stirring rod are rinsed again before using with boiled distilled water and dried by warming the glass tube. A trocar needle is inserted in a congested vein in the arm and the blood drawn directly into the glass cylinder. It is slowly stirred and the fibrin clings to the platinum stirrer. The fibrin generally does not disturb the freezing point, but still it is better to remove it; this is done with sterile gauze. The blood is then placed in the freezing mixture. The freezing point of boiled distilled water is determined anew each time. Heidenhain has demonstrated that the zero point may vary even when the fluid is at rest. Before each measurement the thermometer is rinsed with distilled water and wiped dry with gauze. He usually takes two measurements and records the average as the true freezing point. Thermometers with fixed zero points are not advisable as the actual freezing point varies with external conditions, the temperature of the room, etc., consequently he always determines the exact freezing point anew for each test. He uses a freezing mixture of minus 4 C. The ice must be well broken up and the vessel must be about a third full of water, as otherwise the freezing mixture does not press close against the inner vessel, which is indispensable. Another important technical point is that the blood and the water are cooled before attempting to determine the freezing point. A grain of salt or rinsing the tube in alcohol is a frequent source of error unless guarded

against. In conclusion Neudörfer tabulates a number of cases to show the value of information derived from cryoscopy in various cases; the findings were confirmed by the later course of the affections. He also tabulates for comparison nearly 50 cases of heart disease or pneumonia, without kidney disease, the freezing point of the blood ranging in all merely from minus 53 to minus 57 C. In 17 cases of kidney affections tabulated the range of the freezing point was from minus 58 to minus 79 C. in all but 2, in whom it was minus 56. The trouble in this latter group proved to be due merely to enlargement of the prostate. One patient with interstitial nephritis had a freezing point of minus 56 in February, minus 58 in April, and minus 60 in June, the progressive course of his kidney trouble being reflected in the freezing point of his blood. No influence from cyanosis on the freezing point could be detected, nor from age, pregnancy, nor the presence of a tumor. His youngest patient was a child of 8, his oldest a man of 81; in both the normal freezing point was the same, minus 56 C. It was also within the normal range in 10 cases of large abdominal tumors, cancer or myoma, and also in 10 cases of pregnancy at term.

62. **Staphylococcus Erysipelas.**—Jochmann reports the case of a letter carrier, 38 years old, who complained one morning of pains in the nose, and erysipelas developed from the pustule which soon appeared. In two days the patient was delirious and he died on the sixth day after the first symptoms, with indications of general sepsis. The *Staphylococcus pyogenes aureus* was cultivated in pure cultures from the blood during life (500 colonies in 10 c.c. of blood), and from the tissues after death. No streptococci were discovered at any time.

63. **Rheumatic Calcareous Tendon and Fascia Inflammation.**—Neuwirth gives an illustrated description of a case of primary necrosis in the tendons and aponeuroses over the entire body, with subsequent deposits of lime, mostly in the neighborhood of the joints. The muscles were atrophied and anemia developed, probably the result of gastrointestinal disturbances. Pneumonia or endocarditis were noted as complications in the few similar cases on record. The course is a prolonged one with frequent remissions, but tends inevitably to final cachexia. The affection is differentiated from gout by the lack of restriction to certain points, the multiple involvement of the joints, the chemical composition of the concrements, the microscopic findings and the shadows cast by the Roentgen rays, which differ from the findings in gout. In the case reported the salicylates seemed to benefit.

64. **Etiology of Appendicitis.**—Klemm has become convinced that appendicitis should be regarded as a myeosis of the lymphatic apparatus of the appendix. It does not differ in any respect from myeosis of other lymphatic organs. It may be the result of the action of various bacteria, but the colon bacillus is generally responsible.

65. **Hourglass Stomach.**—Moynihan has had occasion to operate in 23 cases of hourglass stomach. He encountered one case in which cicatricial contraction of the stomach after ulcers had caused its separation into three sacs and another in which there were four sacs. He describes his cases in detail, with the indications for which he operated and his technic. The results were very gratifying, except with the 2 patients who presented evidences of malignant disease.

84 Statistische und anatomische Ergebnisse bei der Freund-Wertheimsche Radikal-Operation des Uterus-Karzinom. R. Schindler.

70. **Plastic Utilization of Uterus for Extensive Prolapse of the Genitalia.**—Fuchs reports 39 patients operated on by Wertheim's technic, using the uterus to make a new floor for the pelvis, as it were. It proved successful even in cases of old prolapse that had previously recurred, despite all kinds of operative intervention. Twenty-one of the 39 patients have been examined recently, and the results have proved extremely satisfactory, except in one case, in which the prolapse recurred.

71. **Tuberculosis of Female Genitals.**—The case related by Nebesky confirms the possibility of permanent cure of clinically isolated tuberculosis of the female genitals, treated by radical removal of all the organs which appear to be affected.

74. **Conservative Treatment of Adnexia.**—In 38 cases of inflammatory processes in the adnexa, Fett used conservative medical measures only, and in 8 operative measures. From the results observed and those recorded by others he has become an advocate of conservative treatment of inflammatory conditions in the adnexa under all circumstances. In the acute stage they should be treated expectantly, and in the chronic stage with the aid of measures to promote absorption. The treatment may require several months, but with few exceptions full working capacity is regained, the results comparing favorably with the best after-operative intervention. Restitution is so complete that pregnancy occurs normally afterward. In case of impending perforation peritonitis, laparotomy is required, and abdominal removal of the adnexa is also justified by the failure of a systematic course of treatment. Even then the ovaries should be left if sound and functioning. Colpotomy is indicated only in case of extensive suppuration and prolonged fever, requiring incision and drainage. The displacements of the uterus which frequently follow the processes in the adnexa may require correction when the conservative treatment has accomplished its purpose.

77. **Puerperal Gangrene.**—Fraenkel's patient exhibited isolated gangrene of both arms in conjunction with endocarditis.

80. **Relations Between Functional Neuroses and Genital Affections.**—Meyer has noticed that nervous disturbances are rarely encountered in severe affections of the genital organs. On the other hand, gynecologic affections are frequently merely the localization in the genital sphere of some general neurosis. Treatment based on this fact is alone liable to be successful in such cases.

83. **Functional Kidney Tests.**—Kermauner concludes from his study of the subject in the literature and from personal experience that none of the functional tests of the kidney yet presented are accurate. Reliable information can be obtained only by combining palpation, the history of the case, examination of the painful points and of the ureter reflexes with cystoscopy and radiography in case of suspicion of stones. Physical, chemical and microscopic tests should be made, with determination of the freezing point and of the nitrogen, the phloridzin test and chromocystoscopy, determination of the urea, nitrogen, salt and electric conductibility.

86. **Water as Obstacle to Radiography.**—Lichtenstein gives diagrams and relates experiences which suggest that the presence of fluids has a disturbing effect on radiography. Not the composition of kidney stones, but the amount of fluid present in the kidney is the criterion for successful radiograms of kidney stones. The presence of fluid is the reason why radiography of the pregnant uterus is so unsatisfactory. Stones in the biliary passages generally cast stronger shadows than those in the gall-bladder, mainly because they are not surrounded by so much fluid.

89. **Tuberculosis of the Esophagus.**—In Kümmell's case nearly four-fifths of the esophagus was occupied by a tuberculous ulceration. No symptoms had been noted pointing to an affection of the esophagus. The patient was a man of 52, alcoholic, with advanced pulmonary tuberculosis.

90. **Test Breakfast or Test Dinner.**—Dörner gives the comparative findings after the test breakfast and the test dinner, his experience being that only the latter is able to indicate the actual functional capacity of the stomach. The organ may be able to take care of the breakfast and the findings will be approximately normal, when the test dinner shows that it is far from being equal to taking care of the more elaborate meal.

91. **Tetany of Intestinal Origin.**—A neuropathic man of 46 with achylia and normal gastric motility presented evidences of tetany. The impossibility of peptotoxin formation excluded the stomach as the source of the trouble. There was no diarrhea, and consequently the tetany could not be attributed to excessive loss of fluids. The intestinal digestion was much disturbed, and he attributes the tetany to the morbid conditions in the intestines and consequent autointoxication.

104. **Tuberculosis in Greece.**—The proportion of deaths due to tuberculosis in Greece is about as 1 to 9 in comparison to the total mortality, according to the figures for the twelve largest towns in the land. Dust is extremely prevalent, but the mild climate and the almost constant sunshine counteract its effects, so that Greece does not suffer from tuberculosis as much as some other countries.

107 **Dynamo Injector for Treatment of Chronic Gonorrhea.**—Filaretopoulo has devised an instrument which, he thinks, is free from the faults of the present technics. It consists of a curved sound dilator in two halves, the outer side of each part rounding and the inner flat, so that the whole, when closed, looks like a simple sound. By turning a thumbscrew in the handle the tips separate to any desired distance, and by turning and reversing the thumbscrew the alternate spreading and closing of the tips enables the interior of the urethra to be energetically massaged at any point desired. One of the branches is made hollow, with four large openings at the tip. He uses an astringent and antiseptic salve with lanolin base for local application. The hollow branch of the injector is filled with the salve from a compressible tube, and it is forced out through the openings in the tip by a piston arrangement. The salve can thus be applied at the exact point needed and massaged into the tissues. The use of this instrument saves much time, all the procedures being done at once and without the least pain. A further advantage is that the topical applications, being in the form of a salve, exert their action much longer than when fluids are used. He has thus cured in two sittings, he states, patients who had been treated in vain for years by other measures. Some of the salve is still evident in the urethra three days after its application. The article is illustrated.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PRACTICAL MEDICINE SERIES, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. By G. P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-Graduate Medical School, in two volumes. Vol. I on General Medicine, edited by F. Billings, M.S., M.D., Head of Medical Department and Dean of the Faculty of Rush Medical College, Chicago, and J. H. Salisbury, A.M., M.D., Professor of Medicine, Chicago Clinical School. SOME OF THE RECENT ASPECTS OF QUARANTINE AND ITS RELATION TO PUBLIC HEALTH.*

M. J. ROSENAU, M.D.

Passed Assistant Surgeon and Director Hygienic Laboratory, U. S. Public Health and Marine-Hospital Service.

WASHINGTON, D. C.

Quarantine may be likened to jails, penitentiaries, houses of detention and other necessary evils of this world. The very absurdity of the word quarantine, coming from the Italian *quaranta,* meaning 40, is an indication that we are dealing with a condition resulting from an imperfect social fabric.

It does not take a prophet to foresee the time when society will be developed to that state of civilization and the sanitary sciences will have reached that point of excellence when restrictive quarantines will be entirely unnecessary. But the millennium is a long way off and we shall not see the end of quarantine restrictions in our day and generation.

In the Middle Ages, when the Hanseatic League of cities held its commercial supremacy, we learn that Venice detained ships arriving at that port with cases of pestilence aboard, for a period of forty days. While isolation and detention had been practiced to a certain extent prior to that time, this was the first instance of the systematic application of maritime quarantine methods, and they have survived in a modified form to this day. Since then, in addition to maritime quarantines, we have land quarantines, interstate quarantines, municipal quarantines, house quarantines, cattle quarantines and quarantines for revenue only. Some of these, especially municipal and interstate quarantines, have developed to large proportions so that they are now replete with intricate medicolegal problems and have become highly specialized like other branches of the medical sciences.

I shall confine myself to a discussion of some of the problems of maritime quarantine and take the opportunity to express some stray thoughts on the underlying principles governing the federal quarantine service, giving some of the recent developments in quarantine methods, and finally pointing out a few of the lessons to be learned from the late epidemic of yellow fever in New Orleans.

THE FEDERAL QUARANTINE SERVICE.

To those not familiar with the principles underlying the organization and methods used by the Public Health and Marine-Hospital Service in its maritime quarantine work it may be interesting to hear the story, briefly told, of how the government protects its citizens.

The object of maritime quarantine is the protection of a country against foes often more deadly than those of war. It is a coast defense against exotic pestilence. We do not quarantine against tuberculosis, scarlet fever, malaria, typhoid fever and other serious communicable diseases which, like the poor, are always with us. We only guard against the invasion of such strangers as, once introduced, might work havoc in our midst. In view of this fact the federal government recognizes but six quarantinable diseases: Cholera, yellow fever, plague, typhus fever, small pox and leprosy.

Some diseases, for instance relapsing fever, have been stricken from the list of quarantinable diseases and the restrictions against others have been very much lightened in recent years. Epidemics of relapsing fever require the sum total of evil sanitary conditions, including overcrowding, filth, poor and insufficient food, vermin, etc.; these conditions do not exist in a sufficiently high degree even in the slums of our centers of population to favor the spread of this disease. Only last winter victims of relapsing fever were admitted into one of our large seaport cities and treated at one of the general hospitals without any more danger to the city than a case of rheumatism.

Our seaports in the yellow-fever zone could render themselves equally secure against yellow fever and would not then fear to admit cases of that disease, as Havana has done for several years.

Another instance of the lightening of quarantine restrictions is that we now no longer detain the vessel itself on account of infection. After proper measures of disinfection, or the extermination of mosquitoes, rats and other intermediate hosts, have been accomplished, the vessel with its cargo is permitted to dock while the personnel is detained at the quarantine station. The introduction of this practice has saved commerce a certain amount of loss and delay. Restrictive measures regarding typhus fever are no longer so stringent as they formerly were. With the comparative degree of improved sanitation of most of our seaports there is little danger of typhus fever occurring in epidemic form. Therefore, if a vessel in good sanitary condition arrives with a case of typhus fever aboard, and the patient has been isolated and other measures taken to prevent its spread, only the patient is removed, the sick bay purified, and the vessel with all its cargo, crew and passengers permitted to land. With the increase of our knowledge of the causes and methods of transmission of the epidemic diseases, our quarantine methods are not only more precise, but may now be carried out with every assurance of success.

I have called maritime quarantine a coast defense. The likeness is stronger than a mere figure of speech. At one time countries tried to build an impassable barrier against the quarantinable diseases which they feared, but all such systems of quarantine, like the great wall of China, are doomed to failure. The principle underlying the modern system of quarantine consists in

* Read before the Medical and Chirurgical Faculty of Maryland.

fortifying the strategic points along the coast with a complete armament composed of lazarettos, barracks of detention and observation, disinfecting apparatus, wharves and vessels, and laboratories for the detection of suspected disease. In addition to these quarantine fortresses, which are the backbone of our line of defense, our country, having such a long littoral, must also have a flying squadron consisting of a floating disinfecting plant, a traveling laboratory, and trained officers and men to concentrate quickly on any particular point of attack.

The federal government operates several floating disinfecting plants, kept at favorable places, is equipped with two traveling laboratories, and has officers trained to make scientific diagnoses of suspected cases; it also has officers who have had long and valuable experience in practical disinfection and the management of epidemic diseases; all these forces may be concentrated on any given point with little loss of time.

Another principle underlying the quarantine defense at small and remote ports is an inspection service. Many small ports, having little communication with foreign countries, are not visited by quarantinable diseases for years. Manifestly it would be poor policy and exceedingly expensive to maintain at all of these minor ports the cumbersome and complicated equipment necessary at a large and busy port, to meet such infrequent emergencies.

At certain of our ports we concentrate this work at favorable places known as "stations of refuge." These places are usually situated on islands along the highways of ocean trade and serve as detention, disinfection and quarantine stations for a number of coast cities.

THE LIMITATIONS OF DISINFECTANTS.

Disinfection is no longer regarded as the panacea that it formerly was. There can be no doubt that at one time we had an exaggerated notion of the powers and proper sphere of disinfection in sanitary work. I do not mean to belittle the great value of disinfection and disinfectants in preventing the spread of communicable diseases caused by bacteria. We now know that most bacterial parasites causing communicable diseases which occur in epidemic form in man are not very long lived, but usually die spontaneously within a comparatively short time.

We have further learned that infection is probably more often carried by means of mild cases or through the medium of a third person than by means of infected objects. For instance, the diphtheria bacillus may be in the throat of persons enjoying good health. When we learned that many communicable diseases are transmitted from man to man through intermediate hosts, especially insects and domestic animals, we found that ordinary disinfectants were not nearly so valuable as insecticides.

Sulphur dioxid still remains one of the oldest and the most valuable of our disinfecting agents, despite its destructive chemical action. It destroys all forms of life, both vegetable and animal.

Formaldehyd gas is seriously limited in this respect, as it has little, if any, toxic action on insects and higher animals. It is, however, exceedingly poisonous to bacteria; but even in this regard it has further limitations, for it is not effective when used in cold or dry weather. Past Assistant Surgeon T. B. McClintic, who worked in the hygienic laboratory under my direction during the past year on this question in relation to car sanitation, has drawn the conclusion that formaldehyd gas, no matter by what method it is evolved, is useless as a disinfectant, provided the relative humidity in the atmosphere is less than about 65 per cent. and the temperature below 60 F. In other words, in cold or dry weather formaldehyd can not be depended on

SANITATION THE ONLY CURE FOR QUARANTINE RESTRICTIONS.

The necessity for quarantine arises from the lack of sanitation. If all communities, especially seaports, were to place their cities in the best sanitary condition, in accordance with the teachings of modern science, there would be little danger of disease spreading to epidemic proportions and practically no need of quarantine restrictions. Modern sanitation is very expensive. It means thorough drainage, proper disposal of wastes, good paving, pure water, and cities constructed with sufficient breathing spaces between houses, so that all the inhabitants may receive their proper proportion of fresh air and sunshine; it also includes the destruction of mosquitoes, rats and other vermin which help to spread disease, and a proper supervision of the food supply.

This thought, which has been so often and so ably advocated by Surgeon-General Walter Wyman, is the great basic principle which actuates the Public Health and Marine Hospital Service in its sanitary work. In line with this principle the surgeon-general has many times urged on the neighboring Central American republics and other governments, with which our country has intimate commercial relations, to take steps looking to a solution of the problems affecting the health of their coast cities. Prompted by this teaching, one of these countries, Honduras, has recently requested that an officer of the Public Health and Marine-Hospital Service be detailed to take charge of its sanitary measures. Our own cities in the yellow fever zone might well take the lesson to heart by exterminating the *Stegomyia fasciata* and so insure their cities against epidemics of yellow fever.

As an outgrowth of this line of action the government has developed what may be termed a prophylactic quarantine, that is, measures are taken at the ports of departure to prevent ships from becoming infected. Medical officers of the service are stationed at seaports in all parts of the world where danger exists of conveying cholera, plague and yellow fever to the United States through the medium of ocean traffic. The officers at these foreign ports issue the bill of health to the departing vessel, supervise the loading, and the embarkation of passengers and crew, so as to ensure that no disease is taken aboard, either in the cargo, the food, water or among the personnel. When necessary, the ship is detained for disinfection or other measures at the foreign port, to render it safe from a quarantine standpoint. These foreign inspectors relieve ocean travel of many annoying quarantine restrictions and are a potent factor in safeguarding the health of our country. Those who appreciate the important service rendered by these foreign quarantine and immigration inspections hope to insure their continuance through legislative and treaty enactments.

Maritime quarantine, to be effective, must be uniform and centralized, for a chain is only as strong as its weakest link. Viewed broadly, maritime quarantine concerns the federal government in much the same way as does the enforcement of the revenue laws; and, further, it must be regarded as the duty of the federal government to protect the health of its citizens against the introduction of foreign germs, just as it protects us against the invasion

of foreign foes. It is only in the enforcement of maritime and interstate quarantine that the government is legally concerned, and sometimes feels the embarrassment resulting from the divided responsibility, owing to the present imperfect laws. The federal government never can and never will take the place of the state and local health authorities, for municipal and state sanitation are largely local questions. In fact, there is greater usefulness than ever for state boards of health and municipal health officers.

The federal government, through its system of cooperation with state authorities, is the medium by which local sanitary measures throughout the country are coordinated. These meetings between the state and federal sanitary authorities are helpful in encouraging active sanitation and further helpful toward uniformity in the health laws and administration throughout the country.

RECENT YELLOW FEVER WORK AND ITS LESSONS.

That it is possible to exterminate the yellow fever mosquito in a large community in a comparatively short time was satisfactorily demonstrated last summer at New Orleans. The sanitary work in New Orleans was marked with such success because it concentrated almost its entire energies on two points: 1. The screening of the sick. 2. The destruction of mosquitoes.

Those who have been in New Orleans in ordinary times need not be told of the unendurable extent to which the city was pestered with mosquitoes, particularly the *Stegomyia fasciata*. The fight against the mosquito, under the personal direction of Surgeon J. H. White, was so successful in New Orleans that when we arrived there in September, we had the greatest difficulty in finding the *Stegomyia fasciata* at all and it was only after setting many traps in many parts of the city that Passed Assistant Surgeon Goldberger and myself were able to secure enough of them to breed for our laboratory work.

Having come to the subject of yellow fever, I think it will be profitable to review some of the recent advances in the study of this disease which have a bearing on quarantine and sanitary work. No discussion of yellow fever would be complete without the mention of the Army Medical Commission, headed by Surgeon Walter Reed, whose work has helped us so much in the prevention of this disease. The discovery that yellow fever is transmitted in nature only through the bite of the *Stegomyia fasciata* has been the stimulus that has led to further work on this disease by men of science throughout the world.

Several commissions, composed of Drs. Salimbeni, Marchoux and Simond, have been sent from the Pasteur Institute, Paris, to Rio de Janeiro, to study yellow fever; also, a German commission consisting of Drs. Neumann and Otto have made further contributions which have naturally advanced our knowledge of the subject. The Public Health and Marine-Hospital Service had another working party in the field last summer during the latter part of the epidemic at New Orleans. Two questions were investigated: 1. The cause of the disease. 2. The alleged hereditary transmission of the yellow fever parasite in the mosquito. We are considerably handicapped in studying yellow fever clinically because of the many instances of mild and atypical cases. Until the cause of the disease is discovered and a certain means of a diagnosis is at hand, there will be great confusion in symptomatology and diagnosis.

The subject, therefore, has important practical, as well as scientific interest. We spent much of our time in attempting to grow the yellow fever parasite.[1]

ATTEMPTING TO GROW THE YELLOW FEVER PARASITE.

In view of the fact that the infective principle causing yellow fever may pass through the close-grained pores of a Pasteur-Chamberland B filter, it seemed to us hopeless, with the limitations of the present microscope, to expect to see the causative agent of this disease by direct examination of the blood.

Novy's work with trypanosomes, both his success in their artificial cultivation and his filtration experiments, indicating the possibility of an "ultramicroscopic" phase in their developmental cycle, suggested to us the possibility of cultivating by similar methods the yellow fever parasite and thus, perhaps, of developing a stage in its life cycle, which might readily be visible. We attempted, therefore, to grow the parasite of yellow fever in the water of condensation of blood-agar tubes.

The culture tubes were prepared in several different ways; both human blood (non-immune) and rabbit's blood were used. Some tubes were prepared with the whole and some with the defibrinated blood. When the whole blood was used it was quickly added while fresh to melted agar at 42 C., in the proportion of about two parts of blood and one of agar. After mixing, the tubes were slanted and allowed to set. The defibrinated blood was prepared by whipping in the usual way and then added to the melted agar in about the same proportions, as before stated. After standing a short time the blood-agar slants thus prepared, developed from several drops to about 1 c.c. of water of condensation. A drop or two of blood from typical cases of yellow fever taken from the arm vein during the early stages of the disease, was planted into this water of condensation.

Other cultures were prepared with much larger quantities of the yellow fever blood, using the yellow fever blood itself as a part of the culture medium. Two tubes containing about 2 c.c. of melted agar and about 4 c.c. of fresh yellow fever blood, were added as quickly as possible after withdrawal from the vein. Other tubes were similarly prepared with the defibrinated yellow fever blood.

Some of the cultures were kept in the incubator at 37 C. and others at room temperature. Of the latter, some were kept in the dark and others exposed to the light, in order to simulate the conditions, as they appear to occur in the mosquito.

The water of condensation was examined from time to time both in hanging drop and in stained smears. It was found to contain large numbers of bodies of various sizes and shapes, some of them exhibiting curious and exaggerated Brownian motion. All of the particles were interpreted as generation products, mostly from the cellular elements of the blood.

HEREDITARY TRANSMISSION OF THE YELLOW FEVER PARASITE IN THE MOSQUITO.

The question of the hereditary transmission of the yellow fever parasite from the *Stegomyia fasciata* to its progeny is of interest both biologically and practically. Reasoning by analogy, such transmission can not be regarded as impossible, as it is known to occur in some probably closely allied diseases, as through the tick in Texas fever and canine piroplasmosis. Schaudinn has satisfied himself that hereditary transmission of the

1. Rosenau, M. J. and Goldberger, Joseph: "Attempts to Grow the Yellow Fever Parasite. The Hereditary Transmission of the Yellow Fever Parasite in the Mosquito." Report of Working Party No. 3. Bulletin No. 15 Yellow Fever Institute, Public Health and Marine-Hospital Service.

tertian malarial parasite (*Plasmodium vivax*) occurs in *Anopheles*, and recently Dutton and Todd have shown that the spirochete of the tick fever of the Congo is passed from tick to tick through the egg. To the sanitarian the question is of interest in its bearing on the problem of the recrudescence of yellow fever.

The recrudescence of epidemics of yellow fever has heretofore been explained in one of two ways: 1. A *Stegomyia fasciata* that had become directly infected by feeding on a yellow fever patient had survived (as they are experimentally known to be able to do); 2. In the interval between the epidemics the infection had been continued by unrecognized cases and on the recurrence of favorable conditions the disease would reassume epidemic proportions.

From time to time a third explanation has been advanced, namely, the transmission of the infection from the mother mosquito through the eggs to her progeny which, under favorable circumstances, were capable of giving the disease to a susceptible individual, without themselves directly having had access to a yellow fever patient. This explanation has now received the support of an experimental case of yellow fever induced by the sting of a *Stegomyia fasciata* apparently hereditarily infected. The case is reported by Marchoux and Simond in a paper on the hereditary transmission of the yellow fever virus in the *Stegomyia fasciata*. Against this one positive case we obtained negative results in attempted inoculations of 13 non-immunes.

In an endeavor to account for the divergence of our results from those of the French workers, we considered several factors in the problem, failure to comply with any of which might readily be productive of negative results. We believe, however, that our work, so far as we can judge from the details in their paper, closely parallels the work of Marchoux and Simond. Naturally, the first factor which arose for consideration was whether the mothers of the *Stegomyia fasciata* used by us for the inoculation of our non-immunes were infected. Marchoux and Simond state that the mother of the insect whose sting produced the positive case of fever had been made to feed on several (number not stated) of their yellow fever patients, in order to determine a heavy infection. In our work one of our mother mosquitoes had three feedings of yellow fever blood from two severe cases during the early stages of the disease. Two other mother mosquitoes had one feeding of yellow fever blood early in the disease.

That the interval between the infecting feed and oviposition is an important element in the transmission of the infection through the eggs to the progeny, if such transmission ever takes place in yellow fever, must be evident. Marchoux and Simond do not report clearly on this point: They state simply that their mosquito was 20 days old at the time of oviposition and that some time prior to the ovipositing it had been made to sting several yellow fever patients.

Another important factor in the problem, and one to which Marchoux and Simond call attention, is the time needed by the hereditarily infected mosquito to become infective. In their case this was 22 days. In our work the inoculations were carried up to and including the forty-ninth day.

A factor in the problem, which is of prime importance and which must always be reckoned with in estimating the value of negative results, is the susceptibility of the subject, used for the inoculation of the disease. We were careful to select only those who, we were satisfied, never had had the disease.

In view of the negative results recorded by us in our efforts to confirm the positive work of Marchoux and Simond, we feel that additional work will be necessary to settle the question of the hereditary transmission of the parasite of yellow fever in the *Stegomyia fasciata*. Nevertheless, the sanitarian will do well to continue his measure of mosquito destruction after the suppression of an epidemic.

TRUTH IS MIGHTY AND HAS PREVAILED.

In our work on yellow fever at New Orleans last summer it was interesting to note the great difference in the practical work of suppressing this epidemic from similar work in former days. Reed, Carroll and Agramonte had published their epoch-making discovery but five years prior. We know that administration, especially in sanitary matters, lags far behind the sanitary sciences. This conservatism is sometimes proper and usually inevitable. In this instance, therefore, we have no cause for complaint when we review the magnificent and successful work in suppressing the epidemic of yellow fever last summer.

In the few years which have elapsed we have learned to fear fomites no longer. This point was brought home very strongly to me when I noticed that the soiled bedding, towels and personal linen from the yellow fever hospital were daily carried, without any precautions, to an outside laundry. We can well imagine how such a procedure would have been regarded prior to our exact knowledge on this subject.

Another striking instance showing how quickly the public mind has been educated to the true facts concerning the disease came to my attention: In the early part of October yellow fever appeared in virulent form in a small Mississippi town. The mother of a certain family—the first to be stricken—fell ill with the fever and died in five days. The head of the household, an intelligent man, fearing that the disease would take other members of his family and not being able to secure proper nursing and medical attention in the small town in which he resided, came with his six children to New Orleans and went directly to the yellow fever hospital, being convinced, he said, that this well screened hospital, although full of yellow fever patients in all stages of the disease, was the safest place in the epidemic area.

I might cite other instances in New Orleans in which patients were attacked by yellow fever in boarding houses. When the mosquitoes in the house were destroyed and the patient screened or removed, the other boarders did not leave, as they had entire confidence in the fact that, although they had been in contact with a sick boarder, they were in no danger from further spread of the disease in view of the measures taken.

THE RENAISSANCE OF THERAPEUTICS.*

RICHARD C. CABOT, M.D.
BOSTON.

A new start in life, a new lease of life, a new movement—that is what we are witnessing to-day, I think, in the theory and practice of therapeutics. There have been other such new shoots before on the old tree, and doubtless there will be many more. Our time is not the turning point of all the ages. Nevertheless, I think I can bring before you a group of phenomena which, taken together, constitute impressive evidence that we have received a new impetus along the old road.

* Read by invitation before the Norfolk Medical Society, Norfolk, Va., April 17, 1906.

Surgery was the last great wave of new life in therapeutics, for of course we must recognize surgery as belonging essentially among the resources of modern therapeutics. Despite its brilliant and most beneficent successes, I think we Americans are somewhat prone to exaggerate the service which surgical therapeutics is capable of performing. Certainly not more than one-tenth of the sick people in the world are capable of being benefited by surgery. The other nine-tenths must, for the present, and I believe also for the future, be helped, if at all, by other methods of cure.

Ten years ago surgery was triumphantly invading the territory hitherto supposed to belong to other types of therapeutics. I believe that to-day the limit of that advance has been nearly reached. There are even signs of retreat. Surgeons are less anxious than formerly to operate on the brain, on the kidney of Bright's disease, and on bleeding ulcers of the stomach, and if our profession advances in honesty as fast as it has in acumen we shall, all of us, live to see fewer operations on the uterus and its appendages.

The hygienic treatment of osseous and glandular tuberculosis and the treatment of tuberculous joints by Bier's method of passive hyperemia, are limiting the applications of surgery on one side as orthopedic apparatus have long since limited them on another. I doubt whether tuberculosis will be operated on as much ten years hence as it is to-day. Cancer of the stomach on the other hand will be operated on far oftener and we hope earlier, thus balancing up the account and leaving surgery on the firm ground of its well-established usefulness, neither advancing nor retreating.

As surgery settles into its place, we see rising a new wave of therapeutic activity along other lines. I will mention first some of the most obvious of its manifestations. Two important bodies of physicians, each body national in its scope, will meet within the next two months, the Association of American Physicians at Washington and the American Medical Association at Boston. Each of these assemblies plans a symposium on therapeutics, and in each such a symposium is a decided novelty. Indeed, I believe that it is the first extended discussion of therapeutics ever entered on by the Association of American Physicians in the whole twenty years of its organized existence.

This state of things would be very puzzling and not a little shocking to the laity, who are not used to the fact that a large part of the labors of the modern physician are and ought to be spent on diagnosis. But there are plenty of parallels in other fields. The statesman and the social worker are in the same position. Without accurate diagnosis of the evil confronting them it is as dangerous for them as it is for us physicians to attempt remedial action.

We have reason to defend, then, the great emphasis placed on diagnosis by the honest and competent medical man as it is by the honest and competent sociologist or legislator. The public always wants a quick remedy and is impatient of prolonged and careful investigation. But it is always the business of the wise public servant to keep the public waiting for a remedy until he has done his best to find out what is the matter.

While we rightly defend the insistence on accurate diagnosis which characterizes all the most competent physicians of our time, we ought not to be blind to the fact that it is possible for us to get so much interested in diagnosis (that necessary preparation for good treatment) that we use up our best energy before we get round to the knotty problems of therapeutics. When the hospital physician has carefully and skilfully diagnosed the new cases in his clinic he is apt to go home to his luncheon and leave his externe to treat them. This habit exemplifies, I think, a deep and widespread tendency among the physicians of our time. Like the man who went back so far for the run preparatory to jumping a brook that he forgot to jump it at all, we sometimes expend a wealth of diagnostic energy altogether out of proportion to our therapeutic attempts.

We used to diagnose with admirable accuracy the precise extent and degree of the tuberculous process in a patient's lungs, quote sardonically the saying that "the treatment of consumption is opium and lies," and proceed accordingly and with great swiftness to the close of the case. We used to fall back on nihilistic epigrams about the self-limitation of disease, the omnipotence of Nature, and the powerlessness of man. It was in this spirit that a wise, conscientious, very successful physician said to me twenty years ago: "What! You're going to study medicine? Oh, don't, or if you do, don't practice it. The study of it, the science of it, is heaven, but the practice of it is hell."

Now in contrast with this we are beginning to see a new trend in therapeutics to-day. That trend shows itself first of all in what I call:

I. THE AGGRESSIVE SPIRIT IN THERAPEUTICS.

The term "aggressive treatment" well characterizes the new method which we have watched Dr. Hawes[1] carrying into effect at the Massachusetts General Hospital. It has been a revelation to me. In the past we have offered the hospital cases of tuberculosis our advice on printed slips, supplemented by a few minutes rather perfunctory talk, and by various prescriptions. If the patients were discouraged at the program we offered them (rest in the open air and forced feeding), and drifted away through the hands of the quack to their deathbeds, we let them go and turned to the next patient.

The new method is to reinvigorate the patient's courage: (a) by long, patient and repeated explanations; (b) by taking (and letting him see that you take) a personal interest in his cure; (c) by the class method whereby one discouraged patient gets hope by hearing and seeing the success of the treatment in other cases; (d) by taking up and helping him to solve some of the practical objections to carrying out the cure which are likely to arise in his mind.

"How can I sleep out doors?"

"Your roof, your back yard, your piazza top, your balcony."

"How shall I keep from freezing?"

"We will show you how to dress and to cover your head on cold nights."

"But how can I leave my work and find money to buy a tent and a steamer-chair, eggs, milk, olive oil and all that you say I need?"

"We will try to interest your lodge, your church, your mutual benefit society, and if all these fail, we will lend you the money without interest."

The old way was to say: "Well, if people will be foolish, what can we do? We can not undertake their education. If they will come here in the proper spirit and do what we tell them we will try to help them, but if they don't want to get well we are helpless." The new way is to undertake their education, to take them into our confidence and show them what we are trying to do, to

1. Hawes, John B.: "The Early Diagnosis and the Aggressive Treatment of Pulmonary Tuberculosis in an Out-Patient Clinic," Boston Med. and Surg. Jour., April 5, 1906.

explain how and why air and food and not drugs are what they need, and to demonstrate to them by ocular evidence—photographs, models—the means of carrying out the treatment and the result of it: cured patients.

Further, an essential of the type of therapeutics which I am now discussing is a patient attention to "fussy" details, which not many good diagnosticians care for. This supervision of details is best carried out in this as in all fields of therapeutics by a nurse. Most women are far better at such things than most men, and the visiting nurse is coming to be as essential a part, I believe, of the therapeutics of this as of many other types of disease.

The results of this aggressive type of treatment are remarkable. In the cold, damp, changeable climate of Boston we are now curing not merely the ideal patients, who have an incipient lesion, good courage and backbone, a country house and real intelligence, but some of the stupid, discouraged, slum-worn cases that we used to abandon as (under the circumstances) hopeless.

Let me recapitulate the essentials of what I have called the aggressive treatment of any disease:

1. We take the patient into our confidence, as ex-President Cleveland[2] has recently begged all physicians to do.

2. We tell him the truth, explain his malady and the means of its cure.

3. We attempt to meet the mental side of the problem by appropriate mental treatment.

4. We try to meet the material and economic side of the case by calling on the resources of his relations, friends and neighbors and by contriving in his home such makeshifts as ingenuity can suggest.

5. We pay patient and long-continued attention to the details of his treatment, the amount and character of his food, his sleep, his hours outdoors, his clothing, his temperature, his weight, as well as to the signs of his chest. In this work we rely on the assistance of women, trained nurses or volunteers, as it is essential that we should.

As another example of what I have called the aggressive spirit in modern therapeutics, let me remind you of the methods of inspecting the health of school children recently brought to a high state of perfection in New York City and now springing up in Philadelphia, Boston and other cities.

The old method was to have the school physician call at the school and examine any children who had complained to their teacher of feeling sick. The physician's attitude was characteristically passive. He would see whoever came to him with complaints. If the disease were contagious he would send the child home and demand isolation; if the case was non-contagious he would recommend the child's family to do something about it, sending the child home with a printed notice which the parents could not read or understand and which, therefore, passed unheeded. The new method is to make a general physical examination of every child in the school at least once a year, whether it complains or not, and if, as is usually the case, a large proportion of the children are partially deaf or partially blind (owing to adenoids or refractive errors), the authorities do not rest content with good advice to the parents, advice couched in such terms and delivered at such long range that it is 1,000 to 1 it will have no effect. Instead of this they come to close terms with the actual details of their problem in the way which experience shows to be the best and surest, namely, through a nurse. A nurse takes the child home, explains the matter in patient detail to the indifferent or stupid parents and finally succeeds in almost every case in getting something done.

In many cases the nurse does it herself. In New York the nurses now treat and cure many cases of skin disease which, under parental neglect or the rare and hasty ministrations of the family physician, used formerly to hang on and deprive the child of its schooling for weeks and weeks. If she does not actually treat the cases she makes treatment possible by taking the child to a hospital for proper care.

In one school district in Boston, previously "inspected" and found healthy by the school physician, the school nurse found within three weeks 27 cases of adenoids causing deafness, 51 cases of defective vision, 7 running ears, 2 cases of scabies and so on. But it is on the treatment, not the diagnosis, of these cases that I wish to insist. That treatment is characterized by the same features to which I called attention in our tuberculosis work:

1. By open-and-above-board explanation of the disease to the persons concerned—this time the parents.

2. By attending to the mental, material and economic aspects of the problem.

3. By paying especial attention to the details of the case through a nurse.

Does all that I have described constitute any addition to the science of therapeutics? No, not to the science, but to its effectiveness in its application. The new life in therapeutics appears not so much in what the man of science conceives as in the benefit received by the patient.

II. THE PART PLAYED BY THE PUBLIC.

The increasing and intelligent interest taken by the public in the treatment of disease is the next aspect of the present therapeutic renaissance to which I invite your attention.

The great and beneficent activity against tuberculosis which has recently sprung up all over the country would have been impossible but for a wholly new attitude on the part of the public. The lay public is now doing fully as much as the physicians in this matter. The tuberculosis exhibits, the new hospitals for phthisis, the laws against spitting (and they are beginning to be enforced), the free examination of sputa and free disinfection of homes are made possible only by the new interest and by the consequent liberality and co-operation of the public. The lay public must pay for these things and it must co-operate to make them effective; not infrequently it goes further and itself initiates the reform. I can never forget the case of an intelligent New Hampshire lawyer who, after coming dangerously near to death from consumption (owing to the lack of proper hygienic treatment from his physicians), cured himself of the disease by following the treatment outlined in an account of the first tuberculosis exhibit at Baltimore, printed in the *Review of Reviews*. The interest of the laity in that exhibit and the evidences of that interest shown in its publication as news in the *Review of Reviews* was the means of bringing to this patient the cure which had not been put into his hands or suggested to him by any of the three physicians whom he had consulted.

What are these tuberculosis exhibits which, first starting in Baltimore, have now been successfully repeated in New York, Philadelphia, Boston, Chicago and other cities? They are simply a piece of *medical education offered free to the public*. They have some of the

2. Cleveland, Grover C.: Address at the 100th Anniversary of the New York Medical Association, Albany, Jan. 31, 1906.

features that I have mentioned as characteristic of the therapeutic renaissance of our day: (*a*) Taking the public into our confidence and appealing directly to its understanding in order that it may actively co-operate in the treatment instead of blindly following directions; (*b*) giving full attention to the details of the application of our therapeutic principles, so that they may be as effective as possible.

That we shall limit this medical education of the public to the single subject of tuberculosis I do not for a moment believe. About malaria, typhoid, yellow fever and other diseases the public must be given the fullest information that we can make them take if we are to fight these diseases successfully.

By slight, hardly noticeable steps, we have arrived at a standpoint commanding a prospect that would have astonished our fathers. We are teaching the public medicine as fast and as far as we can. The fear of alarming them, of leading them to brood over imaginary ills and to attempt recklessly and disastrously to doctor themselves —all these fears prove groundless. Why? Because the public has already drank as deep as it can of the ills which we are now so fearful lest they taste.

The public is already as groundlessly and nervously alarmed about disease as they can be made by the skill of advertisements intended to produce just this effect. So long as our newspapers are crammed with such statements as that pain in the back or frequent micturition means kidney disease, that headache means brain disease, that pimples mean blood poisoning and that varicocele means lost manhood, so long, I say, as these malicious lies constitute the whole stock of information about health and disease received by the public, we need not fear that by spreading a little verifiable truth about disease and its cure we shall poison the public mind.

Equally groundless is the belief that by teaching the public the principles of therapeutics we shall lead them to try to do without the guidance of a physician. For with that evil also they are already tainted past all hope of escape. The $75,000,000 annually spent on "patent medicines" testifies to the truth of what I say. The public will have some ideas about health and disease anyway, and the less we do to spread true ideas the more absolute will be the sway of the false and pernicious legends which are now foisted on them. The people will doctor themselves anyway, many of them, and the blacker their ignorance of health and disease the more they will do it and the worse will be the result.

Professor Councilman, of the Harvard Medical School, said to me a few weeks ago: "The first business of a medical teacher is to teach the public—if we want to get rid of disease; his duty to the physicians and to the medical students is less vital, less immediate if the health of the community is what we seek." This is radical doctrine, but I believe it is the application of this doctrine that is doing most to make therapeutics really effective to-day.

III. THE INCREASING PREVALENCE OF PHYSICAL THERAPEUTICS.

(a) Our hospitals are being rapidly remodeled in recognition of the fact that fresh air is a curative agent, not only for incipient tuberculosis, but in most ailments. Northrup's fresh-air cure for pneumonia will be followed, I venture to prophesy, by a like treatment for typhoid, septic wounds, erysipelas and the acute exanthamata.* I recently heard of an inflammatory eye affection in the child of a brother physician which was advancing with alarming rapidity despite all the measures used to combat it, until, as a last resort, the expedient was tried of putting the child's crib in a bay window surrounded by wide-open windows. An immediate and striking change for the better was noticed within twenty-four hours, and in the course of a few days the danger was over.

Here is, I believe, a new and most hopeful advance in therapeutics. In increasing numbers our surgical cases are being put out of doors, bed and all, very soon after the operation; hospitals are building cheap, open shacks in the country and transferring their patients there for convalescence as soon as possible. The therapeutic effectiveness of the hospital is thus increased, not only by the greater brevity and security of convalescence, but by the increase in the number of patients who can thus be admitted and treated in one set of beds within a given week or month. The beds are emptied so rapidly into the country convalescent home that they are ready for new patients much sooner than formerly.

(b) As a second example of the growth and prevalence of physical therapeutics, the proper use of air, water, food, massage, climate, heat, cold, pressure and the like, I mention the fact that the largest and most recent work on therapeutics known to me, Cohen's twelve-volume book, is devoted exclusively to physical and psychical therapeutics.

Do our patients take kindly to remedial means of this type? Do they actually prove effective? Can we secure the use of open windows in pneumonia, frequent baths in typhoid, of forced feeding in phthisis, of heat and local congestion in joint troubles? Yes, whenever we fulfill the second condition of the modern type of aggressive therapeutics, viz., become ourselves masters of the details of the treatment which we recommend or else turn it over to some one who is usually a nurse.

There is no use disguising from ourselves the fact that on the continent of Europe the wave of improvement in therapeutics, through the effective application of physical agents, has risen much higher than in this country. When we advise a patient to carry out at home the Nauheim treatment of heart disease, the passive hyperemic treatment of joint disease, the dietetic treatment of tuberculosis, we not infrequently lack that intimate and familiar knowledge of the finer details of the treatment, details on which its effectiveness largely depends. Furthermore, we are likely, I think, to continue, many of us, in the same ignorance of such details because we do not like them. *They bore us.* We had rather turn them over to some one else who is interested in them, but as yet we do not always do so.

IV. PSYCHIC TREATMENT.

In what I earlier said of the aggressive treatment of tuberculosis I intimated that one of the factors in the increased effectiveness of the treatment was a realization of the psychic aspects of disease.

This increased awareness on our part of the psychic factors in all disease, organic as well as functional, is one of the most obvious features of the rebirth of therapeutics. A name is a wonderful thing. When we use words of Latin derivation and speak of "mind cure" or "mental healing" we are thought to be speaking of something very irregular and unorthodox, something that has crept on us like other forms of superstition and quackery, something to be repressed by the strong arm of the law whenever that assistance is available. But shift your wording, use a phrase of Greek derivation, "psychic

* Since this was written I have heard from Dr. Walter B. James, of New York, that he has already carried out a good deal of this treatment at the Presbyterian Hospital.

therapeutics," and straightway you are speaking of a legitimate field of medicine! I regard the publication and dissemination (in translation) of Professor Dubois' remarkable work on psychic therapeutics as marking an important epoch in medical history. Here we have for the first time scientific mind cure. Mind cure, first the stock in trade of charlatans, then of devoted but irrational women, has now begun to take its place as an important and, in many diseases, a central branch of therapeutics. Of course we have all of us used mind cure in our practice for years, but not in the systematic and thorough way in which the Swiss neurologist, Dubois, outlines and practices it.

Mind cure with Dubois is not hypnotism, a practice which is, I believe, being very generally abandoned the world over; it is not Christian science, with its perishable freight of overripe theology. *It is essentially the education of the patient.* Like all the best modern therapeutics, it seeks and utilizes to the full the cooperation of the patient himself. Everything is explained to him, no lies are told him. The potent influence of auto-suggestion, for good or for evil, is made clear to him. I recommend very earnestly the perusal of this book. The chapters on the psychic treatment of nervous diseases of the heart, the stomach and intestine, the brain, the sexual organs and the muscles exhibit a combination of powers rarely united hitherto in one author. He is scientific and thoroughly up to date in the details of physical and chemical diagnosis; he has with this the ingenuity and the intimate knowledge of human nature, its foibles, its failings and the sources of its power—a knowledge not often possessed by one so skilled in diagnosis. Besides this he has a big heart, a large charity and a confident optimism—the cause and the result of his abundantly successful career. The discipline and method of science, the art and skill in personal influence, ordinarily used only by the quack and for his base purposes, and the enthusiasm of a lover of mankind—these are qualities which Dubois unites in a remarkable and, so far as I know, unique way. His book is as interesting as a novel, full of instructive anecdotes and personal experiences, yet always systematic and never prolix. I have put it straight into the hands of several patients with good results to all. That nervous diseases are mental diseases, to be cured, if at all, by mental means, is the keynote of his work, and the mental means used are educational throughout. In this and in the recognition throughout of the absolute necessity of recognizing and, if possible, ameliorating the circumstances of the patient, domestic and economic, Dubois well typifies one phase of the rebirth of therapeutics.

V. THE PLACE OF SOCIOLOGY IN THERAPEUTICS.

It is not accidental that we witness in the same year the publication of Dubois' book with its reinstatement of psychic treatment for the psychic element present in all disease, and the establishment at the Massachusetts General Hospital of sociologic work among its patients as a necessary part of thorough medical work. This marks the recognition of the fact that you can not treat a patient without knowing the circumstances, industrial, social, domestic, racial, in which his malady developed, and that you can adequately treat his malady if you recognize its human setting, the condition under which it grew up. A patient comes to me complaining of headache and general weakness. Physical examination is negative, his eyes are sound, he has no fever, but further inquiry shows that he has been lying awake night after night. Pushing the inquiries yet further, we find that it is worry that keeps him awake. To remove the cause of the disease being the first maxim in therapeutics, we are bound to find, if we can, what the cause of the worry is. This eludes us and we refer him for further sociologic investigation to another room, which the hospital has permitted me to organize and to put in charge of two expert and devoted women, for whose whole time we pay. This investigation reveals the fact that his income has of late been slightly less than his expenses and that, in spite of his best efforts, he can not as yet make the two ends meet. His insomnia and the resulting debility date from the time that this anxiety has been weighing him down; poverty is obviously the cause of his symptoms.

I believe it is coming to be recognized as a legitimate and indeed an essential part of therapeutics *to seek for the relief of any cause that is producing disease, no matter how far afield we have to go to reach that cause.* To be thorough is the first of our medical ideals. To treat symptoms without doing our level best to find and remove their cause is to be criminally negligent. The search for this may carry us far beyond what are ordinarily conceived to be the boundaries of medicine. We may have to investigate family affairs, industrial conditions, love affairs, school and college problems, all far enough from the practice of physical diagnosis and drug therapy. But how often this has happened before in the history of medicine! When the neurologist had to learn the laws and workings of electricity and the general practitioner had to become familiar with the use of the microscope they had to advance far beyond the boundaries of medicine, and I doubt whether in the beginning they realized the necessity. One after another of the sister sciences we medical men have had to invade and to some extent to master in order to make use of them in our work.

To chemistry, organic and inorganic, we now have to add some smattering of physical chemistry. To pathology we had to add bacteriology. The science of statistics and the knowledge of the diseases of animals are fields which we have found it impossible to keep out of. Now we have begun to annex psychology and sociology. *The necessity is the same that forced us to take up physics and chemistry—their laws are inextricably interwoven with the phenomena of disease.* To understand and to treat our patients we have to deal with all the causes that go to produce their maladies, so far as we can reach these causes. The recognition of social and psychical factors as causes of disease and the measurably successful effort to reach and to modify these causes is one of the most striking marks of the present rebirth of therapeutics.

VI. THE PLACE OF WOMEN'S WORK IN THERAPEUTICS.

No one can fail to be impressed if he observes the steady increase in the amount of therapeutics now recognized to be best carried out by women. It has long been true that in the division of labor between doctor and nurse the doctor has made the diagnosis and prescribed the treatment, the nurse or the house-mother has carried out the treatment. It has also been long recognized that male nurses are seldom a success. There is in women a strong natural taste and aptitude for the very work of detailed therapeutics which we call nursing, an aptitude very conspicuous by its absence in most men. All this is familiar and trite.

Within ten years we have witnessed a very interesting development in the functions of the nurse. We have now not only the nurses trained for massage and for physical therapeutics of other physical types, but the Nauheim bath nurses, the tuberculosis nurses, the school nurses,

the nurse who teaches and directs infant-feeding. As fast as any branch of physical therapeutics is worked out to any degree of perfection we find it an economy of time and labor to hand it over to those naturally fitted to carry out its details with the patience, tact and deftness that come from natural interest and aptitude.

In the newer psychic and sociologic fields which medicine has begun to invade I have no doubt that women will find a large field of usefulness. Social work and psychic therapy as they are practiced independent of medicine are now overwhelmingly in the hands of women, and I see no reason for shifting these forms of therapeutics into other hands when they come to be more fully recognized and assimilated by medical practice. The effective application of all therapeutics (if you except surgery) is women's work.

VII. ACCOMPANYING DEATHS.

Every birth involves death. The success of the new brings always the rejection of that which once was new, but which now has outlived its usefulness.

The changes which I have described mark the beginning of the end of many evils. I mention two: (*a*) The false mystery that has often encompassed the doctor; (*b*) the conception of drugs as the *alpha* and *omega* of therapeutics. Drugs will always hold an important place in medicine, but they will never hold the unquestioned sway which they commanded before the rise of physical therapeutics, of the aggressive public campaigns now being waged against disease, of psychic therapeutics and the full utilization of women. Drug therapeutics in cases in which drugs do no good represent either mental fatigue or mental myopia on the part of the physician: sometimes mental fatigue because the easiest thing that one can do for a patient when tired is to write a prescription; sometimes mental myopia which prevents the physician from seeing that the habit of giving placebos and of prescribing a medicine for every symptom leads straight to the "patent-medicine" habit.

Why do people take "patent medicines" and expect us to give them a drug for every symptom? They were not born with a desire for nauseous mixtures. They acquired it under instruction, ultimately our instruction. From the patient's point of view the net result of the doctor's expensive visits is too often a row of medicine bottles on the shelf. The thrifty patient thereupon thinks he sees a way to get the net result of the doctor's efforts without so much expense. Why not save the middle man, he says to himself, and get the goods direct? So arises the habit of going to apothecaries or to the "patent-medicine" vendors for a cure. When we stop giving placebos, cease acting as middle men for drugmakers and admit to their rightful place the non-medicinal branches of therapeutics we shall deal a powerful blow at the "patent-medicine" evil.

SUMMARY AND CONCLUSIONS.

1. Therapeutics has become, within the past few years, very noticeably more effective.

2. This increased effectiveness is the result of (*a*) the aggressive spirit as exemplified by the work of the New York Board of Health in school hygiene and school inspection and by the tuberculosis work now being carried on in Boston; (*b*) the greater part now being taken by the laity in medicinal work, both by intelligent co-operation and by financial support; (*c*) our greater acquaintance with physical therapeutics, especially with the details on which their successful application depends; (*d*) the rise of scientific mind cure and of social work, marking a recognition of the psychical and of the social elements in all disease; (*e*) a wider utilization of the unique talents of women in the field of therapeutics.

3. With the rise of the type of therapeutics here described we are now witnessing a limitation of the sphere both of surgical therapeutics and of drug therapeutics. The latter limitation will do much to undermine the superstitions on which the "patent-medicine" habit rests.

THE CAUSE OF THE HEART BEAT.*

W. H. HOWELL, M.D., PH.D.

Professor of Physiology and Dean of the Medical Faculty, Johns Hopkins University.

BALTIMORE.

HISTORICAL REVIEW.

The Seventeenth Century: Harvey and Willis.—It is known to all students of the history of medicine that what may be designated in general as the modern point of view regarding the cause of the heart beat dates from the work of William Harvey. Before his time physicians thought along the lines laid down by the ancient masters, in that they conceived the expansion of the heart in diastole to be an active, or rather the active phenomenon of the heart beat. This expansion was attributed to the innate or implanted heat, to the vital spirits, to the pulsatile force, etc. That the diastole of the heart is an active rather than a passive expansion has been held in a sense by many prominent physiologists, even in the nineteenth century. Magendie, for example, states that at first he entertained this belief. Nevertheless it remains true that Harvey's experiments and observations demonstrated that the pulse of the heart and the arteries is due to a contraction of the musculature of the heart during systole, whereby blood is driven forcibly into the arteries. "The motion of the heart consists in a certain universal tension, both contraction in the line of its fibers and constriction in every sense."[1] This conception of the heart as a muscular force pump, driving out its contents during its active contraction, instead of drawing blood and pneuma into itself by a spontaneous dilatation was, as Dalton says, the first important step in the development of the doctrine of the circulation. Certainly as regards the nature of the heart beat it makes the great dividing line between ancient and modern speculations.

We may regard Harvey also as the founder of the myogenic theory of the heart beat. For although Galen taught that the pulsations of the heart are dependent on an inherent force, which acts through the contractions of the peculiar tissue composing the heart, yet his conceptions of the nature of the heart beat were so different from ours that his ideas are scarcely applicable to the problem as it presents itself to us. Harvey interpreted the systole and the diastole as a contraction and relaxation respectively of the musculature, and, although he did not speculate as to the cause or nature of the contraction, he seems to have considered it an inherent property of the heart muscle itself. Later writers attempted a further analysis of the phenomenon, and in one form or another hypotheses arose, which attributed the initial cause of the heart beat to the activity of the nervous system. Willis[2] taught that the nerves supplying the heart, stomach, intestines, etc.,

arise from the cerebellum, and that, therefore, this organ engenders the animal spirits through which the involuntary movements of the heart are effected. This view found many advocates, but it disappeared in the course of time, after it was shown that the nerves in question do not originate in the medulla, and that so far as the heart is concerned, the beats continue even when the organ is excised. Borelli[3] devised an ingenious hypothesis by means of which he reconciled the last mentioned fact with the view of a nervous control of the heart beat. He assumed that the contractions of the heart depend on an influence derived through the nerves. The liquid, succus spirituosus, conveyed by the nerves, escapes slowly into the heart and sets up there an ebullition, which is the immediate cause of the contraction, or according to his view, the expansion of systole. Since in the excised heart some of this liquid is still contained in the stumps of the adherent nerve fibers, it is evident that the pulsations of the organ may continue for a time after removal from the body.

The Eighteenth Century.—Evidently the century following Harvey's immortal discovery did not add anything of material importance to our understanding of the cause of the heart beat. But the tendency manifested during this period to attribute the initiation of this phenomenon to some direct influence of the nervous system was of value indirectly, in that it led to continual discussion and to some experimental work. Haller devoted much attention to the problem and he succeeded apparently in disproving the neurogenic views in the form in which they had been proposed at that time. In place of them he formulated a clear-cut myogenic hypothesis which served to mark the beginning of a new discussion lasting until the present day. He insisted on the fundamental facts that the heart continues to beat after section of the nerves going to it and even when "torn out of the breast." The musculature of the heart, he says, possesses an inherent irritability or power of contraction, which is independent of the influence of the extrinsic nerves; a view, which to his mind, was demonstrated by the fact that a quiescent heart may be excited to movement by "heat, vapor, cold, poison, current of air, watery liquids, wax, blood, or an electric spark."[4] According to his theory, therefore, the cause of the heart beat lies in the inherent irritability of its musculature, and under normal conditions this property is aroused to action by the stimulating influence of the blood as it flows into the ventricles from the veins and auricles. "By this blood copious, warm and heavy, the sensible flesh of the heart is irritated and excited to contraction." For a time Haller's views met with general acceptance, but some of his contemporaries remained unconvinced. Senac,[5] for example, while admitting that the heart is essentially independent of the central nervous system and is aroused to action by the stimulating effect of the blood, conceived that this stimulus acts on the nerves in the heart, rather than on the musculature directly.

The Nineteenth Century.—About the commencement of the nineteenth century physiology began to assume definitely the characteristics of an experimental science. The greatest masters had, indeed, always made use of experiments in their inquiries, but their disciples, on the contrary, were more keen in the matter of argument and exposition than in devising new investigations. The dawn of a new day for our science was slowly breaking at the close of the eighteenth century. Henceforward, experimental work became more widespread and physiologists adopted promptly all the available methods and appliances that were developing in the sister sciences of chemistry and physics. So far as our subject is concerned, one of the first evidences of the awakening of this experimental spirit is to be found in the numerous attempts to determine directly, whether or not the beat of the heart is influenced by the cardiac nerves. These nerves were stimulated or severed and the effects on the heart beat were observed. Senac, Bichat, Fontana, Treviranus and others reported negative results from the stimulation of the cardiac nerves, while von Humboldt, Burdach, and later Longet and Valentin stated that an increase in the heart beat was obtained.

Many of us may wonder why these capable observers failed to discover the inhibitory action of the vagus nerve on the heart beat, that phenomenon which we now obtain with such ease and certainty that it constitutes one of our usual and always successful class demonstrations. The explanation is, I believe, very evident. These men possessed only crude and inefficient methods of stimulation, such as mechanical compression or section, the action of chemical agents, the electric spark of the Leyden jar or of the statical machine, or the continuous current of the voltaic pile. If we were compelled to resort to the same appliances now it would be difficult or impossible for us to demonstrate with certainty such an effect as the inhibition of the heart by stimulation of the vagus nerve.

In this, as in many other respects, experimental investigations in physiology were immensely aided by the discovery of the induction current, and the construction of instruments capable of giving a rapid series of induction shocks. Magnetic induction currents were first obtained by Faraday, in 1832, and shortly afterward he succeeded in developing similar effects from the current of the galvanic battery, that is, in producing what he called voltaic induction. Both of these discoveries were quickly applied to the uses of physiology. With the aid of a magneto-electric rotator, the brothers Weber,[6] in 1845 and Budge,[7] perhaps independently, in 1846, succeeded in demonstrating the inhibitory action of the vagus nerve on the heart. One of the three talented Weber brothers, Wilhelm Weber, was a distinguished physicist, and it is stated that in 1838 he devised a form of magnetic rotator which was capable of giving a series of induction shocks. Possibly it was through his influence that his brothers, Ernst Heinrich and Eduard Friederich were led to use this apparatus in their investigations on the vagus nerve.[8] This fundamental discovery not only opened a new field to physiologic thought and investigation, but it also disposed finally of the erroneous view that the vagus nerve serves as a motor channel through which the central nervous system controls and originates the beat of the heart.

The general view that the beat of the heart is directly dependent on the central nervous system had meanwhile taken another form. On the basis of excellent experimental work Legallois[9] concluded that destruction of the spinal cord is followed by a failure in the

power of the heart to maintain its contractions; and, indeed, in animals not too young, this result was obtained when any given region of the cord, cervical, dorsal or lumbar, was alone destroyed. We know now that such operations may be performed, with the aid of our better technic, without causing the death of the animal, and it is probable that the fatal results obtained by Legallois were due directly to vasomotor paralysis. He was convinced that his experiments proved that the stimulus or principle which maintains the beat of the heart is derived from the spinal cord in all of its parts, and is conveyed to the heart through the branches of the sympathetic system.

Legallois's experiments and conclusions were passed on and endorsed by a special commission, consisting of von Humboldt, Hallé and Percy, appointed by the French Academy; but the dictum of a commission, fortunately, is not accepted as final in science. The work of Philip and of Clift in England; of Flourens and Brachet, in France and of Bidder, in Germany, soon made Legallois's conclusions doubtful, or altogether improbable.

Throughout this period, during which efforts were made to show that the heart beat is controlled directly from the central nervous system, most physiologists were saved from the intricacies and perplexities of obscure and doubtful interpretations by holding fast to the simple, incontestable fact that the heart continues to beat after removal from the body. This fact says Volkmann[10] proves absolutely that the force causing the heart beat does not arise in the brain or cord. The development of modern physiology has served to demonstrate the correctness of Volkmann's reasoning. By the methods of isolating the heart, first used in this country by Newell-Martin and subsequently modified and improved by Porter, Langendorff, Locke, Hering and others, we are now able to keep the hearts of mammals, including man, beating for hours or days, after all connections with the central nervous system are severed.

That form of the neurogenic theory which made the heart's beat dependent on the central nervous system was finally disposed of when the true functions of the extrinsic nerves to the heart were demonstrated. Physiologists were perhaps more willing to let it depart forever, because, at this period, an entirely different kind of neurogenic hypothesis was meeting with great favor on all sides. According to this newer view, the cause of the heart beat lies in the automatic activity of the sympathetic ganglia, present in the heart itself. In this form the neurogenic hypothesis quickly and completely replaced the myogenic theories as proposed by Haller, the pendulum of physiologic belief taking a strong and a long swing to the nervous side. This particular form of the neurogenic theory seems to have originated in the work of Bichat.[11] In the grand and comprehensive system devised by this remarkable man, the processes of the animal body are divided into the animal and the organic. Over the latter, including the beat of the heart, the central nervous system has no control; they are under the influence of the sympathetic or ganglionic system. The sympathetic nerve in fact was assumed, in accordance with the old idea of Winslow, to consist of a number of small independent systems for each of which a ganglion served as a center or brain. No direct evidence was furnished then, nor has it been furnished since, that such ganglia control the movements of the heart, but the theory offered a plausible hypothesis, and, in the minds of most physiologists, the hypothesis was almost definitely proved when, in 1844, Remak[12] described nerve ganglia within the substance of the heart. From our modern standpoint it is difficult to understand why this anatomical fact should have carried so much weight.

If the isolated heart continues to beat it is surely just as logical to assume that the cause of the beat lies in the properties of the musculature, as in those of the intrinsic nerves. Yet for a long period of years physiologists were practically unanimous in giving the latter interpretation. The consideration that had most weight with them beyond doubt, was the orderly co-ordinated character of the heart beat. The co-ordination of different muscles to give an orderly sequence of contractions is usually under the control of the nervous system, as is shown in voluntary or reflex movements and in the rhythmic play of the respiratory muscles. In the heart beat a similar sequence is presented. The contractions of the veins, auricles and ventricles follow in a definite order, and whether stimulated naturally or artifically the musculature of each chamber contracts in a co-ordinated fashion. For the control of such a complex and yet orderly movement it was natural, reasoning from analogy, to assume that nerve centers are required. Practically all physiologists abandoned the myogenic hypothesis of Haller and accepted the neurogenic theory as formulated by Volkmann.[13] For a period of 40 years this view was taught almost exclusively in the text-books and was accepted in all the discussions of the current literature. Investigation in fact, was directed largely toward discovering the finer anatomy of the intrinsic nervous mechanism and speculating on the specific rôles played by the different ganglia.

In the frog's heart, which formed the classical object of research, two distinct nerve centers were described, one, the ganglion of Remak, situated at the junction of the sinus venosus and auricles, the other the ganglion of Bidder, lying at the level of the auriculoventricular ring. Numerous experiments were made to determine the difference in function, if any, between these two centers. While the original view had assumed simply that the intrinsic ganglia function as motor centers, discharging impulses in regular sequence into the different chambers, numerous corollaries or amendments to this hypothesis soon appeared. For a time the polydynamic theory, as it was designated, obtained increasing acceptance. It was recognized that the beat of the heart begins normally at the venous end and thence spreads in orderly sequence to auricles and ventricles; hence it was concluded that the ganglion of Remak in the sinus constitutes the original or chief motor center in which the first impulses arise automatically. But it was known also that parts of the heart, separated from this ganglion by section or ligature, may also beat rhythmically and respond to artificial stimulation by co-ordinated contractions; hence it became necessary to regard other nerve cells in the heart as subordinate motor centers. Bidder[14] and others believed that the ganglia discovered by him at the junction of auricle and ventricle function as reflex motor centers. So also the inhibitory action of the vagus nerve led naturally to the supposition that an inhibitory center exists in the heart; while numerous pharmacologic studies suggested

still more elaborate views in order to explain the differences in action of various drugs. Schmiedeberg[15] (1870) assumed the existence not only of motor and inhibitory centers, but also of an intermediate apparatus of some sort placed on the course of the vagus fibers before they reach the inhibitory center. Perhaps the latest effort of this kind to differentiate between the functions of the intrinsic ganglia is found in the papers of Kaiser[16] (1893-4) who describes an automatic or excitomotor center at the venous end of the heart, certain subordinate motor centers in auricles and ventricles and an inhibitory center in the auriculoventricular region. The last named center is stimulated reflexly by the systole of the ventricle, and then sends inhibitory impulses to the subordinate motor centers, whereby these latter are inhibited, and diastolic expansion is produced in the ventricle.

From the time of Volkmann to that of Kaiser the neurogenic hypothesis has been given many specific forms by Joh. Müller, Kürschner, Budge, Schiff, Goltz, and others, but in recent years the interest in this matter of subdividing the functions of the various ganglia has obviously subsided. It is recognized that the whole neurogenic theory is again under discussion, and that it is more important at present to decide the fundamental question, whether the nerve cells have anything to do at all with the cause of the heart beat. The neurogenic view held to-day by many physiologists probably asserts no more than was stated by Munk in 1881, namely, that the automatic ganglion in the sinus (in the frog's heart) is the *primum movens* of the heart's activity, and that the excitations proceeding from it through the septal nerves stimulate the auricle, and indirectly the ventricle through the activity of the non-automatic ventricular ganglia. The strict neurogenists must hold in addition that all the ganglion cells (or the elements of the nerve network) in the heart are capable of independent automatic or reflex activity, since isolated bits of the heart under proper conditions give rhythmic pulsations. Friedländer[17] asserts that very minute fragments of the heart, not larger than 0.2 mm., when taken from the sinus, auricle or upper third of the ventricle, continue to beat as long as 48 hours, if kept in a proper serum.[17] The proofs furnished for this neurogenic theory were not really conclusive, and it is, therefore, natural to find that after a certain period of triumph, some investigators began to scrutinize the facts in a skeptical way.

Engelmann, influenced by his experiments on the rhythmic contractions of the ureters, which are devoid of nervous elements, suggested in 1869 that possibly the heart beats have a muscular origin. But the modern renaissance of the myogenic theory dates from the work of Gaskell,[18] from 1881 to 1883. He began his well-known experiments on the rhythmic activity of the heart in frogs and terrapins while still a believer in the neurogenic theory, but the facts that he discovered convinced him that the heart muscle itself possesses the property of automatic rhythmicity, and that this property is most highly developed in the tissue at the venous end of the heart. He proposed, therefore, a theory which, like that of Haller, assumes an independent irritability and rhythmicity in the heart muscle, but which differs from Haller's in that it does not attempt to account for the cause of the contractions.

Gaskell's beautiful experiments led him to believe that the systole of the heart begins at the venous end (sinus venosus), because the property of rhythmicity is most highly developed in this region. Thence the contraction spreads as a peristaltic wave over the rest of the heart, its rate of conduction being rapid in the expanded and modified portions of the original tube which constitute the auricles and ventricle, and less rapid in the more primitive tissue that forms the auriculoventricular ring. The slower velocity at this latter point occasions the apparent pause between the auricular and ventricular systoles. As for the nerve cells found so plentifully in the heart, he considers them merely as peripheral sympathetic cells in which the preganglionic fibers of the vagus end before being distributed to the cardiac muscle. They constitute, therefore, merely a portion of the inhibitory mechanism, and are in no way connected with the causation of the heart beat.

Gaskell's point of view was supported by Engelmann in numerous excellent researches, and from that time the myogenic theory has won many adherents among the physiologists of all countries. The controversy still furnishes material to the current literature, and the fact that this difference of opinion exists at present is in itself evidence that no absolutely conclusive proof has been furnished by either side.

Some of the many arguments advanced by one party or the other have failed to stand the test of subsequent investigations, and have, therefore, dropped out of the case as it presents itself to us to-day, but the actual condition of the question may be understood most clearly by reviewing briefly those facts and deductions which are still used most frequently by the adherents of the two views.

FACTORS IN THE PROBLEM.

Automaticity of the Various Parts of the Cardiac Musculature.—Is it true that all parts of the heart possess the property of giving automatic rhythmic contractions? We know that under normal conditions the beat of the heart begins in the great veins. The contractions of the remaining portions are due to impulses or excitations received from the venous end, either by way of the musculature or the nerves. Under normal conditions, therefore, only the venous end contracts automatically; the remainder of the musculature is stimulated to beat. When, therefore, we consider the automaticity of the heart beat as a whole, it is obvious that it depends for its initiation on the properties of that small portion of the musculature which forms the mouths of the great veins. The question arises whether the rest of the muscle of the heart possesses similar properties. Can any portion of it continue to beat rhythmically if its connections with the venous end are severed? The evidence that has accumulated within the last quarter of a century seems to me to be entirely conclusive on this point. It shows beyond question, so far as the vertebrate heart is concerned, that every portion possesses, in some degree or other, the property of giving automatic rhythmic beats provided the proper conditions are maintained. If the apex of the frog's heart is separated from the rest of the organ it refuses to beat in spite of being supplied with normal blood. But if it is put under a certain tension, or if certain substances are added to the circulating blood, it will give rhythmic contractions.

17. Friedländer: von Bezold's Untersuchungen a. d. physiol. Lab. in Würzburg, 1867.

18. Gaskell: Jour. of Physiol., 1883, vol. iv, p. 43.

When the terrapin's ventricle is cut off from the rest of the heart it remains quiet as a rule, so long as normal blood circulates through it, but a slight change in the inorganic salts of the circulating liquid, such as the removal of the potassium compounds, causes it to begin a series of beats. So, also, strips taken from various parts of the heart may be made to beat rhythmically for long periods by immersing them in special solutions. While it is true, therefore, that certain parts of the heart in some animals are incapable of beating automatically under perfectly normal conditions, that is, when supplied with the animal's own blood, it is evident that such portions of the heart have a latent property of automatic rhythmicity which may be aroused into activity when the proper conditions are provided. The beats under such conditions are of the same order of phenomenon as those normally exhibited by the venous end of the heart. If, therefore, we could find any portion of the heart entirely devoid of nervous tissue and could so modify its conditions as to cause it to give beats of the usual cardiac type, we should be in possession of a fact that would be nearly conclusive proof of the myogenic origin of the heart beats. Very numerous efforts have been made to furnish a crucial experiment of this sort.

Rhythmic Contractions in the Absence of Nerves.—The following instances of rhythmic contractions in muscular tissues devoid of nerves have been cited. The ureters (Engelmann); the veins in the bat's wings (Wharton Jones); the veins in the rabbit's ear (Schiff); certain portions of the veins opening into the frog's heart (Engelmann); the apex and also the bulbus arteriosus (Engelmann) of the frog's heart; strips from the apical portion of the terrapin's ventricle (Gaskell); the hearts of many invertebrates (Foster, Biedermann, *et al.*); the heart of the young embryo (Wagner, His). Most of these instances carry but little weight, as proof of the myogenic theory, at the present time. In regard to the ureters, or the veins in the wing or ear, it may be urged that they prove nothing concerning the heart, even if the absence of nerve tissues were demonstrated beyond doubt. So also regarding the apex or bulbus arteriosus of the frog's heart, or the hearts of invertebrates, the results of histologic work in recent years have tended to make untenable the old belief that these tissues are devoid of nerve cells.[19]

The old observation that the fetal heart begins to beat before it possesses nervous elements is the only one of the facts of this kind which remains unchallenged. Its correctness seems to have been clearly demonstrated in recent years by the careful work of W. His, Jr.[20] Engelmann has cited this fact as the best single proof of the truth of the myogenic theory. Objections, however, have been raised to its conclusiveness. It has been urged that the fact that the beat of the embryonic heart is myogenic in origin is in itself no proof that the older heart, with its intrinsic nervous mechanism, continues to function in the same way. It may be that after the migration of the nerve cells into the heart they assume, as the more automatic tissue of the two, the function of initiating the beat. This mode of reasoning appeals to some physiologists. On the other hand it is pointed out that the negative evidence regarding the presence of nerve elements in the early embryonic heart may disappear, as has happened to such evidence in other cases, when better histologic methods are devised. An improved technic may show the presence of nerve elements in the embryonic tissue, or demonstrate the existence of conducting paths between it and outlying nerve cells. The case at present gives strong support to the myogenic theory, but it has not sufficed to remove the objections of the other side.

Hearts Known to Be Controlled by Nerve Cells.—Among the great variety of hearts studied by physiologists some have been discovered in which the beat is obviously dependent on the presence and properties of nerve cells. These cases merit especial consideration. It is believed by some that the lymph hearts in the frog furnish an example of this kind. Destruction of the spinal cord is followed by a cessation of the beat, and light doses of curare have a similar effect; both facts indicating that the musculature is normally stimulated by impulses received from extrinsic nerve fibers. The case, however, is not a clear one, since according to some observers the hearts may begin to beat again after removal of the spinal cord, and moreover it is at most an instance of a heart controlled directly from the central nervous system and not by the action of peripheral ganglia. A similar case is presented by the caudal hearts of the hag fish. Greene has shown[21] that the beat of these peculiar structures is dependent on the action of a nerve center in the spinal cord. Destruction of this center brings the heart to a standstill.

The contractile apparatus in this case is not a true heart in structure; it is composed, rather, of two specialized striated muscles, belonging to the somatic type, which are so arranged as to compress and dilate two membranous sacs. As Greene says, the whole mechanism is strictly comparable to that of the respiratory muscles in mammals. It furnishes no more support to the neurogenic theory than is already found in the existence of the rhythmic contractions of the diaphragm under the influence of the automatic respiratory center in the medulla.

Recently, Carlson[22] has made the interesting discovery that the heart of the limulus depends for its rhythmic beat on the activity of nerve cells. In this animal the large median nerve stretching along the dorsal surface of the heart contains numerous ganglion cells. When this nerve cord is excised the heart ceases to beat, although still irritable to artificial stimulation. Carlson's work seems to show conclusively that not only the automatic beat of this heart, but the conduction also of the wave of contraction is entirely dependent on the action of the nerve cells in the median nerve cord. We have here, therefore, an instance in which the automatic contractions and the co-ordination of a genuine blood heart are undoubtedly of neurogenic origin. The question arises whether we are justified in applying this result, obtained on an invertebrate heart, to the hearts of the vertebrate animals.

One consideration which presents itself in this connection tends to make an impartial observer doubt whether such a wide induction is permissible. The cardiac muscle in the vertebrate heart possesses certain peculiar properties which serve to distinguish it from the usual skeletal muscle. The most characteristic and fundamental of these properties is a long refractory period. That is to say, when cardiac muscle contracts spontaneously, or in consequence of an artificial stimu-

19. For discussion and literature see Carlson: Pflüger's Archiv., 1905, vol. cix, p. 51.

22. Carlson: Amer. Jour. of Physiol., 1904, vol. xii, p. 67; *ibid.*, 1905, vol. xii, p. 471.

lus, it is entirely unirritable to further stimulation during the whole of its time of shortening. This reaction is shown by the musculature in all parts of the vertebrate heart, and most physiologists regard it as a property which lies at the basis of the phenomenon of rhythmicity. Now the musculature of the heart of the limulus, of the closely related heart of the lobster, and of the hearts of other invertebrates, does not possess this characteristic property.[23] It is, therefore, to all appearances, a kind of muscle different from the cardiac muscle of the vertebrates, and resembles rather skeletal or voluntary muscle. Like this latter form of muscle it does not possess the property of automatic rhythmicity, but receives its stimulating impulses from the nervous system. Unless it can be shown that the refractory period is not a characteristic and distinguishing property of cardiac muscle as it exists in the higher vertebrates, this discovery that the heart beat of the limulus has a neurogenic origin fails to have a direct bearing on the problem that we are considering, namely, the myogenic or neurogenic nature of the heart beat in vertebrate animals.

An effort to show this very thing has been made within the last few months in a paper published by Rohde.[24] The author states that when a frog's heart is dosed with chloral the muscle loses all of its characteristic properties and resembles ordinary skeletal muscle. By paralyzing completely the intrinsic nervous system the chloral gives us a chance to study the heart muscle itself, and according to this paper the muscle under these conditions turns out to be like that of the heart of the limulus or other invertebrates. From this point of view, therefore, what we have called the characteristic properties of heart muscle, the refractory period for example, are really properties of the intrinsic nervous apparatus. It is evident at once to a physiologist that a conclusion of this sort lands us in a difficulty of interpretation to which the author has paid no attention. One may ask such a question as this: If the refractory period is a property of the intrinsic nerves, and if nevertheless the heart muscle is independently irritable to artificial stimulation, how does it happen that an electrical stimulus applied directly to the muscle of the normally beating heart during the phase of systole fails to provoke a contraction? A seemingly unanswerable question of this kind would not, of course, invalidate actual experimental results, and in view of the importance of the far-reaching conclusions of the author his experiments have been repeated in my laboratory by Mr. Schultz.

The results of this work will be published shortly, but I may say that they show conclusively that Rohde was in error in saying that chloral effaces all of the characteristic properties of heart muscle. It modifies in an interesting way the response of this muscle to repeated stimulation, especially in the matter of its tone contractions,[25] but the striking peculiarity of the heart muscle, namely, the refractory period, is still retained. It is difficult to understand how Rohde could have reached a different conclusion, unless indeed he was misled by an inaccurate method of registration. The objection that I have made to the general application of Carlson's results on the heart of the limulus retains, therefore, its full significance and prevents us from accepting this work as giving a final solution to the problem. Some further facts which tend to support the myogenic view may now be considered.

The Reversal of the Beat.—Under various conditions the beat of the heart may be reversed, that is, the wave of contraction may begin in the ventricles, proceed thence to the auricles, and finally to the sinus venosus. As Gaskell, Engelmann and others have pointed out, this reversal, while easily understood on the myogenic theory, is opposed to the usual form of the neurogenic hypothesis. A nervous mechanism, consisting of a principal motor center in the region of the sinus and subordinate motor centers in auricle and ventricle, can not, according to our experience with such mechanisms in other parts of the body, work in both directions; a system of connecting neurons is a mechanism that conducts and co-ordinates only in one direction.

To account for this phenomenon the neurogenists are obliged to assume that the nervous apparatus in the heart forms a peculiar interconnecting network, the like of which is not found in the other automatic nervous mechanisms of the body, not even in those of the intestines. For when any portion of the intestine in a condition of rest is stimulated at a given point the wave of contraction or of contraction and inhibition proceeds onward in normal fashion; the movement is a peristalsis and not an antiperistalsis. In the heart, on the contrary, when at rest, any adequate stimulus applied to the ventricles will set up a reversed rhythm. The necessity forced on the neurogenists to make a new and unproved assumption to meet this case, does not, of course, strengthen their side of the argument. So, too, the well known zigzag experiment by Engelmann fits well into the myogenic theory, but is difficult of explanation in terms of the neurogenic hypothesis without recourse to the unknown properties of a nerve network. In this experiment it was shown that when a ventricle is so cut as to form an irregular piece, with intervening narrow bridges, a stimulus applied at either end arouses a wave of contraction that spreads in orderly sequence over the whole piece. *(To be continued.)*

CEREBROSPINAL MENINGITIS IN NEW YORK CITY DURING 1904 AND 1905.*

J. S. BILLINGS, Jr., M.D.
NEW YORK.

During the past forty years there have been four outbreaks of epidemic cerebrospinal meningitis in New York City. The first and, up to that of 1904 and 1905, the most severe epidemic was in 1872, when there were 782 deaths—a death rate of 8.70 per 10,000. In 1881 and 1893 the outbreaks were not so severe; the number of deaths were, respectively, 461 and 469, and the death rates 3.70 and 2.67. The latest epidemic, the severest in the history of the city, began in the early months of 1904 and continued through 1905. During 1904 there were 1,083 deaths and a death rate of 4.6; during 1905, 1,511 deaths and a death rate of 6.3.

The winters of 1872, 1881, 1893 and 1904 were what are known as "hard winters;" being cold, with considerable snow. The disease has always been abnormally prevalent for a year or two after each outbreak, but hitherto the number of cases during the second year was considerably less. In 1905, however, the epidemic was much more severe in the second than in the first year.

* A report to the commission appointed by the Department of Health, City of New York, for the investigation of cerebrospinal meningitis.

The number of deaths and death rate from cerebrospinal meningitis in the old city of New York (Boroughs of Manhattan and the Bronx) from 1866 to 1905 are shown in Table 1.

TABLE 1.—DEATHS FROM CEREBROSPINAL MENINGITIS, IN THE OLD CITY OF NEW YORK (MANHATTAN AND THE BRONX), WITH POPULATIONS AND DEATH RATES PER 10,000.

Year.	Population.	Number of Deaths.	Death Rate.	Year.	Population.	Number of Deaths.	Death Rate.
1866	767,979	18	.23	1887	1,479,143	203	1.37
1867	808,489	33	.40	1888	1,522,341	173	1.14
1868	851,137	34	.39	1889	1,566,801	145	.93
1869	896,034	42	.47	1890	1,612,559	136	.84
1870	943,300	32	.34	1891	1,659,654	189	1.14
1871	955,921	48	.50	1892	1,708,124	230	1.35
1872	968,710	782	8.07	1893	1,758,010	469	2.67
1873	981,671	290	2.95	1894	1,809,353	213	1.18
1874	1,030,607	158	1.53	1895	1,873,201	204	1.09
1875	1,044,396	146	1.40	1896	1,906,139	178	.93
1876	1,075,532	127	1.18	1897	1,940,553	232	1.20
1877	1,107,597	116	1.05	1898	1,976,572	258	1.31
1878	1,140,617	97	.85	1899	2,014,330	287	1.42
1879	1,174,621	108	.92	1900	2,055,744	201	.97
1880	1,209,196	170	1.41	1901	2,138,209	201	.94
1881	1,244,511	461	3.70	1902	2,182,836	190	.87
1882	1,280,857	238	1.86	1903	2,249,680	195	.86
1883	1,318,264	223	1.69	1904	2,318,831	1,083	4 6
1884	1,356,764	210	1.55	1905	2,390,382	1,511	6.3
1885	1,396,388	202	1.45	1906	.....	....	...
1886	1,437,170	223	1.55	1907	.....	....	...

The same facts are shown in diagrammatic form in Chart 1, the course of the general death rate being also shown.

Table 1 shows: (a) the periodicity (about every ten years) of the outbreaks; (b) the greater severity of the 1904-1905 epidemic; and (c) the lack of correspondence between the general death rate, and that from cerebrospinal meningitis. Only in 1904 did the two rise together, while in 1905 the former fell while the latter rose. The weekly course of the disease during 1904 and 1905 is shown in Chart 2.

It will be noted that in 1905 the epidemic began earlier in the year by over a month than in 1904, reached its highest point seven weeks earlier, exhibited a recrudescence early in May, another slight one in July and died away about two weeks later. Every case of cerebrospinal meningitis reported in the Borough of Manhattan during 1905 was plotted on a large map of the Borough.

This map shows the prevalence of the disease among the poorer classes and in the densely settled districts. That Italians are extremely susceptible to the disease is borne out by the map, the cases being most numerous on the lower East Side, the lower middle West Side, and the upper East Side ("Little Italy").

The deaths for 1904, arranged by wards, are given in Table 2.

TABLE 2.—TABLE OF DEATHS FROM CEREBROSPINAL MENINGITIS BY WARDS FOR THE YEAR 1904, BOROUGH OF MANHATTAN.

Ward	Population Census 1900	Number of deaths	Death rate per 10000	Prevailing foreign population.
1	9,516	5	5.25	Irish, Syrian.
2	1,488	1	6.72	Irish.
3	1,797	1	5.56	Irish.
4	19,554	30	15.34	Italian.
5	8,298	11	13.26	Irish, Italian.
6	20,004	30	15.00	Chinese, Italians.
7	89,237	83	9.30	Irish, Jews.
8	29,059	31	10.67	Italian, Irish.
9	50,650	41	6.87	Negroes, Irish.
10	71,879	45	6.26	Jews.
11	99,144	38	3.83	Jews.
12	476,602	174	3.65	Jews, Italians.
13	64,117	41	6.40	Roumanians, Jews.
14	34,035	44	12.93	Italians.
15	24,066	14	5.82	Italians.
16	52,808	27	5.11	Irish, French.
17	130,796	104	7.95	Hungarians, Jews.
18	61,325	39	6.36	Jews.
19	257,448	94	3.65	Bohemians, Jews.
20	89,798	45	5.01	Negroes.
21	60,211	35	5 81	Irish, Americans.
22	189,261	70	3.70	Negroes, Italians.
Total.	1,850,093	1,003	5.42	

It will be noted that the high death rates (15.34 for the Fourth ward, 15.0 for the Sixth ward, etc.) occur in the wards in which Italians constitute the majority of the foreign population.

A COMMISSION APPOINTED.

An attempt was made to investigate the disease during the spring of 1904, but no definite information was obtained beyond certain facts going to show that infection might be carried by means of the discharges from the body of the patient. Early in 1905 when cerebrospinal meningitis again became prevalent, the Board of Health determined to investigate the disease systematically, particularly as to its mode of spread and possible modes of prevention. To this end, following the same procedure adopted in the case of the acute respiratory diseases, a commission for the investigation of cerebrospinal meningitis was appointed. It was composed of the following physicians: Thomas Darlington, president board of health, Hermann M. Biggs, medical officer, W. K. Draper, B. K. Dunham, Simon Flexner, Walter B. James, William L. Polk, Walter P. Northrup, Joshua Van Cott and Elser. The commission held its first meeting on March 24, 1905, when it divided into clinical and bacteriologic sections, each section to work along those respective lines.

At the same time, a corps of inspectors of the Department of Health was organized for the investigation of the disease. These physicians were especially selected for the purpose, and further fitted themselves for the work by observing a large number of cases of cerebrospinal meningitis in the hospitals.

The commission urging that lumbar puncture be done in every instance for the purpose of diagnosis, for relief of pressure symptoms, and to provide material for bacteriologic study, a special inspector of the Department of Health was assigned to the performance of this operation on the request of physicians.

The subcutaneous and intraspinous administration of diphtheria antitoxin, having been strongly recommended by certain physicians and institutions, the Department of Health put the services of the diphtheria antitoxin inspectors at the disposal of physicians desiring that mode of treatment. Even at that time the Department took no stand for or against this line of treatment; since then, experience has shown it to be useless.

On April 19, 1905, the Board of Health declared cerebrospinal meningitis to be a communicable disease, and required the reporting of all cases by physicians, enforcement of quarantine, isolation of patients, exclusion of other children in the family from school, and disinfection of premises and bedding on termination of the disease. The sanitary supervision of the disease was assigned to the Division of Communicable Diseases of the Department.

ROUTINE PROCEDURE.

As elaborated during 1904 and 1905 the routine procedure is as follows: Cases are reported to the Department of Health (1) by physicians and institutions on postal cards furnished for that purpose; (2) by the forwarding of specimens of spinal fluid to the Diagnosis Laboratory; (3) by death certificates; and (4) by complaints of citizens and others.

Case History.—A full history of each case (home surroundings, symptoms, outcome, etc.) is obtained by a medical inspector on the accompanying history sheet.

When completed, this is filed according to the address of the patient. Each new case reported is compared

with this record. If the patient remains at his home, full instructions as to the nature of the disease are given to the family verbally and by circular, isolation and quarantine are enforced, other children of the family on the premises are excluded from school, and other tenants in the house notified of the existence of the disease. The case is kept under supervision by an inspector until its termination by death, recovery, or removal. In all fatal cases not previously reported during life, an explanation is demanded and obtained from the attending physician. On termination of the case, disinfection of the premises and bedding is ordered.

To make sure that knowledge of all cases reaches the Department of Health, every death from meningitis (simple, tuberculous, etc.) is also investigated. For results see tabulation of cases.

Circular.—The following circular of information has been prepared for distribution by the medical inspectors, one being left with the family of each patient, or sent to the attending physician.

CIRCULAR OF INFORMATION REGARDING CAUSATION AND PREVENTION OF CEREBROSPINAL MENINGITIS.

Cerebrospinal meningitis is an acute, infectious, communicable disease, caused by a specific germ, the meningococcus. This organism is frequently present in the discharges from the mouths, noses, eyes and ears of patients suffering from the disease, and is thus transmitted from person to person. The disease is always present in the vicinity of New York, sporadic cases occurring at all seasons of the year. From time to time, however, it appears in epidemic form, such epidemics having taken place in 1872, 1881, 1893, 1904 and 1905. Table 1 shows the number of deaths and death rate from the disease since 1866.

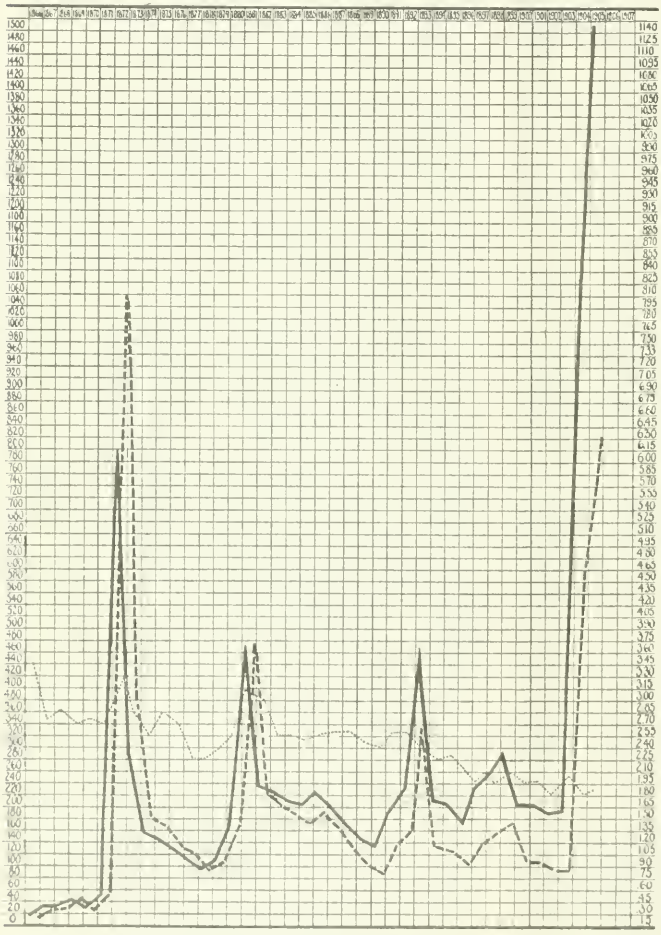

Chart 1. Showing number of deaths from cerebrospinal meningitis in the old City of New York, and death rate per 10,000 of population. Straight line — number of deaths from cerebrospinal meningitis. Broken line — death rate from cerebrospinal meningitis. Dotted line — general death rate.

Cerebrospinal meningitis occurs most frequently in children between the ages of 1 and 10 years, and is very fatal. Of 1,780 cases occurring in New York during 1905, 1,360 ended in death, a mortality of 76 per cent. The meningococcus (*Diplococcus intracellularis meningitidis* of Weichselbaum) sets up an inflammation of the membranes of the brain and spinal cord. This organism is frequently, and probably as a rule, transmitted from the sick to the well by means of the discharges from the nose and throat. It has also been found in the discharge from the eyes and ears. It is occasionally present in the noses and throats of healthy persons who have come in close contact with the sick or used towels or handkerchiefs soiled by them. Such persons, while not contracting the disease themselves, may transmit it to others, so that the disease greatly resembles diphtheria in its mode of spread, etc. An absolute proof that a given case is one of epidemic cerebrospinal meningitis is furnished by the presence of meningococci in the spinal fluid withdrawn by lumbar puncture. The operation of lumbar puncture is simple, and when properly performed, free from danger. It is sometimes actually beneficial by relieving pressure and the symptoms arising from this.

Outfits for forwarding specimens of fluid for examination may be obtained at any of the drug stores throughout the city which supply the various diagnostic outfits furnished by the Department of Health. Such specimens, on being forwarded to the Diagnosis Laboratory, Fifty-fifth street and Sixth avenue, are examined for the presence of the meningococcus and the results telephoned to the attending physician.

Prophylaxis.—Patients shoul be strictly quarantined for at least the first two weeks of their illness. Experience has shown that the danger of infection is much less after this time. The same precautions should be observed as in a case of diphtheria. Those nursing or coming in close contact with the sick should wear gowns while in the sick room and should take great care to disinfect their hands after touching or handling the patients. They should avoid close association with healthy persons, especially children. All discharges from the nose and mouth of the sick should be most carefully disinfected, and all bed linens, towels, handkerchiefs, clothing, etc., should be boiled or soaked

in a disinfecting solution. The dishes, forks, spoons, etc., of the patient should be reserved for his sole use Rubber sheeting should be used over pillows to prevent their saturation with the discharges.

Treatment.—No serum or specific remedy for the disease has yet been discovered. The provision of plenty of fresh, cool air, a carefully chosen diet and the treatment of symptoms as they arise are all that can be done.

Notification.—The Board of Health, in view of the above-mentioned facts, on April 19, 1905, declared cerebrospinal meningitis to be a communicable disease, and required physicians to report all cases coming under their observation to the Department of Health. Since that date the following routine procedure has been adopted:

1. The attending physician must report every case as soon as it comes under his observation. Postal cards are supplied for that purpose.

2. Every case is visited by an inspector to see that the regulations of the Department are being observed. If necessary, the case is kept under observation.

3. A history is obtained from the attending physician.

4. All children in the family are excluded from school until the termination of the case by recovery, death or removal to a hospital.

5. On termination of the case in any manner, the department fumigates the premises with formaldehyd and removes, disinfects and returns bedding, rugs, etc. For further information apply to J. S. Billings, Jr., M.D., Chief of Division of Communicable Diseases, Department of Health.

In conclusion, every physician and layman is urged to co operate with the Department in the contest with this terrible disease. THOMAS DARLINGTON, M.D., President.

HERMANN M. BIGGS, M.D., General Medical Officer.

OTHER BOROUGHS.

As the authority of the Division of Communicable Diseases was extended to the other Boroughs of New York City early in 1905, the same routine procedure in connection with cerebrospinal meningitis was introduced, and information obtained of all cases occurring from Jan. 1, 1905. Table 3 gives the number of cases, deaths, death rates, case fatality and morbidity rate for each of the five Boroughs and Greater New York for 1904 and 1905.

TABLE 3.

Borough.		Number of new cases reported.	Number of Deaths.	Number of Deaths not previously reported.	Death Rate per 10,000.	Case fatality per cent.	Morbidity rate per 10,000.
Manhattan:	1904	1,044	1,003	..	4.86	...	..
	1905	1,892	1,424	..	6.72	75.2	9.7
Bronx:	1904	....	80	..	3.11	...	..
	1905	118	87	4	3.18	73.7	4.3
Brooklyn:	1904	....	277	..	2.09	...	..
	1905	689	455	24	3.33	66.0	5.0
Queens:	1904	....	29	..	1.53	...	..
	1905	38	48	..	2.41	...	..
Richmond:	1904	....	14	..	1.95	...	..
	1905	18	12	1	1.64	66.6	2.5
Greater N.Y.:	1904	....	1,403	..	3.59	...	..
	1905	2,755	2,026	29	5.03	73.5	6.8

It will be seen that the death rate for 1905 was twice as great in Manhattan as in any of the other Boroughs.

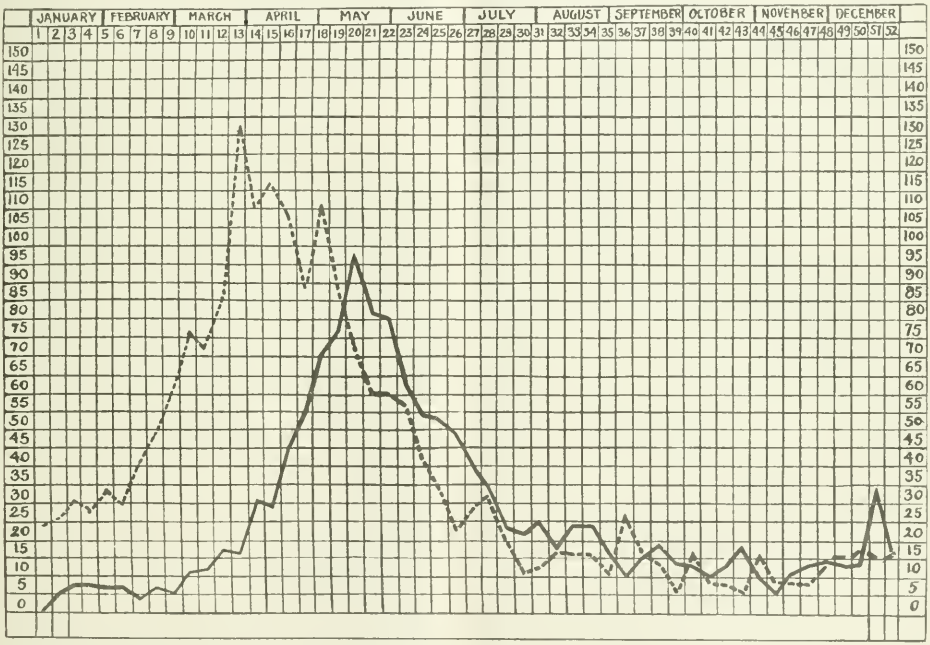

Chart 2.—Showing the number of deaths from cerebrospinal meningitis—is by weeks, for the years 1904 and 1905, in Greater New York Straight line, 1904. Broken line, 1905.

The disease being twice as prevalent in Manhattan as in Brooklyn, two and a half times as in the Bronx, and four times as in Queens and Richmond. It was likewise more fatal in Manhattan than elsewhere, the Bronx coming next in this regard. No accurate record of reported cases could be obtained for Manhattan for 1904, and none at all for the other Boroughs.

Tabulation of Cases.—As previously stated, the Department of Health has endeavored to obtain full information regarding every case of cerebrospinal meningitis occurring in New York City during 1905. There were 2,755 cases reported; information was obtained in 2,180. The results are shown in Tables 4 and 5.

REMARKS.

Sex.—The cases were divided fairly evenly into males, 55 per cent., and females, 45 per cent., the same holding good for all boroughs.

Age.—Sixty-seven per cent. of the cases occurred in children under 10 years of age, and 15 per cent. in infants under one year. Only 19 per cent. of the patients were adults, and only 1 per cent. over 50 years of age.

Nationality.—The statement that Italians are very susceptible to the disease is borne out by the fact that 15 per cent. of the patients were of that race. Excluding Americans, the Italians form 44 per cent. of the remainder. Russians came next, then Germans, and then Irish; negroes constituted only 1 per cent. and 21 of the 22 negroes lived in Manhattan.

Dwelling.—Of the patients, 76 per cent. lived in tenement houses, showing the social status in the majority of the cases. In 533 instances, (24 per cent.), it was found that the halls, areaways, or yards (one or all), or the streets in front of the houses, were dirty and insanitary. In 13 per cent. the light was bad, in 10 per cent. the ventilation was insufficient, and the plumbing insanitary. In 10 per cent. the rooms were dirty, ill-kept, and dusty. A history of the existence of parasites (fleas, etc.) was obtained in 11 per cent. and in 13 per cent. animal pets were kept. A history of other cases of cerebrospinal meningitis in the same house or neighborhood was obtained in 19 per cent. of the cases.

Previous History.—The commonest preceding disease was, of course, measles, followed by whooping cough, diphtheria and pneumonia in the order named.

Present Condition.—Clothing and food were unsatisfactory, and there was a lack of personal cleanliness in only 3 per cent. of the cases. A history of susceptibility to colds was given in 7 per cent.

Present Illness.—In only 6 per cent. of the cases had there been any direct exposure to other cases of cerebrospinal meningitis, and in only a small number was there evidence of direct transmission of the disease. Drs. Bolduan and Goodwin, of the Department of Health,[1] have investigated these multiple cases, of which they claim to have found 88 instances, including in all 200 cases. But less than 100 instances of possible transmission out of over 1,500 cases is not very weighty evidence, and in all but a few, direct transmission was only possible, not probable. In only 4 per cent. was there a history of exposure to over-exertion, and in 3 per cent. of exposure to cold. In the majority of cases, the patients were well just previous to the onset of the disease, only 6 per cent. being in bad health.

Symptoms.—In all but 5 per cent. the onset was sudden. Stiffness of the neck was the commonest symptom, being present in 85 per cent. of the cases. Closely following it came vomiting, headache and convulsions. An eruption was present in 30 per cent. of the cases, being petechial in 19 per cent. and herpetic in 11 per cent. Nasal discharge was noted in only 13 per cent. If the disease is always transmitted by the discharges, it would seem that nasal discharge should be more common. Kernig's sign, of great value in diagnosis, was absent in only 15 per cent. of the cases. Fever and leucocytosis were practically always present.

Complications.—The eyes were most frequently involved. Next came paralysis of other muscles, then otitis.

Diagnosis.—In 33 per cent. of the cases lumbar puncture was performed to confirm the diagnosis, and in 82 per cent. meningococci were found. In the remainder the diagnosis was made by clinical signs alone. Lumbar puncture was performed seven times in Manhattan to once in Brooklyn.

Cause of Death.—This was usually from coma and exhaustion. About 7 per cent. of the patients died on the first day, less than 34 per cent. during the first five days, and 39 per cent. after ten days. Of those who recovered 84 per cent. recovered completely. The majority of the patients did not recover until after the fourth week, but in ten cases (3 per cent.) recovery was stated to have taken place during the first week.

Antitoxin Cases.—Diphtheria antitoxin was used in 313 cases, of which 223 were fatal, a fatality of 71 per cent. Careful study of the individual cases failed to show any ground for believing that the antitoxin had any beneficial effect whatsoever. In most of the cases terminating in recovery, only small doses were given; and late in the disease and in only two was more than one dose given. Whereas in several of the fatal cases very large amounts of antitoxin were used. In one case 15,000 units were given every other day for two weeks—a total of 115,000 units. In other cases 60,000, 88,000, and 32,000 units were given, and in one case 24,000 units were given on the first day of the disease. One thing is shown clearly, viz., the harmlessness of diphtheria antitoxin.

Mistaken Diagnosis.—In 357 instances investigation showed the original diagnosis of cerebrospinal meningitis to have been mistaken. One-third of the cases proved to be tuberculous meningitis. The other conditions most frequently mistaken for cerebrospinal meningitis were simple meningitis, gastroenteritis and pneumonia. Of

Chart 3.—Case history card.

84 instances of meningitis supposed not to be the epidemic cerebrospinal form, 12, or 14 per cent., proved to be cerebrospinal meningitis.

CONCLUSION.

It will be seen that clinical investigation so far has thrown very little light on the mode of transmission of the disease, nor has any effectual mode of treatment been discovered. It is to the laboratory workers that we must look for assistance, and already new and valuable facts have been discovered regarding the meningococcus, its habitat, mode of transmission, viability, methods of identification, etc.

A very important point that has been brought out is that, in all probability, the disease is much more infectious during the first two weeks of its course. Guided by this, the Department of Health has enforced quarantine for at least the first two weeks, in all cases in which the patients remained at home the medical inspectors keeping the cases under observation, giving all necessary instructions, and ordering disinfection of the rooms and bedding on termination of the case. As a possible result of these precautions the number of deaths reported in the first nineteen weeks of 1906 have been 431 as compared with 1,300 in the same period for 1905.

SOME PARASITES INFESTING THE HUMAN INTESTINE.

DESCRIPTION, DIAGNOSIS AND TREATMENT.

JOHN RITTER, M.D., PH.G.
Clinical Assistant, Department of Chest, Throat and Nose, Rush Medical College.
CHICAGO.

Parasites which inhabit the human alimentary canal are usually described as entozoa or intestinal worms. There are about 20 different known species of the entozoa, all of which infest the alimentary canal of vertebrate animals or man. Entozoa of the order of *Cestoda* are commonly known as tapeworms, and of this particular worm about 10 different varieties have been observed and studied. They inhabit either the intestines of some vertebrate animal or man, but it is the parasite infesting the alimentary canal of man with which the physician is chiefly concerned.

DESCRIPTION AND VARIETIES.

Three species of tapeworm are of special interest to the medical practitioner and all are usually found in the upper third of the small intestines.

1. *Tænia Solium* (*Pork Tapeworm*).—This is an armed parasite, the head of which is provided with a circle of minute hooklets for the better attachment of the worm to the mucous folds of the intestines. The larval form of this particular parasite is the *Cysticercus cellulosæ*, which, if present in pork, gives the meat a peculiar spotted appearance, known as "measly pork." This tapeworm is the smallest of the three varieties, measuring, when mature, from 5 to 15 feet, and it is said that a single worm is capable of producing from 4 to 5 million of sexually ripe ova. Erroneously the specific name of *solium* (*solus, solitare, alone*) was given to this parasite, in the belief that it infested the alimentary canal of man only or alone.

2. *Tænia Saginata* or *Medio-canellata* (*Beef Tapeworm*).—This is an unarmed parasite, not provided with hooklets. The larval form of this tapeworm is the *Cysticercus bovis* found in beef. This worm is of moderate length, measuring, when matured, from 15 to 25 feet.

3. *Bothriocephalus Latus* (*Fish Tapeworm*).—This is also an unarmed parasite. It attains great length, from 25 to 30 feet.

The head of the tapeworm, when viewed with the unaided eye, appears about the size of the head of an ordinary pin. On it may be distinctly discerned four minute dark pigmented dots, which, when looked at under an ordinary magnifying glass, are seen to consist of small round discs or suckers. Immediately following the head is the slender, threadlike neck, about one inch in length, from the end of which a distinct segmentation may be observed. New joints are continually produced by budding. On close inspection it will be noticed that all segments or joints assume a distinct shape, that the younger joints are much wider than they are long and very small, but as they grow they gradually widen, and at the same time they grow very much in length, so that by the time the segments reach about the end of the first third of the worm's length the joints are distinctly quadrilateral, from which point they begin to grow in inverse order, the older and more mature segments being very much longer than they are wide and very much larger.

Tapeworms vary much in size. They grow in length from 8 or 10 to 25 or 30 feet. Stories occasionally related of patients passing a single tapeworm measuring from 60 to 80 or more feet should be accepted with a great deal of allowance, as examination of a large number of expelled worms has not verified any such lengths. I have in my possession a specimen of a mass of tapeworm passed by one of my patients which measures about 70 feet, but which, on close inspection, proves to be the remains of five distinct tapeworms, as five distinct heads are seen.

If a patient infested with a tapeworm, in whose case a positive diagnosis has been made, seeks medical advice in order to rid him of his undesirable guest, it becomes the imperative duty of the physician to administer at once such known remedies as will expel the parasite, head and body, so as to avoid more serious consequences which may follow delay. A fit of vomiting in a patient so infested may force one or more of the mature segments up into the stomach and the contents of which, by digesting such segments (should they contain ripe or mature ova), may set the ova free, and by burrowing into and through the various coats of the stomach or some other portion of the alimentary tract they may enter the circulation and be deposited in the liver, the brain or the muscular structure of the body in the larval form (*Cysticercus*), causing most serious disturbances and in extreme cases may be even fatal to life.

SYMPTOMS AND DIAGNOSIS.

The so-called subjective symptoms of the presence of the *Cestoda* infesting the alimentary canal are so variable and so unreliable that too much dependence must not be placed on such signs. However, there are certain distinct symptoms which, if present, may lead the physician to suspect the existence of intestinal worms. Subjective symptoms are usually divided into two classes, gastrointestinal and reflex.

Under the head of gastrointestinal may be chiefly mentioned colicky pains in the stomach and bowels, paroxysmal, at times more or less distress following the ingestion of food or of certain articles of food, a distended or a bloated condition of the abdomen, at other times a ravenous, inordinate or occasionally a perverted appetite, which is again followed by a great dislike for food. Constipation may alternate with diarrhea, more or less nausea or vomiting.

The reflex symptoms are usually manifested by nasal or rectal irritation, by cardiac palpitation, tinnitus aurium, dizzy or fainting spells, depression of spirits, lassitude, salivation, pains in the limbs, and various other nervous phenomena, hypochondria, convulsions, hysteria, in women often menstrual disturbances are attributable to the presence of tapeworms, and not infrequently mania.

Both gastrointestinal and reflex symptoms are only presumptive evidence of the presence of entozoa. A positive diagnosis can be made only when pieces or segments are voided or passed with the stools or pass involuntarily from the anus of the host while either walking or while at work; in fact, usually the very first intimation that the patient has of the presence of a tapeworm is when he seeks medical advice and gives a history somewhat like this: That while out walking he suddenly felt something pass out of the anus and slip down his leg and which, on examination, proves to be a single joint or segment of a parasite. This, then, is the only positive diagnostic sign.

TREATMENT.

From the earliest history of medicine to the present time various remedies and drugs have been offered and recommended for the removal of entozoa. Some are still in use; many more are obsolete. Some possess distinct anthelmintic properties and only a few are truly teniafuges. Some are used chiefly by the laity; others are prescribed by physicians only. From time to time various mixtures and decoctions have been recommended and extolled as specifics which, on careful trial, have been found utterly unreliable and worthless as teniafuges or tapeworm expellers.

A formula which a few years ago was much vaunted as a teniacide, in some quarters heralded as a specific, was a mixture of castor oil, croton oil, chloroform and fluid extract of ergot, which, with mucilage of acacia, was made into an emulsion, and a carminative was added to make the dose more palatable. This heroic dose was given in the early morning on an empty stomach, and, although its ingestion was followed by the removal of large quantities of segments and sections of tenia, it had no effect in completely expelling tapeworms.

A good remedy, although now somewhat obsolete, but occasionally used by old European practitioners, one which has decided tenifuge properties, is the black oxid of copper, given in ½ to 1 grain doses. It is especially recommended in the removal of tapeworm from children, to whom it is given in powders mixed with sugar and flavored with either oil of lemon or peppermint to suit the taste. A powder is taken every morning and evening for 8 or 10 days.

Another remedy used chiefly by the laity, and one which possesses some anthelmintic properties, is coral root (*Polypodium vulgare*). A pint decoction, prepared by taking about 2 oz. of the powdered or bruised coral root, using sufficient hot water to make one pint, is given in divided doses, half an hour apart, on an empty stomach, early in the morning, following a fast the previous day.

In some quarters crude petroleum is still in use as a somewhat efficient tapeworm remedy. It may be made into an emulsion and flavored with oil of peppermint, cinnamon or wintergreen and sweetened in order to make it palatable. The following is a desirable formula:

℞. Olei terrestris crudi.....3iv 16
Olei menthæ piperitæ.....gtt. iv
Pulveris acaciæ
Sacchari albi, āā.....3iv 16
Aquæ q. s. ad.....℥iv 120

M. Ft. emulsio. Sig.: A few teaspoonfuls of this emulsion every morning for eight days.

Oil of turpentine, given either on sugar or in form of an emulsion, has also some advocates, and is an efficient remedy. An emulsion may be prepared as follows:

℞. Olei terebinthinæ rectificati puri.....3ii 8
Olei ricini.....℥i 30
Pulveris acaciæ
Sacchari albi, āā.....℥i 30
Aquæ cinnamomi q. s. ad.....℥vi 180

M. Ft. emulsio. Sig.: Take in the morning, in two doses.

This is taken in the morning in two doses in intervals of one hour.

Another emulsion (*Emulsio pepo*), one which is very efficient and popular with the laity, is prepared from pumpkin seed. This emulsion is best prepared by removing the outer inert shell of the pumpkin seed and pounding, bruising or triturating about two ounces of the inner kernel into a pulpy mass, gradually, in small quantities at each time, adding water until a milky mixture is obtained, then strain through a cloth, press and pour on the mass sufficient water to make a pint. This emulsion is given in two doses early in the morning in intervals of one hour on an empty stomach. The patient is required to fast the previous day in order to "make the worm hungry," as the popular saying is.

These remedies all possess some anthelmintic properties, are all occasionally used and with fairly good success, but can not always be relied on for the complete removal of tapeworms. Remedies of more decided and positive tenifuge properties are the following, and in the order given their value increases as tapeworm expellers.

Kousso or *Kosso.*—The powder of the flowers of *Brayera anthelmintica,* a plant indigenous to eastern Abyssinia, is given in doses of 2 to 4 drams either in infusion, decoction or mixed with some black coffee. It is a most effective tapeworm expeller.

Kamala (*Powdered*).—The powder of the small glands enveloping the fruit of *Rottlera tinctoria,* a tree indigenous to China, Malabar and Philippine Islands, is given in doses of 1 to 2 drams in milk, coffee or coca. It is one of the most reliable of the teniacides, but has this decided disadvantage, that if given to some patients it induces most severe and violent emesis.

Pomegranate Bark.—The bark of the root of *Punica granatum,* a shrub indiginous to the countries bordering on the Mediterranean sea, is next in importance as an entozoa expeller. A decoction prepared from the fresh, dried bark by, taking 2 oz. of the coarsely powdered drug, macerating it in tepid water for about 12 hours, gently boiling, straining and adding sufficient water to make about one pint. This is given in 3 doses in intervals of half an hour in the morning on an empty stomach. A cathartic drug should be administered the evening before.

Pelletierinæ Tannas or *Punica Tannas.*—This is a tannate of the mixed alkaloids obtained from pomegranate bark and is of most decided efficiency and reliability as a parasiticide. It may be given in doses of from 2 to 5 or more grains.

Pelletierinæ Tannas is now official, being one of the newer remedies added to the Pharmacopeia, 1900.

Ethereal Extract or *Oleoresin of Male Fern.*—This

is an extract or oil prepared from the rhizome and rootlets of *Nephrodium, Polypodium, Polystichum, Aspidium filix mas,* a plant indigenous to Europe, and is the most efficient of all reputed teniafuges. In the writings of former therapeutists, as well as of those of the present time, oleoresin of male fern has always held the foremost rank as a tapeworm expeller. Its administration either in capsules, mixtures or emulsions is usually followed by very little, if any, depressing effects and it undoubtedly is the most efficient, reliable and trustworthy of the whole list of anthelmintics. It is usually given in doses varying from 10 drops to a dram or more.

All the various tapeworm-expelling remedies enumerated above are administered either singly or in combination in mixtures, capsules, cachets, emulsions or in any form whatsoever. It is usually required that the patient must abstain from taking food or must take food but moderately for at least one day preceding the taking of the teniafuge, or that the evening meal should consist of such articles of food as sour or pickled herring or fish, stale bread and a glass of water, in order to "make the worm hungry," as the saying is.

THE RATIONAL METHOD.

I have had a large and extended experience in the treatment of patients suffering from tapeworm, and in not a single instance have I failed to expel the undesirable guest, head and all, if the following instructions were closely observed.

As a rule, I do not ask the unfortunate sufferer either to fast or to subsist on certain articles of diet. Fasting is wholly unnecessary, illogical, and no valid reason can be given therefor, as the worm can be expelled without much difficulty either while the patient fasts or freely partakes of food. On the contrary, the patient should be asked to eat a full dinner in the evening, and he should be fully prepared to eat an equally hearty meal in the morning. Between these two meals the unwelcome visitor takes his departure. Begin the treatment by giving the patient, on retiring, an ordinary cathartic capsule or pill somewhat like the following:

℞.	Hydrargyri chloridi mitis............	gr. ii	13
	Extracti colocynthidis compositus		
	Extracti cascara sagradæ, āā........	gr. iv	26
	Pulveris jalapæ......................	gr. vi	39

M. Ft. capsulæ No. iii. Sig.: Take all three capsules at bedtime, making one dose.

It is most desirable to procure good evacuation of the bowels before giving the tapeworm remedy, and in order to obtain ... the formula above given may be varied to suit each indiv...ual case. Should the patient's bowels be unusually obs...nate, the cathartic action may be somewhat increased and correspondingly decreased if the bowels are easily e...acuated. Early the next morning and after the bowels a... well emptied give the following teniafuge:

℞.	Resinæ podophyllini.			
	Oleoresini filicis maris..............	gr. i		06
	Extracti fluidi kamalæ..............	ʒiss	6	
	Spiritus chloroformi	ʒiii	12	
	Mucilago acaciæ	ʒi	4	
	Aquæ menthæ piperitæ	℥i	30	
	... ad........	℥iii	90	

M. Ft. emulsio. Sig.: Take... three equal doses at intervals of half an hour.

A swallow of coffee or wa... water and whisky may be take... milk or a little warm ...after each dose. A very much more pleasant way for ... of a'ministering the above teniafuge is in the form ...le prepared as follows: Put the 3 drams of fluid extract of kamala into a small evaporating dish and over a water bath evaporate the extract to the consistency of a thick syrup; then add the grain of resin of podophyllin and, lastly, while still slightly warm, add the 1½ drams of oleoresin of male fern; thoroughly incorporate all and fill into empty capsules, making either 9 or 12 capsules, and of this number give either 3 or 4 in intervals of half an hour. The above quantity fills about nine No. 0 capsules of standard size or twelve of No. 1.

From the time that the teniafuge is administered all evacuations of the bowels should be passed into a commode about half filled with tepid water so as to secure the parasite for examination. After careful and repeated washings, by repeatedly pouring water into the commode until it is nearly full, allowing all heavy particles to subside, then decanting the supernatant fluid, the mass of the worm will be found at the bottom, head and all. Examine the mass carefully for the head, which is usually attached to the finest or thread-like section of the worm, generally to a piece from half a foot to one and a half feet in length.

170 Colorado Avenue.

PRELIMINARY REPORT OF THE TREATMENT OF IDIOPATHIC EPILEPSY BY APPENDICOSTOMY FOR COLONIC IRRIGATION.*

ERNEST LAPLACE, M.D.
Professor of Surgery, Medico-Chirurgical College.
PHILADELPHIA, PA.

Epilepsy is but a symptom revealing some irritation of the general nervous system. It has been aptly divided for purposes of classification into traumatic and idiopathic. In traumatic epilepsy, the cause is evident. Pressure from bone, foreign body, or blood clot is the source which so irritates the brain as to interfere materially with the normal distribution of nerve force through the body.

Certain chemical substances have a distinct affinity for the cortical cells of the brain and cord and, as a result, excite them. Among the alkaloids, strychnin is prominent. Among toxins resulting from infection, the poison of tetanus and hydrophobia afford us similar examples. These toxins generated in the body under the influence of the developing pathogenic organism finally accumulate to such an extent as to produce a violent action on the cerebrospinal system, followed by contractions of the muscular system characteristic of these diseases. Very similar is the reaction of strychnin, which, if given in sufficient doses, will produce analogous muscular contraction.

One of the curious phenomena attending the physiologic action of drugs is the tendency of some, such as digitalis, to accumulate in the body until a certain amount has been taken, and then the physiologic action of the accumulated doses is manifested. This is known as the cumulative action of a drug.

Is it not possible that some such cumulative manifestation of a toxin as a result of the intoxication from improper food or tissue metabolism may be at the bottom of the spasmodic and periodic manifestations known as idiopathic epilepsy?

In early childhood, spasms are known to be due to

* Read before the Philadelphia Medical Society, May 23, 1906. Patient was exhibited to the society.

improper digestion, or irritation of a foreign body, or the presence of worms. Epileptic patients are generally afflicted with some intestinal disorder. They suffer at least from chronic and habitual constipation. They complain of multiform digestive symptoms indicative of imperfect metabolism, but at the same time so obscure as to give no decided clue as to what the imperfect transformations of food may be.

At present most of those who have given special attention to this class of cases agree that the chief element in the rational treatment of these patients is an intelligent diet; based on restriction of food, its simplicity and predigestion.

The antispasmodics as remedial measures have had a fair trial. These drugs are good for awhile, but they do not give permanent relief; nor do they in any way reach the etiologic factor by tending to remove or control the cause of epilepsy.

FUNCTION OF THE COLON.

Metchnikoff, in his work, "The Nature of Man," says that from a standpoint of anthropology the colon is a receptacle for refuse undigested matter; that human life could be sustained in a purer and more physiologic state without its presence. Sufficient digestive function is performed by the stomach and small intestine; sufficient absorption for the sustenance of the body takes place from these regions; and hence, as a matter of fact, the whole length of the colon could be dispensed with so far as our physiologic necessities are concerned.

In performing surgical operations on the intestinal tract I have often noticed that the character of the intestinal contents becomes really fetid only past the ileocecal valve. When the intestinal contents have passed into the colon, however, the digestive processes are almost completed, and a process of absorption on the part of the colon takes place rather than of further digestion.

The colon fulfills an economic purpose in removing, so far as possible, from the refuse products all the nourishing elements which may still remain. In order to achieve this result, however, the intestinal contents have a long road to travel and may be retained a long time before they are finally expelled. It is during this period of inactivity and comparative quiescence of the contents of the colon that the micro-organisms which normally inhabit the colon have full sway. They develop and produce putrid gases and toxic changes in the albuminoids so complex as to escape the analysis of the chemist.

POSTOPERATIVE CONSTIPATION.

What surgeon does not know the harmful effects of constipation after a surgical operation? The general depression of the patient, rapidity of pulse and elevation of temperature? What physician has not relieved a most obscure form of indisposition by the proper correction of habits of constipation, thereby removing the autointoxication? The power of absorption of the rectum and colon is remarkable. I have nourished a patient exclusively by rectum during a period of seven weeks. This fact illustrates the possibility of absorption on the part of the rectum, which presents the same power of absorption on whatever fecal matter passes through it.

TREATMENT.

With this source of poison as a possible cause, and its cumulative action in certain human bodies, I have thought that it could be a sufficient etiologic factor in some cases for the sudden spasmodic manifestations which are called epilepsy. It would follow, therefore, that any method by which this poison should be either destroyed or its absorption prevented would contribute toward lessening the nature and frequency of epileptic attacks. With this in view, I have performed appendicostomy, creating an artificial fistula at the beginning of the colon. I direct the patient to flush out his colon with two gallons of warm water, morning and night. The patient, in a recumbent position, introduces the nozzle of the irrigator into an ordinary catheter, which, in its turn, is passed down through the appendiceal fistula into the colon. The water is allowed to flow and is received into a bed pan on which the patient lies This copious irrigation does not seem to affect materially the patient's nutrition. His appetite improves, while a sense of well-being gives him a brighter and more cheerful appearance. The irrigation is not accompanied by pain, and the patient soon becomes so skilled in its use as to require no assistance whenever the indication exists.

Patient.—The first patient on whom this method was tried was a man, L. A. S., aged 23, a sufferer from epilepsy since the age of 16, with attacks every week at first, finally as often as three times a day, losing consciousness about one hour each time. He was sent by Dr. C. S. Ruch of Lehighton, Pa.

Operation.—The operation was performed in the Medico-Chirurgical Hospital, July 1, 1904, and the irrigations were begun July 5. He had a violent epileptic attack on the day after the operation.

Postoperative History.—The irrigations were taken systematically twice daily and continued for three months. Then he took but one irrigation three times a week for three months; then one irrigation a week for three months. He has not taken any irrigation since May, 1905, and from the day of the first irrigation until the present time he has never had another attack. He has gained 20 pounds, has returned to work, and feels absolutely well.

CONCLUSIONS.

This and four other cases of a similar nature—not operated on sufficiently long enough to be reported in full, but giving ample encouragement for the continuance of the treatment—should afford sufficient reason for considering this method. The treatment is harmless, based on sufficiently sound theoretical and scientific grounds; and even should improvement not result to the epilepsy it can not fail to do good from a hygienic standpoint in affording general relief from the constipation to which most sufferers from epilepsy are subject.

The repeated flushings of the colon keep it as nearly empty as possible and almost eliminate its presence as a reservoir for undigested and putrefying substances. At all events, although there is a constant flow of intestinal contents from the ileocecal valve, the repeated flushings do not allow these substances sufficient time to serve as a culture medium for the hoards of bacteria present, and hence reduce to a minimum the possible production of obnoxious toxins so liable to be reabsorbed into the system. Fear of a permanent artificial opening into the intestine should not be entertained. It is a matter of the greatest ease to allow the artificial fistula to close; and, after months of treatment, should one desire to discontinue the flushings of the colon, the natural processes of evacuation are resumed without difficulty.

Let it be distinctly understood that we have no reason to expect that all cases of idiopathic epilepsy will improve under this method of treatment; but only those whose existence can be traced to this particular cause. The procedure here advocated should be accompanied by the proper dietetic measures usually resorted to in the treatment of these cases.

ACETANILID POISONING FROM THE USE OF PROPRIETARY HEADACHE POWDERS.*

A. E. AUSTIN, M.D., AND
R. C. LARRABEE, M.D.
BOSTON.

The use of "patent medicines" by the laity has grown to such proportions that it has come to be looked on by physicians as a necessary evil. Many such medicines are inert, in which case their deleterious influence is exerted chiefly on the pocket of the purchaser. Unfortunately, patent medicines containing potent drugs are often sold without the slightest warning concerning excessive doses, and the experienced physician who has not seen injurious effects from them is either hopelessly blind or hopelessly prejudiced. Warnings against overdoses are rarely seen on the labels of such remedies, for the reason that the public would take alarm and the sale be diminished.

No class of remedies is subject to more abuse than the so-called headache cures. In no class is caution more needed, for the chief ingredient is almost always acetanilid. The reason for the wide use of this drug is easily seen when it is noted that the remedy used in the two cases herewith reported costs 25 cents for a box of ten powders, each containing about four grains of acetanilid, or about four grains of acetanilid and about a grain of camphor. Acetanilid may be bought by any one for 40 cents a pound and camphor is high at $1.25 a pound.

The symptoms of acetanilid poisoning need not be given in detail here, but we may say in brief that cases fall into two classes. In acute cases due to single doses the chief phenomena noted are those of collapse and circulatory depression, coldness of the skin, sweating, palpitations, disturbances of the pulse, superficial breathing, cyanosis, dullness of intellect or total unconsciousness, followed in case of recovery by persistent muscular weakness. In cases in which doses too small to produce these effects are taken for a considerable period of time, susceptible persons may show extreme cyanosis, with very little evidence of injury to the circulatory apparatus. In both forms, particularly in the more chronic ones characterized by severe cyanosis, there is a most disastrous effect on the red corpuscles. Their hemoglobin is in part converted into methemoglobin and thus rendered incapable of performing its function of carrying oxygen. The destruction of red corpuscles may result in an anemia of a most severe type.

It is a common practice to "guard" the action of acetanilid in headache powders by the addition of substances like camphor or caffein designed to act as cardiac stimulants. It is conceivable that they might have some effect in preventing the acute collapse, but it is difficult to see how they could have the slightest effect in preventing the conversion of hemoglobin to methemoglobin.

Our attention was called to this subject by two cases, in both of which the popular remedy "Nervease" had been taken for the cure of headache, and which are reported in full as follows. The first occurred in the service of Dr. Larrabee:

CASE I.—A married woman of 43 was seen in the out-patient department of the Boston City Hospital. She gave a long history of aural sepsis, beginning at the age of 6 years. She had suffered from occipital headaches as long as she could remember. In 1901 these became much worse and in 1903 she came to the hospital complaining of this symptom and of vomiting and constipation. Notes made at the time record a palpable enlargement of the spleen and enlargements of the lymph nodes in the neck and left axilla. There was a moderate leucocytosis and the hemoglobin was 60 per cent. The glands afterward suppurated. They were probably the result of the aural disease. Shortly after, Dr. G. A. Leland operated for mastoid necrosis. Though the operation was successful and recovery was prompt the headaches were not wholly relieved.

In January, 1905, two years later, she returned to the hospital. For years she had been taking a proprietary headache powder sold under the name of "Nervease"—often as many as six powders a day, and sometimes even a whole box of ten. At first these gave relief to the pain, but for three weeks the headache had been unusually severe and there had been some nausea. The urine had been red in color and there was slight dyspnea—not enough to be at all disabling. She knew she was blue, but the fact had not appealed to her as indicating anything out of the way. Her appearance on the cold day when she first presented herself for treatment was most astonishing. The color was a deep, dusky blue. The lips and nails were at times almost black. In spite of this her general condition was perfectly good and there was no evidence of dyspnea or suffering. The pulse and respirations were not increased in rapidity. Apart from an easily palpable spleen, nothing further was found on physical examination. Dr. Leland examined her ears and reported that no active disease was present.

The blood was almost black as it flowed from the ear, and when spread on the filter paper the color was such that the hemoglobin could not be estimated by the Tallquist method. The specific gravity by the method of Hammerschlag was 1052 corresponding to a hemoglobin percentage of 70. Red corpuscles, 3,168,000. White corpuscles, 6,400. A differential count of 500 white corpuscles resulted as follows:

	Per cent.
Polymorphonuclear neutrophiles	75.6
Small mononuclear basophiles (lymphocytes)	19.0
Large basophiles (large mononuclear and transitionals)	4.8
Eosinophiles	0
Mast cells	0.4
Myelocytes	0.2

During this count one nucleated red was seen, a normoblast. There was slight polychromatophilia and rare basic stippling. The reds varied much in size and shape. Many were broken and distorted. There was moderate achromia and the hemoglobin appeared unusually irregular in its distribution within the cells. There were no parasites. No abnormalities were noted in the platelets.

Spectroscopic examination of the blood showed methemoglobin.

The urine was normal except for an excess of urobilin; it contained no hemoglobin, methemoglobin nor hematoporphyrin.

She was directed to stop taking the powders and potassium bromid was given instead. She was also given a capsule containing five grains of mass of ferrous carbonate and one-sixth of a grain of extract of nux vomica, three times daily. Also ten grains of potassium iodid three times daily. Three weeks later there was little or no cyanosis or headache. The color of the blood was normal.

Nearly a year later she returned to the clinic, stating that for several months the headaches had again become severe and that she had had pain and swelling in the left ear. For a fortnight she had been using "Nervease" again, never more than two powders daily. The cyanosis had promptly returned, but, save for slight dyspnea, no other unfavorable symptom had accompanied it. The ear was examined by Dr. Leland, who found no active disease. The skin showed the same blue color as before, but to a much slighter degree. The spleen was enlarged.

The hemoglobin could not be estimated by the older colorimetric methods for the same reason as before. By the Sahli test there was no difficulty, the percentage being 81. Red corpuscles, 3,808,000. White corpuscles, 10,500. A differential count of 500 white corpuscles resulted as follows:

	Per cent.
Polymorphonuclear neutrophiles	72.6
Small mononuclear basophiles (lymphocytes)	22.0
Large basophiles (large mononuclears and transitionals)	4.8
Eosinophiles	0
Mast cells	1.4

There were no nucleated reds. The qualitative changes were

* From the Medical Chemistry Laboratory of Tufts College.

about the same as before, but decidedly less severe. The spectroscope again showed methemoglobinemia.

The second case occurred in the practice of Dr. John Warren Achorn:

CASE 2.—The patient, a female, unmarried, dressmaker, complained of headache on the top of her head for which she had been taking six "Nervease" powders daily. She complained of loss of energy and nausea, though she had not vomited. She also said that the night before coming under observation she had taken the contents of one box or ten powders. The patient was livid with dark blue nails. The pulse was tense and hard. The blood contained methemoglobin. The red blood corpuscles amounted to 3,991,000, the whites to 9,855. Hemoglobin could not be estimated by the common color tests on account of the peculiar chocolate shade of the blood. A differential count of 200 leucocytes showed:

	Per cent.
Polymorphonuclear neutrophiles	62.5
Small mononuclear basophiles	19.0
Large basophiles	15.0
Eosinophiles	3.5
Mast cells	0
Myelocytes	0

A very few granular red corpuscles were found.

The use of the powders was stopped and the patient rapidly regained her health.

As the symptoms of both these cases were plainly attributable to the "Nervease," our next efforts were directed to the determination of the character of the deleterious ingredients in the remedy. Samples from two boxes were analyzed, the first bought Jan. 14, 1905, the second Jan. 31, 1906. The powders weigh approximately 0.5 gram; the substance is pink in color with small glistening granules scattered through it, and has a pungent taste. It is but slightly soluble in water. This description applies only to the powders purchased in January, 1905; those bought in January, 1906, have camphor added, which is discernible not only by odor but by chemical tests. On heating with hydrochloric acid and the subsequent addition of phenol and hypochlorite of calcium, both samples gave a red color, which subsequently changed to blue on the addition of ammonia. This is a positive test for acetanilid. A powder of each was then extracted with water acidulated with hydrochloric acid, which separated it from the camphor in the second box, and the solution extracted with chloroform, which was then evaporated and the residue weighed. It was absolutely colorless and showed nothing but glistening crystals.

The average of two determinations of the acetanilid in this manner gave 0.281 gram, the difference between the samples purchased in 1905 and in 1906 being inconsiderable. As the dose is given as from 0.2 to 0.8 gram, with the maximum for twenty-four hours 1.3 grams, we can plainly see that the second patient, according to this, was taking 1.686 grams daily, and in one night had taken 2.81 grams of this substance. Yet in the circular accompanying the box we read: "Contains no opiate and is *perfectly harmless.*" The camphor in the second sample was extracted from the residue from which the acetanilid had been removed with alcohol and found to amount to 0.075 gram. The ordinary dose of camphor is from 0.13 to 0.65 gram, with a maximum daily amount of 1.3 gram, so that the danger from camphor is not great.

The lesson is that drugs of this dangerous character should not be dispensed except on a physician's prescription, and their sale should be as strictly guarded as is that of strychnia or aconite. The use of a danger label would throw the responsibility of an overdose wholly on the patient. The German government limits the character of the ingredients which may enter a headache powder openly sold to the public to harmless substances, like bicarbonate of soda and caffein, and it seems that the time has arrived when this country should do likewise. The least that can be demanded of manufacturers of nostrums is that they state plainly on the label the ingredients of their preparation and the amount of each. Surely they should not be permitted to label "perfectly harmless" a box of powders containing a drug so powerful for harm as acetanilid.

A SIMPLIFICATION OF THE USUAL TECHNIC OF SKIN GRAFTING.*

JOHN EGERTON CANNADAY, M.D.
PAINT CREEK, W. VA.

In several forms of minor surgical work considerable satisfaction is obtainable even when comparatively careless methods are pursued. However, in the particular field of this subject a minutely planned and carefully carried out technic is essential to a successful issue.

The need for repairs to the epithelial covering may arise from the following causes: deep burns, lacerated wounds, the sloughing of flaps, gangrene from frost bite and other causes, varicose and other ulcers, the correction of deformities and the excision of malignant growths. Bared areas can only cover themselves by the reproduction of epithelium around the edges. After a varying length of time, dependent somewhat on the individual case, this border-line epithelium becomes apparently entirely exhausted and ceases to reproduce itself further. Then Nature must be assisted. Indeed, it is not usually best to wait until she has thrown up the sponge.

Unless the denuded area is quite large, it is usually most convenient to take the grafts from the individual needing them. Inasmuch as molecular life persists for some time after somatic death, one can often get about a hospital a suitable material from amputations and other operations. The skin and underlying tissue can be kept in warm normal saline solution for several hours until needed. The skin of the white when grafted on to the negro in time assumes the coloring of its host, and the reverse obtains when the skin of the black is transplanted to the white. Frogs, chickens and pigs have loaned their integument to man with very good grace. Once I grafted skin from a common water lizard on the foot of an Italian with a fair measure of success. The skin of the anterior portion of the arm or thigh is of suitable character for this work and from its location is very accessible. Especially when the defect to be covered is on a limb it is usually advantageous to take the grafts from a nearby location.

Among the many methods in vogue for securing a clean granulating site I have found the bi-daily wet dressing of gauze (wet with chloral hydrate, grs. ii to the ounce of water) kept covered with oiled silk to be satisfactory.

In my work I use the Thiersch graft. I have the part from which the shavings are to be taken carefully cleansed with liquid antiseptic soap, gauze pad, warm sterile water and alcohol. The granulations are irrigated with hot saline solution and the surface is freshened by a very gentle rubbing with an ordinary sterile nail brush. This freshens the granulations without destroying them. Some time since I abandoned the curette for this purpose. With it smooth and even freshening is an impossibility. It tears off the granulations *in toto* and leaves an irregular surface having an

* Read before the Kanawha Medical Society, Charleston, W. Va., Feb. 20, 1906.

insufficient vascular supply for the securing of certain takes. The freshening of the surface by gentle rubbing with a gauze pad, as suggested by Lauenstein, I have tried in several cases; where the granulations are comparatively tender this method is quite effective, but if the granulations are firm I always resort to the use of the nail brush. Hot saline solution and pressure quickly control the slight hemorrhage. A sharp aseptic metal-handled razor should be used. The skin of the part from which the grafts are to be taken is made tense by grasping with the hand. The grafts are sliced off by sawing movements of the razor. I try to have them half the thickness of the skin, half an inch wide and one and one-half inches long, that size being convenient to handle and satisfactory for most cases. As soon as a graft is severed it is turned over the end of the left index finger, skin side next to the finger, carried directly to the denuded site and pressed down on the surface with the finger, a small probe serves to smooth and straighten it out in the position in which it is desired to remain. This process is repeated until the bare area is covered. By the direct transference of the skin strips you will be able to cut them more nearly in proper size, shape and number and the proportion of takes will be larger. I have the surface from which the grafts are taken, dry and transfer them without the intervention of any saline or other solution, which, I believe, only serves the purpose of rendering a delicate piece of work more difficult.

I cover the grafted site with thin dental rubber dam, criss-crossed for drainage if the area is large. I place a small gauze pad over this, securely anchor it on all sides with narrow strips of zinc oxid adhesive plaster to prevent the displacement of the grafts and apply externally a cotton, gauze and bandage dressing. Frequently it will be well to apply a splint or to encase the part in plaster-of-Paris to secure immobilization. In case the grafted locality is on a limb I have it placed on a level with the rest of the body or slightly elevated. A slight degree of pressure will keep the grafts in contact with the part, prevent serum from collecting between the graft and the wound and prevent bleeding. Too much pressure will promptly kill the grafts.

At one time we were taught to keep our skin graft dressings wet with physiologic saline solution. Being valuable for some things, it was supposed to be useful for everything. I discontinued it as being exceedingly troublesome and totally devoid of value for this purpose and began using sterile vaselin and petrolatum as lubricants to prevent the dressings from becoming adherent. Later I adopted the plain dry dressing previously described and have used it for some time without having cause for regret. It possesses the advantages of simplicity and neatness. It lessens the trouble of after care. If the dressing should become adherent it can be easily loosened by soaking it in warm water and removed without disturbing the new epithelium. Ordinarily I leave the first dressing on for a week, and after that the wound often requires but little care. Pus infection in these cases is almost fatal to success and must be guarded against.

I have practiced my method in twenty-three cases without a single complete failure. I have used it principally in the repair of defects caused by burns and lacerated wounds.

In conclusion, I desire to emphasize the advantages of the direct transference of grafts; the substitution of the nail brush for the curette, and the superiority of the dry dressing moored in place by adhesive strips.

THE RATIONAL TREATMENT OF URETHRITIS.*

NOAH E. ARONSTAM, M.D.

Professor of Dermatology in the Michigan College of Medicine and Surgery.

DETROIT.

The rational treatment of this affection depends on the etiologic factors that are responsible for its causation. The non-specific forms demand an entirely different regimen than the specific variety. We must endeavor in all cases to eliminate the cause so far as possible. To dwell at length on the treatment of the various types of the malady under discussion would require more time and space than has been allotted to me. Suffice to state, however, that urethritis dependent on certain dyscrasiæ and diatheses must receive their adequate consideration before we can expect favorable results. To treat any given case of urethritis merely with a hand injection and the internal exhibition of some nondescript "urinary antiseptic," without having recourse to physical, urinary and microscopic examination, if necessary, is just as absurd as to treat the symptoms of a febrile disorder, without taking cognizance of the specific elements which may have precipitated the fever.

Of greater interest to the physician, however, is the treatment of the *gonococcic type* of the disease. Concerning the so-called "aborative plan" the author has nothing good to say. It is an inappropriate procedure and should be condemned by every scientific physician. To destroy the gonococci would necessitate the use of powerful germicidal agents, which undoubtedly injure the intact urethral mucosa and hence are conducive not only to increased suffering, but also to appreciable solutions of continuity therein, damage the canal permanently and eventuate in stricture formation. Its irrationality is apparent at a glance and need not be dilated on. The conservative school of the profession advocates the "expectant plan" of treatment, contending that a gonococcic urethritis is a self-limited affection, uninfluenced by interference of any kind. This is a very reprehensible conception of the real pathology of the malady, is far from scientific and may at times lead to unfavorable sequelæ and not infrequently prolong the duration of the disease indefinitely. This plan is of doubtful propriety and deserves to be ignored as an irrational mode of treatment. Not less reprehensible and still more ridiculous are the remedies in vogue at present, obsolete and obscure methods that have come down to us as a heritage of barbarism or witchcraft from the latter part of the medieval past. I can not refrain from disparaging their employment and shall prove the inefficiency of their highly vaulted therapeutic activity. Their name is legion and to enumerate them all would require a special chapter to be written in the histories of medicine now extant. Prominently among them figure the "alkaline diuretics." The theory is pretty much prevalent, that alkalies, when ingested are absorbed into the circulation and neutralize the normal urine by rendering it alkaline, thus alleviating pain and ardor urinæ, two harrassing symptoms of the acute stage of this disease, simultaneously acting as mild urinary antiseptics. This theory contains much that is futile. When alkalies are absorbed, their identity is completely destroyed as far as the acid radicle is concerned; they are ultimately converted into normal chlorids or salines and not carbon-

* Read before the Wayne County (Mich.) Medical Society, Feb. 26, 1906.

ates, which are known to possess diuretic properties; it is only by the latter virtue that they exercise a beneficial effect on the inflamed urethra, not, however, primarily as alkalies, but as diluents and diuretics. This assertion may not conform to established orthodox doctrines or theories pertaining to this particular phase of the subject, and I, therefore, anticipate being relentlessly criticised for it.

The therapeutic value of boric acid and salol, either alone or in combination which are administered thoughtlessly as a routine measure, with the expectation of disinfecting the urethral tract, is likewise doubtful. The various balsamics, as copaiba, santal oil, gurjun and the oleoresin of cubeb, must be mentioned in order to be condemned not alone as nauseating and repugnant substances, but utterly devoid of benefit in this disease. It is unreasonable to believe that a drug ingested and acted on by the different digestive ferments and fluids found in the gastrointestinal canal, after being absorbed in a modified and chemically altered form, and after being oxidized and in turn converted into simpler products, should act as efficaciously on the urinary passages, as *in vitro* in the chemical and bacteriologic laboratories. The presumably beneficial effects of those remedies as witnessed in practice, are not due to their inherent specific properties, but rather to the intake of large draughts of water proverbially following these antiblennorrhagics, which act not merely as a diuretic, but also as a detergent and diluent, thus allaying painful urination, mitigating as the urinary tenesmus and indirectly acting as a mild antiseptic by virtue of the saline constituents it usually contains.

TREATMENT OF ACUTE STAGE.

The most rational method of treatment of the acute stage of gonococcic urethritis is irrigation, as first introduced by Janet, of France, and extensively used and elaborated in this country by Dr. F. Valentine, of New York. I have, however, utilized a procedure, which for lack of an adequate terminology I have designated the modified Valentine's treatment, and which I will attempt to outline in the subjoined paragraphs. With this method the average duration of an acute urethritis should not exceed three weeks, provided the patient presents himself for treatment within the first three or four days after the entrance of the acute manifestations and his urethra has not been impaired by the previous existence of the same trouble, i. e., provided the patient has contracted this affection for the first time. Recurrent attacks of this disease render it less amenable to this form of treatment and may prove very intractable.

The patient is told to drink plenty of water, and if he be fastidious, he may partake of some of the so-called mineral waters with which the market is teeming, or he may use some of the mildly acidulous beverages, which are abundantly dispensed in confectionaries. All alcoholic and malt beverages must be interdicted, as well as tea and coffee. Condiments of any sort, highly seasoned dishes and nitrogenous foods must be temporarily avoided. Soups are too stimulating and should be taken of sparingly. The anterior urethra is flushed with a normal saline solution by means of the Valentine douche or a similarly devised apparatus with a good valve attachment to regulate the flow. Not more than three pounds pressure should be allowed, or what is the same, the apparatus should not be elevated higher than six feet. A soft rubber catheter encircles loosely the root of the penis, or what is preferable, the fingers of the left hand of the operator gently press the penis at its root, while the right hand manipulates the valve. The latter should be of such a construction so as effectively to regulate the current, which should be continuous and slow. The slight constriction of the root of the penis prevents the fluid from passing the corresponding portion of the urethra and being propelled into the deeper portions of the canal, a very undesirable feature which should be zealously guarded against. The infectious agent during the acute stage is confined to the first two or three inches of the urethra. By allowing a steady stream of normal saline solution to come in contact with the mucosa for about four or five minutes, it not only frees it from detritus and quantities of accumulated pus, but greater resistance is imparted to the cell as well, preventing the extension of the process and at the same time acting as a mild disinfectant. Thus affected, the meatus is dried and 20 minims of a solution of adrenalin (1:1000) is instilled through an ordinary bulb eye-dropper into the canal; the meatus is then compressed and the solution kept there for at least five minutes, after which it is permitted to escape. The suprarenal principle constricts the superficial capillaries and thus removes a prolific source of supply of the pabulum necessary for the multiplication and maintenance of the gonococci, which readily succumb for want of nourishment. Four results are thus achieved with the modified Valentine's treatment, viz.:

1. The removal from the urethra of muco-pus, epithelial débris, etc.
2. Astringent action; constriction of the peripheral vessels and the shutting off of a nutritive supply to the infecting agent.
3. By so doing it acts indirectly as a disinfectant to the urethra.
4. The duration of the affection is decidedly curtailed without endangering the integrity of the urethra.

The effects of the above procedure are very satisfactory, as the discharge is manifestly lessened after a few irrigations, the patient expressing relief from all annoying symptoms. The saline irrigations are continued daily, or what is still better, twice a day, if possible, for ten days, after which period potassium permanganate is substituted in ascending strength, beginning with 1:10,000 and increasing to 1:1,000 by the end of the third week. It will then be noticed that the discharge has come to a standstill and the urethra has been restored to the normal. If there is still a slight serous secretion at times evident at the meatus, we may resort to a prescription composed of zinc sulphate, adrenalin (1:1,000) and colorless fluid extract of hydrastis in distilled water, which, in a short time, will check it completely. Three weeks suffice in the majority of instances to effect a cure, while in favorable cases the disease is brought to an end in ten to fourteen days. This time factor alone bespeaks the advantage of the above treatment as compared with that practiced formerly in a loose, haphazard and empirical manner, when the prognosis as to the time was considered to be from six to eight weeks. This method then has the advantage over the older forms of therapy, that it shortens the duration of the affection, as evidenced by a number of cases on my record book. Specific or gonococcic urethritis under the aforementioned regimen is, therefore, a limitable and abortive disease, and the regimen does not tend to undermine the integrity of the urethral canal, as is commonly the rule with the caustic remedies in vogue during the last two decades, and still used by some under a mistaken conception of the pathology of this disease.

TREATMENT OF THE CHRONIC FORM.

The treatment of the chronic form is more difficult, tedious and complicated than the acute variety, and requires perseverance and patience on part of both physician and patient. Various solutions for injection have been advised, among them the vegetable compounds of silver, alone or in combination with ichthyol and suprarenal principle, either as a hand injection, or, what is still better, applied by the physician himself. We should make it an axiom not to entrust to our patients any mechanical or instrumental method, be it ever so simple. An injection fluid which has found favor with me is a solution of protargol (5 per cent.) together with adrenalin chlorid and Magendie's solution of morphin, if there is tenderness present, with or without hydrastis (the latter in the form of the colorless fluid extract). This is injected either anteriorly, or in case the process has travelled beyond the triangular ligament, which it does in nearly 15 per cent. of cases, through an Ultzman instillator into the posterior urethra. Silver nitrate, which has been extensively used hitherto, has been discarded for the albuminates or nucleates of the same metal, preferably argyrol or protargol. There are cases, however, in which the nitrate acts more favorably than the before-mentioned compounds and is accordingly used by me in preference to them in selected cases. Irrigations with strong solutions of potassium permanganate are likewise useful, either as a recurrent irrigation by the Valentine apparatus, or as a vesicourethral irrigation through a catheter, allowing it to escape by the natural route. Zinc sulphate has also been given a trial and found to be efficacious in those cases where the urethra is the seat of a catarrhal process and where infectious organisms can not be demonstrated microscopically. Ichthyol and belladonna in conjunction have been employed as a retrojection in the chronic form of urethritis. The insertion of sounds for their stimulating effect on the mucosa offers a therapeutic measure of great value, but it is too laxly used by many without knowledge of the indications prompting their employment. As a routine procedure it is not to be advised in all cases. That its intelligent use is followed by marked improvement can not be denied, but as used by some in the unsettled manner already intimated, it must be discouraged. The indications for its use are as follows:

1. In the incipient and formative stages of stricture.
2. In involvement of the posterior urethra without implication of its adnexa.
3. As a powerful stimulant to the urethra in catarrhal conditions affecting its anterior segment, where no gonococci are demonstrable.

The cold sound is the best. It must, however, be thoroughly sterilized with boiling water before insertion and well lubricated to facilitate its passage. The best and most expeditious method of sterilization is to dip the sound in alcohol and immediately ignite it, waiting until it is entirely cool. To be effective the sound must be left *in situ* for at least 10, if not 15, minutes. Various ointments containing minute quantities of ichthyol, silver nitrate and balsam of peru, severally, or in combination, furnish good lubricants, fulfilling a twofold purpose, viz., as an emollient and slightly antiseptic and astringent. Other emollients may be tried if deemed advisable. The introduction of the cupped sound, whereon some ointment of silver nitrate is deposited, is an efficient method in prostatic urethritis of long standing. Our intention is not solely to disinfect the morbid area, but also to stimulate it, e. g., to cause a substitutive inflammation, as well as to dilate the canal. In a number of instances this purpose is readily reached. An acute posterior urethritis, or an exacerbation of the chronic form of greater or less severity is produced. The packing method, recently advanced, must be mentioned in order to advise emphatically against it. Cataphoresis is of doubtful utility, but may be tried. The beneficial results obtained by it are more pronounced in stricture. Massage or centripetal effleurage of the prostate or seminal vesicles per rectum with simultaneous counter pressure by means of a sound in the prostatic portion of the urethra, is a valuable means, but if no improvement be noticed after one week, it should be abandoned as useless.

URETHROSCOPIC TREATMENT.

The most thorough treatment is that afforded by the urethroscope, which reveals not only the actual seat of the trouble, but aids us in the direct application of medicinal agents to the diseased areas. The instrument serves a double purpose: (a) as a means of diagnosis and (b) as a therapeutic auxiliary.

Of course, we must first determine whether the tube can be passed, i. e., whether any bar obstructs its introduction in the form of strictures, polypi, diverticula and other organic obstacles. This ascertained, the posterior urethroscope is passed. The battery is turned on and the field viewed through the fenestrated opening. A great deal of practice is required to differentiate normal from pathologic conditions of the urethra. The possession of a urethroscope means little, to interpret its findings correctly means half of the success gained. It is impossible for me to enter into an exhaustive description of the different states of the urethra, both normal and abnormal, as seen through the fenestra. Long practice and proper recognition of the urethroscopic field are requisite to the correct interpretation of the picture seen. Self-deception and uncertainty may create havoc and thus frustrate our aim. Treatment by the urethroscope is the most rational method of procedure, as applications of divers nature may be made directly to the diseased parts; all ambiguity of treatment and ignorance of the actual existing conditions are thereby thoroughly eliminated. The ordinary slender wooden applicator serves well in urethroscopic work.

The value of internal treatment in chronic gonococcic urethritis is questionable. I have no faith in its efficacy, save for the administration of some urinary sedative after instrumentation, as hyoscyamus, belladonna or urotropin. We can readily dispense with these even if we have our sounds and instruments unscrupulously clean and perfectly sterilized, well lubricated and gently and slowly introduced. No force, except that of a gentle sliding movement, must be used. In patulous canals the sound finds its own way, without much effort on our part.

Treatment also largely depends upon the exact seat of the lesion, which must, in every case, be first determined. The urine must be examined by the three-glass test, to ascertain the probable location of the morbid process; the sound will detect strictures and diverticula, which are by no means so rare as some authorities would suppose. If a stricture is present, its exact side must be made known by the olivary bougie or the bougie a boule. Rectal examination is not merely advisable in some cases, but imperative in nearly all cases of chronic urethritis that come under the physician's observation. Any anomalies of the prostate or seminal vesicles are readily perceived by the palpating finger. Inflammatory states of

these structures, not infrequently give rise to urethrorrhea, which is often mistaken for gleet and unsuccessfully treated for this vague affection. A search must also be instituted for the possible presence of diseased states of the Cowper's glands, as they are equally apt to cause an obstinate urethrorrhea. There is a form of the latter condition that must not be omitted, entitled lacunar urethrorrhea, on account of its being located in the first inch of the urethra, the lacuna magua on the roof of the fossa navicularis, where instruments are not rarely engaged. Again, within the first two inches of the urethra the follicles at its base are more prominent than at other portions of the canal. Folliculitis of the urethral mucosa in its course may induce a muco-purulent discharge. Its exact location must first be discovered prior to the adoption of treatment. A tight meatus is frequently a contributing factor, which must not be overlooked during a urethral examination; the same holds good of a tight prepuce. In the former a meatotomy is indicated before we are enabled to resort to direct medical applications or mechanical interference; in the latter we must have recourse to circumcision. Affections of the bladder, the ureters and pelvis of the kidney or of the kidney itself must attract our attention as possible causes in all ultrachronic cases, where no appreciable cause can be elicited in the urethra and its appendages. Cystoscopy, and if necessary, ureteral catheterization should be performed before definitely arriving at a diagnosis. The possibility of tuberculosis should never be lost sight of. Over-treatment is held to be a potent source for the continuance of a urethral discharge, which ultimately disappears on the discontinuance of injections and instrumentation. Constitutional peculiarities of the individual must also be elicited before beginning treatment, as we are apt to meet with cases that do well on a tonic course of medicine with very little or no topical treatment. In these patients there is depraved health playing an important rôle; either malnutrition, digestive derangements or anemia and other debilitating states may be responsible for the perpetuation of the catarrhal discharge. That these anomalies of the general health must be corrected, goes without saying.

In protracted and persistent cases of posterior urethritis, especially when there is a concomitant prostatic involvement, our last and only resource lies in prostatic drainage, by means of a perineal section. This measure has of late been warmly recommended by some surgeons and the results obtained so far are very promising.

CONCLUSION.

In conclusion, I desire to remonstrate against the vague, unscrupulous and unscientific way of treatment adopted by some practitioners. The routine method displayed must be objected to by everyone who is cognizant of the gravity of gonococcic urethritis. It must not be slighted, for it is a formidable disease and frequently becomes not only a menace to the individual afflicted with it, but also a source of danger to those who are sexually brought in contact with him, who suffer innocently and whose life may be jeopardized, which is, indeed, very deplorable. It may become constitutional and attack the serous surfaces of the body, damage the delicate mechanism of the renal structure and lead to serious after-effects, immediate or remote. The treatment undertaken by the physician must be in conformity with the most modern principles governing it. The author also wishes austerely to censure and rebuke that faction of practitioners which holds itself aloof and is "too good to treat clap," as they deign to express it. Medicine, fortunately, recognizes no aristocracy; it knows of no elite, creed or caste. The only patricians are those, who by ardent endeavor and indefatigable labor, have helped to assuage the pains and heal the ills of suffering humanity, irrespective of whether the disease has been acquired in a moral or immoral sphere.

166 East High Street.

LOCAL AND REGIONAL ANESTHESIA IN RECTAL SURGERY.

A SYNOPSIS OF SEVENTY OPERATIONS.*

A. B. COOKE, M.D.

NASHVILLE, TENN.

One of the most noteworthy advances in the surgery of the rectum during the past decade consists in the development and perfection of the technic which renders it possible to perform the majority of the operations on this organ under local anesthesia. This possibility will be questioned by some, perhaps disputed by others; but theoretical objections are not entitled to weight in the face of facts to the contrary. During the past year and a half I have called attention to this subject on a number of occasions. As my experience with the method has enlarged, I have become more deeply impressed with its value, and in the light of this experience I wish again to bespeak for it the consideration which its many advantages merit.

I have heard other operators, a very few, however, express different sentiments, but so far as my experience qualifies me to speak, general anesthesia remains the bugbear of modern surgery. Refinements in methods of administration and modification of the agents employed have done much to lessen its dangers and discomforts, but little to diminish the popular dread with which it is regarded. I would not exaggerate the popular dread alluded to, nor, on the other hand, do I think it right to belittle it. In past years I have known numbers of patients refuse operation entirely because of their fear of chloroform and ether, while, in pleasing contrast, I have more recently had the satisfaction of operating in at least a dozen instances for patients who eagerly sought relief as soon as they learned that general anesthesia might be avoided.

That adequate means of local anesthesia is to-day one of the most conspicious needs of surgery, is evidenced by the eager avidity with which every announcement of a new method or measure is received. Cocain, eucain, stovain and the various other chemicals of that type, ethyl chlorid, scopalamin-morphin, spinal analgesia and even hypnotic suggestion, each met with enthusiastic welcome, only to be followed by disappointment as its limitations became apparent.

While surgery in general has long felt, and still feels, this need, rectal surgery has suffered especially, and from the writer's point of view, peculiarly, by reason of it. This statement is justified by several considerations. Though abundantly innervated throughout, the terminal two inches of the intestinal tract is practically the only portion supplied with sensory nerve fibers, and rather remarkable to say, this same two inches is more frequently the seat of disease than the whole twenty odd feet above it, or indeed, than any corresponding area of the entire body. But important as these diseases are,

* Read before the Tennessee State Medical Association, Memphis, April 11, 1906.

by reason of their frequency and the pain which attends them, they involve no vital structures and in themselves as a class can not be regarded dangerous to life. Again, when we consider the character of the ordinary operations performed on this part, the conclusion is unavoidable that they properly belong to the domain of minor surgery. Yet the road to relief which the surgeon is accustomed to point out to these sufferers usually begins with general anesthesia and ends some weeks later on emerging from the hospital, a routine which only the exigencies of major surgery should justify. It is not strange that the quack should have flourished and fattened in a field which, productive as it is, the regular profession has cultivated so poorly.

I would not be understood as intimating that rectal surgery has no further need for general anesthesia, nor that such an end is very likely to be attained. On the contrary, such operations as resection, excision, complicated fistulas, strictures, etc., ranking, as certain of them do, among the severest known to surgery, will probably always require for their successful performance those conditions which only the profoundest systemic narcosis can furnish. Happily, such operations are comparatively rarely demanded.

What is claimed, however, is that the great majority of the surgical diseases of the rectum are amenable, under analgesic measures locally applied, to radical operative treatment in which nothing of thoroughness is sacrificed and many real advantages gained. Credit for the method which renders this possible is largely due to Dr. S. G. Gant, of New York, not, strictly speaking, for discovering new principles, but rather for recognizing the value of old ones and by painstaking work, perfecting the technic for applying them in the surgery of the rectum.

Briefly, the principle of the method is pressure analgesia and its mode of application, distension of the area to be operated on with sterile water or a weak solution of some analgesic drug, according to the preference of the operator and the indications in the case. Within the past twenty months I have employed the method seventy times in a series of cases including fistula, prolapsus ani, fissure, and external and internal hemorrhoids. After an experience with the old methods covering a period of some ten years, it is not easy to repress enthusiasm in speaking of the results.

The operations performed by this method may be roughly grouped as follows: Internal hemorrhoids, 38; prolapsus ani, 2; fistula, 5; fissure, 9; external hemorrhoids, 16. It is to be understood that in a number of these cases more than one kind of lesion was found and that in such cases all necessary work was done at one sitting. In internal hemorrhoids, perhaps, the method has seemed most noteworthy. After a record of more than three hundred operations for this malady under general anesthesia, I esteem it among the most gratifying of my professional experiences to have been able to perform the radical operation thirty-eight times with the patients lying perfectly passive and in many instances even laughing and chatting as the work progressed. In only two or three cases was there the slightest complaint of pain and these few were among the earliest attempted by this method.

Faith in a surgical method is best demonstrated by the use one makes of it. In the beginning I employed the local anesthesia method with many misgivings, resorting to it only in selected cases and under most favorable conditions. The extent to which confidence in it and myself has grown, appears in the statement that of my last fifty-seven operations on the rectum, general anesthesia was employed in only thirteen. Six times only in the last thirty-one operations for internal hemorrhoids have I used other than local anesthesia and in each of these six cases something more than hemorrhoids was to be dealt with.

In lesions involving the more sensitive areas, such as fissure and external hemorrhoids, the first and chief object is to anesthetize the overlying integument. For this purpose some modification of the technic is desirable. Here the needle is first entered between the layers of the skin itself, and experience has convinced me that a 0.25 to 0.5 per cent. solution of eucain (beta or betalactate) gives better result than the sterile water alone. By the addition of a few drops of adrenalin solution the anesthetic effect may be prolonged and hemorrhage greatly lessened. The momentary pain caused by the first prick of the needle is the only occasion of complaint in these cases.

At the 1905 meeting of the American Proctologic Society, Pennington, of Chicago, and Tuttle, of New York, reported successful attempts to anesthetize the entire anorectal region for the purpose of operation. A few months later the former published a full description of his method,[1] citing twenty cases in which it had been employed. The possibility of completely anesthetizing a given area or portion of the body by blocking its nerve supply has been recognized for a number of years, the work of Crile, of Cleveland, forming the most notable contribution to the subject, at least in this country. All of us have incised phlegmons, amputated fingers, etc., painlessly by cocainizing the nerves proximal to the site of operation. Crile has even reported an interscapulo-thoracic amputation performed by cocainizing the brachial plexus. To apply this principle successfully in the anorectal region requires accurate knowledge of the location and distribution of the nerves supplying it. The chief nerve supply of this region is derived from the inferior hemorrhoidal which is usually a branch of the internal pudic, being given off from it in Alcock's canal and passing inward across the posterior part of the ischiorectal fossa to supply the external sphincter and the overlying integument. In addition, this region is innervated to a greater or less extent, anteriorly by filaments from the perineal branch of the internal pudic, and posteriorly, by the perineal branch of the fourth sacral and cutaneous branches from the coccygeal plexus. To gain complete control of this field it is only necessary that these several nerves be blocked by depositing the anesthetic solution around them by means of a hypodermic needle. As a rule, this may be accomplished through a single puncture in the median line posterior to the anus, by passing the needle first to one side and then to the other and finally infiltrating the area immediately contiguous to the site of the puncture. In the majority of cases no special attention need be paid to the nerve supply from the perineal branch of the internal pudic, though when necessary this area may be effectively dealt with by a separate introduction of the needle anterior to the anus.

The chief advantage claimed for this method is that it renders possible complete divulsion of the sphincter, when this procedure is necessary, either for curative purposes or to gain access to diseased parts. It has the further advantage of permitting the anesthetization to be completed before the operation proper is begun, thus considerably facilitating the latter. I have only once found it necessary to anesthetize the entire ano-

1 American Medicine, July 29, 1905.

rectal region as described above, though I have succeeded a number of times in blocking limited areas for operation on painful lesions involving the anal margin.

A brief recital of the case referred to will perhaps be of interest here:

Patient.—On Feb. 27, 1906, I was called to see Mr. J. B., aged 23, whom I found in bed.

History.—For several years he had been a sufferer and supposed his trouble was merely the ever-popular "piles."

Examination.—I found three well-developed internal hemorrhoids situated well up in the anal canal, an exquisitely painful fissure with its external "sentinel pile," and, as was to be expected, a spasmodic and hypertrophied sphincter.

Operation.—I advised the patient that a general anesthetic would be necessary. He consented, but his dread of it was so great that I determined first to attempt the operation by blocking the nerve supply of the entire region. This was done on the following day, after the manner outlined above, with complete success, and with practically no pain. The sphincter was divulsed, the internal hemorrhoids ligated and removed, the fissure curetted and incised, and the "sentinel pile" amputated. The patient left the hospital in six days.

The method is certainly a rational one and I shall not hesitate to resort to it in suitable cases.

Following are some of the advantages which, from personal experience, I feel warranted in claiming for local anesthesia in rectal surgery:

1. It is simple, safe and effective.

2. It eliminates the dangers and discomforts of general anesthesia.

3. Pain at the time of operation is usually absent and always so slight as to be easily borne.

4. Postoperative pain is less by far than after the old methods.

5. Time required for the operation is greatly reduced.

6. Confinement to bed is rendered a matter of expedience, rather than necessity.

7. The period of detention from business is diminished fully one half.

8. Under this method the hospital becomes a convenience and luxury rather than a dreaded essential.

9. It is a thoroughly reliable means of affording relief in many cases which would otherwise be unsuitable for operation.

10. It robs these operations of their terrors and makes it possible to reclaim this work from the hands of the "no knife" advertisers.

I hope I will not be misunderstood if, as a final thought in this connection, I say a word or two of caution. The method is simple, but its successful employment demands thorough familiarity with the anatomy of the rectum and anus, discriminating knowledge of the various types of pathology to which they are subject, and no small degree of operative dexterity. Patients afflicted with anorectal diseases are uniformly, perhaps also peculiarly, nervous and apprehensive, and the very thought of operation is sometimes sufficient seriously to embarass even the most skillful efforts in that direction. An air of confidence, gentleness of manipulation and rapidity of execution are of the utmost importance if success with the method is hoped for.

The field of application of the methods above described is, of course, by no means restricted to the anorectal region. I have repeatedly employed them in minor surgical operations, such as excision of superficial tumors, removal of ingrowing nails, amputation of fingers, etc. I am profoundly convinced that it is a duty we owe our patients to spare them general anesthesia whenever it is possible to do so, and that we should welcome and faithfully test all methods looking to this end.

THE SPIROCHÆTA PALLIDA (TREPONEMA PALLIDUM) IN SYPHILIS.*

W. C. ALVAREZ, M.D.

SAN FRANCISCO.

An immense amount of work has been done in the last eleven months on the etiology of syphilis, work that very probably will mark an epoch in our knowledge of that scourge of the human race. It seems worth while to review briefly what has already been accomplished.

HISTORICAL REVIEW.

Lassar calls attention to the fact that more than twenty-five causes of syphilis have been described during the last thirty years. As early as 1837, Donné described a parasite found in syphilitic ulcers and named it *Vibrio lineola.* In 1902, Bordet and Gengou found spirochetes in chancres and throat lesions, but discontinued their researches when they did not find the organisms constantly.

Early in 1905 Siegel observed actively motile flagellate bodies in enormous numbers in the blood of several syphilitics and named them *Cytorrhycetes luis.* Schaudinn had earned a reputation in the study of protozoa, malarial parasites, trypanosomes, etc., and he was appointed by the Imperial Board of Health in Berlin to investigate Siegel's work. He called to his aid Hoffmann, an expert syphilologist, and in April, 1905, they published the description of a very delicate spiral organism which they had found in all of 26 cases of primary and secondary syphilis. The *Cytorrhycetes luis* was not mentioned at all in their reports. Since then a few investigators have found it, many have failed, and some say that it must be an artefact.

Schaudinn and Hoffmann named their organisms *Spirochæta pallida,* and a larger one which they found associated with it they called the *Spirochæta refringens.* This has been found only on the surface of syphilitic lesions, in various other ulcerated surfaces and smegma from healthy men and women.

Hoffmann, in one communication, reports finding the pallida constant in over 300 cases of syphilis, and he has never found it in non-syphilitic material.

LESIONS IN WHICH THE SPIROCHETES HAVE BEEN FOUND.

In the primary sore, the pallida has been found very frequently. Especially in non-ulcerated chancres, and in the upper layers of the lesion there may be very few, so the scraping should be thorough. Many say that the deeper the scraping or section the more the spirochetes. They are also found in the juice from enlarged glands. Smears from mucous patches usually show many pallida, refringens and other spiral organisms, as, e. g., the *Spirochæta Vincenti.* Scrapings and blood from condylomata of the anus and splenic blood show them; but in the peripheral blood of syphilitics with active lesions they are rarely found. Blood and serum from skin lesions occasionally shows the pallida and shows the refringens only when the skin is broken. It has been suggested that the eruption is a true embolic process, the spirochetes being distributed by the blood stream.

The pallida has been found sometimes in enormous numbers, in almost all the organs of congenitally syphilitic children, in macerated fetuses, in a child of 6 and in the fluid of syphilitic bullæ. It is suggestive that the liver, which receives most of the blood coming directly from the placenta, generally contains more spirochetes than any other organ. The pallida has been found in small numbers in the placenta. Pallida and refringens

* Read before the Cooper Science Club, San Francisco, April 2, 1906.

have been found in late secondaries and have been reported found in tertiaries in a very few instances. All the authorities cast doubt on these reports and deny their accuracy, especially when the lesion is ulcerated and the observer inexperienced.

Typical pallida have been found in the primary and secondary lesions in monkeys and apes inoculated from man and from syphilitic monkeys.

Control examinations have been made of material from various venereal and other ulcerating lesions, and most of the observers report not finding the pallida. Kiolomenoglou and von Cube have found in various non-syphilitic lesions, breaking down carcinomata, etc., the pallida, refringens and many atypical forms which can not be classified with either. Schaudinn saw the specimens and admitted the presence of more than two species, but maintained with Hoffmann that all spirochetes found in non-syphilitic conditions can be differentiated from the pallida, either morphologically or tinctorially. Hoffmann has found the refringens in ulcerating carcinoma, and lately Rumpf reports finding spirochetes constantly in carcinoma. He describes these as being coarser and thicker than the pallida, with blunt ends and staining blue with Giemsa. Rosenberger describes many spirochetes in 76 per cent. of specimens taken from the buccal mucous membrane and the tartar of the teeth. Most of these resembled the refringens; some were pale, but a little too thick for the pallida; others resembled the *Spirochæta Vincenti,* and another variety was very delicate, very long, faintly staining and irregular in shape. All had pointed ends. In non-syphilitic lesions, Siebert has seen spirochetes just as delicate as the pallida.

Only the pallida have been found in sections of syphilitic lesions, and it has not been found in sections of carcinomata and other lesions which showed spirochetes in their discharges.

Mercurial treatment does not cause a rapid disappearance of the pallida or the refringens, as was at first reported. Care must be taken that the refringens which only may remain is not mistaken for the pallida.

CLASSIFICATION.

The question very naturally arises, What is the spirochete and what is its relation to other spiral organisms? The clearest answers to these questions can be found in an article by R. Blanchard.[1] He submits the following classification:

I. Spirobacteria: Vegetable in origin.
  Genera: *Spirosoma,* from nose and mouth.
    Vibrio, the comma bacillus, etc.
    Spirobacillus.
    Spirillum, from stagnant water.

II. Trypanosomidae: Protozoa.
  Genera (a) *Spirochæta.*
  Species: *Spirochæta* in stagnant water and tartar of teeth
    Spirochæta Obermeieri.
    Spirochæta of African tick fever and possibly of Texas fever and other diseases of this kind.
    Spirochæta refringens (Schaudinn, 1905).
    Spirochæta pallidula (Castellani) found in paranoi or yaws.
    Spirochæta Vincenti.
    Spirochæta in dysentery.
    Spirochæta constantly found in stomachs of dogs.
    Spirochæta found in surfaces of ulcerating neoplasms.
    Spirochæta in smegma and in ulcers.
  (b) Treponema: (Schaudinn) (syn. *Spirochæta spironema*)
    Species: *Tr. pallidum* (Schaudinn).
  (c) Trypanosoma:
    Species: *Tr. Gambiense* (Dutton) sleeping sickness. There are many other species usually transmitted by insect bites.
  (d) Trypanoplasma: Four species found in fishes.

DESCRIPTION OF THE SPIROCHÆTA PALLIDA.

The *Treponema* or *Spirochæta pallida* is described as being extremely delicate, weakly refractile, spiral or corkscrew-shaped, with three to fourteen bends which are more acute than in any other spirochete, resembling the edge of a saw. Both ends are pointed, which is very important to notice, as it will generally enable one to exclude little shreds of elastic tissue which are often beautifully coiled. The length is 4 to 14 mm.; the breadth immeasurable; it has a rotary motion forward and backward, and it may bend slightly in the middle. A vibratile membrane and flagella have been suspected by many, but as yet have not been clearly defined. The ultramicroscope shows segments and what may be a nucleus. Multiplication is by longitudinal division. It is very refractory to stains, and the pink color obtained with Giemsa is supposed to differentiate it from other spirochetes. Metchnikoff and Roux point out that this can not be depended on and cite an instance. They found in the primary sore of a monkey a delicate pallida, typical in all but that it was stained clear blue. They inoculated a chimpanzee from this monkey, and later obtained spirochetes identical morphologically, but staining a pale rose with Giemsa from the same bottle. The writer has seen in a specimen taken from the gums of a non-syphilitic young man with pyorrhea alveolaris delicate spirochetes with long wavy curves which stained pink with Giemsa. Other thicker spirochetes in the specimen were stained blue.

The refringens is thicker, flatter, the curves are fewer and longer; ends may or may not be pointed; it is also motile, bending on its own axis or stretching out into almost a straight rod, and it may be caught by the fixing agent in any irregular position. It is easier to stain than the pallida and takes the blue of Giemsa.

The *Spirochæta pallida* does not pass through an unglazed porcelain filter, and this may explain the findings of Klingmuller and Baermann, who got no results after inoculating themselves with filtered syphilitic virus. Schaudinn placed the pallida with protozoa after studying two parasites found in the blood of the stone owl. These appear in the stomach of the *Culex pipiens* as trypanosomes and spirochetes.

TECHNIC.

Mucous patches, condylomata, chancres and ulcerating surfaces should first be lightly scraped so as to get a little blood-tinged serum. The scrapings usually show no *S. pallidæ* and may show irregular forms of the refringens. Skin lesions should be well washed with absolute alcohol, a small incision made in the skin and the slide touched only to the drop of blood. Blister fluid may show spirochetes. Flexner finds that the pallida appears only after the vesicant has acted for many hours, and concludes that the spirochetes are not in the lymph spaces or they would appear sooner.

Enlarged glands should be aspirated with a large needle and powerful suction so that small pieces of white gland-substance may be found when the contents of the syringe are washed. These particles may contain spirochetes in enormous numbers. Blood should be taken carefully to avoid contamination from skin lesions and mixed with 10 parts of 0.3 per cent. acetic acid. Centrifugalize, make smears of the sediment and stain. Always make several specimens, as there are often very few organisms and these have a tendency to be all in one place.

Material to be examined unstained should be mixed immediately with a little normal salt solution and the cover-slip may be sealed. The pallida is very difficult to find this way, and the light must be well regulated. So many stains have demonstrated the pallida that I can not begin to describe them here. The Giemsa or azur stain is the surest and is easily used. The other

1. La Semaine Médicale, Jan. 3, 1906.

stains are liable to be erratic, giving good results in one specimen and none in others. The Hastings stain, diluted the same as for blood films and used for 6 to 24 hours, has made the prettiest specimens in my collection; but I generally use the Giemsa in a 1:15 dilution, as its results are more uniform, it acts more quickly and the diluted stain keeps very well. The specimens are first hardened 5 to 60 minutes, in absolute methyl alcohol and then left in the dilute Giemsa 1 to 15 hours.

Goldhorn uses a stain which acts in a few seconds and is said to give beautiful and uniform results. If this be true, it is the stain *par excellence*, as the searching of the specimens is often so tedious that one would gladly save time in the staining.

The Levaditi stain is probably the best for sections and is a modification of Ramon y Cajal's stain for nerve fibers. Several observers have traced their failures in not finding spirochetes in sections to delay in fixing the tissue. They conclude that a specimen is useless six hours after removal. This agrees with the fact that syphilis is so seldom contracted from fomites and cadavers.

PERSONAL OBSERVATIONS.

Ten cases of primary, secondary, tertiary and congenital syphilis and 8 controls have come under my observation. The following is a summary of the primary case:

CASE 1 (by courtesy of Dr. Peck).—Patient was a young man with a chancre on sheath of penis, much indurated and covered with a hard crust. This was softened, scraped, and smears showed no spirochetes after long and careful search. This chancre was excised, sectioned and stained by Dr. Oliver and myriads of pallidæ found. This case demonstrates the value of scraping deeply before taking smears.

The following were secondary cases:

CASE 2.—Man, aged 40, had large condylomata around anus. He had had some treatment. Smears from unwashed surface showed many of the refringens type, no pallidæ. Some spirochetes of pallida type were found, but midway in thickness between pallida and refringens.

CASE 3.—Man, aged 30, had extensive condylomata. Smears taken superficially showed many spirochetes of the pallida type; some of the refringens type. Pallida is frequently bent about the middle.

CASE 4.—Boy, aged 18, had very severe infection, condylomata, mucous patches, large tonsils, extensive skin eruption. Superficial scrapings from condylomata showed few of the refringens type; deep scrapings showed many pallida; mucous patches showed as many as six pallidæ in a field. Twenty injections of mercuric chlorid caused no diminution in the number of spirochetes of either type. The tonsils were removed with the guillotine, and juice from the depths contained no spirochetes of any kind. This was after about thirty injections, and it would be interesting to find if mercury causes a disappearance of the pallida in the tissues when it does not affect those on the surface of the body.

CASE 5.—Man, aged 35, had wart-like condylomata around anus. Few spirochetes of the pallida type were in smears. Ulcer at angle of mouth showed spirochetes of the refringens type and mouth spirillæ. This man had treatment for about four months.

CASE 6.—Woman, aged 25, had large chancroids of vulva, which appeared about same time as secondaries from previous infection. Smears showed spirochetes of both types and long, delicate threads, resembling those found in noma. These occasionally seem to have a tendency to form spirals and loops. Mucous patches in the mouth showed spirochetes of both types.

CASE 7. (by courtesy of Dr. Schmoll).—Superficial smears from mucous patches showed myriads of spirochetes of both types and a few spindle-shaped bacteria, described by some writers as associated with spirochetes.

The following is a summary of a late secondary case:

CASE 8 (by courtesy of Dr. Krotoszyner).—Typical punched out leg ulcers appearing two years after the primary sore. One specimen out of six showed a few typical spirochetes of both types. This case shows that one must take several specimens.

The following is a summary of a tertiary case:

CASE 9.—Patient was a woman. There were typical specific ulcers of legs. No spirochetes of any kind found.

The following is a summary of a case of congenital syphilis:

CASE 10 (by courtesy of Dr. Porter).—Infant, aged 4 months. The mother was syphilitic and the child had a mucous patch on tongue and snuffles. Swab from nose showed pallidæ.

The following were control cases:

CASE 11.—Pus was taken from large ulcerating carcinoma of the jaw. There were myriads of spirochetes as delicate as the pallida but irregularly twisted. Some were very long and straightened out into threads with a curve here and there.

CASE 12.—Epithelioma of hand. Discharge showed a very delicate spirochete resembling the pallida.

CASE 13.—Young man with no history or evidence of syphilis had marked pyorrhea alveolaris. Smears from gums showed at least two varieties of spirochetes, one of which resembled the refringens.

CASE 14.—In stomach contents from case of gastric cancer no spirochetes of any kind were found.

Two chancroids, one of penis and the other of the vulva, a vaccination pustule and pus from tubercular sinus showed no spirochetes.

CONCLUSIONS.

The spirochete was found in 7 out of the 10 cases of undoubted syphilis. Its absence in the smears from the chancres and one condyloma may be due to the smears having been taken too superficially. The tertiary ulcers were entirely negative. This agrees with the findings of other observers. The controls were negative except the carcinoma, epithelioma and pyorrhea alveolaris. These showed what may be several varieties of spirochetes, most of which are very delicate; some as delicate as the pallida, but none of them had the regular sharp bends. Occasionally one is seen which would puzzle an expert. They probably are saprophytes, as they can live in pus. The pallida soon disappears from pus. If the pallida is proved to be the cause of syphilis, doubtful lesions will be examined as sputum is now, but the diagnosis probably will never be as sure, especially in lesions in the mouth, or on the genitalia where other spirochetes are normally found. Even with the circumstantial evidence against the *Spirochæta pallida*, its discovery now in a doubtful skin lesion or genital ulcer would be a good point in the diagnosis. A great deal will depend on the experience of the observer, and to become skilled will take a great deal of time and patience, as the specimens are often few and far between. The *Bacillus lepræ* has been accepted on less evidence than has been brought forward for the *Spirochæta pallida*.

It is dangerous to depend too much on morphology, and it has been suggested that the spirochete is a stage in the life-cycle of a protozoan; perhaps the Siegel flagellate and the *S. refringens* may be another stage of the same organism.

Some of the most significant facts pointing to the pallida being the cause of syphilis are:

1. Its practically constant presence in syphilitic lesions in their various stages.

2. Its constant absence in non-syphilitic lesions, contrary findings being doubted especially when the difficulties in diagnosis are considered; and the fact that the observers are all beginners in this field.

3. Its presence in the organs of congenital syphilities and in the placenta.

4. The fact that only the pallida has been found in the deep tissues of syphilitics.

5. Its presence in syphilitic monkeys and in the secondaries of apes even after passing the virus through these animals.

6. The retention of syphilitic virus by the unglazed filter, showing that the causative organism is not ultramicroscopic.

7. The presence of most spirochetes in the most infectious lesions.

8. The fact that the *Spirochæta pallida* seems to be morphologically more distinct as a species than the other spiral organisms.

9. The fact that it seems to be more highly differentiated as a parasite and soon disappears when removed from living tissues.

It would seem now that there is some analogy between dourine (mal de Cadéras) and syphilis. The former is a disease of horses and asses met with in the Mediterranean countries, transmitted by coitus and caused by the *Trypanosoma equiperdum,* which can pierce a healthy vaginal mucous membrane.

Much work remains to be done especially in the study of sections where there is not the confusion of secondary infections.

We may hope some day to understand the mysteries of hereditary syphilis.

The pallida has not yet been cultivated, and this is not likely to be easy of accomplishment on account of its marked parasitic tendency. It is significant, however, that the trypanosomes have lately been cultivated on human blood with 5 per cent., each, of sodium citrate and sodium chlorid. When this is done, we may hope for immunizing and curative sera which will cause the name of Schaudinn to be placed with those of Jenner, Behring and Pasteur.

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XXIII.

DRUGS ACTING LOCALLY ON THE SKIN AND MUCOUS MEMBRANES.

Local Anesthetics and Anodynes.

The introduction of cocain marked a decided advance in the production of local anesthesia.

Previous to that, freezing the part by immersion in a mixture of salt and snow, or shaved ice, or by spraying with ether or other volatile liquid, was used, and while a procedure of this kind does produce complete anesthesia, the pain experienced during the freezing and thawing greatly exceeds that which would be caused by such a simple operation as opening an abscess or the removal of a small foreign body, such as a splinter or piece of glass, when readily accessible. It is because of the inherent dread which the average person has of the surgeon's knife, that he will undergo suffering akin to that with which he is familiar, rather than endure a lesser one which seems dreadful because it is unfamiliar.

It is also true that the injection of cocain sometimes causes more pain than the operation for which it is given would, and, since surgical operations have become so much more common than they were formerly, many adults willingly bear the brief, sharp pain of a simple incision, rather than resort to cocain, which has come into a certain disrepute because of the abuse of it by its victims, the majority of whom have become such through the use of supposedly harmless nostrums pretending to be valuable remedies for hay fever and other minor affections.

Cocain, which is benzoyl ecgonin, shows a certain chemical analogy to atropin and aconitin, which resemble it somewhat in their action on sensory nerves, and it is also related to phenol through the benzoyl group, since benzoic acid differs from phenol only by having a COOH group in place of the OH of the phenol. The anesthetic action of phenol is second only to that of cocain.

Aside from the systemic effect, which we need not fully detail here, cocain paralyzes sensory nerve endings with which it comes in contact and even nerve trunks when in sufficient concentration; if the solution is sufficiently dilute and the action not too long continued, the nerve endings rapidly return to normal (the nerve trunk more slowly), when the application is discontinued and the cocain removed by absorption into the general circulation, or evacuated.

When a fairly strong solution, 3 per cent., is injected into the area about a nerve trunk, or an even weaker solution, 2 per cent., within the nerve sheath, both sensory and motor paralysis occur in about fifteen minutes, affecting, of course, the entire distribution of the nerve; the effect lasting for some hours after intraneural injection.

Since aqueous solutions are not absorbed from the unbroken skin, they must be injected beneath the epidermis, at least, in order that they may come into actual contact with the nerve ends.

When the solution is injected deeply into the muscular tissue the greater part of it passes into the general circulation and is lost so far as local action is concerned. To avoid this, it is better to inject the solution between the layers of the skin, at the same time limiting the circulation in the part as much as possible by compressing the blood vessels, preferably with a rubber band or other tight bandage.

Practically, the same object may be achieved by the use of a solution of the alkaloid of the suprarenal gland immediately preceding the injection of the solution of cocain. The injection of the solution of suprarenal alkaloid (epinephrin, adrenalin or one of the other trade preparations) causes a local vasoconstriction that in turn prevents the rapid absorption of the cocain solution into the general circulation, and also prevents, for the time being, the excessive hemorrhage that is so objectionable in minor operations. When it is necessary for the solution of cocain to diffuse through a part, a moment should elapse after the injection before applying the constricting bandage.

The combined use of suprarenal alkaloid and of cocain has proved to be of particular advantage in the eye and in the nose. One reason, and probably the most weighty one, is to be found in the fact that normal mucous surfaces have a tendency to absorb cocain very rapidly.

When cocain is applied to mucous membranes, either in powder or in solution, it causes its local effects for a short time and is then absorbed, producing its systemic action. Herein lies one of the chief sources of danger of the many so-called hay-fever remedies, which virtually consist of cocain with some diluent powder, such as sugar of milk, and are intended to induce and to continue the truly terrible cocain habit.

Owing to the brief action and rapid absorption, frequent repetition is necessary to secure relief in "colds" and the user is peculiarly liable to become addicted to the habit which, in its baneful effects, is not exceeded perhaps, in the whole range of drug addiction, not even excepting alcoholism. As a matter of fact, many of the so-called hay-fever nostrums are intended primarily for supplying those who are already victims of the habit and who would find difficulty in buying the drug under its real name. This practice may be said to constitute a disgraceful example of the lack of control of the nefarious nostrum traffic by the law.

We should be particularly careful to warn patients and others against the insidiousness of this type of self medication that our skirts may at least be kept clean in connection with this one phase of the evil.

Cocain in solution is readily decomposed on boiling, but if the solution be made with sterile, cold water there will be little cause to anticipate sepsis from its injection, with the usual precautions. The solution may be sterilized, however, by heat-

ing to 80° C. (176 F.) for half an hour at a time on two successive days, care being taken to eliminate all possible contaminations of even a trace of alkali.

Eucain and stovain have the advantage of resisting decomposition by boiling, but, as just suggested, the disadvantage possessed by cocain is more apparent than real, and the general action of cocain, particularly its possible complications, being well known, that drug, no doubt, will continue to hold first place as a local anesthetic, except where the ubiquitous detail man succeeds in frightening more timid members of the profession into an exaggerated idea of the various dangers attending the proper use of the official article, with a corresponding credulousness concerning the entire harmlessness of the particular substitute in which he is interested.

Cocain, when dropped into the eye, or taken internally, causes an incomplete dilatation of the pupil by stimulating the sympathetic nerve reaction to light being maintained, differing therein from atropin, which abolishes this reflex.

OFFICIAL PREPARATIONS OF COCAIN.

COCAINÆ HYDROCHLORIDUM.—U. S.—Cocain hydrochlorid, the most widely used preparation of cocain, is officially described as the neutral hydrochlorid of an alkaloid obtained from several varieties of coca. It occurs as colorless, transparent crystals of a white crystalline powder. It is soluble in less than one part of cold water and in 2.6 parts of alcohol, but is insoluble in petroleum benzin or in ether.

COCAIN.—U. S.—This is an alkaloid obtained from several varieties of coca, resembling cocain hydrochlorid in many of its properties, but being only slightly (1-600) soluble in water. It is soluble in 5 parts of alcohol and even more soluble in ether or in petroleum benzin. The alkaloid cocain is also soluble in about 12 parts of olive oil and it, or the oleate is to be used in making solutions of cocain in oil.

OLEATUM COCAINÆ.—U.S.—Oleate of cocain contains 5 p. c., by weight, of cocain in a mixture of oleic acid and olive oil.

The liquid preparations of coca, the fluid extract and the wine, are never used externally, although, if applied to the mucous surfaces, or to the abraded skin, their use would not be devoid of danger, from the absorption of the contained cocain, and other coca alkaloids.

Cocain is used locally on mucous membranes to allay irritation and inflammation as in hay fever, but it should be used very guardedly and not be too long continued. It is very much less useful in this condition than was formerly supposed and it has been very largely replaced by the now commonly used alkaloid of the suprarenal gland, which, it is claimed, allays the inflammation equally well and certainly has the marked advantage of not conducing to the possibility of habit formation.

Solution of cocain is very commonly injected hypodermically, to produce local anesthesia during such slight operations as the evacuation of abscesses, the removal of splinters, bullets, and other foreign bodies.

When there is considerable inflammation and extreme tenderness, stronger solutions are required than when a healthy surface is to be incised. In the former case, a syringe having a long, fine needle, is filled with a 4 per cent. solution of cocain hydrochlorid, the needle is then inserted obliquely, or almost parallel with the surface, between the layers of the skin, beyond the zone of increased tenderness, and a small drop of solution is forced beneath the epidermis; a white spot is seen in a moment and the needle is then advanced through that toward the more tender area without removing the point of the needle from beneath the epidermis; with each advance a drop of the solution is injected. When the needle has been passed under the epidermis for its full length, it is withdrawn and the point inserted into the most advanced blanched area; in this way, using a curved needle, a complete circuit may be made of the seat of inflammation. The object of injecting the solution between the layers of the skin is to secure anesthesia with a minimum of absorption into the general circulation.

The psychic effect on the patient of having painless injections made into such an extremely tender region tends to allay the nervous dread of the knife, which is a more important factor, than we, who are accustomed to seeing pain, are apt to realize.

The injection of a solution of cocain into the hand is apt to prove ineffective when the trouble is deep seated, as in palmar abscess, and in such cases it is better to inject a small amount of a 2 or 3 per cent. solution around or into the nerve trunks in the forearm.

The injection of strong solutions into nerve trunks has given rise to much trouble and it is preferable, therefore, to try to secure the effects from weak solutions.

Anesthesia involving all the body below the site of the injection, may be secured by injecting about ten or fifteen minims of a 2 per cent. solution of cocain hydrochlorid into the subarachnoid cavity through a sterilized platinum needle which is inserted at the side of the fourth lumbar vertebra. The patient must be placed in a sitting position, in order that gravity may not favor the passage of the solution up to the medulla.

This method of using cocain (or any other drug), is attended with so much danger that it is not justifiable except when for some reason, general anesthesia is not practicable.

The anesthesia is induced in ten or fifteen minutes, with cocain, but its duration is very variable, lasting from half an hour to five hours.

When the application of a constricting band is not feasible the previous injection of a solution of the suprarenal gland, as previously suggested, will delay the absorption of the solution of cocain into the general circulation. It should be remembered, however, that the use of vasoconstrictor only delays and does not inhibit the absorption of the cocain. When a large amount of the cocain solution is necessary it will probably be preferable to use the infiltration method, as proposed by Schleich. It is difficult here to see what advantage is to be gained by the addition of morphin to a solution that is intended to act locally, instead of directing the injection of the desired amount at once so as to secure its systemic effect. Schleich recommended solutions containing from 0.01 gm. (1/6 grain) to 0.2 gm. (3 grains) of cocain hydrochlorid and from 0.005 gm. (1 12 grain) to 0.025 gm. (1/2 grain) of morphin hydrochlorid in 100 c.c. (3 fluid ounces) of 0.2 of 1 per cent. solution of sodium chlorid to which was added one-fourth of a drop of phenol.

Strong solutions of cocain should not be used in carious teeth, and only small amounts of the weak solution. One or two drops of a 1 per cent. solution often affords relief from toothache.

Cocain is sometimes applied to hemorrhoids to lessen the pain and it may be said that its local use is much more rational than is that of opium, since the alkaloid morphin has no local analgesic or vasoconstrictor action, a fact to be remembered when prescribing urethral injections, and lotions for inflamed surfaces of the skin.

Cocain has also been used, in small doses, to relieve nausea. It may be given alone or with other antiemetics. The following is an example of a combination with cerium oxalate, the latter being used empirically.

R.	Cocainæ hydrochloratis	gr. i	0.06
	Cerii oxalas	gr. xvi	1.0
	Aquæ aurant. flor	f.℥i	30.0

M. Sig.: Shake the mixture and give one teaspoonful every half hour when needed.

Many substitutes for cocain, of greater or less merit, have been brought forward by manufacturers, and while they have been widely heralded as being superior to cocain, they are not free from disadvantages; though the manufacturers have not, as yet, devoted much time or space to the exploitation of these several disadvantages or dangers. Their further consideration, however, does not belong in a treatise on the Pharmacopeia.

THE ATROPIN GROUP.

Atropin, which has been mentioned among the analgesics, acts locally as an anesthetic, its effects resembling those of cocain, but being weaker.

OFFICIAL PREPARATIONS.

ATROPINA.—U. S.—Atropin is officially described as an alkaloid obtained from *Atropa Belladonna* and from other plants of the same family. As it occurs in commerce, it is usually contaminated by a small amount of hyoscyamin from which it can not be readily separated.

Atropin is soluble in 450 parts of water and in 1.5 parts of

alcohol. It is very poisonous, the average dose being 0.0004 gm. (1/160 grain), and, therefore, it should be tasted with the utmost caution and only in dilute solution.

ATROPINÆ SULPHAS.—U. S.—This is the sulphate of the alkaloid atropin. In its physiologic properties and dose, atropin sulphate corresponds closely to atropin. It is soluble in less than one part of water and in about four parts of alcohol.

OLEATUM ATROPINÆ.—U. S.—Oleate of atropin is a mixture of equal parts of oleic acid and olive oil containing 2 per cent. of atropin, in solution.

EXTRACTUM BELLADONNÆ FOLIORUM.—U. S.—Extract of belladonna leaves is directed to be made with a menstruum consisting of two parts of alcohol and one part of water, and should contain, when assayed according to the process given in the Pharmacopeia, 1.4 per cent. of mydriatic alkaloids.

UNGUENTUM BELLADONNÆ.—U. S.—Belladonna ointment contains 10 per cent. of extract of belladonna leaves in a mixture of hydrous wool fat and benzoinated lard.

EMPLASTRUM BELLADONNÆ.—U. S.—Belladonna plaster is now directed to be made by mixing 30 parts of extract of belladonna leaves with 70 parts of adhesive plaster, and corresponds closely with the widely used, commerical, rubber-base plasters. It is further directed that spread belladonna plasters should yield, when assayed by the process given in the Pharmacopeia, not less than 0.38 nor more than 0.42 per cent. of mydriatic alkaloids.

FLUIDEXTRACTUM BELLADONNÆ RADICIS.—U. S.—Fluidextract of belladonna root is directed to be made with a mixture containing four parts of alcohol and one part of water, and should yield, when assayed by the process given in the Pharmacopeia, 0.5 per cent. of mydriatic alkaloids from belladonna root.

LINIMENTUM BELLADONNÆ.—U. S.—Belladonna liniment is virtually a solution of five parts of camphor in a sufficient quantity of fluidextract of belladonna root to make 100 parts.

FLUIDEXTRACTUM STRAMONII.—U. S.—This is directed to be made from the leaves of *Datura Stramonium* with a menstruum containing two parts of alcohol and one part of water. The finished fluidextract is required to contain 0.35 per cent. of the mydriatic alkaloids from stramonium.

EXTRACTUM STRAMONII.—U. S.—Extract of stramonium is made by evaporating the fluidextract to the required consistency, and should contain 1.4 per cent. of mydriatic alkaloids.

UNGUENTUM STRAMONII. U. S. Stramonium ointment contains 10 per cent. of extract of stramonium in a mixture of hydrous wool fat and benzoinated lard.

Atropin and the extracts of belladonna and of stramonium, in the form of ointments, belladonna plaster and belladonna liniment are very commonly employed as local applications for the relief of the various neuralgias. The members of the atropin group are said to be more efficacious in facial than in other neuralgias, but they are also used for the intercostal variety and for lumbago.

Belladonna plasters are very commonly used, particularly by the laity, for a variety of pains, often serving merely to protect the surface or for the retention of body heat.

Suppositories of extract of belladonna are frequently used with benefit in the treatment of hemorrhoids.

They may be directed somewhat as follows:

R.	Extracti belladonnæ	fol. grs. i	0.06
	Olei theobromatis.....	3ii	8.00

M. Ft. Suppositoria No. viii.

Sig.: One every four hours, as directed.

Belladonna ointment may be used for the same purpose. It may be directed to be spread on a little cotton which is placed in contact with the piles and they are then replaced in the rectum. If they still tend to protrude a pad of cotton is placed over the anus and held in position by a bandage. For men the bandage may be attached to the suspenders, both back and front, when the severity of the attack is not such as to compel the patients to lie down.

It must be remembered that the extract of belladonna, whether applied as a suppository or ointment, is rapidly absorbed and the amount so used must not exceed the therapeutic dose.

ACONITE.

Aconite owes its action almost entirely to aconitin, an alkaloid which, like cocain, is composed of a base united to an aromatic acid. Closely resembling aconitin in its local action is veratrin. They both cause irritation when applied to the mucous membrane.

The effect of aconitin when taken by the mouth is very characteristic, the local effect being a tingling and then a disagreeable sensation in the throat which has been variously termed itching or "scratching." Applied to the skin aconitin causes sensory stimulation, which is succeeded by local anesthesia without the production of rubefaction.

Aconitin is much less efficacious than cocain as a local anesthetic, and, of course, its injection is wholly inadmissible, but it is much more useful in the form of a liniment which is to be applied to the unbroken skin, through which aconitin may penetrate to a slight extent.

OFFICIAL PREPARATIONS CONTAINING ACONITIN.

ACONITINA.—U. S.—An alkaloid obtained from the official aconite, the tuberous root of *Aconitum napellus*. There are a number of closely related species of aconite that contain alkaloids which differ widely in their physiologic action and dose. The now official aconitin is the purified crystalline alkaloid of the official root and should not be confounded with the amorphous alkaloid formerly official or with any one of the more potent alkaloids obtained from other species of aconite.

Aconitin is soluble in 3,200 parts of water and in 22 parts of alcohol. On account of the poisonous character of this alkaloid it should never be tasted, except when in very dilute solution.

Average dose: 0.00015 (0.15 mg. 1/400 grain).

FLUIDEXTRACTUM ACONITI.—U. S.—Fluidextract of aconite is directed to be made from the powdered root of *Aconitum napellus* with a menstruum composed of three parts of alcohol and one part of water. It should contain no less than 0.4 per cent. of aconitin.

TINCTURA ACONITI.—U. S.—This tincture now represents 10 parts of the crude drug, instead of 35 parts, as formerly official. It is made with a menstruum containing 7 parts of alcohol and 3 parts of water, and the finished tincture should contain 0.045 per cent. of aconitin.

Veratrin.

Somewhat closely related to aconitin, in its various properties and uses, is veratrin, which is official in several well known forms.

VERATRINA.—U. S.—The official veratrin is a mixture of alkaloids obtained from the seeds of *Asagræa officinalis*. It occurs as a white or a grayish-white amorphous powder that is soluble in about 1,750 parts of water and in 2.2 parts of alcohol.

OLEATUM VERATRINÆ.—U. S.—Oleate of veratrin contains 2 per cent. of veratrin in a mixture of equal parts of oleic acid and olive oil.

UNGUENTUM VERATRINÆ.—U. S.—Veratrin ointment contains 4 parts of veratrin with 6 parts of expressed oil of almonds and 90 parts of benzoinated lard.

LOCAL USES OF ACONITIN.

Aconitin is sometimes used locally in the form of an ointment (from 1 to 100 to 1 to 500), or in the form of an oleate, made similarly to the official oleates of atropin or of veratrin, of 2 per cent. strength, for the relief of rheumatism and neuralgia. Inasmuch as it is absorbed in these forms from the unbroken skin, and much more rapidly from wounds or mucous membranes, it must be used with caution.

For facial neuralgia it may be prescribed as follows:

R.	Aconitini	gr. iij	0.20
	Alcohol q. s. to dissolve		
	Adipis	3iv	15.

M. Ft. unguentum Sig.: Apply a very little of the ointment over the seat of the pain.

The fluidextract of aconite may be further concentrated and used in the form of an ointment, or it or the tincture of aconite may be used as a liniment, applied on cloth, and a hot pad or water bottle laid over the surface.

For muscular rheumatism a liniment composed of equal parts of the tincture, or a corresponding amount of the fluidextract and soap liniment may be rubbed on the surface, or, if desired, this liniment may be further varied by the addition of chloroform liniment, or other alcohol soluble rubefacient in place of the soap liniment.

The following is the formula recommended by Magitot for toothache.

℞ Tincturæ aconiti
Chloroformi, āā.....m. xlv 3
Tincturæ benzoini.....m. cl 10
M. Apply as needed.

Phenol.

Phenol, or carbolic acid, has been considered under the subject of antiseptics.

Applied to the skin, pure or in concentrated solution, it causes tingling and some pain with the formation of a white eschar and a rapidly induced partial or complete anesthesia of the part. It is so prone to absorption when weak solutions are used that its usefulness is interfered with to a great extent.

OFFICIAL PREPARATIONS OF PHENOL.

PHENOL.—U. S.—The Acidum Carbolicum of former pharmacopeias occurs as separate needle-shaped crystals or as a white crystalline mass that is soluble in about 20 parts of water, but is freely soluble in alcohol, glycerin or in fixed or volatile oils. Phenol will absorb or dissolve from 15 to 20 per cent. of water, and then occurs as a colorless or slightly reddish liquid.

PHENOL LIQUEFACTUM.—U. S.—Liquefied phenol should contain not less than 86.5 per cent. by weight, of absolute phenol and about 13.6 per cent. by weight of water.

GLYCERITUM PHENOLIS.—U. S.—Glycerite of phenol consists of 20 parts of liquefied phenol and 80 parts of glycerin, by measure.

UNGUENTUM PHENOLIS.—U. S.—Ointment of phenol is now directed to contain 3 per cent. of phenol, in white petrolatum.

Phenol is rarely if ever used for the production of anesthesia preliminary to incising the skin, but, in the form of the glycerite or, preferably, the ointment, it is very useful in allaying the pain of small ulcers and burns. It may momentarily increase the pain, but this is soon followed by lessened sensibility.

It is, of course, obvious that the use of phenol is not permissible where large surfaces are to be treated.

When antisepsis is not of especial importance the ointment is to be preferred, as the continuous application of even comparatively weak aqueous solutions to the extremities has caused gangrene.

THE AMERICAN MEDICAL ASSOCIATION.

ITS PURPOSES AND OBJECTS HISTORICALLY CONSIDERED.

In the 59 years which have elapsed since the organization of the American Medical Association a number of changes have been made in the original constitution and in the provisions regarding membership, delegates, etc. As few of the present members of the Association know the history of the development of the Association we have thought it advisable to consider them under the heads of the various points involved. We shall, therefore, first discuss the question of membership, later taking up matters relating to qualifications and election of delegates and the relations of county, state and national organizations to each other, as well as some historical points regarding the attitude of the Association toward medical education, proprietary medicines, medical registers, etc.

MEMBERSHIP.

The original plan of organization as adopted in 1847 provided that "members of the American Medical Association . . . should hold their appointment to membership either as delegates from local institutions, as members by invitation, or as permanent members." There are thus created three classes of membership, of which the delegates constituted the bulk and the most important part. They received their appointment from "permanently organized societies, medical colleges, hospitals, lunatic asylums, and other permanently organized medical institutions of good standing." Each appointment was for one year. The basis of representation was one delegate for every 10 regular resident members of the medical society, two for every regularly constituted and chartered school of medicine, two for every hospital containing 100 inmates or more, and one for all permanently organized medical institutions of good standing not included in the above summary. In order to admit of representation from portions of the United States not otherwise represented provision was made for members by invitation. If a physician from sections of the country in which no medical institutions of any sort existed attended an annual session, the Association could constitute him a member by invitation for that session only. He thus became an unofficial delegate for a section that would otherwise be without representation. Thus two classes of members, both, as will be seen, of a purely temporary character and deriving their right of membership either from the organization which they represented, or from the Association which invited them to a seat in its deliberations, constituted the voting membership of the American Medical Association. In order that delegates having once been members of the Association might retain some connection with it after their time as delegates had expired, it was provided that all those who had served in that capacity and such other members as might be appointed by the Association, by unanimous vote, might be made "permanent members." They were entitled to attend the meetings and to participate in the affairs of the Association, without the right to vote. It was, therefore, recognized from the time of the first preliminary convention in 1846, that the right to vote should be limited to the duly elected and qualified delegates of local medical societies, colleges and hospitals, who came bearing credentials of their election as such.

It is evident that by 1850 the provisions regarding members by invitation were being somewhat abused and that many men were proposed at each meeting who, it was thought, were not entitled to this distinction, inasmuch as Dr. Ware of Massachusetts, at the third annual session at Cincinnati, offered a resolution providing for the appointment of a committee, on the first day of each session, to which should be referred all nominations for membership by invitation. At the same session Dr. Hooker of Connecticut and Dr. Evans of Kentucky offered resolutions providing for the repeal of the section of the Constitution relating to members by invitation.

The year following, 1851, at the Charleston session, a minority report was brought in from the committee on amendments of the Constitution, recommending that permanent members be allowed the privilege of voting. According to the official minutes, "the vote being then taken on allowing permanent members the right of voting, it was lost by a large majority."

It will thus be seen that the principle was recognized and steadfastly adhered to from the beginning, that the Association was a delegated body, representing societies in affiliation. No further change of any importance was made until the session of 1869, at New Orleans, at which an amendment was adopted which emphasized the fact that continued membership in a county or state society, where one existed, was essential for eligibility to membership in the American Medical Association, and that continued membership in local societies was necessary for continued membership in the American Medical Association. This applied to permanent members, as well as to delegates and members by invitation.

THE CONSTITUTION REVISED.

In 1874, at the twenty-fifth session at Detroit, Dr. N. S. Davis submitted a report from the committee on revision of the Constitution, which was adopted. The clause regarding delegates, as recommended, provided only for delegates from "permanently organized state medical societies and such county and district medical societies as are recognized by representation in their respective state society and from the medical department of the Army and Navy of the United States."

Later on the United States Marine-Hospital Service was given representation on the same basis as the Army and Navy.

It will thus be seen that the American Medical Association was, from the very moment of its organization, a delegated

body; that only properly elected delegates with credentials from the bodies which they represented were entitled to vote, and that the Association repeatedly refused the privilege of voting to any others except delegates.

In 1881 provision was made for a fourth class of members, viz., members by application. It was provided that members of state or county societies certified to be in good standing by the president and secretary of said society, might make application for admission as members by application. Such members were entitled to receive THE JOURNAL and to attend annual sessions, but without the right to vote. (JOURNAL of the A. M. A., Vol ii, 1884, page 702.)

These provisions regarding membership remained in force up to the St. Paul session, in 1901, at which time the committee on reorganization, appointed the previous year, brought in its report, which was adopted at this session. No change of any importance was made, so far as the provisions regarding membership were concerned, except that county and district societies were now united to form state societies, which were the only ones recognized by the American Medical Association. To-day, as always, membership in an "affiliated" society is required for membership in the American Medical Association. Members of county and state societies do not and never have voted directly, but solely through their duly elected representatives. Two changes were made by the new Constitution adopted at the St. Paul meeting, one being to change the basis of representation from one delegate to every 10 members, to that of one delegate to every 500 members. This change was found necessary on account of the enormous increase in membership, in order to reduce the number who sat as delegates to such a size as would make efficient work possible. Previous to the St. Paul session the proportion of delegates to members was so large that practically every one attending the meeting could and did go as a delegate. The revision of the Constitution reduced the number of delegates to 150, leaving the bulk of the members free to attend the scientific and social features of the session. The other change made was giving this delegated body the specific name by which it is now known, viz., the House of Delegates of the American Medical Association.

It will, therefore, be seen that historically the House of Delegates is the legitimate successor and direct outgrowth of the delegated body known as the American Medical Association.

BODIES ENTITLED TO REPRESENTATION.

Closely related to the matter of membership is that of the bodies entitled to send delegates to the annual sessions of the American Medical Association. In February, 1846, the following resolution was adopted by the Medical Society of the State of New York, the body which issued the call for the preliminary convention: "Resolved, That the preamble and resolutions passed by this society at its annual session, Feb. 6, 1845, did not contemplate the appointment of delegates to the national convention by county or merely local societies in these states, where delegates are appointed by a regularly organized state society." (Proceedings, vol. i, pp. 9-10.) The principle is here clearly recognized that the Association consisted of delegates appointed by state societies, and that delegates from county or district societies were only to be admitted in such states as had no regularly organized state society.

In the first Constitution adopted, as has been seen, it was provided that the American Medical Association should consist of duly elected delegates from medical societies, medical colleges, hospitals and insane asylums. In 1874 representation from hospitals and asylums was abolished. In 1872 the adoption of a new Constitution abolished delegates from medical colleges and provided for delegates from medical societies alone, with the exception of a representative of the medical service of the United States Army and the United States Navy. Later on a representative from the Marine-Hospital Service was added.

SUMMARY.

Summarizing the history of the American Medical Association for the last 59 years, we note: 1. The American Medical Association was from the beginning and always has been a delegated body. 2. Primarily only those persons elected as delegates could become members. Various classes of membership were gradually added, for the reasons enumerated above. Up to the time of the establishment of THE JOURNAL, the only way in which membership could be obtained was by attending an annual session of the Association, either as a delegate or by being elected as a member by invitation. 3. Membership by application was devised to allow members of county and state societies to become members of the American Medical Association without being elected a delegate, or attending an annual session of the Association. 4. The original basis for delegates was one to every 10 members of a state or local society; the present basis is one to every 500 members. With more than 50,000 members of constituent state associations as at present, the House of Delegates on the old basis might include 5,000 members, a number so large as to make the transaction of business absolutely impossible. It is now limited by the Constitution to 150 members, of whom 15 represent the sections and government services. Whenever the number of delegates exceeds this number a reapportionment on a different basis is provided for.

OTHER LINES OF WORK.

The American Medical Association was organized primarily for the purpose of raising the standard of medical education. This question and the relation of the Association to medical schools was discussed at nearly every session of the Association. In 1847, when the Association was organized, there was not a single licensing or examining board in existence in any state in the Union. A diploma from a medical college carried with it the license to practice medicine. It is to the credit of Dr. N. S. Davis that he persistently fought for the establishment of the principle that the licensing body which confers legal right to practice medicine should be entirely and absolutely divorced from the educating or degree-giving body. This question came up every year and resolutions were repeatedly adopted asking different state societies and members of the Association to work for the enactment of a law in every state providing for the organization of a licensing board which should examine all candidates for the right to practice medicine, or at least pass on diplomas presented by them. It is not too much to say that the influence of the American Medical Association more than any other one factor has been responsible for our present system of state examining boards and licensing bodies.

MEDICAL COLLEGES.

Regarding medical colleges themselves, efforts on the part of the Association to improve them extends over practically the entire existence of the Association, and would require too much time for detailed presentation. It is sufficient to say at this time that the Association has continuously and persistently worked for two things: First, the raising of the standard for admission in medical colleges, in other words, the improvement of preliminary education; and, second, the betterment of the courses offered to medical students. Owing to the lack of effective organization up to a short time ago, the work of the Association had been largely limited to the adoption of resolutions and the exercise of personal influence. The Council on Medical Education established recently by the House of Delegates is the first real effective measure inaugurated. It is hoped that it will be able to undertake positive reformatory work along the lines of medical education.

PHARMACEUTICAL REFORMS.

On account of the prominence that has been given in the last year to the work of the Council on Pharmacy and Chemistry and the agitation against nostrums and proprietary preparations, many members of the Association, as well as many physicians not in close touch with the work of the past, labor under the impression that such work on the part of the Association is of comparatively recent origin. An inspection of the transactions of the Association since its organization does not bear out this assumption, however. On the contrary, we find that one of the first questions which came before the preliminary convention in 1847 was the regulation of pharmaceutical matters and of "patent" and proprietary remedies.

The following resolution was offered by Dr. John B. Johnson of Missouri and adopted:

WHEREAS, Numberless and important evils result from the almost universal practice of allowing persons, wholly ignorant of drugs and medicines to engage as apothecaries and still greater evils result from the universal traffic in patent and secret medicines, therefore be it

Resolved, That the Committee on Education inquire into the expediency of establishing a school or schools of pharmacy in the respective states for the special purpose of preparing persons for the business of apothecaries, and also the expediency of adopting a rule that no physician ought to patronize a druggist or apothecary who deals in patent and secret remedies, and report at the next annual meeting of the Association.

DRUG ADULTERATION.

The adulteration and substitution of drugs and pharmaceutical preparations were also considered at the subsequent meeting and committees appointed to work for the enactment of laws prohibiting the adulteration of medicinal preparations. At the session of 1849, Dr. Thomas Wood presented the following resolution, which was universally adopted:

Resolved, That the Committee on Medical Science for 1849 be instructed to inquire into the expediency of establishing a board to analyze the quack remedies and nostrums foisted on the public and to publish the results of their examinations in a newspaper to be published for that purpose, and, further, to append such plain views and explanations thereto as will enlighten the public in regard to the nature and dangerous tendencies of such remedies.

This resolution, adopted fifty-seven years ago, outlines exactly the object and scope of the present Council on Pharmacy and Chemistry, which has been denounced in the last few months as a dangerous innovation and something entirely outside of the original purpose of the founders of the Association. For the present, however, the work of the Council in investigating nostrums advertised exclusively to the public is only incidental, its main work now being directed to the investigation of proprietary preparations advertised to physicians. The only reason why the work was not prosecuted at that time was that the infant association was without the funds for the successful undertaking of such a work. That social conditions were much the same fifty years ago as they are to-day is shown by the following resolution offered by Dr. Phelps of New York in 1850:

WHEREAS, The clerical profession, even though perhaps sometimes unwarily, yield their extensive influence in the community in giving credence to quackery and quack medicines, therefore be it

Resolved, That this subject be referred to the Committee on Hygiene to consider and report at the next annual meeting of the Association.

Dr. Lawson of Ohio offered the following amendment to the resolution:

Resolved, That this Association regard it as contrary to its system of ethics for medical journals to advertise nostrums or secret remedies, even though their composition may have been made known to the editor.

Both of these resolutions were adopted.

(Transaction, vol. iii, pp. 42 and 43.)

In 1879, Dr. William Brody of Michigan presented the following resolution:

WHEREAS, Of late years many drugs and combinations of drugs bearing copyright names, have been placed on the market and especially introduced to the notice of physicians, and

WHEREAS, Such drugs and combinations of drugs, having copyright names, are advocated in the medical journals of the country. Be it

Resolved, That the use of articles thus protected by copyright and the promoting of their use by advertising them in medical journals is a distinct violation of Section 4, Article 1, of that portion of the Code of Ethics treating on the duties of physicians to each other and to the profession at large, and also of Section 4, Article 1, of that portion of the Code of Ethics, treating on the duties of the profession to the public and of the obligations of the public to the profession. (Transaction, vol. xxx, 1879, p. 45.)

It will thus be seen that the regulations and control of pharmaceutical products has been one of the questions prominently before the Association ever since its organization; that the Association has repeatedly expressed itself as opposed to the exploitation of proprietary products having a secret formula; that it even went so far at one time as to establish a committee for the investigation of these preparations and the publication of their findings to the profession and to the laity; that the only reason why this work was not done years ago was the absence of proper organiation and the lack of a sufficient fund for the prosecution of this work.

OFFICIAL REGISTER OF PHYSICIANS.

The publication of a register of American physicians, which so far as possible, should oe of an official nature, was one of the subjects on which the newly organized Association expressed itself at the preliminary convention in 1847. The following resolution was offered by Dr. J. L. Pierce of Michigan, and was adopted:

Resolved, That the delegates of this convention be requested to ascertain as far as may be practicable and report at the next annual meeting the number of practitioners of medicine in their respective states, designating the number who may have received diplomas from a medical college, the number who may have been licensed by a medical society (a practice then in vogue), and the number who practice medicine without any authority whatever.

AMERICAN MEDICAL DIRECTORY PROPOSED IN 1849.

In 1849, Dr. Bacheldor offered a resolution providing for the publication by the several counties and districts represented in the Association of all the physicians and surgeons of such districts who are recognized as regularly educated practitioners. In this connection, it is worthy of note that the phrase, "regularly educated practitioners," refers to physicians who were graduates of medical colleges as distinguished from those who had no training whatever. In 1856, Dr. Denton of Michigan offered the following resolution:

Resolved, That a committee of three be appointed whose duty it shall be to enlist some enterprising publishers to aid in collecting and arranging material for an American Medical Directory. (Trans. vol. ix, p. 41.)

In 1868, Dr. S. D. Gross, then President of the Association, said in his President's address, "The necessity of having an annual register of the members of the regular profession of the United States has long been felt and generally acknowledged. The issuance by the association of such a publication or an expression of its belief in its necessity and usefulness would go far in securing its early appearance and its steady reissue afterwards." (Trans., vol. xix, p. 66.)

The same year the following resolution was adopted, evidently inspired by Dr. Gross' remarks:

Resolved, That a committee be appointed to report next year in regard to the subject of an annual register of the regular profession in the United States and in the meantime to take necessary measures to carry the plan into effect. The following committee was appointed: Dr. John H. Packard, Pa., Dr. Walter E. Gibbon and Ellsworth Elliott, New York. (Trans., vol. xix, 1868, p. 35.)

The following year Dr. Packard, as chairman of the committee, reported progress, and on motion of Dr. Mussey of Ohio, it was resolved that each state medical society be requested to prepare an annual register of all the regular practitioners of medicine in their respective states, giving the names of the colleges in which they may have graduated and the date of diploma or license . (Trans., vol. xx, p. 20.)

The following year, 1870, on motion of Dr. John H. Packard, chairman of the committee, it was:

Resolved, That the Committee on a National Medical Register, appointed in 1868, be discharged and that the whole matter of registration of physicians be referred to the various state medical societies; and

Resolved, That this action of the Association be communicated by the permanent secretary of the said societies that the recommendation that some system be adopted by each so that lists as complete as possible of the practitioners of medicine in the state may be procurable. (Trans., vol.xxi, 1870, p 49.)

It will thus be seen that the matter of a compilation and publication of a register which would be based on official information, as far as possible, has been in the minds of the leaders of the Association ever since its organization. At various times in the last fifty years, local, state and national directories have been published by private parties. As the amount of profit from sales of such a work is necessarily limited, the publishers have been forced to supplement the subscription receipts by carrying advertisements, in many cases of an objectionable nature, and especially by offering, as a special inducement to subscribers, or on payment of a small bonus, the publication of the name of the subscriber in conspicuous type, or the addition to his name of a large amount of extra information. Such methods, perfectly legitimate and unobjectionable from a business standpoint, have necessarily lowered the value of the directory from a professional point of view, inasmuch as the men who are the most eager and willing to pay for prominence and notice are not necessarily the most prominent and worthy members of the profession. No directory heretofore published has made any attempt to confine its entries to legally qualified physicians or to verifying data furnished by individuals by comparison with the official records. The profession needs, and has needed a directory

compiled from official records in which all would be treated alike, regardless of subscription or the payment of a bonus; in other words, a directory published for information, not for profit.

THE ASSOCIATION JOURNAL.

The only remaining factor in the history and development of the Association which we shall consider at this time is the establishment of THE JOURNAL and its effect on the Association. Up to 1882, the proceedings of the Association were published in a volume of transactions which was distributed free to all members of the Association. The membership at that time was less than 2,000, and as the annual dues were $3.00, the financial transactions of the Association amounted to from five to seven thousand dollars in a year, the greater part of which was spent in publishing and distributing the transactions. An examination of the treasurer's reports for the thirty-five years from 1847 to 1882, shows that there was, most of the time, a purely nominal surplus. At one time, however, the cost of publication of the transactions exceeded the amount of receipts from dues so that, in 1866, the treasurer reports as follows: "The difficulties which have been alluded to in these reports have resulted, as therein foretold, in the bankruptcy of the Association. The permanent members of the American Medical Association will not purchase the volume of transactions, although local agencies have labored in the most important cities in the country and circulars have been sent to individual members and publication made in the leading medical journals. The fact has been again and again demonstrated that the members of the American Medical Association do not consider the volume worth the cost of its production." (Trans., vol. xvii, p. 49.) At this time the treasurer also reported a deficit in the treasury of the Association of $404.02.

THE ASSOCIATION IN DEBT.

The following year, 1867, Dr. D. H. Storer, of Massachusetts, "rose to a privileged question, the honor of the Association. It was in debt and he proposed to levy a tax of $2.00 on each member present to liquidate the debt." (Trans., vol. xvii, p. 33.)

The members of the Association were inclined to be remiss in paying their dues. In fact, many of them refused to pay any dues whatever unless they attended an annual session, and, as it was necessary for a member to be three years in arrears before he lost his privileges of membership, it was only necessary for a permanent member to pay $3.00 every three years, or an average of $1.00 a year, in order to retain membership in the Association. The organization was consequently without funds, without any definite or permanent membership, without any home, without any officers who could afford to devote any time to looking after its affairs. In fact, it was practically nothing but an annual mass-meeting, made up of delegates from the various societies throughout the country, many of which had no mutual bond whatever between them. The amount of funds at the command of the Association were so limited as to make any practical work for the improvement of the profession or the public impossible. For instance, in 1868, the report of the treasurer showed a balance for the year of $83.90. (Trans., vol. xix, p. 53.)

JOURNAL FIRST PROPOSED.

The matter of the establishment of a journal to be the property of the Association was proposed as far back as 1852, when Dr. J. B. Flint of Kentucky proposed to amend the Constitution so as to provide for the establishment and maintenance of a quarterly journal. (Trans., vol. v, p. 44.)

The matter was agitated at various meetings of the Association, but no definite action was taken until the session of 1881, at which Dr. Hodgen, President of the Association, warmly advocated the establishment of THE JOURNAL, following which the following resolutions were adopted:

> WHEREAS, In the words of our president, it seems tolerably certain that if for the present bulky, little read and productive volumes of Transactions there could be an active, progressive weekly journal with a large income, such as would naturally come to it from its advertising sheet, there would be in such a change the earnest, rapid and improved growth in the influence and usefulness of the American Medical Association; therefore be it
>
> *Resolved*, That the president appoint a committee of five members, whose duty it shall be to digest and report in detail, as early as possible a plan for the publication of THE JOURNAL etc. (Trans., vol. xxxii, p. 479, 1881.)

The following year, in discussing this proposition, the committee, of which Dr. N. S. Davis was the chairman, reports that after investigating the matter, they are of the opinion that if 3,000 physicians should become members of the Association, paying $5.00 per year for membership, which would entitle them to THE JOURNAL, such membership to be limited to members of county and state societies, that the resulting fund of $15,000 would be sufficient to support the new JOURNAL. They therefore recommended that a journal, to be known as THE JOURNAL of the American Medical Association be issued. (Vol. xxxiii, p. 39, 1882.) This was accordingly done. Dr. N. S. Davis became the first editor of THE JOURNAL. The subsequent history and growth of the Association is known to practically all of the present membership. That the establishment of THE JOURNAL accomplished all the results expected of it is also well known. Its earnings have not only paid its known running expenses, but those of the Association as well, and there has also accumulated a surplus which has enabled the Association, besides gradually increasing the size and attractiveness of THE JOURNAL, to obtain a permanent home, a printing plant adequate for all the needs of the Association, and which now makes it possible, at this late day, to take up the plans and purposes of our professional forefathers and begin, actively and effectively, the work of raising the standard of medical education, investigating the preparation and composition of the drugs and pharmaceutical preparations furnished us, compiling and publishing an official register of the members of the profession, and of doing many things for the betterment of medicine that would not have been possible otherwise. That these movements will be of great value to the profession, both to those who are non-members as well as members of the organization, hardly admits of question. The physician of the future must be a better trained man than his predecessors have been. Both the public and the profession must be protected on the one hand against quacks and charlatans and on the other against frauds and impositions imposed on them for commercial purposes. These are the things for which the Association has been striving throughout the fifty-seven years of its existence, and which are now becoming, not theories, but actualities, which can be realized in the near future.

Clinical Notes

THE UMBILICAL CORD.

A METHOD OF DRESSING.*

A. L. BELT, M.D.

GILMORE CITY, IOWA.

When the first stage of labor is nearing completion it is my custom to procure a common glass tumbler, in which 1/2,000 or 1/3,000 solution of bichlorid of mercury with sterile water is prepared, and into this several pieces of sterile gauze and three strong braided silk ligatures are placed. A pair of shears and a compression forceps are then put in a sterilizer or basin on the stove to boil.

The second stage of labor completed, I tie the cord at two points about six inches from the child's body, cut between and pass the child to the nurse to wash while I care for the mother.

When ready to dress the cord, the hands being sterile, I wash the child's abdomen and the cord with a piece of gauze taken from the bichlorid solution previously prepared, carefully cleansing the base of the cord and the omphalic folds.

This done, I examine the cord for possible congenital hernia, and not having found it, or having reduced it if found, I place the compression forceps on the cord as nearly on a level with the margin of the umbilicus as feasible and make firm pressure for the space of a minute. Removing the forceps, with the third prepared ligature I now tie securely in the path of the forceps just removed. In this way pressure is so applied to the walls of the umbilical artery that there is no danger from hemorrhage "when the cord shrinks."

* Read before the Sioux Valley (Iowa) Medical Society, Jan 18, 1906, at Sioux City, Iowa

I next cut the cord one-half inch from the ligature with sterile shears, thus removing the end of the cord handled by the nurse in washing the child, and with one of the remaining pieces of bichlorid gauze press out all the contents of the cord possible above the ligature, by this method removing all the dead tissue possible. The stump is then covered with some good antiseptic powder.

Then I take an ordinary vaccination shield, fill it either with sterile cotton or dry sterile gauze, on which more of the same powder is dusted, and placing it over the cord secure it in place with a couple of strips of adhesive plaster placed transversely and apply the band.

Already the attention and the admiration of every one in the room, even to the old grandmother, has been attracted by this dressing, and when I admonish them to allow the dressing to remain for six or eight days and then remove it I have no trouble in the carrying out of my orders, and they will promptly report to me if the dressing slips or comes off.

This dressing is particularly valuable in the country, for often we do not see either mother or child for six months or a year after confinement, and some form of a permanent antiseptic dressing is a very desirable thing.

In conclusion, the benefits of this method of cord dressing are: 1, absolute cleanliness; 2, simplicity of application; 3, permanency; 4, freedom from danger of hemorrhage either from (*a*) shrinkage of the cord or (*b*) the tearing or pulling of the cord when it becomes attached to band by drying of its exuded contents in the ordinary method of dressing; 5, the minimum danger of infection. (a) primary or (b) by the removal of the original dressing and the application of a new one by some unskilled attendant; 6, diminished danger of umbilical hernia.

REPORT OF A CASE OF FRACTURE OF THE ATLAS VERTEBRA, WITH COMPLETE RECOVERY OF PATIENT.*

ARTHUR HOLDING, M.D.

ALBANY, N. Y.

Patient.—Male, aged 68, was referred to the Roentgen ray laboratory of the Albany Hospital by Dr. W. G. MacDonald, Albany, N. Y. Previous occupations, dectective, soldier in Confederate army. Present occupation, broker.

Family History.—Father, mother, two brothers and two sisters died of tuberculosis.

Past History.—He uses stimulants. Three years ago he was hit on the head with a brick; the blow rendered him unconscious for a few minutes, but beyond the swelling of the scalp, it did not injure him.

Present Illness.—Nov. 16, 1905, when near the top of a flight of stairs composed of eight steps, while turning to one side to allow some ladies to pass in descending the stairs, he remembers losing his balance and beginning to fall backward; he made a futile grasp at the banister, but fell, landing at the bottom on the back of his head, neck and shoulders. He was under the influence of liquor at the time of the accident. He received several cuts in his scalp over the vertex of the skull. None of them extended to the skull. The patient was placed in bed, and was evidently not thought in a serious condition, as no physician was summoned until two days afterward. At that time the patient was conscious, acted as though recovering from intoxication, complained of stiffness of the neck as well as considerable pain, which was eased by hot packs, and did not require morphin. On the sixth day after the accident slight delirium developed, the pain and stiffness of the neck increased, and Dec. 4, 1905, he was removed to the Albany Hospital. On admission to the hospital, he could not move his head or neck and complained of feeling as though the back of his head had been cut off and hot irons were being applied to the edges of the wound. With the back of his neck on hot-water bags and lying flat on his back he was comfortable, but as soon as he raised his head or tried to sit up the burning sensations returned in his occiput.

Examination.—Posteriorly in the median line the spinous processes could be palpated as high as the fifth cervical; above this point there was an area of muscular spasm, thoroughly masking all bony prominences to a point one inch below the external occipital protuberance. This area of induration or muscular spasm extended laterally as far as the sternomastoid muscles and suggested the sensation frequently felt over deep-seated inflammatory processes. The transverse processes of the vertebræ could not be mapped out without using more violence than was permissible considering the nature of the case. The trachea was freely movable; the tongue protruded in the median line; the pupil reacted directly and concentrically to light and accommodation. He could not distinguish the ticking of a watch held two inches from the ear. He stated that he was deaf before the accident. On palpating the posterior wall of the pharynx with the finger, on a level with the hard palate there could be felt a distinct hard protuberance beneath the mucous membrane, with an estimated elevation of one-fourth inch and with broad sloping sides. Gentle pressure on this eminence elicited no tenderness or fluctuation.

Over the right parietal region he failed to distinguish heat from cold, saying that a test-tube containing hot water felt cold; otherwise there was no impairment of tactile, temperature and painful sensation in the head or neck. He has an impediment of speech, which he states developed forty years ago. There was no difficulty in swallowing, articulating or breathing. He could rotate, flex and extend the head and neck.

Treatment.—This consisted of elevation of the head of the bed with extension applied to the head with weight and pulley, the neck resting on hot-water bags. One month after admission to the hospital the weights were removed and the patient was allowed to sit up. His improvement was steady and uneventful.

Result.—On Jan. 15, 1906, he was discharged as recovered. He has a slight forward tilt of the head, a slight induration of the soft parts over the first, second and third vertebræ (cervical), and all motions of the head are slightly restricted in all directions. Otherwise he is completely cured. He walks as well as ever and is able to carry on his business as well as he could before the injury. He has had no burning sensation in the occipital region since Jan. 15, 1906.

* Presented before the Albany County Medical Society, Feb. 12, 1906.

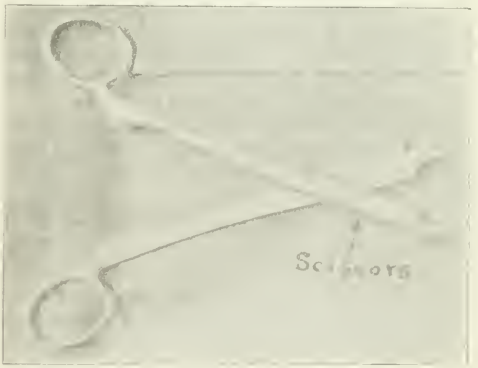
New Instrument

COMBINED NEEDLE-HOLDER AND SCISSORS.

HENRY FLACK GRAHAM, M.D.

BROOKLYN, N. Y.

The accompanying illustration shows a combined needle-



holder and scissors, which I am informed is a new combination. It is intended for office, accident ward and ambulance work, especially, but can be used with advantage in certain conditions in the operating-room. It is the same size as the Abbe needle-holder.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Cable Address . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance
[*For other information see second page following reading matter.*]

SATURDAY, JUNE 2, 1906.

THE MEDICAL LIBRARY AGAIN.

There are in this country several very large medical libraries, some of them as complete as any in existence. Thus the most complete medical library is that in the office of the surgeon-general of the U. S. Army, at Washington. Naturally, the other large libraries are located in large cities, the so-called medical centers of the country, although it is true that certain universities, whose homes are in smaller towns, have fairly extensive collections of medical books.

A few years ago a wave of agitation in favor of better and more medical libraries passed over the country, the influence of which is yet felt, especially in certain cities in which the desire to establish medical libraries seems to have taken firm hold. There has been organized, too, an Association of Medical Libraries which, in addition to holding an annual meeting, renders tangible service to its members by means of a bureau for exchange of books and journals. Then there is the *Medical Library and Historical Journal,* now in its third year and certainly an influential exponent of the cause of the medical library and of medical history, especially American.

There are now, it seems to us, two definite and distinct ways for enlarging the scope and the influence of the medical library movement, namely (1), continuation with renewed vigor of efforts looking to the establishment of real, growing libraries in the large cities, e. g., Detroit, Indianapolis, St. Louis, Omaha, Kansas City, Seattle, as well as in many other places now without the direct advantage of so essential a factor to local medical progress as the medical library; and (2) a larger use on part of medical men of existing libraries.

The time for discussing "The Need of a Medical Library" is passed long ago. Daniel Drake, the great pioneer physician of the Mississippi valley, in 1852, wrote: "Our own rising cities . . . should have their library associations, and collect those stores of scientific aliments, which are not less necessary to the mind's growth and activity, than daily observation at the bedside of the sick." The local conditions vary greatly, of course, and in some cities much may be accomplished by proper co-ordination of institutions of various kinds already in existence, in other places it may be necessary to start anew. In all cases, the outcome depends largely on the wisdom and energy of those in charge. There is no question but that if a small group of active, unselfish and intelligent physicians determine to secure for their city a useful medical library, they will certainly succeed.

The charge is undoubtedly true that comparatively few physicians make adequate use of the medical library. Many never delve deeper into medical literature than the text-book. Contracting the text-book habit during student days they remain content ever afterward with receiving information, so to speak, at second hand, and never think of going directly to the first sources of medical knowledge, namely, original articles in medical journals, complete sets of which, together with the *Index Medicus* and the "Index Catalogue" constitute the most valuable asset of the medical library. While there are many who seek not those stores of scientific aliments that Dr. Drake believed essential to the mind's growth and activity, every effort must be made to bring home to physicians the value and importance of medical libraries. The best time to begin is during the period of undergraduate medical study, and it is gratifying to note that in our best schools to-day the library is regarded as an essential part of the necessary equipment. It was Virchow who said that all scientific work is literary, which has been interpreted to mean that inasmuch as all progress in our knowledge is the result in reality of a continuous development, he who would understand thoroughly the present state of our knowledge on any subject must study the development of that knowledge, and this is possible only through access to collections of journals, monographs and special works, not usually in possession of individuals.

The treasures of the richest medical library can be brought within the reach of any physician by means of loans from the surgeon-general's library in Washington. Against an adequate deposit and on payment of express charges to and fro, this library sends books and journals all over the country. Local libraries can and do perform a most useful service by obtaining loans of this kind for their readers, and where desirable this function might be performed very well also by local medical societies, particularly if the *Index Medicus* and the "Index Catalogue," the indices to the current and accumulated medical literature of the world, were at hand. In this way, the medical society may aid its members materially and unquestionably to great advantage to the character of its own scientific work.

ANTITUBERCULOSIS ORGANIZATION.

The meeting of the National Association for the Study and Prevention of Tuberculosis, at Washington during the present month, and the reports of certain features of its proceedings in the newspapers, will direct renewed attention to the question of the further organization of the movement against tuberculosis which, up to the present time, has proved so encouraging. More and more those outside of the medical profession are becoming interested in the effort to suppress the great white plague of the North, and very naturally it is to physicians that

they turn for guidance in the matter of initiating and increasing the efficiency of public regulations and popular education that will help in this beneficent modern crusade. For those who wish to obtain data at once practical and up to date to reply to such questions we know of nothing better than the recent annual report of the Pennsylvania Society for the Prevention of Tuberculosis, which has just been issued and which includes details of this organization's work down to May 1, 1906.

It may not be generally known that this was the first society for the prevention of tuberculosis organized and that its organization furnished an example which was followed by most of the civilized countries and by the other states of the Union. A short history of its fourteen years of existence is to be found in the president's address, published in this report. Some of the achievements of the society are dwelt on with pardonable pride. It is pointed out, for instance, that until recent years the Eastern Penitentiary of the State of Pennsylvania, located in Philadelphia, which was built with the idea of enforcing solitary confinement to the utmost degree, constituted the awful example of how inevitably tuberculosis would work its ravages among such prisoners. Owing to the activity of one of the members of the Pennsylvania Society for the Prevention of Tuberculosis, however, this has all been changed and the Eastern Penitentiary is no longer a horrible example. This of itself constitutes the most encouraging lesson of how much can be accomplished for the prevention of tuberculosis even under unfavorable circumstances.

Perhaps the most interesting phase of the Pennsylvania society's work consists in the distribution of tracts which are meant to convey in popular language the most important details of present knowledge with regard to tuberculous prophylaxis. These tracts bear such practical titles as: 'How to Avoid Contracting Tuberculosis," "How Persons Suffering from Tuberculosis Can Avoid Giving the Disease to Others," "How Hotelkeepers Can Aid in Preventing the Spread of Tuberculosis," "How Storekeepers and Manufacturers Can Help to Prevent the Spread of the Disease."

With the long and successful experience that the Pennsylvania society has had, it will perhaps be a surprise to most persons to find that its president considers that the problem of tuberculosis sanatoria will probably have to be solved by private beneficence rather than state aid. He points out that in nearly every one of the middle states, in spite of the good will of the people and the passage of favorable laws by the legislatures, there have been serious difficulties in the management of state sanatoria because of political complications. These have proved sufficient to hamper materially the good work of such institutions. The existence of state-aided sanatoria has given to many wealthy persons who would have subscribed to the movement for the eradication of tuberculosis the ready plea that they are supporting state institutions for this purpose by the payment of taxes. The whole report for its suggestive quality is worth careful reading by those who have been interested in the tuberculosis movement and especially by such as now wish to take a more active part in what is probably the most promising field of social endeavor now open.

A FURTHER CONTRIBUTION TO THE STUDY OF UNTOWARD SERUM REACTIONS.

A few weeks ago[1] we referred to the so-called serum disease, in which annoying complications and sequels varying from slight local erythema to troublesome urticaria, joint pains and edema, are encountered with a frequency that has placed obstacles in the way of a wider use of curative serums, and engendered in some a prejudice against them.

Just issued from the Hygienic Laboratory of the Public Health and Marine-Hospital Service[2] is a noteworthy publication by Director M. J. Rosenau and Assistant Director John F. Anderson dealing with an elaborate experimental study of a newly identified poisonous action of blood serum. This investigation concerns itself with the guinea-pig and the reaction of this animal to horse serum in particular, both fresh normal horse serum, old serum, dried serum, antitoxic (diphtheric) serum, and the so-called "refined and concentrated" antitoxin obtained by precipitating and dialysing antidiphtheric serum. The authors have amplified and correlated observations already familiar to those engaged in the production of curative serums, to the effect that severe symptoms or even death occur in guinea-pigs once treated with horse serum, and, after a proper interval, subjected to a second injection of the same agent. They show by a series of brilliant experiments that this toxic action of horse serum bears a direct relation to the sequence of the injections and the interval between the first and second dose, which "incubation period" must not be less than ten days.

A primary injection, either subcutaneous or intraperitoneal, even in considerable amount, is absolutely innocuous; and if daily doses, or at least several doses, be administered during the critical period, harmful effects are avoided. Indeed, repeated injections with an interval of one or two days induced an immunity against the toxic substance in question. But if guinea-pigs are given a single large or small dose of horse serum, they become sensitized during the ten days or more, and when subjected to a second dose after this time has elapsed toxic phenomena indicating a profound effect especially on the respiratory mechanism appear, either with a rapidly fatal outcome or with symptoms of variable intensity leading to death or to recovery.

Emphasis is justly laid by Rosenau and Anderson on the fact that this phenomenon is in no way peculiar to ordinary diphtheric antitoxin. It is not evaded by antitoxin "refined" by the Gibson method, and is as readily provoked by normal horse serum, fresh, old, or dried.

1. THE JOURNAL, April 7, 1906, p. 1034.
2. Bulletin No. 29.

Much stress is attached to the statement, "Diphtheria antitoxin plays no part in this poisonous action and is in itself harmless." However, that the instructive experiments which are set forth in detail in their monograph have a bearing on the question of accidents in serumtherapy in man is concluded by these investigators, though they do not assume that the reaction studied by them satisfies all the conditions met in human beings, and they agree that factors like "individual susceptibility" and status lymphaticus are not entirely ruled out of consideration. In any event, these researches bring us a step nearer to the solution of the problem of serum complications and sequels, and along with a similar fact brought out by von Pirquet and Schick indicate at least one point which can be applied in practice; that is, so to time the injections of curative serums as to avoid the possible danger of sensitizing a human being. In other words, in beginning serum treatment, one should either inject a massive single dose to allow of slow absorption and consequent immunity or repeat a smaller dose several times during the ten days constituting the "incubation" or critical period.

EXPERT MEDICAL TESTIMONY.

It is a familiar fact that at the present time and under the system of practice now in vogue our courts are prevented from using expert medical knowledge in such a way as to secure directly, and to the fullest extent, the assistance that such knowledge is capable of giving to the administration of justice. The fundamental difficulty is that the final decision of complex, technical medical questions must be given by persons who lack the technical knowlege necessary, namely, the court and the jury; and this they must endeavor to do on a basis of more or less contradictory facts and opinions that are brought before them in a most confusing and cumbersome manner, to wit, by the so-called battle of experts.

It is evident that in many cases involving problems of a purely technical medical nature the persons best able to adjudicate with justness the medical questions at issue are those who, in addition to a sense of fairness and justice, possess expert technical knowledge and training. Who are better able definitely to decide, for instance, such questions as whether an accused is sane or insane; whether a dead woman had been recently pregnant or not; whether death resulted from poisoning or not; whether a claimant for damages is or is not injured, and, if injured, whether permanently and to what extent, and other questions of analogous nature—a jury composed, let us say, of intelligent, fair-minded but non-medical persons or a commission of equally fair-minded experts in the particular branch of medicine concerned? The answer is so obvious that our wonder is excited as to what the reason may be that Americans, who commonly are regarded at home and abroad as peculiarly gifted with the valuable faculty of doing things in a direct and practical way, have not long ago instituted reforms in the procedure of their courts of law. Surely our legal machinery is not rooted and fixed so irrevocably in constitutional regulations and precedents that adoption of some better system than the present of deciding important medicolegal problems, now passed on by persons without adequate knowledge and consequently incompetent to decide intelligently, is wholly out of question.

The present system of privately retained experts who appear as witnesses in our trials might well have been replaced long ago by the system of nominated experts in use in other countries, perhaps modified better to suit our conditions, whose opinion, derived from consideration of all the facts, should be final and constitute the basis for adjudication of questions that require for intelligent solution technical, expert knowledge. Naturally the fees of such experts should be fixed by legal tariffs. Only in some such way as this will it be possible for the administration of justice to obtain the greatest and most direct aid from expert knowledge in the various departments of medicine.

MENTAL DISEASES AND GENERAL PRACTICE.

Statistics show a great increase during the last few decades in the number of patients suffering from mental diseases. This increase is not only relative and due to the increase of population, but it is absolute in the sense that the number of insane people to the population is proportionately greater than before. There is little doubt that the reason for this greater frequency of mental affections is that the strenuous life in our large cities almost inevitably leads to a loss of mental equilibrium in those who are of inadequate mental caliber. The better hygiene as a consequence of the enforcement of sanitary regulations and advancement in medical science have led to the preservation of a great many weaker individuals who would have fallen victims either to the various infantile diseases in childhood or a little later would have succumbed to the infectious diseases which used to be such effective agents in removing the less fit from among the population. It is these less vital individuals whose minds especially prove incapable of standing the strain put on them by our modern life and who live to be the increasing population of our insane asylums.

There is no doubt but that these factors which are at work in the production of more frequent mental affections will continue to exert their influence. Hygiene and sanitation will persist in their beneficent work. There is no likelihood, however, of any let-up in the strenuous life. The present state of affairs would seem to demand that there should come a special development in present methods of studying and caring for the insane. It is extremely important that the beginnings of mental diseases should be recognized as early as possible, partly for the sake of the patient himself, because in this way a violent access of mental disturbance may be avoided, and partly for the sake of friends and relatives in order that there may be fewer of the sad attempts, only too often successful, at suicide or homicide. Every

general practitioner, therefore, should have definite knowledge of at least the ordinary and more frequent types of mental diseases, and especially of their early symptoms and of the possibility of serious development as regards violence or other infractions of law and order.

The time has come for the general practitioner to have a better understanding of mental diseases than has been thought necessary in the past.

One of the most important things regarding mental affections is that patients suffering from them should be brought as soon as possible under the influence of suitable surroundings. At present, owing to the lack of definite knowledge by many general practitioners, this most important element in the therapeutics of these diseases is likely to be neglected. Friends, because of their wish to avoid, if possible, the stigma of asylum confinement, are deterred from being urgent in the matter of care for such patients unless something serious seems actually impending. There is besides, unfortunately, under present circumstances the law's delay by which during the process of preparation for proper disposition, patients are often kept for some days under extremely unsuitable conditions.

If there were wards in general hospitals in which patients suffering from mental diseases could be cared for for a few days most of these difficulties would disappear. Friends would be willing to have patients taken to hospitals early, with the idea that careful observation should be made in order to determine the precise condition and to apply as far as possible suitable treatment. At present, the attitude of suspicious fear with which patients in beginning mental diseases are regarded by those at home is quite sufficient of itself to cause further deterioration of the mental condition. Many cases of mental diseases are sure to improve. The prognosis as to the improvement, however, depends to a large extent on how far the physical condition of the patient has suffered, and then the degree to which mental symptoms have been allowed to proceed before proper arrangements for treatment have been made. If early in the cases of beginning mania and melancholia patients could be placed under the firm, careful management of nurses trained properly to care for them, there would often not be the serious outbreaks of mental disturbance that eventually develops under present conditions.

It has been pointed out that it would be considered unpardonable in the present state of our knowledge if typhoid-fever patients had to be kept for several days under observation in unsuitable conditions. The same is true of mental diseases. Undoubtedly, many a patient is rendered much worse than would otherwise be the case by the neglect of his physical health consequent on lack of care, but still more on lack of knowledge of the necessities of his condition on the part of those who wish him well enough, but are too timorous and anxious properly to provide for him. Most of these unfortunate circumstances could be remedied at once by the establishment of psychopathic departments in connection with general hospitals. Many objections, of course, can be urged against this, but they do not seem of sufficient weight to overbalance all the advantages for the patients and the community that would accrue from it. This seems to be a definite advance demanded by the increase of mental diseases.

GERMS FROM MUMMIES.

In a rather curious monograph a French authority credits the spread of consumption in Europe to the archeologic investigations of the time of the first Napoleon in Egypt, when the mummies of the Pharaonic period, laden, as he says, with the germs of tuberculosis, were first sent out wholesale to the museums of Europe. He claims, it is said, that experiments made in Paris have demonstrated that these 3,000-year-old bacilli, in spite of the antiseptic methods employed by the Egyptian embalmers, are far more deadly than the active living ones of to-day, and that the opening of a mummy case is a perilous undertaking for those who have it in hand. This is news that we can not accept too implicitly. It seems much like the popular notion that the seeds of ancient Egyptian cereals found with the mummies are always ready to germinate under proper conditions, a notion which, we believe, botanists do not accept. Even if tuberculosis germs could exist and could still retain their vitality after 3,000 years, it would hardly be necessary to invoke their agency for the causation or even the exacerbation of tuberculosis in Europe 100 years ago. We suspect that if any reliable sanitary statistics could be obtained it would be found that there was no need of imported mummy tuberculosis at that time; affairs were bad enough as they were. It is just one of those sensational speculations which, while interesting and possibly even a little suggestive, are not helpful.

THE PURE-FOOD BILL.

At the present writing it looks very much as if the opponents of the Pure-Food Bill would win out again. For some weeks this measure has been the special order in the House of Representatives; but there it is blocked. Whether it will come up during this session, unless some special effort is made by its advocates outside of Congress, is now a little doubtful. There is no organization to represent the people, except the American Medical Association, to bring pressure on those who have the matter in charge; but there are any number of organizations to represent those who are opposing the bill. Aside from the whiskey trust, the "patent-medicine" association, the various manufacturers who are putting out misbranded or fraudulent foods, there are many others whose financial interests are at stake, and all these, collectively and individually, are continuously active in various ways. Gentlemen have been sent to Washington from all parts of the country to see their congressmen about the matter, and a little personal talk from an influential constituent often has considerable weight. If we are rightly informed, considerable of this influence has been forthcoming during the last few weeks. It is

well known that there is a goodly majority in the House in favor of the measure, especially if we count those who have to appear to be in favor of it to please their constituents, and if the bill comes to a final vote its passage is almost sure—hence, the keeping of the bill in committee until it is too late to act on it. Furthermore, amendments of various kinds are in readiness both to delay and to weaken the measure if they are adopted. So, altogether, the outlook is not encouraging for this session, and the next is a short one, which means that there will be a good excuse not to push it then. But it is not worth while to be discouraged or to give up. The people are in earnest in their demand for the law, and there are more who are interested and who are demanding it year by year. The awakening of public opinion in regard to this matter during the last two or three years is remarkable, and it will not become dormant until satisfactory legislation is enacted.

MOSS AS FOOD.

A Norwegian authority, Dr. Hansteen of the agricultural school at Aas, according to the London dispatches, has made the discovery that moss, probably of the succulent Arctic variety, is a palatable and nutritious food for man and that it will become an important addition to our food resources. It has long been known that certain forms of mosses or lichens can serve as dietary adjuncts or as food in emergencies, but any very extensive dependence on them has not been ordinarily thought possible. The human species is not even claimed by the vegetarians to be a strictly herbivorous or grazing animal, but Dr. Hansteen's alleged discovery would very nearly make him such. If Hansteen is correct, the Arctic plains will become regions of plenty and the almost annual starvation periods of the dwellers in those regions have been needless. The discovery is one that can be taken with some allowances.

Medical News

ALABAMA.

Physicians Fined.—Drs. William W. Ransom and Wallington P. McAdory, Birmingham, were each fined $1, May 10, in the police court, on the charge of failure to report births to the city health officer.——T. B. W. Brooks, Montgomery, was convicted on the charge of practicing medicine without a certificate in Marion County and fined $25 and costs.

State Medical Association.—The Medical Association of the State of Alabama held its thirty-third annual meeting in Birmingham, April 17, 18, 19 and 20, under the presidency of Dr. Eugene D. Bondurant, Mobile. The association was welcomed on behalf of the Jefferson County Medical Association by Dr. Lewis C. Morris, Birmingham, president. Hon. Henry B. Gray delivered the address of welcome on behalf of the city of Birmingham. In his annual address the president referred to the advances made in the treatment of various diseases, and especially to the work of the quarantine officers in keeping yellow fever out of the state of Alabama. He commended the anti-tuberculosis campaign and recommended that the association publish and own a medical journal to be devoted strictly to its interest. He advised that the county boards of examiners be done away with and that the basis of representation in the state convention should be the membership of the subordinate organization. The senior vice president in his report noted a large increase in the membership of the county medical societies and stated that of the 1,005 legal physicians in the state 821 were members of the association. The papers read during the session were of unusual interest. The address of Surgeon James H. White, United States Public Health and Marine-Hospital Service, New Orleans, on the "Sanitary Needs of the Cities of the South," was of especial interest. He stated that the crying need of the southern cities is for drainage, sewage, pavements and water supply, and that when the necessary aridity has thus been obtained, the seacoast cities of the South can carry on commerce with their natural tributaries in the tropics with as much impunity as do New York and Boston, and with a great deal more convenience to themselves and tributaries. The board of censors recommended the creation of an anti-tuberculosis committee to consist of nine members and to be empowered to act independently or in cooperation with the state officers or organization. It also endorsed the recommendation for the establishment of an inebriate institution and also for a state hospital for epileptics. It endorsed a state journal for the association, but suggested further consideration. The following officers were elected: President, Dr. George T. McWhorter, Riverton; vice-presidents, Drs. Louis W. Johnston, Tuskegee, and Andrew J. Coley, Alexander City; state health officer, Dr. W. H. Saunders, Montgomery; secretary, Dr. J. Norment Baker, Montgomery (re-elected); treasurer, Dr. Henry G. Perry, Greensboro; censors, Drs. Dyer F. Talley, Birmingham, and John R. G. Howell, Dothan; orator, Dr. Toulman G. Gaines, Mobile, and councilors, Drs. William R. Jackson, Mobile, Edwin B. Ward, Selma, Allan A. Greene, Anniston, J. D. S. Davis, Birmingham, Enoch J. Conyngton, Decatur, and Jacob U. Ray, Woodstock. The association adjourned to meet in Mobile in 1907.

COLORADO.

Personal.—Dr. Ella A. Head has been appointed city physician of Greeley.——Dr. Francis B. Rothrock, Colorado Springs, has returned from Europe.

Again Found Guilty.—George A. Rietzel, alias Dr. George Elliott, who recently completed a sentence in the state penitentiary for criminal malpractice, was convicted in Denver, May 18, of sending improper matter through the mails, and was remanded for sentence.

Health Report of Colorado Springs.—During April 45 deaths occurred, equivalent to an annual death rate of 16.87 per 1,000. Of the deaths 17 were due to tuberculosis. The births of the month numbered 31. No typhoid fever, measles, smallpox nor diphtheria was reported during the month.

Commencement.—Denver and Gross College of Medicine celebrated its annual commencement exercises May 19. Judge Ben B. Lindsey made the address to the students, and Chancellor H. M. Buchtel of Denver University conferred degrees on a class of 26. The annual banquet was held at the Savoy after the exercises. Dr. Melville Black presided as toastmaster and toasts were responded to by Chancellor Buchtel, and Drs. Leonard Freeman, Claude E. Cooper and Robert B. Porter.

CONNECTICUT.

Diphtheria.—North Canton has several cases of diphtheria, one patient being the son of the postmaster. The village school has been closed by the health authorities and the post-office has been moved temporarily.

Personal.—Dr. William W. Brackett has been appointed health commissioner of New Britain, vice Dr. William P. Bunnell.——Dr. J. W. Ives has been appointed medical examiner for the town of Milford, vice Dr. Elias B. Heady.

April Deaths.—During April 1,414 deaths were reported, equivalent to an annual death rate of 17 per 1,000. The deaths from infectious diseases were 17.8 per cent. of the total mortality. Pneumonia was the cause of 210 deaths; diseases of the nervous system, 163; heart diseases, 152; consumption, 120; accidents and violence, 83; bronchitis, 46, and influenza, 34.

Infectious Diseases.—During April 24 cases of smallpox were reported in one town only, Putnam; 681 cases of measles from 76 towns; 169 cases of scarlet fever from 40 towns; 10 cases of cerebrospinal meningitis from 5 towns; 120 cases of diphtheria from 32 towns; 143 cases of whooping-cough from 17 towns; 46 cases of typhoid fever from 20 towns, and 49 cases of consumption from 17 towns.

Want a Hospital.—Forty Roman Catholic physicians of New Haven met May 9 and considered a proposition for the establishment of a Roman Catholic hospital in New Haven. Dr. John F. Luby presided and Dr. Thomas A. O'Brien was secretary of the meeting. A committee was appointed, consisting of Drs. Matthew C. O'Connor, John F. Luby and Stephen J. Maher, to make a thorough inquiry into this question and report at a subsequent meeting.

GEORGIA.

Personal.—Dr. Stewart R. Roberts has resigned his professorship of physiology in Emory College and will practice in Atlanta.——Dr. Charles H. Hall, Macon, is seriously ill.

Cornerstone Laid.—The cornerstone of the new building of the Atlanta School of Medicine was laid May 11 with appropriate ceremonies. The new building will cost about $70,000.

Pasteur Institute.—Dr. James N. Brawner, physician in charge of the Pasteur Institute, Atlanta, reports that since the foundation of the institute in 1900, 387 patients have been treated, of whom only two have died.

County Physicians Exonerated.—Drs. Everard D. Richardson and John W. Hurt, county physicians of Fulton County, who were recently indicted by the grand jury for neglect of prisoners in the custody of the county, after full investigation, have been exonerated by the Fulton County commissioners.

Society Meeting.—At the annual meeting of the Troup Medical Society, May 10, the following officers were elected: Dr. Joseph S. Horsley, West Point, president; Dr. A. J. Tuggle, La Grange, vice-president; Dr. Henry W. Terrell, La Grange, secretary and treasurer (re-elected), and Dr. Isaac H. Lane, La Grange, censor.

INDIANA.

Diphtheria Closes Schools.—Two school houses in Marion have been closed on account of the prevalence of diphtheria.

Physician Burned.—Dr. Marion F. Parrish, Munroe, suffered severe burns on the face, hands and arms in an explosion of chemicals, May 19.

Personal.—Dr. Roy W. Earhart, Mulberry, has sailed for Colon.—Dr. Thomas A. Kearns, Muncie, has left for Vienna.——Dr. George W. McCaskey, Fort Wayne, has returned from a trip to Europe.——Dr. Nelson D. Brayton, Indianapolis, has been appointed interne in the Medical Department of the Canal Zone.

Favors One Medical School.—The Daviess County Medical Society, at its meeting May 11, adopted resolutions endorsing the action of the several medical colleges of the state in merging their faculties and equipments and forming the Medical Department of Purdue University, and protesting against the movement being made to organize a medical school in connection with the State University.

Stemen Leaves Fort Wayne.—Dr. Christian B. Stemen, chief surgeon of the Wabash System, has resigned on account of removal. Dr. Stemen has also resigned as dean of Fort Wayne Medical College and as trustee of Purdue University. A luncheon was given by the physicians of Fort Wayne, May 14, in honor of Dr. Stemen, who has accepted a chair in the Medical School of Kansas University, Kansas City. Dr. Kent K. Wheelock acted as toastmaster.

Commencement.—The graduating exercises of the Medical College of Indiana, Department of Medicine of Purdue University, took place in Lafayette, May 13, when a class of 122 received diplomas. The graduates, faculty and friends came from Indianapolis on a special train. President W. E. Stone delivered the introductory address on "Education and Efficiency." Prof. George E. Vincent of the University of Chicago delivered the doctorate address. The dean, Dr. Henry Jameson, Indianapolis, presented the class to the president of the university, who conferred the degrees.

Sickness and Death in Indiana.—The State Board of Health reports tonsillitis as the most prevalent disease in the state during April. Then follow rheumatism, pneumonia, bronchitis, influenza, scarlet fever, whooping-cough, intermittent fever, remittent fever, measles, pleuritis, diarrhea, typhoid fever, erysipelas, diphtheria, cerebrospinal meningitis, typho-malarial fever, smallpox, cholera morbus, puerperal fever, dysentery and cholera infantum. Smallpox occurred in three counties, Adams having 15 cases, Allen 20 cases, and Miami 15 cases. The deaths of the month were 2,976, equivalent to an annual mortality of 13.2 per 1,000. This compares unfavorably with the rate of 12.1 per 1,000 in 1905. Of the deaths, 31 per cent. were of individuals of 65 years and over, and 14.1 per cent. of infants under one year. Tuberculosis caused 415 deaths; pneumonia, 386; cancer, 126; violence, 124; cerebrospinal meningitis, 42; typhoid fever, 34; influenza, 28, and whooping-cough and diarrheal diseases, each 27. Of the 124 deaths from violence 28 were suicides and 2 homicides. Of the suicides, 7 were due to gunshot wound, 5 to asphyxiation and 12 to poison.

KANSAS.

New Hospital for Emporia.—The new hospital which is being erected in Emporia will be completed and ready for occupancy about June 1.

Smallpox.—Two smallpox patients in Iola have broken quarantine and departed for parts unknown.——Hutchinson has had five cases of smallpox in the last four weeks.

Graduation.—A class of 18 was graduated at Kansas Medical College, Topeka, April 18. James A. Troutman delivered the general address, Dr. Herbert L. Alkire the faculty address, and Dr. William S. Lindsey conferred the degrees.

Charter Revoked.—The charter of the Kansas State Medical and Surgical Institute, Kansas City, a mail-order medical establishment, was revoked May 13, on recommendation of Dr. George H. Hoxie, editor of the *Journal of the Kansas Medical Society*.

Contract for Medical Building Awarded.—The contract for the construction of the new laboratory and administration building of the University Medical School, Rosedale, was awarded by the board of regents to the Urban Construction Company, Kansas City, May 5, for $16,824.

Supports Pure-Food Bill.—The committee on public health and legislation of the Shawnee County Medical Society presented a resolution at the meeting of May 7, supporting the original pure-food bill and instructing the secretary to send a copy of the resolution to the Kansas congressman.

Personal.—Dr. Franklin P. Hatfield, Grenola, has been appointed a member and secretary of the State Board of Medical Registration and Examination.——Dr. W. H. Robinson, Ubera, is suffering from paralysis of the right optic nerve.——Dr. C. E. McClung, dean of the Kansas University Medical School, was seriously injured by an explosion of dynamite, May 19.

Vital Statistics for 1905.—The report of Dr. S. Jay Crumbine, secretary of the State Board of Health, shows that the total number of deaths reported during 1905 was 3,005. Consumption caused 965 deaths; pneumonia, 780; typhoid fever, 397; diphtheria, 251; cholera infantum, 195; dysentery, 120; influenza, 99; scarlet fever, 70; whooping-cough, 58; smallpox, 38, and measles, 27. During the year 744 deaths from violence were reported; of these 116 were from suicide, and of the suicides 34 chose poison and 31 firearms as the route of death. The deaths from tuberculosis amounted to 63.7 for each 100,000 of population. There were 4,116 cases of smallpox reported during the year, with only 33 deaths, an average of less than 1 per cent.

State Society Meeting.—The fortieth annual meeting of the Kansas Medical Society was held at Topeka, May 9, 10 and 11, the president, Dr. Charles E. Bower, Wichita, in the chair. Prof. W. H. Carruth, Lawrence, delivered an address on the relation of Kansas University with the Kansas Medical Association, and Dr. Jeptha Dillon, Eureka, read an interesting article on organization. A committee of three was appointed to prepare several amendments to the laws now on the statute books relative to the illegal practice of medicine. The following officers were elected: President, Dr. Lyman L. Uhls, Osawatomie; vice-presidents, Drs. William F. Sawhill, Concordia, John P. Kaster, Topeka, and Paul S. Mitchell, Iola; librarian, Dr. Samuel G. Stewart, Topeka, and editor, Dr. George H. Hoxie, Kansas (re-elected). The meeting next year will be held in Kansas City.

MARYLAND.

Baltimore.

Bequest.—Mr. E. Greenbaum left $500 to the Hebrew Hospital.

Suicide.—There were two cases of death from suicide last week, making 33 since January 1.

Commencement.—At the commencement of the Baltimore Medical College, held May 22, 96 candidates received degrees. The diplomas were conferred by the mayor.

Personal.—Dr. Henry M. Wilson left for Europe, May 22, on account of the illness of his daughter there. Others who expect to leave for Europe shortly are Drs. John C. Hemmeter, Randolph Winslow, J. Mason Hundley, Hiram Woods and Gordon Wilson.——Dr. E. Miller Reid has resigned from the faculty of the Baltimore University, in which he has held for about 20 years the chair of nervous diseases, throat and chest.——Dr. Herbert Schoenrich left Baltimore May 22 for New York City, where he becomes assistant to the pathologic department of the Presbyterian Hospital.——Dr. Edward A. Smith has been nominated as captain and assistant surgeon, Fourth Infantry, M. N. G.

The Typhoid Fever Epidemic.—The prevalence of typhoid fever in the northern section of the city has caused much alarm there this week. The city water supply is claimed to be pure, but many houses in that section are not supplied with it, and pumps and wells which are known to be con-

taminated are used. The streets, yards and alleys are said to be in a dreadful condition, clogged with refuse and reeking in filth and bad odors. On May 26, by mutual understanding, the people turned out and gave the section a thorough cleansing, giving up the half-holiday for that purpose. The city authorities gave their assistance. More than 130 cases of typhoid fever are said to have occurred in this part of the city.

MICHIGAN.

The Afflicted.—Dr. Festus F. Pitcher, Battle Creek, has been adjudged insane and committed to the State Hospital, Kalamazoo.——Dr. W. Clay Bastar, Benton Harbor, was operated on in Chicago, May 15.——Dr. Albert L. Walker, Salem, suffered a cerebral hemorrhage May 13.

Communicable Diseases.—Marinette still has three cases of smallpox, which the health officer claims did not originate in the city.——Diphtheria is said to be raging at Lincoln Lake, where eight families are under quarantine, two schools have been closed, and church services have been prohibited for the time being.——Five cases of smallpox and two of varioloid are reported from Greenville, Mich.

Personal.—The Alumni Association of the Detroit College of Medicine presented a silver loving-cup to Dr. Theodore A. McGraw, May 11.——Dr. Josiah L. Ambrose, Bay City, has been appointed city physician.——Dr. Gilbert S. Field, Detroit, sailed for Europe from Montreal, May 7.——Dr. Wilber S. Henderson has been elected city physician of Port Huron.——Dr. Zelpha C. Walker has been made a member of the Benton Harbor board of health.

Alumni Election.—At the annual meeting of the Detroit College of Medicine Alumni Association, May 17, 400 were present. The following officers were elected: Dr. Louis J. Hirschman, Detroit, president; Dr. Richard C. Buchanan, Green Bay, Wis., vice-president; Dr. John C. Dodds, Detroit, secretary and treasurer; Dr. E. C. Rumer, Davison, Mich., historian, and Drs. H. Wellington Yates and Richard E. Mercer, Detroit, members of the executive committee.

Commencements.—The thirty-eighth annual commencement exercises of the Detroit College of Medicine were held May 17. For ten days preceding that date the annual clinics for the alumni of the institution were in progress, at which Drs. James P. Tuttle, New York City, and Dr. Howard Kelly, Baltimore, took part. A class of 82 was graduated. Dr. Frank B. Walker delivered the faculty address, and President Sidney Miller of the board of trustees conferred the degrees.——The Michigan College of Medicine and Surgery, Detroit, held its annual commencement exercises May 11. Prof. William A. Hackett presided. Rev. Dr. Whelan, Port Huron, delivered the address, and Dr. Hal C. Wyman, dean of the faculty, conferred degrees on a class of 22.

MISSOURI.

Sentenced for Criminal Operation.—Dr. Edward J. Hogan, St. Louis, was fined $250 and sentenced to six months in the workhouse, May 25, for performing a criminal operation.

Smallpox.—Dr. L. J. Dandurant reports seven cases of smallpox in Willowtown, south of St. Joseph, and one in Hyde Valley, and complains that the patients do not respect the quarantine. He was authorized to take such means as might be necessary to enforce rigid quarantine.

Personal.—Dr. Downey S. Harris, assistant to the chair of pathology in the Medical Department of St. Louis University, has been appointed city bacteriologist of St. Louis.——Dr. Max A. Goldstein, St. Louis, will sail for Europe in a short time.——Dr. Heine Marks, St. Louis, has been elected chairman of the joint committee of the municipal assembly to make plans for the reorganization of the board of health.——Dr. Ira C. Young, St. Louis, has returned from a vacation trip to Southern California.——Dr. Daniel D. O'Gorman, St. Louis, has been appointed supreme medical director of the Catholic Ladies and Knights of America.——Dr. and Mrs. Omar Morgner, St. Charles, left for Europe, May 16.

Commencement Exercises.—The medical department of St. Louis University held its annual commencement exercises May 19, when a class of 91 was graduated. The address was made by the dean, Dr. Young H. Bond, and Dr. R. C. Atkinson delivered an address on "The Needs for Greater Clinical Facilities," and Dr. C. M. Jackson spoke on "Two Desirable Reforms."——The commencement exercises of the Medical Department of Washington University were held May 24, when a class of 55 was graduated. Dr. Maurice H. Richardson delivered the address of the evening on "The Ideal Surgeon."

State Association Meeting.—The forty-ninth annual meeting of the Missouri State Medical Association was held in Jefferson City, May 15, 16 and 17. The address of welcome was delivered by Governor Folk. On the first evening the warden of the state penitentiary entertained the association at a supper at the institution, where the regular ration for prisoners was served the guests. The secretary made a report which showed the association to be in good financial condition, there being a balance of $4,000 in the treasury. He reported that 95 of the counties in the state had been organized on the standard plan. The council is to be enlarged by adding 10 more districts, to be 28 instead of 18 in the state, each district being composed of three to five counties. The election of officers evolved a considerable degree of excitement. Eventually Dr. Charles H. Wallace, St. Joseph, was elected president, the other candidate being Dr. C. R. Woodson, superintendent of the State Hospital for the Insane No. 2, St. Joseph. Dr. Wallace declined to enter on the duties of his office until after investigation into the alleged charges of consulting with and accepting a fee from a quack had been made. The other officers elected were: Vice-presidents, Drs. F. W. Allen, Callao, William G. Cowan, Sedalia, C. J. Orr, St. Louis, E. H. Thrailkill, Kansas City, and Dr. H. L. Reid, Charleston; secretary, Dr. C. M. Nicholson, St. Louis; treasurer, Dr. A. Franklin Wells, Salisbury, and chairman of the committee of public health and legislature, Dr. Frank J. Lutz, St. Louis. The house of delegates, among other matters, took under consideration the movement to change the statute of limitation from five years to one year as regards the possibility of suits for malpractice.

MONTANA.

Diphtheria in Anaconda.—Diphtheria has prevailed in Anaconda for several months and at present appears to be on the increase. The health authorities now propose to make a thorough examination of all suspects, and to inaugurate a system of isolation and quarantine in the hope of stamping out or at least checking the progress of the disease.

State Association Meeting.—The twenty-eighth annual session of the Montana State Medical Association was held at Butte, May 9 and 10, with the president, Dr. Donald Campbell, Butte, in the chair. Of the 175 members 63 were present, so that this meeting of the society was the most fully attended of any in its history. The different sections of the state were better represented than heretofore, and great interest was manifested in the proceedings. The president's address dealt with medical progress of the past year, and he paid especial attention to the publicity given the nostrum question. One of the most interesting papers of the session was that read by Dr. H. T. Ricketts of the University of Chicago on spotted fever, or the tick disease. Dr. Ricketts came to Montana as an original investigator in the hope of discovering the cause of the spotted fever which has existed so long in the state. He found eight cases in the western part of the state and seven of the patients died. The most common theory of the cause of the disease is the tick fever. This is combated by the inhabitants, because many people who are bitten by ticks do not get the disease. Dr. Ricketts strongly urged the appointment of a legislative committee to investigtae this matter and the appropriation of sufficient money by the legislature to carry on the investigation. The following officers were elected: Dr. O. Y. Warren, Warm Springs, president; Drs. Thomas D. Tuttle, Billings, Lawrence R. Packard, Whitehall, and Edgar F. Dodds, Missoula, vice-presidents; Dr. Grace Wilson Cahoon, Butte, secretary (re-elected); Dr. W. W. Taylor, Kalispell, treasurer, and Drs. George W. King, Helena, Edward W. Spottswood, Missoula, Thomas J. Murray, Butte, W. W. Williams of Northeastern Montana, J. H. Irwin, Great Falls, Elmer L. Southerland, Sheridan, and Fred F. Addix, Lewistown, councilors. The society will meet next year in Billings.

NEBRASKA.

Alumni Meetings.—The alumni banquet of Creighton Medical College was held May 14, at which over 80 alumni were present. Dr. T. J. Dwyer served as toastmaster.——The special alumni clinics of the University College of Medicine, Omaha, were held May 23 and 24. The alumni meeting was held May 23 and the annual alumni luncheon, May 24.

Hospital Cornerstone Laid.—The cornerstone of the new Methodist hospital, Omaha, was laid by Bishop John W. Hamilton, May 24. The new hospital will cost about $100,000.——The building fund of the new Clarkson Hospital now amounts to about $22,000, and the committee is confident that the $13,000 additional required will be secured within the year.

Commencement.—The Omaha Medical College, University of Nebraska College of Medicine, held its annual commencement exercises May 24, when a class of 7 was graduated. The address of the evening was delivered by Dr. James Carroll, United States Army, on the "Microscope in Medicine." Dr. Alexander S. von Mansfelde, Ashland, delivered an address on the "History of Medicine in Nebraska," and Dr. William F. Milroy, Omaha, spoke on the history of the college.—Creighton Medical College, Omaha, graduated a class of 39, May 15.

NEW HAMPSHIRE.

Dartmouth Alumni Meet.—At the annual meeting of the Dartmouth Medical College Alumni Association, held in Concord May 17, the following officers were elected: President, Dr. William A. Mcgrath, Louden; vice-presidents, Drs. Roy V. Baketel, Methuen, Mass., and David P. Goodhue, West Springfield, N. H., and secretary and treasurer, Dr. Howard N. Kingsford, Hanover.

Military Surgeons Meet.—The annual meeting of the New Hampshire Military Surgeons was held in Concord, May 17. It was voted to hold an adjourned meeting on governor's day at the Grand Army encampment at The Weirs this summer. Dr. Granville P. Conn reported progress on his history of New Hampshire military surgeons, which will make a book of about 500 pages. Dr. Ezra Mitchell, Lancaster, was elected president; Dr. Granville P. Conn, Concord, secretary, and Dr. Ferdinand A. Stillings, Concord, treasurer.

New Hampshire Medical Society.—The one hundred and fifteenth annual meeting of the New Hampshire Medical Society was held in Concord, May 17 and 18, under the presidency of Dr. Ferdinand A. Stillings, Concord. One of the principal subjects for discussion was the question of the taking of contract work by members of the profession and society, but no definite conclusion was reached. The following officers were elected: President, Dr. Ira J. Prouty, Keene; vice-president, Dr. John H. Neal, Rochester; treasurer, Dr. David M. Currier, Newport; secretary, Dr. D. Edward Sullivan, Concord, and necrologist, Dr. Eli E. Graves, Penacook. At the annual banquet Dr. Forrest L. Keay, Rochester, presided as toastmaster.

NEW MEXICO.

State Association Meeting.—The New Mexico Medical Association convened for its twenty-fifth annual session at Albuquerque, May 2 and 3, under the presidency of Dr. Percy G. Cornish. The mayor of Albuquerque welcomed the association to the city, and the members were the guests of the Bernalillo County Medical Society at a banquet on the first evening, over which Dr. P. G. Cornish presided as toastmaster. The following officers were elected: President, Dr. Thomas B. Hart, Raton; vice-presidents, Drs. Samuel M. Lane, Silver City, William T. Joyner, Roswell, and Daniel H. Carns, Albuquerque; secretary, Dr. E. R. McBride, Las Cruces; treasurer, Dr. Harry M. Smith, Las Vegas; councilor, Dr. Samuel D. Swope, Deming (re-elected); editor-in-chief of the *Territorial Medical Journal*, Dr. G. L. McLandress, Albuquerque, and associate editors, Drs. Francis T. H. West, Las Vegas, James H. Wroth, Albuquerque, William W. Phillips, Roswell, and R. E. McBride, Las Cruces. Las Cruces was selected as the next place of meeting.

NEW YORK.

Clairvoyants Licensed.—An ordinance was recently enacted in Buffalo requiring clairvoyants to pay an annual license fee of $100. This is equivalent to the recognition by the city of parasites to rob the ignorant and poor.

Recovers Damages.—Dr. Edward McGuire, Buffalo, recovered $200 damages and costs in the municipal court for damages sustained to his automobile, which was wrecked by colliding at night with a pile of coal on which there was no danger signal.

Personal.—Hon. D. S. Lockwood, Buffalo, a member of the state commission in lunacy, is seriously ill.——Dr. William Gaertner, Buffalo, has been elected president of the local branch of the German-American National Alliance.——Dr. Frederick Preiss, Buffalo, who recently underwent a serious operation at the Sisters' Hospital, is progressing toward recovery.——Dr. J. F. Munson, a graduate of the University of Michigan, for two years an assistant to Prof. Victor C. Vaughan, has been appointed resident pathologist at the Craig Colony for Epileptics, Sonyea.

Buffalo Health Report.—Health Commissioner Greene submitted his annual report, which shows the death rate was only 14.14 per 1,000 for 1905. The rate for children under 6 years old was 4.05. Dr. Greene rehearses what the department has done to preserve the health of the city, and makes various recommendations looking toward better sanitation. He also asks for additional milk inspectors to inspect the milk supply at its source in the country.

Alumni Arrangements.—The executive committee of the alumni of the Medical Department of the University of Buffalo has arranged for a four-day meeting of the association, to be held at Buffalo, May 29, 30, 31 and June 1. Clinics will be held at all the hospitals and dispensaries of the city. Dr. Denslow Lewis, Chicago, is to give an address on "The Social Evil." On May 29 the resident alumni will entertain the visiting alumni at luncheon at the University Club. On May 30 the teaching staff will entertain the alumni at luncheon at the University Club, and a luncheon will be given to alumni at the Saturn Club on the following day.

Increase in Insane.—An increase of 547 in the total insane persons cared for in institutions over any previous year in the history of the state is shown in the annual report of the State Charities Aid Association to the state commission in lunacy. The number of insane in 1905 was 27,408, or one demented for every 294 of population, while in 1900 there was one for every 305. As a mitigating circumstance the report points out that while the total of insane cared for last year was larger than ever before, the increase in new cases was the smallest of the last 15 years. The number recorded in 1905 is accounted for by the improvements in the care of the health of insane persons by which many lives are declared to have been spared which would formerly have been lost. In 1904 the state hospitals showed more than 3,000 patients over their certified capacity, while in 1905 the excess was but slightly over 1,600.

New York City.

Sanatorium for Hebrew Children.—The twenty-eighth annual report of this institution announces that the new wing will be opened this summer. During the last season 2,023 children were cared for, and also many nursing mothers.

Sea Breeze Home Opens.—The summer season of this home has begun, and while it is unable to care for all the needy mothers and babies in New York, it has sent invitations to hospitals, clinics, dispensaries, schools, physicians and employers, asking them to inform it of those in need.

For Seaside Hospital.—Mrs. Andrew Carnegie has given the Seaside Hospital for Crippled Children $10,000 toward the new hospital. This brings the Association for Improving the Condition of the Poor within $44,000 of the $125,000 which must be raised in order to secure the $125,000 offered by John D. Rockefeller.

Spotted Fever More Fatal.—The records of the health department show that while cerebrospinal meningitis is less prevalent since the weather has become warmer, the fatality has increased. In the ten weeks after the middle of March 369 cases were reported, with 285 deaths. From the beginning to the middle of May there were 96 new cases and 97 deaths from the disease.

Physician Held for Performing Autopsy.—Dr. I. O. Woodruff, Jr., head of one of the babies' pavilions at Bellevue, has been charged with performing an autopsy without consent of the next of kin on the body of a seven-months-old baby who died of typhoid fever. Dr. Woodruff claimed that the undertaker gave him permission, and thought as only three cases of this disease in infancy had been reported in medical annals, an autopsy would be helpful to science.

Red Cross Hospital.—The cornerstone of the American Red Cross Hospital was laid May 22 by William T. Wardwell, who gave the land on which the building is erected. The hospital is not new, though it has had to close its doors during the erection of the present building. The site is valued at $100,000, and the new building, which will be ready for occupancy in August, will cost $120,000. It was stated that the hospital would eliminate not only beer, but all alcoholics, which might be used as a regular part of hospital diet.

Health in the Schools.—This was the subject discussed at the regular meeting of the New York Academy of Medicine on May 24. Dr. J. J. Cronin, assistant chief sanitary inspector, read a paper on "Health of the New York School Child from the Point of View of the Department of Health." Dr. Maxwell stated that no child should be allowed to attend school until 7 years of age. Dr. Abraham Jacobi thought the money expended for the military and pensions might be used to better advantage for the schools. Dr. J. G. Freeman hoped that the time would come when a midday meal would be provided for the schools, as was done in Paris. Dr. Henry Dwight Chapin said that physicians were generally agreed that the large majority of New York children were under-developed.

More sleep and better hygienic surroundings were needed. He hoped the time would come when the teeth of the school children would be attended to, as the eyes, noses and throats are at present.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended May 19, 1,252 cases of measles, with 37 deaths; 383 cases of tuberculosis, with 193 deaths; 370 cases of diphtheria, with 54 deaths; 305 cases of scarlet fever, with 28 deaths; 37 cases of whooping-cough, with 5 deaths; 31 cases of cerebrospinal meningitis, with 32 deaths; 15 cases of typhoid fever, with 4 deaths, and 83 cases of varicella, making a total of 2,476 cases, with 353 deaths.

Personal.—Dr. Stephen G. Cook, for 20 years police surgeon and for many years president of the board of police surgeons, has applied to be retired on account of failing health. ——Dr. Austin Flint, one of the oldest medical instructors in the country, received a silver loving-cup from the class of 1909, Cornell University Medical School, on the occasion of his resignation of the professorship of physiology, which he held continuously since 1861.——Dr. and Mrs. Charles T. Poore and Dr. and Mrs. Thomas E. Satterthwaite sailed for Europe on the *Finland* on May 26.

OKLAHOMA.

Many Insane.—The report of the superintendent of the Territorial Insane Hospital, Norman, shows that on May 7, 504 patients were registered at that institution, the highest mark in its record.

Convicted of Manslaughter.—Dr. John B. Irvin, Kaw City, because of killing Alpha Mann, a halfbreed Kaw Indian, has been found guilty of manslaughter, the penalty for which is not less than four years.

County Society Secures Home.—The Oklahoma County Medical Society has leased rooms in the new Martin Building, Oklahoma City, as its permanent headquarters. A room has been set aside for a medical library and pathologic museum.

Personal.—The governor has reappointed Dr. Benjamin F. Hamilton, Shawnee, and has appointed Drs. R. Hall, Pawhuska, and Edward F. Davis, Oklahoma City, as members of the commission to examine the Territorial Insane Hospital.—— Dr. Lewis T. Gooch has been elected alderman of the Third ward in Lawton.

OREGON.

Hospital News.—The new St. Mary's Hospital, Astoria, was dedicated with proper ceremonies by Architect Christie, Portland, April 29.

Alumni Election.—At the annual meeting of the alumni of Willamette University, Medical Department, Salem, May 1, Dr. Elza D. Johnson, Portland, was elected president; Dr. W. W. Allen, Jefferson, secretary.

Diphtheria in Portsmouth.—Diphtheria is so prevalent in Portsmouth that the investigating committee has recommended that the school children of the city be examined each morning for two weeks and that in all suspicious cases special examination of the throat shall be made; that the school be thoroughly fumigated and disinfected once a week and that special officers be detailed to enforce quarantine regulations.

State Health Association Formed.—The Oregon State Health Association was organized at Portland, May 16. It is composed of state, county and city health officers, with county judges, mayors of incorporated towns and members of the service as honorary members. Dr. Edward P. Geary was made first president of the association; Dr. Esther C. Pole, vice-president, and Dr. Robert C. Yenney, secretary and treasurer, all of Portland.

County and City Society Meeting.—At the annual meeting of the Portland County and City Medical Society, May 17, Dr. Robert C. Yenney was unanimously elected president; Dr. Luther H. Hamilton, vice-president; Dr. Allen W. Smith, secretary; Dr. Joseph A. Pettit, treasurer, and Drs. Katherine C. Manon, Ernest F. Tucker and Arthur H. Johnson, councilors. In the annual report of the retiring president he dwelt especially on the admission into the society of 72 new members.

Commencements.—The forty-first annual commencement exercises of Willamette University, Medical Department, Salem, were held May 1, when a class of 14 obtained degrees.——The University of the State of Oregon, Medical Department, Portland, graduated a class of 16, April 30. Dr. Andrew C. Smith delivered the annual address on "The Duties of the Medical Citizen," Dr. George F. Wilson the charge to the graduates, and President P. L. Campbell of the University of Oregon conferred the degrees.

State Association Meeting.—The thirty-second annual meeting of the Oregon State Medical Association was held in Portland, May 15 and 16, under the presidency of Dr. George F. Wilson, Portland. Dr. Harry Lane, mayor of Portland, delivered the address of welcome to the visiting physicians, and Dr. Wilson in his presidential address devoted especial attention to organization, urging that physicians organize along broad and practical lines. The resolutions introduced by Dr. J. P. Tamiesie, recommending the establishment of state and national sanitoria for tuberculosis, were adopted with modifications. The following officers were elected: President, Dr. E. Barton Pickel, Medford; vice-presidents, Drs. John A. Reuter, The Dalles, H. M. Shaw, Ashland, and Edna D. Timms, Portland; treasurer, Dr. Amelia Ziegler, Portland; secretary, Dr. Luther H. Hamilton, Portland; delegate to the American Medical Association, Dr. Henry W. Coe, Portland; alternate, Dr. George F. Wilson, Portland, and councilors, Drs. Andrew C. Smith, Portland, and William J. May, Baker City. The Portland City and County Medical Society entertained the association at a banquet May 16, over which Dr. Henry W. Coe presided as toastmaster. The association adjourned to meet in Astoria in July, 1907.

PENNSYLVANIA.

Philadelphia.

Money for Hospital.—An entertainment given by patronesses of the Bryn Mawr Hospital, May 25, at the Merion club, realized $2,000 for the institution.

Antiquack League.—An antiquack league is in process of formation in this city, directed against irregular physicians, "patent-medicine" dealers, and all forms of quacks and charlatans. The league is headed by Drs. S. Solis-Cohen, Persifor Frazer and Henry Beates.

Personal.—Dr. John H. Brinton, professor of surgery in Jefferson Medical College, has tendered his resignation, to take effect at the end of the present college year.——Dr. Charles A. Groff was thrown from a trolley car May 23 and sustained a fracture of the left fibula.——Dr. Martha G. K. Schetky sailed for Europe May 24.——Dr. W. W. Keen was elected president of the American Baptist Missionary union at the meeting held in Dayton, Ohio, May 22.

Hospital Site Purchased.—At a meeting of the board of trustees of the Frankford Hospital May 25, announcement was made of the purchase for $37,000, of a new site at Frankford avenue, Franklin and Wakeling streets, covering an area 220 by 240 feet. A stone three-story house on the property will be used as an administration building. To this additional wings will be added. The report of the hospital shows that 1,300 cases have been treated in the institution in the last fifteen months.

Women Physicians Banquet.—The alumnæ of the Woman's Medical College held a banquet May 24, the largest in the history of the college. Graduates were present from San Francisco and Pasadena, Cal., Ontario, Seattle, Wash., and Manhattan, Kan. Dr. Mary Butler was toastmaster, and the following responded to toasts: Dr. Elizabeth Keller, Boston; Dr. Frances Baker, Media, Pa.; Dr. Mary Griscom, Philadelphia; Miss Agnes Repplier; Dr. Alice W. Tallant; Dr. Elizabeth Harden, Baltimore; Dr. Mary Evans, Pottstown; and Dr. Frances Bartlett, Philadelphia.

Coroner to Probe Illicit Drug Trade.—The coroner has taken steps to expose persons who sell drugs of a habit-producing character. This is done as a result of a death being reported to his office of a young woman, a victim of the cocain habit. It was learned by the deputy coroner that in certain sections of this city cocain, morphin and opium are sold, disguised as catarrh cures, and other proprietary remedies. The deputy purchased these materials, without difficulty, in half a dozen different stores, and examination by the coroner's physician revealed them to be composed of practically unadulterated cocain and morphin. As a result of the investigation several arrests have been made.

Health Report.—The total number of deaths reported for the week reached 519. This is a decrease of 48 from last week and an increase of 119 over the number in the corresponding period of last year. The principal causes of death were: Measles, 4; scarlet fever, 3; pertussis, 5; diphtheria, 10; meningitis, 2; consumption, 54; cancer, 29; apoplexy, 23; heart disease, 47; acute respiratory disease, 68; enteritis, 35; cirrhosis of the liver, 6; Bright's disease, 34; appendicitis, 7; suicide, 4; accidents, 23; and marasmus, 3. There were 381 cases of contagious disease reported, with 47 deaths, as compared with 428 cases and 48 deaths in the previous week. There were 255 cases of typhoid fever reported, with 33 deaths; in the previous week 309 cases of typhoid fever, with 48 deaths were reported.

Medical Inspections for April.—The report of the division of medical inspection of the bureau of health shows that the number of inspections made, excluding the schools, during the month, aggregated 6,295. The inspectors ordered 1,089 fumigations and examined 40 patients for special diagnosis. They made 4,921 visits to the schools throughout the city and excluded 786 children from attendance. They performed 479 fumigations, administered 224 injections of antitoxin, and collected 168 cultures for examination. During the month 5,775 inspections of milk were made, comprising 112,430 quarts. Of this number 170 quarts were condemned. Four of the examinations were chemical and 859 were microscopic. The division of disinfection of the bureau of health shows that the number of fumigations performed were for smallpox, 3; scarlet fever, 174; diphtheria, 333; typhoid fever, 176; tuberculosis, 213; miscellaneous, 1,417, and schools, 31.

Scientific Sewage Disposal.—A meeting of the water commission recently appointed by the mayor was held May 21, and plans to do away with the use of water ways, as open sewers, by the construction of a system of sanitary sewage disposal along modern scientific lines, were discussed. The commission's conference is preliminary to the action to be taken by the council's survey committee, which has before it the draft of an ordinance providing for a special sewage commission of five members, to be named by the mayor. Plans for such a system were drawn some years ago by Chief Webster of the survey bureau. He advocated a system of sewage-disposal independent of a system for surface and storm-water drainage. The plan is to construct intercepting sewers along the banks of the Delaware and Schuylkill rivers, with basins at the junction of the sewers in the southern part of the city, where the sewage is to be treated chemically and rendered bacteria free. In view of the great cost of the installment of such a plan, and the present expenditure of $25,000,000 for water filtration, the project will not be instituted until the completion of the filtration system and the repletion of the city's funds. It is thought that the adoption of plans herein set forth will pave the way for the compulsion by the state of the adoption of similar systems in all towns draining their sewage into the city's water supply.

SOUTH CAROLINA.

State Association Meeting.—The annual meeting of the South Carolina Medical Association was held in Columbia, April 17, 18 and 19. Dr. Paul B. Barringer of the University of Virginia gave the public address on "The Drugs that Enslave," and Dr. W. T. English, Pittsburg, delivered an address on "Subsidiary Contributions to Medical Success." Drs. James L. Napier, Blenheim, and William M. Lester, Columbia, were re-elected, and Drs. William L. Mauldin, Greenville, and Harry H. Wyman, Aiken, elected members of the State Board of Medical Examiners. Dr. Paul M. Barringer of Virginia was made an honorary member of the society. The following officers were elected: President, Dr. T. Prioleau Whaley, Charleston; vice-presidents, Drs. W. P. Timmerman, Edgefield, Henry Holbeck, Columbia, and Michael G. Salley, Orangeburg; secretary, Dr. Walter Cheyne, Sumpter; treasurer, Dr. Charles P. Aimar, Charleston; councilors, Drs. Theodore G. Croft, Aiken, F. H. McLeod, Florence, Hugh R. Black, Spartansburg, James H. McIntosh, Columbia, and William B. Cox, Chester; associate editor of the *State Medical Journal*, Dr. J. Wilkinson Jervey, Greenville; delegate to the American Medical Association, Dr. J. H. Hamilton, Union, and delegate to the Medical Society of the State of North Carolina, Dr. William C. Black, Greenville.

TEXAS.

Northwestern Association Meeting.—The Northwest Texas Medical Association and the Wise County Medical Society met in joint session in Decatur, May 8. The following officers were elected: President, Dr. John A. Embry, Decatur; vice-president, Dr. Wade H. Walker, Wichita Falls, and secretary and treasurer, Dr. L. H. Reeves, Decatur. The next meeting will be held in Decatur in October.

Hospital News.—One of the new buildings of the North Texas State Hospital, which will accommodate 200 patients, is completed, and the other two buildings, which will accommodate 300 additional patients, will be ready in 60 days.——Arrangements have been made with the Sisters' Hospital, Waco, for the care of injured or sick employés of the M., K. & T. System. Emergency or branch hospitals are to be established at Smithville and Greenville.——The Baptist Memorial Hospital, Dallas, which is being erected at a cost of $250,000, will, it is expected, be ready to receive patients in November.——The sanitarium of Drs. Arthur C. Scott and K. R. White, Temple, is to be enlarged by the erection of a two-story addition designed especially for surgical cases.

State Association Meeting.—The thirty-eighth annual convention of the State Medical Association of Texas was held in Fort Worth, April 24, 25 and 26, under the presidency of Dr. J. Edward Gilcreest, Gainesville. Mayor W. D. Harris delivered an address of welcome on behalf of the city, and Dr. Bacon Saunders, president of the Tarrant County Medical Society, welcomed the association on behalf of that organization. Dr. Gilcreest responded to the addresses of welcome. Among the important papers read in the section on state medicine were those by Dr. William S. Carter, Galveston, on "Education and Sanitation; Dr. John S. Lankford, San Antonio, on "Medical Supervision of Public Schools," and Dr. Frank Paschal, San Antonio, on "The Tuberculosis Problem in the State of Texas." The house of delegates discussed the question of desirable legislation for the protection of public health and endorsed the proposed anatomic bill. The president in his annual address spoke of the need of state medical inspection for public schools and of the better regulation of the licensure of physicians in the state. The annual oration was delivered by Dr. Milus M. Morely, Greenville, on "Diversion Is Essential for the Healthy Active Mind." Dr. E. C. Dudley, Chicago, presented a paper on "The Preservation of the Functions of the Broad Ligaments in Connection with Other Pelvic Operations," and Dr. George V. I. Brown, Milwaukee, a paper on 'Surgical Treatment of Hare-lip and Cleft Palate." The members of the Tarrant County Medical Association entertained the state association at a barbecue at Handley in which nearly a thousand physicians participated. The following officers were elected: Dr. Garland B. Foscue, Waco, president; Drs. F. P. Miller, El Paso, D. Stuart Wier, Beaumont, Andrew B. Small, Waxahachie, vice-presidents; Drs. Stephen T. Turner, El Paso, J. W. McCarver, Brownwood, Hatch W. Cummings, Hearne, Joseph H. McCracken, Mineral Wells, and Millington Smith, Sulphur Springs, councilors; Drs. J. T. Wilson, Sherman, Charles E. Cantrell, Greenville, Arthur C. Scott, Temple, Stephen T. Turner, El Paso, and Frank Paschal, San Antonio, delegates to the American Medical Association; Drs. John S. Turner, Terrell, Benjamin M. Worsham, Austin, Thomas F. Kittrell, Texarkana, M. L. Graves, Galveston, and Robert W. Knox, Houston, alternates; Dr. Samuel C. Red, Houston, trustee, and Dr. William S. Carter, Galveston, orator. A vote of thanks was tendered to Dr. George R. Tabor, state health officer, for his work in keeping the state free of yellow fever last year, also for limiting the spread of smallpox. The association adjourned to meet in Mineral Wells in 1907.

UTAH.

Personal.—Dr. and Mrs. Everett O. Jones, Murray, left May 10 for a trip to Europe, and may return by way of the Pacific.——Dr. William R. Calderwood, Salt Lake City, has been appointed assistant physician of Salt Lake County, vice the late Dr. James Osterman.

Will Establish Medical School.—At a special meeting of the board of regents of the University of Utah, April 13, it was decided to establish a medical school as a regular part of the institution. Prof. R. V. Chamberlain was elected dean and the regents authorized the establishment of a faculty of 15.

County Medical Society.—At the annual meeting of the Utah County Medical Society, May 2, in Provo, the following officers were elected: President, Dr. Robert E. Steele, Lehi City; vice-president, Dr. George E. Robinson, Provo; secretary and treasurer, Dr. Frederic Clift, Provo (re-elected), and censors, Drs. Westwood, John W. Aird and Fred W. Taylor, of Provo.

Warning Against Spotted Fever.—Dr. Theodore B. Beatty, Salt Lake City, secretary of the State Board of Health, on May 11 instructed the health officers of Bingham and Murray to isolate patients suffering from cerebrospinal meningitis. Several deaths from the disease are reported to have occurred recently in Salt Lake City, and Dr. Beatty considers that extra precautions should be taken to prevent the spread of the disease.

State Society Meeting.—The Utah State Medical Association convened for its twelfth annual meeting at Salt Lake City, May 8, under the presidency of Dr. Emerson F. Root, Salt Lake City. About 250 were in attendance. The president in his annual address gave a retrospective view of the medical conditions in Utah during the days when it was a territory, and laid stress on the present conditions existing, the large number of hospitals and medical institutions in the state, and predicted that a second medical college would soon be needed. The following officers were elected: Dr. Frederic Clift, Provo, president; Drs. Augustus C. Behle, Salt Lake City, and Edward M. Conroy, Ogden, vice-presidents; Dr. Walter S. Ellerbeck,

Salt Lake City, secretary, and Dr. James N. Harrison, Salt Lake City, treasurer. Drs. John W. Aird, Provo, and Philo E. Jones and Ira A. E. Lyons, Salt Lake City, were chosen as trustees. The association voted $200 for the relief of physicians in San Francisco and $50 for the N. S. Davis memorial. It was decided that a committee should be appointed for the purpose of revising the constitution and by-laws to conform to the plan recommended by the American Medical Association. The association voted to accept the proposition of the *Utah and Denver Medical Journal* for the publication of the transactions of the organization. The Cache Valley Medical Society was recognized as a component branch of the association. In the evening a banquet was given to the association by the local members, at which Dr. Eugene W. Whitney presided as toastmaster. It was decided to hold the next meeting in Salt Lake City.

GENERAL.

Supplement.—A loose supplement accompanies this issue of THE JOURNAL, containing a photograph of Dr. W. J. Mayo, the president-elect of the American Medical Association.

Vacancies in the Army Medical Corps.—A preliminary examination of applicants for appointment in the medical corps of the Army will be held at various military posts throughout the United States on July 31, 1906. Full information in regard thereto may be obtained from the surgeon general of the Army. Applications must be filed prior to June 30. Thirty years is the prescribed maximum age, and individuals whose age exceeds that limit are not eligible for examination.

Does Not Want to be Governor.—The newspapers of Kentucky have been urging Dr. J. N. McCormack for governor of Kentucky, and for a while it appeared to be a foregone conclusion that he would be the next nominee of the Democratic party, which would mean election. But it seems that the doctor's name was used without his authority, for he has published a statement to the effect that he is not a candidate, and will not be. The following is from the Kentucky newspapers:

> Almost constant absence from the state for several months has prevented me from giving earlier attention to the kind statements by newspaper friends in many sections of the state that I would probably be a candidate for governor before the next convention or primary. It may seem unnecessary and somewhat indelicate to decline an honor which has never been tendered me, but I am receiving so many inquiries on the subject that it seems proper for me to speak. I not only will not be a candidate for this or any other office, but am absolutely without political aspirations not connected with medical and public health work.
>
> The rapid development in the field of preventive medicine, and the knowledge that almost half of the sickness and deaths in Kentucky every year are due to domestic pestilence, consumption, typhoid fever, diphtheria, scarlet fever, dysentery, cholera infantum and other communicable diseases, is arousing more and more popular attention every year, and will soon make the state board of health one of the most important and useful branches of the state government, and I have long since decided to devote the remainder of my days to this life-saving work. I am not the less grateful to my friends all over the state, in whose confidence and partiality this suggestion originated, and ask them to give their support to one better trained and qualified to succeed our great young governor."

Health Report of the Isthmus for April.—In his official report for April Dr. Gorgas calls attention to the constantly decreasing hospital sick rate among the employés. During the month there was an entire absence of any quarantinable disease, either smallpox, yellow fever or plague. There has been no case of plague since last August, no case of yellow fever since last December, and no smallpox during the preceding year. Among the civil population, not employés of the canal commission, the showing is equally as good. The death rate among 5,000 whites was 14 per 1,000, and among 22,000 negroes was 33 per 1,000; 6 white and 62 negro employés having died during the month. Pneumonia was by far the heaviest cause of death among the employés, 32 having died from this disease; of these 2 were whites and 30 were negroes. Malarial fever caused 7 deaths, a very much smaller number than any former month. All the deaths from malarial fever were among the negroes. Dysentery caused 6 deaths, 2 among the whites and 4 among the blacks. Of employés from the United States only 3 died, 1 from pneumonia, 1 from dysentery and 1 from accident. There has recently been criticism of the water furnished by the commission, and Dr. Gorgas calls attention to the small number of water borne diseases this report shows among the employés, namely, 6 from dysentery and 2 from typhoid fever. In the civil population, outside of employés, there were 2 deaths from typhoid fever, 8 from dysentery and 19 from other intestinal diseases. This, considering the fact that the Isthmus is a tropical country, and the large proportion of the population who are children in the towns of Panama and Colon, is not a bad showing. This report, Dr. Gorgas states, is the most favorable one that the health department has been able to make since its establishment.

CALIFORNIA.

Books, Instruments, Etc., Needed.

In behalf of the physicians of San Francisco, we again make an appeal to our readers for books, instruments, etc. From private letters and from personal conversation with those who have been there and know actual conditions, we do not hesitate to say that there has never been a time when there was greater need for a practical illustration of fraternalism between physicians than there is at present. Most physicians have duplicate copies of books in good condition, books for which they have no use, bound volumes of journals, etc., which they can contribute without any self-sacrifice whatever. There need be no fear of getting too many copies of one book for there are at least 500 physicians, besides the libraries, among whom to distribute such volumes. The plea for surgical instruments of all kinds is still being repeated. While THE JOURNAL will be glad to receive books, etc., to be forwarded, it will probably be just as satisfactory if those who have anything to contribute will send direct to the chairman of the committee on collection of books, instruments and medical supplies, Dr. Philip King Brown, Lane Hospital, corner of Clay and Webster streets, San Francisco.

The California Relief Fund.

As will be noticed below, the contributions to the San Francisco relief fund now exceed $10,000; but it ought to be $100,000, and would be if those who are able to give realized the actual need of financial help at this time by the physicians of San Francisco. From information received we know that many societies are in course of collecting funds yet to be forwarded. While we are asking for "more" in behalf of the California physicians, we extend thanks for what has already been received.

Pennsylvania Fund.

The following additional subscriptions have been received for the Pennsylvania fund since last week:

Center County Medical Society	$15.00
Gardner, J. H., Stoystown	1.00
McKinley, H. C., Somerset	1.00
Northampton County Medical Society	50.00
Reber, Wendel, Philadelphia	5.00
Unaccounted	5.00
Wayne County Medical Society	5.00
Wilson, Henry	1.00
	$83.00
Previously acknowledged	$1,916.50
Total	$1,999.50

The following additional contributions have been received at THE JOURNAL office to Tuesday morning at 9 a. m.:

Academy of Medicine of Toledo and Lucas County	$100.00
Bardin, Z. M., Lynchburg, S. C.	2.00
Bridgham, S. D., Walla Walla, Wash.	5.00
Crawford County Medical Society	6.00
Dodge, F. A., Le Suer, Minn.	5.00
El Paso County (Colo.) Medical Society	60.00
Fairfax, H. R., McComas, W. Va.	5.00
Gage, Homer, Worcester, Mass.	10.00
Howe, H. A., Chicago, Ill.	1.00
Kerr, Abram, Ithaca, N. Y.	5.00
Lincoln County Medical Society	10.00
Lundgren, C. E., Harris, Minn.	2.00
Mayer, L. H., Johnstown, Pa.	2.00
Monongalia County Medical Society	50.00
Morris, W. E.	1.00
Perkly, A. B., Morenci, Ariz.	5.00
Roberts, T. M.	1.00
Scott County Medical Society, Davenport, Iowa	25.00
Simpson, A. W., Washington, Ga.	5.00
Smith, F. C., New York City	5.00
Teschan, Rudolf C., Milwaukee, Wis.	5.00
Thompson, Harry French, Buffalo Center, Iowa	10.00
Thorn, J. W., Cllo, Ark.	2.00
Tupper, A. M., Rockport, Mass.	5.00
Tuthill, A. M., Morenci, Ariz.	5.00
Washington, J. N., Van Buren, Mo.	2.00
Welst, Sard, Longmont, Colo.	5.00
Lafayette County (Wis.) Medical Society, $2.00	
Birkbeck, S.	$1.00
Lehnkering, C. F.	$2.00
Lawrence County (Ind.) Medical Society, $12.00	
Berns, J. D.	$1.00
Sherwood, W. C.	$1.00
Dines, W. H.	1.00
Shrum, Riley	1.00
Dynemn, J. R.	1.00
Smith, W. H.	1.00
Emery, C. H.	1.00
Stipp, F. E.	1.00
Hunter, F. S.	1.00
Walls, G. W.	1.00
Kelly, J. C.	1.00
White, G. W.	1.00
Pottawatomie County (Okla.) Medical Society, $11.00	
Anderson, R. M.	$1.00
Rowland, V. D.	$1.00
Bradford, W. C.	1.00
Sanders, T. S.	1.00
Douglas, G. R.	1.00
Sanborn, G. H.	1.00
Ellis, J. B.	1.00

Total	$ 570.00
Additional Pennsylvania contributions	83.00
Previously acknowledged	9,531.40
Grand total	$10,184.40

FOREIGN.

Queensland Leper Lazarette.—The government has decided to remove the lazarette from its present position near Dunwich, on Stradbroke Island, to Amity Point. The *Australasian Medical Gazette* states that it is probable that the lazarette on Friday Island will be closed, and the inmates removed to Amity Point. The new lazarette will be in two establishments, one for whites and the other for colored patients.

Damages for Roentgen Ray Burn.—Prof. G. Holzknecht of Vienna is one of the leading authorities and experts in Roentgen ray work, and has long been the official Roentgen ray medicolegal expert for the courts of Austria and director of the Roentgen ray department of the Vienna General Hospital. A cable report states that he was sued for damages of $7,500 on account of a serious *x*-ray burn resulting from his therapeutic application of the rays in 1902 in treatment of a cutaneous affection on the back of a male patient. There was no insinuation as to carelessness or neglect, but the court awarded the plaintiff the damages asked.

Syphilis of the Lungs.—Stoicescu and Bacacoglu of Roumania assert that syphilis of the lungs is liable to simulate tuberculosis of the lungs or pneumonia, pleurisy, chronic bronchitis or bronchiectasia. It probably is often mistaken for one of these affections, but mixed specific treatment is liable to do wonders. The trouble is usually a gumma which in time, untreated, entails a cavity and sclerosis. It is liable to develop in children with inherited syphilis as well as in adults. The treatment found most promptly effectual was daily inunctions with 4 gm. of blue ointment and administration of potassium iodid in progressive doses of 4 to 12 gm. a day. An abstract of their original article in a Roumanian paper is published in the *Munch. med Wochft.* for March 27, No. 13.

Insurance Fees and Lodge Practice

The Recent Reduction in Fees.

UNION P. O., LA., May 22, 1906.

To the Editor:—The question of fees for life insurance examinations is up for discussion and final settlement, and it should be settled right once for all, so that it may not be continually bobbing up in the future as a half-finished question.

Whether or not life insurance is now an honest enterprise may well be considered debatable. That it was so at one time may be allowed, but the recent probing into the *modus operandi* of these large corporations has demonstrated beyond all reasonable doubt that the original purpose for which they were brought into existence has lapsed or been lost sight of, and that they are now nothing more or less than immense aggregations of capital, that are being manipulated for the benefit of those who may obtain control of the management.

Mr. Lawson's advice in regard to the other large industrial enterprises might well apply to these, and it is doubtless true that the general public has ceased to invest in their stock as extensively as in the past. Whether or not the investment in a policy of any life insurance society under the existing régime is sound business would seem rather doubtful, and if no one purchased life insurance these corporations would of necessity soon go out of business. Mr. Lawson's statement that the promoters of industrial corporations, organized for the sole purpose of fleecing the general public, would cease to be when there was no longer a market for their fictitious wares becomes a self-evident proposition.

As a side light on this question is the medical examination fee which the various companies have suddenly discovered must be curtailed 40 per cent. in line with other proposed economics. If the interests of the policy-holders were being considered as is now the main contention, then their interests have been daily neglected, lo these many years, for the necessity seems to have arisen quite recently. The New York Life began economizing with its medical staff of examiners some years ago in the same way that is now proposed by the others, yet its policy-holders not only did not benefit thereby, but fared worse.

I venture the following statement, with full understanding of its import: I would not, as a simple business proposition, leaving out many other equally weighty considerations, invest money in a life insurance corporation that could not employ and pay full prices for the best medical talent to make its examinations; that did not always require a full urinary examination, and that did not use every means that medical science places at its disposal to secure favorable risks. The last place to economize for the benefit of the policy-holders is in the pay of those who stand between the unfavorable risk and the treasury of the company.

That medical men will be found to make examinations for $3, $2 or even $1, and in job lots at 50 cents each, is probable, but that any legitimate business enterprise can be conducted in this way is very unlikely.

There are in every community some physicians who reach out for everything available, by fair means or foul. They do fake work, cut prices, take any kind of questionable business that comes along, just so long as there is a dollar in it, and would drag the medical profession down into the mire, if it were not for counteracting influences. But these are not the men whom the respectable element of society or those with valuable business interests usually employ when in need of counsel.

I trust that the American Medical Association, at its next meeting, will take the stand for a flat examination fee of $5.

B. A. COLOMB, M.D.

Reduction in Fees an Injustice to the Physician.

CRESCENT CITY, CAL., May 23, 1906.

To the Editor:—I have been much interested in the communications recently published by you in relation to the examination fees for life insurance, and I think abundant argument has been adduced to convince any fair-minded person that any reduction in fees from the old scale is both unjust to the physician and detrimental to the best interests of the policy-holders.

Thirty years ago I received my degree and entered the practice of medicine and surgery, which I have continued until the present time; not a year having passed that I have not had more or less examining to do for nearly all the old-line companies. In fact, during a part of the first three years I traveled with one of the best life-insurance agents on the Pacific coast and did nothing but examine. I have given the matter of life-insurance work special study, and think I am fairly competent to say what a reasonable fee is for the professional knowledge and skill required in an intelligent and honest examination.

It seems strange to me that physicians not in sympathy with the reduction (and there certainly can not be many who are), are waiting for medical organizations to say whether or not they will submit to the cut. The consciousness of being right and reasonable should be all any high-minded physician, who scorns the idea of being a "cheap John" man should need to prompt him in at once to refuse to submit to the reduction.

When I was notified several years ago by one of the leading eastern companies that thereafter I would be allowed only $3 for an examination, I promptly notified them to revoke my commission. They very promptly replied, saying that owing to my past services and our very satisfactory relations in the work, they would make an exception in my case, and that I should continue as their examiner at the old rate of $5. I have done considerable work for the company since and my bills have been paid without a protest.

Recently I have been notified by circular letters by other companies to the effect that they would make a grading of fees from $3 up, according to the size of the policy applied for. In response to them I simply advised them that my minimum fee for examination is $5, and if that is not satisfactory to them they may erase my name from their list of examiners. I have not heard from them since.

We are not a labor union that must be organized to strike, nor do we want to be considered as such and shut out arbitrarily by a few arrogant insurance nabobs. It is well enough for medical societies to pass and to adopt resolutions protesting against arbitrary dictation of insurance companies, but there is a large percentage of practicing physicians throughout the United States who do not belong to any society, and I appeal to the manhood and professional dignity of those men and ask them to act independently in refusing to accept a "picayune" fee for a high-grade service.

GEORGE J. BROWN, M.D.

"An Effort to Repress the Evils of Contract Practice."

A correspondent writes: "The Niagara Falls Academy of Medicine is circulating a petition which is to repress the evil of contract and lodge practice which so belittles and degrades the profession. It is to be hoped that this degradation to commercialism in medicine will be effectually checked in Niagara Falls, New York and elsewhere. It would be well for the profession in larger cities, especially those in which there is a large foreign element, to follow the example of Niagara Falls, Let there be no honorable place in the medical profession for one who will so far degrade himself as to sell himself into bondage for a *per capita* price of from 75 cents to $1 per lodge member and signify his willingness to answer all calls. No conscientious well-educated physician can afford to accept such a contract. No freeman can ask from our profession such worthless services."

Societies Take Action.

DOCTORS' CLUB OF CHARLOTTESVILLE.

CHARLOTTESVILLE, VA., May 21, 1906.

To the Editor:—I inclose a blank to be used by our members in pursuance of a resolution adopted by the Doctors' Club of this city. I am happy to say that only one man has declined to live up to it and we hope he will reconsider the matter. The Piedmont Medical Society, composed of the most prominent physicians in four or five adjoining counties, has passed a similar resolution. Dr. McCormack is doing a good work for the honor and dignity of our profession.

To the ..... Life Insurance Company.

Gentlemen:—At a meeting of the Doctors' Club of Charlottesville, Va., on April 27, 1906, the following resolution was adopted:

Resolved, That it is the sense of the Charlottesville Doctors' Club that its members shall examine no applicant for Life Insurance for a less sum than $5, his fee to be paid direct by the Company—and that any member who examines for less stands expelled from the society without further action on the part of the society. This resolution does not apply to industrial insurance nor to companies not requiring a physical examination.

In compliance with the above resolution I hereby respectfully tender my resignation as examiner for your company after thirty days from date, unless I receive communication from the company, instructing me to make your examinations at the uniform rate of five dollars for the examination. Very respectfully, —— M.D.

J. H. BROWNING, M.D.

NORTH DAKOTA MEDICAL ASSOCIATION.

At the annual meeting of the North Dakota Medical Association at Fargo, May 16-17, 1906, the following resolution was unanimously adopted:

Resolved, That we endorse the action of the physicians of the Sixth District Medical Society in adopting a schedule of fees commensurate with the time required in such examinations; and

Believing that the duties of insurance medical examiners require a high degree of professional skill, absolute integrity and special attention to the interests of the insurance companies, we do hereby pledge ourselves to exercise skill and care in all examinations and to make no discrimination in examinations or fees to different companies, and further agree to be governed by the following schedule of fees:

$5.00 for each ordinary examination, including urinalysis.

$10.00 for each examination where microscopic examination of urine, sputum or other secretion is required.

$3.00 for each certificate of health for renewal of lapsed policy.

SCREVEN COUNTY (GA.) MEDICAL SOCIETY.

At a meeting of this society, held March 21, the following resolutions were passed:

WHEREAS, The Screven County Medical Society, after due deliberation, finds that a fee of less than $5 for life-insurance examinations is not commensurate with the work done; therefore be it

Resolved (1), That we, the members of the Screven County Medical Society, refuse to make any more life-insurance examinations for less than $5.

(2) That a copy of this resolution be sent to THE JOURNAL of the American Medical Association for publication, and also that a copy be sent to each of the old-line insurance companies.

OTHER COUNTY SOCIETIES.

At a meeting of the Troup County (Ga.) Medical Society, May 10, a resolution was adopted making the minimum fee for life-insurance examinations $5.

Similar resolutions were passed by the Fayette County (Pa.) Medical Society and the Cochise County (Ariz.) Medical Society.

At a regular meeting, held in Camden, April 3, the Medical Society of the County of Wilcox (Ala.) unanimously adopted a resolution making the fee for each life insurance examination $5, and deciding that under no circumstance would this rule be deviated from.

Correspondence

Cheaper Antitoxin.

CHICAGO, May 21, 1906.

To the Editor:—The statements in THE JOURNAL, May 12, page 1449, that the Memorial Institute for Infectious Diseases is said to be supplying antitoxin to the city for $1.50 per 3000 units as against $5.25, the sum charged by the alleged antitoxin trust, is misleading, as it compares the purchasing price of the Memorial Institute with the retail price to the general public of the other producers of antitoxin. The statement was not taken from the Chicago *Health Department Bulletin*, nor did the statement come from me.

The correction of the above statement in THE JOURNAL for May 19, page 1533, gives our purchase and selling prices correctly, $1.50 and $2.25 per 3000 units, and states that other firms have offered the Department of Health antitoxin at practically the same price. This latter statement is true also, but there is a story behind it. All the large producers about the first of the year 1904 doubled the price of antitoxin, not only to the public, but to the Department of Health of Chicago. They offered "Board of Health Serum" after a time at a low figure, but this "Board of Health Serum" had been branded by one of the high price firms as "inferior," and of course we could not consider the use of this antitoxin, as nothing but the

best can find a market in the Department of Health of Chicago. Not until within a few months has any of the high-priced firms offered to sell us the high grade product at the reduced price—not until we secured two ample sources of supply—the New York Department of Health, and the Memorial Institute for Infectious Diseases.

That there may be no further misunderstanding among physicians as to what I said in the Annual Report of the Department of Health on the subject of antitoxin, from which newspapers have quoted, and in some instances conveyed the wrong meaning, I wish you would publish the article entire, as this is all I have said on the subject at any time or place. It reads as follows:

The control of diphtheria and the saving of life depends largely on the early and liberal use of antitoxin. The almost prohibitory price of antitoxin established by the commercial houses has been and continues to be responsible for many deaths from this cause. Numerous examples which go to prove this assertion have been observed. A man earning by hard work $2 a day with seven in family to feed, house, clothe and school, finds three of his children complaining with sore throat. He calls a doctor, who suspects diphtheria. The father is told that it is best to give antitoxin at once and not wait for proof by microscopic examination. The cost of the first dose for the three children is $15, besides the doctor's fee. The doctor is not able to say positively at the moment that the cases are diphtheria and the man hesitates to pay out $15 on an uncertainty. The doctor is dismissed and goes away with a tortured mind. Two days later another doctor is called. The diagnosis is easy now. Antitoxin enough to use up the earnings of a month's labor is used, but too late—death claims two of the neglected children. If antitoxin were sold at a reasonable price such instances as just related would be exceedingly rare. When I related this instance to the agent of one of the high-priced producers of antitoxin, he replied that "the remedy is cheaper than coffins." And so we learn that the price of antitoxin is governed not by the cost of production, but by the price of coffins. The Department of Health will furnish anyone antitoxin at half the manufacturers' present price and if need be furnish the remedy free, but many do not know this, and others with a self-supporting though meager income hesitate to receive charity, and while they hesitate to seek the aid of charity or to pay two prices for a life-saving remedy, diphtheria is doing its deadly work on the innocent.

We can hardly blame a hard-working man who has a large family and a small income if he hesitates to pay $5 a dose for antitoxin when there is a doubt about the diagnosis, as often there is in the early stage of diphtheria. It is the difficulty of early diagnosis and the high price of antitoxin combined which delays the administration of the remedy and is responsible for many needless deaths from this disease. Antitoxin should be as cheap and as free as vaccine. Diphtheria, like smallpox, has been robbed of its terrors by science, but without the intelligent application of the remedies deaths from these diseases will be recorded as before the discoveries were made. Commercialism can be justly charged with the crime of delaying the application of one of these remedies. The public good is paying tribute to private greed.

What is the remedy? It is plain to the sanitarian for he has learned that a life lost is money lost. It is plain to the sanitarian that it would be true economy for a state or a city to establish and maintain laboratories for the production of antitoxin and vaccine to be distributed free to the people for protective and curative purposes. It is difficult for the sanitarian to demonstrate to law makers the wisdom and economy of spending money for saving human lives, but if these diseases were menacing the lives of hogs or cattle there would be less trouble in securing attention from such bodies. The law-making assemblies of this country have spent more time, money and thought on methods and means for saving from disease animals having a commercial value than they ever have for safe-guarding human life. The farmers of this country, through the teachings of the Department of Agriculture, understand animal dietetics and are taught how to prevent and cure diseases in marketable animals. They are taught little from any source how to protect themselves from disease or premature death. The burden of teaching people how to observe the laws of health and hygiene falls on the medical profession—the only body of men in the world that constantly and without regret works against its own financial interests. The physician unceasingly works to keep away epidemics and by advice and warning and by the discovery and application of remedies contributes materially to the health and longevity of the human race.

There is nothing unreasonable in calling on the city or state to aid in applying the remedies discovered and freely given to the people by the physicians. The physicians are reaping no pecuniary reward from the use of vaccine or antitoxin; on the contrary, their visits to the bedside of smallpox and diphtheria cases would be increased manifold if these two remedies were not known. Then why should commercial houses be permitted to reap a harvest from the discoveries made by physicians who have given them without price for the benefit of humanity? Antitoxin and vaccine could be produced at the state university at a minimum cost, which would be far less than is now paid to commercial houses. Not alone money but lives would be saved by placing the price of antitoxin within easy reach of all. Let Illinois keep pace with New York and Massachusetts and begin the manufacture of antitoxin and vaccine at once. It has been demonstrated during the last five years that vaccine properly used renders a person absolutely immune to smallpox. More than 2,000 exposures to smallpox were made at the Isolation Hospital without a single case resulting, thus demonstrating the complete protection from this disease afforded by vaccination when the remedy is properly used. Antitoxin, when early, freely and intelligently used, will render diphtheria practically harmless. The proper application of the remedy awaits the action of the city or state to free us from prohibitory prices.

HEMAN SPALDING, M.D.,
Chief Medical Inspector Chicago Department of Health.

The McBurney Incision in Appendicitis with Abscess.

NEW YORK, May 22, 1906.

To the Editor:—In THE JOURNAL, May 19, 1906, Dr. J. E. Summers says, on page 1510: "I have done the McBurney incision in hundreds of patients, a few of these being pus cases, but it is a dangerous incision for this latter class, even in the hands of the most experienced." My own experience has been so directly at variance with this statement that it seems best to go on record in the matter. For some years I have employed the McBurney incision almost exclusively in all sorts of appendicitis work, pus cases, general septic peritonitis and all the complications that one commonly runs across. If one uses a short McBurney incision in his pus cases, working rapidly by touch instead of by sight, avoiding gauze packing and all drains except a small wick, avoiding counter-openings and other unnecessary procedure, "leaving his patient as nearly alone as possible," and making it a rule to have the entire operation completed in from five to fifteen minutes, I think that he can keep his death rate within 5 per cent. in cases in which infection has invaded structures beyond the appendix. There are very few fields in abdominal surgery in which I can keep the death rate and the hernia rate lower than in appendicitis with abscess in my own practice, and I count the McBurney incision as one of the prime factors. ROBERT T. MORRIS, M.D.

616 Madison Avenue.

Bats as Bedbug Carriers.

PASADENA, CAL., May 18, 1906.

To the Editor:—The editorial in THE JOURNAL, March 17, 1906, page 804, on "Bedbugs and Disease Possibilities," interested me greatly. The reference to small animals as their source of food supply reminds me that when I resided in New York City a small bat that came into my rooms was covered with genuine bedbugs. These were especially numerous under the wings. It seems to me that this little animal could be a very great source of danger as a carrier of disease, as he has free access to our bedrooms, frequently coming directly from the worst lofts or hovels, or even pesthouses. Since this bug-infected bat came to me I have looked on these animals as a sure means of spreading bedbugs themselves. If these bugs are able to transmit infectious diseases, it causes a little animal otherwise not only harmless but in several ways useful to be a great source of danger. I have not seen any mention of the bat being a possible carrier of disease.

EDWIN R. CHADBOURNE.

The Country Doctor.

WARE, MASS., May 24, 1906.

To the Editor:—In the article on "The Country Doctor," in THE JOURNAL, May 19, the author, Dr. John G. Wilson, in my opinion, has overshot the mark; while recognizing a vein of truth in what he says, I consider that some of his statements certainly need qualifying.

The man does not live who has the time and the ability to do good work in surgery, bacteriology, chemical analysis and refraction and attend to a general practice of any size at the same time. The physician who is dependent on his practice for a living must first attend to that part of his work which brings in some adequate return for time spent, and this is more than can be said for most chemical and bacteriologic work as done by the general practitioner. The results of such work are as often negative as positive in the hands of even the most expert. The average patient does not appreciate and will not pay for hours spent in the laboratory, especially if no definite knowledge is gained thereby. While the careful scientific physician is delving in his laboratory his showy, smooth-tongued neighbor is making calls and pocketing two dollars to his one.

The claim that any physician who is capable of making a diagnosis of appendicitis should also be capable of operating is not well founded to say the least. Pray, are years of constant and almost exclusive study and practice of surgical technic to count nothing? It is continuous practice which enables one to do really good work in surgery; and this is well nigh impossible for the general practitioner remote from

hospitals to have. I am a country doctor. I do the minor surgery that comes my way, and in emergency a laparotomy or an amputation. I am fairly well equipped for bacteriologic work and chemical analysis of stomach contents, and can do both. I have a first-class static machine and *x*-ray equipment for skin work, skiagraphy, etc., and have had good results, but not more than one-tenth of my income is derived from all of these combined. So much for my experience. I should be glad to hear from others.

It may be that this community is less favorable for such work than others. I am inclined to think that this is the case.

M. W. PEARSON.

Association News

Extension of Return Limit to Pacific Coast and Mexico.

The Trunk Line Association announces that by deposit of ticket in person by original purchaser with validating agent not later than June 18, and payment of fee of $1 at time of deposit, an extension of return limit may be obtained to leave Boston to July 31.

Lake Transportation Between Detroit and Buffalo.

All rail tickets reading between Detroit and Buffalo over the Michigan Central, Grand Trunk and Wabash railways are optional for transportation between Detroit and Buffalo via the Detroit & Buffalo Steamboat Company. Those who wish to take advantage of this can secure reservations by applying to A. A. Schantz, Detroit, general superintendent Detroit & Buffalo Steamboat Company.

NEW MEMBERS.

List of new members in the American Medical Association from May 1 to May 28, 1906:

ALABAMA.

Jenkins, L. A., Cardiff.

Marriages

EJNAR HANSON, M.D., to Miss Sara Francis Jenner, at New York City, May 23.

W. J. BINGHAM, M.D., Toronto, Ont., to Miss Fanny K. Rice of Clinton, Mo., May 17.

GEORGE F. BLOUGH, M.D., to Miss Anna M. King, both of Camp Grove, Ill., May 16.

VERNON ROBINS, M.D., to Miss Mary Elizabeth Buck, both of Louisville, Ky., May 24.

ARTHUR H. HARMS, M.D., Sterling, Ill., to Miss Alice Ward of Rock Falls, Ill., May 29.

HAROLD G. GOLDBERG, M.D., Philadelphia, to Miss Florence Good of Bala, Pa., June 2.

WILLIAM T. MURPHY, M.D., Waukesha, Wis., to Miss Kitty Murphy of Chicago, May 29.

JOHN B. KOUWENHOVEN, M.D., Yonkers, N. Y., to Miss Grace Atlee of Philadelphia, May 24.

LEWIS M. CAREY, M.D., Novesta, Mich., to Miss Lulu M. Hall of Bad Axe, Mich., May 12.

JESSE CLIFFORD MOORE, M.D., Clio, Iowa, to Miss Edna May Gardner of Eddyville, Iowa, May 17.

GEORGE K. MCDOWELL, M.D., Spokane, Wash., to Miss Jean Dunlop of Parry Sound, Ont., May 30.

FREDERICK GOCHNAUR, M.D., Upperville, Va., to Miss Pearls Fitzhugh Peak of Norfolk, Va., May 23.

CHARLES DUANE COBB, M.D., Boston, Mass., to Miss Ella Elizabeth Rogerson of Bradford, Pa., May 19.

Deaths

Boerne Bettman, M.D. Medical College of Ohio, Cincinnati, 1878; a member of the American Medical Association; a prominent specialist in diseases of the eye, ear, nose and throat; a resident of Chicago since 1883; president of the Illinois State Board of Charities under Governor Altgeld; for many years chief surgeon of the Illinois Charitable Eye and Ear Infirmary; professor of ophthalmology in the College of Physicians and Surgeons, and professor of ophthalmology and treasurer of the Post Graduate Medical School of Chicago, who had been ill for 12 years with insular multiple sclerosis, died from intercurrent pneumonia, at his home in Chicago, after an illness of five days, May 25, aged 49.

Jacob Lafayette Williams, M.D. Harvard University Medical School, 1848; a member of the American Medical Association, Massachusetts Medical Society, American Academy of Dental Sciences, New York Odontological Society, Society for the Advancement of Oral Sciences, etc.; one of the oldest and best known practitioners of Boston; for many years a specialist in oral surgery, died at his home in Boston, May 15, aged 82.

John Elba Owen, M.D. Evansville (Ind.) Medical College, 1879; a member of the Vanderburg County Medical Society and the Indiana State Medical Society; professor of anatomy in the Evansville Medical College and especially skilled as an anesthetist, died at his home in Evansville, May 20, from cirrhosis of the liver, after an illness of three months, aged 51.

Henry Clay Barton, M.D. Jefferson Medical College, Philadelphia, 1896; formerly of Wilkesbarre, Pa.; a member of the Hare Medical Society and the Medical Society of Wilkesbarre; for the last few months a resident of Philadelphia, died in Jefferson Hospital, March 12, from typhoid fever, after an illness of four weeks, aged 32.

Horace M. Shallenberger, M.D. Jefferson Medical College, Philadelphia, 1876, a member of the American Medical Association and a prominent physician of the Beaver valley, Pa., died at his home in Rochester, Pa., May 5, from typhoid fever, after an illness of one month, aged 52.

Adrian D. Williams, M.D. College of Physicians and Surgeons in the City of New York, 1896, formerly a contract surgeon in the United States Army and on duty in the Philippines, died recently and was buried from his late residence in Greenpoint, Brooklyn, May 6.

Henry Lee Cabell, M.D. Medical Department of the University of Pennsylvania, Philadelphia, 1861, of Cedarville, W. Va., a veteran of the Mexican War and Civil War, died at Winchester (Va.) Memorial Hospital, May 16, from brain disease, after a prolonged illness, aged 78.

Robert P. Davis, M.D. Northwestern Medical College, St. Joseph, Mo., 1888, of Woodruff, Mo., a member of the State Medical Association of Missouri and a delegate to that association, died suddenly in his apartment in Jefferson City, May 16, from heart disease.

William J. Gilfillan, M.D. College of Physicians and Surgeons in the City of New York, 1862, a surgeon in the Navy during the Civil War, and an officer of the health department of Brooklyn, died at the home of his nephew in that city, May 23, aged 66.

Harvey Shannon, M.D. New Orleans (La.) School of Medicine, 1868; a Confederate veteran and later a member of the Mississippi legislature; a practitioner of Ocean Springs, Miss., died at the home of his daughter in Nashville, Tenn., May 14, aged 75.

Charles Carroll Bombaugh, M.D. Jefferson Medical College, Philadelphia, 1853, a surgeon in the United States Army during the Civil War, thereafter devoted to literary pursuits, died at his home in Baltimore from gastritis, May 24, aged 78.

Harry A. Brouse, M.D. Jefferson Medical College, Philadelphia, 1878, a member of the Philadelphia County Medical Society, died at his home in Manhattan, Kan., May 10, from locomotor ataxia, after an illness of six years, aged 55.

John R. Davis, M.D. (Examination, W. Va.), a member of the American Medical Association, and one of the oldest practitioners of Moundsville, W. Va., died at his home in that city, May 15, after an illness of several weeks, aged 62.

Thaddeus C. Montague, M.D. Medical College of Virginia, Richmond, 1860, a Confederate veteran and member of the legislature of Virginia, died at his home in Fredericksburg, Va., May 16, after a lingering illness, aged 69.

William Mead Page, M.D. University of Virginia, Medical Department, Charlottesville, 1853, a surgeon in the United States Navy and in the Confederate army, died at his home in Fauquier County, Va., May 9, aged 74.

William Hackett, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, of Highbridge, N. J., died in the Philadelphia Hospital, May 19, from the effects of an overdose of morphin, aged 68.

Albert Hull Seeley, M.D. University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1853, died at his home in Woodhull, N. Y., probably from aortic aneurism, after an illness of five hours, May 4, aged 78.

Eli Allison, M.D. Geneva (N. Y.) Medical College, 1861, a member of the Steuben County Medical Society and several times an officer thereof, died at his home in Wayne, N. Y., May 17, after a long illness, aged 70.

Sardis L. Crissey, M.D. Medical Department of Columbian College, Washington, D. C., 1871, a veteran of the Civil War, died at his home in Washington, April 28, from heart disease, after a long illness, aged 66.

Joseph S. Crane, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1844, of New York City, died at the home of his son in New York, from heart disease, May 20, aged 85.

Edgar Arthur Day, M.D. Long Island College Hospital, Brooklyn, N. Y., 1887, organizer of the Newfoundland (N. J.) Health Association, died at his home in Newfoundland, May 15, after a long illness.

Jacob L. Shriver, M.D., a practitioner of Jolleytown, Pa., for 55 years, died at his home in that place, May 5, from cerebral hemorrhage, after an illness of two weeks, aged 78.

Benjamin F. Pitman, M.D. Cleveland (Ohio) Medical College, 1861, surgeon during the Civil War in an Ohio battery, died at his home in Nantucket, Mass., May 17, aged 78.

Henry H. Chase, M.D. Chicago Homeopathic Medical College, 1881, died at his home in Rock Island, Ill., May 23, from septicemia due to an operation wound, aged 46.

A. Churchill, M.D. Physio-Medical College of Indiana, Indianapolis, 1874, for 50 years a practitioner of Nevada, Mo., died at his home in that city, May 22, aged 70.

M. R. George, M.D. Jefferson Medical College, Philadelphia, 1875, died at his home in College Springs, Iowa, May 10, from consumption, after a protracted illness.

Charles Clipenger Davis, M.D. Medical College of Ohio, Cincinnati, 1854, died suddenly at his home in Robinson, Ill., May 11, from heart disease, aged 76.

John H. Amrock, M.D. New York University, New York City, 1901, died at his home in New Bedford, Mass., May 20, after a long illness.

L. F. Nelson, M.D. University of Maryland School of Medicine, Baltimore, 1849, formerly of Edina, Mo., died in Moberly, Mo., May 17.

Adam E. Ford, M.D. Toronto School of Medicine, 1855, died at his home in Denver, May 17, aged more than 80.

Book Notice

ESSENTIALS OF GENITO-URINARY AND VENEREAL DISEASES Arranged in the Form of Questions and Answers, Prepared Especially for Students of Medicine. By S. S. Wilcox, M.D., Professor of Genito-Urinary Diseases and Syphilology, Starling Medical College, Columbus, etc. Illustrated. Cloth. Pp. 313. Price, $1.00 net. Philadelphia: W. B. Saunders Co., 1906.

This work is a worthy addition to the Saunders Question-Compend Series. We find a few subjects on which we do not agree, namely, that urinary fever is an acute or chronic condition caused by trauma to some part of the urinary tract. It should be regarded as an infection. The treatment advised for acute gonorrheal urethritis can hardly be accepted as the most approved and modern. The work, considered as a whole, is good, and the student and practitioner will find it of much value.

Miscellany

Effectual Vaccination of Mice Against Cancer.—Ehrlich of Frankfurt has had extensive experience in this line. According to his statements published in the *Zeitft. f. aerztliche Fortbildung* for April 1, he has found 230 mice with tumors. All the "tumor mice" were females; most of them had been used for breeding purposes, and the tumors were exclusively on the mammæ. The microscope showed several types of structure in these spontaneous tumors, but all were of epithelial origin. He lays great stress on his success in inoculating successive generations with these tumors, selecting constantly the most virulent strains. By this means he has obtained a strain with a virulence beyond anything ever realized in this line. The Paris strain kills only 10 per cent., and the Jensen strain only 30 or at the most 40 per cent., while his strain is deadly for nearly every mouse inoculated. Among other features of his experimental research is his discovery that the spontaneous carcinoma of one mouse is harmless for all other mice, that is, there is less than one chance in a hundred that inoculation of another animal will give positive results. He found, however, that this inoculation acts like a vaccination, and the inoculated animal is protected thereafter against inoculation with the most virulent specific cancer material. This kind of vaccination proved successful in from 66 to 94 per cent. of the various series of tests, the fluctuations due to the tentative quantities used for the inoculations. A decided immunizing effect was unmistakably apparent in every instance. This immunity develops in the course of a week or so, and lasts for weeks and months. His numerous and repeated tests during more than twelve months always produced the same impression of successful immunization. The results were even better when mice which had given negative results to the primary inoculation of the virulent material were then inoculated a second time with the same material. The first inoculation invariably conferred complete immunity to further inoculations. The immunity conferred is a pan-immunity, protecting against all the types of malignant disease encountered in the experiments, sarcoma and chondroma as well as carcinoma and adenoma. He theorizes in regard to the rôle of the receptors in cancer formation, suggesting that possibly the tumor receptors are those that take up the "growth material." This view is sustained by Starling's experiences in which the rudimentary mammæ of female rabbits increased in size and assumed the aspect of the mammæ in pregnancy when an extract of rabbit embryos was injected subcutaneously. Under the influence of the anchoring of this "growth material" (Wuchsstoff) by the special receptors, the nourishment of the cells became much more abundant, possibly with the formation of more numerous and more rapacious "nourishment receptors." He is convinced that during the colossally complicated processes of fetal

and postnatal development germinal cells frequently become aberrant and misplaced. The protecting appliances of the organism, however, hold these aberrant germinal cells in abeyance and they remain entirely latent through life, thanks to the defensive arsenal of the organism. Otherwise cancer would be much more frequent than it is. He has never met with any evidence to prove a parasitic origin for cancer. For working purposes he accepts with Jensen the assumption that the cancer cell may be regarded and handled as, in itself, a colony-forming parasite.

OSLER AT THE TOMB OF LOUIS.

A. C. KLEBS, M.D.
CHICAGO.

One day last October a small group of men was crowded in the narrow room of the doorkeeper's house of the Mont Parnasse Cemetery in Paris. Outside the autumnal rain was pouring down, not in the least disconcerting those within. A few soaked gendarmes peeped in through the window, no doubt wondering who were these foreign-looking men who spoke the English language and still could not be from across the channel, because of the absence of formality and stiffness evident in their conversation. They seemed like a little band of intimate friends bound together by a great common interest and full of enthusiasm for it. No outsider could have told that they were men working and striving toward the same goal, although separated by wide stretches of that fertile land across the Atlantic. As they chatted on, no difference of age among them was apparent: they all seemed to be in that blessed middle age, with its enthusiasm, hope and eagerness to learn. But there was one who instantly was recognized as their leader, not because of his greater stature, but for his dark eyes, his high forehead and especially for his dignified though jovial and friendly demeanor—Professor Osler, Dr. Osler or plain Osler they called him. And he seemed a young man among young men and happy to be with his "boys." He was the man we had followed through the wards of Johns Hopkins in some early morning hour, had admired his wonderful gift of perception, his penetrating, thorough scrutiny of all the intricate details of morbid manifestations, his never-failing kindness and attention to the individuality of a patient, and before everything his lucid rendering in simple language of the facts before him for the benefit of his hearers. Never can one forget the scenes in the out-patient department, where he stood surrounded by his boys, helping them as a friend in their struggles with some difficult case. He would go to one, put his arm around his shoulder and then begin a friendly inquiry, interspersed with humorous remarks and allusions to the work done by special students on a given subject. Urging, encouraging, inspiring, so we saw him, exact always, dogmatic never, and when the humorous and friendly fire kindled in his eyes we could not help but love him and with him the task we had chosen as our lifework. Thus we imagine those *maitres* of the old French school, a school no longer limited by national boundaries, one of those men who have trodden the paths through the wards of the Salpetrière, the Charité and Laribosiere, the Necker, the Hotel Dieu, making apostles and missionaries in the great cause of scientific medicine.

The photograph shows from left to right the following: Klebs, Chicago; Kayserling, Berlin; Beyer, U. S. N.; Whitman, Paris; McCarthy, Philadelphia; Norton, Paris; Osler, Oxford; Pearson, Philadelphia; Magnin, Paris; Jacobs, Baltimore; Knopf, New York; Evans, San Francisco; Lowman, Cleveland; Brennan, New York; Pottenger, Los Angeles.

The shower had stopped and the sun shone through the clouds and out went the little band. They stopped at the door of a mausoleum which bore the inscription, "Famille Louis," and which held the remains of that great French master of medicine, Pierre Charles Alexandre Louis. And their leader and master who had brought them hither placed a wreath of autumnal leaves on the steps of the mausoleum and told this simple story of Louis:

"While not sitting with Bichat and Laennec on the very highest seats of our professional valhalla, Louis occupies a seat of honor and distinction with his friends, Andral and Chomel, and with Bretonneau and Corvisart, with Bright, Addison and Hodgkin, with Skoda and Schonlein—among the men who gave to the clinical medicine of the nineteenth century the proper methods of work. Louis has special claims to remembrance as the introducer of the numerical method, by which he made his works on typhoid fever and on phthisis storehouses of facts which are consulted to-day by students of these diseases.

"Returning from a prolonged residence in Russia, he took up work at the Charité as a voluntary assistant to Chomel, and for years he noted with the greatest accuracy and detail the chief symptoms in certain diseases and then correlated these with the postmortem appearances. It was an original attempt to introduce mathematical accuracy into the study of disease. The story of his work has no parallel, so far as I know, in our profession. On his return to Paris he was 33 years of age. He entered the hospital as a clinical clerk with his friend Chomel, and for nearly seven years he devoted his entire energies to the rigorous and impartial observation of disease. He took no private practice and allowed nothing to interfere with his daily routine. A number of important researches appeared as a result of these studies. But the two diseases to which he devoted the greater part of his energies were phthisis and typhoid fever, the works on which appeared in 1825 and 1829. Both of these are worth studying to-day as illustrating methods of accurate clinical analysis and pathologic observation.

"But it is not on account of these works or for his subsequent important studies that we meet to-day to do him honor. He has a far higher claim on our affection and gratitude, as through his students he may be said to have created the American school of clinical medicine. Between 1830 and 1850 a group of young men from America studied here and came under his influence in a very special manner. Earliest to arrive, and chief among them in his affection, was James Jackson, Jr., son of Prof. James Jackson of Harvard, and him Louis loved as a son and mourned his untimely death, as we learn from the touching letters to his father. To give the names of Louis' American students is to mention the men who, in the third quarter of the nineteenth century, occupied the most prominent position in our ranks: from Boston, Oliver Wendell Holmes, Henry I. Bowditch, George C. Shattuck; Metcalf, Alonzo Clark, John A. Swett of New York; W. W. Gerhard, Alfred Stille, Pepper, Sr., and Meredith Clymer, of Philadelphia; from the southern states, Power of Baltimore and Cagell, of Virginia. Not only were these men inspired with enthusiasm for medicine and with high ideals in their calling, but there was a personal devotion to their master of a most intimate and delightful character.

"It was my privilege on several occasions to hear Henry I. Bowditch speak of Louis and of his extraordinary kindness to

the young men from America who frequented his clinic, and Dr. Alfred Stille, whose death a few years ago removed the last of this notable band, has often told me of the lifelong affection which he and all of the American pupils had for their great French master.

"It is not too much to say that it was the direct inspiration derived from him that laid the foundation of accurate clinical methods in the United States.

"At the congress concerned directly with a disease so accurately studied by Louis it seems appropriate that we should gratefully acknowledge, on behalf of our brethren in the United States, the deep debt which we owe to this great Frenchman, and in loving memory lay a wreath on his tomb."

And back these men went to their work at the Tuberculosis Congress, inspired by the memories of the great Frenchman's work and that glorious period of 1815 to 1840 of French medicine, the result of the inspiration of the two master minds, Bichat and Laennec. Deeply impressed they were by the solemnity and meaning of this tribute by their American master, their Osler, to one who has passed away, leaving behind him the fruits of his works to the whole world and their country so particularly. And as they went out with Osler's words still in their ears the sense of Ovid's lines came to their minds:

Morte caret animæ, semperque priore relicta
Sede, novis domibus habitant, vivuntque receptæ.

The Relations of the Medical Profession to the Public.—The following editorial appeared in the *Stanford Interior Journal:*

According to program, Dr. McCormack, the representative of the American Medical Association, came on Wednesday and delivered his lecture on "The Relations of the Medical Profession to the Public," at the court house, to a large and appreciative audience. Judge R. C. Warren gracefully introduced the speaker. Dr. McCormack, who is no novice, having spoken on this and kindred subjects all over the United States, immediately began his text. His commanding and graceful presence, his mastery of the English language, his distinct and elegant enunciation, the knowledge of his subject, apparently inexhaustible, and his scholarly methods, commanded instant and persistent attention. He saw that he "had the day" and he used it wisely, simply, brilliantly. There are men made into doctors and there are doctors who were made doctors as soon as they became men. "Yea, from their birth up they were called to treat the sick." Dr. McCormack belongs to this class, and he might have been born talking, too, so far as we know. He has a fluency which is rare, an Irish wit that is exhilarating, and in the presentation of facts and principles all is done with science and skill. Technicalities were so far eliminated that every one, the school children as well as the older ones, readily followed the speaker from start to finish. The large crowd, composed of our best citizens, we are sure will never regret having heard him. They carried home with them impulses more generous to the medical profession; impressions pleasing to remember and suggestions beneficial to their health and happiness. Doctors themselves, and a goodly number was present from Lincoln and Casey—were uplifted by the unswerving firmness with which he upheld the honor and dignity of the medical procession. They had placed before their minds many striking facts which they all should and doubtless will remember. Dr. McCormack, as the poet puts it, is just a very few years past the "Quiet half-way hostelrie on life's long road." His mission is to do good; is not grandiloquent, not exalting his function, not anxious for cheap effects, not making broad the phylacteries, but is loyal to truth, striving after far-reaching results and is most careful not to mislead. In very truth an Apostle of Medicine. May he live long and prosper in the noble work.

Gallstone Colic Without Icterus.—A handsomely illustrated article on this subject by Riedel is published in the *Zeitft. f. aerztliche Fortbildung* for April 1. He remarks that a few years ago he wrote to the presidents of a number of medical societies asking them to have the members as they entered the next meeting requested to state what does the gall bladder contain at the first attack of colic, aside from gallstones? Nearly everyone wrote "bile"; only a few "mucus" or "pus." Riedel found in 100 patients operated on during or soon after the first attack that the bile was normal in none; it was thick and black in 10, and in the other 90 the gall bladder was more or less filled with serum, mucus or pus. The first attack is nearly always due to acute dropsy of the acutely inflamed gall bladder. The stone obstructs the outlet, the bile accumulates and in time its pigments are reabsorbed, leaving the serum. Then comes the acute explosion of the inflammation in a chronically affected organ. He reviews the whole field of differential diagnosis of gallstone affections without icterus, and remarks in regard to treatment that it is not so advanced as that of appendicitis. Physicians strive to make the gallstone "quiet," but, alas, he adds, there is nothing that will make the gallstone stay quiet and at the same time protect against the development of cancer at the spot. He regards every "unsuccessful" attack of gallstone colic as an indication for extirpation of the gall bladder, on the same principles as appendicectomy. This is the only means to guarantee against the passage of the stone into the common bile duct at the next attack, or that smaller stones may not form and cause intoxication if lodged at the papilla, and also to protect against cancer of the gall bladder. Unfortunately, it seems to be true that cancer generally develops in persons whose attention has never been called to their gallstone affection. Careful examination may reveal, however, a history of occasional mild attacks or inflammation of the gall bladder, in the form of stomach cramps. If there is a family record of gallstones, the physician must be on the lookout for such "stomach cramps," and examine the patient carefully during such an attack. If the region of the gall bladder is painful on pressure, some gallstone affection probably exists, and he should advise operation. It is extremely simple in such cases; there is no need even for tamponing, to which much of the after-effects of extirpation of the gall bladder are due. In his experience with about 1,100 gallstone operations, he found carcinoma in 82, ulcer of the stomach or duodenum in 60, and adhesions with floating kidney in 45.

Alligator Oil.—Few people know, says the *Oil, Paint and Drug Reporter,* that the alligator is not only valuable for its skin, but that its grease has a commercial value. It is used principally by manufacturers of chamois leather, probably in conjunction with fish oils, such as crude cod oil, the tanning action depending on the oxidizing of the oils during the fulling and air-drying processes. The preparation of this alligator fat is simple, the flesh of the animal being well sliced and boiled. It is said that the species of alligator indigenous to Madagascar furnishes more solid greases than any other variety of the cayman species, some going so far as to say more than can be obtained from any kind of fish oil. A peculiarity of alligator oil is that it solidifies at the point of congealing, most other marine or fish oils only thickening at the same temperature. After the oil is extracted the flesh is sundried and forms an excellent manure. Certain glands of the alligator, contain a substance having a similar odor to musk, which is used in the manufacture of perfumes.

The Address of Dr. Shipp.—An error in an exchange was copied in THE JOURNAL, April 28, page 1317, paragraph 20. Dr. F. N. Shipp is of Indianapolis instead of Columbus.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

THE FIRST MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

MORGANTOWN, W. VA., May 22, 1906.

To the Editor:—Kindly inform me where and when the American Medical Association held its first meeting, what the attendance was and the number joining. S. S. W.

ANSWER.—The first meeting of the American Medical Association was the first preliminary convention held in New York on May 5-6, 1846. The attendance was 119. The second preliminary convention was held at Philadelphia May 5-7, 1847. The first annual meeting was held at Baltimore, Md., May 2-5, 1848, at which the attendance was 266. Election as a delegate was the only method of obtaining membership at that time.

STATES RECIPROCATING WITH ARKANSAS.

FALCON, ARK., May 23, 1906.

To the Editor:—What states reciprocate with the state of Arkansas, based on an examination taken before the State Board of Medical Examiners of the State of Arkansas? J. H. D.

ANSWER.—Arkansas has made no provision for reciprocity. For further information we suggest that you write to Dr. J. P. Runyan, Little Rock, secretary of the Arkansas Board of Medical Examiners.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending May 26, 1906:

Robbins, Chandler P., asst.-surgeon, ordered to proceed from Fort Ethan Allen, Vt., to Madison Barracks, N. Y., for temporary duty.

Marrow, Charles E., asst.-surgeon, reported for temporary duty at Army General Hospital, Washington Barracks, D. C.; left Fort Monroe, Va., May 20, 1906.

Harvey, P. F., asst.-surgeon-general, relieved from station at Governor's Island, N. Y., and will take station in New York City, in connection with his duties as chief surgeon, Department of the East.

Hogan, David D., contract surgeon, granted an extension of one month to his leave of absence.

Springwater, Samuel A., contract surgeon, left San Francisco, Cal., on leave of absence for two months.

Wing, Franklin F., dental surgeon, left Fort Washakie, Wyo., and arrived at Fort Robinson, Neb., for duty.

Long, Charles J., dental surgeon, left Fort Missoula, Mont., and arrived at Fort Yellowstone, Wyo., for duty.

Carpenter, Alden, dental surgeon, left Vancouver Barracks, Wash., for a professional tour of the posts in Alaska.

Byars, Caspar R., contract surgeon, ordered from Jefferson Barracks, Mo., to duty at Arcadia Rifle Range, Mo., during the target practice season.

Macy, Fred S., contract surgeon, ordered from Fort Adams, R. I., to Fort Ethan Allen, Vt., for temporary duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending May 26, 1906:

Wilson, H. D., surgeon, detached from the Naval Hospital, Portsmouth, N. H., and ordered to the *Dixie*.

Traynor, J. P., P. A. surgeon, ordered to the Naval Hospital, Portsmouth, N. H., for additional duty.

Allen, A. H., asst.-surgeon, ordered to the Naval Hospital, Naval Home, Philadelphia, Pa.

Orders issued by Commander-in-Chief of Asiatic Station.

Edgar, J. M., surgeon, detached from the *Monadnock* and ordered home.

Nash, F. S., surgeon, detached from the *Rainbow* and ordered to the *Monadnock*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending May 23, 1906:

Bailhache, P. H., surgeon, granted leave of absence for one month, from June 9, 1906.

Stoner, G. W., granted leave of absence for three days, under Paragraph 189 of the Regulations.

Stoner, G. W., surgeon, directed to proceed to Liverpool, England, and other points in Continental Europe for special temporary duty, on completion of which to rejoin his station at Ellis Island, N. Y.

McIntosh, W. P., surgeon, granted leave of absence for ten days, from May 25, 1906.

Brown, D. W., P. A. surgeon, granted leave of absence for two months, from July 2, 1906.

Rodman, J. C., acting asst.-surgeon, granted leave of absence for five days, from May 29, 1906.

Townsend, F., acting asst.-surgeon, granted leave of absence for five days, from May 22, 1906.

Weldon, W. A., acting asst.-surgeon, granted leave of absence for thirty days, from July 15, 1906.

BOARD CONVENED.

A board of medical officers was convened to meet at Baltimore, Md., on May 19, 1906, for the purpose of making a physical examination of an officer of the Revenue Cutter Service. Detail for the board: Surgeon L. L. Williams, chairman; Asst.-Surgeon W. H. Frost, Recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended May 25, 1906:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, April 28-May 12; 5 cases.
California: Los Angeles, April 28-May 12, 2 cases; Mill Valley, May 12, 1 case; Oakland, May 7, 3 cases, in camps; Petaluma, May 12, 1 case; Pleasanton, 1 case; Stockton, April 1-30, 1 case.
District of Columbia: Washington, May 5-19, 18 cases.
Florida: General, May 12-19, 14 cases; Jacksonville, May 5-19, 4 cases.
Georgia: Augusta, May 7-21, 4 cases.
Illinois: Chicago, May 12-19, 3 cases.
Kansas: Abilene, April 14, 12 cases; Topeka, May 5-12, 1 case.
Louisiana: New Orleans, May 5-19, 12 cases.
Maryland: Baltimore, May 12-19, 1 case.
Michigan: Detroit, May 12-19, 2 cases.
Missouri: St. Louis, May 5-19, 3 cases.
Montana: General, April 1-30, 3 cases.
Nebraska: Omaha, May 12-19, 1 case.
North Carolina: Greensboro, May 5-19, 2 cases.
Ohio: Cincinnati, May 4-18, 12 cases; Dayton, May 12-19, 2 cases.
Pennsylvania: Lancaster, March 29-April 19, 2 cases; Philadelphia, March 31-April 7, 2 cases; April 14-21, 2 cases; April 28-May 12, 2 cases; Pittsburg, 4 cases, 1 death.
Tennessee: Memphis, April 28-May 19, 29 cases; Nashville, May 12-19, 3 cases.
Wisconsin: Appleton, May 5-19, 3 cases; La Crosse, May 5-12, 3 cases; Marinette, May 7-19, 5 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, April 7-14, 7 cases; Monrovia, March 1-30, 3 cases.
Argentina: Buenos Ayres, Feb. 1-28, 38 cases, 25 deaths.
Belgium: Antwerp, April 21-28, 4 cases, 1 death.
Brazil: Pernambuco, March 18-April 15, 25 deaths; Rio de Janeiro, April 15-22, 1 case.
Canada: Toronto, April 28-May 12, 4 cases.
China: Hongkong, March 31-April 7, 15 cases, 15 deaths.
France: Marseilles, April 1-30, 2 deaths.
Germany: Bremen, April 28-May 5, 1 case.
Great Britain: Bristol, April 28-May 5, 1 case; Cardiff, 2 cases; London, 3 cases; Newcastle-on-Tyne, 1 case.
Greece: Athens, April 21-May 6, 5 deaths; Patras, March 27-April 10, 2 cases, 2 deaths.
India: Bombay, April 17-24, 18 deaths; Calcutta, April 7-24, 206 deaths; Karachi, April 15-22, 20 cases, 13 deaths; Madras, April 14-20, 42 deaths; Rangoon, April 7-14, 51 deaths.
Italy: General, April 26-May 3, 35 cases.
Japan: Hironuma, April 21-28, 1 case.
Russia: Odessa, April 14-28, 30 cases, 6 deaths; St. Petersburg, March 31-April 21, 28 cases, 6 deaths.
Spain: Barcelona, April 20-30, 12 deaths.
Turkey: Constantinople, April 15-29, 2 deaths.

YELLOW FEVER—FOREIGN.

Cuba: Matanzas Province, May 18-23, 2 cases, 1 death.
Mexico: Merida, May 10-12, 3 cases, 2 deaths.
Panama: Colon, May 22, 1 death.

CHOLERA—FOREIGN.

India: Bombay, April 17-24, 40 deaths; Calcutta, April 7-14, 48 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, May 13-21, 2 cases, 1 death.

PLAGUE—FOREIGN.

China: Hongkong, March 31-April 7, 24 cases, 2 deaths.
India: Bombay, April 17-24, 1,084 deaths; Calcutta, April 7-14, 260 deaths; Karachi, April 15-22, 253 cases, 198 deaths; Rangoon, April 7-14, 64 deaths.
Japan: Wakayama, April 21-28, 1 case.
Peru: Lima, April 1-9, 6 cases, 1 death; Mollendo, 1 case, 1 death; Pascamayo, 5 cases, 1 death; Reque, 1 case, 1 death; Trujillo, 4 cases, 3 deaths.

Society Proceedings

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Boston, June 5-8.

American Academy of Medicine, Boston, June 2-4.
Amer. Assn. of Life Insurance Exam. Surgeon, Boston, June 4.
American Gastro-Enterological Assn., Boston, June 4.
American Urological Assn., Boston, June 4-5.
American Proctologic Society, Boston, June 5-6.
American Medico-Psychological Society, Boston, June 12-15.
Massachusetts Medical Society, Boston, June 12-13.
Maine Medical Association, Portland, June 13-15.
Minnesota State Medical Association, Minneapolis, June 20.
West Virginia State Medical Assn., Webster Springs, June 20-22
Medical Society of New Jersey, Atlantic City, June 19-21.
State Medical Society of Wisconsin, Milwaukee, June 27-29.
American Ophthalmological Society, New York City, June 28-29.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held March 28, 1906.

The President, DR. CHARLES K. MILLS, in the Chair.

Sanitary and Moral Prophylaxis.

DR. PRINCE A. MORROW, New York, president of the American Society of Sanitary and Moral Prophylaxis, said that the prophylaxis of venereal diseases has long been recognized as the most difficult and delicate of all problems of social hygiene, and that the satisfactory solution of this problem would represent the greatest possible benefit that preventive medicine could render humanity. Notification, the first and most essential condition of sanitary control, does not appear to him to be practicable; here the medical secret dominates the situation. It is evident that medical measures must be supplemented by influences and agencies which can more effectively intervene in the correction of the causes of these diseases and the conditions under which they are spread; especially must they be adapted to their peculiar nature and communicative mode. He declared it to be the duty of the medical profession to let men know to what they expose themselves, and especially to let them know that the introduction of these diseases into marriage has on their dependents and on future generations all the consequences of crime.

The peculiar difficulties in the way of this prophylactic education was referred to. Experience in dealing with other communicable diseases has shown that the most essential condition of success is the creation of public sentiment. It is especially needful that the light of publicity should be turned on a class of diseases which infect unseen the social body, which aptly typify "the pestilence that walketh in darkness" and whose ravages have been concealed. This, he believes, can be done most effectively by exposing the grave dangers to health from venereal infection, the economic and social interests involved and especially the dangers to the family. Dr. Morrow recounted the experimental work done by the American Society of Sanitary and Moral Prophylaxis organized in New York twelve months ago. It was found that the society must be composite in character, embracing in its membership medical men, representatives of the clergy, the law, public educators, sociologists and public-spirited citizens interested in the social welfare. For the first year it was decided that the meetings should be a sort of continued educational symposium, embracing the subjects of the education of the youth of the country in sexual physiology and hygiene, studying the nature and scope of this instruction, the age at which it should be given, whether it should be progressive according to the age of the individual, through what agencies it should be given, etc. There were further considered the subjects of the education of the young men and young women of the working classes, education of the men of the Army and Navy, and finally the great body of the general public. In the practical application of this educational scheme popular educators and practical pedagogists were invited to point out specific methods for carrying out the work. The question of the education of young women of the working classes was submitted to women physicians for discussion. In the matter of educating men of the Army and Navy the co-operation of the national government was solicited. It was shown that venereal diseases constituted the largest factor in impairment of the efficiency of the service of the Army. The enlightenment of the great body of the general public was regarded as, perhaps, the most important and yet the most difficult part of the society's program. The newspaper press is absolutely barred to the mention of venereal diseases, and yet, Dr. Morrow believes that certain types of newspapers are the most powerful of all agencies in the dissemination of venereal diseases by printing quack advertisements which hold out deceptive promises of cure of gonorrhea in from three to ten days, of syphilis in from 30 to 60 days, leaving their dupes to sow broadcast the seeds of disease which might have been sterilized by scientific treatment. Dr. Morrow states that whether or not this be false ethics, it must be accepted as newspaper ethics. He regards it a fortunate matter that the entering wedge which may serve to open up communication with the public has been found in the *Charities and the Commons*, whose editor has the courage and public spirit to disregard traditional prejudice and print the papers and discussions of the American Society of Sanitary and Moral Prophylaxis.

The educational feature does not represent the entire scope of the society's work. There are in addition committees on treatment, on "the social evil," and on legislation. Dr. Morrow was emphatic in his declaration of the duty of the medical profession to proclaim the doctrine that continence is not prejudicial to health. The almost universal infection of the minds of young men with the converse of this doctrine—the so-called "sexual necessity"—is, in his opinion, the most powerful determining cause of masculine immorality.

Syphilis and Gonorrhea of the Innocent.

DR. EDWARD MARTIN spoke of the women and children as two classes who suffer from gonorrhea acquired innocently. A third class, he said, are the doctors who acquire syphilis in the practice of medicine or surgery. In so far as the children are concerned, he thought it fair to state that a large percentage of hydrocephalic and epileptic children and those exhibiting various dystrophies are due to hereditary syphilis. Possibly 10 per cent. of those blind from birth are so from gonorrhea innocently acquired; 5 to 10 per cent. of the deaf and dumb are so because of syphilis. Dr. Martin regarded as extraordinary the fact that the law compels report of a case of diphtheria, which is easily controlled, the transmission of which can be absolutely prevented by modern means, and that syphilis, which can be conveyed directly to the innocent and passed to the next generation, must not be reported. He would approve, through the public school system of Philadelphia, of all children being educated not only in the prophylaxis and the ultimate results of syphilis and gonorrhea, but of all contagious diseases. He sees no more reason why young women should be taught the functions of digestion than that they should be taught the functions of reproduction.

A second step in prophylaxis, he believes, is in holding to strict accountability those responsible for the conveyance of the disease. A third step is in clearing the streets of soliciting women. He agreed with Dr. Morrow in his estimation of the enormous power of the press in the education of the people.

Influence of Municipal Authority in Suppressing Venereal Diseases.

DR. W. M. L. COPLIN, director of public health of Philadelphia, said that any great public movement to be efficient must be supported by a stronger influence than the written law, namely: the irresistible force of public opinion. He spoke of the concealment from the general public of the dangers surrounding venereal disease as a factor in weakening official efficacy and lessening the activity of departmental energy. He was emphatic in his denunciation of official supervision that gives to vice the suggestion of legal sanction. Although highly desirable, he is not certain that there is the legal machinery necessary for exerting a custodial care by immuring or quarantining individuals known to be actively infected and who continue a line of contact propagating venereal diseases. A form of official suppression partaking more of the nature of a police regulation than a sanitary measure, especially directed toward brothels, he believes of value. He noted that coincident with the recent activity of the police and private societies, the number of admissions to the venereal wards of the City Hospital had perceptibly diminished. He thought that all those who have studied the social evil are agreed that the most efficient influence that at present can be exerted must be educational rather than restrictive, and directed to the awakening of the public mind, morally and physically, to this form of immorality. He suggested the co-operation of health authorities with physicians in popularizing appropriate knowledge contained in pamphlets judiciously distributed. Physicians are undoubtedly negligent in not calling the attention of their patients to the danger of propagating venereal disease both to the innocent and to the official offender. As a part of the educational campaign, he suggests the possibility of the city authorities, through the board of health or the board of education, arranging definite lines of instruction, preferably by lectures, to the advanced classes and especially to youths at that age when the sexual functions first conspicuously become manifest. Dr. Coplin regards as within the realm of the practicable the suggestion that the man contemplating marriage should be certified to as free from venereal infection.

Transmission of Venereal Diseases to the Wife.

DR. JOSEPH PRICE spoke of the great number of women on whom he has operated whose reproductive organs were destroyed as the result of venereal disease. He considers the disease equally destructive to the male reproductive organs. He believes that very few men and women are sterile who have lived a "Bible virtuous life."

Influence of the Young Man in Control of Venereal Diseases.

DR. ROBERT N. WILLSON expressed his great pleasure in realizing in this meeting some results of an effort started six years ago in the university toward awakening the medical profession to the needs outlined by Dr. Morrow. He stated his belief that the matter lies in the hands of the young men and of the mothers of this country. Of the 14,000,000 young men under 30 years of age in America he said that probably 50 per cent. are infected with venereal disease before their thirtieth year. In speaking of the control of the evil, Dr. Willson said that the leading newspapers printed, in the last month, columns on the subject of venereal disease and in plain

terms. Pamphlets had been widely circulated and a million American mothers had had placed in their hands facts which should secure their aid in combating the evil. Literature on this subject had been especially distributed among students. He believes that the laymen can do more than the medical men if the facts were in their hands. The mother can add her influence by educating her boys and girls in the knowledge of simple and normal sexual life, and in telling them of the danger from abuse of these functions.

Social Evil from the Publicist's Viewpoint.

Dr. W. B. Hale of the *Public Ledger* said that in his judgment the chief considerations in the combating of this evil are the reflections concerning the physical effect of transgression on one and on others closely related to him, and a remembrance of those higher obligations of which Dr. Tomkins would speak. The part of the newspaper, he said, is (1) positive—to give whatever publicity may seem wise to both these considerations; and, (2) negative—to decline to give publicity to matter calculated to inflame unlawful desires, and to refrain also from publishing items which will pander to the satisfaction of these desires. While in full sympathy with the movement, he felt that the work of the newspaper, in particular, must be chiefly on the negative side. He thinks much would be gained if the newspaper press were persuaded to refuse to publish inflaming news stories, or, at least, displaying them, as is now the case with a certain class of the newspaper press. He does not believe it wise in the accounts of disorderly houses raided to give the streets and numbers of these houses, and as to advertising places like this in due form of advertising, he declared that a community that would tolerate it is not a decent community. He thought the effort against the social evil can be directed to no better purpose than to discourage the circulation of papers advertising lewd houses, massage houses, rooms with privileges, and illegal practitioners. As to the positive influence for good which the newspaper might exert, he feared that in the present state of public sentiment it would not be possible to print the facts presented to the meeting. He is not convinced that it is the function of the newspaper to enter on a specific campaign against the social evil, but believes that it is one of the responsibilities of the press to fight the evil as it can and at least to do all possible to keep the general tone of the press sweet, sound and wholesome so that the particular work under discussion can be carried on effectually by those on whom it must chiefly rest, the fathers, the mothers, the medical profession and the pulpit.

Social Evil from the Viewpoint of the Pulpit.

The Rev. Dr. Floyd W. Tomkins said that the pulpit believes, first, that the ideal of social morality must be kept very high, and there must never be any question of lowering it; the licensing or segregation idea can not be considered; second, there must be equal justice in judgment so that the one who sins shall be judged as severely as the other; there must be the teaching in plain terms that there is no difference between the sin of the man and the sin of the woman, unless it make the sin of the man the greater. Much is heard of "fallen women," but nothing of "fallen men." The woman, sinning from love, is ostracized; the man, sinning from lust, is not only allowed to go scot free, but is welcomed in social circles and allowed to mingle with the wives and daughters who should be protected. In the third place, everything possible must be done to educate in the schools and colleges, as well as in the family. In the fourth place, there must be impressed on physicians as well as on ministers the necessity of firm personal appeal and earnest warning.

NATIONAL ASSOCIATION FOR THE STUDY AND PREVENTION OF TUBERCULOSIS.

Second Annual Meeting, held at Washington, D. C., May 16-18, 1906.

The work of the association began with a joint meeting held with the Association of American Physicians on Wednesday evening, President Billings of the latter society presiding.

Immunity in Tuberculosis.

Dr. Simon Flexner, New York, gave a general review of the work accomplished since the inception of this idea. The question of the difference between tubercle bacilli in different types of mammals is of great importance in the problem, the avian infection occurring rarely in man. Human tuberculosis is caused by either the human or the bovine bacillus. The attempts to limit the disease in man must depend largely on the methods of infection. The reduction of 35 per cent. in the mortality from the disease in New York since 1886 is a great encouragement. Immunity has been attempted by various products. Tuberculin will increase the resistance in some animals, but not in a marked manner, it being almost innocuous to the bacillus-free body. Dead bacilli produce a reaction, but the body is still susceptible to the living organism. The only immunity worthy of the name has been produced by the inoculation of living bacilli. Acquired immunity does not appear in man, yet there appears to be a refractory condition that is increased by infection, the human body possessing a strong inherent capacity to overcome the action of the tubercle bacillus. Dr. Flexner reviewed the efforts of various observers to induce immunity, stating that Behring deserves credit for demonstrating that in animals some degree of resistance can be produced. The question as to the duration of this resistance, which Behring thinks is during life, is still open. When immunity has been produced in cattle by the action of living human tubercle bacilli, are the cattle dangerous to the consumer? There are but few observations on this question, and no scientific deductions have been made. Finally, reference was made to the new use of tuberculin in treatment advocated by Wright, the cautious injection of this material tending to produce a rise of the opsonic index. This problem is one of great intricacy, but there appears the possibility of arousing the organism to put forth greater effort against the invading bacillus.

Duties, Responsibilities and Opportunities of the Association.

Dr. Lawrence F. Flick spoke of the good work accomplished by the association during the past year. Three things are prominent: the bringing to this country of the next meeting of the international congress, the establishment of exhibition meetings throughout the country and the creation of an advisory council. For the congress he urges the raising of a fund of $100,000 for expenses, and the early opening in Washington of an office for arranging the details of the meeting. The local exhibitions held in a number of the cities of this country during the past winter accomplished a great deal of good in educating the people. The program is to be extended to other cities and towns. The advisability of establishing permanent exhibitions in the large cities is to be considered.

Surprise has been expressed that physicians who are paid for curing disease should make such efforts to prevent it and thus take away their livelihood; the physician goes into such a crusade as a philanthropist, not as a physician. There is not enough knowledge regarding tuberculosis among others than physicians. More women should become members. Professors in colleges should enlist in this work, as no other class possesses such opportunities for enhancing the cause. The medical profession as a whole has hindered rather than helped the crusade against tuberculosis. Business men do not respond to the call as, for several reasons, they should do. The great work of the society is the creation of public sentiment in favor of its aims. A press bureau for furnishing reliable information concerning every aspect of the tuberculosis problem would be of inestimable value in this respect. The press is now ready to aid and the papers want correct statements about the disease. A lecture bureau to furnish men thoroughly competent to address the people would also help much in spreading knowledge regarding the prevention of tuberculosis.

Report of the Secretary.

Mr. Livingston Farrand, general secretary of the association, stated that the membership at the meeting last year was 406; now it is 1,012. There are now 10 state societies in correspondence with the association, 8 more are forming organizations, and 6 have started a movement against tuberculosis. The exhibition meetings in the various cities were a

success, the attendance being more than 160,000. The association is constantly forming affiliations with societies or organizations that will aid in the dissemination of knowledge. It now has the co-operation of the National Federation of Labor, and numerous magazines are interested in the promulgation of its ideas.

The association adopted the double red cross as the official insignia of the society. The scientific work was carried out under five sections, the sociologic, pathologic and bacteriologic, the clinical and climatologic, the surgical and that on tuberculosis in children.

SOCIOLOGIC SECTION.

Tuberculosis Nostrums.

MR. SAMUEL HOPKINS ADAMS, New York, said that from the perusal of advertisements he has arrived at the conclusion that any one except the regular practicing physician can cure tuberculosis. Physicians do not believe this, but thousands of people do, and therein consists the harm of these frauds. Of the nostrums there are two classes: The positively harmful nostrum containing opium, hasheesh, alcohol or chloroform. The negatively harmful nostrum, which comprises a large list and, unfortunately, contains many so-called ethical preparations endorsed by physicians, though the names of some are frauds, as are the medicines. Improvement is coming from the agitation against these nostrums. Some are now omitting their claim to cure consumption; one says the public is getting "wise" on consumption and something else, as cancer, must be taken up. The work of the public schools is creating a commendable sentiment in the minds of the young. The whole matter of nostrum control is now under readjustment throughout the country. The "patent-medicine" bill in New York passed the senate, but was killed in the house by the pernicious activity of drug interests, which secured the concession of certain unimportant drugs as amendments. These were adopted on the last day, and meant that the bill could not be passed at that session. Maryland fought a good fight, but the Bull's cough syrup and the bromo-seltzer people won out. In Mississippi a bill was killed by the committee on public health. Ohio and Indiana failed, and in Massachusetts a compromise bill was adopted. Many influential journals have come out for legislation. Another hopeful thing is that numerous journals have taken to publishing legitimate news regarding nostrums in spite of their advertisements.

DISCUSSION.

DR. FRANK BILLINGS, Chicago, said that it was unfortunate that in the discussion of this subject the two classes most needing to hear were not present—the laity who suffer from the nostrum traffic and the numerous members of the medical profession who aid the nostrum dealers. He made emphatic the point that all drugs for the specific cure of tuberculosis, whether ethical or not, do more harm than good. The treatment of tuberculosis by drugs to-day is largely the outcome of methods in vogue years ago, when we did not know the nature of tuberculosis. The laity believe in the efficacy of drugs and so, unfortunately, do many physicians who are not educated up to the present-day knowledge of the disease. These physicians in numerous instances are to be reached and educated rather than condemned. Their circumstances do not permit of travel and even of reading as they should. Education of this class is the duty of the association.

DR. J. W. IRWIN, Philadelphia, has made inquiry of druggists regarding the class of people who buy these nostrums for curing tuberculosis. Some believe that poor people buy to escape paying physician's fees, but it is surprising to find what a large number buy the preparations on the advice of physicians. Wealthy people also are patrons. The campaign of education must reach physicians, the laity, school children, teachers and pharmacists.

DR. E. L. TRUDEAU, Saranac Lake, as an illustration of the value of education, mentioned Saranac Lake, where are gathered a large body of people who certainly need cures as much as any one can, yet it would be difficult for nostrum sellers to go among the boarding-houses and dispose of their preparations; the people have been educated against them.

(*To be continued.*)

ASSOCIATION OF AMERICAN PHYSICIANS.

Twenty-first Annual Meeting, held at Washington, D. C., May 15-16, 1906.

(*Continued from page 1643.*)

Perinephritis Simulating Stone in the Kidney.

DR. JAMES TYSON, Philadelphia, has seen four cases in which the symptoms pointed to nephrolithiasis, but in which operation revealed no stone in the kidney. Search for a cause led to the discovery that there were dense adhesions of the perirenal fat to the capsule, and in some instances also adhesions between the capsule and the kidney itself. The capsule in certain of the organs showed distinct cicatricial markings. Relief was invariably obtained from operation, which consisted in splitting the capsule and thus freeing the kidney from pressure and other interference arising from the inflammatory condition. Three of the four patients were totally relieved, the fourth being helped for a time, the symptoms afterward returning. In this case the kidney was also adherent to the liver, the bands being freed when the capsule was split. The return of the symptoms after operation is attributed to the reformation of the attachment to the liver.

Disseminated Sclerosis: Its Infrequency in This Country, and Its Clinical Manifestations.

DR. JOSEPH COLLINS, New York, said that this disease is quite frequent in Europe, but that relatively few cases are reported in this country. The belief that the disease is extremely infrequent here is not justified. The diagnosis is seldom made unless the four classic symptoms of Charcot—nystagmus, intention tremor, spastic paraplegia and scanning speech—are present, but all these are not found in every case. Dr. Collins has seen 65 cases of the disease; in only 26 of them were all the characteristic symptoms present. In 11 of the remaining 39 cases the patients were under observation long enough for all the symptoms to develop. Several types of atypical cases were described: 1. Spastic paraplegia in a non-syphilitic person under 40, with no bone disease, should raise the question of disseminated sclerosis, and if, in addition, there is loss of the abdominal reflex, there is no doubt as to the diagnosis. 2. In persons with pallor of the optic disc, with no inflammatory condition, unchanged by treatment, the chances are that within ten years one or all of the symptoms of sclerosis will develop. 3. The existence of spastic paraplegia, unaccompanied by the history of syphilis or pallor of the optic disc, means disseminated sclerosis. 4. Disseminated insular sclerosis not infrequently gives rise to symptoms like those of acute inflammatory processes in the cord or brain.

DISCUSSION.

DR. B. SACHS, New York, did not regard the diagnosis of disseminated sclerosis as easy. In 220 cases of organic nerve lesion he has made the diagnosis of multiple sclerosis 15 times, five additional cases being doubtful. He thinks that the disease is probably a little less common in this country than in Europe.

DR. WHARTON SINKLER, Philadelphia, believes that disseminated sclerosis is more common in this country than it is thought to be. However, there is apt to be a tendency to go to the other extreme and to make the diagnosis too frequently.

Mental Disorders Associated with Acute Chorea.

DR. B. SACHS, New York, spoke of cases not belonging to chorea insaniens in which varying types of mental disturbance are associated with the choreic disturbances, the two developing simultaneously. These occur during the course of or follow toxic and infectious processes, and are met in cases of acute general chorea in subjects from 10 to 20 years of age. There if often mental dullness or possibly delirium, distinctly different than occurs in ordinary cases. The prognosis is usually grave. In one case the condition was associated with acute rheumatic endocarditis, the rheumatism, endocarditis and chorea all probably being due to the same cause.

Recurrent Acute Pulmonary Edema.

DR. DAVID RIESMAN, Philadelphia, reported six cases of a variety of pulmonary edema which, though rare, is of great

clinical interest, as each attack seems to put the patient in imminent danger of death. Onset is sudden, the lungs and air passages rapidly filling with fluid which, as it is expectorated or runs from mouth or nose, is serous, frothy, and at times blood-tinged. Dyspnea is intense and râles are heard over the chest. Pulse is full and bounding or imperceptible at the wrist. At height of attack the patient appears in danger of suffocation. The first attack may kill, but recurrence is the rule. Dr. Riesman has seen this condition in association with chronic interstitial nephritis, arteriosclerosis, angina pectoris, asthma, and during pregnancy. Two of the six patients died during attacks, and one from cardiac dropsy. The cause is obscure, there being no single explanation. In the two cases of asthma the explanation of Welch suffices. When there is high arterial tension the action of toxins is the best explanation. Treatment, when there is high arterial tension and cyanosis, is venesection. Dry cupping, atropin and diffusible stimulants are indicated in certain cases.

DISCUSSION.

DR. F. P. KINNICUTT, New York, regards the pathogenesis as varied. In those cases occurring in arteriosclerosis there is hypertonicity of the vessels, which usually leads to damage of the myocardium. The sequence then in the production of edema is hypertonicity of vessels, vasomotor spasm, and sudden dilatation of the left ventricle.

DR. H. A. HARE, Philadelphia, emphasized the need of more accurate language regarding the condition of the vessels; by vasomotor spasm is probably meant vascular spasm. Rather against this view are the facts that the vessels in the pulmonary area possess a poorly developed musculature and there is also a scanty vasomotor supply. He regards pulmonary edema as the result of toxemia.

DR. S. J. MELTZER, New York, believes that change in the vessels is the cause of edema. He regards the use of adrenalin as dangerous in pulmonary edema, having seen patients die from the effects of a second injection of that drug. He recommends nitroglycerin.

DR. E. G. JANEWAY, New York, said there are other ways of eliminating serum without its being thrown into the lungs. Excessive perspiration sometimes occurs, and in one of his cases there was profuse diarrhea, the leakage of excessive fluid needing removal thus taking place in other ways. This suggests that the excess of fluid is the condition present and that more changes exist than those in the heart and vessels.

DR. F. P. SHATTUCK, Boston, stated that in acute pulmonary edema of the arteriosclerotic type he employs nitroglycerin. In one case the râles disappeared five minutes after the use of the drug. Morphin is also valuable.

DR. KINNICUTT has used adrenalin frequently in hospital wards. It never has given bad results and frequently does good.

DR. F. FORCHHEIMER, Cincinnati, has used adrenalin and obtained good results. He does not believe that adrenalin also produces edema.

DR. A. L. MILLER, Chicago, confirmed the point made by Dr. Meltzer as to the production of pulmonary edema in animals by the use of adrenalin.

DR. S. SOLIS-COHEN, Philadelphia, said his experience with adrenalin applied locally in edema of the larynx is good, but that edema of the larynx may also be caused by adrenalin. Acute pulmonary edema came on in a physician who was taking large doses of nitroglycerin under the supposition that he had angina pectoris. Adrenalin was given by Dr. Cohen and the edema subsided. Small doses of nitroglycerin were recommended. A second attack of edema subsided under the use of camphor. The patient is now doing well under the influence of one-thousandth grain doses of nitroglycerin, the supposed angina pectoris being really pulmonary edema.

DR. R. H. BABCOCK, Chicago, referred to a case of fatal pneumonia, during which the patient had several attacks of pulmonary edema, which were relieved almost at once by one fiftieth of a grain of atropin.

DR. J. H. MUSSER, Philadelphia, uses morphin early in these cases because there is shock in all of them. Nitroglycerin follows the morphin. In such cases the differential diagnosis between pulmonary edema and acute dilatation of the heart must be made.

DR. JAMES TYSON, Philadelphia, believes atropin to be the most satisfactory remedy in these cases.

Some Dangers of Thoracentesis with Special Reference to Pneumothorax.

DR. GEORGE G. SEARS, Boston, spoke of the two accidents that may follow thoracentesis—sudden death and pneumothorax. Of the former there are 10 cases on record. Of the latter he has found 51 cases in the literature and adds four. The diagnosis in some instances is not easy, and this may account for some cases being overlooked. About one-third of the patients died, but it is doubtful if many died from the presence of air. The puncture of the solidified lung in one case suggests the need of avoiding the reckless use of the needle. It should be used only after all other resources of diagnosis have been exhausted.

Therapeutic Principles Based on Pathologic Physiology.

DR. RICHARD C. CABOT, Boston, said that by pathologic physiology is meant the effort of Nature to react against the causes of disease, as by leucocytosis, hyperemia and similar methods. This form of treatment is to be distinguished from that directed against the etiology, from that destined to remove the results of disease, and from that intended to neutralize symptoms. This treatment aims first, to imitate or to supplement Nature, as illustrated by putting the patient in bed in asthenic conditions, setting broken bones, purgation, establishing passive hyperemia. Second, it aims to oppose Nature, as in forced feeding in Graves' disease, restraining a delirious patient, massage, counterirritation. Third, it aims to modify or to guide Nature, as in diverting thought from disease, giving opium, bathing in typhoid, dieting in diabetes. This type of treatment is not the best nor the worst; it is not so good as treatment directed to the etiology, or so bad as that given to combat symptoms. By this method one must depend on individual factors. Histories must be long and detailed. Not the diseased spot, but the whole patient must be studied.

Pathologic Physiology of Chronic Arterial Hypertension and Its Treatment.

DR. THEODORE JANEWAY, New York, looks on hypertension as the attempt of the organism to maintain capillary flow through important organs and to overcome the effects of disease. This must be followed in turn by organic and functional changes. There are three lines of treatment—preventive, adjuvant and emergent. The first includes hygienic and dietetic rules, the giving of iodids and the exclusion of hypertensive influences. The second includes the use of vasodilators. The third, in cases of sudden conditions, includes venesection, vasodilators, etc. A point emphasized was that the height of the blood pressure is no criterion for the type of treatment.

Therapeutics of Insufficient Kidney, Based on Pathologic Physiology.

DR. ROBERT B. PREBLE, Chicago, regards all the physicochemic methods of testing the function of the kidney, as cryoscopy, the use of methylene blue, etc., as open to grave objections. They should be used only in conjunction with older clinical methods. In cases of low excretion of urine due to heart disease the same precautions should be used as are employed in kidney lesions. The clinical manifestations of nephritis are due to toxins, hence the quantities of toxic materials ingested must be limited and the excretion of those already acting favored. The formation of toxins from food in the intestinal tract must also be borne in mind. Venesection is the most prompt means of eliminating toxins.

Therapeutics Based on the Physiologic Principles of Environment.

DR. WALTER B. JAMES, New York, said that not enough attention is paid to environment in hospital wards. This includes two phases, the psychic and the physical. Under the former are such points as showing the specimens from one case in the presence of another patient with the same disease, recovery from anesthesia in the presence of others to

undergo operation, death in the presence of other sick people. Under the second head he discussed ventilation. There is a difference of opinion as to what ventilation is. He regards expired air as harmless, except for the CO_2 it contains. The temperature and stillness are important features. Most artificial systems of ventilation are faulty, as they attack the problem from the standpoint of respiration instead of the cutaneous needs. He has had a ward cut off from the ventilating system and opened the windows. Typhoid fever patients have been under a sheet only at a temperature of 36°; why not abstract heat continuously, he asks, instead of every three hours? On the whole, his results have been satisfactory.

Physiologic Principles of Feeding in Typhoid and Other Fevers.

DR. F. P. KINNICUTT, New York, reported composite statistics made up from many different hospitals, and discussed at length the general principles governing this method. He secured 733 cases in which the so-called liberal diet was given, and 4,277 in which the milk or fluid diet was followed. In relapses the two are about equal, but in the matter of hemorrhage, perforation and mortality, the liberal diet has a decided advantage over the other. Kinnicutt favors basing the diet on individual cases and not on a routine, especially a fluid diet. If more food is given, the patient will suffer less, and the long, tedious convalescence will be wiped out.

Physiologic Limitation of Rectal Feeding.

DR. D. L. EDSALL, Philadelphia, asserted that the physiologic limitation of rectal feeding is a very narrow one. In a very large proportion of cases the quantity absorbed is only a small part of the amount necessary to maintain nutritional equilibrium. Water and salts are the principal ingredients that are absorbed by the intestine. In the great majority of cases 150 to 300 calories only are thus obtained; in a few cases 500 to 600, and in rare instances the person is kept in good condition. The last group of cases are explained in various ways. Persons who are greatly reduced when feeding is begun may maintain their lowered equilibrium, but this is not health. Emaciated persons may thus increase in weight by the absorption of water. Many cases reported as doing well by this feeding are examples of loose statements. It is possible that in rare instances the ileocecal valve allows the passage of the enemata into the small intestine. Dr. Edsall does not anticipate very much improvement in this method of feeding, as the limitations are of a nature not to be overcome. It may be bettered by the production of artificial substances which the bowel will more readily absorb. At present the dextrinized carbohydrates are the most promising of the carbohydrates employed.

DISCUSSION.

DR. W. S. THAYER, Baltimore, said that Dr. Janeway's experiments show that polyuria begins before blood pressure rises, increased pressure and secondary heart hypertrophy coming on after the polyuria has been present some time. Thayer declared that he has always felt that diet in typhoid fever should be regulated as in other cases of septicemia. The patients of country doctors often are given the best chance in some respects, because there is not the routine as laid down in hospital work.

DR. W. H. THOMPSON, New York, said no mention had been made of changes in the veins analogous to those in the arteries. In them are found hyperemia, inflammation of the intima, atheroma, and calcification when there is no toxemia to cause them. Here strain is acting. Atheroma anywhere is a sign of abnormal strain and means an excess of adrenal substance in the blood.

DR. THOMAS MCCRAE, Baltimore, prefers conservatism on the side of simple liquid diet in typhoid fever. While probably 75 per cent. of patients will recover without this care in diet, we do not know which they are, and we must look out for the others. The statistics presented deal with series in which the mild and the severe cases were fed differently and hence are not of great value.

DR. H. A. HARE, Philadelphia, endorsed the feeding of typhoid patients. During the first ten days he gives milk diet; then when the patient is accustomed to the bed, the surroundings, the attendants, etc., the diet as outlined by Dr. Kinnicutt is ordered. Patients may not do well if the liberal diet is given at first, but it is exceedingly advantageous, he considers, during the later periods. Typhoid ataxia is not seen in patients thus fed. The nitrites are entirely futile in some cases of hypertension, those in which fibrosis of the vessels is present. Iodids, massage and rest do better. Nitroglycerin in these cases will not cause the headaches it does in spasm cases.

DR. ALFRED STENGEL, Philadelphia, stated that while a certain degree of sclerosis probably exists in cases of high arterial tension, there are additional causes and consequently considerable fluctuation in pressure is possible. The diastolic pressure is of great importance in the study of the condition, as if it be not taken into account, an apparent fall with pressure really about the same, may be taken for a real drop.

DR. F. P. SHATTUCK, Boston, has been using the liberal diet for typhoid patients for 13 years, feeding according to the digestive power of the individual rather than according to the disease. The subjects so fed go along more comfortably, and convalescence is shorter. He gives this diet during ulceration, as he supposes all patients have at least some ulcers, but not during attacks of diarrhea.

DR. HENRY KOPLIK, New York, gives more than a milk diet to prevent extreme emaciation in children, who do not recover from this condition so readily as adults. If emaciation be extreme, it is advisable to give the liberal diet even early in the attack.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Miliaria (Prickly Heat).

In carrying out the prophylactic treatment of prickly heat the *Cyclopedia of Medicine and Surgery* recommends that children be lightly clad in thin woolens and exposed to heat as little as possible. Constipation should be avoided. The following is recommended, to be applied locally:

R.	Acidi carbolici	m. xxx	2
	Acidi borici	ʒi	4
	Zinci oxidi	ʒiss	6
	Glycerini	ʒii	8
	Alcoholis	ʒii	60
	Aquæ q. s. ad	ʒvi	180

M. Ft. lotio. Sig.: To be applied locally to the skin.

As a dusting powder the following combination is of value:

R.	Magnesii carb.		
	Acidi borici		
	Pulv. amyli, āā	ʒii	8

M. Ft. pulvis. Sig.: To be dusted over the areas involved.

When the entire body is involved the patient should receive bran, starch or alkaline baths.

Hyde recommends lotions of lead or of lead and opium in some cases, or alcoholic and ethereal solutions containing camphor and glycerin similar to the following:

R.	Acidi carbolici	ʒiss	6
	Glycerini	ʒii	8
	Mentholis	ʒi	4
	Spts. vini rectif.	ʒi	30
	Aquæ q. s. ad	ʒviii	240

M. Ft. lotio. Sig.: To be applied locally.

Or the following:

R.	Olei lini		
	Liq. petrolati, āā	ʒii	60
	Olei bergamii	ʒss	2
	Aquæ calcis q. s. ad	Oi	500

M. Sig.: To be applied externally to the body.

The foregoing combination makes a creamy solution which often is very grateful to the skin. If desired, zinc oxid or carbolic acid may be added.

The general treatment of the patient, according to Hyde, should consist in withdrawal from light and heat, the use of unstimulating food and drink, unirritating apparel, and rest. The free use of lemonade or vichy water or any reliable carbonated water is of value in aiding elimination and in supplying the fluids demanded by the cutaneous loss through evaporation. Lassar's paste is serviceable in some cases of pruritus. It is composed as follows:

℞ Resorcini
Zinci oxidi
Pulv. amyli, āā 5i 4
Liq. petrolati 5ii 8

M. Ft. unguentum. Sig.: To be applied locally.

Or resorcin may be used in the following combination:

℞ Resorcini ..... gr. xxx 2
Creosoti ..... m. xv 1
Lanolini 5ii 60

M. Ft. unguentum. Sig.: To be applied locally to the affected areas.

Copaiba.

Copaiba, according to Beasley, is a diuretic and a stimulant to the mucous membranc in general. It is of value in diseases of the genitourinary organs, as in gonorrhea and gleet, and as an expectorant and disinfectant in bronchitis. Its disadvantages are that it occasionally produces disagreeable eructations and sometimes produces an erythematous rash.

In gonorrhea the following combination is recommended:

℞ Copaibæ 5ss 2
Spts. etheris nitrosi
Liq. potassæ, āā ..... m. x 65
Mucil. acaciæ 5i 4
Aquæ cinnamomi q. s. ad 5i 30

M. Sig.: One such dose after each meal. Or:

℞ Copaibæ
Essentiæ pepsini, āā 5ss 2
Liq. potassæ ..... m. xii 75
Pulv. acaciæ 5ss 2
Aquæ menth. pip. q. s. ad 5i 30

M. Sig.: One such dose three times a day after food.

In the later stages of gonorrhea the following combination is recommended:

℞ Copaibæ ..... m. xx 1 30
Balsami peruviani ..... m. iii 20
Tinct. benzoini ..... m. x 65
Mucil. acaciæ 5iss 6
Syr. aurantii 5ss 2
Infus. buchu q. s. ad 5i 30

M. Sig.: One such dose to be taken three times a day, diluted with an equal volume of water. Or:

℞ Copaibæ ..... m. xx 1 30
Mucil. acaciæ 5i 4
Tinct. belladonnæ ..... m. iii 20
Ext. buchu fld. 5ss 2
Decoct. tritici q. s. ad 5i 30

M. Sig.: To be taken at one dose in a wineglassful of water, and such a dose repeated three times a day.

The following combination is recommended by Beasley in cases of gleet:

℞ Olei copaibæ ..... m. v 30
Salol ..... gr. v 30

M. Ft. capsula No. i. Sig.: One such capsule three times a day. Or:

℞ Olei copaibæ ..... m. v 30
Methylene blue ..... gr. iii 20

M. Ft. capsula No. i. Sig.: One such capsule twice daily.

As a disinfectant and expectorant in bronchitis the following is of value:

℞ Olei copaibæ
Olei cubebæ
Olei santali, āā ..... m. iii 20
Mucil. acaciæ
Syr. tolutani, āā 5ss 2
Decoct. hordei decort. (1:15) q. s. ad 5i 30

M. Sig.: To be taken at one dose and repeated three times a day in similar doses.

Itching of the Skin.

In the treatment of itching of the skin, Biddle, in *Journal of the Mich. State Med. Society*, recommends lukewarm and moderately hot baths, very hot applications and alternate applications of heat and cold. In some cases he recommends acid baths, while in others alkaline baths are preferable. For an acid bath the following combinations are recommended:

℞ Acidi nitrici fortior 5ss 2
Acidi hydrochlor. fortior 5i 30
Aquæ q. s. ad for bath.

Or for an alkaline bath the following:

℞ Potass. carb.
Sodii carb., āā 5iii 90
Sodii biboratis 5ii 60
Pulv. amyli 5viii 240
Aquæ q. s.

Sig.: For a bath.

The most commonly used and the most successful antipruritics are phenol, camphor and menthol, owing to their stimulating and to their local anesthetic effect. Biddle never recommends carbolic acid in strong solutions. The following strength, according to his experience, is preferable:

℞ Acidi carbolici ..... m. xx-xl 1 30-2 60
Aquæ q. s. ad 5iv 120

M. Ft. lotio. Sig.: Apply locally.

Or the following combination:

℞ Acidi carbolici 5iii 12
Glycerini 5i 30
Aquæ ..... Oi 500

M. Ft. lotio. Sig.: Apply locally.

Menthol is recommended, combined as follows:

℞ Menthol ..... gr. x-l 65-3.30
Olei olivæ 5i 30

M. Sig.: To be applied locally.

Astringents may be indicated and in such cases he recommends applications containing alum in weak solution, citric acid or the subacetate of lead in the following combination:

℞ Plumbi subacetatis 5ii 8
Aquæ ..... Oi 500

M. Fiat lotio. Sig.: Apply locally. Or:

℞ Acidi hydrocyanici, dil. 5ss 2
Aquæ ..... Oi 500

M. Fiat lotio. Sig.: Apply locally.

In the class of disinfectants Biddle recommends some preparation containing tar. For its anesthetic effect locally, cocain solutions are recommended, especially in cases of pruritus vulvæ, using great care in its use in order not to establish the habit. For this same purpose resorcin may be prescribed in solution or ichthyol or a silver nitrate solution, the latter applied locally with a brush.

Cholera Infantum.

In considering the treatment of cholera infantum, Cotton, in his text-book of "Diseases of Children," states that the sudden onset and rapid progress of the disease leaves but little time in which to employ remedies, which are frequently successful in gastrointestinal intoxications of a milder type. The early indications for treatment are to counteract the profound depression and to overcome the tendency to blood concentration by increasing the volume of fluids in the body. Food is not indicated in the first forty-eight hours, as digestion and assimilation are impossible in such a disturbed state of the circulation. Brandy is recommended from the beginning or small doses of iced champagne. Digitalin and caffein may be resorted to, given hypodermically, to sustain the heart's action.

In the algid state the empty superficial vessels and a failing pulse may demand nitroglycerin in doses ranging from gr. 1/200 to gr. 1/100 (.0003-.00065); morphin, gr. 1/50 to 1/100 (.0013-.0006), with atropin, gr. 1/500 to 1/1,000 (.00013-.00006), for a child 1 year of age, given hypodermically, is regarded by Cotton as a valuable agent. This dose may be repeated every hour or two for the relief of vomiting and purging and to sustain the heart's action.

When stupor comes on, opium is contraindicated. He mentions the probable value of suprarenal extract in this disease accompanied by such high mortality owing to the similarity of symptoms between chloroform intoxications and those pro-

duced by functional arrests of the suprarenal gland. Next to the need of stimulation is the demand of the system for water. Ice water is recommended given in small quantities by the mouth. Enemas of sterilized water containing sodium bicarbonate and sodium chlorid, each a dram (4.00) to the quart of water, are advised.

Hypodermoclysis of normal saline solutions, from four to six drams (15. to 24), should be given every one or two hours, depending on the frequency of the discharges. Hot baths and hot packs are indicated in the algid state and to aid superficial circulation.

Method of Disguising the Taste of Castor Oil.

Dr. Charles J. McGee, Leavenworth, Kan., writes that while no doubt many of the published formulas for disguising the taste of castor oil answer the purpose, the following method does not require the aid of the pharmacist and yet completely masks the disagreeable taste of the oil:

"Place a tablespoonful of castor oil in an ordinary glass, and to this add the juice of a medium-sized lemon and stir. Then add a little ordinary baking soda (a lump about the size of a large bean), stirring quickly, and drink while effervescent."

Dr. McGee states that he uses this method exclusively and has never had a complaint from a patient when a second dose was ordered.

Medicolegal

Injury as Cause of Tuberculosis.

The First Appellate Division of the Supreme Court of New York says, in the case of Sallie vs. New York City Railway Co., where a man was thrown to the ground while he was in the act of alighting from a car, that the evidence tended to show that before he was thrown from the car he was in perfect health; that when he was thrown from the car one of his ribs was fractured and he was injured in other respects; that he was immediately taken to his home and put in bed; that he gradually grew worse from day to day, and at the end of the second week pleurisy developed in the region of the fractured rib; that the pleurisy progressed rapidly, and shortly thereafter a tubercular condition of the left lung was discovered, which also progressed so rapidly that the injured person died about nine weeks after he was injured. These facts being established, the jury might have found that the injury was the direct cause of the tuberculosis, and this whether the tuberculosis were brought about by the pleurisy or from the weakened condition of the man, which permitted the tubercular germs to develop. If it be conceded, as contended by the defendant, that tuberculosis is a germ disease, and that the germs must enter by the mouth, this would not deprive the plaintiff (the administrator of the man's estate) of a recovery if the germs would not have developed, except for the weakened condition of the man caused by the injury received through the wrongful act of the defendant. There are authorities to the effect that if there is evidence from which the jury may find an unbroken connection and continuous operation between a disease, no matter what, and the injury, then it is for them to say whether the wrongful act which caused the injury is the proximate cause of the disease. If they find it is, then the plaintiff is entitled to recover such damages as may have been sustained. There must, however, be satisfactory evidence justifying such a finding. The matter can not be left to conjecture or speculation. There must be an unbroken connection between the injury and the disease. The evidence here, as already said, would have justified a finding that there was such unbroken connection between the disease which caused the death of the man and the injury to his rib, and therefore there was error in dismissing the complaint.

Statements on "Patent Medicine" Labels and Wrappers.

The United States Circuit Court in Rhode Island says, in Moxie Nerve Food Co. of New England vs. Holland, that there is force in the argument that extravagant claims, statements of marvelous recoveries and secrecy and mystery as to ingredients are such badges of fraud as to warrant a court of equity in refusing to extend a presumption of good faith to a complainant making such claims and in refusing relief. If, however, in respect to ordinary sales, courts of law base the rule of *caveat emptor* (let the purchaser take care) on the commonsense view that in disposing of their wares men will not adhere to the truth, and that a vendor's opinion concerning the merit of goods is, as a practical matter, presumptively unreliable, is it not somewhat inconsistent for a court of equity to act on a presumption that a "patent-medicine" vendor tells the truth on his labels and wrappers? The statements on the label or wrapper of a "patent-medicine" bottle do not prove themselves, and are not competent to prove, the efficacy of its contents. Notoriety, general use and commercial value can more readily be attributed to enormous sums expended in advertising than to actual merit. Would it not be reasonable for a court of equity to hold that a complainant seeking to protect his proprietary rights as the owner of a "patent medicine" should produce legal evidence that it is in fact what it purports to be? Assuming that the efficiency of medicine is a matter of opinion, the only evidence legally admissible to support claims of this character is the testimony of experts whose qualifications to testify are made to appear to the satisfaction of the court. In this case the complainant introduced affidavits of laymen, who said that they had had various diseases which had been cured. It would seem that this evidence is legally inadmissible on the issue of the curative efficiency of a medicine. The only competent legal evidence to prove this is the testimony of experts giving their opinion. Again, the court says that it is a somewhat novel and serious question of law whether the representations as to curative power can be regarded, in view of certain decisions, as a representation whose truth may be inquired into. But this court would be very loath to adopt a rule that in determining whether a complainant comes into court with clean hands a technical line should be drawn between representations of pure fact, such as the ingredients of a medicine, and representations as to the curative power of the contents of a bottle, and classify the latter as representations of opinion, the falsity of which is practically incapable of proof.

Contract by Employe to Allow Examination Invalid.

The Court of Civil Appeals of Texas says, in Galveston, Harrisburg & San Antonio Railway Co. vs. Hughes, an action for personal injuries brought by the latter party, that the defendant company, among other things, pleaded in bar of the action an agreement signed by the plaintiff, in consideration of his employment, to the effect that, if he should sustain any personal injury in the service of the defendant, he would allow its surgeon and any medical examiner he might select to examine his person as often as the company might deem necessary in respect to the alleged injury, waiving all objection to such surgeon or medical examiner testifying whenever called on by the company, and agreeing that his refusal to allow such examination to be made or testimony to be given, should be a bar to the institution and prosecution of any action on account of such injuries. But the Texas statute provides: "No contract made between the employer and employé based on the contingency of death or injury of the employé and limiting the liability of the employer under this chapter, or fixing damages to be recovered, shall be valid or binding." This statute has reference to any contract made in advance of an injury to the employé, based on the happening of such injury, which seeks to limit or restrict the employer's liability. The contract in question was based in part on the event of injury to the plaintiff, and restricted the defendant's liability by doing away with it altogether. Therefore the plea in bar alleging a refusal to allow an examination constituted no bar to the further prosecution of this action.

Statements as to How Accident Occurred Not Privileged.

The Third Appellate Division of the Supreme Court of New York says that, in the case of Benjamin vs. Village of Tupper Lake, brought to recover damages for an injury alleged to have been sustained on a defective sidewalk, a physician who had treated the plaintiff for the injury was called by the defendant and testified that he had a conversation with her as to the

manner in which this accident occurred. He was then asked: "What did she tell you as to that?" Besides, he stated that this talk was while I was making an examination of her in order to prescribe for her and as a part of my examination." The court holds that it was error to sustain an objection to the question. He says that the witness nowhere stated that it was necessary for him to know how the accident happened in order to enable him to act for the plaintiff in a professional capacity, but it was apparent that it was not necessary for him to know how the accident happened in order to enable him so to act. It was sufficient for that purpose that he knew or was informed of the character of the injuries received and not as to how they were received. If the plaintiff in such talk made admissions to the physician as to the manner in which the accident happened, it not appearing that the information so acquired was necessary to enable him to act in that capacity, such admissions were not protected by section 834 of the New York Code of Civil Procedure forbidding a physician to disclose information acquired while attending a patient in a professional capacity and necessary to enable him to act in such capacity.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below

Medical Record, New York.

May 19.

1 The Russian Red Cross. J. Van R. Hoff, U. S. A.
2 *Treatment of Chronic Diseases of the Heart by the Nauheim Methods; Its Indications and Contraindications. F. P. Kinnicutt, New York.
3 *Treatment of Tabes Dorsalis. F. Von Raitz, New York.
4 *Sanitary Supervision of Pulmonary Tuberculosis and Other Communicable Diseases by the Department of Health of the City of New York. J. S. Billings, Jr., New York.
5 Case of Complete Inversion of the Uterus. J. S. Emans, New York.

2. **Treatment of Chronic Diseases of Heart by Nauheim Methods.** In Kinnicutt's experience the most brilliant successes are obtained from this method of treatment in cases of enfeebled, relaxed, dilated hearts, with or without a murmur of muscular or relative mitral incompetence following prolonged and exhausting diseases, the various acute infectious diseases, and also associated with anemia of varied causation.

3. **Treatment of Tabes Dorsalis.**—Von Raitz emphasizes the necessity of employing such means in tabes dorsalis as will improve the nutrition, not only of the system as a whole, but of the affected nerve tissues, and which will change the pathologic conditions to the normal state. He advocates the breathing of pure air, exposure to sunshine, congenial surroundings, plenty of sleep, and occupation of mind and body. The patient should eat what agrees with him best. He also advises salt brine friction of the body in a warm bath twice a week. Clothing should be warm but not overheating. Electricity will increase the nutrition of the cord and brain and the muscular and peripheral nerves. Von Raitz does not believe in the rest treatment, but requires his patients to walk as much as possible.

4. **Sanitary Supervision of Communicable Diseases.** Billings gives the general procedure which the department of health follows in its sanitary supervision of the diseases mentioned. All cases of pulmonary tuberculosis, typhoid fever and cerebrospinal meningitis occurring in the city of New York are registered at the department of health, and all necessary steps are taken to render that registration as accurate and complete as possible. Every person (or the family of such persons) suffering from these diseases is furnished instruction as to the measures to be taken to prevent its extension. Bedding, and so on, used by persons suffering from these diseases, is disinfected. All premises which have been occupied by persons suffering from pulmonary tuberculosis or cerebrospinal meningitis, on death, removal, or recovery of the patient, are disinfected with formaldehyd, or renovation is ordered. Charitable assistance or hospital care is provided so far as is possible for all persons wishing or requiring it. The general public is educated as to the nature of the above diseases, the precautions to be taken against their spread, the advisability of institution and sanatorium treatment and so on. Patients suffering from pulmonary tuberculosis, with no attending physician, are visited at their homes by nurses and given necessary assistance and advice, are provided with extra diet (milk and eggs) when necessary, and are given free medical treatment in the department clinics. Information as to the probable source of infection (water, milk, oysters) is obtained in every case of typhoid fever, and suitable action is taken. In cases of cerebrospinal meningitis quarantine of patients at their homes is enforced and other children in the family are excluded from school. Malarial fever, abortion, puerperal fever, septicemia, erysipelas and pneumonia are reportable diseases, but at present the patients are not visited.

11 Surgical Treatment of Chronic Dyspepsia. G. E. Brewer, New York.
12 Puerperal Infection. H. J. Boldt, New York.
13 Delayed Value of Surgery in Epilepsy in Certain Cases. W. P. Spratling, Sonyea, N. Y.

6. **Rectal Anastomosis of Ureters.** Regarding unilateral implantation of the ureter, as it becomes indicated in defects caused by destructive processes, like tuberculosis or carcinoma of the bladder, or by tumors, vesicovaginal fistula with destruction of ureter, ureteral fistula or trauma, Beck finds that the stenosis is best avoided by splitting the lower end of the ureter so that two flaps are formed which, like two wings of a folding door, are placed into the slit made in the bowel. The ends are made triangular so that a rhomboid figure is attained when the flaps are fastened to the bowel. The large surfaces thus created favor agglutination.

7. **Surgical Treatment of Floating Kidney.**—McRae makes the initial incision, beginning just back of the anterior border of the erector spinæ, immediately below the twelfth rib, extending obliquely to about one inch behind the anterior superior iliac spine, down to the deep fascia. A short cut, one and one-half to two inches long, is next made, in the same direction, beginning just over the anterior border of the erector spinæ, through the fibers of the latissimus dorsi. The deep lumbar and transversalis fasciæ are cut directly downwards to the iliac crest. The latissimus dorsi, the erector spinæ and the quadratus lumborum are pulled backward, the abdominal obliques and transversales forward. To this point the operation is similar to the muscle splitting operation of Mayo Robson. This freely exposes the fat and the iliohypogastric and ilioinguinal nerves. These nerves are pushed aside and the kidney delivered between them, by forceps traction on the fatty capsules, without handling or trauma. A flap of the fibrous capsule about one and one-half inches square is next raised from the posterior surface of the kidney, beginning just in front of the hilum, separated from the cortex by careful dissection, to the convex border of the kidney. The capsule is incised along the convex border of either pole of the kidney, reflected toward the hilum, thus completely exposing the posterior surface of the organ.

Two mattress sutures are next inserted, somewhat similar to the method of Bradle, through capsule just in front of the hilum, including the reflected flaps. These sutures with the suspensory ligament made from the reflected posterior fibrous capsule, hold the kidney high up, well back in the hollow of the loin, nearer in its normal position than is done in any other operation. The fatty capsule pushed in front acts as a protecting cushion. The raw posterior surface adheres firmly. The kidney is next replaced, the mattress catgut sutures passed deeply through the posterior muscles in front of the ilioinguinal nerve and tied over muscles, but underneath fat and skin. A heavy catgut suture is next passed through either angle of the 12th suspensory ligament so as to approximate

the separated muscles and cut fasciæ. A cigarette drain is placed between these sutures to the raw surface of the kidney. The muscles and fasciæ are accurately closed with catgut, above and below these sutures. The skin and superficial fat are accurately approximated by interrupted silkworm gut sutures, with a needle on each end, passed from within out, each suture taking a good bite of deep fascia and muscles. A few catgut sutures are put between the silkworm gut sutures where necessary to approximate the skin.

The wound is dressed with gauze wrung out of hot salt solution and absorbent cotton, held smoothly in place by broad adhesive strips, with an abdominal binder over all. The dressing is changed daily until the drain is removed, usually in twenty-four to forty-eight hours, according to amount and character of drainage. After the drain is removed a dry sterile dressing is put on and allowed to remain until time to remove the sutures, generally on the seventh or ninth day. The patient is kept on the back or operated side for two weeks, and in bed for three to four weeks. A well-fitted abdominal supporter, properly padded, is recommended to be worn for from three to six months. It is a valuable adjunct to the operation. The supporter tends to correct any coexisting enteroptosis, inspires confidence and makes it difficult to wear a tight corset.

8. **Myomectomy.**—Noble claims that myomectomy preserves the possibility of conception, but the probability of it is slight, and in most cases the advantage to the patient lies rather in the fact that the woman has the hope of conception, as contrasted with the certainty of having lost it. From the practical standpoint, the conclusion is inevitable that, so far as the question of pregnancy is concerned, it is of little moment, except in the group of women who ardently desire to bear children, and that in considering the question of hysterectomy versus myomectomy in a woman who does not so express herself, the question of pregnancy is of small practical importance. In his own practice there have been 66 myomectomies out of a total of 337 operations for fibroid tumors.

Noble says that he is not inclined to broaden the field of myomectomy beyond this proportion. If he were to make any change in his practice it would be in the direction of increasing the proportion of vaginal myomectomies in comparatively young women in whom it is still desirable for pregnancy to occur. Vaginal hysterotomy, combined with anterior colpotomy, will enable the surgeon to remove submucous and partly intramural fibroids with safety in many cases. Otherwise he shall continue in the future as he has in the past, to limit the field of myomectomy to the removal of fibroid polyps and submucous fibroids by the vaginal route, and subperitoneal fibroids, when single, or at all events limited to two or three tumors, occurring in childless women less than 40 years of age, by the abdominal route.

14. See abstract No. 2.

15. **Pneumatic Cabinet in Organic Heart Disease.**— After nearly 30 years' observation and reasonably careful study of the results obtained by other methods in the hands of acknowledged authorities, and 14 years' personal experience in the use of the cabinet, Quimby is firmly convinced that it affords more immediate, extensive and lasting relief than any other known measure, although it does not cure incurable organic heart lesions. He says that its use is based on such strictly scientific principles, and the results are so plainly determined by established physical laws, as to justify its description as the nearest approach to the ideal method of treatment in organic cardiac disease.

16. **Depletion in Heart Disease.**—Shattuck accomplishes this either by the abstraction of blood, by means of venesection or leeching or wet cups, by purging and by sweating. The first is the more rapid. If leeches are used the hepatic region is a convenient place, and it is usually well to increase the bleeding by a poultice over the bites. Outside of a hospital he considers purging preferable if there is time. An ounce or two of Epsom salts, in saturated solution, in black coffee, is often serviceable if the stomach will stand it. In some cases compound jalap powder, elaterium or croton oil is preferable. Sweating is best carried out in a cabinet, the patient sitting up. The serous cavities can be tapped. If edema of the legs be hard and brawny, he finds Southey's tubes, modified, helpful. A thoroughly sterilized aspirator needle or trocar of fair caliber can be thrust an inch or more upward into the subcutaneous tissue of the outer aspect of each lower leg or of the thigh, the skin having been previously carefully cleaned. The needle is then packed around with sterile cotton or gauze in order to keep the skin as dry as possible, and is connected by rubber tubes with a bottle hung under the bed. Shattuck regards the old practice of scarification as dangerous. He does not use calomel either as a purgative or diuretic unless he is certain that the kidneys are suffering from nothing more than passive-congestion.

26. **Typhoid Perforation.**—The average period of the disease at which perforation occurred in Woolsey's group of 17 hospital cases was the twenty-seventh day of the disease. In 4 of the 17 cases there had been previous hemorrhage, in at least 1 case distention had been a marked feature, but in the majority of cases the previous course had been that of a typical typhoid and not unusually severe. There was only one symptom that was nearly uniformly present in all the cases, and that was abdominal pain, usually coming on suddenly and generally severe. It was present in 15 out of 17 cases, and slight pain was present in another case. It was usually complained of in the lower half of the abdomen and most often on the right side. In the one remaining case there was no pain, and here an apparently walled-off cavity containing fecal matter and lymph was found on operation. In the case in which the pain was slight there was no perforation in the ileum, but sloughing areas in the sigmoid with perforation. Tenderness was the next most common symptom, being noted in 7 cases in the early stages and in 5 others subsequently. Rigidity was only mentioned in 4 cases at the outset, but developed in 9 others before operation.

Vomiting was present in 4 cases as one of the initial symptoms, often in consequence of the severe abdominal pain, but in one case without any pain or other symptom but weakness. Vomiting was present in 7 other cases. An initial fall of temperature was not noted in any case. Among the late symptoms more or less distention or tympanites was noted in 13 cases, dullness in the flanks in 4, diminution or absence of abdominal breathing in 5 and of the liver dullness in 5. The leucocyte count was high (over 12,000) in 3 cases and somewhat high for typhoid in 4 (7,700, 7,900, 8,000, 9,200), but in one of the latter it had been 12,000 six days before. In others it remained low. Rise of temperature, pulse and respiration was the rule; in some cases the temperature became high. Woolsey emphasizes that (1) the value of severe pain of sudden onset in the lower half of the abdomen as an early sign of perforation and its increased value as an indication for operation when associated with localized tenderness and rigidity; (2) the importance of exploratory operations in case of doubt in view of the good results which follow if no perforation is found and of the earlier period at which the operation is done if perforation is present.

27. **Combined Operation of Appendectomy and Herniotomy.**—Torek describes the operation as follows: An imaginary line is drawn from the anterior superior spine of the ileum to the umbilicus. A point on this line at a distance equal to one-quarter of its length from the iliac spine marks the beginning of the incision, which is carried down from here to the external inguinal ring. The aponeurosis of the external oblique is exposed throughout the length of the incision. This fascia is then incised in the direction of its fibers, as is customary in the gridiron operation for appendicitis, exposing the internal oblique muscle; but the incision is prolonged downward so as to terminate at the apex of the external inguinal ring. The aponeurosis of the external oblique is pared off from the underlying parts in the usual manner, on the outer side exposing Poupart's ligament. Then the hernia operation is proceeded with up to the point where the sac is cut off. Here the hernia operation is intermitted and attention turned to the appendix. The fibers of the internal oblique and transversalis are separated bluntly in the usual manner, the peritoneum is opened, the appendix removed; then the peritoneum, transversalis fascia and muscles are closed again. The appendicitis operation is completed, except that the aponeurosis of the external oblique is still left open. Next the internal oblique and transversalis are sutured to Poupart's ligament, according to any of the approved methods, and finally the aponeurosis of the external oblique is sutured in the entire extent of its incision, so as to close both the appendicitis and the hernia operation. Lastly the skin is sutured. Torek claims that the combined operation has decided advantages over the performance of the two operations at separate sittings. It saves the patient one operation and it takes only very little longer than the hernia operation alone would require. Furthermore, there is greater firmness of the abdominal wall, as it is certainly better to have one incision in the aponeurosis than two.

28. **Appendicular Femoral Hernia.**—A study of 100 cases has shown Wood that appendicular hernia is more frequent than has been supposed. When occurring in conjunction with the cecum no special considerations may be involved, but when occupying the sac alone new problems of treatment are introduced. The appendix is more apt to be found in femoral than in inguinal hernias. It has occasionally been observed on the left side. A herniated appendix is apt to become adherent and inflamed, and as a matter of clinical experience this danger appears to be greater when it occupies the sac alone than when it is accompanied by other portions of the intestine. The diagnosis of appendicular hernia has not been made, as a rule, before operation. In all cases operated on it is desirable to remove the appendix unless the patient's general condition or safety contraindicates this course.

49 Dr. Gregory as a Medical Teacher. F. J. Lutz, St. Louis.

37. **Medicine a Looted Profession.**—To restrain the nefarious custom of manufacturing chemists of flooding the community with their myriads of remedies, Lockwood suggests that the medical profession request manufacturers to remove from all containers of manufactured products everything except the title label, asking them to refrain from having the name of the drug or of the firm blown in the bottle, not to use any peculiar or conspicuously shaped container, nothing but a plain packing bottle with a common label, leaving off formula, medical properties, usages and dose. They should also be asked not to publish such information as is now found in the literature distributed broadcast for the public to read. If manufacturers object to granting this request, Lockwood suggests that the proper plan to pursue would be to petition the legislature to take the matter in hand and force a final issue in behalf of human welfare and professional righteousness.

38. **Ureter Catheterism.**—Mark believes that ureter catheterism is an essential in the differential diagnosis of disease of the upper urinary tract. It is a *sine qua non* in the determination of the relative functionating activity of the two kidneys preliminary to renal operations. In the treatment of certain pathologic conditions of the kidney pelvis and ureter, ureter catheterism is invaluable, and in skilled hands and under proper precautions the use of the ureteral catheter is devoid of danger to the patient.

44. **Subhyaloid Hemorrhage.**—In the case reported by Ball the right eye presented, in the lower temporal quadrant of the fundus, a large hemorrhage, shaped much like the letter D turned 15 degrees to the right. Its upper external extremity was separated from the optic nerve head by a space of one papilla diameter. It was bounded below by a red crescent, which was separated from the main body of the clot by a grayish white line. Scattered along the side of the vessels above the clot were a number of small white round areas of retinal degeneration. Throughout the area of hemorrhage the retinal vessels were invisible.

55 Multiple Abdominal Tumors, Due to Cystic Kidneys, Double Hydronephrosis and Great Dilatation of Ureters, Etc., in a Child Dying at Fourteen Months. L. E. Holt, New York.
56 Examinations of the Urine of Infants. H. D. Chapin, New York.
57 *Lipomatosis Universalis in an Infant Eleven Weeks Old. J. Sobel, New York.
58 *Hypertrophic Pyloric Stenosis in an Infant Ten Weeks Old with Surgical Report of Gastroenterostomy. L. Fischer and A. Stormdorf, New York.
59 Acute Circumscribed Edema. A. D. Smith and F. S. Meara, New York.

57. **Lipomatosis Universalis in Eleven Weeks' Infant.**—Nothing unusual was noted in the case reported by Sobel until the

fifth week of life, when the mother noted a fullness of the cheeks. After this fat began to accumulate in the nape of the neck, the chest, suprapubic region and other parts. The baby became less sensitive to its surroundings and the mother thought it blind. The child nursed and slept well and there was no cough or convulsions. The head was held direct and did not fall backward. There were no evidences of craniotabes. The body length was 19½ inches, the chest measured 15½ inches and the abdomen at the umbilicus 16 inches; circumference of thighs at widest part, 9 inches; weight, 14 pounds. There were no evidences of rickets. In fact, the infant appeared to be normal except for the immense deposition of fat. Death occurred one week later, evidently from pulmonary edema.

58. **Hypertrophic Pyloric Stenosis.**—The case reported by Fischer and Sturmdorf is considered an illustration of a typical hypertrophic stenosis of the pylorus, in which the active symptoms began when the baby was 6 weeks old. All medicinal treatment proving useless, operation was advised. The stomach and intestines were irrigated thoroughly. Through an inch and a half incision, carried slightly to the right of the mid-epigastric line, the hypertrophied pylorus was drawn forward just sufficient to bring the duodenum and the pyloric end of the greater curvature of the stomach into easy apposition, somewhat in the manner of the first step in the Finney operation. The contiguous parts were anastomosed rapidly by a double-tier suture when the abdomen was closed. The operation lasted 22 minutes. The infant lived 30 hours, when it was suddenly seized with clonic and tonic convulsions and died.

60. **Clinical Significance of Urinary Nitrogen.**—As the result of careful observation Ewing and Wolf believe that changes in the partition of the urinary nitrogen may be taken as an index of metabolic disturbances escaping other methods of detection, but they are by no means certain how far the present knowledge of this subject will render this type of urinary analysis practically available to the clinician.

64. **Fetal Ichthyosis.**—This article appeared in the *Journal* of the Missouri State Medical Association, March, 1906, and was abstracted in THE JOURNAL, April 14, 1906, page 1130.

67. **Autosuggestion in Hysteria.**—In the case reported by Gordon there were noted numerous psychic phenomena of autosuggestion, which developed under the influence mostly of reading, and simulated to a remarkable degree some forms of psychoses of which the patient was totally unaware and which developed outside of personal consciousness. There was also an association of hysteria and epilepsy.

68. **Form of Red-Blood Corpuscle.**—In examining series of slides representing tissues derived from autopsies on fetuses, Radasch noted the constant presence and great numbers of red cells that did not possess the classic biconcave shape. A review of the literature shows that the earliest accounts of the red cells ascribe to them a bell shape. The tissues studied were derived from about twelve autopsies performed on fetuses from five months to term, and on one infant 11 days old. Radasch concludes that the majority, if not all, of the circulating cells are bell-shaped and not biconcave. Their presence in the adult body, as well as that of the fetus, is shown by a study of the placenta. Their presence in the fetus and infant seems undoubted, as shown by their abundance and uniformity in shape and size in the fixed tissues. On contact with the air the bell shape is changed to the biconcave, the result of collapse. This is shown by the fixation of blood that has not been exposed to the air, on the one hand, and blood that has been so exposed, on the other.

70. **Ulcer of Stomach.**—Schroeder claims that surgical treatment of gastric ulcer is indicated only when there is organic obstruction, either cicatricial or by adhesions, or when there are frequently recurring hemorrhages. The operations performed may be gastroenterostomy, excision of the ulcer or plastic operations on the pylorus. Schroeder reports a case in which there was marked gastrosuccorrhea with hyperchlorhydria, pylorospasm and gastrectasia. Under carefully prescribed medical treatment the patient made a complete recovery.

71. **Appendicitis Result of Foreign Body.**—Patterson presents a very thorough review of the literature on this subject and reports one case in which the appendix contained a small piece of eggshell.

80 *Dangers of Common Drugs as Seen by the Ophthalmologist. E. E. Blauuw, Buffalo, N. Y.

75. **Atypical Exophthalmic Goiter.**—The patient whose case is reported by Würdemann and Becker presented great exophthalmos, attended by a loss of vision and ulceration of the corneæ, purulent discharge from both nares. The thyroid was slightly enlarged. The heart-beat was rapid, but physical examination did not show any apparent lesion. Death resulted from meningitis. At the autopsy there was found an endothelial degeneration of the pituitary body. No evidences of acromegaly were found.

77. **Traumatic Iridocyclitis.**—In the case reported by Risley four injections of two minims each of tuberculin resulted in a complete relief of the trouble.

80. **Dangers of Common Drugs.**—Blauuw reports from the literature cases of poisoning with various well-known drugs used in eye work, such as common salt, iodoform, β-naphthol and naphthalin, and the effects on the eye of some common alteratives, vermifuges, antipyretics and antirheumatics.

8 What Influence Have Use of X-Rays Had On Treatment of Fractures and Dislocations. J. L. Thomas.

1. **Surgical Complications of Tabes.**—Among the complications mentioned by Bowlby as having occurred in the cases reported are Charcot's disease, spontaneous fractures and perforating ulcers of the foot.

2. **Bacteriology of a Common Cold.**—Of twenty-seven cases examined bacteriologically by Benham, diphtheroid organisms were found to be present in 20 cases out of 21—that is, 95 per cent.—and were isolated in 5 of the cases, also in one of the sanatorium cases. Cocci negative to Gram's stain were seen in 10 out of 21 cases—that is, 48 per cent.—and isolated in 2 cases. Other cocci positive to Gram's stain were seen in 14 cases—67 per cent. Some of these were undoubtedly pneumococci. They were not present in large numbers in any of the cases, nor was it found possible to isolate them. Pfeiffer's bacillus, though carefully looked for, could be found in only 2 cases in small numbers, and was not obtained in pure culture. Other organisms were found in small numbers, much as in normal throats and noses.

4. **Identification by Finger-print Impressions.**—Bateson says that the value of finger-print impressions as a means of identification is not as yet appreciated by insurance companies. There is no doubt that the impression of the finger of a dead person taken before decomposition sets in would fix its identity in a most convincing way if at any previous time the deceased had been required to give an impression of the same finger. Its value as a means of authenticating testamental dispositions can not be overestimated. He says that the simplicity of the process of recording these finger-prints is one of its chief attractions. The apparatus consists of (1) specially prepared printer's ink; (2) a small roller for spreading the ink; (3) a slab of glass, polished copper or porcelain, on which the ink must be rolled out into as thin a film as possible; (4) the paper or card on which the prints are taken, this not to be too highly glazed; (5) a solution of washing soda to remove the ink from the fingers. The ink, roller and slab must be kept scrupulously clean and free from dust, hairs or grit. To take a plain impression, press the finger lightly on the inked slab and then on the receiving surface, and imprint the

design as from a stamp, which in this case happens to be a whorl.

Another more useful form is the rolled impression, which has the advantage of showing a much greater surface and a larger number of points for comparison. To take a rolled impression, the finger is laid on one side and rolled over to the other, so that the plane of the nail is at right angles to the plane of the slab at the commencement and termination of the inking, and if the finger lay on the ulnar side to begin, the movement ended when it lay on the radial edge. The same rotation of the inked finger imprints the design, which by its greater breadth gives the Brobdingnagian impression.

5. **Serum Therapy by the Month.**—For eight years Paton has been using serums by the mouth, both normal serums and the product of immunity, with remarkable results. He says that the theory which best explains their action is that of tissue resistance. That is, that along with antitoxic and antibacterial resistance to infection, or alone when those other elements are absent, there is produced an increased resistance in the tissues to the pathogenic action on them of the organisms present; that this produces what may be called a sterile soil without harmfully affecting the organisms themselves. The organisms themselves having no suitable soil for their action, are readily eliminated.

7. **Case of One Cerebral Hemisphere.**—The patient whose case is reported by Grills was certified as an imbecile when 19 years of age. She was said to be an epileptic, but was not known to have had a fit for twenty years. She was able to mix with the other patients and to walk about the grounds. She could use both arm and leg of the right side, but they were slightly contracted and stiff; she did not make such skilled movements with them as with the left; they were equally well nourished. Sensibility was normal, so far as one could make out, but she had a great dislike of anything cold. Knee-jerks and plantar reflexes showed no appreciable difference on the two sides and were apparently normal. She was not ataxic in gait. Mentally she was imbecile, slow and stupid, but understood spoken language, and sometimes spoke even of her old associates before admission, recalling them by their correct names. She died at the age of 42. About a week before her death she began to walk about in a drunken fashion, rapidly became quite helpless, and died, the cause of her death being certified as congenital malformation of the brain.

At the postmortem all the organs were healthy and normal, with the exception of the central nervous system, which presented the following features: The left hemisphere of the cerebrum was quite symmetrical and was as well shaped as the right hemisphere, except that the gyri were indicated by linear marks and not by deep sulchi. On tapping any part of the hemisphere the percussion wave could be felt, showing that the hemisphere was merely a sac filled with fluid. On an average the membrane was less than one-fourth inch thick. Microscopically it showed no typical motor cells. The cells in the membranous covering were almost all of the globose character, and had few and often no processes which could be demonstrated by the freezing method. The cells in the right hemisphere, on the other hand, were very rich in processes, which could be traced for great distances even among arborizations, and this especially from the large pyramidal cells, which were very prominent. The contents of the sac was a clear and transparent, slightly alkaline fluid. The temporo-sphenoidal lobe on the left side and the region of the island of Reil were not membranous and showed very thin layers of gray and white matter. The corpus callosum was represented by an extremely delicate, white membrane, which tore on the slightest separation of the hemisphere. The right side of the cerebellum was atrophied and weighed 40 grams, as compared with 63, the weight of the left. The olivary body and anterior pyramid of the left side were about one-third the size of the same bodies of the right side. The basal ganglia were not apparently atrophied, except the left caudate nucleus. The left internal capsule was represented by a very thin white band. The right lateral ventricle was about half as large again as it should have been.

The spinal cord on transverse section showed no appreciable difference in size or shape between the right and left halves, and both anterior and posterior cornua were identical in size and shape on the opposite sides, and showed typical ganglionic cells, which were about equal in number and size on the opposite sides. There was no degeneration of fiber in the spinal cord, and the only point in which the cord seemed to differ from the normal was that narrow strands of gray matter swept back through the white matter from the anterior cornu of one side across the anterior commissure and into the base of the opposite cornu.

27. **Diagnosis and Treatment of "False Gastropathies."** In THE JOURNAL, May 12, page 1482, the first communication by Déjérine on this subject was reviewed. He here summarizes his method of treating these purely imaginary stomach affections. The diagnosis must be based on the history of the case without objective examination. Any attempt at the latter aggravates the symptoms, as a rule, and fixes the patient in his notion of stomach trouble. The functional disturbance follows some emotion, worry or shock, and is forgotten when life becomes serene once more, but business or domestic

troubles cause its reappearance. The patients apply to one physician after the other; one of his patients had consulted fifty. They thus learn the symptomatology of all kinds of stomach diseases, and experience them in turn or superposed, this blending of the classic syndromes of various gastropathies being one of the important diagnostic signs. The avoidance of certain foods supposed to be harmful leads to emaciation in some cases, and if continued through years, as frequently occurs, the appearance of the patients suggests malignant disease. The long duration of the trouble is evidence against this assumption, coupled with the absence of specific signs of a neoplasm. Fully 90 per cent. of the cases of gastric affections observed at the Salpêtrière come under the heading of "false gastropathies." This diagnosis is confirmed by the complete recovery under appropriate treatment, which consists in strict avoidance of objective examination of the stomach, functional or somatic; strict isolation, bed screened if in the hospital, with exclusion of visitors, and strict milk diet—more than five quarts of milk a day, sipped in frequent small amounts. In short, these patients recover and gain in weight as if by magic under purely psychopathic treatment: "milk isolation." psychotherapy and re-education of the stomach. These gastropathies of psychic origin must not be confounded with true stomach affections occurring in neurasthenies, which require quite different treatment.

29. **Retrouterine Shortening of the Round Ligaments.**—The methods of taking up a loop in the round ligaments, hitherto presented, fasten the loops together in front of the uterus. This technic has several disadvantages, Dartigues states, which can be avoided if the shortening is done at the back of the uterus. The laparotomy and the entire technic, including the suturing of the abdominal incision, can be completed in ten minutes. The two loops are merely tied together, without the necessity for suturing. Nothing is cut nor punctured, no stitches are taken, and consequently not a drop of blood is lost. The uterus is raised and held in normal position without abnormal fixation anywhere. The technic can be readily understood from the illustrations that accompany the description in the article. It has been used on 2 patients at Pozzi's clinic, answering all anticipations.

32. **Etiology of Atheroma and of Arteriosclerosis.** — Loeper defines the lesions of atheroma and arteriosclerosis as sclero-atheromatous endarteritis and calcifying mesarteritis in the arteries and of pure sclerosis in the arterioles. All are the result of a dual process of sclerosis and calcification, alone or in combination, the result of slow, gradual, prolonged action of toxic irritation on the tissues of the artery. Among these arterial poisons, suprarenal extracts, lead, tobacco, ergot and theocin have a decidedly elective action on the arterial system, in which they induce calcification. The aorta suffers most, and rabbits and cows are affected more than dogs, possibly owing to their vegetable diet. The calcification is due more to a nutritional disturbance than to inflammation or necrosis.

38. **Long Remissions in Tuberculous Meningitis.**—This article is based on 3 cases personally observed and 7 from the experience of others. Study of these cases shows that tuberculous meningitis is not necessarily soon fatal, but may allow remissions of varying length. These remissions are very rarely recognized, but several causes are responsible for this. During the remission a few signs persist, showing that the tuberculous affection is only dormant and that a relapse is to be feared. The last relapse has generally an abrupt onset and rapidly fatal course. The pathologic anatomy explains the remissions. The lesion, the initial cause of all the trouble, is localized and undergoes fibrous transformation, but remains, nevertheless, a permanent menace of future irritation and inflammation. Energetic treatment should be instituted during the remission: hygienic measures, tonics (arsenic, glycophosphates and lecithin), avoidance of physical overexertion and of much brain work, with administration of a little calomel now and then for constipation and to increase the secretions, are indicated. Potassium iodid daily in small doses promotes absorption and favors elimination of bacillary toxins. Creosote by the rectum has given good results in his experience. In one of the cases reviewed the remission lasted for five years and a half. Some of the patients seem to be clinically cured at present.

40. **Prophylaxis of Diphtheria in Barracks, Etc.**—Roussel and Job conclude their long study of this subject with the suggestions that prophylaxis should include isolation of every patient with an affection in which the Loeffler bacillus is recognized as the cause. Isolation should be continued until negative results are obtained in two bacteriologic examinations with an interval of a week at least. If the positive findings persist after 40 days of convalescence the patient can be dismissed, but the health of persons in his environment must be supervised. They advise, further, collective isolation of contaminated groups, with daily medical surveillance, for 15 days after the last pathologic manifestation due to the diphtheria bacillus. They also advise preventive injections of diphtheria antitoxin for healthy persons who have been exposed, when the manifestations of the disease are particularly serious, and the number of persons exposed is not too large, and disinfection of all the objects and rooms that the diphtheria patient might have infected in a radius of 39 inches around him. These measures may be regarded as ample under the above condition, namely, daily medical surveillance. The convalescents and the healthy suspects should use a local disinfectant for the throat every day, possibly promoting its action with ammonium bicarbonate to dissolve the mucus. An extensive bibliography is appended.

41. **Injurious Influence of Cooked Meat in Experimental Tuberculosis.**—Richet here gives the details of his experiments with tuberculous dogs fed with cooked meat. He found it the most harmful of all methods of feeding, while raw meat, as the sole food, proved incontestably the best.

43. **Recovery from Pernicious Anemia.**—Chauffard and Laederich report 2 cases of pernicious anemia which, instead of proving progressive, showed retrogression, with the complete recovery of the patients. One was a typical "plastic" anemia, that is, with the marrow elements of the blood assuming abnormal forms, while the other case was of the "aplastic" type, that is, without any evidence of an organic reaction There were no nucleated reds and scarcely 3 myelocytes to 100 leucocytes, and yet in seven weeks the number of reds increased from 560,000 to 3,264,000. The blood-forming organs were aroused to action by the treatment, which included organotherapy and subcutaneous injections of liquor potassii arsenitis. The doses were progressive, from 6 to 20 drops a day, with intermissions of a week every second or third week Calves' red marrow was given in amounts from 40 to 100 gm., chopped or mashed in warm bouillon. It is important to know that the marrow is really red marrow, even if a cyto-

logic test is necessary. Iron and inhalation of oxygen may be useful as adjuvants, but can not be depended on exclusively. Several other cases of cures of pernicious anemia under marrow therapy have recently been recorded.

45. **Treatment of Obesity.**—Labbé and Furet outline the rational treatment of obesity as abstention from salt and free ingestion of fluids, with regulation of the diet.

Semaine Médicale, Paris.

51 (XXVI, No. 17.) *Diagnostic des ruptures utérines. R. de Bovis.

51. **Rupture of Uterus.**—De Bovis reviews his experience with a number of cases of rupture of the uterus and discusses the diagnosis. In the first place, he says, whenever there is dystocia, no matter how slight, the possibility of rupture should be borne in mind. It must be sought for, as whenever it causes symptoms that attract attention the trouble is already irreparable. It is especially liable to occur with face, shoulder and breech presentations, in women who have borne many children, in twin pregnancies, and in case of contracted pelvis. In one-half or one-third of all cases under his observation the trouble has been the result of hydrocephalus or encephalocele. Whenever the obstetrician has had occasion to interfere in the delivery, he should seize the opportunity to verify the integrity of the uterus. The most important sign of a rupture is the sudden exclamation of the patient during the course of labor, a cry of sharp pain, and sometimes an exclamation that "something has broken loose inside." This is followed by a deceptive calm—the labor pains generally stop at once when the uterus ruptures. The exclamation of pain may not have attracted the attention of the attendants, but the arrest of the labor pains is generally noticed and is a valuable aid in differentiation. Hemorrhage generally does not appear with the onset of labor, but is noted after twenty-four or forty-eight hours or longer. It may occur and be very severe as the child is delivered, and the compression on the walls and arteries is thus suddenly removed. Another important sign is the painfulness on pressure of the lower segment of the uterus, in the iliac fossæ toward the superior strait or a little lower, contact of the parts other than the skin causing extreme pain. He remarks that if he had trusted to this sign and operated at once he might have saved one of his patients who succumbed. He hesitated, not liking to open the abdomen on that one sign alone. He believes that many instances of supposed puerperal fever are in reality cases of unsuspected and infected rupture. This may be surmised when hemorrhage occurs secondarily from suppuration of the wound of the rupture and erosion of the arteries, such hemorrhages appearing after the third day or later, sudden, brief, recurring and sometimes occurring at night. Accumulation of blood in the pelvis may cause severe pain from irritation of the peritoneum or compression of nerves. As it is impossible to say what will become later of a once ruptured uterus, he advocates prompt hysterectomy, before infection has had a chance to develop.

55 *Fall von Ulcus ventriculi rotundum mit Cholelithiasis, Cholecystitis, Pericholecystitis und konsekutiver motorischer Insuffizienz II. Grades des Magens; Operation; Heilung. G. Haas.

52. **Physiologic Action of Administration of Hydrochloric Acid on Gastric Secretion.**—Heinsheimer's experiments were made on dogs with a Pawlow fistula and blind stomach pouch. When the hydrochloric acid was given before feeding, it had no more influence on the secretion than simple water. When given at the beginning of secretory activity the latter persisted longer than when water alone had been given.

53. **Phlegmonous Gastritis.**—On the basis of 3 cases personally observed and 80 described in the literature, the history and clinical picture of phlegmonous gastritis are outlined and treatment discussed. Recovery is known in only 4 instances. The affection has a course of from one to twenty days, as a rule, although Glax has reported a case in which the patient recovered by the end of four weeks. Boas recommends in treatment ice externally and internally, opiates in the form of suppositories, morphin, quinin and stimulants, with operative treatment in case of an abscess. In Lengemann's case, the patient, a young woman, was operated on for supposed perforation of an ulcer in the stomach. The findings were those of a localized peritonitis and the anterior wall of the stomach was found transformed into a thickened, rigid plate, characteristic of the phlegmonous affection. The region was washed, tamponed and dressed with hot wet compresses, and the patient soon recovered. Lengemann advocates early laparotomy and tamponing in all such cases, as this is the only means of preventing peritonitis and thus allowing recovery. In 44 of the cases on record there were alcoholic antecedents in 8 cases: in 5 the trouble was referred to errors in diet; in 2 to getting chilled; in 6 to intoxication; to trauma in 2; puerperal fever in 2; pyemia in 2; to swallowing pus from an ulcer in 1; to cancer in 6; to articular rheumatism or typhoid 2 and 1; septic esophagitis in 1; round ulcer of the stomach in 4; and secondary to leg ulcer, to gastrostomy, and to bronchiectasia in 1 each.

About two-thirds of the patients were males, the youngest 11 and the oldest 76. The symptoms are not characteristic and are generally masked by the co-existing peritonitis. The affection was very seldom diagnosed during life. In 3 cases on record no stomach symptoms had been noted and the findings were an autopsy surprise. In 3 cases pus was found in the vomitus and these were the cases that terminated in recovery. The trouble is a diffuse acute suppurative inflammation of the stomach, principally located in the submucous coat, a suppurative infiltration spreading thence to involve the intermuscular connective tissue, and possibly also the serosa, while the mucosa may be swollen and permeated with pus cells. The rarity of pus in the vomitus is explained by Leube as due to the fact that the pus evacuated through the mucosa is digested in the stomach and thus is not macroscopically visible. Vomiting is generally excessive at first but subsides later, to recur again as peritonitis becomes installed. Fever is generally present, and of a pyemic type. In 3 instances there was thrombosis of the liver veins and in some others complicating suppurative pleurisy and pericarditis. The 3 cases personally observed are described in detail with the postmortem findings illustrated. The first description dates from 1656.

54. **Attempts to Introduce a Sound into the Colon.**—Lilienthal gives some radiograms which confirm the assumption that it is almost impossible to succeed in pushing a sound into the colon. When this can be done, it is owing to some individual peculiarity which allows the rectum, sigmoid flexure and descending colon to lie in a straight line.

55. **Round Ulcer of the Stomach Plus Gallstone Affection.**—The patient was a man of 36, who presented symptoms of round ulcer of the stomach, cholelithiasis and cholecystitis, with motor insufficiency. The latter was not due to the ulcer, but was the result of adhesion of the liver to the pylorus, the consequences of pericholecystitis, with resulting stenosis of the pylorus. The patient refused operative treatment at first, but finally consented after three years. He was restored to health by a gastroenterostomy.

56. **Uterine Cancer Operations.**—Veit expatiates on the danger from virulent streptococci and other germs in the early stages of cancer and the danger from the almost invariably degenerated heart in the advanced cases. Antibodies against the germs have developed by this stage, but the heart is ill able to stand chloroform anesthesia. He prepares the cancer for the operation the evening before by curetting and covering with gauze saturated with an antiseptic solution. When the gauze is removed the vagina is wiped dry with sublimate and alcohol. He then administers antistreptococcus serum, and commences the operation by the "hunt for the glands." After detaching the vagina and suturing, he flushes freely the wound in the peritoneum and its vicinity with alcohol, wiping it quickly away. He has been using spinal analgesia instead of chloroform in these cases, and has been much pleased with the technic and results since he adopted it a year ago, although a large amount of the anesthetic is necessary for these abdominal operations. Even if a little chloroform may be required to complete the operation, the amount is trifling in comparison. He places great stress on absolute stillness in the room during the disinfection and anesthetization. His experience confirms Lennander's in regard to the lack of sensibility in the peritoneum. Traction causes pain, but not mere contact.

Venous thrombosis is prevented by tying off the afferent arteries. In his last series of 20 cases, 2 patients died for whom he was unable to procure enough antistreptococcus serum, while all the other patients made a smooth recovery. He regards this as significant. He even affirms that death after this, as after other operations, is always avoidable. The operation must be successful if all conditions for success are insured, with special regard to infection from the germs already in the cancer and the weakness of the heart.

58. **Esophagoscopy.**—Glücksman gives 21 views seen with the esophagoscope in various affections. Most of them are drawn from nature, but two were obtained with the aid of a photographic camera.

59. **Radium in Therapeutics.**—Blaschko relates his experiences with various skin affections treated with radium. He has been particularly pleased with the effect of what he calls a radium plaster, the radium bromid being spread evenly over a celluloid plate, in a very thin layer, protected with lacquer, and fastened to the skin with adhesive plaster. He has found radium an extraordinarily effectual and absolutely harmless remedy for circumscribed, superficial tumors, malignant and innocent, and for a number of otherwise obstinate, chronic inflammatory cutaneous affections.

63. **Rachitis as Result of Domestication.**—Rachitis occurs among children and among animals as the result of defective hygiene, and von Hansemann states, is never observed in animals or children living in freedom. It develops almost inevitably in monkeys kept in captivity, no matter where. It is never observed in uncivilized peoples. In all his extensive research he has never found any evidences of rachitis in a native African. He has made numerous inquiries and has had specimens and pictures sent him of every case of alleged rachitis of which he could learn in the native tribes of the East Indies and Africa. In every instance the trouble proved to be some anomaly in cartilage development, never true rachitis. The latter develops when there is lack of pure air and freedom of movement. It is not known in Japan, but will probably appear there if the Japanese adopt European methods of building houses and dressing the babies. He remarks that we have been able to domesticate dogs, horses and cattle, but not cats. Cats are tamed, but not domesticated. This aspect of domestication was presented by von Hansemann at the Lisbon congress.

65. **Cure of Laryngeal Tuberculosis.**—Alexander gives the details of 7 cases of laryngeal tuberculosis, in which the patients were clinically cured by general and operative measures. In some cases curettement and lactic acid cauterization seemed to do actual harm, and the laryngeal process did not heal until left to itself under general measures. In one case healing proceeded by a kind of membrane formation. No operative measures were attempted in this case for fear of arousing the bacilli bound up in the membrane.

66. **Aortic Affections in Congenital Syphilis.**—Bruhns has found in a number of cases of congenital syphilis indications of inflammatory foci which correspond in every respect to the "productive mesaortitis" described by Chiari in acquired syphilis.

67. **Present Operative Treatment of Laryngeal Tuberculosis.**—Finder reviews the present status of the question and the technic practiced by various surgeons.

74 Address on Awarding the Kussmaul Medal to Bier. Rede. V. Czerny.

68. **Vaccination Against Plague.**—Kolle reports successful results from inoculation of 42 men with cultures of living plague bacilli attenuated by keeping the cultures at a temperature of from 42 to 43 C. The men were kept under observation for four months at least after these protective inoculations, and the absolute harmlessness of the method was fully established. The work was done in collaboration with Strong of Manila, and has already been reviewed editorially, April 14, 1906, page 1114.

69. **Prophylaxis of Epidemic Cerebrospinal Meningitis.** Ostermann remarks that the measures to prevent the spread of meningitis in the great epidemic in Silesia last year proved utterly useless. Never was there such an extensive and obstinate epidemic, and never one so strictly supervised from the start, with medical prophylaxis so scrupulously enforced. Flügge thinks that he has discovered the reason for this failure to be the extensive distribution of the meningococci in the mouths and throats of sound individuals in the environment of the sick. At most the cocci cause in them a catarrhal pharyngitis. The cocci die off quickly on clothing, and on articles contaminated. They thrive, however, as on a congenial culture medium, in the throats of other individuals. Here they persist and infection is spread from this source. Ostermann discusses how best to cope with this danger. Nothing is yet known which will destroy the cocci in the throats without injury to the tissues, but he hopes that some substance will soon be discovered which will answer the purpose in local application. The cocci do not cause general disturbance, but remain strictly localized.

He outlines a warning circular for distribution among the laity. It describes the dangers of the disease and its dissemination by contact, by droplets of moisture in coughing and loud speaking, etc. The public are warned to observe the following precautions for three weeks after contact with a case: 1. To avoid unnecessary intercourse with other people, especially in large gatherings, and to avoid contact, kissing, and the use of common drinking and eating utensils. 2. The discharges from mouth and throat should be deposited on rags or paper handkerchiefs, which should be burned at once. If handkerchiefs are used, they should be boiled for ten minutes or left for an hour in "cresol water." If any of the discharge gets on the fingers they should be washed in this solution and floors and clothing soiled with the discharges should be copiously moistened with it. 3. During speaking and coughing keep at arm's length from other persons. The article issues from Flügge's Hygienic Institute at Breslau. It adds that as the cocci die so soon, it is of little use to send material to a bacteriologic institute for examination. It would be much better to send a bacteriologist to the spot when a case of meningitis occurs, and the author pleads for the appointment of a special bacteriologist to be sent at once to the place and there to co

operate with the local officials. It is wise to regard every individual in the immediate environment as probably infected. The great extent of the epidemic in Silesia was probably due to the fact that the men are nearly all miners and are thus thrown into very intimate contact with each other. The cocci taken home by some of the sound "carriers" found a congenial soil in the throat of some predisposed member of the family, or were handed along to some other family. This explains why the intermediate links in the chain were not always apparent. Isolation of the sick need not be so strict as heretofore, and the disinfection of the rooms after recovery may be restricted to washing the floor, bed etc., with a solution of sublimate, and soaking suspicious body linen in the same solution. The remarkably low resisting powers of the meningococci, as soon as they have left the human body, render further measures superfluous.

75 and 76. **Tuberculous Infection in Early Childhood.**—Salge tested 80 children for serum agglutination of tubercle bacilli. All but 9 were infants. In 20, that is, in one-fourth of all the children, the reaction was positive. These findings were discussed editorially in THE JOURNAL, May 19, page 1528, as also the following article by Schkarin. The latter found positive agglutination in 25 per cent. of the children examined, belonging to what Czerny calls the "exudative diathesis," while 62 per cent. of those with what Heubner calls "scrofulosis," gave a positive reaction, and nearly 80 per cent. of those with clinically evident tuberculous processes.

77. **Acidosis in Infants.**—Among the causes of acidosis in infants with acute stomach trouble, Meyer and Langstein include hunger, disturbance in carbohydrate metabolism, and great increase in the volatile fat acids in the feces. The latter reduces the alkalinity to a notable extent, evidenced by the fact that acids appear in the stools almost completely neutralized. This explains the high ammonia coefficient in catarrhal affections of the intestine, as also in other severe nutritional disturbances. In such conditions entailing acidosis, the ingestion of fat increases the amount of the intermediate acids, and also contributes materially to the formation of fat acids in the intestines. Salge has been very successful in curing infants with catarrhal intestinal affections by removing the fat from their milk, even when breast milk was used.

78. **Blood Pressure in Infants.**—Trumpp presents here the data of 1,300 measurements of the blood pressure in healthy and sick infants. He used Gaertner's tonometer without disturbing the infant in any way. He wished to learn if measurements of the blood pressure might serve as an indicator of whether or not increase of weight was due to normal growth or to the retention of water. His experience in 2 cases seemed to confirm this last assumption, the blood pressure falling and rising abruptly, parallel to the weight.

81. **Acute Postoperative Dilatation of Stomach.**—Beck describes a case observed in a girl of 15 after appendicectomy. He knows of only one similar case in a child on record (Staffel, 1888), in which the patient was a lad of 11, operated on for contraction of both knees and deformed feet. The child succumbed sixty hours after the first symptoms: vomiting and extension of liver dullness over the entire abdomen to the symphysis, with a small area of resonance over the stomach. The amounts of fluid vomited by Beck's patient were far in excess of the amounts ingested. Differentiation was based on the comparatively tardy onset of the vomiting, the third day after the operation—this was the more striking, as the patient had not vomited under the anesthetic—and on the physical signs, the normal pulse and temperature, and the absence of fecal elements in the vomit. The stomach should be rinsed out daily; morphin subcutaneously will aid in reducing the tendency to vomit. The thirst should be relieved by sucking ice or rinsing the mouth with ice water, swallowing very little, supplemented by saline infusion and nutrient enemas. The atony of the stomach may cause compression or kinking of the duodenum, and this may be combated by the patient lying on the side or abdomen, or changing to the knee-elbow position. If these measures fail, gastroenterostomy is indicated. If the dilatation subsides, the atony of the stomach may require faradization and administration of strychnin. After recovery, great care must be exercised in the diet. Beck attributes the dilatation in his case to a postnarcotic, toxic paralysis of the stomach, with compression of the duodenum by some local peritonitic adhesions, which later retrogressed. His patient was dismissed cured in about a month, but required lavage of the stomach once or twice a day for several days before the dilatation gradually subsided.

83. **New Symptoms of Rectal and Anal Affections.**—Svehla has had occasion to observe a number of cases in which some slight irritation of the rectal mucosa, evidenced by hyperemia, or fissure of the anus, caused special symptoms hitherto supposed to be characteristic of other affections. Among these symptoms are colic-like pains, and pains in the legs, and more especially pains such as have heretofore been regarded as peculiar to hip-joint disease. In men he has known fissure of the anus to induce prostatorrhea and thus to simulate a gonorrheal affection. He cures fissure of the anus by arresting the painful spasm by a cocain suppository and salve. The relief from pain puts an end to the reflex contraction, and the fissure then heals in peace under sitz baths three times a day and after stool, with local application of a salve, and measures to insure soft stools. One or two 0.01 gm. cocain suppositories are used daily. The largest number ever required by his patients was 22, healing generally being complete in about six days. Slight irritation of the mucosa around the anus, in infants, is sufficient to cause the symptoms mentioned. [The cocain, however, must be used with caution, as there is possibility of inducing a habit.]

89. **Menstruation.**—Schaeffer has been collecting data in regard to the commencement, duration and extinction of menstruation. His material includes 10,500 women examined at the Berlin Gynecologic Clinic. He tabulates his data and compares them with those of other writers.

90. **Tuberculosis of Female Urinary Apparatus.**—Mirabeau's later experience has amply confirmed his previous assertions in regard to the secondary nature of tuberculosis of the female bladder. It is always of renal origin, and has no direct connection with tuberculous processes in the genitals. He affirms also that in more than 50 per cent. of all cases only one kidney is affected. A positive diagnosis can be made without fail by the aid of cystoscopy and catheterization of the ureters, but

palpation of the thickened ureter is the most important diagnostic symptom in general practice. In case of unilateral affection, the functional capacity of the sound mate can be determined, as a rule, with sufficient accuracy by clinical observation and chemical and microscopic examination of the segregated urine. It must not be denied, however, that in isolated, dubious cases functional kidney tests may afford valuable information. The only treatment, he says, is early removal of the affected kidney. An existing pregnancy is no contraindication to operation. The tuberculous enlarged ureter can be readily palpated in bimanual examination of the vault of the vagina. Non-tuberculous processes never induce this characteristic thickening. It may be regarded as a sure sign of descending tuberculosis. Its absence on the other side indicates presumptively that the connected kidney is sound. The ureter shows this characteristic thickening even in the early stages of the affection, while the bladder is very little if at all affected. As a rule, patients with renal tuberculosis are treated for years for cystitis or gynecologic troubles, and only the lack of success of these measures suggests some morbid process elsewhere. Even then, gallstones or some gonorrheal affection is thought of rather than tuberculosis. Early search for the thickened ureter will reveal the true nature of the trouble in time for promptly successful operative treatment.

92. **Puerperal Fever Cured by Removal of Uterus.**—In Vertes' case the infection was due to the staphylococcus which had induced a septic affection in the uterus, although not very virulent. Colonies did not grow until after forty-eight hours of cultivation. It is the first case in Hungary treated by removal of the uterus. The presence of a large myoma justified the hysterectomy. The chills did not recur afterward.

93. **Importance of the Appendix and Lymphatic Apparatus of the Intestines.**—Albrecht styles the appendix the "tonsil of the large intestine," believing that it is part of an important lymphocyte camp in the intestines. The main task of the apparatus, he says, is the supplying of antibodies in fluid and organized form. He thinks it probable that the lymphatic apparatus of the entire body produces antibodies against not only the pathogenic, but also the saprophytic bacteria of daily life. It is possible, he adds, that the formation of antibodies is only part of a more general reaction to organized matters.

Riforma Medica, Naples.

101 *Contributo all' etiologia dei reumatismo articolare acuto. G. Volpe.

102 *Contributo alla fisio-patologia del grande epiploon (omentum). A. Cernezzi.

96. **Unusual Forms of Typhoid Fever.**—Bruno analyzes 3 cases of typhoid with peculiar manifestations, and advocates puncture of the spleen as a valuable diagnostic aid in dubious cases. He never found it in the least injurious, while the findings were always decisive.

98. **Chloroform Morphin-Scopolamin Anesthesia.**—Lorenzelli reports the use of this method of anesthesia in 40 cases at Ferrari's clinic. The impressions were favorable. The absence of vomiting, the small amount of chloroform required, and the reduction of the patient's excitement and dread of the operation commend the method. The greatest inconvenience is that the dosage can not be individualized as the response of different individuals is not known. Another disadvantage is that the tongue is apt to drop back into the throat, and requires constant surveillance to prevent suffocation.

100. **Research on Thyroid-Parathyroid Apparatus.**—Lusena has been studying on dogs the physiopathology of the thyroid and parathyroid glands for more than eight years. His findings confirm those of others, especially in regard to the syndrome of severe intoxication which follows removal of the parathyroids alone and the attenuation of the intoxication when the thyroid is removed soon after, or pieces of parathyroids are transplanted into the animals or when parathyroid extract is injected or parathyroids ingested. These measures help the animal to survive the severe intoxication that follows removal of the parathyroids. He has found also that temporary obstruction of the circulation through the thyroid (less than six hours) has the same effect as extirpation of the thyroid in attenuating the manifestations of the intoxication that follows removal of the parathyroids. Suspending the functions of the thyroid for even a few hours enabled the animals to survive the height of the intoxication, and it gradually became attenuated afterward. His experiments all had positive results.

101. **Bacteriology of Acute Articular Rheumatism.**—Volpe has had constantly negative findings and thinks that none of the germs hitherto proposed can be accepted as the true cause of this disease.

102. **Absorption of Necrotic Kidney by Omentum.**—Cernezzi's experiments and research on the physiopathology of the omentum showed that it is capable of completely absorbing the kidney when this organ is excluded from the circulation and from its hilus and necrosis ensues. If the conditions do not favor this encircling of the kidney by the omentum and formation of adhesions, then the animal promptly succumbs to fatal intoxication.

103 (XXIV, Nos. 11-12). Experiments on Dogs During Kakke Investigation. Baron Takaki.

104 Experiences During Russo-Japanese Naval War, 1904-1905. S. Suzuki. Read at annual meeting of Association of Military Surgeons. See THE JOURNAL for Oct. 14, 1905, p. 1194.

105 (XXV, Nos. 1-2.) *Etiological Investigation of Scurvy. K. Okada and Y. Saito.

105. **Etiologic Study of Scurvy.**—Okada and Saito report the discovery of a special micrococcus in the blood in cases of scurvy, which reproduces the principal manifestations (hemorrhages) of the disease in animals. It has agglutinative properties, and they believe it to be the specific causal agent. They cite among other arguments as to the infectious nature of the disease, that physicians unanimously report that when a case develops all the persons occupying the same room with the patient contract the disease. On the other hand, those who keep their bodies clean and are well fed are not attacked by the disease. The micrococci proved very resistant to desiccation and cold, but succumbed readily to the action of steam and of carbolic acid (2 per cent.), corrosive sublimate (10 per cent.) and alcohol (30 and 50 per cent.).

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

A MANUAL OF THE ECLECTIC TREATMENT OF DISEASE. Designed for the Many Students and Practitioners, Who Are Now Diligently Searching for Knowledge of the Most Direct Action of Drugs, as Applied to Specific Conditions of Disease. By F. Ellingwood, M.D., Professor of Materia Medica and Therapeutics and *pro tempore* Professor of the Practice of Medicine in Bennett Medical College, etc. In two Volumes, Vol. I. Cloth. Pp. 455. Chicago: Published by the Chicago Medical Times Co., 1906.

OPHTHALMIC YEAR BOOK, Containing a Digest of the Literature of Ophthalmology, with Index of Publications for the Year, 1905. By E. Jackson, A.M., M.D., Professor of Ophthalmology in the University of Colorado, and G. E. de Schweinitz, A.M., M.D., Professor of Ophthalmology in the University of Pennsylvania, with 42 Illustrations. Vol. III. Cloth. Pp. 286. Denver, Colo.: The Herrick Book and Stationery Company, 1906.

CAUSE AND PREVENTION OF DENTAL CARIES. By J. S. Wallace, M.D., B.Sc., L.D.S., Hon. Dental Surgeon, West End Hospital for Nervous Diseases; and Assistant Dental Surgeon, National Dental Hospital, W. Cloth. Pp. 81. Price, 2s. 6d. net. London: Ballliere, Tindall and Cox, 1906.

ENTOPTIC VISION. By W. F. Barrett, F.R.S., Professor of Experimental Physics, Royal College of Science for Ireland. Scientific Proceedings of the Royal Dublin Society. May Paper. Pp. 88. Price, 1s. Dublin: Published by the Royal Dublin Society, 1906.

ARMY LIST AND DIRECTORY, OFFICERS OF THE ARMY OF THE UNITED STATES. May 20, 1906. The Military Secretary's Office. Paper. Pp. 103. Washington: Government Printing Office, 1906.

BIENNIAL REPORT OF THE DEPARTMENT OF HEALTH OF THE CITY OF CHICAGO for the Years 1904-1905. By Charles J. Whalen, M.D., Commissioner of Health. Cloth. Pp. 368. Chicago, 1906.

Address

THE MEDICAL PROFESSION AND THE ISSUES WHICH CONFRONT IT.

PRESIDENT'S ADDRESS AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT BOSTON, JUNE 5-8, 1906.

WILLIAM J. MAYO, A.M., M.D., HON. F.R.C.S., EDIN.
ROCHESTER, MINN.

The American Medical Association begins its fifty-seventh Annual Session under the most auspicious circumstances. After an interval of forty-one years it again meets in Boston, the guest of this great commonwealth which has ably upheld the highest medical traditions since the founding of New England.

Another cause of felicitation: The sectional differences in New York have been overcome and the Empire State, for the first time in twenty-five years, presents a unified delegation.

The House of Delegates of the American Medical Association (which technically is the American Medical Association) represents directly about 55,000 and indirectly the 120,000 regular practitioners of medicine in the United States. The official organ, THE JOURNAL, reaches each week over 43,000 subscribers, and, under the able editorship of Dr. George H. Simmons, has become the leading professional magazine in the world.

The medical profession is to be congratulated on these evidences of a useful organization, but much remains to be done. In his individual capacity the medical man has not been found wanting. Go where you will in civilized lands, you will find the physician self-sacrificing, patient and charitable, upholding the honor and dignity of his noble calling. Collectively medical men do not have the influence which we might expect and without which great movements for the welfare of humanity can not be carried on. A lack of unity has prevented a realization of our hopes, and if we are to gain and maintain the pre-eminent position to which we are entitled we must unite for the common good.

The present organization of the American Medical Association is but a beginning: we must further the interests of this body unselfishly, not for ourselves alone, but that we may better fulfill our sacred obligations to mankind. The people must be educated up to a point where they can understand the broad humanitarianism of modern medicine. Society appreciates the saving of a sick person's life by the skilled physician, but fails to see the priceless gifts to the human race made by preventive medicine and sanitary science. It views everything in detail and misses the perspective. We have failed to secure the support of the mass of the people to much-needed sanitary reforms, because we have appealed to them as one individual to another without the weight of an authoritative organization.

That the people are ignorant of medical affairs is due to bad education rather than prejudice. They are more than two decades behind advanced medical thought; it is our duty to keep them better informed. The theory of medicine did not contain the essential principles of a science until within the last quarter of a century. Originally a part of priestcraft, the profession had its beginnings in a time of mysticism and superstition. Anatomy, gross pathology and chemistry were among the early foundation stones which made progress possible. Clinical treatment was based on a very few specific remedies and a considerable number of drugs of proved value in the cure or alleviation of disease. But, lacking a sound theory of causation, the results were not much better in the average self-limited malady than those claimed by the various "systems" based on the giving of inert or useless remedies which, like the incantation of the Indian medicine man, kept the patient and friends interested until cure came about through natural processes. The public found that the large majority of sick persons got well under any, all or no treatment, and, not rightly understanding the reason, have never been able to comprehend why one method or form of treatment, as long as it apparently yielded about the same average of results, was not as good as another.

The germ theory promulgated by Pasteur and given surgical significance by Lister, strengthened our foundation by adding to it the long-sought-for causation of the majority of diseases, and this, with the aid of experimental research, has led the practice of medicine out of the wilderness and established it as one of the exact sciences.

New and fundamental truths have followed each other so rapidly that we have scarcely been able to digest them and much less can we expect the public to have kept pace. The layman's view is that of twenty-five years ago. He accepts with avidity new dogmas and "pathys" based on theories incredibly foolish in the light of modern investigation, and we have allowed him to become fixed in these beliefs. We have permitted the public to be educated by "patent-medicine" advertisements and the voluble charlatanism of the commercially interested. In return we are classed with these schemers, and efforts for the general good are believed to be selfishly inspired.

The Utopianism of our profession is too idealistic for ready comprehension in this commercial age. The time has come for the public to be taken into our confidence; if we wish better results we must enlighten the people, for with them lies the final word.

THE PROFESSION AND THE PUBLIC.

General sanitary matters of the greatest importance are becoming understood through medical influences. The public has been and is being educated in regard to the "great white plague," tuberculosis, and statistics are beginning to show the effect of this diffusion of knowledge. In Massachusetts and some other states a committee has been appointed in each district to promulgate measures for the relief and control of tuberculosis. This should be imitated in every state in the Union.

We can already see the good which has resulted from the teaching of the habits of mosquitoes, the short distances they travel from their breeding places, and especially the necessity for the quarantine of patients afflicted with yellow fever and malaria, not directly to protect mankind, but to prevent infection of the little pests who act as carriers of the contagious micro-organisms.

Society must be taught the early symptoms of cancer, the greatest foe of humanity, that its manifestations may be recognized while in the curable period. A propaganda of this kind, inaugurated by the profession of Germany, has borne fruit.

The typhoid-fever crime of cities through polluted water supply is not the least of the many branches of popular education. There is no reason why a man who has become infected with typhoid from a city's neglect should not sue for damages as he would for personal injury sustained from falling through a defective sidewalk. Unavoidable sickness is bad enough, but when we stop to consider that the life of the individual is worth $5,000 to the state, and that those who recover undergo great disability and expense, the continuance of unsanitary conditions is criminal. The experience of Vienna, which was converted from a typhoid center to one of freedom from such outbreaks by bringing in a pure water supply, has now been repeated over and over again in every civilized land. Yet hundreds of deaths from this preventable source yearly attest that the lesson has not yet been learned.

How can the work of education be best continued? The answer, as shown by our very efficient chairman of the Committee on Organization, Dr. J. N. McCormack, is through the local society. Occasional meetings to which the public shall be invited must be devoted to questions of general interest, and the proceedings published in the local newspapers. The county society must become the unit, and the allied professions of pharmacy and dentistry urged to attend and take part in the deliberations.

To the *Ladies' Home Journal* and *Colliers' Weekly* the public owe the successful crusade against poisonous substances and intoxicating beverages which are sold under the guise of "patent medicines," patent only in the sense that the name is copyrighted; the constituents can be changed at any time and in any way.

Do you think that our American mothers will continue to give "Kopp's Baby's Friend" and "Mother Winslow's Soothing Syrup" to their babes when they find that these mixtures contain opium and that instead of securing rest the little ones are narcotized and that many deaths are directly attributable to this cause?

Will the American people continue to use Bromo Seltzer and similar dangerous preparations to an extent which causes them to exhibit blueness of the skin surfaces from poisonous coal-tar products, or become victims of drug habits from cocain catarrh cures, when they discover the harmful and dangerous character of these agents?

Will our prominent people, statesmen, politicians, ministers and ladies of note continue to allow their photographs over signed testimonials to be published, telling their fellow-citizens how much better they have felt after taking Peruna, Warner's Safe Cure and the various Nervines and Tonics, when they find that most of these preparations depend on alcohol for the stimulating effects which they describe? The success of most "patent medicines" depend on the fact that they contain drugs and stimulants which create a craving and must be repeated. Once get the public conscience awakened and we will have a demand that every "patent medicine," before being sold, shall have its exact component parts printed on its label, and its claims to cure verified by scientific investigation. The action of the Postoffice Department in denying the use of the mail service to some of the worst offenders against common decency is to be commended.

PUBLIC HEALTH LEGISLATION.

One of the few misfortunes of the individual freedom afforded by a republican form of government is that it enables the most ignorant man, through prejudice, to interfere with and delay needed legislation, with the result that, by the time the law can be passed, the immediate object to be obtained has often disappeared.

In Germany compulsory vaccination has practically caused smallpox to disappear from the army and country, a person properly protected being immune. In the state of Minnesota inability to enforce vaccination in the late smallpox epidemic permitted, from a few sources, 27,876 persons to become infected with this disorder; all due to a small but vociferous band of anti-vaccination agitators.

Contagious disease in any place is not a matter of local or state interest alone, as the ease and freedom of transportation render local control impracticable and properly place it in the hands of the general government.

The keenness with which the American people are watching the affairs at Panama argues well for the future. The communication of Dr. Charles A. L. Reed awakened public interest. His portrayal of red tape and obstruction to sanitation in the Canal Zone has resulted in obtaining for that most able army medical officer, Colonel Gorgas, power to carry out the necessary reforms and has made the Canal Zone the most sanitary place in Latin America.

Compare our record in the Spanish-American War with that of the Japanese in the war with Russia. We had 14 deaths from disease to 1 from wounds and more than 95 per cent. due to disregard of the simplest problems in sanitation—therefore, unnecessary and avoidable. In the Japanese army there were 4 deaths from wounds to 1 from disease, a difference of 56 to 1. This was not due to the fact that the Japanese had superior knowledge, but that their medical officers were thoroughly organized and in sanitary matters were supreme. The knowledge which they used was obtained in western institutions and was the product of the Occidental, not the Oriental, civilization.

The army and navy medical departments have worked intelligently against overwhelming odds. Their individual members have international reputations honestly achieved. Their schools for the special training of their men are in the highest degree efficient and deserving of every praise; but the departments have been so small as to be unable to act even as nuclei about which in time of war competent forces could be gathered and the militia of our country enter into conflict fearfully handicapped. The indications, however, are that these matters will now be rectified, and if so it will guarantee to the patriotic American that should he again be called on to serve his country his enemies would be in front and that he will not be destroyed by his own side through neglect of sanitary laws.

The United States Public Health and Marine-Hospital Service has been and is doing splendid work in sanitation. Its skilled investigators have revolutionized quarantine measures and have placed preventive medicine on a solid basis. Their powers should be extended so that such unnecessary outbreaks as occurred in New

Orleans shall not be repeated. They should be given control of national quarantine in all its phases.

MEDICAL EDUCATION, STATE LICENSURE AND RECIPROCITY.

What is needed is a higher standard of requirements and more and better supervision of professional schools. The Council on Medical Education is working hard and is now in a position not only to show what should be done, but to initiate needed reforms. No more important work has ever been taken up by the profession. At the present time medical education is uncontrolled and each state has its own standard of requirements. We can not rid onrselves of dogmas and "pathys" until we can secure a universal primary law as to the minimum amount of knowledge on fundamental branches. To accomplish this the American Medical Association must co-operate with and encourage medical colleges to do better work. The profession owes it to itself to investigate in some manner what the schools are actually doing and to make it known whether or not they fulfill their obligations to the student. No well-conducted college could object to such reasonable supervision.

Another question of great importance is that of reciprocity in medical license. The conditions now are wellnigh intolerable and restrain the individual freedom guaranteed by the Constitution. The boundaries between states are imaginary lines; yet a physician on one side of a border can not relieve human suffering on the opposite side without becoming amenable to the law or subjecting himself to vexatious examinations which he has already successfully passed in his own state. This must be met and speedily by agreement between examining boards as to the minimum of requirements. After all, this is but a part of the educational problem. If we could solve this, licensing boards could at once adopt more uniform examinations and reciprocity.

RELATIONS TO INSURANCE COMPANIES, CORPORATIONS, ETC.

We come now to consider some abuses from which the physician suffers. It is a matter of professional pride that, in the general condemnation of the life insurance companies, although every other part of the control has been shown to be corrupt, no breath of scandal has touched the medical department. Yet the local examiner has the most cause of all to be dissatisfied. The New York Life, some years ago, cut the fee for examination 40 per cent., apparently not as a matter of economy, for at that time the most corrupt practices existed, but rather to enable the agent more easily to pass "new business" at any cost. This action has lately been imitated by the Equitable and some others and has resulted in forcing the resignation of many of their best examiners. The general officers have taken great credit on themselves for voluntarily reducing their salaries 20 per cent. It is a rank injustice that the one body of men who have emerged clean from the insurance scandals should suffer the most for the crimes of others. A thorough medical examination to prevent fraud by the admission of unsafe risks is essential. With few exceptions the line companies pay a fair fee and less should not be accepted. The casualty companies, such as the Maryland, are the worst offenders, and some concerted action should be taken to compel them to mend their evil ways.

Lodge practice is another scheme by which officers of an association draw salaries ostensibly to give medical services at a figure below the possible point at which a professional man can live and continue his education. The people are badly served, as competent physicians can not be secured to do the work, and the whole scheme is properly condemned by the various medical associations all over the country.

Public service corporations abuse hospital privileges in a way that is no more or less than an open scandal. In Pittsburg the steel companies pay $1.00 a day for the care of their injured men at the hospitals, and for the class of patients under discussion this can not be provided for less than $1.60 per day. The companies pay the surgeons at the hospitals absolutely nothing for their services to its injured, which amount to thousands of dollars a year. The same condition exists with many of the large railroad and street car companies and other public corporations.

Hospital abuse by patients who are able to pay, through the neglect and indifference of the trustees, is prevalent, and thereby the profession is robbed of just returns for labor and the funds of charitable persons misused to an extent which is almost beyond belief. All hospitals should have competent individuals whose business it is to see that no one secures free treatment who is able to pay.

Some great hospitals go still further and receive any patient, rich or poor, allow him to have a suite of rooms and bath and several nurses if he can pay for the same; but will not allow him, even if he is willing to do so, to pay the surgeon who operates on or the medical man who takes care of him. If the patient is disposed to be more just than the trustees of the hospital, he can do so only by giving a gratuity at Christmas, as would be done with a servant. Such indignity should be resented by every right-feeling man.

It is a misfortune that the large majority of hospitals have no physicians among their directors. Hospital management is often extravagant and wasteful, due to official influence in furnishing comfortable berths for incompetent relatives or unfortunate friends in some salaried executive position.

Fortunately the list of grievances is not large, and I believe that they can be harmoniously adjusted if taken up with the proper authorities in a conciliatory spirit. Our first object must be to see that no poor person shall be subjected to the slightest inconvenience or annoyance and that every worthy charity shall have our united support; but we must look to it that the charitable practitioner's time, knowledge and skill shall not be misused.

THE PRACTICE OF MEDICINE AS A BUSINESS.

It is a hard matter to adjust the financial side of the practice of medicine; that doctors are poor collectors and bad investors is a notorious fact and makes them the easy prey of the various investment "gold bricks." A physician owes it to himself, to his family, to his profession, and especially to the community at large, to manage his finances well. Otherwise he can not pursue his studies and give to the sick his best efforts, which they have a right to expect and demand. No sensible man enters on a medical career with a view of making money. I have never known a physician who has become rich solely from this source, and it is better so, for beyond that reasonable competence which leaves him free to pursue his life work the care of money interferes with the highest aims of the true physician, and few who have been burdened with wealth have reached their ideal in a calling which makes no distinction between the rich and the poor.

One of the demoralizing tendencies in this commercial age is the money standard of success. Physicians are not called or chosen; accident or environment brings about their choice of profession. While professional life

broadens the mental horizon and increases sympathy, it can not change man's nature, and men who are unfair in business affairs are to be found in our midst.

The one crying evil, which fortunately is not widespread, is the giving of commissions—in other words, the selling of the confidence which the patient has in his practitioner—to some specialist who will divide the fee in return for reference of the case. The one secretly takes money from the patient without his consent, and the other, in order to complete the bargain, charges more than he should. This is equally harmful to the one who receives and to the one who gives. Such matters can not be kept secret, and I have personal knowledge of men of good attainments and remunerative practice who have been ruined through losing the confidence of their communities by this pernicious traffic. Some attempts have been made to justify it, but the very fact that it is secret shows that both parties are ashamed to have it known and is an acknowledgment of its moral obliquity.

Our relations with the allied profession of pharmacy are not on as ethical a footing as they were twenty years ago. Then the druggist was the faithful friend of the physician. To-day, in putting up from 50 to 60 per cent. of the prescriptions sent to him, the educated pharmacist can not use his skill as a chemist, but simply acts as a distributor of copyrighted preparations which the physician calls for a few times only to take up with something new and leave the shelves of the druggist filled with the unused remnants.

Many physicians compound their own prescriptions, to the detriment of the pharmacist. The proprietary medicine people have managed this very cleverly; to the medical profession they are continuously calling out that the druggist is "substituting;" with one hand they have given the physician remedies to dispense himself, and with the other furnished the druggist with "patent medicines" with which to compete with the physician, and these two natural allies have drifted apart. The average pharmacist can not live on physicians' prescriptions alone, but he should be treated justly, and both physician and druggist would profit by mutual concessions to the great benefit of the public.

The higher grade of pharmaceutical houses already see the danger to honest pharmacy in the forced promotion of "ethical" and fake nostrums under catchy names, and it is to be hoped, in the future, will confine themselves to the open compounding of legitimate preparations; and these and these only should be found on the advertising pages of reputable medical journals.

MEDICAL PROGRESS.

Graduation from a college is merely a commencement of a life study of medicine. Therefore, young men without special training under competent teachers should not be encouraged in wanton assaults on major surgical diseases unless justified by necessity. The future will demand schools for advanced training for those who desire to do special work.

The recent graduate in medicine should begin in his county society by contributions to the newer methods which will be interesting to the older men. This should be his kindergarten; from there he will carry his papers to the district meetings; and at the end of five years he will be competent to bring useful material to the state society and later to the sections of the American Medical Association.

In the practice of medicine the student days are never over. There is so much to be learned that a long and industrious life leaves one with the feeling that he is but a beginner. The most important habit a young physician can form is the "daily study habit." Let him put in even one hour a day with the reading of journals and books of reference and much can be accomplished. He should keep an account of the time, and if something interferes for a day he should charge himself up with it. A two weeks' vacation means fourteen hours to be made up. Most men can do more, and no man has a right to do less, no matter how busy he may be. The leaders in our profession make a daily average of five or six times this amount of study the year round, in addition to the demands of an active practice.

The practitioner must make frequent trips away for the purpose of observation. In no other way can he avoid the rut of self-satisfied content, which checks advancement and limits usefulness. No amount of diligence as a student can take the place of personal contact with men in the same line of work.

What are the rewards of so laborious a life? They can not be measured, because there is no standard of comparison. To realize that one has devoted himself to the most holy of all callings, that without thought of reward he has alleviated the sufferings of the sick and added to the length and usefulness of human life, is a source of satisfaction money can not buy. I know many a man grown gray in the profession with little of a tangible nature to show as a result of his work, but who is not only contented with his lot, but proud to have served in the ranks, and who looks back on a life of privation and hardship for the benefit of humanity as a privilege which he is thankful has been vouchsafed him.

Let us continue to strive as individuals for the honor and dignity of our profession. In this we but follow out the aims and ideals of those who have gone before and prepared the way. But the great movements of the future can not be brought about by individual action. They must be initiated and controlled by united effort, and in no other way can the epoch-making truths of preventive medicine be made to bear fruit. Unity is the spirit of the times; it marks the difference between the old and the new.

The vital need of the medical profession is a harmonious organization—an organization that will encourage right thinking and good usage among ourselves, help to secure needed medical reforms, compel redress of grievances and promote and encourage the highest interests of its individual members; and in this lies the future usefulness of our profession as a whole.

Orations

THE NATURE AND PROGRESS OF MALIGNANT DISEASE.

ORATION ON SURGERY AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, BOSTON, JUNE 5-8, 1906.

JOSEPH D. BRYANT, M.D.

NEW YORK CITY.

My first words are words of thanks, profound and sincere thanks, addressed to my colleagues of the American Medical Association because of my estimation of the high honor conferred in inviting me to address you on this occasion. My first desire, the dominating desire of earnest appreciation, is that I may say something that will justify the choice of my colleagues and my presence before you. My first hope, the fond hope which I most cherish at this time, is that some one who may be influenced by what I shall say will gain in comfort and

life thereby; for, be the gain but little, even then those who are accessory to my presence may claim acquittal because of it.

Since it may not be known to all here present, I am prompted to say at once that, some time during the course of the meeting of this Association, an address, denominated "An Oration on Surgery," is a part of the scientific proceedings. In this instance it is not my intention to attempt a review of the whole field of surgery, nor even of a year's experience, but, instead, to devote the brief time given me to the consideration of a surgical topic which to-day is engrossing more of the time and energy of scientific medical endeavor than is any other subject in the entire range of surgery. Hence the topic of the evening, "The Nature and Progress of Malignant Disease."

It seems not unfitting, in a city whose early resistance to the oppressive encroachments on human liberty awakened the demand for American freedom, that an earnest warning should be voiced against the advancing encroachments on human comfort and life of a malevolent disease which obviously afflicts with dire results, all classes of vertebrate beings. The expression, malignant disease, is used here in the general sense, just as later the term cancer will be employed. It is better thus than to attempt to speak of the varieties of malignant disease, since only a general idea of its nature and progress can be considered in the comparatively short time allotted for the purpose.

Cancer is a general and not a local variety of disease. The field of its activity is quite as extensive as is the world itself. The vertebrate order of creatures is more or less afflicted with cancer throughout the entire classified series. The highest vertebrate orders of life suffer from cancer more than do all other orders combined. The civilized and the domesticated classes of higher rank suffer more from this form of infliction than do those of lower rank, or of the natural state. Mankind everywhere pays distinctive vital tribute to this disease; not, however, in equal proportions, but in accordance with the standard of the civilization of which he is a part. The higher the standard the greater is the contribution to malignant fate; the humbler and more natural the standard the less onerous is the demand. The rulers of mighty nations and the humblest human factors of savage existence, each in their respective ratios, succumb to the mysterious lethal influences of cancer. Also fish and flesh, staple articles of food of man, each in a varying measure, is the abode of malignant action, and more especially is the latter class thus afflicted. The fish of pure streams and ponds and those of salty habitations are in no small degree the subjects of cancer. The genteel trout and the beneficent cod are examples of this fact, respectively. Even the invertebrate oyster in one instance is widely reported to have yielded to malignant change.

The myriads of oysters subject to the scrutiny of hosts of gustatory and scientific observers for many years, with apparently but one reported instance of malignant disease under all of these circumstances, suggested to us the idea of reviewing the facts in this particular case. A careful examination was made, therefore, of the acknowledged record[1] of the case the recital of the chief points of which merits your indulgence at this time. It appears that the late Professor Leidy, the famous anatomist of Philadelphia, came into possession of an oyster having a large tumor of the soft parts which he presented to the late Professor Ryder in January, 1887. In commenting on the growth at that time Professor Ryder spoke as follows: "The tumor seems to have been benign in character, as the oyster in other respects appears to be healthy." A description of the tumor of quite minute and apparently of microscopic kind is reported along with the above statement, which is now regarded by competent authority[2] as being congenital, thus sustaining the belief in benignity expressed by Professor Ryder at the outset.

I consider it proper to enter thus fully into the merits of this specimen, since, for some reason, it has been regarded as the first and perhaps the only proof of malignant invasion of invertebrate life. We will now return to the main channel of the discourse.

The flesh of cows and oxen is the seat of cancer in the unsuspected proportion[3] of 2 per 1,000, as is revealed by the careful inspection of their slaughtered products. The young animals, however, of divers kinds, exhibit no such evidence under these circumstances.

Advanced age, both real and comparative, sets the pace of malignant progress, especially in mammals. Real age numbered by many years, and comparative age numbered by fewer, each alike invites the presence of cancer. And, too, in tissues of the human body this same age peculiarity is noted, those whose life's duty is ended, whose full years of usefulness are reached, become the frequent prey of cancer, while other contiguous tissues endowed with later function and those of the body at large remain in a healthy and useful state. In this connection it may be said that youth and youthful tissues comparatively seldom hold communion with cancer.

For a long time the solution of the problem of malignant disease has been uppermost in the minds of many of the best students of pathologic phenomena in the medical world. During the last few years the efforts directed to the solution of the mystery of malignancy, stimulated by the thought of the possible parasitic nature of the disease and the apparent increase in its extent and activity, have been markedly extended through the logical efforts of special commissions established for the purpose. Commissions organized under the patronage of crowned heads and public dignitaries of exalted station, and conducted by medical and lay minds of superlative attainment, supplemented by unlimited opportunity and ample financial support, are searching the animal world in the effort to shed light, beneficent light, on the mystery of cancer. In England and Germany especially, the resources of the governments and the sympathetic support of the King and the Emperor, respectively, are directed to the benevolent purpose of determining the origin and the true nature of malignant disease. Also in this country notable institutions of learning are patiently engaged in the efforts to accomplish the same purpose. Individuals of eminent attainment are of themselves fighting in the battle along lines of their own selection with the same object in mind. Laymen of munificent means, prompted by humane motives or perhaps by personal dread, offer bountiful endowments for the discovery of the nature and the cure of cancer. The thoughts and efforts of the civilized world, as represented in scientific medical attainment and benevolent endeavor, are to-day mainly centered on securing the control of tuberculosis and on determining the true nature and the cure of malignant disease.

1. Proc. of the Academy of Natural Sciences of Philadelphia, 1887, p. 25.

2. Profs. E. K. Dunham and Harlow Brooks.

3. Imperial Cancer Research Fund (Bashford).

It is proper to say, I believe, that the widely separated instances of cancerous infliction as noted between the civilized and barbarous peoples, between the dwellers in the flesh and salt media, and between the lower classes of mammals seem to indicate forcibly that the circumstances of human life in the civilized state have not given origin to cancer, although they may have added much, indeed, to its frequency.

That cancer is a distressing part of the history of the animal kingdom can not be gainsaid. And, unfortunately, the more comprehensively and critically the investigations relating to it are carried forward the more widespread it appears to be. As already expressed, mankind in the civilized and also in the undeveloped condition suffers from cancer, and it is probable that no race or condition of the human family is entirely exempted from this infliction. Also no organ or tissue of the human body is entirely free from its visitation. The dumb companions of man are similarly afflicted, but in a less degree, and it is altogether probable that as the search progresses along the various lines of animal existence malignant manifestation will appear now and again, reminding us, perhaps, that the penalty of the violation of a universal law of development of organized beings is relatively promptly enforced on the object or on the part concerned in the offense.

In this connection it is not amiss to heed the fact that experimentally and practically the transmission of cancer from man to animals or from one animal to another of different species has not yet been successfully witnessed beyond gainsay, notwithstanding the repeated attempts to attain the purpose and the results of long critical observation. On the contrary, the apparent transmission of cancer between animals of like species and its unquestionable extension by metastasis in those already afflicted is of common knowledge.

The vegetable kingdom suffers at times and in isolated places from a form of local progressive disease apparently akin in nature to the malignant characteristics of the animal economy. In fact, the realization that these peculiar vegetable afflictions were caused by a parasite in many instances prompted the renewed suggestion on the part of Hutchinson that similar appearing growths of human origin might later be found to depend on the presence of parasites. Since that time, more especially during the last fifteen years, the contention in this respect between the supporters of the parasitic and non-parasitic ideas regarding this disease has been continuous and spirited, and as yet without a generally satisfactory conclusion.

It is no part of the purpose of this address to discuss the various theories relating to the nature of the inherent cell activity characteristic of cancer, or of any other form of malignancy. To the members of the medical profession here present such a course would necessarily be inconclusive and disappointing. To those of the lay order whose feeble hold on technical expressions would present insurmountable difficulties of appreciation the result would be the same. Moreover, the chief aim of this discourse would be missing and, besides, as is expressed in a well-known play:

> "The result is a very pretty quarrel as it stands;
> We should only spoil it by trying to explain it."

The period at which this contention will be ended is too uncertain to merit other than hopeful anticipation, and too important to be neglected in any respect in opposing malignant advance.

The time when malignant disease first appeared in the path of human existence and added its insatiate affliction to the burden of human suffering can not be stated except in a general way. It is fair to presume, however, that at a definite period of early recorded time malignant activity in some form was present and contributed its portion to the physical distress of the age. But it is difficult, indeed, to find ancient documentary evidence of cancer in such countries as India, China, Egypt and Greece, despite the fact that their medical literature is quite extensive, especially that of Egypt, whose medical records contain descriptions of great antiquity, comparing favorably in forms of phrase and detail with many of those of the present day. Nor can the ancient history of cancer be correctly written at this late time, as it would not be possible to distinguish between cancer and benign tumor, on the one hand, and between ulcerated cancer and other severe forms of ulcer, on the other.

The comparatively limited knowledge in diagnostic discrimination at that time, as expressed in written characters, forbids the forming of definite conclusions in diagnostic purposes. It is apparent, however, that the ancient Greeks had a very good clinical idea of cancer, as a modern Greek writer, Couzis of Athens (1903), in reviewing the past history of Greek medicine, says that the practical knowledge of the Hippocratic school was not inferior to that of his own day. The works of Hippocrates (460-370 B. C.) barely mention cancer, stating in connection with the treatment that "deep-seated forms are best untreated, for if treated the patient soon dies; otherwise he may hold on for a long time." It is not difficult for us of the present day to comprehend the full significance of this statement, as no doubt a few of us, at least, have witnessed the exemplification of this ancient expression written quite 2,300 years ago. The old Greeks described fully the various distinguishing characteristics of cancer, noted the clinical differences in its various phases, portrayed quite accurately cancerous metastases and prescribed treatment not differing, especially in the palliative sense, from that in use at the present time. Galen (131-201 A. D.), in his extended works, considered cancer quite fully in its important aspects. But from his time to that of Ambrose Paré (1517-90 A. D.) little of special significance was added thereto.

Many of the notions entertained regarding the nature of cancer since Hippocrates' time seem droll to those whose enlightenment on the subject of bacteriology is a matter of recent years. The Galenic notion—probably that of Hippocrates—attributed cancer to the local effect of "overheated and unusually acrid 'black bile' that can not be purged away." Paré ascribed cancer to the effect of improper diet influencing unfavorably the liver and spleen, followed by "a shutting into the part to be attacked of thickened acrid black bile." The emotions, anger and hate, aggravated the condition, he said. Harvey (1578-1657), the discoverer of the circulation of the blood, regarded cancer as a parasite on the body, living an independent existence at the expense of the latter.

John Hunter (1728-1793) seems to have been the first to recognize the influence of traumatism as a causative factor of cancer, aided by the consequent exudation of coagulable lymph into the interstitial tissues.

Many attempts to inoculate cancer date from the experimental period inaugurated by John Hunter. And early in the nineteenth century positive results were reported and the parasitic doctrine became prevalent. The era of pathologic anatomy, which culminated in the histologic studies of Müller and Virchow, at first fa-

vored the idea of the parasitic nature of the cancer cell, but ultimately condemned it when Virchow showed, as then appeared true, that cancer cells were derived from pre-existing normal elements.

From this period to the present day, theories regarding the nature of cancer have multiplied to a bewildering extent. The two extremes at present are the following: (1) That cancer, like many other morbid processes, is due to a micro-organism; (2) that cancer represents a morbid proliferation of certain normal cellular elements as the result of diminished inhibitory action.

A few words more relative to the parasitic theory may not be amiss at this time. The view that cancer itself is a parasite was expressed by Harvey in 1651. By Dupuytren in 1805, Laennec in 1816, Cruveilhier in 1827, and Lobestein in 1829, all adopted this view as part of their teaching of pathologic anatomy. A little later the positive results of inoculation experiments were recorded, seeming to confirm the view, and Müller's description of the histologic elements of cancer in 1842 give a remarkably clear exposition of this theory, making the cancer cell the actual parasite which, if implanted in sound tissue, caused a cancerous growth. The question of transmission of cancer, however, remained unsolved, for it was then believed that cancer cells in the natural state could live but a short time outside of the body, and that their great size seemed to preclude their being taken up by the ordinary ports of entry. Also cancer did not appear on abraded surfaces, but in the parenchyma of tissues. In the face of these facts the parasitic origin appears to have languished, and to have been superseded by the later teachings of Virchow and others which derived cancer from pre-existing normal elements.

It was quite apparent at an early period of investigation that the study of the nature and activity of this disease could not shed substantial light on the problem of its control, when based alone on the few cases falling under the notice of a small number of individual observers. The logical corollary of this situation laid the foundation for statistical inquiry and collective investigation. It was not, however, until a comparatively recent date that statistical knowledge attained sufficient rank in this regard, to arouse apprehension respecting the presence of cancer. In fact, it was not until the possibility of its being of a parasitic nature was again set forth, and the fact that perhaps it was communicable, that observers of cancer were impressed with the acute sense of a new danger.

It should be stated, although perhaps superfluous, that the deductions based on statistical estimates are not always conclusive, except perhaps to the minds of those whose contentions are encouraged or supported by the calculations. A preconceived notion relative to a disease, or a prejudiced opinion regarding it, can usually gain substantial comfort from the study of plastic statistics. The product of the data may be "very like a camel," "or a weazel," or perhaps "like a whale," accordingly as a biased statistical Polonius may fancy. One has only to keep pace with the conflicting deductions often drawn from isolated examples of statistics, whether amended or not by additional knowledge, to realize the wealth of uncertainty that frequently attend statistical conclusions. Especially is this true in the instances of afflictions with subtle natures and divers environments such as characterize cancer.

The geographic and time-of-life distribution of cancer especially concern statisticians and sanitarians. The anatomic distribution appeals directly to practicing physicians and surgeons. The local occurrence-center-feature of the infection invites the reflections of pathologists and students of morphology. Geographically considered, cancer, as already stated, is a heritage of the human race in nearly all, if not in all, parts of the world. While it is yet unknown in some parts of South Africa (Snow) and other obscure places, it is not at all certain but that it exists, remaining hidden, however, from civilized view, because of the restraining influence of some heathen conception relating to it; especially as such conceptions have before this time thus controlled the doings of savage or superstitious peoples in other matters. Among the chief objections to the scientific value of statistical facts relating to cancer may be mentioned the inability to secure authentic complete diagnosis. The statement that a growth is malignant, when determined only by macroscopic examination, is so often fallacious as not to merit scientific confidence. Only microscopic reports of morbid growths should be given the privilege of membership in the rank of trustworthy data. I am aware that there are not a few distinguished observers who to-day seem to place quite as much confidence in the macroscopic findings of experience—their own experience—as in the conclusions of those with equal experience whose senses are fortified by the mechanism of a more exact knowledge. In any event such reports as these should be classed by themselves, unless confirmed by reliable microscopic testimony. According to the report[3] of qualified authority, the frequency of error thus arising is 7 per cent. in accessible growths, and for apparent reasons is increased when the growths are deep seated.

The undoubted increase in human longevity of recent time adds many, indeed, to the list of those who from augmented years fall within the age limit of cancer attack, and thus apparently increase the spread because of a seeming greater morbid activity. And, too, it should not be forgotten that many from without seek harbor in a city for the relief which its hospitals and extended experience afford, some of whom, unfortunately, add their sad contribution to the city's death rate from cancer. On the other hand, the life-saving means now employed in defending and rescuing the young from the baneful onset of infectious disease, is increasing the number of the living, and, therefore, neutralizing proportionately the apparent increase in death from cancer.

It is not impossible that the significance of the so-called "cancer localities" may be reduced to the standard of other fields of importance, when subjected to closer analyses of circumstances that are no essential part of cancer development or propagation. It is certainly evident that the slow and continuous increase of cancer, regardless of preventive measures and of human understanding is controlled by influences of such subtle kind, as thus far to perplex beyond satisfactory solution, the minds of the most astute observers.

The relative extent of cancer invasion of the accessible,[3] of the inaccessible, and of the intermediate parts of the human body in England and Wales during a three-year period affords an interesting study of this disease of great apparent significance, as will appear a little further along. Those superficial parts of the body falling readily under the scrutiny of the unaided eye and the touch of the physician are manifestly the seat of accessible cancer. Those deep and internal parts of the body, conveniently placed beyond the limits

of unaided vision or mere touch, are the sites allotted to inaccessible cancer. Those portions of the body within the reach of the finger and aided inspection are, for the most part, the sites of intermediate cancer.

The development of cancer of the parts included in each of the foregoing divisions of the body, is comparatively much less manifest in individuals under 25 years of age, than in those above that period, standing in this respect nearly as 1 to 70. The male sex suffers nearly 22 per cent. greater infliction from malignant disease than the female, during this time, which can be accounted for in part, I think, by the greater strenuousness of the male and the effect of the exposures incident thereto. The probable reasons for the greater infliction of the sexes under, than over, 25 years of age, it seems to me, have been considered sufficiently already.

The comparative difference between the frequency of occurrence of accessible and inaccessible cancer in both sexes, under and over 25 years of age is astonishing, even when proper deductions are made for the greater uncertainty of diagnosis in the latter kind. Inaccessible cancer in males of 25 years and under is 80 per cent. more frequent than the accessible kind. Inaccessible cancer in females of 25 years and under is nearly twice as frequent as accessible cancer. Inaccessible cancer in males above 25 years of age is three times more frequent than the accessible variety. Inaccessible cancer in females above 25 years of age is about 2¼ times more common than accessible cancer. Inaccessible cancer in males regardless of age, is approximately three times more frequent than the accessible variety. Inaccessible cancer in females, irrespective of age, is 2 1/5 times more common than the accessible. Inaccessible cancer is, without regard to age or sex, a trifle more than 2½ times more common than cancer accessibly located.

While it is now, and has long been conceded, that external influences, traumatic and otherwise, contribute to the frequency of accessible cancer in a greater or less degree, it is also self-evident, I think, that other and more potent agencies than these must be invoked to account not only for the occurrence of inaccessible cancer, but also for its great preponderance over those accessibly located at all periods of life, more especially the dominant one, that above 25 years of age. The increase in cancer visitation, in connection with advancing years, has long been a matter of common knowledge. But that the location of cancer, at all times of life and especially in adult life, should be of inaccessible, rather than of accessible nature, is more than remarkable, it is even startling, suggesting in no common tone the idea that, directly or indirectly, subtler influences than external traumatism or infecting agents can exercise are active in the development and spread of cancer. Perhaps it may be consistently said that the traumatisms thoughtlessly inflicted on the gastrointestinal tract by the yielding to the temptations and pleasures of life—while less emphatic than those directed to the external surface—are none the less potent for evil because of the fact that their frequent and prolonged action may increase correspondingly an ill effect. However this may be, it appears quite reasonable to some that cancer organisms coming somewhere from without, implant themselves in the tissues and develop there, notwithstanding the inhibitory effect of cooking, the power of digestion, the opposition of phagocytosis, and the fickle element of chance.

It is fitting now to remark that there appears to be no good reason to believe that the food of a people influences their relation to malignant disease in an appreciable degree.

Intermediate cancer in both sexes under 25 years of age is about half as frequent as is accessible cancer in both at the same period, possibly showing thus early in life the benign effect of protection of the intermediate parts from ordinary external influences. In the male after 25 years of age, intermediate cancer shows a comparative decrease in rate from that of the accessible form of about 32 per cent., suggesting that the evil effect of external influences are superior in potency or greater in number in the male than are those causing intermediate cancer. In the female during this period (after 25 years) the rate of accessible cancer exceeds that in the male by about 37 per cent. The intermediate variety, however, at this time in the female exceeds the accessible form by more than 48 per cent., showing the rapid increase in the intermediate variety due to pelvic disease, which can not be attributed in any practical degree to infection, but mainly to the traumatisms of maternity and the age limit of certain near-by tissues. It should be stated in this connection that the liability in both sexes to cancer of the gastrointestinal tract, gradually and quite uniformly diminishes from the stomach downward toward the external opening, but not including it. This fact seems to justify the thought already stated regarding the possibility of the effect of dietary traumatism on the stomach and the upper intestinal tract.

The age limit of the tissues of the stomach in health conforms to the nutritive requirements of the life to which they are all important, consequently this feature of the causation of cancer, which so freely contributes to the total of this disease in the mammary gland and the uterus, can play no part in the causation of cancer of the stomach, making it, therefore, the more apparent that alimentary traumatisms and dietary abuses are dominant influences in the causation of gastric cancer. Another fact which seems to confirm this position is that cancer in the male in the alimentary canal is quite seven times as common as in the female, notwithstanding the further fact of the general tendency of females to suffer from cancer of the alimentary canal at an earlier age than males. Surely, if cancer of the stomach were dependent in an appreciable degree on parasitic infection of alimentary substances this great difference in the relative proportions of infliction of the sexes should not exist. Finally, in males 80 per cent.[4] of all cancer affects the alimentary canal. In females 80 per cent. of all cancer affects the reproductive tract, including therewith the breast.

It seems that not a little that has been said in this relation is corroborative of the belief of those who regard cancer as a non-parasitic disease, which, in any circumstance, is not communicable.

A longer continuance in theoretical indulgence would necessarily deprive us of the opportunity of speaking in an emphatic manner, of an exceedingly important practical part in the contest against malignancy. This statement is prompted by the facts, that cancer appears to be on the increase in civilized countries, and also that the limit of effective operative therapy, the only agent of cure of general settled repute, has already quite reached the confines of highest efficiency, under the present established lines of action. It naturally occurs to thoughtful members of the profession, therefore, to enquire regarding what can be done by way of admonition and protective forethought, that will secure the holding of that already in hand, while the search for increased power in

4 Middlesex Hospital Reports, 1905.

curative therapy is advanced, let us hope, to a more successful issue.

As in any other field of human contention, so here the resources of every avenue of effort should be determined with care, and utilized with vigilance and pertinacity. The operative warriors in the conflict against malignancy, have striven faithfully and logically during the last years of the struggle, gaining advanced foothold by means of approved technic and prompt aggressiveness. By these masterly means in the cure of cancer of the breast, of the uterus and of the stomach, many, many years of comfort and happiness have been added to the lives of the afflicted and given to those who rejoice because of their preservation. These striking illustrations of cure in organs so profoundly concerned in the inception and preservation of life, are also an earnest of the outcome in other fields of operative endeavor in this respect. Unhappily, our fond anticipations of approaching relief, encouraged by this gain on malignant disease, are so often demolished by the ruinous delay of the afflicted, in utterance and action, as well nigh to arrest the increasing hope from operative measures. Too often, indeed, during the consideration of operative interference is heard the utterance of the sad truth, "too late," "too long deferred," and the like, on the part of all concerned. The remedy for this lamentation is prompter surgical action; and prompter surgical action requires a prompt acknowledgement of the presence of an unwelcome growth or manifestation on the part of the sufferer, supplanted by earnest co-operation in diagnosis and treatment.

It is surely not amiss to repeat, that the outcome of operative endeavor in malignant cases, has well nigh reached the highest possible success, unless aided by increased faith and lessened secretiveness on the part of the sufferers from a malignant infliction. Those who are afflicted with accessible growths are comparatively early aware of the presence of these unwelcome visitors. And when they shall have exercised the same degree of resentment because of physical intrusion on the part of a growth, as commonly distinguishes social or business intrusion on the part of a meddler, then, indeed, will much be gained for increased success in the struggle against malignancy. Since it now appears that cancer is located most often in the deep internal parts, beyond the safe limits of unaided sight and mere touch—(inaccessible cancer) 2½ times more frequently than is accessible cancer, regardless of age or sex, then, indeed, is the fact doubly impressed, of the necessity for prompt acknowledgment of the presence of morbid manifestations and prompt determination of their nature. The handicap imposed by inaccessible cases because of their greater distance from the surface, often enables the disease to advance undiscovered to a degree forbidding operative action when their presence is finally known. In too many instances of cancer, especially the inaccessible kind, the reasonable suspicions of its presence on the part of the patient or friends, are quieted by the soothing platitudes of medical advice, until all opportunity of relief is at an end. The physician and the surgeon should join in the observation and treatment of all such cases as these, early fostering a mutual plan of action that contemplates prompt explorative investigation in doubtful instances, and forbids delay in those of undoubted character.

It is "carrying coals to Newcastle" to state in this presence, or in that of any medical gathering of the present day, that cancer invades contiguous tissues early in the course of its development. How early no one can know. How late no one can tell. Of this, however, we are assured: Malignant activity is measured by the inherent nature of the morbid process, or by the receptive character of its host, and sometimes by both, and unfortunate indeed is the patient who is the helpless victim of both of these influences. But, on the contrary, correspondingly fortunate is one in whom each af these influences is at a minimum. A knowledge of such facts should admonish us to be charitable on the one hand, and discreetly aggressive on the other; charitable to the professional brother whose operative results may, therefore, be less fortunate than our own; discreetly aggressive so that the area of infliction may be timely removed by operative effort. Early explorative determination of the nature of disease, followed at once by operative relief in suitable cases, is today the potent measure of succor pending the advent of means of greater beneficence than those now at hand.

In emphasizing the pre-eminent importance of early measures of relief, one has only to point to the astonishing results which have attended the operative practice of many distinguished surgeons of this and foreign countries. And I believe that it will not be regarded by anyone as evidence of unwarranted pride or of bad taste, if in this connection and on this occasion, we should mention the name of our distinguished president.

If to these means of cure there be now added another for the sake of greater security, the picture in this respect will be complete—a means contemplating the education of the people on the great importance of overcoming reticence regarding such matters in their incipiency, rather than sacrificing life by senseless delay. Patients should be taught that the evidences which they may regard as important and entitled to serious thought and decided recognition, are but a step removed from the presence of hopeless despair and final destruction. They should be told that the subtle onset of malignant disease often baffles the keenest perceptions of the most experienced, requiring for arrest and for cure the best we have, and far too often, more than we can give. The exercise of vigilance in patients already operated on by those who are profoundly concerned in the cure, should be periodically and untiringly practiced, in order that the first evidence of disease may be quickly detected and remedied by renewed operation. The stake of the contest in such cases as these is a human life, and all the comfort and happiness relating thereto. Every victory is another triumph over malignant infliction, of which there are very many in surgical experience. In the general struggle for victory against malignant disease, it should not be forgotten that all those fall who do not seek relief; and that all those who early seek relief, will surely secure added years aud increased comfort, and that not a few will be finally cured. And important it is to remember that the number cured will be measured by the promptness of early diagnosis and curative action followed by untiring periodic scrutiny of the vulnerable points of return. The degree of fortitude required to sustain a patient under repeated malignant attacks, and prompt operative defense, is akin to that with which martyrs are endowed.

Finally, an emphatic warning should be given to all against the seductive influence exercised on the afflicted, by the "perversions of judgment and vain imagings" which too often allure them from the path of scientific beneficence, trodden by honest, sympathetic aid, into the wilderness of arrant quackery, infested by ghouls of heartless gain. Nor should one hasten unduly to substitute for established method in operative cases, means

which are still on trial, even though encouraged to do so by honest, yet unsettled opinion.

Rather than this one should grow in courage, stimulated by examples of successive cures from early effort, and by sentiments attuned in verse by our profession's greatest poet and our hosts' brightest ornament:

"Here stand the champions to defend
From every wound that flesh can feel;
Here science, patience, skill shall blend
To save, to calm, to help, to heal."

HOW PROGRESS COMES IN MEDICINE.

ORATION ON MEDICINE AT THE FIFTY-SEVENTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT BOSTON, JUNE 5-8, 1906.

FREDERICK C. SHATTUCK, M.D.
BOSTON.

During the past year there has been no very conspicuous advance in medicine. Advance there has been, of course, but it has been all along the line rather than any one direction. I propose, therefore, to-night to attempt roughly to sketch, as far as the limitations of time and my knowledge permit, some features of the progress of medicine in the past, its irregularity, apparent lack of logical sequence, dependence on the progress of science (knowledge) as a whole, the way in which advance along a very narrow line may lead to advance along the whole front.

We may for a moment compare the whole body of scientific workers to an army determined to enter into and possesss the empire of ignorance, a country of vast extent and presenting every conceivable physical difficulty to advance and occupation. This is one obstacle. Another lies in the fact that the army has not—nor can it have—an organization comparable to that of the ordinary army with its commander-in-chief, chief of staff, corps and division and brigade commanders, although it has the corps and divisions. Each has its leaders, who owe their position solely to merit. Influence, dynastic, political, family, does not count. Promotion is from the ranks. The rise to high position may be very rapid; deposition is occasionally correspondingly so. Far more than in even Napoleon's army *la carriere est ouverte aux talents.* The freest criticism is permitted, nay encouraged; government is largely by discussion based on observation and experiment. There are many scouts and skirmishers who are necessary to any advance, even of a division. There are also, alas! camp followers. As organized to-day we may distinguish six army corps—anatomy, physiology, chemistry, physics, pathology, clinical history.

Permit me now, dropping analogy, to call your attention to some of the lines of march which have been traversed, some of the territory won, some of the means by which it has been gained.

Gross anatomy was about as well, though, of course, not so widely known three hundred years ago as it is to-day. Medicine had got about as far as it could until the knowledge of a heart, of blood, bright and dark, of blood vessels, was vivified by Harvey, who, without instruments of precision, by experiments on living animals, by clear sight and straight thought, solved the mystery of the circulation of the blood. This step in physiology, in knowledge of function, threw a flood of light backward on structure and was indispensable to further progress. Harvey, a practicing physician, paved the way for Malpighi, anatomist, father of histology, who saw what Harvey had no means of seeing—the capillary circulation. He was contemporary with Leeuwenhoek, the lens-maker, improver of the microscope, and then the microscopist making important contributions to the structure and function of the living organism. Here we see one of the first contributions of physics to medicine. It is remarkable that Leeuwenhoek could do what he did with the simple microscope. He had been in his grave more than a century before any essential advance was made in the compound microscope, gradually leading up to the instrument which has played such a vital part in the progress of modern medicine, and to which I shall again have occasion to allude.

Bichat, indeed, performed his great work and founded the anatomy of the tissues without the aid of the microscope, so imperfect in his day that he thought it more likely to promote error than to discover truth. The ultimate anatomic component of the tissues and organs alike, the cell, though seen and described by Robert Hooke long before, was first seen in its developmental relations in plants by the botanist, Schleiden. Schwann extended this knowledge into animal life. Thus was founded the physiology of the cell. Fresh impetus was given to embryology, so deeply indebted to Caspar Friedereich Wolff of the previous century, and the way was smoothed for Virchow and the pathology of the cell.

In the past hundred years the anatomy of the central nervous system has not been illuminated by anatomists. The microscope showed that the grey matter is composed mainly of cells, the white of fibers. No mere anatomic study could possibly have differentiated the function of grey and white matter, the anterior and posterior nerve-roots, the motor and sensory nerves running in a common cable. Charles Bell, the surgeon, by vivisection, made a great step in physiology and thus advanced anatomy. Marshall Hall, the physician, and Johannes Mueller, the physiologist, again made a further advance in explaining reflex action and its mechanism. Waller, the physiologist, teaches us the lesson of the degeneration of nerve fibers separated from their centers. Anatomy never could have taught us the great lesson of cerebral localization, nor could animal experimentation or physiology alone. The starting point came from the clinician who, through careful comparison of the experiments of disease on the human being during life and after death, pointed out the way for physiologic experiment to follow. Critical clinical study first, pathologic anatomy second, physiology third, anatomy fourth; structure and function, function and structure; indissolubly bound together; advance in one must lead to advance in the other.

Time does not permit me to take up chemistry by itself. In other connections I shall allude to the help it has given to medicine and its progress. Chemistry looms large in the future, and we must look to the biologic chemist to solve, or aid in the solution of, some of the biggest problems which confront us to-day.

Morgagni may be regarded as the founder of pathologic anatomy, John Hunter of its greater outgrowth—pathology. Pathologic anatomy, however, remains sterile until wedded to clinical observation. Laennec is the high priest who officiated at this alliance. Borrowing percussion from Corvisart, who resurrected it from the grave of Auenbrugger, and, with the aid of physics, developing mediate auscultation, he compared the signs of thoracic disease in life in the ward with the changes wrought by it after death, and in ten years performed one of the most stupendous feats in medicine, putting

the recognition of cardiac and pulmonary disease in the living at a level from which it had advanced little for sixty odd years, when the physicist with his *x*-rays made a new advance. Not only so, but Laennec's conception of tuberculosis in the lungs was far more true than that to which a too exclusively anatomic point of view led Virchow, whose great authority again led astray Buhl, Niemeyer and a host of pathologists and clinicians. How Laennec's view of the unity of tuberculosis was confirmed and extended I shall touch on later. Louis follows close on Laennec and enforces the lesson of the value of method and accuracy in the study of disease. It is he who inspires his young American pupils to separate typhus and typhoid fever. Neither pathologic anatomy nor clinical study alone sufficed; in conjunction they succeeded. The power to distinguish between the two diseases clinically has done much to bring about the practical extinction of the contagious typhus. In very recent times the clinical resemblance of typhoid fever, the estivo-autumnal form of malaria and of trichiniasis was in some cases so close as to render timely diagnosis difficult, to say the least. Laveran's discovery of the plasmodium, Widal's of the reaction bearing his name, and Brown's of eosinophilia in trichiniasis go far to insure diagnosis, to aid treatment, to promote preventive medicine. Laveran directly aided diagnosis, but he also paved the way for Theobald Smith's brilliant demonstration of the cause of Texas cattle fever, of the rôle played by insects in the transmission of certain infections to man and animals. Thus the accusation of Manson of mosquitoes in general has ended in the conviction of some species as necessary links in the development, first, of malaria, next of yellow fever. The mysterious sleeping sickness of man and the tsetse fly disease of horses in Africa are found to rest on a similar pathology. The alarming spread of the sleeping sickness coincident with opening up the country and increased travel is noteworthy. In 1873 Obermeier discovered the spirillum of relapsing fever. In the African form of the disease at least it seems to have been recently conclusively proved that a tick plays the part of intermediate host. The life history of the teniæ was worked out by close observation and experiment without much aid from the microscope, such is their size; but the analogous life history of these minute forms of life and their relation to disease must, per force, await the modern microscope. These are some of the latest triumphs in the application of bacteriology to medicine.

Bacteriology was brought into being by the conjunction of the perfected microscope: the chemist Pasteur, who gave the death-blow to the doctrine of spontaneous generation; another chemist, Hoffman, who made his own fortune and then promoted the welfare of humanity by his discovery of the anilin dyes which enable us to see and distinguish organisms many of which are otherwise invisible or unrecognizable; and the physician, Koch, whose solid media on plates so greatly facilitated the isolation and perpetuation of pure cultures of this and that organism. Cut out any one of these four links and we should not be where we are. Laennec's conception of the unity of tuberculosis of the lungs is confirmed, and it is proved that lupus and scrofula, which I have heard the great Hebra suggest to be manifestations of syphilis in the second or third generation, are tubercular in nature.

More than a century has elapsed since Edward Jenner, the provincial practitioner, conferred one of the greatest boons humanity has ever received by rendering it possible to practically annihilate the loathsome and deadly smallpox. The great pox remains a mystery—*pace* the *Spirochæta pallida*. We anxiously await some discovery which will do for scarlet fever and measles what Jenner's discovery did for variola, what antitoxin has done for diphtheria. We are still in outer darkness as to the pathology of these eruptive infections, though the studies of Councilman and his pupils fill us with hope.

The demonstration by Fitz of the relation of the appendix to peritonitis and his work on the pancreas involve another combination of accurate pathologic knowledge, clinical observation, unusual critical acumen, and the experience of the past as collected and recorded in the library, a factor in the progress of medicine the importance of which is daily winning recognition. Would that we had with us to-day in the flesh James R. Chadwick, to whose enthusiasm, energy and devotion in building up the Boston Medical Library not this community alone, but the country at large is deeply indebted. His interest, counsel and duplicates were always at the service of infant medical libraries, to many of which he was wet nurse.

Between Sir Humphrey Davy, chemist, and Morton, dentist, the possibility of surgical anesthesia lay in an almost dreamless sleep for half a century. How sudden the awakening, how momentous its effects! Surgery ceases to be a last resort. Half its terrors are shorn away. Bacteriology shears away the other half, and today scarce an organ, cavity or part remains a sanctuary of disease. Anatomy, physiology, pathology are all enriched by the surgeon's knife used for beneficent purposes on the living man—literally vivisection. I specify alone tubercular peritonitis, supposed to be necessarily fatal until the surgeon, operating under the false diagnosis of ovarian cyst, proved that it may be recovered from. Some cases of tubercular peritonitis need the knife; but many cases get well without any sort of operative intervention. For this advance, I repeat, we have to thank the surgical clinician.

The story of myxedema seems to be one of the most thrilling in medicine, and serves my present purpose in that it shows how the searchlight of clinical observation may illuminate dark places in physiology and pathology. The anatomist finds and describes the ductless glands. The physiologist is at a loss to explain their function. The thyroid is a riddle. Its endemic enlargement, often associated with faulty development alike bodily and mental, is noted, excites interest and speculation, but is another riddle. The great clinician, Gull, describes "A Peculiar Cretinoid State Supervening in Women in Adult Life." He puts forward no theory, but describes merely what he sees, a change coming over previously healthy grown women, producing a state similar to that of the cretin, and quite apart from endemic influence. He opens eyes which so easily overlook what is directly under them. Ord makes the first autopsy, and from the mucin reaction in the swollen tissues cuts the name down to one word, myxedema, still mainly descriptive. So also is Charcot's name—cachexie pachydermique. Clinical surgery now steps on the scene, and we see that the result of the extirpation of the thyroid for goiter, as reported by Kocher and Reverdin, is identical with myxedema. Thus the pathology of the condition is rendered clear, and for the first time we get a definite idea as to the function of the thyroid. The riddle is largely solved. Very soon myxedema becomes one of the most gratifying diseases to treat, and the remarkable fact appears that neither cooking nor gastric digestion notably impair the efficacy of the gland. It is note-

worthy that this great advance comes purely from clinicians, medical and surgical. The experiments of Schiff and Horsley on monkeys, although interesting and confirmatory, are not essential stones in the structure. The evidence is sufficiently complete without the aid of what is ordinarily termed the laboratory; and here it may be remarked that the tendency of the present day is too much toward the limitation of the term scientific medicine to that part of investigation carried on either apart from hospitals or by men not directly dealing with the sick. The work of the clinician may be every whit as scientific as that of his laboratory brother. The purely laboratory man has the advantage that he can inaugurate, systematize and govern his experiments, most of which must be on animals. The clinician has the advantage that the experiments performed for him by disease are on human beings and are oftentimes of such a nature as can not possibly be made artificially. On the other hand, the clinician is apt to find his time and strength so drawn on by individuals clamorous for relief that his highest work suffers. Does medicine afford a better illustration of the interdependence of workers in different fields than lies in the story of myxedema? Great as was the specific discovery of the function of the thyroid, still greater was its direct outgrowth, the broad fact of internal secretion, the sole function of the ductless glands, perhaps also an important function of glandular structures pouring out a secretion through a constant and definite channel.

Before turning aside from the work of the clinician I should like to mention one other advance which has been made and several riddles which still confront us. In the index of Watson's Practice, a book not read to-day as much as it should be, American edition of 1872, neuritis is found only as optic neuritis. James Jackson had recognized paralysis due to alcohol. Buzzard popularizes the knowledge that the trouble is seated in the peripheral nerves in these cases, and that alcohol is only one of many toxic agents liable to cause this result. How easy it is to-day to recognize multiple neuritis, usually to determine its cause in any given case; but there were just as many cases of it fifty years ago as there are to-day. Jaundice was formerly a disease. It is now a symptom only. Rheumatism we now recognize as a tangled skein, the threads of which we are just beginning to unravel. We are dissatisfied with diabetes as a final diagnosis, and are groping for light which may enable us to differentiate the causes of sugar as we have those of bile in the blood and the tissues. We suspect an infection behind purpura. We speak of purpura simplex and purpura hemorrhagica. We know that there are many infections which, when intense, are liable to cause hemorrhage. Our ignorance is dense as to the part played in any case by individual peculiarity as well as to other features of many cases of purpura.

From the side of physics has come one of the most notable of recent advances. Roentgen rays are doing much for the clinician, medical as well as surgical. Are there *y*- and *z*-rays? How long must we wait for their discovery? What will be their practical application? Physics, again, has given us the ophthalmoscope and exposed a prolongation of the brain to direct vision. The aurist owes it much. It enables us to illuminate the interior of the bladder, larynx and trachea, and other cavities; to localize pathologic processes, to watch their progress in the living body, intelligently to relieve and cure conditions which otherwise and formerly were necessarily left to that *vis naturæ* which may be *medicatrix*, but is too often *lethalis*.

The debt of medicine to all those half-truths which are too indiscriminately classed under the terms quackery or charlatanism is real and should be recognized. We believe homeopathy to rest on assumptions unfounded in fact, untenable to-day. The most bigoted of us, however—for there is a bigotry of science as well as of religion—can not deny that homeopathy has advanced medicine, leading to a clearer knowledge of the limitation of the therapeutic action of drugs, of their uses and abuses.

The power of suggestion, the influence of mind over body, whether exercised through hypnotism, mind cure, faith cure, Christian science, what you will, throws a flood of light on physiology and pathology, stimulates the study of experimental psychology, illuminates the influence of the nervous system on the circulation and thus on nutrition. An eminent orthopedist recently classed the natural bone setters, so-called, as forerunners of science, at a time when ignorance as to the action of trauma and disease on joints was profound. They, relying on common sense and observation alone, achieved results which science, timid from knowledge of its ignorance, failed to achieve. There is always a germ of truth in every form of irregular (unscientific) healing—a fact which it behooves us to recognize and be ready to apply.

The services of a laywoman, Lady Mary Wortley Montague, in the introduction of inoculation for smallpox, bitterly fought by our profession of the time, should not be passed without recognition.

All the sayings of a wise man are not necessarily wise, and Solomon, probably when tired or dyspeptic or worried with some family strife, said that there is nothing new under the sun. New things, certainly new in their relation to us, are coming forward every day. Not only so, but the new things spread abroad with wonderful rapidity in these telephonic days, becoming common property.

I have brought you nothing new to-night. I have simply tried to illustrate from the history of the past, how imperfectly I only too well realize, the apparently inconsequent advance of knowledge, the correlation of the sciences, the way in which a fact seemingly perhaps unimportant is always potentially fruitful, often bearing fruit of a totally unexpected kind, it may be after many days. In a positive sense we know more than our predecessors; in a relative sense we may be said to know less. The farther we advance into the empire of ignorance the larger we find it to be, each mountain peak showing higher peaks in the distance.

Life consists in the exercise of our faculties, happiness in the performance of duty and in achievement. We have an abiding faith that "all things work together for good."

Paratuberculosis.—A. Ferranini (*Arch. Gén. de Méd.*), suggests that what is commonly called hereditary predisposition to tuberculosis may be really only the manifestation of an infection by the tubercle toxin transmitted from tuberculous parents in an extremely attenuated form—a paratuberculosis. All the symptoms of the so-called predisposition, he thinks, are those that might easily be due to a very attenuated tuberculous infection, and this view is supported by the clinical and experimental observations of later immunity to the graver forms of the disease. For further testing the question he suggests the use of the serum reaction of Arloing and Courmont, which is positive with negative tuberculin test, would indicate paratuberculosis, and also the urinary test of Mariani and others for the presence of latent or attenuated tuberculosis.

THE CAUSE OF THE HEART BEAT.

W. H. HOWELL, M.D., PH.D.
Professor of Physiology and Dean of the Medical Faculty, Johns Hopkins University.
BALTIMORE.

(*Concluded from page 1670.*)

The Auriculoventricular Bundle.—It was formerly held that the myogenic theory is inapplicable to the mammalian heart because no muscular connection exists between auricles and ventricles. This objection has been completely removed in recent years.

On the anatomical side the work of Kent, W. His, Jr., Retzer, Braeunig, Humblet and Tawara has shown beyond doubt that a small muscular slip passes from the auricle into the ventricular septum. In man, according to Retzer, this bridge is about 1.5 mm. in thickness, 2.5 mm. in width and 18 mm. long.

On the physiologic side the experiments of His, Hering, Humblet, Fredericq and especially of Erlanger, have proved with equal certainty that it is along this narrow bundle that the wave of excitation is conveyed from auricle to ventricle. The last named observer has shown in a series of brilliant experiments that if this bridge be compressed by a specially devised clamp, the sequence of the ventricular on the auricular contractions may be removed either completely or partially. In the former case there is complete heart block, and the ventricle, after a preliminary pause, beats with a slow rhythm entirely independent of that of the auricle. In the latter case the block is partial, and the ventricular beats exhibit a 1 to 2 or 1 to 3 rhythm, as compared with those of the auricle.

Erlanger has succeeded in showing that in man under certain pathologic conditions an exactly similar condition prevails, forming the important feature of the Stokes-Adams syndrome.[26]

Autopsies, indeed, have shown that in some of these cases a demonstrable lesion exists in the region of the bundle. No one can deny the importance of this bundle as the physiologic link connecting auricles and ventricles. If it so happened that the tissue composing it was entirely devoid of nerve fibers the myogenic hypothesis would be practically demonstrated. According to Tawara, however, the bundle is provided with a nerve network similar to that found enveloping the muscular tissue of the rest of the heart, and naturally the neurogenists attribute to this network the functions that the myogenists would assign to the muscular bundle itself.

A definitive answer to our problem is, therefore, again postponed. The myogenists may, however, urge with justice that the probabilities here are once more in favor of his view. This bundle constitutes the only known muscular connection between auricles and ventricles, while nerve connections between the two chambers exist freely in other parts of the auriculoventricular ring;[27] yet severance of this small muscular bridge is all that is necessary in order to interrupt completely the physiologic connection between auricle and ventricle. Investigation of this interesting structure has but just begun. We may hope that future work will develop facts of fundamental significance for the physiology and pathology of the heart. Already one suggestion has arisen out of the work, which indicates the possibility of a new point of view regarding the cause and sequence of the heart beat. Tawara maintains that the cells composing the bundle are not ordinary heart muscle, but that variety of cardiac muscle which has been designated as Purkinje fibers or cells. He believes that the bundle after entering the ventricle spreads out to constitute the Purkinje cells that are known to form a layer beneath the endocardium, and one may conceive that this layer has a still further distribution within the mass of the heart musculature. There is thus presented the possibility of a widespread occurrence of a specially modified type of contractile tissue which may be intimately connected with the phenomenon of automatic rhythmicity as well as of conduction. We must, however, await further investigation before attempting to speculate on this modification of the myogenic theory.

The Action of the Accelerator Nerves.—It has been known that the hearts of both warm-blooded and cold-blooded animals may be kept alive for hours after excision from the body, provided they are supplied with an artificial circulation.

Recently the possibilities of thus maintaining an isolated heart, or of reviving its activity after death, have been developed in a remarkable way. Kuliabko was able to restore the beat of the heart in animals that had been dead three or four days, by the simple process of supplying the coronary vessels with a Ringer's solution. He obtained also similar successful results on human hearts as late as twenty hours after death. In an experiment made on the heart of a man who had been dead eleven hours, Hering was able to restore its beat for a period of several hours. Hering has made use of this possibility to study the source of the heart's automatic rhythm.[28] He found in the course of experiments on the isolated mammalian heart that the inhibitory and accelerator nerves continued to give their respective effects for a long period of time. In one case in a monkey the vagus retained its inhibitory action for six hours after death, and the accelerator for more than fifty-three hours. On the other hand comparative experiments made on rabbits and dogs showed that sympathetic nerve ganglia, such as the superior cervical or the ciliary, lose their irritability very quickly after death, even when supplied with an artificial circulation of Ringer's solution. It seems probable from these experiments that the maintenance of an automatic rhythm in the heart so long after excision or after somatic death can not be due to the activity of intrinsic ganglion cells. Since, moreover, the accelerator fibers retained their irritability in these experiments for very long periods after death it would seem probable that they do not end in the ganglia of the heart but are distributed rather directly to the heart muscles. Such a conclusion implies that the rhythm of the heart beat originates in automatic processes within the muscular tissue itself.

THE MYOGENIC THEORY OR THE NEUROGENIC THEORY?

From consideration of the brief review of the current literature and discussions on this subject it appears to me that every impartial observer will be forced to come to the same conclusion as that reached by Hofmann in his excellent critical paper published in 1898, namely, that the myogenic theory is the most probable of any that have been proposed so far. The theory in its most general form assumes that contraction waves or excitation waves arise in the sinus region and are conducted by the muscular tissue over the whole heart, the visible

effect at each point being dependent on the condition of the musculature at that moment. At the passage from auricle to ventricle there is a slowing of the conduction due to the small size and special properties of the narrow bundle connecting the two chambers. Moreover the condition of the musculature at any point may be influenced in opposite directions by nervous influences, inhibitory and accelerator, which, however, have nothing to do directly with the origination or conduction of the initial motor impulse.

This theory gives in general an adequate explanation of the phenomena of the normal heart beat, and of those variations that occur under pathologic and experimental conditions, but in order to apply it in detail we need to know more of the processes that lead to contraction and relaxation. In fact, the phenomenon of the co-ordination of the beat is not sufficiently accounted for, whether we adopt the myogenic or the neurogenic theory. The difficulty is apparent if we stop to consider those conditions which lead to inco-ordinated contractions, such as are exhibited in the peculiar fibrillated movements of auricle or ventricle. In this condition the mass of the musculature of the ventricle, instead of contracting simultaneously or in a rapid wave running from one end to the other, exhibits feeble local contractions and dilatations which involve only small areas, and give the entire ventricle the appearance of a fluttering, trembling mass.

One of the most remarkable means of thus throwing the co-ordinated contraction of the ventricles into inco-ordinated fibrillary movements is the heart puncture as described by Kronecker and Schmey.[29] A needle thrust into the heart at the lower border of the upper third of the septum may produce the transformation almost instantaneously. In my experience the phenomenon is somewhat difficult to obtain. In many cases the heart may be punctured a number of times in the region indicated with no other result than a temporary acceleration of the beat. At other times, however, the first thrust of the needle is followed by the development of fibrillary contractions. Kronecker's first explanation that the needle penetrates a co-ordinating nerve center situated in this part is, as we have seen, not supported by other facts; and his second suggestion that the phenomenon is due to excitation of a vasomotor center which causes an ischemic condition of the ventricle is likewise difficult to accept, in view of the small evidence that we possess of the existence of vasomotor nerves to the cardiac vessels.

It is, I believe, equally impossible to furnish an entirely adequate explanation of the phenomenon on the myogenic theory, although possibly, a fuller understanding of the properties of the tissue composing the auriculoventricular bundle may throw some light on it. In the terrapin I have seen a similar phenomenon occur in the auricles as a result of stimulation of the vago-sympathetic nerve, when the heart was being irrigated with a solution containing an excess of calcium chlorid (0.138 per cent.) or a solution which was lacking in potassium salts. The fibrillation in the former case took place at the end of the stimulation, that is, after the inhibition had passed off.[30] It may be, therefore, that the fibrillary contractions are the result of those influences which lead to the development of an augmented rhythmicity throughout the muscular tissue. In our present condition of knowledge, however, it is perhaps wiser not to speculate on the cause of this singular phenomenon.

THE FUNDAMENTAL QUESTION.

Whichever of the two opposing theories we may adopt there remains for discussion the further deeper question of the initial cause of the heart beat. Under normal conditions it will be remembered that the beat arises spontaneously in the sinus region, the rest of the heart contracting in turn only as a result of the stimulus received from the venous end.

The Automaticity of the Heart Beat and the So-called Inner Stimulus.—It has been customary to refer the cause of the spontaneous beat to the production of an inner stimulus, and we have to consider what suggestions have been offered as to its nature and origin. Haller assumed that the venous blood excites the heart, acting presumably as a chemical stimulus. This conclusion seems to have rested mainly on the observation that the heart ceases to beat when deprived of blood. Those who advocated this view made no hypothesis as to the special constituents of the blood which are charged with this important function. Later some of the older observers suggested that the blood acts simply as a mechanical stimulus to the heart, its pressure on the heart walls being the initial cause of the beat.

The experimenters of the early part of the nineteenth century had abundant opportunities to observe that in the cold-blooded animals the heart continues to beat for a long time after removal from the body and even when its cavities are widely opened by incisions. This fact influenced most of the physiologists throughout the nineteenth century to take the stand that the blood has no direct influence on the production of the heart beat. While it furnishes nutriment to the heart as to the other tissues, it is not immediately concerned in the causation of the beat. On the contrary it was assumed that the inner stimulus is autochthonous, that is, arises within the heart itself as a result of its own metabolism. The most concrete statement of this point of view is found in the aphorism used by Langendorff, "*Das Lebensprodukt der Zelle ist ihr Erreger.*"[31] That is to say the normal catabolism within the heart muscle or its intrinsic nerve cells gives rise to some substance which acts as a stimulus. There is no evidence, however, other than the automaticity itself, that such a stimulating substance is produced and no suggestion is made as to its nature. That a substance of this sort is not produced during the specific catabolism leading to the contraction is indicated by the fact that in a heart brought to rest by the inhibitory nerve the inner stimulus continues to increase during the period of quiescence, until at last it breaks through the inhibitory control and the heart again beats.

Those who hold to this view, therefore, must assume that this unknown stimulating substance is a product

29. Kronecker: Zeits. f. Biol. (Jubilee volume), 1896, p. 529.

30. Dr. Erlanger tells me that in several cases he has observed that stimulation of the vagus nerve in the dog, during experiments in which the chest was widely opened and the pericardium was dissected off, was followed after interruption of the stimulation by a period of inco-ordinated contractions. McWilliam (Jour. of Physiol., 1888, vol. ix, p. 392) records that in the isolated heart of a cat stimulation of the vagus caused rapid fluttering movements of the auricles instead of the usual inhibition. Knoll (Pflüger's Archiv., 1897, vol. lxvii, p. 591) refers also to the fact that in the mammalian heart stimulation of the vagus may call forth fibrillary movements in the auricles. Direct stimulation of the heart with induction shocks, if strong enough, will throw the heart into fibrillary movements and a similar result follows or may follow conditions of marked anemia. In strips of the ventricle from the terrapin's heart it is sometimes observed that excessive doses of calcium salts in the bathing liquid may so change the irritability of the muscle that a simple induction shock calls forth fibrillary movements instead of the usual contraction (Schultz).

31. Langendorff: Archiv. f. Anat., u. Physiol. (physiology division), 1881, supplementary volume, p. 1.

of the resting metabolism of the heart. This, in fact, is the view advocated by Engelmann.[32] He holds that there is a continual production of stimulating substance at the sinus end of the heart, which as soon as it reaches a certain quantity excites the muscle and starts a wave of contraction. Since, moreover, each systole is followed by a period of inexcitability which constitutes the diastolic or resting phase, it is a necessary part of this theory to assume that the process of contraction in some way arrests the production of stimulating substance and indeed destroys or antagonizes that already formed. Hering[33] seems to adopt a similar point of view. Without venturing on any speculations regarding the nature of this stimulating substance or the processes leading to its production, he develops the idea that a similar process may occur in the atrioventricular region or in the ventricle itself, the effective stimulus produced in these latter locations being designated as heterotropic in contrast with the normal stimulus which arises at the venous end. In other words he adopts the view that parts of the heart other than the sinus region may develop automaticity under certain conditions.

Many investigators have been unwilling to remain content with such general explanations and have sought, therefore, to ascertain what substance or substances constitute the actual stimulus for the heart's contractions, or bear such a close relation to this phenomenon as to form a necessary step in its development. Most of the investigators in question have directed their attention to a careful examination of the specific influence of the individual constituents of the blood. They have followed the general line laid down by Haller in seeking the immediate cause of the heart's activity in the action of the blood itself. The fact that an apparently bloodless heart continues to beat is no argument against such a view, for it is obvious that a heart whose cavities have been depleted of blood by washing is still saturated throughout its substance with tissue lymph, which must be considered in this connection as an actual part of the blood.

One somewhat peculiar view of the relations of the blood to the heart beat has been proposed by Kronecker. As far back as 1874[34] this author expressed the opinion that the heart muscle can continue to contract only when it receives a constant supply of fresh food material. Subsequently in a series of papers published by himself and his pupils[35] he attempted to show that the serum albumin contained in the blood (and lymph) forms the immediate source of the energy of the heart's contractions, and that these contractions can continue only as long as a supply of this material is present in the liquid bathing the tissue. The insufficiency of the experimental data on which this hypothesis was based has been demonstrated by others[36] and the progress of investigation in recent years has been such as practically to remove it from the field of discussion. At the time that Kronecker's chief investigations were made the importance of the effect of the inorganic constituents of the blood was not adequately understood.

Recent Investigations.—The most modern and seemingly the most hopeful line of investigation on the cause of the heart beat was started by Ludwig in 1875. Under his guidance Merunowicz began the study of the relations of the inorganic constituents of the blood to the heart beat. Before that time and for many years subsequently, perhaps even at the present day, physiologists were accustomed to consider only or mainly the organic constituents of the heart or of the blood in discussing the cause and conditions of the rhythmic beat. In the theories of Langendorff and of Engelmann referred to above it is implied, although not specifically stated, that the unknown substance constituting the "inner stimulus" is organic in nature. Merunowicz was able to show that aqueous solutions of the ash of blood, free from all organic matter, have a remarkable efficacy in causing and maintaining the contractions of the frog's heart.[37] He attempted to analyze the specific influence of the several constituents of the blood ash, but in this effort he and the workers in the same laboratory who continued his investigations, were unfortunate in overlooking the importance of the minute amounts of calcium salts present.[38] Nevertheless it was made clear by their work, particularly by that of Merunowicz, that the inorganic constituents of the blood have an important relationship to the development of the heart beat.

In 1883, Ringer, by a fortunate accident, was led to study the effect of calcium salts on the heart's contractions,[39] and on the basis of his experimental results he devised an artificial serum, known now as Ringer's solution, which is capable of maintaining the beat of the heart in a wonderful way. This solution contains certain amounts of sodium, potassium and calcium salts, and for some hearts also a trace of alkali in the form of sodium carbonate. Its extraordinary efficiency in developing and maintaining the beat of the isolated heart both in the cold-blooded and the warm-blooded animals is known to all physiologists. The heart of the dog, rabbit, cat and of man himself has been kept beating on this inorganic diet for many hours, or even for days. Locke has succeeded recently by making use of a modified Ringer's solution, containing dextrose, in keeping a rabbit's heart beating for four days after removal from the body. The action of this artificial serum and the specific effects of its different constituents have since been the object of a large number of investigations by Ringer himself and by many other workers in various parts of the world.[40] It is entirely evident that a simple aqueous solution containing only sodium, calcium and potassium salts, together with oxygen, cannot furnish nutriment to the heart in the sense of supplying it with a source of energy for its contractions. The rôle of these salts must be found in their relations to the origination of the heart beat, that is to say, their connections with the chemical changes in the organic constituents which give rise to the energy of the contraction.

Experiments on the hearts of the cold-blooded animals indicate that so far as the circulating liquid is concerned the potassium salts do not form an absolutely necessary constituent. The heart as a whole, or different parts of it, may continue to give rhythmic beats when immersed in or supplied with a solution containing only sodium and calcium salts. There is no doubt, however, that for the heart as a whole, and, therefore, especially for the venous end of the heart, the presence of potassium salts makes a better balanced mixture, and one which maintains a normal beat for a longer period

of time. We must bear in mind that the heart muscle contains a considerable store of potassium, and the fact that it continues to contract rhythmically when supplied with a mixture containing only sodium and calcium salts, is no proof that the potassium does not continue to play its important and necessary rôle, whatever that may be. All the evidence from experimental work indicates that the potassium salts are concerned chiefly with the production of the condition of relaxation, the phenomena of diastole and inhibition.[41] In the matter of the contraction of the heart, therefore the rôle assumed by the sodium and the calcium respectively, has excited the chief interest. One set of observers (Loeb, Lingle[42]) have believed that the sodium salts (or rather sodium ions) stand in the most immediate relation to the process originating the contractions. "Among the ions found in blood, those of sodium are the producers of rhythmic activity. They constitute the primary stimulus." While others (Ringer, Howell, Langendorff, *et al*) believe that it is the calcium salts which are most directly concerned in the actual contraction, although the manner and extent of their action are differently interpreted by the several authors. A large literature has sprung up in recent years on the specific effects of these salts under different conditions.

The time at my disposal does not permit me to enter into the details of the discussion, and, indeed, the facts at present are not so numerous nor so definite that one is able to draw any very satisfactory conclusions in regard to their real manner of action. Instead of attempting to present or discuss these details permit me to call your attention to certain general conclusions that may be derived from the accepted fact that these inorganic elements play an essential part of some sort in the processes underlying the heart beat.

GENERAL CONCLUSIONS.

In the first place what is or may be their relations to the so-called inner stimulus? Langendorff[43] and others while admitting the necessity of these substances, characterize them simply as conditions which must be supplied in order that the inner stimulus may act; conditions of the same general character, for example, as a suitable temperature or the presence of oxygen. From this standpoint, therefore, the inorganic salts have nothing to do directly with the initiation of the beat, although this phenomenon can not take place in their absence. On the other hand Lingle has stated that the sodium ions form the direct stimulus to the heart's activity, while I have been quoted by several authors as advocating the view that the calcium ions constitute the inner stimulus. I must object to this interpretation of my views on the action of the calcium salts. In my last paper on the subject I have stated simply "that the energy of the heart beat is derived from material stored in its own substance. For the utilization of this supply of energy, however, certain conditions are necessary, and the principal one of these conditions seems to be the presence in the liquids of the heart of a supply of calcium in some form." And again, "Under normal conditions the stimulus that leads to a heart contraction is dependent on the presence of calcium compounds in the liquids of the heart."

These views do not differ materially from those finally accepted by Langendorff, except in the fact that he supposes the creation in the heart of some as yet unknown substance which acts as the "inner stimulus." We have no proof that any such substance is formed and, indeed, to my mind there is no necessity for assuming the existence of a specific inner stimulus. In discussing such a point one must define first of all what is meant by a stimulus. Ordinarily by this term we mean some form of energy which, acting on the irritable living substance, causes it to exhibit its specific form of activity. If the chemical reaction underlying functional activity is directly induced by a special compound or even by a specific ferment, I presume that we should be justified in characterizing this compound or this enzyme as a stimulus. But if, as may well be the case, the living substance is of sufficient instability to break down spontaneously, under the conditions prevailing in the tissue, then the chain of events leading to the display of functional activity may be inaugurated without the activity of a specific inner stimulus. It is in this manner that I conceive that the spontaneous beat of the heart arises.

The immediate cause of the contraction is a chemical reaction or a series of such reactions. In accordance with the knowledge of our day we may assume that the first step in this series consists in the dissociation, the falling into pieces of a complex, unstable molecule, and that this dissociation is followed by an oxidation of the split products. The undoubted necessity of the oxygen for the normal production of a heart contraction may be referred, therefore, to the part that it plays in the second stage of the process, and not to its action as a primary or initial stimulus. The "inner stimulus," if such a thing exists, must be concerned in the production of the initial step of dissociation. We may inaugurate this first step, as is well known, by the application of some external form of energy, such as a mechanical impulse, an electrical current, a nerve impulse, etc., and it is conceivable, of course, that it may be started, as Langendorff and Engelmann have supposed, by some specific substance formed in the metabolism.

It seems to me, however, equally as probable or more probable that this initial step takes place really automatically or spontaneously, in consequence of the instability of the substance in question. My own work has convinced me that the calcium salts are in some way of prime importance in this matter of the initial dissociation of the energy-yielding substance, but I do not believe that they act as a direct chemical stimulus. Speculations on this subject must at present go beyond the limits of our real knowledge and are, therefore, liable to be partly or completely erroneous.

The following facts must be taken into account by any hypothesis which attempts to picture the processes causing the rhythmic contraction and dilatation of the heart muscle:

1. The heart possesses within itself a store of energy-yielding material, such that it may continue to give many hundreds or thousands of contractions after its supply of nutriment has been cut off.

2. Each contraction, whether caused normally or by an artificial stimulus is maximal, and, therefore, probably uses up all of the energy-yielding material which is at that moment in an irritable condition, that is to say, in such a condition that it may be acted on by a stimulus.

3. The amount of this material in irritable form is nil during the phase of systole, but increases in amount throughout the period of diastole. We know, for

41 See Howell: Amer. Jour. of Physiol., 1900, vol. xv, p. 280.
42 See Lingle: Amer. Jour. of Physiol., 1900, vol. iv, p. 265.
43. See Ergebnisse d. Physiol., vol. i, part ii, 1902; also vol. iv, part ii, 1905.

example, that if stimulated just at the beginning of diastole the heart muscle gives a small contraction and that the contraction, which may be obtained later by artificial stimulation, increases in extent the farther the diastole has progressed.

4. If the above statements are correct it follows that the store of energy-yielding material in the heart exists in some non-irritable form and that during the phase of diastole a portion is converted into an irritable form capable of being acted on by a stimulus.

5. The presence of certain inorganic salts is necessary for this transformation from the non-irritable to the irritable condition.

In order to picture the relations of the inorganic salts to this process the hypothesis which I have adopted as a heuristic principle to guide my own investigations, may be stated as follows: The well-nourished heart contains a large supply of energy-yielding material, which is in stable form, so that it neither dissociates spontaneously, nor can be made to do so by the action of external stimuli. It is possible that this stable, non-dissociable form consists of a compound between it and the potassium or the potassium salts, and that herein lies the functional importance of the large amount of potassium contained in the tissue. This compound reacts with the calcium or with the calcium and sodium salts, and a portion of the potassium is replaced and a compound is formed which is unstable. At the end of the diastolic period this compound reaches a condition of instability such that it dissociates spontaneously, giving rise to the chain of events that culminates in the normal systole. Before spontaneous dissociation occurs it may be hastened prematurely by an external stimulus, as we know to be the case when a mechanical or electrical shock is applied to the heart at any time after diastole has begun.

From this point of view the rôle of the calcium, or of the calcium and sodium salts consists in replacing the potassium and converting a part of the store of stable material into an unstable, easily dissociable compound. We are not obliged, therefore, to assume the existence of any specific inner stimulus. An hypothesis of this character accounts readily for some of the most characteristic features of the heart beat.

Each contraction must be maximal since it involves the dissociation of all the material existing in unstable form. The contractions must be rhythmic since, after each contraction a certain interval, which will be constant when the conditions are uniform, is needed for the production of more of the unstable material. At each systole the heart will exhibit a refractory phase, since the ready-formed, unstable material has been used up and the rest of the energy-yielding substance exists in a stable, non-irritable form. In terms of the hypothesis the refractory phase should pass off gradually as new, unstable material accumulates, and this we know to be the case, since a weaker stimulus is required to force the heart to contract the later it is applied in the diastolic phase.

Whether or not this or any other of the hypotheses described turns out to be correct, we may congratulate ourselves at least that the labors of the experimental physiologists during the last quarter of a century have added to our store of knowledge this new and important fact, namely, that the inorganic salts of the blood and lymph play an essential rôle in the production of the heart beat.

ULCER OF THE STOMACH: PATHOGENESIS AND PATHOLOGY.

EXPERIMENTS IN PRODUCING ARTIFICIAL GASTRIC ULCER AND GENUINE INDUCED PEPTIC ULCER.*

FENTON B. TURCK, M.D.

CHICAGO.

DEFINITION.

By artificial gastric ulcer is meant ulcer produced by experimental means, as by some local, mechanical or chemical injury; by induced ulcer is meant ulcer produced by more indirect and natural means, such as feeding methods, as presented in this paper. The term peptic is retained on account of long usage.

INTRODUCTION.

Ulcer of the stomach is one of the most important

Fig. 1.—Deep ulcer in which perforation occurred, resulting in general peritonitis and death.

pathologic questions that engage the attention of scientific workers.

Clinically, it has led to the investigation of numerous conditions with which it is directly or indirectly associated, such as the local manifestations of pain, hemorrhage, perforaton; the secondary results, as adhesions, cicatrices, and contractions; carcinoma formed at the site of the ulcer, and, finally, the systemic conditions of toxemia, lowered vitality, anemia, etc.

The pathogenesis of gastric ulcer, however, is what has called forth the best scientific effort. The rôle that

* Presented before the International Medical Congress, Lisbon, 1906. The preliminary report on these experiments was first presented in the symposium on Gastric Ulcer before the American Gastro-Enterological Association, 1904, and withheld from publication for more careful revision and research. Presented before the joint meeting of the Chicago Pathological Society and Chicago Medical Society, March 21, 1906.

* From the Research Laboratory of the Turck Institute, Chicago

cytolysis and autocytolysis play in the formation and persistence of ulcer must be recognized as an important one. It points back to the fundamental problem: What prevents self-destruction of the stomach; and, moreover, what prevents autocytolysis of all tissues of the body? That some sort of protection existed to prevent self-destruction was even recognized by the ancients, who attributed it to some supernatural power.

Stahl[1] regarded our protection to be the "sensitive soul." He states: "This very preservation of a thing essentially destructible by which its destruction through its own activity is prevented is exactly what we ought to understand by the common word 'vital.' In any case the fermentation which takes place in the alimentary canal is not an ordinary fermentation, such as occurs in a merely compound, not-living body, but a most special character is impressed on the change by energy of the soul."

John Hunter,[2] in his vital principle, expressed a similar idea, and in place of the "sensitive soul" he believed that the "vital power" protected the body by some inherent energy.

As cellular pathology developed, the word tissues was added to the same vital power of Hunter, and, as Riegel[3] expresses it, "The main reason why the stomach does not digest itself is unquestionably the vital resisting power of the tissues."

The conception of resistance of the tissue against the formation of ulcer has developed various ideas of local protection, either as a vital power residing in the cell or some secretion acting as a mechanical or chemical protection. Thus Vaughan Harley[4] thought the mucus acted as a protective coat of mail to the mucosa of the stomach, and Claud Bernard[5] believed that the regeneration of cells rapidly replaced those destroyed by the gastric fluid.

The modern idea of this local protection is shown in Weinland's[6] work, who holds that an anti-pepsin ferment residing in and as a part of the gland cells protects them from destruction.

Antipepsin Ferment Residing in and as a Part of the Gland Cell	Weinland

From the large amount of experimental work on blood serum, by numerous investigators, we are able now to clothe our ideas of "protective bodies" in more technical and definite language. We may speak now of natural histogenic immunity, of hemolysins, of agglutinins, of precipitins, of cytotoxins, etc. We may go a step further in our understanding of this same histogenic immunity towards infectious diseases in the light of amboceptors, and of the alexins or complements, with their

respective toxophore, haptophore, or receptor groups. It is easy to understand what a clear field of investigation was opened in the study of natural and acquired immunity towards infections diseases in the light of amboceptors and complements of toxins and antitoxins. It is no less evident to one investigating the problem of the

Fig. 5.—Duodenal ulcer, second portion.

production and persistence of gastric ulcer that we have here, not a question of local pathology, but of general blood pathology, of complement and amboceptor, of cytolysis and autocytolysis.

HISTORY OF EXPERIMENTS BY PREVIOUS INVESTIGATORS.

In the following classified list of methods adopted by various observers, it will be observed that most of the efforts to produce ulcer by artificial methods have been directed towards obtaining purely local cellular changes. This is apparently the direct influence of Virchow and his school in experiments and clinical observation of the pathology and pathogenesis of ulcer up to the present time. Virchow offered the hypothesis of vascular obstruction or aneurismal dilatation of vessels, but these are far too inconstantly found in ulcer.

Fig. 6.—Duodenal ulcer at jejunal junction.

Ulcers produced by some form of mechanical injury to the stomach wall heal even more readily than in other parts of the body, and attempts to produce ulcer, by chemical injury, either fail to produce the lesion, or the lesion heals more or less promptly. As anemia is frequently associated with ulcer, various attempts have been made to produce ulcer by combining resection and some mechanical injury, as resection of the mucosa, with bleeding, or the injection of laked blood or chemical substances, as practiced by Cohnheim, Silbermann and others. If the anemia was sufficiently profound and the injury well-marked, ulcers were produced in the stomach, just as one would expect in injury to any part of the body.

The production of ulcer of the stomach by destroying areas in the brain, or section of the cord or vagi, can not be satisfactorily explained, but seems rather too violent and foreign to the conditions present in ulcer of the stomach. One explanation of the cause of ulcers produced by the above methods might be suggested by the work of Pawlow, who noted loss of motor power of the stomach after section of vagi, and of the recent work of Ophüls, who noted great dilatation of the stomach after section of both vagi below the diaphragm. Both these conditions would be very important factors in causing change in the bacterial growth in the stomach and intestines. How far this bacterial factor may be an ex-

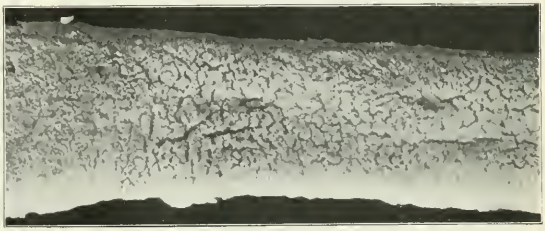

Fig. 7.—Duodenal ulcers, near pylorus.

planation of the ulcers produced after injury to the peripheral and central nervous system will require further investigation.

The following tables of the different authors' experiments in the production of artificial gastric ulcers are classified and arranged for convenience and ready reference. A few clinical and postmortem observations are included in these tables:

TABLES OF EXPERIMENTS BY PREVIOUS INVESTIGATORS.

A. MECHANICAL AND PHYSICAL INJURY.

		RESULT.
Ritter[8]	Violent bruises	
Decker[9]	Heat	Ulcer
Matthes[10]	Trauma (with 5 per cent. HCl)	Ulcer
Schmidt[11]	Trauma (with HCl)	
Körte[12]	Pinching stomach with clamps	Ulcer

B. CHEMICAL.

Roth	Crystals of nitrate of silver introduced into stomach	Ulcer

1. HCL AS A NECESSARY FACTOR.

Riegel[13]	HCl necessary	
Matthes[10]	Trauma (without HCl)	Negative
	Trauma (with 5 per cent. HCl)	Ulcer
Schmidt[11]	HCl and trauma	
Ewald[14]	HCl essential factor	

2. CONTRA HCL.

Pawlow[15]	Hyperacidity a consequence.	
Du Misini[16]	Superacidity without significance.	
Ageron[17]	HCl may be persistently absent.	

8. Ritter: Beits. f. klin. Med., 1887, p. 12.
9. Decker: Berl. klin. Wochft., 1887, p. 21.

16. Du Misini: See Riegel, "Diseases of the Stomach," 1903, p. 570.
17. Ageron: Münch. med. Wochft., July 29, 1902.

Kavelsky[18]	Synchronous ulcer of the stomach and bladder.	

C. GENERAL DYSEMIA.

Virchow[19]	Anemia and chlorosis.	
Quincke and Daetwyler[20]	Anemia by producing gradual hemorrhage and local trauma.	Ulcer, which healed with difficulty.
Silbermann[21]	Hemoglobinemia	Ulcer
Flütterer[22]	Hemoglobinemia	Ulcer
Cohnheim[23]	Hemoglobinemia by mechanical injury and injection of laked blood	Ulcers

D. DISTURBANCE OF LOCAL CIRCULATION.

Virchow[24]	Embolism, thrombi, aneurism or varicose veins.	
Klebs and Welti[25]	Thrombi.	
Panum[26]	Injection of emulsion of wax into into femoral vein.	Gastric infarcts, ulcer.
Talma[27]	Ligation of esophagus and pylorus	Ulcer
Rindfleisch[28]	Venous stasis; prolonged ischemia.	
Axel Key[29]	Prolonged ischemia due to contraction of gastric muscle.	No experiments.
Müller[30]	Tied portal vein	Ulcer

E. INJURIES TO NERVES AND NERVE CENTERS.

Schiff[31]	Intersection of thalami and peduncles	Ulcer
Ebstein[32]		
Brown Sequard[33]	Anterior corp. quadrigemina	Ucer
Vidova[34]	Injection of Alcohol into vagus	Negative
Vidova[34]	Section of the sympathetic	Ulcer
Yzeren[35]	Section of the sympathetic with section of vagi below the diaphragm	Ulcer
Saitta[36]	Section of the sympathetic with section of vagi below the diaphragm	Ulcer
Ophüls[37]	Section of the sympathetic with section of vagi below the diaphragm	Ulcer
Koch and Ewald[38]	Section of cord, and 5 per cent HCl in stomach	Ulcer

Fig. 8.—Deep peptic ulcers of duodenum (first portion).

F. LOCAL INFECTION.

Cohnheim[23]	Injection. Infected suspensions of lead chromate	Erosions and ulcers.
Büttcher[39]	Infection as cause of ulcer	Opposed by Körte.
Nauwerck[40]	Infection observed at edge of ulcer.	

The following tabulated record of my experiments is introduced here, although many of the methods apparently come under the above classification, yet they are sufficiently distinct to permit a separate presentation:

AUTHOR'S EXPERIMENTS.

A. MECHANICAL.	RESULTS
Excision of the mucous membrane. Also application of local irritants and removal of mucous membrane by nippers, observed through a permanent gastric fistula.[41]	No visible lesion.
Trauma and hemorrhage by wire brush. (Repeated for one month.)[42]	Hemorrhagic erosions
Cardiac and pyloric ligations.[43]	No erosion.
Partial ligations of portal vein.[43]	Erosions near ligation.
Ligations of veins of stomach.[43]	

B. CHEMICAL.

Application of tannic acid, gastric juice to mucosa with the gyromele.[43 42 43]	Negative.
Application of chromic acid, silver nitrate crystals with gyromele.[43 42 43]	Negative.
Same; pyloric end partially tied.[43]	Hemorrhagic erosions.
Tannic acid daily for several weeks.[43]	Negative.
Mustard oil, large doses.[44]	Acute gastritis only.
Mustard oil for 14 months.[45]	Chronic gastritis. No ulcer.

C. LOCAL INFECTION.

Sarcinæ and yeast introduced into stomach; pylorus partially tied.[46]	Negative.
Stomach contents from infected stomach injected into dog's stomach through fistulous opening.[43]	Increased HCl. No ulcer.

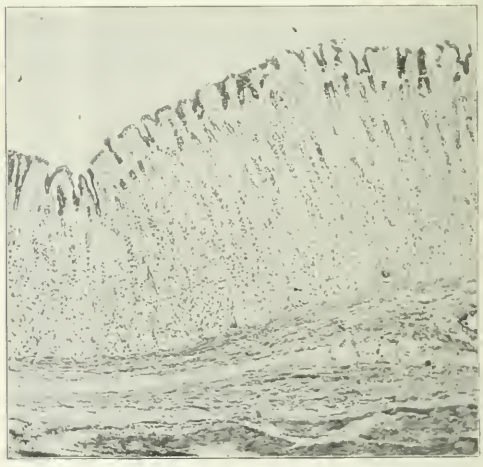

Fig. 9.—Stomach of dog. The mucosa is practically normal. The glandular structure is well shown and the surface epithelium is intact. (Low power.)

D. INJECTION OF TOXINS.

Diphtheritic toxin injected into stomach wall.[47]	No ulcer, pinhead hemorrhagic foci in duodenum.
Same.[47]	Same. Local necrosis near pylorus.
Diphtheritic toxin injected into mesenteric vessels.[47]	No ulcer, foci of necrosis after two weeks in duodenum and near pylorus.
Intravenous injection of extracts and emulsions of gastric mucous membrane.[48]	Necrosis of mucous membrane near pylorus
Intravenous and subcutaneous injection of stomach contents from patients into animals.[49]	No ulcer

E. SYSTEMIC DISTURBANCES.

Shock and infection. Laparotomy. Exposure of stomach to air three hours repeated. Inoculation peritoneal cavity.[50 42]	No ulcer

Prolonged use of chloroform and ether: two to six hours.[51]	No ulcer.
Guinea pigs and rabbits closely confined in small cages.[52]	Six ulcers; two spontaneous, four by local lesions.

F. INJECTION OF PEPTONES.

Intravenous and subcutaneous injection of peptones for two to four weeks after removing portions of the mucous membrane of the stomach.	Six dogs: Two scars, two delayed healing, two negative.

In the above series of my experiments, most of which have been previously reported, those of injecting mustard oil into the stomach and those of animals kept in confinement, are of special interest.

In the experiments with mustard oil, increasing doses were injected into the dog's stomach at intervals of two to three days for nine to fourteen months. One hundred c.c. of a 1 500 emulsion of the oil was injected at the outset, but the dose was gradually increased, so that at the end of three months 125 c.c. of a 1 50 emulsion could be given, and later the oil was simply added to the dog's food.

Vomiting and acute gastric symptoms followed the earlier injections, but later no reactionary symptoms occurred. At the end of nine months dog No. 1 died. At the end of eleven months dog No. 2 died. No ulcer was found in the stomach or intestines in either dog No. 1 or dog No. 2. At the end of fourteen months dog No. 3 was chloroformed. The dog was emaciated. The stomach was dilated and occupied a large

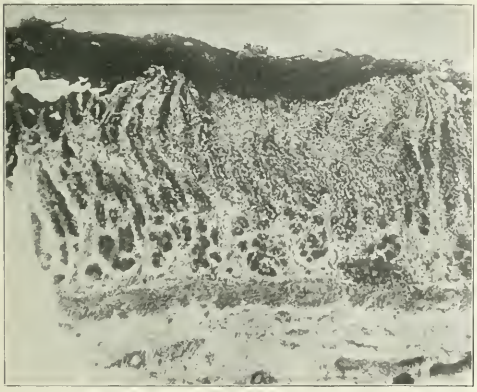

Fig. 10.—Stomach of dog, early stage. The black mass on the surface and the finger-like projection downward into the crypts is an accumulation of mucus, cellular débris, blood serum, etc. (Low power.)

portion of the abdominal cavity, the greater curvature extending to the line of the anterior superior spinous process. The mucous membrane in the fundus of the stomach showed etat mamillæ. Microscopic examination showed chronic gastritis. No ulcer was found in the stomach or intestines.

Failure after such radical means as the feeding of mustard oil for fourteen months demonstrated the futility of attempting to produce ulcer by simply local irritation.

The possibility of systemic disturbances, altered metabolism, impaired nutrition being etiologic factors in the production of ulcer led to the experiment of confining animals in very close quarters for a long period of time.

Ninety six guinea pigs and 36 rabbits were used in the experiment, which was continued nine months. The animals were confined in small sterilized cages (made of wood, except the bottom, which was of wire netting), 4x6x6 inches. The top was closed by a hinge cover, light being excluded, but air admitted through two small holes on either side. The cages were placed in sterilized pans, in a solution of permanganate of potassium, and were sterilized every other day. The animals were thus restricted to a small allowance of air, light and exercise, but were given the usual amount of food, and kept in as sterile cages as possible.

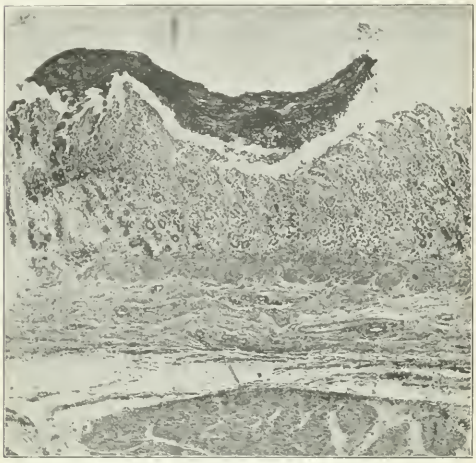

Fig. 11.—Stomach of dog, later stage, with necrosis of the mucosa. The plug is still adherent to the ulcer cavity. The surface epithelium has disappeared; disarrangement of glandular structure. (Low power.)

At the outset a blood count and hemoglobin estimation were made, and again after two to three months' confinement, and finally after seven to eight months. As soon as an animal

Fig. 12.—Stomach of dog. More advanced stage, with necrosis reaching almost the muscularis, exposing a small blood vessel. (Low power.)

showed any signs of infection it was removed. During the first two or three months the animals gained in weight as a result of deficient exercise and oxidation, but later became emaciated.

Red Cells.		Percentage of Hemoglobin		Months.	Result.
Before	After	Before	After		
6,408,000	3,296,000	85	75	4	Ulcer
5,840,000	4,900,000	80	70	4½	Ulcer
6,410,000	4,850,000	85	60	6	Ulcer
4,992,000	4,200,000	75	60	5½	Ulcer
5,120,000	4,250,000	70-75	60	3	Ulcer
5,360,000	4,120,000	80	65	6	Ulcer
6,200,000	3,130,000	85	65	6	No ulcer
5,450,000	3,800,000	80	50-55	5	No ulcer

Result, after nine months: All the rabbits died. Of the 96 guinea pigs, only 6 survived. In 4 of these animals ulcers produced by removing portions of the mucous membrane failed to heal. Two induced peptic ulcers were found in the other 2 guinea pigs.

Fig. 13. Stomach of dog. Edge of ulcer reaching to the muscularis, showing marked degenerative changes with breaking down of the entire glandular structure. (Low power.)

For the first time, then, in the author's long series of experiments, induced peptic ulcers were formed, but in such a small per cent. of the animals that even positive results were of little value in solving the problem of the

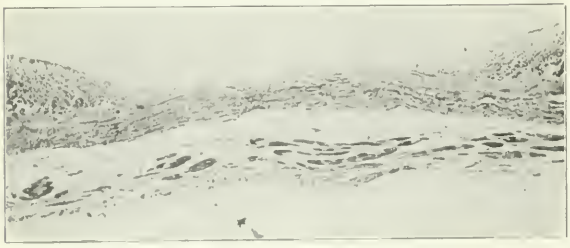

Fig. 14. Smooth walled ulcer. No inflammatory changes. (Low power.)

etiology of peptic ulcer. They suggested, however, the possibility that systemic conditions were important factors, that alterations in the toxic state of the alimentary canal, with consequent changes in the blood, might play some rôle in the formation of ulcers. The next step was to select some more definite means of modifying the normal conditions of the alimentary tract and general system.

Experiments were begun with *Bacillus coli communis* because it is the organism found normally present in such large numbers in the intestines, and is the organism which multiplies so luxuriantly in catarrhal and atonic conditions of the stomach. Morphologically and culturally no difference could be found between the strain of *B. coli* isolated from the stools of normal individuals, and that from cases of ulcer of the stomach. But the possibility of a difference in their pathology led the author to use in his experiments strains isolated from the feces of cases of ulcer of the stomach. The toxin of *B. coli* being intracellular suggested the experiments of using killed as well as living cultures. In my earlier experiments the bacteria were introduced directly into the circulation, but later they were fed the animals. By this latter method the bacterial status of the alimentary canal could be more directly modified, and a better approach be made to more natural conditions.

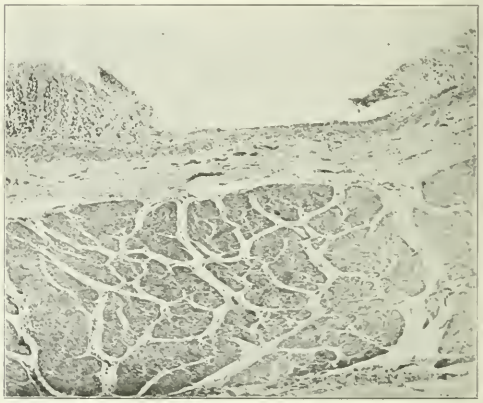

Fig. 15.—Ulcer with undermining of the mucosa. (Low power.)

Meat extractives were fed certain of the animals in connection with the bacteria, as will be seen by reference to the table of experiments with *B. coli*. It was found that *B. coli* grew most luxuriantly in media containing meat extractives, hence the possibility was suggested that a more active growth might be produced in an alimentary canal which contained meat extractives.

Positive results have been obtained thus far in every experiment in which cultures of *B. coli* were fed to dogs. The number and extent of the ulcers have varied, however, from a few ulcers in the duodenum to numerous typical peptic ulcers in the stomach. In one case death resulted from hemorrhage from a large ulcer at the pylorus.

To give these positive results true scientific value, it was essential to find out the percentage of gastric ulcer in a large number of dogs not experimented with.

The dogs were obtained from two different sources—one, healthy dogs that had been asphyxiated at the city pound; the other, dogs that had died from disease, injury, poisoning, etc. From the first source, 189 dogs were examined; from the second, 82, making a total of 271. Antemortem observations as to the general condition of the dogs could be made at the city pound, because the dogs were kept there ten days before being killed. The stomachs and intestines, after being removed from the bodies, were treated in a uniform manner, e. g., opened, washed in weak creolin solution, hardened for six hours in

dilute formalin, and finally examined very carefully macroscopically. Of the 189 healthy dogs examined, few showed any changes in the alimentary tract; of the 82 dying from disease, poisoning or injury, many showed diseased conditions of the various organs. But no peptic ulcers were found in either the stomach or intestine of any of the 271 dogs examined. Absolutely negative findings of peptic ulcers in both the healthy street dogs and the diseased animals shows that the percentage of ulcers present in dogs is at most exceedingly small.

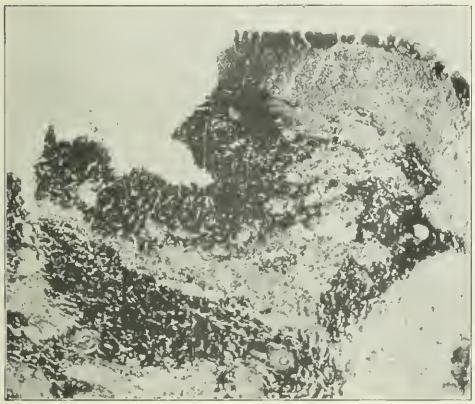

Fig. 16.—Destructive changes in the submucosa, showing necrotic areas which refuse to stain.

EXPERIMENT: WITH BACILLUS COLI COMMUNIS.

I. INOCULATION EXPERIMENTS WITH DOGS.
   1. Intravenous injections of living cultures of *B. coli communis.*
   2. Intravenous injections of cultures of *B. coli communis* killed by heat.

II. FEEDING EXPERIMENTS WITH MICE AND RATS.
   1. (a) Feeding raw beef.
      (b) Feeding raw beef and *B. coli communis.*
   2. (a) Feeding beef extractives.
      (b) Feeding beef extractives and *B. coli communis.*
   3. (a) Feeding extract free beef.
      (b) Feeding extract free beef and *B. coli communis.*

III. FEEDING EXPERIMENTS WITH DOGS.
   1. Feeding bouillon culture of *B. coli communis.*
   2. Feeding cultures of *B. coli communis* and beef extract.

EXPERIMENTS IN INJECTING LIVING CULTURES OF B. COLI COMMUNIS INTO DOGS AND RABBITS (1, 1).

FIRST SERIES OF INJECTING EXPERIMENTS.

Methods.—The strain of *B. coli* used was isolated from water and from the feces of cases of ulcer of the stomach.

The injections were made subcutaneously, intraperitoneally, and into the internal jugular vein, at intervals of two to five days. Six dogs and twelve rabbits were used in this experiment. After a period of one month, the abdomen was opened under aseptic precautions, and an artificial ulcer made by removing a portion of the mucous membrane of the stomach. The injections were continued, and at the end of two weeks the abdomen was again opened.

Results.—In most of the animals the lesion was entirely healed, so that not even its site could be detected. Scars were visible in some of the stomachs and defective healing in others. In four animals ulcers were found, which did not show a tendency to heal.

SECOND SERIES OF INJECTING EXPERIMENTS.

Methods.—The strain of *B. coli* used was isolated from the feces of cases of ulcer of the stomach.

The injections were made into the external jugular vein of dogs and were continued for six months, at intervals of two to ten days. Four c.c of a twenty-four hour bouillon culture of *B. coli* was used for two months; then the amount was increased to emulsions of the surface growth of two petri dishes, and later of four petri dishes.

Results.—The reaction to the injection at first was anorexia and vomiting, with general lassitude for a day or two. After an interval of ten days the reaction to inoculation would be considerable, but would be much less pronounced, if the inoculation was then repeated in a day or two. Later, that is, after three months of such inoculation, no reaction could be obtained, even though large numbers of bacteria were introduced.

B. coli was agglutinated by the dog's serum in dilution 1 5,000 ten days after the first inoculation.

Operation.—An artificial ulcer was produced in the stomach four and one-half months after the first injection. The injections were continued two months longer.

Postmortem.—The dog was chloroformed three months after the production of the artificial ulcer, and the stomach and intestines examined for ulcers. The lesion produced at the time of the operation had entirely healed. No ulcers were found in the stomach. In the duodenum and ileum numerous oval-shaped raised areas were found, with depressed centers resembling Peyer's patches. The entire bowel was very pale, with the exception of a few hyperemic areas. Two irregular patches of erosion were found in the ileum. No ulcers were found in the intestines.

EXPERIMENT IN INJECTING INTRAVENOUSLY DEAD CULTURES OF B. COLI COMMUNIS (1, 2).

Methods.—The strain of *B. coli* was isolated from the feces of cases of ulcer of the stomach. The injections were made into the external jugular vein, and were continued for four months, at intervals of two to four days. Emulsions of the surface growth on two to eight petri dishes were used after being boiled to kill the bacteria. The constitutional reaction to inoculation was much less than in the case of living cultures.

Operation.—An artificial ulcer was made in the stomach three months after the first injection. The external wound healed readily. The injections were continued one month longer, and then the dog was chloroformed.

Postmortem.—No ulcers were found in the stomach. The duodenum showed six typical peptic ulcers, about 5 cm. from the pylorus. The ulcers were grouped together, somewhat oval in outline (6x1 mm.), transverse to the long axis of the bowel, with abrupt margins, and floor smooth and covered with a mucous-like accumulation (Fig. 8).

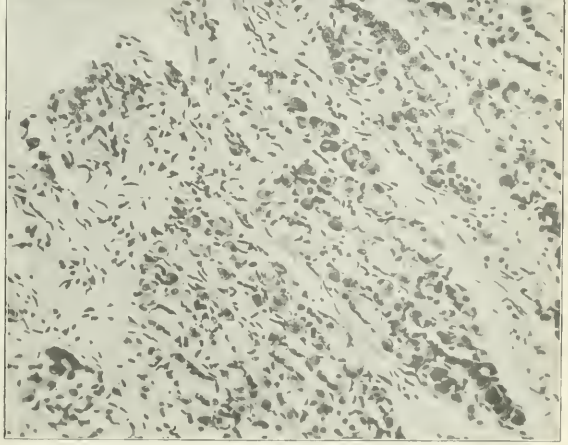

Fig. 17.—Showing the increased proliferation parietal cells and the degenerated, broken down and disarranged chief cells. Surface epithelium disappeared. (High power.)

FEEDING EXPERIMENTS WITH MICE AND RATS (II).

The object of these experiments was to determine the relative effect of the feeding of *B. coli communis* with and without meat extractives.

Methods.—The meat juice obtained by pressing raw beef was used in the experiments with beef extractives. The extract free beef was prepared from the pressed meat, and after being steamed under 15 pounds' pressure for one hour was again pressed and fed the rats dry.

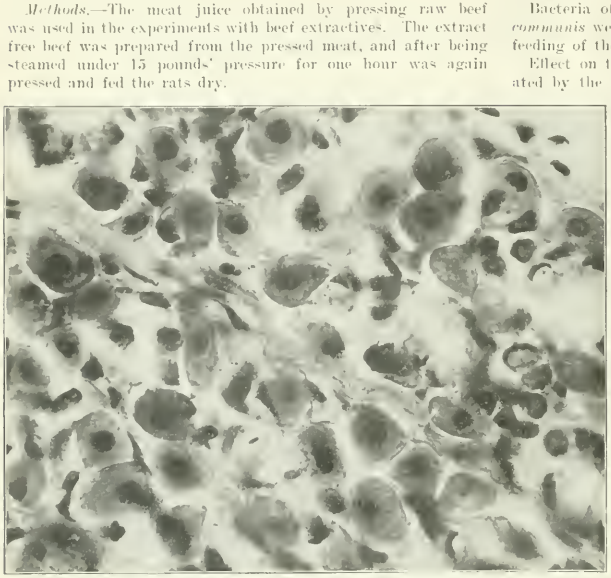

Fig. 18.—Showing the parietal cells. They are larger and increased in numbers, between them are seen a few degenerated chief cells. (Oil immersion, 1-12.)

Bouillon cultures of *B. coli* were added to the raw beef in one experiment, to the beef extract in a second experiment, and to the extract free beef in a third experiment. The rats were given as much of the cultures as they would take. As controls a second series of rats were given raw beef, beef extract and extract free beef respectively. The experiment was continued one month.

Results.—At the end of a month the rats fed on extractives and extractives containing *B. coli* died. The other rats of the series were killed at the same time for comparison.

During the course of the experiment little if any difference was noted in the behavior of the rats fed meat and extract free beef with and without bacteria. The extractive fed rats showed some bloating of the abdomen early in the experiment. They drank readily all the extractives and cultures fed them, but appeared restless and hungry.

Postmortem.—Negative so far as macroscopic appearances were concerned in all except the extractive fed rats. These showed a marked decrease in fat. Their organs, especially the liver, were pale in color.

FEEDING EXPERIMENTS WITH DOGS (III).

FEEDING BOUILLON CULTURES OF B. COLI COMMUNIS (III, 1.)

Methods.—Increasing quantities of a 24 to a 48 hour growth of *B. coli communis* in bouillon were fed daily to the dogs, together with an ordinary meat diet, beginning with small amounts and increasing to 1,000 c.c. Watery emulsions of the surface growth on agar plates were occasionally substituted.

The strain of *B. coli communis* used was obtained from the feces of cases of ulcer of the stomach. The length of time of feeding the dogs varied, in one case being 81 days before death occurred, and in another case 102 days.

RESULTS OF THE FEEDING.

Bacteria in Blood: The blood remained sterile during the course of the experiment. The heart's blood at death was also sterile.

Bacteria of the Stomach: Nearly pure cultures of *B. coli communis* were obtained from the stomach 9 hours after each feeding of the bacteria.

Effect on the Blood.—Agglutination: *B. coli* was agglutinated by the dog's serum in dilution 1 to 500 and slightly in dilution 1 to 1,000 after 20 days' feeding. Marked hemolysis of the blood was present 20 days after feeding.

Coagulability: Coagulation of the blood was slow, the clot formed being soft.

General Constitutional Reaction: The dog appeared perfectly normal until one week before death, when symptoms of hemorrhage gradually developed, e. g., coffee ground vomit, tarry stools, loss of strength and appetite, lowered temperature, with death in shock.

Postmortem.—Dog No. 1 (Series III, 1). Liver and kidney showed marked venous congestion. Stomach and intestines contained coffee-colored liquid. Stomach had large blood clot at pylorus and some coagulated blood over mucous membrane. Multiple peptic ulcers were found in the stomach and one large one at the pylorus, from which the hemorrhage occurred, resulting in death (Figs. 2, 3, 4).

Dog No. 2 (Series III, 1). A dog which had been under feeding experiment with *B. coli* was placed under anesthesia, abdomen opened, stomach found flabby and a small well-formed ulcer was found on anterior wall near the pylorus, which perforated on inflation of the stomach with air; the contents escaped through the opening, which showed sharpened edges ("punched out" appearance) the size of a dime; about a pint of fluid was found in the stomach; free HCl absent; peptones present.

Dog No. 3 (Series III, 1). Dog fed 500 c.c. bouillon cultures of *B. coli* daily for two months, then chloroformed.

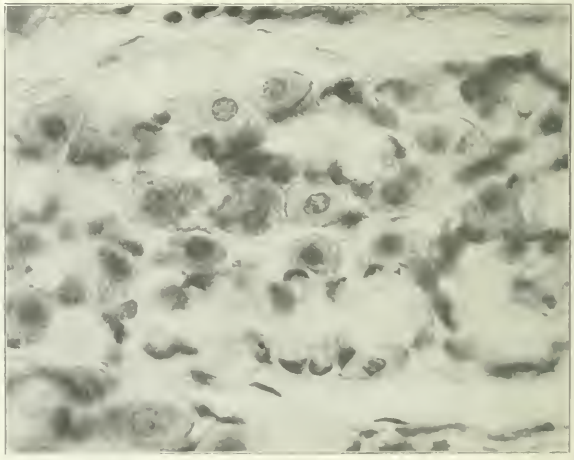

Fig. 19.—Showing the parietal and chief cells. Note the large size of the parietal cells, showing beginning degeneration; also, the crescent shaped nuclei of the degenerated chief cells. (1-12 oil immersion.)

At postmortem the stomach was found to be large, full of food. Mucous membrane hyperemic. In the pylorus were 6 round, pale colored raised areas about 3 mm. in diameter, with central depressions, margins raised and somewhat irregular in outline. No ulcers were found in the stomach.

Intestines.—Mucous membrane pale. In the duodenum were

three typical peptic ulcers in the wall opposite to the mesenteric attachment longitudinal to the axis of the bowel, circular in outline when stretched. Floor of the ulcers was smooth, clean cut, margins raised and abrupt (Fig. 5). No ulcers were found in the ileum or colon.

FEEDING BOUILLON CULTURES OF B. COLI COMMUNIS AND BEEF EXTRACTIVES (III, 2).

Methods.—Beef extract was fed the dogs in saturated watery solution or in capsules, approximately 25 gm. being fed daily, together with an ordinary meat diet. Cultures of *B. coli communis* were fed as in experiments III, 1. The length of time of feeding the dogs was 104 days.

RESULTS OF THE FEEDING.

Effect on the Blood: Experiments III, 2, same as in experiments III, 1.

General Constitutional Reaction.—Diarrhea was produced in three days, which lasted four to six days and was more pronounced in the case of the *B. coli* fed dog. Whenever during the course of the experiment the above feeding was stopped for a few days, there was a recurrence of the diarrhea on beginning the feeding again. With the exception of the above diarrhea both dogs remained perfectly healthy for three months, then the *B. coli* fed dog began to show some slight indisposition.

Operation.—After 100 days' feeding of beef extract and *B. coli communis* an exploratory operation was made, but no ulcers of the stomach were found. An artificial ulcer was made by removing a small portion of the mucosa in the posterior wall near the pylorus. Three days after the operation the dog died of peritonitis resulting from perforation of the artificial ulcer (Fig. 1).

Postmortem.—General peritonitis. Perforation of the stomach at site of artificial ulcer. Perfect closure of incision in anterior wall of the stomach made at the time of operation, with no signs of inflammation there. Venous congestion of liver and kidney. Duodenum showed 13 peptic ulcers (Figs. 6 and 7).

HISTOLOGIC EXAMINATION OF LIVER, KIDNEY, STOMACH AND INTESTINES OF DOG OF EXPERIMENT III, 1.

Dog died of hemorrhage from pyloric ulcer after being fed cultures of *B. coli* for 81 days.

Liver.—Marked degenerative changes are present in the liver cells of the central portions of the lobules. The liver columns here are broken up into one or more cells. The cells have a shrunken appearance, are irregular or roundish in outline, stain diffusely with eosin, or are broken down as granular or vacuolated masses. In these cells the nuclei have disappeared, while in others the nuclei appear as faintly bluish irregular rings. In the peripheral portion of the lobules, the liver cells contain numerous small vacuoles, are somewhat granular, and stain fairly well. The liver columns throughout are compressed by the congestion of the intertubular capillaries. Many leucocytes are seen in these vessels.

The blood vessels in the portal system are all engorged with blood. There is no increase in the stroma of the portal system, but it has an edematous appearance. The bile ducts are closed by their swollen epithelial cells.

Kidney.—Histologic examination of the kidney sections also shows marked degenerative changes. These are present largely in the secretory (convoluted) tubules. The epithelial cells lining these tubules are swollen and cloudy and fill the lumen of the tubules; others are granular and vacuolated; their outlines have disappeared, are fused together and broken down. In these cells the nuclei stain very poorly or have disappeared. The glomeruli have a swollen or cloudy appearance. The capillaries of the tufts are engorged with blood. The glomeruli are separated from Bowman's capsule, the spaces of which are filled with granular detritus.

The tissue throughout has an edematous appearance. The intertubular capillaries are all distended with blood.

Intestine.—Histologic examination of the sections from swollen Peyer's patches shows acute catarrhal changes with marked swelling of the follicles. The surface of the mucosa is covered with a bluish-stained, viscid mucous material in which are intermingled many detached epithelial cells, some leucocytes red blood cells and bacteria. Some of the surface epithelial cells have an elongated appearance, the ends of which are lost in the exudate. The glands are all swollen and filled with bluish homogeneous material. The goblet cells are swollen and filled with mucus. The capillaries in the mucosa are all engorged with blood. The Peyer's patches are well defined and swollen. There is a great increase in lymphoid cells in the follicles as well as surrounding the follicles infiltrating the surrounding tissue. The central portions of the follicles are paler and stain pinkish with eosin, due largely to an increase of the epithelial cells, many of which are undergoing degeneration. There are no changes in the other coats except the engorged blood vessels.

Stomach.—For histologic examination, sections were taken from various areas of the stomach wall, e. g., those which showed typical ulcers; those with slight defects in the mucosa, and others in which no changes could be detected with the naked eye. The tissues were hardened in bichrom-acetic-alcohol imbedded in paraffin and stained with the usual stains, hematoxylin and eosin, polychrome methylen blue and toluidin blue, etc.

For the sake of clearness those sections will be described first which appear almost normal and show the least changes, followed by those which show changes of a more marked character. As seen in Figure 9 the mucous membrane has a normal appearance; the glandular structures are all fairly well preserved. Here and there the surface columnar epithelial cells are disarranged or entirely broken away (possibly due to the technic), exposing the connective tissue stroma of the columns. The stroma in the mucosa appears normal in amount and shows no changes. The capillaries are tortuous, distended with blood and plainly seen beneath the surface and the deeper portions of the mucosa. The chief cells of the glands do not show very well and their arrangement is somewhat broken up; otherwise they appear normal. The parietal (acid) cells are prominent, large, stain well and show an occasional mitotic figure or a deeply stained nucleus. In certain areas they appear to be increased in number.

Catarrhal Stage (Fig. 10.)—In tracing the different stages of the formation of ulcer, the catarrhal stage appears to be the earliest. First we find the surface of the mucosa covered by a more or less homogeneous pink (eosin) stained material, which has a resemblance to serum and in which are seen many red blood corpuscles, a few leucocytes, fragments and débris of detached columnar epithelial cells and many long bacilli. In other sections the material on the surface is made up of bands or layers, staining blue or bluish red with polychrome methylen blue and toluidin blue. From the staining reactions and appearance this material consists largely of mucus. These mucous bands also dip down into the neck of the glands, almost to one-half of their depth, and on close examination with the high power are shown to be intimately connected with the columnar epithelial cells. The surface epithelium and the cells lining the glands are well preserved, especially in the deeper portions of the mucosa.

In some areas, the surface cells are detached in groups and have a swollen appearance. The protoplasm of the cells is vesicular and vacuolated. Their shape is oval, elongated, spindle-shaped and tortuous. They usually have a greatly elongated and drawn out appearance like strings. The nuclei of these cells have an elongated and flattened appearance, and stain diffusely. These elongated cells become lost or appear to be intimately connected with the mucous bands which cover the surface of the mucosa and which fill up the glands themselves. As a result of the accumulation of this material, the glands are greatly distorted, the necks or openings of the glands widened or pressed apart. The deeper glands in the mucosa, also show a swollen appearance, their lumen being closed by the swollen cells. The protoplasm of these cells stains reddish blue (polychrome methylen blue) and is highly granular. The stroma of the mucosa has a swollen edematous appearance. In some areas there is a great infiltration with red blood corpuscles and a few leucocytes. All the blood vessels (smaller veins and capillaries) in the mucosa and submucosa are engorged with blood. The muscularis is normal.

From the above description it will be seen that we have in these sections, first a great outpouring of mucus, some serum and red blood corpuscles, followed by desquamation of the surface and lining cells of the glands, and later a mucoid degeneration of the cells themselves, which become entangled and intimately connected with the mucous secretion of the surface, and through various influences are easily detached or broken away from their lining, leaving defects underneath.

The further process with loss of the glandular tissue is the next step in the formation of ulcer which can be seen in another series of sections taken from a different area of the stomach walls, and which is shown well in Figures 11 and 12.

As shown in the photographs, there is a necrotic mass fitting into the concavity of the mucosa or supposed ulcerated area. In some sections the base of the concavity in the mucosa reached to the muscularis. The necrotic mass may still be connected to the mucosa by bands or may lie loosely attached, giving the edges a ragged appearance. With the high power the necrotic mass is seen to be composed largely of detached, proliferated and broken-down cells derived from the mucosa, and is made up of thick bluish stained bands, in which are entangled epithelial cells, acid or parietal cells, red blood corpuscles, and connective tissue cells. The glandular structure beneath the necrotic mass on either side is greatly disarranged and has lost the glandular outline.

The epithelial cells (chief cells) are scattered irregularly throughout the stroma (Fig. 17). They show marked degenerative changes; are small and irregular in shape; their protoplasm is vacuolated and the cell body deformed or compressed, while their nuclei are small, elongated, distorted and pale or refuse to stain. These chief cells seem to be crushed out of existence largely by the acid or parietal cells. The latter are so numerous that they almost replace the entire field of the mucosa and are proliferating in large numbers. The proliferation of the parietal cells is a marked feature in all these sections (Figs. 17, 18, 19). Mitotic figures are very numerous; many of the cells contain two nuclei. They vary in size, being sometimes two and four times their natural size. Hand in hand with proliferation of these cells there are also degenerative changes going on. The protoplasm stains deeply or poorly, or may be granular or broken up. Some cells are vacuolated and swollen; their nuclei appear vesicular, granular and have a pale and distorted appearance. These cells in some areas are so numerous that 50 can be counted in a single field with the high power. The connective tissue stroma in these areas is disarranged or broken down by the proliferated cells. Underneath the necrotic mass the stroma has lost its usual character; it is looser in texture, fibrillar or homogeneous and granular and refuses to stain well; throughout the stroma in these areas there are hemorrhagic extravasations. As the various cellular elements break down, the loosely fibrillar stroma collapses and later also breaks down, leaving larger and smaller defects in the mucosa.

Some distance away from this area the stroma appears somewhat increased. The surface epithelium has more or less disappeared or become detached, exposing the stroma underneath. Here also is active proliferation of the parietal cells; they are seen in solid columns, one on the other, while the chief cells are disarranged and imbedded between the parietal cells. The chief cells are small, irregular, vacuolated and distorted with peculiar vesicular nuclei, or they may be so overwhelmed by the parietal cells that their outlines are lost.

The mechanical factor in the destruction of the chief cells by the proliferated acid cells is only a secondary feature.

Primarily marked cytolytic changes are to be noted in the chief cells themselves. In areas where the glandular structure is fairly well preserved, the chief cells may still be attached to the basement membrane, or if detached, lie loosely in the lumen of the glands. Here the chief cells are small, distorted and shrunken, with almost complete loss of protoplasmic contents. Their nuclei are peculiarly distorted into half-moon shapes and stain faintly, the cells appearing in areas as shadow ghost cells. These changes are purely cytolytic.

Other sections of this series show more advanced stages of the same process. As seen in Figure 12, the necrotic mass has dropped out or broken away, exposing a more or less well-defined, irregular smooth ulcer, reaching almost to the muscularis and exposing at the base a larger sized blood vessel, which is broken down, showing how hemorrhages occur. Otherwise the changes are as described above. There are no changes in the submucosa or muscularis except engorgement of the veins and capillaries with blood.

DESCRIPTION OF THE TYPICAL ULCER.

The typical ulcer, as shown in Figures 13, 14, 15, is a well-defined smooth-walled concavity. It gradually slopes inward and downward from either side to the base at the muscularis mucosa. In some sections the concavity is more or less square, or somewhat irregular in outline; in others the edges may be overlapping with undermining beneath. The edges or walls of the ulcer as a rule are smooth and consist of remnants of the stroma. It is a poorly stained or colorless loose fibrillar, almost fibrin-like, homogeneous or granular material, in which are imbedded round, oval or elongated nuclei, fragments of epithelial cells especially parietal cells, which in certain parts are fairly well preserved and stain well. There are no inflammatory changes of any kind present. The same appearance of the stroma is noted some distance from the ulcer. The surface of the mucosa has the same appearance as the edges of the ulcer. The surface epithelium has all disappeared. The deeper glands show changes as described in previous specimens. The chief cells are disarranged and crowded out by the large increased number of the parietal cells. The deeper glands are fairly well preserved, but have a swollen, cloudy and granular appearance.

The outline of the cells has disappeared and the individual cells have fused together, so that the gland is composed of a coarsely granular mass, through which are scattered deeply stained nuclei. Some of these glands in cross section show the early changes in the parietal and chief cells. The chief cells are swollen, opaque or coarsely granular, while the parietal cells show beginning proliferation. They stain intensely pink (eosin), are increased in size, and crowd or press the chief cells inward into the lumen of the glands. In the upper portion of the mucosa the glandular outline becomes gradually deranged. The parietal cells are increased in number, while the chief cells crowded in between are small, appear as shadows or have disappeared. Usually nearer the ulcer, both kinds of cells are scattered irregularly through the tissues. Degenerative changes are seen in both kind of cells, but they are more pronounced in the chief than in the acid cells.

SUMMARY.

According to my experiments the factors concerned in the production and persistence of ulcer of the stomach

and duodenum appear to indicate a dual condition. Some toxic condition seems to be produced which overcomes natural resistance, resulting in cytolysis, and possibly some chemical substances formed within the alimentary tract, which when absorbed may neutralize the protective bodies in the blood and tissues resulting in autocytolysis.

This hypothesis must present itself after a careful study of the local and systemic changes that take place in the production of induced peptic ulcer. In my experiments in feeding cultures of the colon bacillus, pronounced changes were revealed in the blood and tissues. Agglutination of *B. coli* by the dog's serum in high dilution was noted; hemolysis of the blood was evident; cytolysis and autocytolysis of the cells of the mucous membrane of the stomach, of the kidney and of the liver were marked on microscopic examination. But there was no bacteriemia, no inflammatory reaction in the form of round cell infiltration such as one would expect in a reactionary inflammation induced by pyogenic micro-organisms or toxins. It was not the picture of reaction to an infection, not the picture of a local, acting agent, but rather of a systemic condition, and of an induced cellular change.

What have we accomplished by our experiments? Gastric ulcers have been produced by other investigators, as will be seen by reference to the literature, but for the first time we have, by our feeding experiments, brought about spontaneous or induced peptic ulcer in the stomach and duodenum. We are as yet at the experimental threshhold, for our experiments have been comparatively few in number, but a percentage of 100 in our results signifies a true grasp of an etiologic factor. We are at least justified in saying that we have now a firm working basis for the further investigation of the pathogenesis of gastric ulcer. There are now a number of problems before us under investigation. Perhaps the widest field is opened in the study of the blood changes in these animals. Further determinations must be made of the hemolytic, agglutinating, bacteriolytic and phagocytic strength of the blood, and its coagulability, reaction, the action of the serum on digestion, the hemoglobin curve, the number of red and white blood corpuscles and the differential count of the leucocytes. It is of prime importance that the pathology of ulcer be further studied by histologic examinations of the ulcers at various stages of their development, that an examination be made also of the liver, kidney, spleen, lymph glands and bone marrow. The problem of altered metabolism must be studied by an analysis of the urine, feces, stomach contents, etc. It must be determined also whether the feeding of bacteria other than *B. coli* will produce ulcer, and whether all animals are equally susceptible.

CONCLUSIONS.

1. Ulcer of the stomach and duodenum can be produced in dogs by feeding *B. coli communis* for a variable length of time.

2. We have now for the first time a firm basis by which to solve the finer or underlying etiology of ulcer.

TRYPSIN IN MALIGNANT GROWTHS.

W. A. PUSEY, M.D.
CHICAGO.

Following the experiments of Beard of Edinburgh with the use of trypsin in Jensen tumors in mice and his suggestion for the use of trypsin in carcinoma, many attempts undoubtedly are being made at present with trypsin in inoperable malignant growths.

I have used trypsin in seven cases of inoperable carcinoma in different parts of the body and in one inoperable round-cell sarcoma of the thigh. I began the work ten weeks ago, and in some of the cases continued the injections for six weeks. All except one were hopeless cases from the standpoint of operation or *x*-rays, but in none of them was cachexia marked. I have used Fairchild's sterilized trypsin solution with the commercial name of *injectio trypsi*, which, I believe, was the preparation used by Beard. Beard's successful dose of one drop in mice is equivalent to 600 drops in an adult of 150 pounds weight. I began with injections of from 5 to 10 drops daily, and in some cases rapidly increased it to a maximum dose of 60 drops daily.

The results can be readily epitomized. Sometimes the doses—whether small or large—caused little pain and no subsequent irritation at the site of injection; in one or two patients there was bitter complaint occasionally after an injection; frequent inflammatory swellings resulted, and in six or eight instances abscesses developed at the site of injection. These developed several days after the injections, and I believe the question of accidental infection can be eliminated because the injections were given with scrupulous attention to aseptic technic and other patients who were having hypodermic injections at the same time of other drugs developed no abscesses. The abscesses which formed began as ordinary phlegmonous swellings. When they opened there was a discharge, not of ordinary pus, but of a thick, sticky, almost transparent serous fluid containing broken-down cheesy masses. After evacuation of an abscess there was left an unhealthy sinus with dirty-grayish, flabby walls, and in three or four instances these enlarged until they formed unhealthy, deep, indolent sinuses of the diameter of a finger or larger. These are slow to heal, but are painless.

I think that in one case in which there was a circumscribed mass of carcinoma in the pectoral muscle on the front of the shoulder there has been very distinct benefit from the injections. In this case there was a phlegmonous swelling which was opened with the discharge of more than two ounces of fluid and broken-down tissue, but the opening did not become larger and the cavity is now healed. As a result of the procedure the carcinomatous mass has disappeared as though it had been digested. I believe that in this case positive benefit has been done.

In the other cases I believe appreciable harm has been done to the patients. In several instances after large injections the patients have had chills. Except for these chills, there has been no immediate constitutional effect; but in all the patients who had numerous injections cachexia has developed and they have failed more rapidly than they were failing before. The experience has been so uniform that I have no doubt the trypsin has done the patients harm. The one case in which there has seemed to be benefit showed only a circumscribed mass, and in a similar case I should try trypsin again, but unless I could hope with a few injections to destroy a localized mass I should not at present feel justified in using the remedy. In none of the other cases has there been any appreciable influence on the neoplasms.

I know that so short and so small an experience is in no way convincing, but, as it has forced on me some conclusions and as there are no published reports on the effect of trypsin in human carcinoma, I venture to believe the experience is worth recording at this time.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER XXIV.

Parasiticides and Antigonorrheics.

It will be convenient to consider under this head, agents used for parasites other than bacteria, which infest the skin and intestines, together with a brief reference to the antigonorrheics.

Cleanliness prevents nearly all hurtful skin parasitism, and the only one which we shall consider here is that of the pediculi, since other forms are commonly treated more advantageously by the specialist.

The louse which infests the head requires no medication, since it is easily removed with a fine comb and thorough washing with tar soap. The ointment of red mercurie oxid or red precipitate has been used as a popular domestic remedy, and the tincture of larkspur or of stavesacre, to be mentioned again later, may be useful in many cases.

The louse which infests the genital regions, *Pediculus pubis*, is smaller and more difficult to remove mechanically.

A dilute solution of mercuric chlorid (corrosive sublimate) is sometimes used and is very effective for this troublesome parasite. It should not be stronger than one to five hundred (2 grains to 2 fluidounces or 0.1 gm. to 50 c.c.), and this should be used cautiously. A less cleanly but very efficient remedy is mercurial ointment.

A 20 per cent. tincture of staphisagria, or of larkspur, diluted with water, bay rum, dilute alcohol or soap liniment is much used in some parts of the country.

Among the names of staphisagria which indicate its common use are semen staphidis pedicularis and läusekörner.

In lieu of the unofficial tincture the now official:

FLUIDEXTRACTUM STAPHISAGRIÆ.—U. S.—Diluted with from 8 to 10 parts of soap liniment, or of bay rum, will be found equally serviceable.

It may not be amiss to call attention to the fact that carbolic ointment not only kills the troublesome chigger, but also relieves the smarting which that parasite occasions, or which is more frequently caused by scratching the place where the parasite is embedded.

ANTHELMINTICS.

The term anthelmintic, meaning literally against a worm, embraces vermifuges and teniafuges, which expel the round and tape worms, respectively, and vermicides and tenicides which kill them; but, as a matter of fact, the parasites are rarely killed before their expulsion.

Küchenmeister attempted to establish a rational basis for the use of anthelmintics, more than fifty years ago, but his work, which was widely quoted for a long time, has but little value at present.

v. Schroeder studied the effects of a large number of agents on ascarides and found that the latter are remarkably resistant to poison placed in the media with the parasites, which are to a certain extent able to resist absorption. These parasites are surrounded by a chitinous substance, and when that is not acted on by the agent the mouth is the principal means of ingress to their bodies. Santonin, even in concentrated solution, was found to be harmless to the parasite, which, however, found it objectionable and sought to escape from the solution containing it, the movements being particularly active; from this it would appear that santonin drives the round worm out of its normal habitat into the large intestine, from which it must be swept by purgation.

The statement that the presence of castor oil greatly increased the toxicity of santonin for this parasite arose from a mistake, and santonin is now usually given with calomel. Since it is not intended to be dissolved in the stomach, a compressed tablet or lozenge of calomel and santonin is to be preferred. For the same reason, when santonin is given to a child, with a little sugar, the two substances should be lightly rubbed together without being powdered. Sodium santoninate which is soluble, should not be used, therefore, and it has, very properly, been dismissed from the later editions of our Pharmacopeia.

The following are among the now official substances that are useful as vermifuges.

SANTONICA.—U. S.—Santonica or Levant worm seed, as it is frequently called, is officially described as the dried unexpanded flower heads of *Artemisia pauciflora*. It is now but seldom employed as such, being generally displaced by:

SANTONINUM.—U. S.—Santonin, the inner anhydride or lactone of santonic acid, obtained from santonica, was discovered in 1830, by two German apothecaries, quite independently of each other, Kahler in Düsseldorf, and Alms in Mecklenburg.

Average dose: 0.06 gm. (1 grain).

SPIGELIA.—U. S.—Spigelia or pink root is the dried rhizome and roots of *Spigelia marilandica*.

Average dose: 4 gm. (60 grains).

FLUIDEXTRACTUM SPIGELIÆ.—U. S.—This is made with diluted alcohol and is the preparation now generally used when this drug is to be administered.

Average dose: 4 c.c. (1 fluidrachm).

OLEUM CHENOPODII.—U. S.—Oil of chenopodium is a volatile oil distilled from *Chenopodium anthelminticum*, more popularly known as American wormseed.

Average dose: 0.2 c.c. (3 minims).

QUASSIA.—U. S.—The wood of *Pierasma excelsa*, Jamaica quassia, or of *Quassia amara*, Surinam quassia, is most frequently used in the form of a decoction or an infusion, made in accordance with the general formulas for these several preparations.

Average dose: 0.5 gm. (7½ grains).

EXTRACTUM QUASSIÆ.—U. S.—This is an aqueous extract and represents ten times the weight of the crude drug.

Average dose: 0.06 gm. (1 grain).

FLUIDEXTRACTUM QUASSIÆ.—U. S.—This is directed to be made with a mixture of three parts of alcohol and six parts of water.

Average dose: 0.05 c.c. (8 minims).

TINCTURÆ QUASSIÆ.—U. S.—This is a 20 per cent. tincture and is made with 35 per cent. alcohol.

Average dose 2 c.c. (30 minims).

The *Ascaris lumbricoides*, or round worm, is a very common parasite in the small intestine of children particularly. The most useful remedy for this parasite is santonin; this has been given in a variety of methods. Some authorities recommend from one-half to one grain (0.02 to 0.05 gm.) morning and evening during three days for a child and on the fourth day a purgative. This suggestion was evidently based on the supposition that the parasites were killed or injured and were then to be swept out, but since we know that this is not true, the method in vogue at the present time is to combine santonin with a slowly acting purgative, such as calomel in small doses. The purgative should follow the santonin in a few hours at the latest. It should be remembered at all times that santonin is not an absolutely safe remedy and that it is far better to try a small dose and to repeat it in a few days if not effective than to give the maximum dose in the beginning.

A lozenge containing half a grain (0.03 gm.) of santonin given morning and evening, to a child, for three days will usually be found effective. Twice this dose is used for an adult.

If it is desired to give santonin in powders, it may be prescribed somewhat as follows:

℞ Santoni (cryst.) . . . . . grs. iii 0.2
Sacchari . . . . . grs. xxx 2
M. Et in chart. No. vi div.
Sig.: One powder night and morning, the last dose to be followed by a purgative.

The purgative may consist of calomel or syrup of senna, or, according to the more modern teaching, 1/6 grain (0.01 gm.) of calomel may be directed to be incorporated in each paper. The mixture should be dispensed in granular form and not finely powdered. Santonin taken in this way has very little taste.

While santonin is perhaps the most effective remedy we have for ascarides, the fluidextract of spigelia has been recommended and is said to act somewhat like santonin. It is recommended that a laxative be given before the spigelia and a purgative some hours later, or the combination of pink

root and senna, that was at one time quite common, may be preferred.

Spigelia, however, has also given rise to toxic symptoms in children.

Oil of chenopodium, or oil of American wormseed, has long enjoyed a certain reputation, particularly as a housebold remedy, tor round worms. It has a very disagreeable odor and taste. It may be given combined with castor oil, or from one to three drops may be mixed with sugar for a child.

The thread worm or pin worm, *Oxyuris vermicularis*, infests the rectum and colon, and is often spoken of as the seat worm.

The common anthelmintics, such as santonin, together with purgatives, are usually effective in removing them, but they sometimes prove very troublesome and difficult to dislodge.

Injections of large amounts of watery infusions are often useful. Infusion of quassia enjoys an especial reputation, it lessens the mucous secretion and probably increases the movements of the parasites, which facilitates their removal when the bowel is emptied.

As suggested in connection with the official preparations of quassia, an aqueous infusion of the extract or even a correspondingly diluted fluidextract may be used, with some promise of satisfactory results, in cases in which the infusion can not be readily obtained.

Phenol has also been recommended, but the danger of absorption entirely precludes its common use.

Osler recommends the cold injection of a strong solution of common salt for children, repeated for ten days at least. The hips are elevated to favor the retention of the injection as long as possible.

TENIAFUGES.

Remedies used for tape worm are commonly spoken of as teniafuges, even though the parasite may belong to a different genus, but as a matter of fact, the *Tænia saginata*, which is derived from beef, is very much more commonly found in the human intestine, while *Tænia solium* from swine is met with much less frequently in man.

Bothriocephalus latus is mentioned in all text-books, but as it is extremely rare in this country, and practically never originates here, it may be disregarded in this place.

Male fern, or the much more widely used oleoresin, which fully represents the rhizome, is said to be very much less efficacious against the *Tænia* than against the *Bothriocephalus*, while pelletierin, obtained from the bark of pomegranate root, is especially efficacious against the *Tænia*. If this be true, we have but another example of our tendency to take everything originating in Germany as being universally correct, without exercising our own judgment, for male fern has certainly enjoyed a greater popularity than the circumstances appear to justify. On the other hand, its wide use in northern Germany is more rational, since the *Bothriocephalus* is very commonly found there in man.

v. Schroeder found that one part of pelletierin in ten thousand parts of a solution containing 1 per cent. each of sodium chlorid and sodium carbonate, was very rapidly fatal to *Tænia serrata* and to *Tænia inermis*, while much stronger solutions were practically harmless to round worms.

Estimating the content of the human intestine at 200 c.c. after purgation, if only 0.2 gm. (3 grains) of pelletierin escape absorption from the stomach and pass into the intestine, it would be present in the proportion of one part in one thousand of intestinal content, or ten times the concentration found necessary by von Schroeder.

Pelletierin is but mildly toxic to man, hence it appears to be an almost ideal teniafuge or tenicide.

Kamala, which was formerly official, and is still used, acts as an intestinal irritant, causing purging and therefore requires no subsequent purgative. It is said to be effective against tenia and is usually administered in substance, being given in doses of from 4 to 8 gms. (one to two drachms).

Kostoxin, obtained from kousso, resembles male fern in its pharmacologic action, but is said to be efficacious against *Tænia* as well as against *Bothriocephalus*.

Aspidium, or male fern, has repeatedly given rise to toxic symptoms and death has occasionally followed its use. It is apparently inferior to pomegranate in the treatment of tenia, and there seems to be little reason for giving it the preference.

Filicic acid was formerly regarded as the active principle, however, it seems that there are a number of principles which share the action.

Pepo or pumpkin seed enjoys some reputation as a teniafuge, but is not often prescribed alone. It has, at least, the advantage of not being toxic to the patient.

Some Official Substances Used as Teniafuges.

ASPIDIUM.—U. S.—Aspidium, or male fern, the dried rhizome of *Dryopteris Filix-mas* or of *Dryopteris marginalis*, was known to Dioscorides, and advocated by him as being an efficient remedy for tape worm, but fell into disuse and was subsequently nearly forgotten until revived as a secret remedy, for the same parasite, about the middle of the eighteenth century.

Average dose: 4 gm. (60 grains).

OLEORESINA ASPIDII.—U. S.—Oleoresin of aspidium is now directed to be made with acetone. This preparation was first suggested by Peschier of Geneva, about 1825, and has gradually displaced the other preparations of male fern.

Average dose: 2 gm. (30 grains).

GRANATUM.—U. S.—Pomegranate, the bark of the stem and root of *Punica Granatum*, was also known to the ancients as a remedy for tape worm. It appears to have been completely forgotten and was introduced into Europe from India during the first decade of the nineteenth century.

Average dose: 2 gms. (30 grains).

FLUIDEXTRACTUM GRANATI.—U. S.—Fluidextract of pomegranate is made with a menstruum of diluted alcohol containing 10 per cent. of glycerin.

This is a new addition to the Pharmacopeia and has, as yet, not been widely used.

Average dose: 2 c.c. (30 minims).

PELLETIERINÆ TANNAS.—U. S.—Pelletierin tannate is officially described as a mixture, in varying proportions, of the tannates of four alkaloids (punicin, iso-punicin, methyl-punicin and pseudo-punicin) obtained from *Punica Granatum*.

Average dose: 0.25 gm. (4 grains).

CUSSO.—U. S.—Kousso, also known as kosso, koso and Brayera, consists of the dried panicles of the pistillate flowers of *Hagenia abyssinica*. It was discovered by Bruce, about 1768, but was not generally known as an anthelmintic until after Brayer, in 1822, published his observations on the use of the drug in Constantinople. Kousso is usually administered in the form of an unstrained infusion, the object being to secure mechanical irritation by the hairs which are found on the flowers, but they probably play only a minor part in the action of the drug.

Average dose: 16 gms. (240 grains).

PEPO.—U. S.—Pepo, or pumpkin seed, the ripe seed of *Cucurbita Pepo*, is usually administered in the form of the ground seed, deprived of the hull, or, as an emulsion, prepared by treating the ground seed with hot water.

Average dose: 30 gm. (1 ounce).

The tannate of pelletierin, being but slightly soluble, is preferred as a teniafuge, but it is somewhat expensive, and the decoction of the root bark is therefore frequently directed. It has been suggested that the alkaloid, being volatile, is driven off in the process of boiling, but the loss in this way has proved to be unimportant. The fresh bark is much more efficacious than that which has been kept for some time. It is stated that the deterioration is due to chemical change that takes place in the alkaloid.

As we have no means of knowing the quality of the bark which will be used in making the decoction, it is better to use the pelletierin tannate or to direct the preparation of an extract[1] made according to a formula devised by von

1. The ground bark is exhausted by heating with water on a water bath for an hour, the decoction is cooled, milk of lime is added in excess, the mixture filtered, water being added to the precipitate to wash out the alkaloid, the washings added to the filtrate, the filtrate neutralized with dilute sulphuric acid and again filtered. It may be taken in this form, after adding about a gram of tannin, or the neutralized filtrate may be evaporated on a water bath until nearly solid, and then extracted with 70 per cent. alcohol, this is then filtered and subsequently evaporated to a dry extract which is approximately equal to pelletierin.

Schroeder to enable one to get a fairly uniform product regardless of the quality of the bark used.

About one gram or less of the extract, together with one or two grams of tannin, constitute the ordinary dose for tape worm.

Pomegranate root bark contains a large amount of tannin, too much, in fact, considering the amount of bark required to yield the requisite amount of pelletierin, hence none has to be added to the decoction. So abundant is the tannin that it may cause vomiting and defeat the purpose for which the dose is given, hence the extract mentioned has a decided advantage over the decoction.

The following is the method of using pelletierin tannate, the extract described above, or the decoction. Beginning in the evening the patient takes a light meal, which should be exclusively of carbohydrates, and then a laxative; on the following morning, while fasting, he takes 0.4 to 0.5 gm. (6 to 8 grains) of pelletierin tannate, or a corresponding amount of the extract or decoction, followed in half an hour to two hours by a brisk purgative, such as castor oil or syrup of senna.

Of 33 cases treated in this way, the entire parasite, including the head, was removed in 29 cases. Failure in some cases is to be attributed to the head being securely protected by the folds of the mucous membrane.

It is somewhat significant that the many formulas which have acquired some reputation in the treatment of tape worm contain pomegranate bark. The following taken from Osler is almost identical with a formula which has been held as a proprietary by a southern firm for a great many years, among whose patrons it enjoys a considerable reputation:

R. Granati	3iv	15
Pepo	3i	30
Ergotæ pulveris	3i	4
Aquæ bull.	f3x	300

An infusion is directed to be made [better a decoction], from which is formed an emulsion, by adding:

Oleoresina aspidii	3i	4
Olei tiglii	mii	12
Acaciæ q. s.		

The oleoresin of aspidium may be given as an emulsion or in capsules, or it may be combined with other teniafuges, somewhat after the formula given above.

Pumpkin seeds are harmless and may be given either in substance or in the form of a decoction, using an ounce or more of the bruised seed.

Of the other, official, substances that have been used to assist in expelling tenia it will suffice to enumerate: ether, chloroform, rectified oil of turpentine, naphthalen and thymol. These are all comparatively active drugs and must, therefore, be used with caution.

ANTIGONORRHEICS.

The title antigonorrheics would appear to suggest that we have medicaments that have a specific action on gonorrhea, or the causative factor of that disease, instead of representing, as it really does, a somewhat meaningless array of substances that have been used more or less empirically as remedies for gonorrhea.

The name gonorrhea should properly be reserved for the acute, contagious, inflammation of mucous membranes caused by a specific organism, the gonococcus of Neisser. In an even more restricted sense it is now frequently applied to the specific inflammation caused by that micro-organism in the male urethra.

Prior to the discovery of the gonococcus, by Neisser, in 1879, there was probably no one common disease about which there existed such widely varying theories and opinions, and certain it is that no known disease has been so persistently and so widely maltreated.

From the time of the early Greeks and of the Romans the treatment of gonorrhea appears to have been relegated to the incompetent, the charlatan and the quack, and it may be safely asserted that no one disease, with the possible exception of syphilis, has been the direct, or the indirect, cause of more misery, more suffering and more untimely deaths because of this neglect and maltreatment.

Recognizing the seriousness of the disorder it would be futile to attempt to give suggestions for exhaustive treatment, and practically the only apology that we have to offer for introducing even a mention of the disease, and of some of the official remedies that may be of use in its treatment, is to be found in the fact that victims of this disorder are even now subjects for neglect and malpractice. Evident proof of this can be found in almost any one of the daily papers which regularly advertise specific cures for all forms and kinds of urethral discharges.

The heinousness of this practice, and the really far-reaching and serious consequences of the practice in its ultimate results have not as yet been properly appreciated even by such members of the medical profession as should be more thoroughly well informed. This is, in a measure, evidenced by the recently published statement, made by a prominent genito-urinary specialist, that he frequently uses and recommends a popularly advertised nostrum, the manufacturers of which deliberately mislead the layman into believing that he can be cured in 48 hours.

As suggested above, the treatment of gonorrhea is not by any means the simple procedure that might be wished for and even the differentiation of true gonorrhea from a non-specific inflammation is one that requires more than ordinary skill and experience, and should, wherever possible, be entrusted to a safe and conscientious specialist, who not alone has the interest of the patient in mind, but who will also attempt, so far as in him lies, to prevent the spread of the infection by impressing on the patient the advisability of observing certain necessary rules of cleanliness, decency and abstinence.

Using the name, gonorrhea, in its most restricted sense, as applying only to the specific urethritis in the male, we may consider this as a type, and recount some of the suggestions for treatment that have been made in connection with it.

This type of gonorrhea is said to be acute, subacute or chronic, according to the stage of the inflammatory process, and it may involve the anterior urethra alone or include, by continuity, the posterior urethra.

The generally accepted routine of treatment is to use only a mild astringent and antiseptic local application for the first or acute stage, to supplement this with the internal use of diuretics, of a terebinthinate or resinous nature, in the subacute or secondary stage, and to use more active astringents and antiseptics as local applications in the chronic stage of the disease.

It will be noted by this that what is usually referred to as an antigonorrheic is in reality but a diuretic, an antiseptic or an astringent.

Of the several official drugs and preparations that have been found to be more particularly useful, in these several stages of the disease we may enumerate:

POTASSII PERMANGANAS, U. S.—This is recommended to be used, as an irrigation, in very dilute solutions (1-2,000 to 1-6,000).

ARGENTI NITRAS.—U. S.—This was formerly quite popular, in very dilute solutions, but has fallen into disuse and is now frequently substituted by one or the other of the non-official so-called organic silver salts. These latter preparations, while unduly numerous, are usually expensive and the more active of them are inexpressibly filthy.

A satisfactory and apparently efficient substitute for the several silver preparations has been found in silver iodid. Drs. Siter and Uhle[2] have reported a series of cases in which this preparation was used, in the form of an emulsion of the freshly prepared silver iodid, with excellent results.

A preparation such as was used by Drs. Siter and Uhle may be prepared by any pharmacist, as follows:

Argenti nitratis		
Potassii iodidi, āā	gr. xxviii	2
Mucilago chondri N. F.	f3vi	25
Aquæ dest q. s. ad.	f3iii	100

M. Sig.: Use as an injection.

The best method of preparing a finely divided precipitate is to dissolve the potassium iodid in all of the water and add the

2. University of Pennsylvania Med. Bull., May, 1905.

crystals of silver nitrate gradually, shaking well after each addition; when the silver nitrate is dissolved, add the mucilage and shake thoroughly once more.

The resulting mixture will represent approximately 3 per cent. of silver iodid. This strength may be increased or decreased as desired. If prepared in this way, the weaker mixtures will require a correspondingly smaller amount of mucilage to hold the powder in suspension and mixtures below 1 per cent. may be dispensed without the addition of any foreign material.

Of the drugs that are frequently used for internal administration in the second or sub-acute stage of the disease the Pharmacopeia includes, in the order of their present popularity:

OLEUM SANTALI.—U. S.—Oil of santal, or oil of sandalwood, is a volatile oil distilled from the wood of *Santalum album*. The Pharmacopeia directs that this oil contain not less than 90 per cent. of santalol. This requirement is readily met by the better grades of oil of santal now on the market, so that there is little or no need to resort to proprietary specialties containing, or purporting to contain, true oil of santal.

Average dose: 0.5 c.c. (8 minims).

COPAIBA.—U. S.—Copaiba, balsam of copaiba, as it is more popularly called, is derived from one or more South American species of copaiba. It was introduced into Europe by the Portuguese, during the latter half of the seventeenth century, and has long enjoyed the reputation of being of especial use in connection with specific urethritis in the male.

Average dose.—1 c.c. (15 minims).

OLEUM COPAIBÆ.—U. S.—Oil of copaiba is officially described as a volatile oil distilled from copaiba.

Average dose: 0.5 c.c. (8 minims).

OLEORESINÆ CUBEBÆ.—U. S.—Oleoresin or cubeb represents the alcohol soluble portion of the dried, unripe, fruit of *Piper Cubeba*.

Average dose: 0.5 c.c. (7½ grains).

OLEUM CUBEBÆ.—U. S.—Oil of cubeb is a volatile oil distilled from cubeb.

Average dose: 0.5 c.c. (8 minims).

Of the more active astringents that are used in the third, or chronic stage of gonorrhea, in the male, and form such a prominent part in the treatment of the more common form of gonorrhea in the female, we may enumerate:

ZINCI SULPHAS.—U. S.—Zinc sulphate.

ZINCI ACETAS.—U. S.—Zinc acetate.

ZINCI CHLORIDUM.—U. S.—Zinc chlorid.

ZINCI PHENOLSULPHONAS.—U. S.—Zinc phenolsulphonate.

ALUMEN.—U. S.—Alum.

ACIDUM TANNICUM.—U. S.—Tannic acid.

ARGENTI NITRAS.—U. S.— Silver nitrate.

These several astringents, with or without the addition of well-known antiseptics, such as boric acid, phenol, thymol, glycerin, and the several combinations or preparations of them, practically constitute all that is necessary in the treatment of the most persistent of the chronic forms of gonorrhea.

Clinical Note

ACETANILID POISONING FROM BROMO-SELTZER.*

ALBERT ENGLES BLACKBURN, M.D.
PHILADELPHIA.

Patient.—I was asked by his mother to see the patient, a man, aged 22 years, recently married. The patient did not consider himself sick and did not desire medical attention. It was with great difficulty that I obtained a distinct and correct history. I do not believe there was the intent to deceive, but his marked hebetude and obtuseness made it especially difficult to obtain a connected history. When the facts were finally obtained from his wife and he was asked as to their correctness, he acknowledged their truthfulness and promised to desist taking the drug.

History.—Following an acute illness some six months previous he began taking an occasional dose of bromo-seltzer for headache. The relief desired was temporarily obtained, and as the headaches recurred the bromo-seltzer was taken in larger amounts and at shorter periods. The quantity consumed grew larger and larger until the six weeks previous to my seeing him his wife assured me he consumed as much as $4.50 per week, which is approximately ten or twelve bottles. The patient would sit for hours if undisturbed, complained of being tired, and was unable to perform muscular effort, there was dyspnea on exertion. He was given to attacks of despondency and again to outbursts of passion, in which he threatened violence, but soon collapsed.

Physical Examination.—His appearance was appalling; his face was ashy white, the lips and lobes of the ears blue, the fingers were deeply cyanosed up to the second joint. His mucous membranes were very pale; the pupils reacted to light and distance. His expression was vacant, seldom speaking until spoken to. The tongue was heavily coated with a white fur, red at tip and margins; breath the foulest I ever noticed. Bowels constipated; the pulse varied from 85 when at rest to 130 on the slightest exertion, regular, fair volume, low tension. The left ventricle was enlarged downward and to the left. The first sound of the heart was very weak; a soft systolic mitral murmur was present The surface was cold and lifeless. Urine contained indican, but no albumin or casts. General tremulousness and loss of motor powers were marked. No blood examination was made.

To find the constituents of bromo-seltzer I wrote the Emerson Drug Company of Baltimore. Inasmuch as *Collier's Weekly* had lately given them a writeup, a member of the firm called. He told me that bromo-seltzer contained to the 100 grains (a heaping teaspoonful):

Acetanilid	gr. ivss
Potassium bromid	gr. x
Caffein	gr. ii
Soda bicarb.	
Citric acid.	

THE JOURNAL A. M. A., Feb. 10, 1906, states its analysis to be, to the 100 parts:

Potassium bromid	10.53 parts
Acetanilid	4.58 parts
Caffein	1.20 parts

Assuming an average dose to be a teaspoonful—not heaping as above stated—to weigh 76 grains, the dose would contain:

Potassium bromid	7 grains
Acetanilid	3 grains
Caffein	8 grains

Since many people take a tablespoonful repeatedly, the quantity of acetanilid varies between 12 and 15 grains, an amount which is exceedingly dangerous. For "business reasons" the representative requested that I refrain from quoting him.

Course.—Herrick states in his paper that great difficulty is experienced in withdrawing the drug. This was not the case in this patient. He was plainly told the cause of his trouble, and the effect if he continued taking it. He was carefully watched, but made no effort to secure the drug. At no time did he express a desire for it, which was probably due to the relatively short time of taking it. His improvement was steady, but slow. The cyanosis disappeared in about a week; the anemia was the last to disappear.

The treatment consisted merely of withdrawing the drug, administering the cardiac stimulants, strychnia and digitalis, and regulating the bowels.

Dr. Quigley reports in THE JOURNAL A. M. A., Vol. XLVI, No. 6, a case that went into collapse from a tablespoonful of bromo-seltzer, and states he would have died had not his stomach been emptied and stimulants administered.

* Reported before the West Philadelphia Branch of the County Medical Society, March 16, 1906.

First Total Gastrectomy in South America.—The *Semana Medica* for April 19 relates the successful removal of a cancerous stomach by B. Vasallo of Rosario, Argentina. The patient was a woman of 39 and was apparently in perfect health at date of writing, four months after the operation, with no digestive disturbances.

SATURDAY, JUNE 9, 1906.

MODERN IDEAS CONCERNING PUERPERAL ECLAMPSIA.

The profound anatomic changes that occur in the kidneys and liver, and to a less extent in the other parenchymatous organs, in eclampsia, leave no room for doubt that in this condition the blood of the patient is loaded with materials possessed of a high degree of toxicity. Both the origin and the nature of these poisons remain, however, among the most baffling of medical mysteries. The frequent association with marked albuminuria and the occurrence of convulsions quite similar to those of uremia led Frerichs and others to consider eclampsia as identical with uremia, and a specific disease only in that it occurs in pregnancy. That this is not the case, however, has been abundantly proved. In the first place the anatomic changes are quite different from those in uremia, in which the toxic materials seem to exert their influence chiefly on the central nervous system. In many cases of eclampsia the kidneys have been found to be entirely or almost free from structural changes, while in nearly all the liver shows severe alterations, which not infrequently are so great that it is quite impossible to draw a sharp line between eclampsia and acute yellow atrophy. Also, according to Zweifel, eclamptic blood contains no more urea and ammonium compounds than does normal blood, which is contrary to the condition in uremia.

By far the most characteristic and striking feature of eclampsia is the rapid improvement that usually follows the emptying of the uterus, particularly when this is done in the early stages of the attack. The albuminous urine clears up rapidly, the amount of urea increases until for a few days it may be much more than normal, and the constitutional manifestations subside correspondingly. This, of course, indicates that the source of the intoxicating substances is in the products of conception, rather than in a disturbed metabolism of the mother, which has been frequently assumed in analogy with acute yellow atrophy. A natural hypothesis is that the additional amounts of metabolic products thrown into the maternal blood, both from her own overactive organs and from the fetal tissues, cause injury to the liver and kidneys, as a result of which there is a deficiency in renal elimination, coupled with a loss of the normal detoxicating function of the liver and abnormal nitrogenous metabolism resulting from the injury to the same organ. The accumulation of toxic products from these two sources leads to further renal and hepatic injury, and thus a vicious circle is established. This plausible idea, however, does not fit so well with the fact of the prompt subsidence of the disease after removal of the contents of the uterus, as does the hypothesis that the fetus or placenta, or both, furnish most or all of the toxic substances. On this basis, numerous observers have sought for a toxic substance in these places, with varying results. The German journals of late have contained numerous reports of the work of Zweifel and his associates, which are based on the observation by Zweifel of small quantities of lactic acid in the blood and urine of eclamptic women. More recently the same author reports[1] observations on the occurrence of lactic acid in the fetus, obtaining it in much larger quantities from the blood escaping from the umbilical cord of children delivered from eclamptic women than in the blood of the mothers. This observation he interprets as indicating that the lactic acid is formed in the fetus rather than in the mother, and he looks on eclampsia as an acid intoxication of fetal origin.

Many objections, however, can be raised against this view, which has perhaps received too ready acceptance because of the recent development of interest in the subject of acid intoxication. In the first place, the symptomatology of eclampsia is by no means identical with that of poisoning with organic acids, as illustrated by diabetic coma. Secondly, the amounts of organic acids found in the urine in eclampsia are, as a rule, very small and not sufficient to account for the severity of the manifestations of puerperal eclampsia; thus in a typical case examined by Zweifel there was isolated but 0.4155 gram of the zinc salt of paralactic (sarcolactic) acid in nearly a liter of urine, which is a mere trifle as compared with the amounts of organic acids frequently found in diabetic coma. To be sure it is claimed that the sarcolactic acid is more toxic than the diacetic and oxybutyric acids of ordinary acid intoxications, but there is no sufficient reason for believing that the minute amounts so far detected in eclampsia are capable of causing such severe anatomic changes and so violent an intoxication as are present in eclampsia.[2] Furthermore, much can be said against the view that the origin of the toxic substance, whether it is sarcolactic acid or some other more complex body, is in the fetus. This has been particularly urged by Liepmann,[3] who calls attention to the fact that the children, particularly when delivered early in the attacks before asphyxia has become profound, show no evidences of having been subjected to the action of any severe toxic substance, such as are manifest in the organs of the mother. If the toxic materials were produced in the fetus it might be expected that its tissues would suffer more change than those of the mother. Even more convincing against the fetal origin of the poison is the frequent development of

1. Münch. med. Wochft., 1906, vol. liii, p. 297.
2. Wolf: New York Med. Jour., 1906, vol. lxxxiii, p. 813.
3. Münch. med. Wochft., 1905, vol. lii, pp. 687 and 2484.

eclampsia after delivery of the child, and particularly the case of Hitschmann[4] of a patient who became eclamptic when pregnant in the fifth month with a hydatid mole, and no fetus at all. For these and other reasons Liepmann contends that the source of the toxin must be in the placenta.

It may be recalled that Weichardt, Ascoli, and many others have done considerable work based on the idea that the placental tissues, being foreign to the body, were toxic to the maternal organism, which, therefore, developed antitoxic substances to neutralize the placental elements that might enter the maternal circulation. Failure to develop such antitoxic substances (or possibly their overdevelopment, according to various ideas) was thought to be responsible for the eclampsia. It can only be said that this work on the "syncytiolysins" has led to little but confusion and interesting hypotheses, while some of the most recent observers question all the positive results obtained by their predecessors.[5] This phase of the subject of eclampsia must be held *sub judice*. Liepmann, impressed by the importance of the placenta in eclampsia, has examined a great number and finds that they are highly toxic for rabbits, whereas normal placentas are not; the poisonous substance seems to be closely related to the proteids of the placenta, to be extremely labile and as yet impossible of isolation. This work, of course, needs much more elaboration and confirmation.

The contention of many clinicians and pathologists, particularly Stroganoff,[6] that eclampsia is an infectious and semi-contagious disease seems not to have been sustained. It is hard to tell, on the evidence yet submitted, how much weight is to be attached to the view of Lange[7] that in at least some of the cases eclampsia is due to an insufficiency of the thyroid, whereby its detoxicating effect is lost. One other unproved theory may be mentioned, that of Dienst,[8] who believes that eclampsia is due to an abnormal communication between the fetal and maternal circulations whereby the heterogeneous fetal and maternal bloods become mixed.

Of particular practical importance, however, is the fact to be noticed in the reports of the supporters of these various hypotheses that all agree in urging as essential for the treatment of eclampsia the most prompt and early emptying of the uterus possible as against the expectant treatment advocated by the earlier supporters of the autointoxication theories of Bouchard and others. Some clinics claim a death rate of but from 1.8 to 5 per cent. in this disease as a result of early interference.

GONORRHEAL VAGINITIS.

Gonorrheal vaginitis in children is always of special interest to physicians associated with hospitals. The difficulty often of making a diagnosis and of ascertaining the means of transmission on account of the almost endless number of possibilities make any new contributions on this subject of great value. There are not many endemics of gonorrheal vaginitis among children cited in the literature. This is probably due in part to the fact that when cases occur in a hospital physicians hesitate to report them on account of fear of bringing criticism on the institution. This is unfortunate, as by the study and publication of such instances light may be shed on the causes and means of transmission of this disease and new means discovered of prevention of further cases. The value of such information is seen in a recent article by Harmsen,[1] who furnishes several valuable suggestions on the diagnosis and prognosis of gonorrheal vaginitis.

One of the most important of his observations is that, contrary to the general belief, in many cases of gonorrheal vaginitis in children, during the first stage, the gonococcus is not present in the secretions. Very often simply a purulent catarrh, with scarcely any clinical symptoms, is the beginning of the specific disease, and only by later examination of the secretion is one successful in finding the gonococcus. Harmsen points out that, while the normal vaginal secretion contains a large number of flattened epithelial cells and a more or less great variety of bacteria, he generally observed at the onset of gonorrhea a purulent discharge, which did not contain these organisms, nor did it contain the gonococcus. In this discharge the epithelial cells were replaced by numerous leucocytes. As a rule in a few days the gonococci appeared. With the abatement of the infection the leucocytes and gonococci are replaced by epithelial cells and the micro-organisms normally present, so that if the vaginal secretion of a child contains exclusively leucocytes without the usual bacterial flora and epithelial cells one must be suspicious of the beginning (or end) of a specific vaginitis.

Fränkel and others have called attention to the absence of various micro-organisms and epithelial cells in gonorrhea, in which the gonococcus and leucocytes are present, but Harmsen appears to be the first to lay stress on the absence of the gonococcus in the first stage of specific vaginitis as a significant indication. These observations on the secretions would seem to be of value, in that it may be possible to make an earlier diagnosis than previously and so greatly to diminish the danger of the infection.

Harmsen considers it essential to make a microscopic examination of the vaginal secretions of all children admitted to hospitals in order to make a diagnosis of gonorrheal vaginitis as soon as possible. In this way treatment may be begun sooner and the danger of the dissemination of the disease greatly lessened. He believes that this microscopic examination should be carried out for a week or more on account of the length of the incubation period. This, we believe, is already the

1. Zeits. f. Hyg. ü Infektionskr., 1906, vol. liii, p. 89.

rule in some of our American hospitals in which the officials have had experience with endemics of this disease.

By examining the vaginal secretions, one may also be able to determine, not absolutely but with some probability, when a case is cured, by the absence of the gonococci and the reappearance of the epithelial cells and the various kinds of micro-organisms.

CANCER.

In the Oration on Surgery, Dr. J. B. Bryant discusses the nature of cancer and the progress made in its treatment in recent years. Notwithstanding all that has been, and is being done, the vast amount of theorizing and the frequent announcement of alleged discoveries, the true nature of malignant disease is still, he states, an elusive mystery. The more we study the subject and the more we learn of its extent and importance the more apparent to us is our own ignorance of the essential facts of its real nature and origin. Cancer is almost universal through the higher orders of the animal kingdom, and even in the vegetable world apparently analogous conditions exist. We have evidence that cancer was known at a very early period, and that the ancient Greeks had a very good clinical idea of its nature.

Bryant states that cancer seems to be pre-eminently, though not exclusively, one of devolution and that, while it is apparently increasing in frequency in civilized communities, this may be due in part to the greater number of those who, through the increase of human longevity due to medical and sanitary advances, fall within the age limit of cancer attack. He points out that the slow and continuous increase in cancer mortality must be controlled by influences of such subtle kind as thus far to perplex the most astute observers, and makes an interesting study of the statistics of the location of cancer in the body. One of the most striking facts against the parasitic theory brought out is the vast difference between the sexes in the incidence of cancer in the gastro-intestinal tract. He shows that cancer of the male alimentary canal is seven times more frequent than in the same location in the female, and calls attention to the fact that there is no physiologic or anatomic difference in the two sexes which would account for such a parasitic selection as this—a parasitic theory being allowed. The fact also that the alimentary tract is affected in 80 per cent. of the cancers in males and that in females the same percentage occurs in the reproductive organs, including the breast, is strongly suggestive of a general condition of non-resistance to pathologic processes induced by traumatism in the aging organism.

In discussing the surgical treatment of cancer he states that the danger of delay is at the same time encouraging and discouraging, according to the aspect in which we view it. The vast amount of human misery that unquestionably has been relieved by surgery and its hitherto unparalleled success of late years are in the highest degree encouraging. On the other hand, the fact that it is almost impossible to insure early diagnosis and recourse to treatment, both on account of the insidious character of the approach and the inaccessible location of the disease in so many cases, seriously detracts from any satisfaction we may derive from the limited successes so far attained.

The subject of malignant disease is one of the most suggestive in medical science. There is a wide field here for studies in comparative, as well as in human pathology and even in the collateral sciences of anthropology, ethnology and archeology. There is ample room for all the work that can be done in all the special and general centers of research on the subject, and the fact that our progress has thus far been slow in elucidating the mystery should only be a stimulant to further effort.

THE PRESIDENT'S ADDRESS.

In his presidential address, published in this issue of The Journal, Dr. Mayo goes directly to the point, without any rhetorical flourishes, and shows that, with all our better organization and reconciliation of differences, for which we are to be duly congratulated, we are as yet only at the beginning of what is to be done, not only for ourselves, but also in the fulfillment of our duty to mankind. The public is a quarter of a century behind advanced medical thought in matters which it ought to know, and it is one of the misfortunes of a free government that ignorance sometimes sits in high places where, together with selfish interest, it can obstruct or nullify the measures needed for the welfare of the people. The public does not sin wilfully in this matter, but it needs education, and to furnish this the medical profession, which alone can guide this education correctly, will have to give not only the required individual effort, but more trained team work, to use a popular expression of the day. We have failed, as Dr. Mayo says, to secure the public's support for needed sanitary reforms because heretofore we have appealed to them too much as one individual to another, without the appeal carrying with it the weight of an authoritative organization. That a necessary piece of legislation demanded by the public, like the pure-food bill, can be so long blocked by the efforts of skilled lobbyists in the interest of adulterators is in itself sufficient evidence of the need of a united medical profession knowing its strength and how to use it intelligently. Dr. Mayo's statements in regard to medical education are in accord with the traditions and policy of the Association from its beginnings, and there are few who will not agree with him in what he says in regard to state licensure and reciprocity. His remarks also on the attempted and too often accomplished exploitation of our profession by public corporations, insurance companies and hospital authorities are all timely and true. Still more so are those on the evil of the acceptance of the money standard of success which is one of the most demoralizing tendencies of our social organization and is absolutely incompatible with the true professional spirit and ethical standard of the honorable

medical practitioner. This spirit, involving, as it does, a life of devotion to study and to the interests of others as well as of ourselves, can best be fostered and accentuated by harmonious co-operation among the members of an united profession.

THE BOSTON SESSION.

For the reason that our last forms are closed on Wednesday morning, it is impossible to give a complete report of the Boston session. Consequently, we shall not attempt to do so, believing that it will be preferable to publish the proceedings in full next week. We are advised by telegraph that the registration when the office closed Tuesday night was approximately 3,600. This far exceeds that of any preceding sessions. The total registration at Atlantic City in 1904 was 2,890. Judging from previous years' experience, therefore, we may estimate that the total registration for this meeting will be about 4,500. The immense number in attendance, however, is being cared for in a satisfactory manner.

Medical News

CONNECTICUT.

Personal.—Dr. David H. Monahan, Bridgeport, has been appointed almshouse physician, vice Dr. Henry Walls, resigned.

State Society Meeting.—The Connecticut State Medical Society held its one hundred and fourteenth annual meeting in New Haven, May 23 and 24, under the presidency of Dr. Nathaniel E. Wordin, Bridgeport. The presidential address was on the subject of "Influence of the Medical Profession on the State." Dr. Wordin warned the physicians of their duty toward humanity and the general cause of health and the necessity of unselfishness in that duty. He denounced the attempt of the legislature to abolish the law compelling vaccination, and spoke at length on the work accomplished by the society in influencing the different state governments in the campaign against insanitary conditions and the consequent spread of disease. The following officers were elected: President, Dr. William L. Higgins, South Coventry; vice-presidents, Drs. Charles E. Brayton, Stonington, and Dr. Samuel D. Gilbert, New Haven; secretary, Dr. Walter R. Steiner, Hartford, and treasurer, Dr. Joseph H. Townsend, New Haven.

ILLINOIS.

Physician Pays Fine.—Dr. Charles A. Nichols, Urbana, who was recently convicted of sending unmailable matter through the mails, on May 29 paid his fine and costs, which amounted altogether to $700.

Honor Old Practitioner.—Thirty members of the Champaign County Medical Society and many citizens of Rantoul gave a banquet in honor of Dr. James C. Harmon, one of the oldest practitioners in the county, May 21. Dr. James M. Bartholow, Urbana, presided as toastmaster, and tributes were paid to Dr. Harmon by a number of his old friends.

Decrease in Coroner's Cases.—The monthly report of the coroner of Cook County for May shows a total of 333 deaths as compared with 356 for April. Of these 11 were homicides; 32 were due to suicide; falls and railway accidents each caused 29 deaths, and 112 deaths were assigned to natural causes. Of the suicides 23 were male and 9 female.

Webster Judgment Set Aside.—The judgment recently rendered against Dr. George W. Webster, president of the State Board of Health, in a suit for alleged malpractice, was set aside May 26 by Judge Wright on the ground that the plaintiff failed to show any connection between the alleged want of skill and care, and the outcome in the case, which was the loss of the girl's leg. The case will probably be heard again by Judge Wright during the present term of court.

Communicable Diseases.—Canton has at present an epidemic of chickenpox, with about 200 cases.——Roscoe, Winnebago County, reports 26 cases of smallpox, and Cambridge, McHenry County, 8 cases; in Waukegan 4 cases of smallpox in dowieite families have been reported.——An epidemic of smallpox is reported from Lincoln. The city council has voted money to build an isolation hospital and quarantine will be strictly observed.——Decatur reports 4 cases of smallpox.——Four new cases of diphtheria have been reported from Pontiac.

Personal.—Dr. Ernest J. Miller, Sycamore, who has been seriously ill, is improving.——Dr. George A. Wash, Palmyra, who was operated on in St. Louis recently, has returned home convalescent.——Dr. and Mrs. Amos F. Conard, Homer, are taking a trip to California.——Dr. James R. Hull, Good Hope, has started for Seattle, en route for Japan.——Drs. Byron C. Stolp, Swartout and Conley have been appointed members of the board of health of Wilmette.——Dr. Daniel L. Jewett, Watseka, is seriously ill with pneumonia.——Dr. J. Millard Maury has been appointed city physician of Wheaton.——At the last meeting of the Court of Honor, Dr. James E. White, Urbana, was elected supreme medical examiner. This necessitates Dr. White's change of residence from Champaign to Springfield. Dr. James S. Mason, Rantoul, succeeds Dr. White in Urbana.

How to Save the Babies.—The Illinois State Board of Health has issued a new pamphlet written on the same general lines as that issued last summer, but containing more information and with more illustrations. Suggestions are given for the nursing mother; artificial feeding is fully discussed, and the advantages and disadvantages of the various infant foods are carefully considered. Cows' milk, properly modified, is advocated as the ideal food for infants, and the proper methods of modification are plainly described. The mother is taught not only how to feed the baby, but how it should be bathed, how it should be dressed in hot weather and how it should be cared for indoors and out. A chapter is also added which is devoted to suggestions to bottle men and milk dealers. This pamphlet is issued for gratuitous distribution, and those who wish copies should apply to the secretary of the State Board of Health, Springfield.

Investigation of State Institutions.—On account of the recent scandals at the Illinois Eastern Hospital for the Insane, Hospital, and the Illinois Hospital for the Incurable Insane, Bartonville, the State Board of Charities has made a preliminary examination, the salient points of which are as follows: The unfortunate condition of the patient, Katie Ward, in the former institution, occurred in consequence of conditions which have prevailed in the institution for many years. It has been the custom for employés outside of the medical staff to carry keys which would unlock the doors of the women's wards and dormitories. There were not enough nurses on duty at night to safeguard the women patients. The board calls attention to the defects of administration and lack of sufficient medical and nursing help which renders possible such unfortunate occurrences, and does not believe that blame should be fastened on individuals who are in a sense helpless agents in the care of these unfortunate people, but that a change should be made in the methods of administration of the institution.

Chicago.

Select President from Chicago.—At the annual meeting of the American Academy of Medicine in Boston, June 2-4, Dr. Casey A. Wood was elected president.

Appropriation to Fight Fever. The council finance committee has granted an emergency appropriation of $10,000 for the purpose of combating the epidemic of scarlet fever.

Hospital Enlargement.—The directors of the Chicago Baptist Hospital contemplate the erection of administration offices and an addition to their present building at a cost of about $10,000.

Deaths of the Week.—The total deaths from all causes for the week ended June 2 were 465, equivalent to an annual death rate of 11.83 per 1,000. This is a reduction of 115 deaths from the preceding week and 2 fewer deaths than was reported in the corresponding week of 1905.

Personal.—Dr. Anders Doe has gone to Norway to represent the Norwegians of Chicago at the coronation of the king.——Dr. Groesbeck Walsh will return from Panama to assume the duties of senior physician at the Cook County Infirmary, Dunning.——Dr. John L. Porter sailed for Europe June 7.

Society of Social Hygiene.—A number of physicians, business men and clergymen met May 28 and organized a Chicago Society of Social Hygiene, with the object of combating in a systematic way the social evils of Chicago. Dr. William T. Belfield was made temporary president, and Mr. William Hallam, temporary secretary. It is proposed to carry on an active propaganda by lectures and other means.

Health Report.—The report of the health of Chicago for the week ended May 26 shows 580 deaths, equivalent to an annual mortality rate of 14.6 per 1,000, or a reduction of more than 11 per cent. as compared with the preceding week, but an increase of 24 per cent. over the corresponding week of 1905. Compared with the preceding week there were 45 fewer deaths among young children and 15 fewer deaths among individuals over 60.

Mortality of May.—During May 2,561 deaths were reported, equivalent to an annual death rate of 14.71 per 1,000. In May, 1905, 2,180 deaths occurred, equivalent to an annual mortality of 12.89, and in April, 1906, 2,770 deaths, an annual mortality of 16.44. Pneumonia caused 472 deaths during the month; consumption, 295; violence (including suicide), 198; nephritis, 186; heart diseases, 160; acute intestinal diseases, 123; and cancer, 121.

INDIANA.

Scarlet Fever.—Three new cases of scarlet fever developed in Rockville last week, and in consequence the lower grades of the public schoools have been closed.

Would Bribe Examining Board.—It is reported that a woman applicant for license to practice medicine in Indiana offered $5,000 to Dr. W. Mott, secretary of the State Board of Medical Examination and Registration, as an incentive to a favorable consideration of her papers.

Insanitary Schoolhouses.—Dr. J. N. Hurty, secretary of the State Board of Health, is making investigation of the schoolhouses of Northern Indiana with reference to their healthfulness. Thus far the State Board of Health has condemned four schoolhouses in Wabash County.

College Incorporated.—Articles of incorporation were filed with the secretary of state, May 23, for the State College of Physicians and Surgeons, Indianapolis, in connection with the Indiana University. The articles mention no capital stock, the college not being organized for pecuniary benefit.

Personal.—Dr. Miles F. Porter, Fort Wayne, has been appointed surgeon for the Pennsylvania System, vice Dr. Christian B. Stemen, resigned.——Drs. Dawson D. Van Osdel, John G. Lewis and Henry G. Linn have been appointed members of the health board of Rushville.——Dr. Overton H. Mennet, Columbus, has been appointed receiver of the Janney Manufactnring Company.——Dr. Maynard A. Anstin, Anderson, has been appointed professor of principles of surgery in the medical department of Indiana University, Indianapolis.——Dr. Logan Stanley, assistant surgeon at the Indiana State Soldiers' Home, Lafayette, has resigned.

State Society Meeting.—The annual meeting of the Indiana State Medical Society was held at Winona Lake, May 23, 24 and 25, under the presidency of Dr. George H. Grant, Richmond. The association was welcomed to Winona Lake by Rev. S. C. Dickey and proceeded at once to take up the scientific work. The total membership was reported to be 2,227. Dr. Francis S. Watson, Boston, a guest of honor of the society, delivered an address on "The Commercial Spirit in Medicine." The following officers were elected: President, Dr. George J. Cook, Indianapolis; vice-presidents, Drs. John B. Berteling, South Bend, and Charles Chittick, Frankfort; secretary, Dr. Frederick C. Heath, Indianapolis (re-elected); treasurer, Dr. Albert E. Bulson, Jr., Fort Wayne; and delegates to the American Medical Association, Drs. John B. Berteling, South Bend, and A. M. Hayden, Evansville.

IOWA.

Smallpox.—The prevalence of smallpox in Northboro and vicinity has caused the closure of the public schools in that place.

Diphtheria Epidemic.—Diphtheria in malignant form has appeared in Sully. Schools and churches have been ordered closed, and all public gatherings have been prohibited for the time being.

Iowa Medical Women.—The ninth annual convention of the State Society of Iowa Medical Women was held in Des Moines, May 15, under the presidency of Dr. Evaline Peo, Boone. The following officers were elected: President, Dr. Mamie A. Coveny, Clinton; vice-presidents, Drs. Jennie G. Ghrist, Ames, and Georgia Stewart, Des Moines; secretary, Dr. Kate S. Harpel, Boone, and treasurer, Dr. Evelyn Frisbee, Des Moines.

Personal.—Dr. Henry Wiedow, Worthington, has started East and will sail next week for Germany.——Dr. John Hamilton has been elected city physician of Cedar Rapids.——Dr. Francis H. Batty has been appointed health officer of West Liberty, vice Dr Otis B. Wyant.——Dr. J. M. Gahringer, Oelwein, is seriously ill with rheumatic arthritis.——Dr. Frank S. Hough has been elected health officer of Sibley.——Dr. Edward L. Rohlf, Waterloo, has been appointed coroner of Blackhawk County, vice Dr. Thomas U. McManus, resigned.

Alumni Election.—The alumni of Drake University, Medical College, Des Moines, held a reunion May 16 and organized, with the following officers: Dr. Ernest R. Limbocker, New Virginia, president; Dr. C. N. Leir-Olsen, Des Moines, vice-president, and Dr. Lenna L. Meanes, Des Moines, secretary.——At the annual meeting of the Medical Alumni Association of the State University of Iowa, Iowa City, May 1 and 2, the following officers were elected: President, Dr. Charles J. Saunders, Fort Dodge; vice-presidents, Drs. Joseph H. Sams, Clarion, and John T. McClintock, Iowa City; secretary, Dr. Walter L. Bierring, Iowa City; treasurer, Dr. Mamie A. Coveny, Clinton; and executive committee, Drs. Edward E. Dorr, Des Moines, William A. Rohlf, Waverly, and Fred W. Powers, Waterloo. The session was made especially interesting by a number of clinics and demonstrations.

State Society Meeting.—The fifty-fifth annual meeting of the Iowa State Medical Society was held in Des Moines, May 16, 17 and 18, under the presidency of Dr. William Jepson, Sioux City. The address of welcome was delivered by Hon. C. S. Bradshaw, Des Moines, and was responded to by Dr. Frank E. Sampson, Creston. The following officers were elected: President, Dr. Elbert W. Clark, Grinnell; vice-presidents, Drs. Henry A. Liepziger, Burlington, and Michael J. Kenefick, Algona; delegates to the American Medical Association, Drs. William Jepson, Sioux City, and Edward E. Dorr, Des Moines. The committee on public health and legislation for the year is composed of Drs. E. Luther Stevens, Des Moines; Joseph M. Emmert, Atlantic; Fred W. Powers, Waterloo, and the president and secretary. The work of the tuberculosis society of the state was approved and $250 was appropriated to further the work. A contract for five years was made by the society with Dr. Edward E. Dorr, Des Moines, editor of the *Iowa Medical Journal*, for the publication of the proceedings of the association. The society also appropriated $300 toward the memorial to Dr. N. S. Davis.

KENTUCKY.

Warrants Issued for Physicians.—On May 19 warrants were issued for the arrest of eight Louisville physicians who had failed to take out the license required by the local authorities.

Graduation Exercises.—The annual commencement exercises of the Medical Department of the University of Louisville were held May 4, when a class of 48 was graduated. The class was presented by the dean, Dr. James M. Bodine, to the president of the board of trustees, T. L. Burnett, LL.D., who conferred the degrees. The faculty valedictory, a eulogy on the life of the late Dr. John A. Ouchterlony, was delivered by Dr. Henry A. Cottell.

Southwestern Physicians Meet.—The thirty-fifth annual meeting of the Southwestern Kentucky Medical Association was held in Paducah, May 8 and 9, under the presidency of Dr. Shandy Z. Holland, Grahamville. The following officers were elected: President, Dr. Edward B. Shelton, Blandville; vice-presidents, Drs. W. G. Kinsolving, Dulaney, and Ben. P. Earl, Charleston; secretary, Dr. Van A. Stilley, Benton, and treasurer, Dr. Charles H. Brothers, Paducah.

Personal.—Dr. William E. Truesdell has been appointed physician to the Campbell County jail, Newport, vice Dr. Virgil F. Barker.——Dr. William E. Irvin has been elected secretary of the Owensboro board of medical examiners for schools.——Dr. J. L. Phythian, Newport, president of the board of trustees of the Spears Memorial Hospital, Dayton, has resigned.——Dr. Adolph O. Pfingst has been appointed eye, ear, nose and throat specialist, and Dr. A. O. Brennan placed in charge of the male and female ward of the Louisville Hospital for July and August.——Dr. and Mrs. Maverell K. Allen, Louisville, sail for Europe on the *Moltke*, June 12.——Dr. James Weir, Owensboro, has been made a member of the American Geographical Society.

McCormack in Kentucky.—Dr. J. N. McCormack made a trip to Kentucky in May, delivering addresses before medical societies, urging the benefits of organization and defining the relation of the physician to the public. His lectures have been very generally attended by representative people and have been enthusiastically received both by the medical profession and the laity. In Lebanon the circuit court was in session, but adjourned for the purpose of attending Dr. McCormack's lecture. It is reported from Danville that the lecture might well be repeated in that place and would have an overflowing house. About 300 were present at the lecture in Harrodsburg, both laity and the profession. In Cynthiana the lecture was

well received and the lecturer was given a rising vote of thanks. At Newcastle a large audience was addressed at the court house. Dr. McCormack addressed the Southwestern Kentucky Medical Association at its meeting in Paducah.

LOUISIANA.

New Orleans Health Improving.—The mortality record for April was at the rate of 14.34 per 1,000 compared with 15.41 per 1,000 for April of last year. The March record was at the rate of 16.81 per 1,000 as compared with 19.08 for March of 1905. During April 45 cases of smallpox were reported, or three less than during the previous month. No deaths from this disease occurred in either month.

Report Cure of Leprosy.—In the report of the Board of Control of the Louisiana Leper Home, submitted to the governor, May 22, it is announced that a definite cure has been obtained in three cases of leprosy. The cases are reported by Dr. Ralph Hopkins, visiting physician, and Dr. Isadore Dyer, consulting leprologist. The patients have been discharged. The board requested the legislature to locate the point of infection and suggested that an appeal be made to the federal government to establish a national hospital for lepers.

Cuban Quarantine.—The State Board of Health, on April 28, took more stringent action relative to Cuba when it promulgated the following order:

By direction of the President, you will not permit any person to go aboard any vessel anchored in the harbor of Havana who is not immune. This rule will apply to both laborers and representatives of various transportation companies; you will require every person boarding the vessel to exhibit to you a certificate of immunity, which certificate must be satisfactory to you. In addition to the above, you will also take the temperature of all persons boarding the vessel. You understand that the only persons allowed aboard the vessels are one representative of the Southern Pacific Company, Illinois Central Railroad Company and the Express Company during any one trip, and the laborers actually employed in loading and unloading the vessel. This rule effective and in force on and after May 1, 1906.

State Medical Meeting.—The twenty-seventh annual meeting of the Louisiana State Medical Society was held in New Orleans, May 8, 9 and 10, under the presidency of Dr. Cleophas J. Ducote, Cottonport. Dr. C. Jefferson Miller, president of the Orleans Parish Medical Society, welcomed the society on behalf of that body. In his annual report, the president spoke of the increase in membership of the society, of the yellow-fever epidemic and the work done by the physicians of the state, the United States Public Health and Marine-Hospital Service, and of the general acceptance of the mosquito doctrine of the transmission of yellow fever. Dr. John L. Scales, Aldenbridge, was appointed councilor for the fourth district and Dr. Stuart L. White, Ruston, councilor of the fifth district, vice Dr. R. F. Harrell. Among the guests of the society were Dr. Warren S. Bickham, New York, Dr. James Carroll, U. S. Army, and Dr. William H. Sanders, Montgomery, state health officer of Alabama. On the first evening a symposium on the sanitary control of yellow fever was held. Dr. James Carroll, U. S. Army, presented the principal paper on "Yellow Fever in Louisiana." Dr. Hamilton P. Jones, New Orleans, spoke on "Isolation Hospitals"; Dr. H. Dixon Barnes narrated his experiences during the 1905 epidemic; Dr. Sidney L. Theard, New Orleans, presented a paper on "Requirements of Maritime and Inland Sanitation in the Light of the Mosquito Doctrine," and Dr. Luther Sexton, New Orleans, discussed some of the difficulties in the diagnosis on yellow fever. The matter of federal quarantine evoked active discussion. Dr. William H. Sanders, state health officer of Alabama, read a paper in which he showed the evil features of federal control, and Dr. Henry P. Garth discussed the relation of the state and national quarantine. He called attention to the action of other states in 1905 which virtually declared war against Louisiana and stated that he believed federal quarantine the only remedy for such conditions. Dr. Warren S. Bickham, New York City, a guest of the society, delivered an address on the "Operative Surgery of the Spine and Cord," illustrated by operations on the cadaver. Just before closing the society adopted a resolution pledging the medical profession of the state to a policy of publicity with respect to the existence of yellow fever whenever the disease is present. The election of officers resulted as follows: Dr. Henry D. Bruns, New Orleans, president; Drs. Charles McVea, East Baton Rouge, George F. Wilson, Bienville, and Allen J. Perkins, Lake Charles, vice-presidents; Dr. P. Leonce Thibaut, New Orleans, secretary; Dr. Jules Lazard, New Orleans, treasurer; Drs. Paul E. Archinard and Edwin J. Graner, both of New Orleans, and Dr. J. Wofford Sanders, New Iberia, councilors; and Drs. Francis M. Thornhill, Arcadia, and James C. Willis, Homer, members of the board of medical examiners. The banquet was one of the most successful events of the meeting. Dr. Marcus J. Magruder officiated as toastmaster; Dr. Edwin B. Craighead, president of Tulane University, was the principal speaker, and toasts were responded to by Drs. C. Jefferson Miller, H. Dickson Bruns and others.

MARYLAND.

Baltimore.

May Deaths.—During May there were 867 deaths and 629 births reported, also 143 cases of typhoid fever with 12 deaths.

Sewage Plant Plans.—It is claimed that the sewage plant of Baltimore will be the most perfect in the world. The estimated cost is $3,283,000, and the method will be that of septic tanks and sprinkling filters, with supplementary intermittent filtration through sand. About 1,200 acres of land will be needed.

Personal.—Dr. John C. Hemmeter has been elected an honorary member of the Imperial Society of Austrian Physicians at Vienna. He sailed for Europe June 6.——Dr. Archibald C. Harrison has been appointed surgeon of the Northern Central and the Philadelphia, Wilmington & Baltimore railroads, to succeed the late Dr. Thomas S. Latimer.

Failure to Report Cases.—Attention is being directed to the failure of physicians here to report cases of infectious diseases. Not over 40 per cent. of such cases in the city are reported. There is a difference of opinion between the city and state health authorities regarding the ability to enforce the law requiring reports, the former claiming that it can not be enforced. A physician living in the northern section—the area of the typhoid fever epidemic—has been arrested by the state board on the charge of failure to report cases of that disease. It is claimed that had he obeyed the law there would have been no epidemic.

Commencements. The University of Maryland School of Medicine held its one hundredth commencement June 4, when a class of eighty-three was graduated. Dr. Robinette B. Hayes, of North Carolina, carried off the gold medal, the highest honor, with a mark of 97.64. Mr. Francis King Carey delivered the address.——The Woman's Medical College graduated a class of two, May 31.——The College of Physicians and Surgeons graduated a class of sixty-five, May 31, at the thirty-fourth annual commencement. Rev. Dr. Huckel, in his address, urged that a systematic study of the mind should be included in the medical curriculum of colleges.

University Alumni Meet.—The Alumni Association of the University of Maryland School of Medicine held its annual meeting and banquet June 1. Dr. Randolph Winslow delivered the address on "The School in 1871 and 1906," and announced that a dormitory would be built for the use of students on ground recently purchased. He spoke of a plan for the union of the Baltimore Medical College with the university. Dr. Howard E. Ames, medical director, United States Navy, presided, and about 350 sat down to table. Dr. Samuel C. Chew was elected president for the ensuing year. Dr. Summerfield B. Bond was toastmaster, and addresses were made by Drs. Shipley, Caspari, Hirsh, Hopkinson, Neale and Carroll. The class of 1881 held its twenty-fifth reunion the same evening, Dr. Charles W. Mitchell presiding.

MASSACHUSETTS.

Bequest.—By the will of the late Alfred Cross of Lynn $5,000 is devised to the Lynn Hospital.

Maternity Ward Opened.—The new maternity ward at the Lawrence General Hospital was formally opened May 19. The ward contains accommodations for 16 patients.

Founder of Floating Hospital Resigns.—Rufus B. Tobey, Boston, who founded the Boston Floating Hospital in 1895 and who has since served this institution without compensation, was obliged to sever all relations with the institution, his resignation taking effect June 1.

Summer Courses at Harvard.—Harvard University Medical School will continue its usual summer courses during the months of June, July, August and September. A total of 71 courses is announced and the students in the medical school will be allowed all the privileges of the summer school of arts and sciences.

District Society Meeting.—The Middlesex East District Medical Society held its annual meeting in Stoneham, May 9, and elected the following officers: President, Dr. Harrison G. Blake, Woburn; vice-president, Dr. Corydon W. Harlow, Melrose Highland; councilors, Drs. George N. P. Mead, Winchester, Francis E. Park and Arthur H. Cowdrey, Stoneham, Silas H. Parks and Robert T. Edes, Reading; censors, Drs. Francis E. Park, Stoneham, Mott A. Cummings, Winchester, George F. Dow, Reading, Ernest S. Jack, Melrose, and William H. Kele-

her, Woburn, and auditor, Dr. Lilley Eaton, Winchester.——The annual meeting of the North Essex District Medical Society was held in Lawrence, May 2. The following officers were elected: Dr. William J. Sullivan, Lawrence, president; Dr. Charles E. Durant, Haverhill, vice-president; Dr. Maurice D. Clark, Haverhill, secretary and treasurer; Dr. R. D. Hamilton, Newburyport, corresponding secretary; Dr. J. S. Pierce, Haverhill, auditor; Dr. Leyander J. Young, Haverhill, supervising censor; Drs. Israel J. Clark, Haverhill, J. Forrest Burnham, Lawrence, Joseph A. Hogan, Lawrence, Richmond B. Root, Georgetown, John A. Douglass, Amesbury, and Ernest H. Noyes and Warren W. Pillsbury, Newburyport, councilors; Dr. Israel J. Clark, Haverhill, nominating councilor; Dr. Warren W. Pillsbury, Newburyport, alternating councilor, and Dr. John F. Young, Newburyport, commissioner of trials.

MICHIGAN.

Medical Student Killed.—Leland P. Beverlin, 29 years of age, a senior student of the Michigan College of Medicine, Detroit, was instantly killed in a runaway accident, May 17.

Diphtheria.—A number of cases of diphtheria are reported on Washington Island, near Jackson Harbor. All efforts to stamp out the disease appear thus far to have been futile.

Alumni Meeting.—The Detroit College of Medicine Alumni Association has just completed a ten-day clinic. At the annual luncheon, May 17, 400 guests were present, and the following officers were elected: President, Dr. Louis J. Hirschman, Detroit; vice-president, Dr. Richard C. Buchanan, Green Bay, Wis.; secretary and treasurer, Dr. John C. Dodds, Detroit, and historian, Dr. E. C. Rumer, Davison, Mich.

Wayne County Officers.—Wayne County Medical Society, at its annual meeting in Detroit, May 18, elected the following officers: President, Dr. J. Henry Carstens; vice-president, Dr. William F. Metcalf; secretary and treasurer, Dr. Walter D. Ford; and directors, Drs. George W. Wagner, H. Wellington Yates, Louis J. Hirschman, Guy L. Kiefer and Frank B. Tibbals, all of Detroit. The society now has 475 members, an increase of 85 since the last annual meeting.

Personal.—Dr. Ernest C. Lee, Detroit, having passed the required examination before the state military medical board, has been commissioned assistant surgeon in the Michigan National Guard, with the rank of first lieutenant.——Dr. Edward M. Libby has been appointed health officer of Iron River.——Dr. Charles J. Sorsen, Calumet, sails from New York for Europe, June 9.——Dr. John L. Chester has been appointed health officer of Emmett.— Dr. Joseph B. Griswold, Grand River, has resigned from the State Board of Legislation and Medicine on account of press of other duties.

April Mortality.—During April 3,097 deaths were reported in the state, equivalent to an annual rate of 14.6 per 1,000. This is slightly lower than the rate for the preceding month, 14.8, but a little higher than the death rate for the corresponding month of 1905, which is 14.4. There were 1,259 births returned during the month. Among the important causes of death were: Pneumonia, 341; tuberculosis, 255; accident and violence, 157; cancer, 131; influenza, 61; meningitis, 51; diarrheal diseases of infants, 50; whooping cough, 45; measles, 42; diphtheria, 36; typhoid fever, 30, and scarlet fever, 28. There was an increase in the mortality from tuberculosis, typhoid fever, measles, enteritis, meningitis, influenza and violence, but a decrease in the deaths from other important causes.

State Society Meeting.—The forty first annual meeting of the Michigan State Medical Society was held in Jackson, May 20, 21 and 22, under the presidency of Dr. David Inglis, Detroit. Mayor Todd welcomed the visitors to Jackson, and Dr. Albert E. Bulson delivered the address of welcome on behalf of the Jackson County Medical Society. Aside from the literary work, the society declared its belief that the code of ethics was not adhered to with sufficient strictness and adopted a resolution recommending that all medical schools give special instructions in this regard. A committee was appointed to investigate the so-called lodge practice and contract work, and a recommendation was adopted advising amendments to the laws of the state providing for compensation for animals killed after tests for tuberculosis. A committee on study and prevention of tuberculosis was added to the list of standing committees of the society. The following resolution was also passed unanimously:

That in order to attain the highest efficiency in medical education in this state, giving the greatest number of instructors to a given number of students, together with greatly increased clinical facilities, we view with favor the proposed amalgamation of the medical department of the University of Michigan with the Detroit College of Medicine

Drs. J. N. McCormack, Bowling Green, Ky., John B. Murphy, Chicago, William Parmenter, Vermontville, Mich., and Johann Flintermann, Detroit, were elected honorary members of the society. The following officers were elected: President, Dr. Charles B. Stockwell, Port Huron; vice-presidents, Drs. William Fuller, Grand Rapids, Edward T. Abrams, Dollar Bay, Delbert E. Robinson, Jackson, and Allison R. Stealy, Charlotte; secretary-editor, Dr. Benjamin R. Schenck, Detroit; treasurer, Dr. George W. Moran, Detroit; delegates to the American Medical Association, Drs. Albert J. Lawbaugh, Calumet, and Leartus Connor, Detroit, and alternate, Dr. Orton H. Clark, Kalamazoo. The 1907 meeting will be held in Saginaw.

MISSOURI.

Dispensary Physician Resigns.—Dr. Edward J. Ernst, assistant chief dispensary physician of St. Louis, has resigned.

Smallpox.—Carthage has had 10 cases of smallpox in its vicinity. There is no disease reported in the town at present and the jail quarantine has been raised.

Smallpox Closes Schools.—The McKinley and Hosea schools, St. Joseph, have been closed for the remainder of the term on account of smallpox among the pupils.

Portrait Presented.—A life-size oil painting of Dr. Gustaf Baumgarten, who has been a member of the faculty of the Medical Department of Washington University for 33 years, was presented by the faculty and students of the department, to the institution, May 27.

Graduation Exercises.—A class of 55 was graduated from the Medical Department of Washington University, May 24. Chancellor W. S. Chapman, Washington University, conferred the degrees. Dr. Robert Leudeking awarded the prizes and the doctorate address was made by Dr. Maurice H. Richardson of Harvard University Medical School.

Physicians and Nurses for School Emergencies.—The board of health of St. Louis has approved a proposition submitted by the Provident Association to supply physicians and trained nurses to be within call of all public schools for emergencies. The matter was referred to the legislative committee, consisting of H. A. Foreman and A. Merrel,' who will draft the ordinance.

Found Guilty. Dr. John B. French, St. Louis, was found guilty by a jury in the United States District Court, May 23, of sending unmailable matter through the mails and offering for sale medical preparations prohibited by law. Indictments were found against him on four counts by the federal grand jury, and he was found guilty on three of the four. Sentence was deferred.

Board of Health Appointments.—The following appointments were made May 24 by the St. Louis board of health: Dr. John W. Shanklin, assistant superintendent of the City Hospital, and Drs. Paul McMullan, R. C. Strohl and S. K. Guggenheim, assistants; Dr. C. H. Shoot, assistant superintendent, and Drs. Edwin Sheehan and H. F. Lineoln, assistants at the Emergency Hospital; Dr. Daniel Shoemaker, assistant city bacteriologist.

Postgraduate Teaching in St. Louis.—At a conference between the secretaries of the Missouri State University and the trustees of the Barnes Hospital Fund, held May 25, it was decided to establish a postgraduate medical department of the State University in St. Louis and to make it a part of the new Barnes Hospital. A committee was appointed to meet the Barnes trustees and complete arrangements for the erection of the institution. The Barnes Fund, which amounts to $1,000,000, was bequeathed for the endowment of a hospital to be known by the name of the Barnes Hospital. The site for this institution was purchased some time ago. The work of erection will begin some time this summer. The next legislature will probably be called on to appropriate money for the maintenance of the new department of the university.

NEW YORK.

Municipal Hospital. The new municipal hospital, Buffalo, is to be completed and turned over to the health department early in June. It has been erected at the cost of $50,000, and is intended to care for all varieties of contagious diseases.

Commencement.—The sixtieth annual commencement of the University of Buffalo, Medical Department, was held June 1, when a class of 14 was presented to Vice-Chancellor Norton by Dr. Ely H. Long, secretary of the faculty, and received diplomas. Dr. Edward N. Brush, Baltimore, was the principal orator of the day.

Personals.—Dr. Augustus G. Pohlman, Buffalo, has been appointed associate professor of anatomy in Indiana University, Bloomington.——Dr. William J. O'Donnell, Buffalo, sails for Europe early in June.——Drs. Nelson G. Russell, Norman L. Burnham and Eugene A. Smith have sailed for Europe.——Dr. Ray Beardsley has been elected health officer of Binghamton, vice Dr. J. Adelbert Ilix.——Dr. Adolph Latellier has been elected health officer of Seneca Falls.

New York City.

Want Investigation.—Within a week two patients with fractured skulls have been transferred to Bellevue as alcoholic cases. Both patients died, and Superintendent Armstrong is about to make an investigation in order to place the responsibility of the transfer of the dying patients to the hospital under wrong diagnoses.

Memorial to Fowler.—At the last meeting of the Kings County Medical Society a tablet in memory of Dr. George Ryerson Fowler was unveiled in the library of the society. It is oblong, with panels for inscriptions on either end, and a bronze bust of Dr. Fowler in the center. The presentation was made by Dr. Lewis S. Pilscher, and Dr. William F. Campbell received the tablet on behalf of the society.

Contagious Diseases.—During the week ended May 26, 1,111 cases of measles were reported, with 35 deaths; 404 cases of tuberculosis, with 184 deaths; 378 cases of diphtheria, with 46 deaths; 219 cases of scarlet fever, with 31 deaths; 38 cases of whooping cough, with 7 deaths; 37 cases of typhoid fever, with 9 deaths; 35 cases of cerebrospinal meningitis, with 23 deaths; 111 cases of varicella, and 2 cases of smallpox, a total of 2,335 cases and 335 deaths.

The Seaside Hospital.—The board of estimate heard suggestions for the proposed park and convalescent hospital on June 2. The legislature has authorized the city to spend $2,500,000. The committee will probably report in favor of Rockaway Park, where the site under consideration consists of 800 acres. The unreasonable demands of the Rockaway owners stand in the way of progress at present, but it is hoped that the city will be able to procure the property at its own price.

Uniform Hospital Accounting.—The hospital committee has turned in its final report, in which it recommends a system of uniform accounting, which shall take into consideration differences of conditions affecting different hospitals. It will first be necessary to have an intelligent classification of the various hospitals of the city, so that in the comparisons that are to be made only those institutions that are fairly comparable shall be classed together. Roosevelt, Presbyterian, New York and St. Luke's hospitals have already perfected a system of uniform accounting for themselves. It is suggested that, after the adoption of a uniform system of accounting, the city's per diem allowance to the hospitals already receiving municipal aid be increased.

NORTH DAKOTA.

Smallpox.—A case of smallpox has developed at Emerado. ——Five cases of smallpox are reported to be under quarantine at Antler.——An alderman of Grand Forks is quarantined in his house on account of smallpox.

Grand Forks Wants Hospital.—The Commercial Club of Grand Forks has already obtained subscriptions amounting to $6,100 toward the $15,000 required, before Bishop Shanley will undertake the erection of a 60-bed hospital in Grand Forks.

State Society Meeting.—The nineteenth annual session of the North Dakota State Medical Association was held at Fargo, May 16 and 17, under the presidency of Dr. Paul Sorkness, Fargo. Mayor Johnson welcomed the association and Dr. Dwight S. Moore, Jamestown, responded. The president in his address advocated that the association take an active part in the national movement to arrange for the erection of a monument to Dr. N. S. Davis. He also made recommendations relative to fees for life insurance examinations and expert testimony. The committee on tuberculosis submitted a report, recommending that a bill for the prevention of the disease be drafted and introduced at the next session of the state legislature. Prof. F. E. Ladd of the state pure food department gave an address in which he sketched the history of pure-food legislation in North Dakota, and detailed the improvement in food and the decrease in adulteration since the work was initiated in 1902. He inveighed against the use of "patent medicines" and nostrums, and described the majority of nostrums as intended to defraud the public without regard to the effect they might have on the health. The following officers were elected: President, Dr. Robert D. Campbell, Grand Forks; vice-presidents, Drs. Charles MacLachlan, New Rockford, John E. Countryman, Grafton, and W. H. M. Philip, Hope; secretary, Dr. Hezekiah J. Rowe, Casselton (re-elected), and treasurer, Dr. J. Dempster Taylor, Minot; and councilors, Drs. Paul Sorkness, Fargo, Andrew Carr, Minot, Edgar A. Pray, Valley City, and John Crawford, Esmond. Dr. James P. Aylen, Sheldon, and Henry G. Woutat, Grand Forks, were recommended for reappointment on the State Board of Medical Examiners. At the annual banquet Dr. Hezekiah J. Rowe, Casselton, officiated as toastmaster. The society adjourned to meet in 1907 at Minot.

OHIO.

Ohio Ophthalmological Society.—The eye, ear, nose and throat section of the Ohio State Medical Association elected the following officers: Chairman, Dr. Charles F. Clark, Columbus; secretary, Dr. Walter H. Snyder, Toledo, and treasurer, Dr. Wylie McL. Ayres, Cincinnati.

Hemmeter in Cleveland.—Dr. John C. Hemmeter of the University of Maryland, Baltimore, addressed the Academy of Medicine, Cleveland, May 11, on "Certain Diseases of the Digestive Tract that are on the Border Line between Internal Medicine and Surgery." On the following day Professor Hemmeter gave a clinic at the Northwestern Reserve University.

State Pediatric Society.—The Ohio State Pediatric Society held its annual session at Canton, May 8. The following officers were elected: Dr. William W. Pennell, Mount Vernon, president; Drs. J. Morton Howell, Dayton, and John D. Dunham, Columbus, vice presidents; Dr. Jesse M. Moore, Cleveland, secretary and Dr. Myron Metzenbaum, Cleveland, treasurer.

State Dermatological Society.—At the annual meeting of the State Dermatological Society, which has decided to affiliate with the State Medical Association, the following officers were elected: Dr. Meyer L. Heidingsfeld, Cincinnati, president; Dr. Edward A. Montenyohl, Akron, vice-president; Dr. E. Otis Smith, Cincinnati, secretary, and Drs. Walter Q. Le Fevre and William E. Sampliner, Cleveland, and Edwin D. Tucker, Toledo, executive committee.

Ohio State Medical Association.—The annual meeting of the association was held in Canton, May 9, 10 and 11, under the presidency of Dr. Thomas C. Martin, Cleveland. It was reported that of the 88 counties in Ohio 87 were organized, leaving Pickaway County the only one still unorganized. Dr. John C. Hemmeter, of Baltimore, was the guest of honor of the association and delivered an address on "Autointoxication from the Digestive Tract." Dr. Harvey Gaylord, Buffalo, delivered the address in surgery on "The Etiology of Cancer." The following officers were elected: Dr. Benjamin R. McClellen, Xenia, president; Drs. John S. Deemy, Bellefontaine, Frank E. Bunts, Cleveland, William W. Pennell, Mount Vernon and Charles F. Clark, Columbus, vice-presidents; Drs. Frank D. Bain, Kenton, and Alonzo B. Walker, Canton, delegates to the American Medical Association, and Drs. John S. Beck, Dayton, B. H. Blair, Lebanon, Edmund C. Brush, Zanesville, Frank Winders, Columbus, and Harris G. Sherman, Cleveland, alternates. The following councilors were elected: Drs. Frank D. Bain, Kenton, third district, and Charles S. McDougall, Athens, eighth district. Dr. Charles A. L. Reed, Cincinnati, was elected delegate to the national legislative council. The society adjourned to meet at Cedar Point, in 1907.

PENNSYLVANIA.

Acquitted.—Dr. Edward J. Hadfield, Phœnixville, charged with performing a criminal operation, was acquitted May 5.

Hospital News.—At a special meeting of the trustees of Lewiston Hospital, Dr. Alexander S. Harshberger was re-elected president and the other officers were also re-elected. ——The new Johnstown City Hospital has been formally opened and is now ready to receive patients.——Sewickley is to have a new hospital, to cost $40,000, $30,000 of which has already been subscribed.

Neurologic Clinics.—Drs. Theodore Diller and Thomas M. T. McKennan, Pittsburg, have been appointed visiting neurologists to Marshalsea, the municipal hospital for the insane, Pittsburg. A series of six weekly clinical conferences is being held at the institution, which is open to physicians and medical students. This series began on May 18. The hospital at Marshalsea contains about 600 patients and the various psychoses are well represented.

West Branch Society Meeting. The annual meeting of the West Branch Medical Association, made up of eight counties in Central Pennsylvania, was held at Williamsport, April 26. The following officers were elected: President, Dr. Spencer M. Freer, Du Bois; vice-presidents, Drs. G. Franklin Bell, Williamsport, and William E. De Laney, Slate Run, and secretary and treasurer, Dr. Joseph M. Corson, Chatham Run. It was decided to hold the next meeting at Lock Haven in 1907.

County Society Meeting.—At the regular meeting of the Susquehanna Medical Society, held in Montrose, May 1, the following officers were elected: President, Dr. Clayton Washburn, Susquehanna; vice-president, Dr. William B. Beaumont, West Auburn; secretary, Dr. Edward R. Gardner, Montrose; treasurer, Dr. John G. Wilson, Montrose; censors, Drs. John G. Wilson, Irving P. Schoonmaker, Halstead, and Dever J. Peck, Susquehanna, and district censor, Dr. Samuel Birdsall, Susquehanna.

Typhoid in Berks County.—During the past three months there have been reported in Wernersville thirty cases of typhoid fever and several persons are still ill with the disease. At the direction of the state commissioner of health, Dr. Israel Cleaver, Reading, medical inspector of Berks County for the State Health Department, made an investigation. Many of the patients are school children, and an analysis of the water from the wells which supply the school demonstrated that this was the probable source of infection.

Personal.—Dr. Joseph D. Findley has been elected physician of the board of health of Altoona.——Dr. Lawton M. Hartman, York, has sailed for Europe.——Dr. Lorenzo W. Swope, Pittsburg, has been appointed chief surgeon for the Wabash Lines. ——Dr. Daniel W. Jefferis, Chester, has been appointed city physician.——Dr. John F. McGrath has been appointed physician for the department of public safety of Pittsburg, vice Dr. Alexander E. McCandless.——Dr. James F. Edwards, U. S. Army, retired, has been appointed superintendent of the Pittsburg bureau of health.——Dr. Alfred L. Dennis, Conneautville, has been appointed surgeon for the Bessemer Railroad.——Dr. A. Miner Straight, Bradford, is recovering from his recent serious illness.——Dr. Philip L. Reichard, Allentown, was operated on recently in Philadelphia for the removal of a cataract.—— Dr. Walter Davis, Wilkesbarre, suffered a dislocation of the shoulder and serious lacerations and contusions in a runaway accident, May 21.

Philadelphia.

Convicted of Illegal Practice.—Amos Glasgow, a negro, was convicted on May 18 of practicing medicine without being a registered physician and was fined $50 and costs.

Medico-Chirurgical Commencement.—The annual commencement of the Medico-Chirurgical College was held June 2, when a class of 118 was graduated. The class-day exercises were held June 1 and the address was delivered by Dr. Judson Daland of the faculty.

Pass Examinations.—The Civil Service Commission announced yesterday the results of the examination for resident physicians to the Philadelphia General Hospital. The examination was held May 12, and eighty-six of the contestants received a mark of 70 or higher.

Faith Curists Indicted.—Three faith curists, members of the "Faith Tabernacle," were indicted by the grand jury June 2 on the charge of manslaughter, arising from the death of a little girl, the daughter of one of the men found guilty. Medical attention was absolutely denied the child.

Dr. Brinton Resigns.—Dr. John H. Brinton, for twenty-four years professor of surgery and clinical surgery at Jefferson Medical College and one of the four who comprised the first board of surgeons of the present Jefferson Hospital, has resigned, to take effect at the end of the present term.

Dr. Coplin to Be Honored.—The appreciation shown by the Philadelphia profession of the progressive work instituted by Dr. W. M. Late Coplin, medical director of the Department of Health and Charities, will be evidenced by a reception in his honor, arranged by the Medical Club, to be held in the Hotel Majestic, June 15.

Jewish Hospital Report.—At the forty-first annual meeting of the Jewish Hospital Association, May 27, the president reported that 7,131 patients had been cared for during the year, or 246 more than those treated in the preceding year. Of these, 1,586 were free patients. During the year 17,446 prescriptions were compounded.

Women Graduates.—At the annual commencement of the Women's Medical College a class of twenty-four was graduated. The diplomas were awarded by Mrs. Mary E. Mumford, president of the board of corporators of the college, and the doctorate address on "The Woman as a Physician" was delivered by Dr. Elliott, of New York City.

Hospital Dedication.—The new wing of St. Agnes Hospital was dedicated with appropriate ceremonies May 29. With this addition to the institution St. Agnes Hospital becomes the largest hospital building in the city under one roof, and the capacity of the institution is more than doubled. There are 300 private rooms. The majority of these have been furnished by individuals. The ground floor contains the new dispensary, operating room for minor accident cases; the fourth floor contains three operating rooms, and connected with each of these is a complete sterilizing plant and rooms for the administration of anesthetics.

Health Report.—The total number of deaths reported in the city during the week aggregated 444, as compared with 519 reported last week and 450 in the corresponding week of last year. The principal causes of death were: Typhoid fever, 28; measles, 7; whoopingcough, 13; diphtheria, 10; consumption, 53; cancer, 25; apoplexy, 18; heart disease, 41; acute respiratory diseases, 46; enteritis, 22; Bright's disease, 38; suicide, 4; accidents, 19, and marasmus, 5. There were 308 cases of contagious disease reported, with 39 deaths, as compared with 381 cases and 47 deaths. Typhoid fever is on the decrease. 170 cases being reported this week, whereas 253 cases with 33 deaths were reported in the preceding week.

Personal.—Dr. De Forest Willard, who is suffering from pneumonia and is still seriously ill, has been operated on for pulmonary abscess. A rib was resected and drainage instituted. He bore the operation well.——Dr. Charles P. Noble gave a reception in honor of Drs. Wesley Bovée, Washington; Guy S. Hunner, Baltimore, and Elliee McDonald, New York, on May 9.——Dr. Mary W. Griscom sailed for Europe June 2. ——Dr. George E. Pfahler sailed for Europe May 31.——Dr. Clara Marshall, dean of the Woman's Medical College, whose resignation was presented to the trustees some months ago, relinquished her connection with the institution June 1 and has been succeeded by Dr. Arthur A. Stevens.

Jefferson Alumni Meeting.—At the annual meeting of the Alumni Association of the Jefferson Medical College, June 1, the following officers were elected for the ensuing year: President, Dr. W. M. Late Coplin; recording secretary, Dr. Charles S. Barnes; corresponding secretary, Dr. Aller G. Ellis, and treasurer, Dr. Randle C. Rosenberger. The annual dinner of the association was held on the evening of the same date at the Bellevue-Stratford, 250 members being present. Dr. George B. McClellan, the retiring president and newly elected professor of anatomy, acted as toastmaster. Toasts were responded to by Albert Johnson, representing the board of trustees; Dr. Edward C. Spitzka, the newly elected professor of anatomy; representing the faculty; Dr. William B. Hale for the press, Dr. Harvey Buchanan for the class of 1896, Dr. F. O. Lewis for the class of 1906 and Dr. J. W. West for the alumni.

SOUTH DAKOTA.

Personal.—Dr. George H. Stidworthy, Viborg, sailed for Europe May 10.——Dr. Vladimir Siakin Ross, formerly superintendent of the State Insane Hospital, Yankton, has decided to locate in Sioux Falls.

Medical Examiners Appointed.—The governor appointed as members of the State Board of Medical Examiners to succeed themselves, Drs. Stephen Olney, Sioux Falls, Hans M. Finnerud, Watertown, and H. E. McNutt, Aberdeen.

District Medical Society.—The annual meeting of the Fourth District Medical Society of South Dakota was held in Huron, April 13. Dr. John L. Foxton, Huron, was elected president; Dr. Isaac M. Burnside, Highmore, vice-president; Dr. Charles J. Lavery, Fort Pierre, secretary, and Dr. Delorme W. Robinson, Pierre, treasurer.

State Association Meeting.—The twenty-fifth annual meeting of the South Dakota State Medical Association was held in Watertown, May 22, 23 and 24, under the presidency of Dr. Adelbert H. Bowman, Deadwood. On the evening of May 23 the members were the guests of the Watertown District Medical Society at a banquet. Mayor J. W. Martin delivered the address of welcome, which was responded to by Dr. E. Frank Reamer, Mitchell. It was decided to hold the next annual meeting at Sioux Falls. Dr. Edwin T. Ramsey, Clark, was elected president, and Dr. Frederick Freyberg, Mitchell, councilor for the district and secretary of the board of councilors.

CALIFORNIA NEWS.

Ready to Give Aid.

The physicians' relief committee on May 18 announced that it was prepared to issue aid to physicians and their families. Members of the profession in need were requested to apply to Dr. Fred W. Lux at the Lane Hospital. It was then stated that there were about 1,500 physicians without money and with no prospect of earning any at present.

Tribute to San Francisco Physicians.

Dr. N. K. Foster, secretary of the California State Board of Health, says:

There is no class of people on earth who have made such a record for themselves as have the physicians of San Francisco and vicinity during the late disaster, and it is due to their efforts that no epidemic followed the fire that made many thousands homeless. This disaster has been harder on the fraternity than any other class, and none of them will fully recover from their losses. They have lost their practice, instruments, their libraries, and in some instances, lost heart, which is the worst loss of all.

Books for California Physicians.

Dr. G. C. Savage, Nashville, Tenn., writes that he has sent 35 copies of each of his two latest books to the San Francisco committee, and suggests that it would be well if other authors in the United States would do likewise.

Acknowledgments.

The San Francisco relief committee has sent the following acknowledgment to the Norfolk District (Mass.) Medical Society:

The committee begs to tender you and your confrères its sincere thanks for your noble and generous impulse. By those only who have sustained a similar affliction, being bereft of all they possess in a few short hours, can the action of your society be truly and deeply appreciated.

Dr. James W. Ward, president of the health commission of San Francisco, acknowledges in the following words the high esteem in which the services of Oregon physicians were held:

I desire on the part of the health commission of the city and county of San Francisco to extend to you, and through you, to the Third Regiment of the Oregon Hospital Corps, our sincere appreciation of your valuable service in San Francisco. It has been an object lesson to the medical profession of San Francisco to note the exactness with which your duties were performed, which have been to the satisfaction of all who know the extent of your services.

Funds for California Sufferers.

NEW YORK CITY, May 27, 1906.

To the Editor:—The committee on medical relief of the California sufferers, i. e., of medical men and their families, appointed by the New York Academy of Medicine and the county societies of New York and Richmond, have raised up to date $5,706. Most of this has been by individual subscriptions, but several medical societies have contributed most generously. When the promised funds are all in we shall have over $7,000.

Through the kind offices of Dr. Francis P. Kinnicutt, the chamber of commerce has appropriated $5,000 out of its fund to be used for relief of medical men in connection with our fund. CHARLES L. DANA.

California Fund.

The following additional contributions have been received at THE JOURNAL office up to 9 a. m., Wednesday, June 6:

Brooks, G. F., Stevenson, Minn.	$ 5.00
Buffum, J. H., Vermont	1.00
Decatur (Ill.) Medical Society	6.00
Caverly, C. S., Wallingford, Vt.	5.00
Colby, B. D., Vermont	2.00
Fawcett, W. C., Devil's Lake, N. Dak.	10.00
Hack, T. H., Vermont	2.00
Hammond, S. W., Vermont	1.00
Hirschberg, J. (Prof.), Berlin, Germany	10.00
Lape, R., Vermont	2.00
Louisville (Ky.) Society of Medicine	25.00
Manchester, H. L., Vermont	1.00
Marshall, G. G., Vermont	1.00
Michigan State Medical Society, Detroit, Mich.	500.00
Moeller, Thor., Devil's Lake, N. Dak.	5.00
Peck, C. W., Vermont	1.00
Rutland County (Vt.) Medical and Surgical Society	50.00
Swift, H. H., Wallingford, Vt.	5.00
Woodward, A. T., Wallingford, Vt.	5.00
Strobell, C. W., Vermont	1.00

Kanawha (W. Va.) Medical Society, $33.00:

Barber, T. L.	$1.00	McConihay, J. M.	$2.00
Burns, R.	2.00	McMillan, W. A.	1.00
Cannaday, J. E.	1.00	Nicholson, H. G.	1.00
Champe, I. P.	2.00	O'Grady, Charles	2.00

Grand total	$10,926.40

GENERAL.

Physicians Needed for Navy.—It is reported that there are a number of vacancies in the medical corps of the United States Navy. In addition to the salary there is opportunity for a varied professional experience and practical work along lines which do not present themselves to the ordinary practitioner.

Leper Colony in the Philippines.—The first permanent leper colony in the Philippine Islands has been established at Colion Island and 200 lepers have been removed to that place from Cebu. Four Roman Catholic sisters have volunteered their services and are now on their way to the settlement to nurse the afflicted.

Dermatologists Elect.—At the thirtieth annual meeting of the American Dermatological Association, held in Cleveland, May 31 and June 1 and 2, the following officers were elected: President, Dr. Arthur Van Harlingen, Philadelphia; vice-president, Dr. William A. Pusey, Chicago, and secretary and treasurer, Dr. Grover W. Wende of Buffalo.

Aesculapian Society Meeting.—At the fifty-ninth semi-annual meeting of the Æsculapian Society of the Wabash Valley, held in Robinson, Ill., May 31, Dr. John F. Percy, Galesburg, president of the Illinois State Medical Society, was the guest of honor. Dr. Herbert N. Rafferty, Robinson, was elected secretary and treasurer to fill the vacancy occasioned by the death of Dr. Harry McKennan, Paris.

Food Standards.—The committee on food standards, Association of Official Agricultural Chemists, which has been commissioned by the authority of congress to collaborate with the Secretary of Agriculture in fixing standards of purity for foods and determining what shall be regarded as adulterations therein, will hold its next meeting June 18, at the bureau of chemistry, Washington, D. C.

Genitourinary Surgeons Meet.—At the twentieth annual meeting of the American Association of Genitourinary Surgeons, held at the Academy of Medicine, New York City, June 1 and 2, the following officers were elected: President, Dr. William K. Otis, New York City; vice-president, Dr. Harvey G. Mudd, St. Louis; secretary and treasurer, Dr. John Van der Poel, New York City, and member of council, Dr. Hugh H. Young, Baltimore.

American Surgical Association.—At the twenty-sixth annual meeting of the American Surgical Association, held in Cleveland, June 1, Dr. Dudley P. Allen, Cleveland, was elected president; Drs. Thomas W. Huntington, San Francisco, and Augustus F. Jonas, Omaha, Neb., vice-presidents; Dr. Robert G. Le Conte, Philadelphia, secretary; Dr. Charles A. Powers, Denver, treasurer; Dr. Richard H. Harte, Philadelphia, recorder, and Dr. Albert Van der Veer, Albany, N. Y., councilor. It was decided to hold the next meeting in Washington, D. C.

Civil-Service Examinations.—The United States civil-service commission announces the following examinations: On July 5 and 6 an examination will be held to secure eligibles from which to make certification to fill vacancies in the positions of hospital internes (male) under the Isthmian Canal commission as they may occur. Two days will be required for the examination. Each applicant must submit to the examiners a recent photograph of himself as a means of identification. An unmounted photograph is preferred. The age limit is between 20 and 30 years; salary, $100 a month, with quarters, but without board and washing. Only graduates of reputable medical schools having not less than a three years' course will be admitted to the examination. On the same date the examination originally scheduled for June 6 and 7 will be held to secure eligibles from which to make certification to fill at least two vacancies at $600 per annum each, with maintenance, in the position of medical interne in the Government Hospital for the Insane, Washington, D. C. Two days will be required for the examination. Men only will be admitted. Age limit, 20 years or over at the time of the examination, and the applicants must be graduates of reputable medical colleges. Applicants for either of these positions should apply

at once at the United States Civil-Service Commission, Washington, D. C., which will also give information as to the places where examinations will be held.

Oklahoma and Indian Territory Society Meeting.—The Oklahoma and Indian Territory medical associations held a joint meeting in Oklahoma City, May 7, 8 and 9, under the presidency of Dr. Newton N. Rector, Hennessey, president of the Oklahoma State Medical Association. The address of welcome was delivered by Dr. Aarcha K. West, Oklahoma City, and responded to on behalf of the Indian Territory association by its president, Dr. Virgil Berry, Wetumka, and on behalf of the Oklahoma association by Dr. A. L. Blesh, Guthrie, chairman of the council. The house of delegates adopted a resolution that hereafter the rules and by-laws of the association conform with those of the American Medical Association. Dr. Jabez N. Jackson, Kansas City, Mo., guest of the association, delivered an address on the standing of the medical fraternity in the West and on the future of the organization. The association adopted the title of Oklahoma State Medical Association, pending the union of Oklahoma and Indian Territory into one state. The following officers were elected: Dr. Benjamin F. Fortner, Vinita, I. T., president; Drs. Mahlon A. Kelso, Enid, Okla., Walter C. Bradford, Shawnee, Okla., and Floyd E. Waterfield, Holdenville, I. T., vice-presidents; Dr. Eugene O. Barker, Guthrie, Okla., secretary and treasurer; and Drs. Fred S. Clinton, Tulsa, I. T., and John A. Hatchett, El Reno, Okla., delegates to the American Medical Association. The following councilors were elected: Drs. A. L. Blesh, Guthrie, LeRoy Long, South McAlester, I. T., Franklin M. Duckworth, Claremore, I. T., Bascom J. Vance, Checotah, I. T., Eliphalet N. Wright, Olney, I. T., Ney Neill, Mangum, Okla., Herbert P. Wilson, Wynnewood, I. T., Everett S. Lain, Weatherford, Okla., James H. Medaris, Helena, Okla., and Gregory A. Wall, Oklahoma City. Shawnee was selected as the next place of meeting, and $100 was subscribed for the relief of the physicians of San Francisco.

CANADA.

Toronto Clinical Society.—The following are the officers elected for 1906-1907: President, Dr. H. B. Anderson; vice-president, Dr. H. A. Bruce; treasurer, Dr. Geoffrey Boyd; recording secretary, Dr. George Elliott; corresponding secretary, Dr. W. J. McCollum.

Toronto Pathological Society.—The Toronto Pathological Society has elected the following officers for the ensuing year: President, Dr. J. A. Amyot; vice-president, Dr. W. H. Pepler; treasurer, Dr. C. J. Wagner; corresponding secretary, Dr. E. Stanley Ryerson; recording secretary, Dr. H. G. Hutchison.

Annual Meeting of the French-Speaking Physicians of North America.—The third congress of the Association of the French-Speaking Physicians of North America will be held at Three Rivers, P. Q., June 26-28. The president is Dr. L. P. Normand, Three Rivers, and the general secretary, Dr. Charles De Blois, Three Rivers. The principal questions to be taken up and discussed at this meeting will be alcoholism, infantile hygiene and tuberculosis.

FOREIGN.

Epidemic Cerebrospinal Meningitis in Germany.—Owing to the appearance of epidemic cerebrospinal meningitis at Döberitz, the maneuvers of the troops have been abandoned for the present. The disease has also appeared in epidemic form at Posen, and 38 cases have been reported in Switzerland.

Degree Conferred on von Bergmann by Edinburgh University.—In April E. von Bergmann of Berlin went to Edinburgh to receive the degree of Doctor honoris causa which was conferred on him at the ceremonies attending the graduation of 200 baccalaureates.

Pension for Madame Curie. The French government has bestowed a pension of 12,000 francs, about $2,400, on the widow and children of Professor Curie. Madame Curie has also been appointed to a chair of physics at the university, with laboratory, continuing her husband's life work and her own research.

Plague in Straits Settlements. Consul-General Michael, at Calcutta, reports that the government of Bengal, in consequence of the outbreak of plague in Wellesley province, Straits Settlements, has declared Penang an infected port, and that the regulations for the prevention of the introduction of plague by sea, which are in force in the port of Bengal, will be enforced in the ports of Orissa.

International Antiquackery Committee. The organization of an international committee to discuss ways and means for combating quackery was recently mentioned in these columns. It is announced that five European bodies have already appointed delegates to the committee. They are the Carl-ruhe board of public health, and the Swedish, Dutch, German and Austrian national associations for combating quackery.

Privileges for Physicians.—The *Deutsche med. Wochft.* states that the German government has ordered that the expenses of courses of mineral waters at certain spas are to be remitted in case of registered physicians and dependent members of their immediate families, including their servants. At Ems the baths, inhalations and mineral water for drinking are free to them; at other resorts only the baths and waters.

Hospitals for the Straits Settlements.—A new hospital for the treatment of beriberi has been built at Passid Panjang, in the Straits Settlements, to isolate and to deal under the best conditions with the cases of this disease which occur among the patients in the lunatic asylum, the general hospital and the prisoners in jail. The *Indian Medical Gazette* states that a new lunatic asylum is also being built for the Straits Settlements.

Silver Jubilee of a Hungarian Medical Journal.—The leading medical journal of Hungary, *Orrosi Hetilap*, recently celebrated its fiftieth anniversary. A special number of 250 large quarto pages was issued on the occasion, containing important articles from ninety of the most prominent physicians of Hungary, we are told by the Budapest correspondent of the *Deutsche med. Wochft.* The journal is not much known in this country.

Strikes Affecting the Publication of Our Exchanges.—As already mentioned, the *Presse Médicale* of Paris has been suffering from a strike among the printers. It is now at an end, but our esteemed exchange has a gap of several numbers in its publication, the numbers between 32 and 39 being missing. The *Deutsche med. Wochft.* for May 10 also arrives with an apology for slight delay on account of a strike among the binders. The number received is not stitched.

Baeumler's Seventieth Birthday.—In 1901 Prof. C. Baeumler celebrated the twenty-fifth anniversary of his taking charge of the medical clinic at Freiburg. His seventieth birthday occurred May 13, and was duly celebrated by his friends. The *Deutsche med. Wochft.* publishes an illustrated sketch of the popular clinician in the issue for May 10, extolling especially his work as an inspiring teacher. He practiced for nine years in London, and has been a frequent contributor to German and English medical periodicals.

Brouardel Retires.—The eminent Paris authority on medico-legal questions and practice, Prof. Paul Brouardel, will be 70 years old next February. He has recently sent in his resignation from the chair of medical jurisprudence, and intends to retire definitely from his public career. He has published many works on his specialty and on medicine in general, and has been since 1878 one of the editors of *Annales d'hygiène publique et de médecine légale.* His classic volumes on death, sudden death and other medicolegal subjects have been translated into several languages. He is a familiar figure at national and international medical congresses.

Organization of the Profession in Germany. Satisfactory arrangements have finally been concluded between the sickness insurance societies at Vohwinkel and their medical officers. This place has been on the black-list of the *Leipziger Verband* since Jan. 1, 1904, and all honorable colleagues have been warned not to accept the positions with the company. One physician was found who accepted the office and terms, but he gives up the position now without demanding an indemnity on condition that he be allowed to remain as a physician in the town and is accepted as in good ethical standing, to which the local physicians agreed.

Bubonic Plague in Australia. It is reported that plague has again broken out in Sydney, Brisbane and West Australia. The health authorities in New South Wales, according to the *British Medical Journal*, are of the opinion that the outbreak is due to a fresh infection brought by rats from over-sea. The health authorities throughout Australia are urging more thorough destruction of rats. In Victoria the board of health has decided to enforce the regulations for shipping from other ports unless it is known that no infected rats can be found in the other states. The restrictions differ in each state and it is highly desirable that they should be uniform.

Disapproval of Design for the Virchow Statue at Berlin. As already mentioned, the design that won the first prize represents a titan contending with a sphinx, portraying Virchow's struggle with the mysterious origin of disease. The group stands on a solid rectangular pedestal with four doric columns

carved in relief at the corners. It is a very handsome and imposing design, but the local medical societies have presented an official protest against its adoption. They say that the idea of the mysterious, the fabulous and symbolic, is so entirely opposed to all Virchow's conceptions, his whole being breathing the most lucid and limpid clarity and simple truth, that the world of science protests against such an unworthy and uncharacteristic monument to his memory. He was the highest exponent of the search for exact truth, and they state that to hand down his memory to posterity in such an involved, symbolic fashion is to honor it no more than with some cheap decoration. Our Berlin exchanges speak of it in the same tone. The design that won the second prize represents the scientist seated in an academic chair on a broad, spreading pedestal. Both are illustrated in the *Deutsche Med. Wochft.* for May 17.

Medical Progress in Turkey.—The Constantinople correspondent of the *Lancet* states that the Ottoman government has decided to build a medical school at Salonica. The necessary funds will be contributed partly by the ministry of public instruction and partly by various municipalities. This medical school is intended to be erected on the same working principles as the one existing at Damascus. This is another proof of the progress which scientific medicine has made of late in the Ottoman empire. The Turkish metropolis now possesses a good number of hospitals and medical establishments, some of which are very well organized. The Imperial Military Medical School now supplies the Turkish army every year with a numerous staff, while the Imperial Civil School of Medicine sends out annually a large number of qualified practitioners into the provinces. The medical school which was erected not long ago in Damascus serves the provinces of Syria, and many of the more important cities in the various provinces now have a hospital. Steps have also been taken to create in the far-away districts institutes for hydrophobic patients on the model of the one working at present with fairly satisfactory results in Constantinople, and this has lately received additional equipment. Veterinary science, the importance of which is so obvious when a country depends largely on the proper development of agriculture, has made similar strides of late. The ministry of public instruction has lately ordered a large number of the most modern surgical instruments from Berlin. These have already arrived and form a valuable addition to the equipment of the medical schools.

Therapeutic Prevention of Syphilitic Infection.—An important experiment with inoculation of syphilis into a human being was recently reported to the French Académie de Médecine, but the strike among the printers has prevented the publication of the official reports of the proceedings. From accounts in our British exchanges for May 19 we learn that Metchnikoff and Roux, continuing their researches on monkeys, found their previous statements confirmed in regard to the effectual prevention of the development of syphilis if inoculation with virulent human material is followed at once with inunction of a 1 to 3 calomel and lanolin ointment. Their work in this line has already been mentioned in these columns on page 310. As experiments on more than a dozen monkeys had always given positive results, they considered themselves justified in experimenting on a human subject. A fourth-year medical student, free from syphilitic taint, inherited or acquired, volunteered for experiments. On February 1 he was inoculated with syphilitic virus from two chancres, one of eight to ten days' duration, the other a month old. The inoculation was made by scarification at the junction of the glans and prepuce. At the same time they inoculated four macaques and one chimpanzee with the same material. One hour after the inoculation the medical student and one of the macaques were given an inunction with the calomel ointment, which was rubbed into the inoculated parts for eight minutes. A second macaque was given the calomel inunction after twenty hours. The chimpanzee died in a few days of bronchopneumonia. The two control monkeys developed the primary sore seventeen days after the inoculation. The macaque treated twenty hours after the inoculation developed a chancre on the thirty-second day. No symptoms appeared in the medical student or in the macaque treated with the ointment, no signs or changes in the skin or mucous membranes, lymphatic glands or viscera. Three months having now passed since the experiment, Metchnikoff and Roux regard it as conclusive, demonstrating that calomel ointment can be used as a therapeutic preventive of syphilitic infection. Of course, the confirmatory experiment of inoculation of man without the preventive inunctions is out of the question, but the result of the single experiment is confirmatory of results obtained in similar experiments on monkeys. The calomel ointment did not cause any local irritation.

LONDON LETTER.

Gloves and Postmortem Examinations.

A postmortem clerk at the Westminster Hospital died from blood poisoning after performing a necropsy. He had been out of health and had recently returned from a holiday. He seemed so ill that the assistant pathologist put him off duty and completed the necropsy himself. The deceased had a number of small abrasions and did not wear gloves. At the inquest, on being questioned on this point, the assistant pathologist stated that at the Westminster Hospital gloves were never worn at necropsies. It was not a regulation, but a "principle founded on experience and common sense." In addressing the jury, the coroner said that though at Westminster Hospital it might be regarded as common sense not to wear gloves, it was not easy to say that institutions where gloves were worn were not actuated by common sense. As proofs of the risks run he stated that he had held inquests on the bodies of three mortuary keepers.

Medical Report on Ceylon.

The report of Sir Allan Perry, principal medical officer of Ceylon, which has just been issued, contains an interesting account of the medical condition of the island in 1904. The chief infectious diseases were cholera (7 cases and 4 deaths); smallpox (10 cases and 2 deaths); malaria (5,288 cases and 75 deaths); typhoid fever (341 cases and 70 deaths). Compared with the previous year, malaria was the only disease that showed an increase. The cases of cholera did not originate in the island, but were brought by a steamer. In regard to leprosy, Dr. Rost's "leprolin" serum was used with satisfactory results in three cases. Perhaps the most interesting feature of the report is the fact that Sir Allan Perry, unlike the great majority of colonial physicians, is a follower of Mr. Hutchinson in the belief that parangi or yaws is syphilis. He has instructed his officers to treat the cases more vigorously with antisyphilitic measures. The report of Dr. Aldo Castellani, who it may be remembered discovered the trypanosome of sleeping sickness, is of particular value. He has carried out much bacteriologic work on the island. For dysentery and paradysentery he has prepared a polyvalent vaccine, which is harmless. The blood of an inoculated person agglutinates the *Bacillus dysentericus* of Kruse in from twenty-four to forty-eight hours after inoculation. The immunization passes off in a few weeks. Dr. Castellani has determined the presence of three forms of dysentery. He finds that ipecacuanha has no effect on the amebic variety.

Report of the Antityphoid Inoculation Committee.

The committee appointed by the army council to investigate the value of methods of immunization against typhoid fever has held six meetings since its inauguration a year ago. It consists of Dr. W. Bulloch, Dr. P. Foord Caiger, Dr. James Galloway, Major W. B. Leishman, Dr. Bruce Low, Dr. A. Macfadyen and Prof. A. E. Wright, with Dr. C. J. Martin as chairman. It has now issued an interim report. It finds that antityphoid inoculation in the army has resulted in a substantial reduction in the incidence and death rate from typhoid fever among the inoculated. The statistical records support the scientific observations that the protective substances which are developed after inoculation are identical with those developed during typhoid fever, and that animals can be rendered resistant to typhoid fever by the same method. The committee recommends that the practice of voluntary inoculation against typhoid fever in the army be resumed. It also urges the army council to provide facilities for the following investigations: 1. Investigations with the present form of vaccine (standardized typhoid cultures sterilized by heating to 60 C.) on troops leaving for foreign service, with a view to determining the protective value of varying doses of vaccine, the number of doses to be given, and the duration of the protection conferred. 2. Investigations on animals in order to improve the vaccine if possible. 3. An investigation for the development of protective substances in the blood of patients suffering from and convalescent from typhoid fever. They also suggest the following arrangements: 1. Inoculation under careful supervision at least one month prior to embarkation of volunteers proceeding to India. 2. Attachment of a junior army surgeon to each regiment to proceed abroad and to remain with it for at least three years, acting under the directions of the committee as regards the inoculations and the collection of statistics in connection with them. 3. The collection by the headquarters of the army medical department of statistics relating to inoculations which may be carried out in addition to those mentioned above. The difficulties of the investigations will, it is thought, in the first instance, at least,

necessitate the active supervision of experts who have made a special study of this kind of research. Owing to the laboratories of the Royal Army Medical College being at present incomplete, vaccine must be derived from some other source to be approved by the committee. A minority report is made by Professor Wright and Dr. Bulloch, who, while agreeing with the general recommendations of their colleagues, think that the temporary calling in of experts is not sufficient. They suggest that a quasi-permanent organization is necessary in order that the vaccine and the details of the inoculations may be continually modified in the light of further research.

Pharmacology

Church Papers and Nostrums.

It is a very discreditable fact that in spite of good examples of right doing in the lay as well as in the religious press some church papers still retain their "patent-medicine" advertisements. The service of Mammon is evidently hard to give up. It is still more discreditable when a religious paper even indirectly lends its aid to the nostrum evil in its editorial columns, as appears to be the case with an eastern religious magazine, the *Watchman* of Boston, which tries to show that in case of sickness the alternative of a family of moderate means, owing to the expenses of trained nurses, doctors, etc., is between death, debt and self-administered medicines. It is a libel on the medical profession, which now as in times past, has ever been considerate of the true needs and conditions of its patrons, and it does not speak well for the intelligence of those who would mention self-administered nostrums, even by inference, as a preferable alternative to intelligent treatment in case of serious illness. Few religious papers have gone quite so far as this. The plea is generally made that the advertising department is out of editorial control. This, however, implies a weakness that practically amounts to a vice, and if religious papers can not promote the cause of religion without advertising alcoholic and narcotic-containing and habit-breeding nostrums, they had better go out of the business. It would be a good thing if some more of our profession would follow the example of Dr. Blair of Ohio and supply for the reading matter of these periodicals something in the way of a necessary antidote for their advertising columns. A word fitly spoken might stiffen the backbone of a weak brother in the editorial chair and, possibly, might induce him to apply the antidote himself, even if it had to be sandwiched between advertisements of Dr. Shoop's restorative and Drake's palmetto wine. A religious paper that in practical morals falls behind the best of the lay press is not deserving of Christian patronage.

Societies Take Action.

WESTERN DISTRICT (I. T.) MEDICAL SOCIETY.

At a recent meeting, held at Sapulpa, the following resolutions were adopted:

WHEREAS, The American Medical Association has seen fit to inaugurate a crusade against "patent medicines" and nostrums which will prove invaluable both to the public and to the medical profession; be it

Resolved, That the Western District Medical Society of Indian Territory heartily commends the action of the American Medical Association and wishes them success in this undertaking, and

Resolved, That this society proffers the services of this body and each individual in this valuable work.

ERIE COUNTY (PA.) MEDICAL SOCIETY.

At its last meeting this society expressed its approval of the efforts of the Council on Pharmacy and Chemistry of the American Medical Society and of *Collier's Weekly*, the *Ladies' Home Journal* and others to enlighten the profession and public in regard to the nostrum evil.

LUNA COUNTY (N. M.) MEDICAL SOCIETY.

At a full meeting of this society, with all the practicing physicians in the county present, the following resolution was unanimously adopted:

Resolved, That the opposition to the sale of "patent medicine" nostrums, now being waged against the nostrum venders of the United States by the medical profession and their representative, the American Medical Association, is the right move in the right direction, and is heartily indorsed by the Luna County Medical Society of Luna County, N. M.

MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND.

The following resolutions were adopted at the annual meeting of this society:

Resolved, That the Medical and Chirurgical Faculty of the State of Maryland expresses its hearty approval of the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry for the investigation of non-official drugs and medical preparations and endorses the plan of action proposed by the Council.

Resolved, That the Medical and Chirurgical Faculty of Maryland desires to record its appreciation of the change which has taken place in the advertising columns of THE JOURNAL of the American Medical Association and to express the hope that this JOURNAL will soon be entirely rid of advertisements that may in any sense be considered questionable. Looking to the accomplishment of such a state of affairs, the faculty hereby instructs its delegates to the American Medical Association to endeavor to induce the House of Delegates of that body to consider favorably the advisability of excluding all medical advertisements from the columns of THE JOURNAL.

OTHER SOCIETIES.

The Norfolk (Va.) Medical Society, at a meeting held May 8, adopted resolutions commending the Council on Pharmacy and Chemistry of the American Medical Association, as well as the *Ladies' Home Journal* and *Collier's Weekly*, for the stand they have taken against nostrums, condemning the advertisement of medicinal agencies in the lay press, denouncing manufacturers who advertise compounds, the formula of which is not given to the medical profession, discountenancing the practice of certain local druggists who advertise the products of such houses, and pledging the members of the society, so far as possible, not to allow their prescriptions to be filled with the products of such houses.

Dr. E. E. Clark, secretary of the Vermillion County (Ill.) Medical Society, reports that at a meeting held May 14, the society unanimously endorsed the action of the American Medical Association in appointing the Council on Pharmacy and Chemistry. The opinion was generally expressed that this was an attempt at a much-needed reform. *Collier's Weekly* and the *Ladies' Home Journal* came in for their share of commendation for the grand work they are doing.

The Camden County District (N. J.) Medical Society, at its annual meeting, adopted resolutions favoring the passage of the Pure Food Bill and the establishment of a department of public health.

Letters of Endorsement.

Dr. E. R. Herring, Shell Lake, Wis., secretary of the Washburn, Sawyer and Burnett Counties Medical Society, writes:

> "I take this opportunity to express the appreciation of the society of the work of the Council on Pharmacy and Chemistry. It is invaluable and can not be too much encouraged."

Dr. P. J. McCourt, New York City, writes:

> "I cordially endorse the general policy of the Association and of its JOURNAL."

Dr. J. Reynolds Brown, Tacoma, Wash., writes regarding the nostrum campaign:

> "I am heartily with you in the crusade."

Dr. John Fassett Edwards, Manila, P. I., writes:

> "Permit me to convey to you my keen approval of the good work you are doing in the battle against 'patent medicines' and their relatives. The struggle is certainly opportune and should not be relinquished until successful."

Dr. Edward P. Stimson, Tiverton, R. I., writes:

> "I am particularly interested in the 'secret' prescription work you are doing. Keep at it. Why should there be a mixture with a secret formula? Only to enrich the pocket of the producer. I can not see the necessity of any proprietary prescriptions any way. I and my pharmacopeia can write for and prepare anything needed in my work. This proprietary business, if there were no unusual profit in it, would soon become a thing of history."

Some Good Advice to Physicians.

Dr. Frank L. Day, president of the Providence Medical Association, in his annual address, published in the *Providence Medical Journal*, said: "We should publicly aid in the movement for the suppression of quack medicines in the interest of public health, as is being done by *Collier's Weekly* and the *Ladies' Home Journal*. And, first of all, we should turn the searchlight on our own prescription books lest recipes for antikamnia, sanmetto, and scores of secret or doubtful nostrums bear our signatures; for it is to be feared that few of us have warded off the lazy, insidious habit of ordering these ready-made preparations."

No Longer Members of the Proprietary Association.

The Fraser Tablet Company, Brooklyn, N. Y., have notified us that the firm is no longer a member of the Proprietary Association of America.

Formulas and Fatuity.

In an editorial with this title the *Druggists' Circular* makes the following pertinent comments regarding self-medication:

Nickle-in-the-slot therapy is a thing of the past, but many people are still living in the past. By this we mean that when a man is sick he can not ascertain the name of his disease and get a sure cure for it by dropping the price into the slot labeled with that name, and pressing on the lever. Many men and women—especially women—among the laity, seem to think that if they find in a book or paper a formula for a remedy for a certain disease, they can take that formula, get some of the medicine, and go forth armed to conquer any case of that particular malady which they come across; in short, that they know what the doctor knows about such cases and can do what he does. Such people, having no appreciation of the limitations of even the correct remedy, when such has been found, are a menace to the health of the community in which they are allowed to roam at large; and the greater the sphere of their activity the greater the menace.

Of course druggists, physicians and others who have studied a little bit about diseases and the means of their cure, know that mere formulas are for the fatuous, and that blind followers of printed directions for combating disease are fools.

In order that remedies may be applied in a more intelligent than a mere hit-or-miss manner, the man who has the remedies prepared and directs their application should be possessed of certain knowledge as to the temperament and surroundings of the patient, the stage to which the disease has arrived, its possible complications, and many other things connected with the case. Often the more he knows about these things the more he is convinced that the kind of remedy needed is one which can not be doled out by the spoonful in capsules. Recently a physician remarked that he had been doing a good deal of study along certain lines lately, and as a result many old troubles which he formerly had not been able to diagnose were now perfectly plain to him, while things about which he had had no doubts, had taken on a different and puzzling aspect.

When those who under the most favorable conditions have made a life study of disease, who are able to examine with an experienced eye the appearance of the patient, to observe his temperature, to inquire as to the food he eats, the water he drinks, the air he breathes, to post himself as to his family history, and to do all the things which doctors do, have to experiment and deliberate before saying just what treatment is required, does it not seem vain for a man who never saw the patient or who would not have known what was the matter with him if he had, to say that a preparation made by a certain formula is what the sufferer needs?

Medicine is a highly specialized science. Some of its votaries make a specialty of surgery, some of therapeutics, some of compounding remedies, and others of various other branches or subdivisions; and the man who can diagnose a case and prescribe for it may not be any more able to fill the prescription properly than the expert dispenser or manufacturing chemist is able to do the physician's part of the work.

The "Patent Medicine" Evil.

In his presidential address before the Nashville Academy of Medicine (*Southern Practitioner*, May), Dr. Lucius E. Burch discussed the "patent medicine" evil. He compared the nostrum evil to a plague which has wrecked homes, though it is supported by many newspapers and has millions backing it. To overcome it, he said it is absolutely necessary to have a united profession. He declared that while this evil is one which indirectly assists the medical profession financially by creating chronic sufferers, the majority of the laity believe that physicians oppose the use of these nostrums because they keep people from seeking medical advice. Dr Burch said that to remedy this state of affairs we must proceed in a sensible way by explaining to patients the dangers of taking drugs which produce unlooked for effects. He referred to the harm done by quack advertisements in the daily press and to the fact that millions are spent in advertising on condition that newspapers print nothing detrimental to the articles advertised. He praised the lay journals and papers which refuse such advertisements, particularly the work of the *Ladies' Home Journal* and *Collier's Weekly* in showing how fraudulent testimonials are obtained and how the business of these firms is carried on. He urged that the society endorse the passage of a law compelling all manufacturers of "patent medicines" to print the ingredients on the label.

Insurance Fees and Lodge Practice

Societies Take Action.

GUADALUPE COUNTY (TEXAS) MEDICAL SOCIETY.

At a recent meeting of this society the following resolutions were adopted:

WHEREAS, The class of examinations required by life insurance companies is of a nature which entails responsibility, and which in justice to the medical profession should not be made for a less fee than $5.00 heretofore allowed, and whereas we charge a similar fee to private patients for examinations of like character, therefore be it

Resolved, That we, the undersigned members of the Guadalupe County Medical Society hereby agree to make no examinations for any life insurance company, or society, for a less fee than $5.00.

Resolved, Further that these resolutions be forwarded to the respective life insurance companies whose accredited examiners we are:

M. B. Grace, A. L. Knolle, O. G. Pearson, Wm. Myers, T. W. Moore, A. M. Stamps, Seguin; J. W. Williams, Staples; J. M. Ehlert, Kingsbury; S. S. Beakley, Seguin; Louis Hirschfeld, E. G. Burgess, Marion; D. A. Watson, Schertz.

The Dauphin County (Ky.) Medical Society, about a year ago, amended its by-laws so that no member could examine applicants for life insurance for less than $5.

ACTION BY PHYSICIANS OF SELMA, ALA.

Dr. Clarence Ritter, Selma, Ala., sends us the following copy of an agreement signed by all the physicians of that city:

We, the undersigned practicing physicians of Selma, Alabama, hereby enter into and bind ourselves to the following agreement, to-wit: That on and after the 15th day of March, 1906, we will not examine applicants for what are known as "old line" insurance companies for less than five dollars ($5.00) for each examination.

T. G. Howard, Clement Ritter, B. B. Rogan, S. Kirkpatrick, Goldsby King, T. E. Lockhart, John T. Chapman, John P. Furniss, Samuel G. Gay, W. W. Harper, James Kenan, McLean Pitts, John N. Furniss, F. G. DuBose, I. C. Skinner, E. B. Ward.

Correspondence

Fraud Advertisements in Religious Journals.

FREDONIA, KAN., May 28, 1906.

To the Editor:—For several years I have been taking the *Christian Standard*, a religious weekly published by the Standard Publishing Co. of Cincinnati. "Patent-medicine" advertisements are scattered profusely throughout both the advertising pages and the reading matter. I have written several letters to the editor, but he has not replied to any of them.

Piso's consumption cure, sure cures for rheumatism, absorbent treatment for eye diseases, etc., are among the many advertisements. Inasmuch as a direct appeal to the publishers has had no effect, and has not even received the courtesy of a reply, and believing that it is not only dishonest but unchristian for any editor of a religious periodical to allow advertisements which are plainly fakes to appear week after week in his paper, I would like to ask every physician in the United States who has any influence with those reading the *Christian Standard* to make such representations as may seem fit and proper. I believe that in this way we can in time cause the editor of the *Standard* to take a little different view of his obligations to his readers.

I am strongly in sympathy with the stand taken by THE JOURNAL of the American Medical Association, and am in favor of ridding our state journals of the objectionable advertising matter. There are some independent journals that are strictly right; for instance, the *Medical World*, which has been one of the foremost of the independents. When I see some little editor attacking the American Medical Association and talking of medical politics, as being merely to promote the interests of those at the head, it makes me think of Landseer's painting "Dignity and Impudence." E. C. DUNCAN.

Marriages

JOHN P. GRIMES, M.D., to Miss Cora Wells Ritchie, both of Chicago.

EDWIN BROWN, M.D., to Miss Aida Stout, both of Philadelphia, May 29.

CARL L. LARSEN, M.D., Buffalo, Minn., to Miss Ruth Cooper of St. Paul, May 31.

COOPER R. DREWRY, M.D., to Miss Mary Tasker James, at Catonsville, Md., June 2.

FRANK M. RIDLEY, M.D., Jr., LaGrange, La., to Miss Mabel Hood, at Baltimore, June 6.

ARTHUR R. FLEMING, M.D., Tamaqua, Pa., to Miss Jennie Shelley of Newberry, Pa., June 2.

S. F. RUDOLF, M.D., Ellsworth, Wis., to Miss Mayette M. Casey of Oshkosh, Wis., May 22.

THERON E. QUIMBY, M.D., to Miss Katherine L. Gaffney, both of Syracuse, N. Y., May 22.

WILLIAM J. BAMBER, M.D., Wilson Mills, Mo., to Miss Florence Mathews of Salem, Mo., May 17.

ERNEST L. GATES, M.D., Kirkmansville, Ky., to Miss Fannie Bell Carter of Herndon, Ky., May 16.

ANDREW ALLISON O'DANIEL, M.D., to Miss Ethel I. Bower Goodwin, both of Philadelphia, June 4.

JOHN G. POINDEXTER, M.D., Bridgeport, Texas, to ANNIE E. LYNCH, M.D., of Terrell, Texas, May 29.

WILLIAM LAUNCELOT BROWN, M.D., to Miss Katherine Anna Murphy, both of El Paso, Texas, June 2.

EDWARD W. PERKINS, M.D., Jr., Reams, Va., to Miss Nolis Perkins of Dinwiddie County, Va., May 23.

FRANK T. BRIGHAM, M.D., Two Harbors, Minn., to Miss Katherine Thompson of Duluth, Minn., in April.

EDWARD CORNELIUS CARTLEDGE, M.D., Atlanta, Ga., to Miss Mary Meredith Rounsaville of Rome, Ga., June 6.

BENJAMIN VAN DOREN HEDGES, M.D., Plainfield, N. J., to Miss Adele Cutts Williams of Washington, D. C., in Chicago, June 6.

Deaths

Louis A. Weigel, M.D. University of Maryland, School of Medicine, Baltimore, 1875; one of the earliest to employ the Roentgen rays and an acknowledged authority on the subject; president of the American Orthopedic Association; a member of the Medical Society of the State of New York, American Electrotherapeutic Association, Monroe County Medical Society, Rochester Pathological Society and the Rochester Academy of Medicine; orthopedic surgeon to Rochester City and St. Mary's hospitals, and consulting orthopedic surgeon to the Craig Colony for Epileptics, Sonyea; professor of orthopedic surgery in Niagara University, Buffalo; who had been affected with malignant disease supposed to be due to the constant use of the x-rays which caused the loss of both of his hands in 1904 after repeated operations, died May 31 from a recurrence of the disease, at his home in Rochester, aged 52.

Cornelius Collins Beard, M.D. Jefferson Medical College; acting assistant surgeon in the Army during the Mexican War, and surgeon on the staff of General Beauregard during the Civil War; one of the founders of the New Orleans School of Medicine in 1856, and professor of anatomy in that institution; some time city physician of New Orleans; a specialist in diseases of the eye and ear, who established wards for the treatment of these diseases in Charity Hospital, New Orleans, died at his home in Brookline, Mass., May 15, from senile dementia, after an illness of three years, aged 78.

Philip H. Barton, M.D. College of Physicians and Surgeons in the City of New York, 1864; a member of the American Medical Association; the oldest practitioner of Danville, Ill.; assistant surgeon on the gunboat *Shamrock* during the Civil War; for many years local surgeon for the Wabash Railway Co., and chief examining surgeon of the pension department under the Cleveland administration, died at his home in Danville, Ill., May 29, from cerebral hemorrhage, after an illness of three weeks, aged 71.

Frederick Farwell Long, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1883, local physician in Chester, Pa., for the Pennsylvania System; a member of the Delaware County Medical Society; medical officer of the Pennsylvania Military College, Chester, and a member of the staff of the Chester Hospital, died at his home in Chester from typhoid fever, May 27, aged 41. At a meeting of the staff of the hospital, held May 29, resolutions of regret and condolence were adopted.

Darwin D. Eads, M.D. Jefferson Medical College, Philadelphia, 1859; a botanist of wide repute, whose contributions to the botanical collection of the Smithsonian Institution, Washington, included almost all the flora of the central states; a practitioner of Paris, Ky., for more than 40 years, and a member of the Mississippi Valley Medical Association, died suddenly at the home of his son in Chicago, May 27, from angina pectoris, aged 70.

Jacob S. Raub, M.D. Long Island College Hospital, Brooklyn, N. Y., 1864; a veteran of the Civil War, in which he served as assistant surgeon and was awarded a medal of honor by congress for gallantry in action; for many years an officer of the National Guard of Pennsylvania, and from 1897 to 1902 chief medical referee of the Pension Bureau, Washington, died suddenly in the Pension Office, May 21, from heart disease, aged 66.

George W. Johnson, M.D. College of Physicians and Surgeons, Chicago, 1895; after his graduation an interne in Cook County Hospital, and for three years a member of the medical staff of the Cook County Institutions, Dunning; a member of the American Medical Association, Illinois State Medical Society and Chicago Medical Society, who was operated on for appendicitis May 31, died at the Augustana Hospital, June 4, aged 45.

Samuel W. Wetmore, M.D. University of Buffalo, Medical Department, 1862; for about 15 years professor of surgery and materia medica in the University of Buffalo; once president of the Erie County Medical Society; surgeon in the Army during the Civil War; for several terms health physician of Buffalo, died at his home in that city, May 28, from cerebral hemorrhage, after an illness of one week, aged 74.

Charles Warrenne Allen, M.D. College of Physicians and Surgeons in the City of New York, 1878, of New York City; for several years a member of the American Medical Association; a member of the New York Dermatological Society and American Dermatological Association; professor of dermatology in the Post-Graduate Medical School, died from typhoid fever in the Colonial Hospital, Gibraltar, May 30, aged 51.

James Winniett Digby, M.D. McGill University, Medical Department, Montreal, 1862; for nearly 40 years a practitioner of Brantford, Ont., acting assistant surgeon in the Army and afterward regimental surgeon of the Sixteenth United States Infantry during the Civil War; councilor and deputy reeve of Brantford, and for three years mayor of that city, died at his home, May 29, suddenly from heart disease, aged 64.

Francis L. Shepard, M.D. University of Buffalo, Medical Department, 1896, of Buffalo, N. Y., was found dead on the tracks of the Erie Railway near Batavia, N. Y., early on the morning of May 26, aged 39. As valuables which he was known to possess were missing, he is supposed to have been murdered and his body placed on the tracks.

N. J. Alexis Mueller, M.D. Chicago Medical College, 1886; vice-president of the Cedar Valley and Dubuque (Ia.) Medical Association; for 17 years chief medical examiner of the Roman Catholic Protective Society of Iowa, died at his home in Dyersville, Iowa, May 23, from cerebral hemorrhage, after an illness of two months, aged 61.

John Denniston, M.D. New York University, New York City, 1867; hospital steward in the Army during the Civil War, and for 39 years a leading practitioner of Seneca County, N. Y.; president of Ovid for two terms and once coroner of Seneca County, died at his home in Ovid, May 24, after an illness of four weeks, aged 62.

Herbert W. Rogers, M.D. Northwestern University Medical School, Chicago, 1903, of Montevideo, Minn., a member of the Minnesota State Medical Society, died May 10 from septic peritonitis, due to abscess following an operation for appendicitis nine months before, in St. Barnabas' Hospital, Minneapolis, aged 27.

Daniel Lee Jewett, M.D. College of Physicians and Surgeons in the City of New York, 1862; a member of the American Medical Association, Illinois State Medical Society and Iroquois County Medical Society; a practitioner of Watseka, Ill., for more than 40 years, died at his home in that place, June 5.

Edwin M. McAffee, M.D. Hahnemann Medical College, Philadelphia, 1855; Philadelphia Medical College, 1855; formerly of Clinton, Iowa, and for several years physician in charge at Mudlavia, Ind., died in a hospital in Chicago, May 27, from osteosarcoma, after an illness of nearly three years, aged 73.

Isaac M. Neely, M.D. (Years of Practice, Illinois), 1887; for many years recorder of vital statistics in the office of the clerk of Cook County; formerly a practitioner of Benton and of Du Quoin, Ill.; for eight years postmaster of the latter town, died at his home in Evanston, June 4, aged 80.

Frederick Preiss, M.D. Trinity Medical College, Toronto, 1890, of Buffalo, N. Y.; a member of the Medical Union, Buffalo Academy of Medicine, and Erie County Medical Society, died at the Sisters' Hospital in Buffalo, May 30, twelve days after an operation, aged 37.

Houston T. Guinn, M.D. Medical Department, University of Texas, Galveston, 1892, a member of the State Medical Association of Texas and of the Leon County Medical Society, died from pneumonia at his home in Roger's Prairie, Texas, February 27.

Elbridge Meighs Palmer, M.D. Ohio Medical College, Cincinnati, 1881; Bellevue Hospital Medical College, New York City, 1882, died at his home in Warren, Ind., May 18, from rheumatism and dropsy, after an illness of nearly nine years, aged 51.

Jacques J. Trudell, M.D. University of Vermont, Medical Department, Burlington, 1886, a member of the Rutland County Medical Association, died at his home in Rutland, Vt., May 18, from tuberculosis, after an illness of seven months, aged 43.

Albert H. Wilton, M.D. Detroit (Mich.) College of Medicine, 1900, contract surgeon United States Army, formerly of Flat Rock, Mich., on duty at the Army Medical School, Washington, D. C., died in that city recently, and was buried May 26.

George N. Swartz, M.D. Bellevue Hospital Medical College, New York City, 1875, president of the Northampton County (Pa.) Medical Society, died May 23 at his home in Pen Argyl, Pa., from pneumonia, after a short illness, aged 55.

Elijah Carroll Dycus, M.D. 1843; the pioneer practitioner of Jackson Purchase, Ky.; a member of the Marshall County Medical Society, died at his home in Benton, Ky., March 5, from uremia, after an illness of one day, aged 86.

Smith Dayton Steer, M.D. Cleveland, 1856, for many years a practitioner of Burton, Ohio, and surgeon in the Army during the Civil War, died suddenly at his home in Tacoma, Wash., from heart disease, April 20, aged 79.

Edwin W. Thomas, M.D. Medical Department, Arkansas University, Little Rock, 1880, of Booneville, Ark., died in Magazine, Ark., May 28, from the effects of an overdose of morphin, taken with suicidal intent.

Spencer P. Irvin, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1900, of Philadelphia, died in the hospital of the University of Pennsylvania, from typhoid fever, May 30, aged 27.

B. J. Miles, M.D. Memphis Hospital Medical College, 1892, a member of the State Medical Association of Texas and of the Hunt County Medical Society, died at his home in Merit, Texas, Dec. 26, 1905, aged 42.

John R. Maxwell, M.D. Keokuk (Iowa) Medical College, 1896, lecturer on diseases of the rectum and assistant to the chair of surgery in his alma mater, died at his home in Keokuk, June 4, from nephritis.

Homer Summerville Quinn, M.D. (Examination, Ohio), once a representative from Madison County in the legislature, died at his home in West Jefferson, Ohio, May 17, after an illness of seven months, aged 69.

Joseph Ambrose Dean, M.D. Baltimore University, School of Medicine, 1901, died at his home in New York City, May 14, from endocarditis following septicemia, after an illness of seven weeks, aged 31.

Zelman E. Scott, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1900, of Barren Plains, Tenn., died at the home of his sister in Springfield, Tenn., May 22, after a long illness, aged 29.

John W. Frost, M.D. Howard University, Medical Department, Washington, D. C., died at his home in Washington, May 17, from the effects of carbolic acid accidentally administered, aged 50.

H. C. Spears, M.D. Transylvania University, Medical Department, Lexington, Ky., 1850, for many years a practitioner of Taylor, Texas, died at his home near Hillsboro, Texas, May 18, aged 78.

Amelia A. Dolson, M.D. (Examination, New York), for many years a practitioner of Buffalo, died in Rome, N. Y., April 25, from pneumonia, after an illness of two days, aged 74.

David Ernest Sedgwick, M.D. Rush Medical College, Chicago, 1877, formerly a member of the Wisconsin legislature, died at his home in York, Neb., May 17, from heart disease, aged 55.

Henry Clay Black, M.D. 1850, a member of the Stillwater Medical Association, died at his home in Freeport, Ohio, April 25, from vesical hemorrhage, after an illness of 16 days, aged 80.

Jesse B. Stone, M.D. Bellevue Hospital Medical College, New York City, 1890, of New York City, died suddenly at the home of his parents in Wichita, Kan., from uremia, May 23, aged 39.

Hugh A. McFatrich, M.D. Eclectic Medical Institute, Cincinnati, 1852, for 30 years a practitioner of Red Oak, Iowa, died recently at the home of his daughter in Denver, Colo., aged 82.

Fritz Mechtold, M.D. New York University, New York City, 1881, an inspector of the New York health department, died at his home in Stapleton, Staten Island, May 19, aged 54.

Jacob Hoke, M.D. Chicago Medical College, 1869, one of the oldest medical practitioners in Illinois, died at his home in Cordova, May 28, from senile debility, aged 90.

Leander Snyder, M.D. Cincinnati Medical College, 1848, died at his home in Lafayette, Ind., May 20, from cerebral hemorrhage, after an illness of ten days, aged 79.

W. Updyke Selover, M.D. New York University, New York City, 1864, in 1888 mayor of Rahway, N. J., died at his home in Newark, N. J., May 21, aged 64.

T. M. Goldsberry, M.D. Kansas City (Mo.) Medical College, 1880, of Viola, Kan., died from tuberculosis in San Antonio, Texas, May 18, after a long illness.

Isaac G. Wheeler, M.D. Albany (N. Y.) Medical College, 1874, died at his home in Buffalo, N. Y., May 22, after an illness of one week, aged 74.

James A. Knight, M.D. Atlanta (Ga.) Medical College, died at his home in Eatonton, Ga., from nephritis, after a prolonged illness, May 19.

C. W. Miller, M.D. Missouri Medical College, St. Louis, 1877, formerly of Doniphan and Toledo, Mo., died at Excelsior Springs, Mo., May 17.

Albert Toepfer, M.D. Göttingen, 1873, died at his home in Jersey City, May 18, from angina pectoris, after an illness of six weeks, aged 57.

Claude R. Norton, M.D. New York Homeopathic Medical College and Hospital, 1872, died at his home in Philadelphia, May 31.

John F. Edwards, M.D. New York University, New York City, 1848, died at his home in Raritan, N. J., May 23 aged 87.

George Given, M.D. Marion-Sims College of Medicine, St. Louis, 1892, died at his home in Mexico, Mo., May 14.

James Mosgrove, M.D. Medical College of Ohio, Cincinnati, 1846, died recently at his home in Havana, Ohio.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

METHOD OF DETERMINING THE OPSONIC INDEX.

COLORADO, TEX., May 23, 1906.

To the Editor:—Please tell me where I can ascertain the method of determining the opsonic index after Wright.

THEODORE MERRILL.

ANSWER.—The method of obtaining the opsonic index is briefly as follows: A certain amount of the serum of the patient whose index we wish to determine is mixed with, let us say, the same amount of a suspension of blood corpuscles, washed three or four times in physiologic salt solution in order to remove all traces of plasma or serum, and to this mixture is added a small quantity of a homogeneous suspension in salt solution of the particular bacterium on which we wish to test the opsonic power. The mixtures for the control tests are made exactly in the same way except that in one the serum of a normal person is substituted for the serum of the patient, and that in the other serum is replaced by physiologic salt solution. After thorough mixing of the ingredients these mixtures are placed at 37 C. for 30 minutes or so when smears are made and stained and the average number of bacteria taken up by the leucocytes determined by counting the number of bacteria in, say, 40 leucocytes from each mixture and dividing the total number of bacteria obtained in this way in each case by the number of leucocytes counted. The opsonic index is the relation of the number of bacteria taken up by the leucocytes in the mixtures containing

the patient's serum to the number taken up by the leucocytes in the mixtures containing the normal serum.

The following outline may serve to illustrate the foregoing explanations:

Mixtures.	Average phagocytosis (40 leucocytes counted).
1. Serum of tuberculous patient 0.1 c.c. + washed blood 0.1 c.c. + suspension of Tubercle B. 0.1 c.c..	3
2. Serum of normal person 0.1 c.c. + washed blood 0.1 c.c. + suspension of Tubercle B. 0.1 c.c.....	4
3. NaCl solution 0.1 c.c. + washed blood 0.1 c.c. + suspension of Tubercle B. 0.1 c.c.....	0.1

In this case, the opsonic index of the tuberculous patient is .75 (3 ÷ 4 = .75); if the figures are reversed the index will be 1.33 (4 ÷ 3 = 1.33), as compared with 1, the normal index. The result indicated in the third mixture emphasizes the fact that in the absence of serum there is very little phagocytosis. It is necessary in this work to make sure that the corpuscles used have been washed quite free of serum, and this is the reason for the third mixtures.

The blood necessary for these tests is obtained easily from the lobe of the ear, a few drops being collected in a small *u*-shaped tube that is centrifugated in order to free the corpuscles from the plasma which is withdrawn with a fine pipette. The corpuscles can now be washed in salt solution. In order to prevent all clotting a small amount of citrate solution may be mixed with the blood, but this is really not essential. The point is that the various mixtures be so made that the results are comparable. The mixing may be done in small pipettes marked so that the same quantity of the various ingredients may be drawn in. After mixing thoroughly by drawing the fluids in and out, the pipette with contents is placed in the incubator.

It is quite impossible to describe fully all the details. The only way to learn all about them is by practical work in the laboratory. Thus the preparation of uniform suspensions of tubercle bacilli, for instance, requires special methods which are described by Wright (*Lancet*, 1904, vol. ii, p. 1138). In the case of other bacteria the main points are to secure uniform suspensions of proper density. If too many bacteria are present the leucocytes may be so crowded with bacteria that the latter can not be counted with accuracy. As to staining methods, Leischmann's method or some modification, e. g., Wright's, answers very well for ordinary bacteria. In the case of mixtures containing tubercle bacilli carbolfuchsin followed by acid and methylene blue gives serviceable pictures. The whole literature on phagocytosis and opsonins is discussed by Hektoen in THE JOURNAL for May 12, 1906, and those who wish to learn more about the actual technical details should read particularly the earlier articles by Wright and Douglas and by Leishmann referred to in Hektoen's article.

PREVENTION OF MOSQUITO BITES.

MELLEN, WIS., May 24, 1906.

To the Editor:—Will you please send me a formula for a solution to use on the face and hands to keep mosquitoes and flies away. They are very troublesome here and I can not find anything to help me.

ANSWER.—Oleum hedioma (American pennyroyal) is a very good remedy applied locally to the hands and face.

State Boards of Registration

COMING EXAMINATIONS.

MICHIGAN State Board of Registration in Medicine, Ann Arbor, June 12. Secretary, B. D. Harlson, Sault Ste Marie.

SOUTH CAROLINA State Board of Medical Examiners, Columbia, June 12. Secretary, W. M. Lester, Columbia.

TEXAS State Board of Medical Examiners, Dallas, June 12. Secretary, T. T. Jackson, San Antonio.

OHIO State Board of Medical Registration and Examination, Cincinnati, Cleveland and Columbus, June 12-14. Secretary, George H. Matson, Columbus.

BOARD representing the Medical Society of Delaware and Board representing the Homeopathic Medical Society of Delaware State and Peninsula, former held at Dover, and latter at Washington, June 19. Secretary, P. W. Tomlinson, Wilmington.

NEW JERSEY State Board of Medical Examiners, Trenton, June 19-20. Secretary, E. L. B. Godfrey, Camden.

NEW YORK Boards of Medical Examiners, Albany, June 19-22. Secretary, Charles F. Wheelock, Albany.

PENNSYLVANIA State Board of Medical Examiners, Annex Hotel, Pittsburg, and North Building, Philadelphia, June 19-22. Secretary, Joseph E. Willetts, Pittsburg.

VIRGINIA State Board of Medical Examiners, Richmond, June 19-22. Secretary, R. S. Martin, Stuart.

MARYLAND Board of Medical Examiners, Baltimore, June 20-23. Secretary, J. McP. Scott, Hagerstown.

Arkansas April Report.—Dr. J. P. Runyan, secretary of the State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, April 10, 1906. The number of subjects examined in was 7; total number of questions asked, 52; percentage required to pass, 75. The total number of candidates examined was 96, of whom 66 passed, including 48 non-graduates, and 30 failed, including 28 non-graduates. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Memphis Hospital Med. Coll., (1885) 75; (1892) 75; (1896)		75
Louisville Med. Coll.	(1874)	75
Keokuk Med. Coll.	(1876)	75
Baltimore University	(1905)	87
Vanderbilt University	(1901)	77
Barnes Med. Coll.	(1895)	75
University of Arkansas	(1906) 75, 76, 82	86
Bellevue Hospital Med Coll.	(1896)	75
University of Tennessee	(1884)	75
University of Louisville	(1896)	75
Northwestern University	(1890)	75
University of Virginia	(1901)	92
Hannibal Med. Coll., Memphis, Tenn.	(1895)	75

Non-graduates, the grade of 75 was reached by eleven, 76 and 77 by four each, 78 by two, 80 by seven, 81 and 82 by two each, 83 by three, 84 by two, 85 by four, 86 by one, 87 by three, 88, 89 and 92 by one each.

FAILED.

University of Louisville	(1875)*	
University of West Tennessee	(1906)	38

* Failed on account of sickness.

Non-graduates, the grade of 48 was reached by one, 51 by two, 57, 58, 59, 61 and 63 by one each, 64, 65, 66 and 67 by two each, 68 by one, 71 by two, 72 and 73 by two each, and 74 by one. In two cases no grade was given.

The following questions were asked:

ANATOMY.

1. At what time in the development of the fetus is the hair formed. 2. Describe a red blood corpuscle. 3. Describe the ulna. 4. Name the peculiar ribs. 5. Describe the deltoid muscle. 6. Name nerve supply of the stomach. 7. Bound Scarpa's triangle. 8. Name the lobes of the liver. 9. Name the glands of the alimentary tract. 10. Name the muscles of the eyeball.

SURGERY.

1. Describe fully the symptoms of acute suppurative appendicitis and give the treatment. 2. Describe a gastroenterostomy and name the indications for the operation. 3. Describe a Colle's fracture and give the treatment. 4. Define cholecystitis and describe the surgical treatment. 5. Describe the operation of trephining and give some of the indications for the operation. 6. Give general rules governing the treatment of gunshot wounds of the abdomen. 7. What are hemorrhoids? Give their cause, classification, diagnosis and surgical treatment. 8. In a case of anuria, how would you determine whether due to suppression or retention? Name the causes of retention of urine and give treatment.

MATERIA MEDICA AND THERAPEUTICS.

1. What is the difference between empirical and rational therapeutics? 2. Name four ways by which medicine may be introduced into the circulation. 3. Name four classes of medicine and give example of each class. Give dose of each example. 4. In what manner do emetics act? Name two vegetable and two mineral emetics. 5. From what is salicin derived? Give first dose and physiologic effect. 6. What precaution would you use in the administration of chloroform? 7. Give physiologic effect of opium and treatment of opium poisoning. 8. Strychnia poisoning is similar to what disease? How would you distinguish them? 9. Give indications for the use of aconite in the early stage of pneumonia. 10. Write a complete prescription for a brisk cathartic containing not less than three ingredients.

PHYSIOLOGY.

1. Give location, size, capacity and function of the stomach. 2. Describe the mechanism of gastric secretion. Give composition of gastric juice. 3. Describe the mechanism of absorption. 4. What is meant by internal secretion? 5. (a) Describe in detail, the medulla oblongata and give its function. (b) Name some of the special nerve centers located there.

PRACTICE OF MEDICINE.

1. What is the one characteristic physical sign of pneumonia? When heard? 2. Give treatment of specific urethritis. 3. What is the clinical significance of the constant appearance in the urine of albumin? Of sugar? 4. Give diagnosis and treatment of pleuritic effusion. 5. Differentiate between cerebral anemia and hyperemia and give treatment for each condition. 6. Give diagnosis and treatment of malarial hematuria.

CHEMISTRY.

1. What is meant by specific gravity? 2. What liquid is used as the standard by which the specific gravity of another liquid is tested? 3. Give chemical composition of human urine. 4. Give specific gravity (approximately) of normal healthy urine. 5. Is urine acid or alkaline? 6. What is urea? 7. Give test for albumin in urine. 8. Give test for sugar in urine.

OBSTETRICS.

1. How does the peritoneum cover the uterus? What and where are the ovaries? 2. What is the danger of incomplete abortion? Give treatment of same. 3. What are the indications for the use of the forceps? Would you tie the cord before or after the child cries. Why? 4. Define cephalhematoma; caput succedaneum and explain difference. 5. What is treatment of septic infection of the breast.

Arkansas Eclectic April Report.—Dr. J. L. Vail, secretary of the Eclectic State Medical Board, reports the written examination held at Little Rock, April 9-10, 1906. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. Two candidates were examined, one of whom was a graduate of Bennett Medical College, Chicago, 1883, and the other an undergraduate.

Georgia April Report.—Dr. E. R. Anthony, secretary of the Regular Board of Medical Examiners of Georgia, reports the written examination held at Augusta, April 3-4, 1906. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 39, all of whom passed. The following colleges were represented:

PASSED.	Year Grad.	Per Cent.
College.		
University of Georgia, (1903) 88; (1906) the grades of 78 and 79 were reached by one each, 80 was reached by two, 81 by three, 82 by two, 83 by seven, 84 by one, 85 by three, 86 and 87 by two each, and 88 by four.		
Howard University	(1905)	83, 86
Maryland Med. Coll., (1904) 78, 81; (1905) 83, 85, 85, 85; (1906) 75.		
Chattanooga Med. Coll.	(1903)	79

The following questions were asked at the examination held at Augusta, April 3-4:

PHYSIOLOGY.

1. Describe a white blood corpuscle. Where are they formed? What is their function and what is their ultimate end? 2. The salivary secretion is derived from what three glands? What is the physiological action of saliva? 3. What are the three motions of the heart and their cause? 4. What is the volume of air taken in the body in an ordinary inspiration? How is this chemically represented, and how much of the O is absorbed? 5. What is the result of a lesion of the spinal cord in the cervical region? In the sacral region?

PATHOLOGY.

1. Mention the pyogenic bacteria. 2. Describe the blood changes in pernicious anemia. 3. Give the structural changes which take place in chronic and acute appendicitis. 4. Differentiate between a typhoid ulcer and a tuberculous ulcer of the intestines. 5. Describe the process of repair.

GYNECOLOGY.

1. Define menorrhagia and metrorrhagia. (a) Give causes and treatment. 2. Describe an operation for the repair of a lacerated cervix. 3. Give symptoms of carcinoma of the uterus. (a) Treatment. 4. Define retroversion and retroflexion of the uterus. (a) symptoms and treatment. 5. Give symptoms and treatment of ectopic gestation.

PRACTICE.

1. Define lobar pneumonia. (a) Give symptoms and treatment. 2. Define malaria. (a) Give prophylactic and medical treatment. 3. Differentiate between chicken pox and smallpox. 4. Define measles; point out the most dangerous complications. 5. Differentiate true croup and spasmodic.

OBSTETRICS AND DISEASES OF CHILDREN.

1. Give symptoms, causes and treatment, of acute mastitis? 2. Give principal causes and treatment of rupture of uterus. 3. Treatment of inertia uteri. 4. Differentiate between diphtheria and the disease with which it might be confounded. 5. Give treatment of bronchopneumonia.

CHEMISTRY.

1. Give the formula of each of five compounds, giving the name in each case and the dose. 2. Give the name and formula of Epsom salt, Glauber salt and Rochelle salt. 3. Mention five mineral poisons and give the antidote for one of them. 4. Name the non-metallic chemical elements, which in various combinations are found in the tissues of the body. 5. How may you decide whether a urinary deposit is urates or phosphates?

ANATOMY.

1. Describe the inferior maxillary bone. 2. Name muscles of posterior tibeo-fibula group, superficial and deep. (a) Give origin and insertion of (1) Pectorails major; (2) External oblique; (3) Sartorius; (4) Triceps muscles. 3. Give course, relations and branches of external carotid artery. (a) Give blood supply of rectum. 4. Give origin, course and distribution of great sciatic nerve. (a) Give nerve supply of heart. 5. Describe the stomach.

SURGERY.

1. Give treatment, constitutional and local, of burns. 2. Name the varieties of fractures. (a) State the cardinal principles in the treatment of fractures. 3. Describe an operation for the radical cure of oblique inguinal hernia. 4. Define hemorrhoids. (a) Give varieties and treatment. 5. Define a chancre. (a) State period of primary and secondary incubation. (b) Treatment, local and constitutional.

MATERIA MEDICA AND THERAPEUTICS.

1. Source of ergot; define its use in obstetrics. 2. Name four preparations of mercury; give dose of each. 3. Source of quinin; for what is it a specific? 4. What is meant by hemostatics? Describe their mode of action; name several of them. 5. Write a prescription for a general tonic with tincture nux vomica and a preparation of arsenic.

OBSTETRICS AND DISEASES OF CHILDREN.

1. How would you manage a shoulder presentation? 2. Differentiate between a five months' pregnancy ovarian-cystoma-ascites and uterine fibroid. 3. What is the Braxton-Hick's sign of pregnancy? How obtained? 4. Under what condition would you be justified in inducing premature labor? 5. What direction would you give the nurse as to care of infant during first week?

The following questions were asked at the examination held at Atlanta, April 5-6:

PHYSIOLOGY.

1. Describe a red blood corpuscle. How are they formed? Give function and relative number to the white corpuscles. 2. What effect has pancreatic juice on proteids? On carbohydrates? On fats? 3. What is the heart's size, weight and capacity per beat? How much force does it put out at each systole? 4. What quantity of air per hour is necessary for health? What proportion of CO_2 in the air would make it dangerous? 5. What effect has section of the anterolateral columns of the spinal cord? Of the posterior columns?

PATHOLOGY.

1. Define pathology. 2. What steps are necessary in preparing a pathologic specimen for microscopic examination? 3. Give steps in examination of blood to determine the presence of malarial parasite. 4. Describe the pathologic changes in liver produced by cirrhosis (interstitial hepatitis). 5. Differentiate between fatty degeneration and fatty infiltration. 6. Give diagnostic points relative to carcinoma. 7. Describe changes in the tissue produced by tuberculous infection. (Answer five of these questions.)

GYNECOLOGY.

1. Describe the ligaments of the uterus. 2. Describe the blood supply of the uterus and ovaries. 3. Give symptoms and treatment of fibroid tumors of the uterus. 4. Describe an operation for the repair of a complete laceration of the perineum. 5. Describe an operation for the removal of the uterus through the vagina.

PRACTICE.

1. Gallstones; their origin, symptoms and treatment. 2. Etiology and treatment of rickets. 3. Define scarlet fever; outline method of handling same. 4. Enterocolitis; etiology and treatment. 5. Typhoid fever; general prevalence and modes of conveyance.

OBSTETRICS AND DISEASES OF CHILDREN.

1. What symptoms would make you positive of the diagnosis of pregnancy at three months? 2. Diagnosis and treatment of fetal death in utero. 3. Give treatment of prolapse of cord. 4. Differentiate between ileocolitis and cholera infantum. 5. Give early symptoms and usual courses of hip-joint disease.

CHEMISTRY.

1. Give the symbol, valence and a principal compound of each of five chemical elements. 2. Give the chemical name and formula of sugar of lead, blue stone, copperas. 3. Mention five vegetable poisons and give the antidote for one of them. 4. What metallic chemical elements are found in various combinations in the body? 5 How much urea is voided by a healthy adult in 24 hours? How may the amount be determined?

ANATOMY.

1. Describe the humerus. 2. Name the muscles of anterior radio-ulna group. (a) Give origin and insertion of following muscles: (1) Biceps, (2) gastrocnemius, (3) supinator longus, (4) tibialis anticus. 3. Give course, relations and branches of the common femoral artery. (a) Describe the "Circle of Willis." 4. Give origin and distribution of the pneumogastric (vagus) nerve. (a) What nerve supplies the diaphragm. 5. Give relations of the liver; name lobes of liver.

SURGERY.

1. Define fistula in ano. (a) State varieties. (b) Treatment. 2. How would you differentiate between concussion and compression of the brain? 3. Give rules for governing you in trephining. (a) Describe the operation. 4. Describe an operation for removing stones from the male bladder. (a) Give your preference and state reasons.

MATERIA MEDICA AND THERAPEUTICS.

1. Source of strychnin; dose, therapeutic indication. 2. What is Fowler's solution; dose of same. 3. Give chief alkaloids of opium, belladonna, hyoscyamus, stramonium; give dose of each. 4. Give symptoms of acute and chronic lead poisoning; treatment. 5. Name the chief heart depressants and their indications.

OBSTETRICS AND DISEASES OF CHILDREN.

1. Diagnose breech presentation. What are the dangers to the mother and child? Give treatment. 2. Give presumptive, probable, positive signs of extranterine pregnancy. 3. What is Hegar's sign? 4. Discuss nephritis as a complication of pregnancy. 5. What is the average length and weight of a full term fetus?

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending June 2, 1906:

Duncan, Louis C., asst.-surgeon, granted fifteen days' leave of absence.

Whitmore, E. R., asst.-surgeon, order of relief from duty at Fort Jay, N. Y., and assignment to duty at Fort Warren, Mass., is revoked.

Grissinger, Jay W., asst.-surgeon, relieved from duty at Fort Jay, N. Y., and ordered to Fort Warren, Mass., for duty.

Ekwurzel, Geo. M., asst.-surgeon, ordered to proceed from West Point, N. Y., to Army General Hospital, Washington Barracks, D. C., for temporary duty.

Crosby, Wm. D., surgeon, granted fourteen days' leave of absence.

Duval, Douglas F., asst.-surgeon, leave of absence extended twenty days.

Wells, Francis M., contract surgeon, ordered, on arrival at Fort Niagara, N. Y., to Fort Robinson, Neb., for duty. Granted leave of absence for ten days.

Ware, William H., dental surgeon, returned to Fort Wingate, N. M., from leave of absence.

Halliday, Francis A., contract surgeon, granted leave of absence for fifteen days.

Slater, Ernest F., contract surgeon, returned to Fort Hancock, N. J., from temporary duty at Fort Hamilton, N. Y.

Adair, George F., contract surgeon, returned to Fort Wadsworth, N. Y., from temporary duty at Madison Barracks, N. Y.

Williamson, J. William, contract surgeon, granted leave of absence for ten days.

Campbell, George F., contract surgeon, ordered from Wheatland, Wyo., to Philippine service.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending June 2, 1906:

Iden, J. H., P. A. surgeon, detached from the Naval Hospital, Newport, R. I., and ordered to the *Columbia*.

Brown, E. M., P. A. surgeon, detached from the Naval Hospital, New York, N. Y., and ordered to duty in the department of government and sanitation, Ancon, Panama.

Simons, M. H., medical director, detached from duty in command of the Naval Hospital, Mare Island, Cal., and ordered to duty in command of the Naval Hospital, Philadelphia, Pa.

Persons, R. C., medical director, detached from duty in command of the Naval Hospital, Norfolk, Va., and ordered to duty in command of the Naval Hospital, Mare Island, Cal.

Kindleberger, C. P., surgeon, detached from the *Independence* and ordered to the Asiatic station.

Farenholt, A., surgeon, ordered to the *Independence*.

Lee, A. E., asst.-surgeon, appointed assistant surgeon, with rank of lieutenant junior grade, from May 9, 1906.

Dollard, H. L., surgeon, appointed acting assistant surgeon, from May 26, 1906.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending May 30, 1906:

Blue, Rupert, P. A. surgeon, relieved from special temporary duty in San Francisco, Cal., and directed to proceed to Washington, reporting at Bureau.

Amesse, J. W., P. A. surgeon, directed to proceed to Stapleton, N. Y., for special temporary duty, on completion of which to rejoin station at Ellis Island, N. Y.

Lloyd, B. J., P. A. surgeon, leave of absence granted for fifteen days, from May 1, 1906, revoked.

Lloyd, B. J., P. A. surgeon, relieved from duty at Guayaquil, Ecuador, and directed to proceed to Fort Stanton, N. M., for duty and assignment to quarters; order revoked.

Ebert, H. C., asst.-surgeon, relieved from duty at Seattle, Wash., and assigned to duty on the U. S. Revenue Cutter *Perry*.

Pettyjohn, Joseph, asst.-surgeon, assigned to duty on the U. S. Revenue Cutter *Thetis*.

Frost, W. H., asst.-surgeon, relieved from duty at Baltimore, Md., and assigned to duty on the U. S. practice ship *Chase*.

Kennedy, S. R. M., acting asst.-surgeon, granted leave of absence for four days, from May 27, 1906.

Rice, W. E., acting asst.-surgeon, granted leave of absence for five days, from June 2, 1906.

Watters, M. H., pharmacist, relieved from temporary duty in San Francisco, Cal., and directed to rejoin station in Chicago.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended, June 2, 1906:

SMALLPOX—UNITED STATES.

California: Los Angeles, May 12-19, 6 cases.
Colorado: General, April 1-30, 16 cases.
Florida: General, May 19-26, 2 cases.
Illinois: Galesburg, May 19-26, 1 case.
Kentucky: Covington, May 19-26, 1 case.
Louisiana: New Orleans, May 12-19, 5 cases, 1 death.
Massachusetts: Boston, May 19-26, 2 cases; Quincy, 2 cases.
Mississippi: Natchez, May 12-19, 1 case, imported.
Missouri: St. Louis, May 19-26, 4 cases.
New York: New York, May 19-26, 2 cases.
Ohio: Cincinnati, May 18-25, 10 cases.
Oklahoma: Oklahoma City, May 12-26, 13 cases.
Pennsylvania: Altoona, May 19-26, 1 case, imported; Lancaster, 2 cases, 1 death; Pittsburg, May 12-19, 2 cases.
Tennessee: Knoxville, May 19-26, 1 death.
Utah: General, April 1-30, 76 cases.
Virginia: Petersburg, May 19-26, 1 case.
Wisconsin: Appleton, May 19-26, 4 cases; Marinette, May 12-26, 4 cases; Milwaukee, May 19-26, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, April 14-21, 5 cases.
Australia: Brisbane, March 31-April 7, 1 case; Fremantle, March 24-31, 3 cases, 1 death; Perth, March 24-31, 1 case.
Austria: Freudenthal, April 14-21, 2 cases; Gallicia, April 8-14, 7 cases; Vorarlberg, April 14-21, 2 cases.
Chile: Antofagasta, March 1-31, 23 deaths; Iquique, April 22-29, 3 cases.
Gibraltar: April 29-May 6, 2 cases.
Great Britain: Bristol, May 5-12, 2 cases; Newcastle-on-Tyne, 2 cases.
Greece: Athens, May 6-13, 1 death; Patras, April 10-17, 1 cases, 1 death.
India: Calcutta, April 13-20, 174 deaths; Karachi, April 22-29, 20 cases, 15 deaths; Madras, April 21-27, 31 deaths; Rangoon, April 14-21, 41 deaths.
Italy: General, May 3-10, 39 cases.
The Netherlands: Rotterdam, May 5-12, 3 cases.
Russia: Moscow, April 21-May 5, 25 cases, 8 deaths; Odessa, April 29-May 12, 46 cases, 6 deaths; St. Petersburg, April 21-28, 7 cases, 1 death.
Spain: Barcelona, May 1-10, 11 deaths; Seville, April 1-30, 34 deaths.

YELLOW FEVER.

Mexico: Merida, May 6-12, 3 cases, 2 deaths.

CHOLERA—FOREIGN.

India: Calcutta, April 14-21, 86 deaths; Rangoon, 1 death.

PLAGUE—INSULAR.

Hawaii: Honolulu, May 24, 1 death.

PLAGUE—FOREIGN.

India: Calcutta, April 14-21, 207 deaths; Karachi, April 22-29, 307 cases, 246 deaths; Rangoon, April 14-21, 65 deaths.
Peru: Lima, April 23-30, 3 cases, 1 death; Trujillo, 4 cases, 1 death; Mansefu, 1 case.
Straits Settlements: Wellesley Province, April 18, present.

Society Proceedings

COMING MEETINGS.

American Medico-Psychological Society, Boston, June 12-15.
Massachusetts Medical Society, Boston, June 12-15.
Maine Medical Association, Portland, June 13-15.
Minnesota State Medical Association, Minneapolis, June 20.
West Virginia State Medical Assn., Webster Springe, June 20-22.
Medical Society of New Jersey, Atlantic City, June 19-21.
State Medical Society of Wisconsin, Milwaukee, June 27-29.
American Ophthalmological Society, New York City, June 28-29.

ILLINOIS STATE MEDICAL SOCIETY.

Fifty-sixth Annual Meeting, held at Springfield, May 15-17, 1906, under the Presidency of Dr. H. C. Mitchell of Carbondale.

Duties and Obligations Relating to Tuberculosis.

DR. C. W. LILLIE, East St. Louis, dealt with what may be termed the ethical aspects of this subject—the duties of parents and guardians; of teachers in our common schools; of employers of labor of all kinds; of city and county officials, and boards of health and overseers of the poor; of legislators, governors and others whose duty it is to promote the passage of laws for the preservation of public health; of charitable persons in each community; of philanthropic and wealthy citizens; of managers of steam and street railways; of hotel proprietors; of the individual in his personal habits; of all doctors, and especially members of state, county and city medical societies, and more particularly the doctor's duty to make sure of his diagnosis. Lastly, he pointed out the duty of the physician in instructing all others in regard to tuberculosis.

Etiology and Diagnosis of Tubercular Spondylitis in Infancy and Childhood.

DR. J. H. HESS, Chicago, reported two interesting cases, and emphasized the great importance of early *x*-ray examinations in these cases, which was illustrated in Case 1, where the degree of destruction, though only moderate, could be localized beyond a doubt; also the common danger of misinterpreting the reflected pains as local diseases in the parts affected, as illustrated by conclusions in both of the cases reported.

Hysteria in Children.

DR. D'ORSAY HECHT, Chicago, said that this subject merits the attention of the general practitioner and specialist in pediatries and neurology. Inquiry into hysteria in children has not been a searching one. The general belief is that hysteria is a malady of adult life. He spoke of the physical and mental factors conducive to the development of hysteria in children, and cited several illustrative cases. The diagnosis was discussed with special reference to the exclusion of organic disease, the recognition of organic disease complicated by hysteria, and the detection of simulation. The prognosis and treatment were likewise discussed briefly.

Manifestations of Rheumatic Infection in Children.

DR. C. MARTIN WOOD, Decatur, pointed out the difference between adults and children in their reaction to rheumatic infection, and said that there is more extensive and lasting damage in the latter. He spoke of tonsillitis, endocarditis, arthritis, chorea and erythemas as rheumatic manifestations. He emphasized the importance of recognizing both mild and obscure cases. He said there is a marked tendency on the part
